Regia; Royal Boa. With longitudinal striped neck, and body variegated either with brown and grey, or orange and rofe-colour. This species, which is described by Seba, is, in its general shape, most allied to the canina and the phyrgia. It varies very much with respect to colour, the ground-work being white, but the variegations sometimes dusky or chefln, and sometimes of an elegant orange-red, accompanied by a tinge of blossom-colour on the lighter parts of the pattern; the top of the head is filled by a large patch, from which run two long parallel stripes to a considerable distance on each side the neck, leaving a wider stripe of the ground-colour along the upper part, and which afterwards ceasing, forms a part of the general variegation, which consists of a large chain-like dorsal band running down on each side, at moderately distant intervals, into oblique processes, or situations regularly bordered by the white ground-colour, the intervening lateral spaces being much lighter, and each is marked by a dusky patch on the upper part; the under parts of the body and tail are white, the head is covered in front with large scales, the tail is extremely short, and tapers rather suddenly.

Pheroga; Embroidered Boa. White, with a greyish call on the back; the body is most elegantly marked with black lace-like variegations.

This is unquestionably one of the most elegant species of the whole serpent tribe; its variegations are so conducted, as to bear a striking resemblance to an embroidery in needle-work. It is a native of the East Indies, where divine worship is paid to it.

Fascia; Faffcated Boa. With subtriangular body annulated with blue; is a native of India, and most generally found in the country of Bengal. It is of a yellow colour, marked with numerous dusky-blue transverse bands, continued at equal distances throughout the whole length of the animal, each band completely investing the body; the body is of a trilong form, the fides sloping very considerably; along the ridge of the back runs a continued series of hexagonal scales. This snake is among the number of poisonou species, and its bite is considered by the Indians as fatal. A specimen was brought to Dr. Ruffel in the month of November 1788, in an apparently very weak and languid state. Being fet at liberty, it chewed no disposition to bite; it suffered a chicken to get on its back, without noticing it; but the thigh of the bird being put within its jaws, it flewed immediate symptoms of having been poisoned, and it expired in the course of half an hour. This was the only experiment which was made, the snake dying the next day; but from the languid state in which it appeared, and the effect of its bite on the chicken, it may be concluded that, when in full vigour, it must be an animal of a highly dangerous nature.

Viperina; Viperine Boa. Grey, with a black, undulating, dorsal band, edged with white; and the fides spotted with black. It is about a foot and a half in length, and of a moderately brown colour. It is said to produce by its bite a slow wasting of the fingers and toes, similar to what happens in some leprous cases. A living specimen, however, was obtained in 1778, and though in good health, yet its bite was not followed by any deleterious effects.

Lineata, Lincated Boa, called also Gredi Paragoudon,
is of a flender form, with the general appearance of a coluber rather than a boa. It is of an extremely dark blue colour, so as to appear almost black in certain lights, and is marked throughout the whole length of the upper part by several transverse curved and dotted white lines at unequal distances, and varying in number in different individuals, from about 42 to 50; they are so disposed, as almost to represent fo many large spotted circles. Dr. Shaw has given an account of some experiments on this animal, to whose work we refer our readers. See General Zoology, vol. iii. part ii.

**Horaita.** This is of a dark brown, with a waving yellow bauld on each side, and a row of dorsal spots. This is one of the smaller species, measuring only about fifteen inches in length. The fangs, or poisioning organs of this snake, shew that it is noxious, but in what degree has never been ascertained; it is, however, said to be one of the most fatal.

**Palpebroa.** Whitish, obscurely fcalated with grey; with prominent eye-lids; this has 112 abdominal scuta, and 51 on the tail.

**Annulata.** Suhaffiguineous, with black, orbicular, dor- sal spots included in rings; reniform, ocellated, lateral spots, and abdomen undulated with dusky variegations. This is about two feet long, and in its general appearance it is allied to the B. horitaria and eydysis. It is a native of South America.

**Serpents, in Astronomy, a constellation in the northern hemisphere, called more particularly Serpens Ophiuchi. The stars in the constellation Serpens, in Ptolemy's catalogue, are 18; in Tycho's, 13; in Hevelius's, 22; and in the British catalogue, 64. See Constellation.**

**Serpent Cucumber, in Botany. See Trichosanthes.**

**Serpent Hypnoticus.** See Hypnoticus.

**Serpent Marinus.** See Sea Snake.

**Serpent Rubeus, the red serpent-fish, in Ichthyology, the name of a fish, properly of the tunja kind.** It resembles the common snake in figure, and is of a fine brown-red colour, and marked with oblique lines all down the sides, and long ones from the gills to the tail, one on each side; its mouth is but small, and its teeth sharp and serrated; and it has all over its back a number of fine capillaments, set at distances from one another, even to the tail, and the same on the belly; its tail ends in a single fin.

**Serpent Terminus, the earth-serpent, a name given by some of the chemical writers to nitre. It was originally given to the nitre of the ancients, a fact very different from that which we call nitre, but it has since been applied also to that salt.**

**Serpent-Stone.** See Snake-Stone.

**Serpent's Tongue, in Botany, a genus of the cryptogamia filices clasf, comprehending five species. See Adder's-tongue.**

**Serpents' Tongues.** The island of Malta abounds with glosophile, or the petrified teeth of sharks, which, from their resemblance to a tongue, are by the vulgar supposd to be the tongues of serpents turned into stone by some miracle of St. Paul, when he was there. This island abounds not only with these, but with bufo, and salt numbers of other remains of sea productions.

**Augustino Scilla, who has written at large on the fossils of this island, gives a very rational account of their being the real remains of animals, which, according to his system, it is no way wonderful to find there.**

In regard to the island of Malta, which so abounds with them at this time, he supposes that long since the time of the creation, and even without the assistance of the general deluge, it may have been formed out of the sea, and that it appears plainly to have been at first no other than a mass of foit mud, with an immense number of sea-shells, teeth of fishes, and other remains of sea-animals mingled among it; and that these fossilizing so slow as they could among that thickening matter, have made the island what we now find it, that is, a heap of earth with these things in vast quantities buried in it, and at different depths. Philos. Trans. No. 219 p. 182.

And though there are found among these teeth, &c., in the island of Malta, great quantities of shells, of such species as are not native of these seas, this is no objection to the opinion; since it is well known, that the winds, when violent, as they probably were about the time of the formation of that island, will bring such light bodies as shells a vast way in water.

The mountains of Sicily afford some few glosophile, or snakes' tongues, but they are few in number, and worse prepared than those of the island of Malta; which is probably owing to the high ground of those mountains being less likely to receive the refuse of the sea, and its foil, which is sandy, being left fitted to preserve them when there than the marl, of which the island of Malta consists.

The echini marini, or sea-eggs, and their species, which are very frequent among the serpents' tongues of Malta, all lie upon the surface of the ground, or near it; whereas the glosophile are deeper, though at no great depth. This is a plain effect of all these things having been really animal bodies, and having floated in the mud, of which that island was formed; for in this it could not be otherwise, but that the glosophile, or serpents' tongues, being heavy, would subside in the water, while the light shells of those other animals would float on or near the surface.

Whenever the glosophile are taken carefully up out of the earth in Malta, the marl or earth, which served for their bed, is found to contain all their minutest traces and lineaments, like wax from a feal. This is a proof that the marl was as soft as melted wax when they were put into it, and that they were of the full size and growth when placed there, not having grown, or had any increase in that place.

The apophyses, or proceses in the glosophile, are also a strong proof of their being no other than real sharks' teeth, since they exactly answer to those in the teeth of recent sharks, by which every tooth is received or inserted into its neighbour in the jaw. Nay, whereas sharks' teeth are mortified into one another in such a manner, that a man may easily tell which belongs to each side, which lie near the throat, and which near the front of the mouth; and whereas, in a shark's mouth, the teeth on the left side will not fit on the right, nor those above serve below, but that on seeing a recent tooth, a person of judgment will be able to say what part of the moth it belonged to; so in the fossil shark's teeth, or glosophile, there is not any one which may not be referred to the particular part of the moth of the living animal, and could have belonged to no other. Augustino Scilla, de Petrific. See Glossopetra.

**Serpent, in Music, a wind instrument of the baffeon kind, blown by a mouth-piece. It has its name from its serpentine figure; and is composed of two pieces of walnut-tree wood, and covered with thin leather or leather.**

This instrument has fix holes, which give it a compass of twenty-seven notes. The mouth-piece is fixed in a socket of copper or silver. Its neck is curved, and its mouth-piece is of wood or ivory.

It is held in such a manner, as that the fore-finger, the middle-finger, and the ring-finger of the left hand, cau stop the
the holes 1, 2, and 3; and the same fingers of the right hand, flop the holes 4, 5, and 6.

The abbé de Beauf, in his History of Auxerre, tom. i. p. 643, says that, about the year 1590, Edmond Guillaume, a canon of Auxerre, found the means of boring and turning a cornet in the form of a serpent, which was used in concerts at his house, and the instrument having been perfected became common in the great churches. For the scale and compass of the serpent, see Laborde.

In France, the serpent used to be confined to the military bands; at present, says M. Laborde, it is confined to the church and processions. In cathedrals there is one on each side the choir.

Merennus, who had studied this instrument, says, that if unfolded and straight, it would be more than six feet long. Laborde says eight feet. The compass of the instrument is now probably extended, which in the scale given in the folio Encyclopédie is from double B flat in the bass, to F in the first space of the treble.

Merennus, who has particularly described this instrument, mentions some peculiar properties of it, e. g. that the sound of it is strong enough to drown twenty robust voices, being animated merely by the breath of a boy, and yet the sound of it may be attempered to the softness of the sweetest voice. Another peculiarity of this instrument is, that great is the distance between the third and fourth holes appears, yet, whether the third hole be open or shut, the difference is but a tone.

SERPENT, in Mythology, was a very common symbol of the fun, and he is represented biting his tail, and with his body formed into a circle, in order to indicate the ordinary course of this luminous; and under this form it was an emblem of time and eternity.

The serpent was also the symbol of medicine, and of the gods which preided over it, as of Apollo and Aesculapius: and this animal was the object of very ancient and general worship, under various appellations and characters. In most of the ancient rites we find some allusion to the serpent, under the several titles of Ob, Ops, Python, &c.

The idolatry is alluded to by Moses, Lev. xx. 27. The woman of Endor, who had a familiar spirit, is called Oub, or Ob, and it is interpreted Pythonis: the place where the reeded, says the learned Mr. Bryant, seems to have been named from the worship then instituted; for Endor is compounded of En-ador; and signifies font pitionis, the fountain of light, the oracle of the god Ador; which oracle was probably founded by the Camaanites, and had never been totally suppried. His pillar was also called Abbadir, or Abadir, compounded of ab and adir, and meaning the serpent deity Adir, the name as Arabus.

In the orgies of Bacchus, the perfons who partook of the ceremony, used to carry serpents in their hands, and with horrid fermons call upon Eva! Eva! Eva! being, according to the writer just mentioned, the name as epha, or opha, which the Greeks rendered ophis, and by it denoted a serpent.

These ceremonies, and this symbolic worship, began among the Magi, who were the fans of Chus; and by them they were propagated in various parts. Wherever the Phoenicians founded any places of worship, and introduced their rites, there was generally some story of a serpent. There was a legend about a serpent at Calthis, at Thbes, and at Delphi; and likewise in other places. The Greeks called Apollo himself Python, which is the name as Oupis, Opis, or Oub.

In Egypt there was a serpent named Thermuthis, which was looked upon as very sacred; and the natives are said to have made use of it as a royal tiara, with which they ornamented the statues of Isis. The kings of Egypt wore high bonnets, terminating in a round ball, and surronded with figures of aps; and the priests likewise had the representation of serpents upon their bonnets.

Abadon, or Abaddon, mentioned in the Revelations, xx. 2, is supposed by Mr. Bryant to have been the name of the Ophite god, with whose worship the world had been so long infected. This worship began among the people of Chaldea, who built the city of Ophis upon the Tigris, and were greatly addicted to divination, and to the worship of the serpent. From Chaldea the worship passed into Egypt, where the Serpent deity was called Caneph, Can-cph, and C'noph; it also had the name of Ob or Oub, and was the name as the Basilicus, or royal Serpent, the name as the Thermuthis, and made use of by way of ornament to the statues of their gods. The chief deity of Egypt is said to have been Vulcan, who was called Opis; he was the same as Osiris, the Sun, and hence was often called Ob-el, or Python sol; and there were pillars facred to him, with curious hieroglyphic inscriptions, bearing the same name, whence among the Greeks, who copied from the Egyptians, every thing gradually tapering to a point was called obelos, or obeliscus.

As the worship of the serpent began among the sons of Chus, Mr. Bryant conjectures, that from thence they were denominated Ethiopians and Aethiopians, from Aeth-ops, or Aeth-opes, the god whom they worshipped, and not from their complexion: the Ethiopes brought thee rites into Greece, and called the island where they first established them, Ellopia, Solis Serpentis infula, the same with Eubua, or Oubia, i. e. the Serpent island.

The same learned writer discovers traces of the serpent worship among the Hyperboreans, at Rhodes, named Ophiura, in Phrygia, and upon the Hellespont, in the island Cyprus, in Crete, among the Athenians, in the name of Cecrops, among the natives of Thebes in Babylonia, among the Lacedaemonians, in Italy, in Syria, &c. and in the names of many places, as well as the people where the Ophites settled. One of the most early-heresies introduced into the Christian church was that of the Ophite. Bryant's Analysis of Ancient Myth. vol. i. p. 47, &c. p. 473, &c.

SERPENT ISLANDS, in Geography, small islands near the N. coast of lake Huron. N. lat. 46° 2'. W. long. 82° 45'.

SERPENTS, Island of. See SALGEN.

Serpentina, in Botany. See SERPENTARIA.

Serpentine, in Chemistry, a worm, or pipe of copper or pewter, twilted into a spiral, and ascending from the bottom of the alembic to the capital, and serving in the dililution of rectified spirit of wine.

Serpentine, in Mineralogy, a stone, which derives its name from the variety of its colours, supposed to resemble those of the serpent. The ancients called this stone ophis, from the Greek ophis, a serpent, as being speckled like a serpent's skin. The most prevailing colour is green of different shades, spotted with red, or with dark green, and also clouded and veiny. Some serpentines are red, varying from a peach-bloom to blood-red or scarlet. In rich variety of colours, this stone far exceeds any other of the great rock-formations. It will receive a high polish, and is nearly indestructible by fire or acids, and is therefore eminently fitted for ornamental sculpture or architecture. The hardness of serpentine is variable: some kinds scarcely yield to the knife, others are easily worked. It is intitible by the blowpipe; the fracture is splintery, passing into small con-
choidal; the fragments are translucent at the edges; the luster is somewhat reнизious, and when powdered, it has an unctuous foamy feel. The specific gravity varies from about 2.6 to 2.7. Serpentine feems nearly allied to the mineral called hornblende, from which it differs in its constituent parts by containing more magnesia and less iron. Chrome has been found in some serpentines. The analysis of different serpentines shews a considerable variation in the proportion of their constituent parts,

Some serpentines contain 6 per cent. of lime.

The disciples of Werner divide serpentines into two species, the one called the noble serpentine, the other the common serpentine; the former they consider as older, and having a different geological position to the common serpentine; but for this distinction there does not appear sufficient reason, as the same beds will furnish specimens of both kinds. The noble serpentine has the richest variety of colours and the greatest degree of translucency. Serpentine, though not very rare in many alpine districts, is by no means common as granite, f에, and limestone. Serpentine occurs in beds in gneis and primary limestone, and in mica-flake; it also covers many rocks in amorphous masses, and may be observed passing into chlorite or talc-flake. Serpentine has been remarked to exist generally at a low level in alpine districts; but there are some remarkable exceptions to this, particularly in the Jurassic series which surround the central parts of Mount Rofa, in Switzerland. These quartzites have an elevation of more than 1700 fathoms, formed of bands of serpentine lying in a position generally horizontal.

Serpentine is more abundant in Europe than any other part of the globe that has been yet explored. The whole front of the Alps facing Italy contains serpentine almost in every part, although there is very little in the fide towards Switzerland. It extends through Italy, where it is called gabbro. One of the finest varieties is at the hills of Improntetta, near Florence; it contains much of that green, leucitflanatous, and fatty substance, which Sauvage calls smaragdine, on account of its fine emerald-green colour. France has some mountains of serpentine, especially in Limousin.

The finest serpentines of Spain are from Sierra Nevada; two leagues from Grenada, they have a green base filled with glittering plates of a yellow colour. Superb columns have been made of it, which decorate the churches and palaces of Madrid. According to Patria, serpentine is almost entirely wanting in northern Asia, with the exception of the eastern part of the Ural mountains, which separate Europe from Asia. There are some hills of serpentine, which at great intervals accompany their bafe, following their direction from north to south; there are also some detached branches which appear near Tobolik, which is not far from these mountains. But from hence to the river Amur, a space of about three thousand miles, scarcely any vestiges are found either in the great chains of Altai, Sayennes, or the mountains of Dauria. The serpentines most known in Europe are those of Saddelberg in Sweden, and Zeolitz in Saxony, from which vases of every kind are turned and exported to distant countries. The serpentine of Bayreuth is filled with garnets of the size of a pea, dispersed equally through the mafs. When the stone is polished, they present a pleasing mixture of fine red spots in a green base. Trinkets and other ornaments are made of it.

The mountain called Roth Horn, or Red Horn, which faces mount Rofa towards Italy, is elevated 1556 fathoms; it is composed of immense masses of serpentine of an irregular shape. The surface of this serpentine becomes a deep red by the action of the atmosphere, which oxygenates the iron it contains. It is this colour, and the elongated form, that have occasioned the mountain to be called Red Horn.

The serpentine of this mountain is covered by a sheet of a fee-green colour, mixed with carbonate of lime and grains of felspar. On this serpentine are laid beds of micaceous schist, intermixed with limestone, composed of more than one half of mica. These are again covered by serpentine; all the beds are nearly horizontal; riling a little towards mount Rofa.

Mount Crevin, another mountain near mount Rofa, is an inaccessible obelisk of a triangular form, which is elevated 2359 fathoms above the sea. It is composed of three different masses; the uppermost, which forms the summit, is of a yellow ifabella colour. It is composed of serpentine mixed with micaceous schill, containing limestone and quartz. The middle is of gneis and micaceous schill, and the lower one or base of the pyramid is serpentine; but the most remarkable hill of serpentine is in the chain of mountains which separates the margravate of Bayreuth from the Upper Palatinate. Its elevation above the plains is about 300 feet; it extends in a direction from east to west. The rocks which crown the summit are of very pure serpentine, divided into beds, and resting on gneis and hornblende.

M. Humboldt having brought his compas near these rocks of serpentine, saw with surprise, that the north pole of the needle flew round to the south. He further observed, that the rocks on the northern and southern declivities have opposite poles. The eastern and western extremities of the hill do not exert any action on the magnetic needle, though the appearance of the stone is the same as on the north and south declivities. In the magnetic parts of the hill certain rocks are also observed, which are not magnetic in junction with similar rocks, that exert a strong action on the needle, some of them at the distance of 22 feet. The mountain not only exerts its action on the needle in its whole mafs, like some other hills, it is manifest even in small fragments.

Humboldt observed, that minute fragments are briskly moved on presenting them to the point of a weak magnet; but they have not the least attraction for iron not magnetized. Humboldt convinced himself that this serpentine does not contain an atom of magnetic iron, all which contains is in the flate of oxide. Its specific gravity is much less than that of other serpentines, fearfully reaching to 3.000, that of common serpentine being upwards of 2.700. This mountain of serpentine, taken in the aggregate, may be regarded as one large natural magnet, having two poles, the part equidistant from each displaying no signs of magnetic power, as is the case with small natural and artificial magnets. Like them too, if a fragment be broken from the mafs, each small piece has its north and south pole, and a central part, which is not magnetic. That particular kind of soft serpentine, which is capable of being turned into vessels that refill the action of the fire, is called pot-stone, and has been already described. See Pot-Stone.

Steatite and amianthus, a fibrous asbestos, are almost always associated with serpentine. (See Asbestos and Steatite.) The finest amianthus occurs in Corfica form-
ing beautiful white silky threads of two or more feet in length, and is so abundant, that Dolomieu made use of it instead of flax to pack his minerals in when in that island.

Serpentine exists in various parts of the highlands of Scotland and the Hebrides; it is found both pure and alternating with mica-flake and limonite.

No well-characterized rocks of serpentine are known in South Britain, except in Cornwall and the Isle of Anglesea. The serpentine of Cornwall is not particularly distinguished for the beauty of its colours. Rocks of this mineral extend to the Lizard Point.

The most beautiful variety of serpentine in Great Britain, or perhaps in Europe, is that on the western side of Anglesea. It occurs at a low elevation associated with rocks of talcous slate. The beds are of considerable size, and divided by seams of albite. Some of the serpentine is intermixed with white crystalline limonite, like the verde antique from Italy; but the particles of white are generally smaller. Vombs of quartz and felsite, with brilliant lamina of cheller spar, also occur in some of the beds. It is sufficiently hard to relit the point of a copper tool, and has a high polish. The colours are various: shades of light and dark green and red, varying from a peacock-bloom to a bluish-red scarlet. The colours are intermixed and distributed in an infinite variety of spots and clouds, the effects of which are heightened by polishing.

Mellers, Bullock & Co. in Oxford-street, have established a manufacture of chimney-pieces, columns, and other ornamental articles of this stone, which has the advantage, being railed in small blocks, so as to form columns and slabs in one piece, from 12 to 20 feet in length, and of proportionate diameter and breadth. A column of 12 feet in one shaft, composed of red serpentine, which we measured at Mellers. Bullock's manufacture, weighed two tons, and had no perceptible flaw or blemish in the whole piece. This is the most durable as well as the richest of British stones applied to ornamental sculpture, and is not exceeded in the variety or freshness of its colours by any of the costly marbles of Italy.

The Cameron marble, as this serpentine is called by the proprietors, was not liable to have its colours injured by common fire, which is the case with many marbles, when made into chimney pieces; neither are the colours affected by acids, air, or moisture.

With such a valuable material for ornamental sculpture in our own island, it is greatly to be regretted, that such large sums should be annually paid to foreign nations in the purchase of stone for similar purposes, which is less durable and less beautiful. It would surely be more patriotic to encourage the proper application of the mineral treasures of our own country.

The stone called verde antique is a mixture of green serpentine with white granular limonite. See Verde Antique.

Serpentine, in the Ronces. A horse is said to have a serpentine tongue, if it is always talking and moving, and sometimes passing over the bit, instead of keeping in the void space, called the liberty of the tongue.

The Romans, in breaking and drenching their horses, used to work them in sawing or serpentine lines, as the practice is, or ought to be, at present. The French call this riding a horse en serpentin. The Greeks and Romans knew it by the term of riding in Meanders, in allusion to the windings and doublings of the celebrated river which bore that name.

Serpentine Column. See Column.
SER

half, long, resembling those of *Veronica agriflia*. Flowers monoecious, four-cleft, reddish, very minute.

* S. occidentalis. American Serpica. Pursh n. 1. (Elo- dea canadensis; Michaux Borel-Amer. v. 1. 20.)—"Flowers united. Stigmas ligulate, cloven, reflexed. Leaves ternate, linear, acute."—Frequent in stagnant waters, from Canada to Virginia, flowering in July. Perennial. Flowers white, very small and delicate. Leaves when magnified very finely ferrulated. In the early part of the season they are, as Michaux describes, oblong and obtuse, but at the flowering time long, linear, and acute. Pursh.

**SERPIGO,** in Medicins, from *fergere, to creep,* is nearly synonomous with *herpes,* and signifies, in the language of the older writers, any spreading tender, or exaration of the skin. When the latter is lichenous, according to Forellus, it is called *impetigo,* but when it spreads and creeps from one place to another, it is called *serpigo.* (See Forel. Obs. Chirurg. lib. ii. obf. 11.) It is the property, however, of many eruptive diseases to spread in this manner, though very different in their nature from each other; whence in the more accurate nomenclature of the present day, the term *serpigo* is not used. It would be applicable, in fact, to diseases of every class, putulur, fcaly, papular, and vesicular; to the diseases called imperfecta, lepra, pellorians, lichen, herpes, eczema, &c. It is, therefore, unjustly exploded.

**SERPUCOV**, in Geography, a town of Russia, in the government of Moscov; 40 miles S. of Moscow. N. lat. 55°. E. long. 37° 2'.

**SERPULA,** in Conchology, a genus of the order Tef- taces, of which the generic character is, animal a terebella: shell univalve, tubular, and generally adhering to other sub- stances; often separated internally by divisions at uncertain distances. There are about fifty species included in this genus, of which several are found in our own country.

Species.

**NAUTILOIDES.** Shell flattish, minute, confluent, verru- cose, spiral, with very thin semilunar internal divisions. It is found in the seas about Norway, adhering to the Madre- pora proliferas, is very minute, brownish, or white; of an uncertain figure, sometimes rather oblong, sometimes more orbicular; the divisions are parallel, the aperture very narrow.

**SEMILUNUM.** The shell of this is regular, loofe, glabrous. It is found in the Adriatic and Red Seas, and sometimes it is obtained fossil. The shell is scarcely larger than a grain of sand, white and yellowish; the whorls are prefixed close together; the aperture is narrow, and com- pressed.

**PLANORBIS.** In this species the shell is orbicular, regu- lar, flat, equal. It is found adhering to shells. The shell resembles a round scale, and when broken horizontally it exhibits the appearance of a spire in minute concentric circles.

**SPIRILLUM.** Shell regular, spiral, orbicular, pellucid, with round gradually decreasing whorls. It inhabits the ocean, on zoonothes, furtoria, and other marine substances; it resembles the next, which is a native of this country, but is much less than it.

* SPIRORBS. Shell regular, spiral, orbicular, the whorls slightly carinated above and inwardly, and growing gradu- ally less towards the centre. It inhabits molt seas, adher- ing to fæci and zoophytes. There is a variety; the shell is white, without pellucid, not complicated, but dispoled closely on the substance to which it is attached; the aperture is circular.

**Triquetra.** The shell of this is creeping, flexuous, triangular. It inhabits the ocean, adhering to marine sub- stances, fæces, and the bottoms of ships; is from half an inch to an inch long. The shell is white, pellucid, irregularly twirled, carinate on the back, sometimes denticulate, with a narrow circular aperture.

**ISTRICATA.** Shell filiform, rough, round, intricately twirled. It inhabits the European and Indian seas, and often on our own coasts, upon shells. The shell is of a greenish-white, a little rugged and coarse.

**Filograna.** Shell capillary, faciculate, in branched complications, and cancellate. It inhabits the Mediterranean; is four inches long, and forms a beautiful kind of network.

**Granulata.** The shell of this is round, spiral, glo- merate, with elevated ribs on the upper side. It inhabits the North seas, in large males, adhering to shells, &c. The shell is white, and the size of a cowrie.

**Contortuplicata.** The shell is angular, rugged, and irregularly entwined. It is found in the European and Ame- rican seas, and on our own coasts; is from three to four inches long, and sometimes it is as large as a goose-quill; the shell is white, cinereous, or yellowish-brown; within it is smooth, transversely flirrate.

**Glomerata.** The shell of this species is round, glo- merate, with deciduate wrinkles. It inhabits the European and Atlantic seas, in large males. The shell is white, grey, or brownish; within it is smooth.

**Lumbricalis.** The shell of this is round, flexuous, with a spiral acute tip. There are three varieties of this species, which are found in the Atlantic and Indian seas, in large males. The shell is from three to five inches long, transversely ribbed and longitudinally wrinkled.

**Polythalamia.** The shell of this is likewise round, diaphanous, smooth, straightish, with numerous internal di- visions. It inhabits the Mediterranean and Indian seas, under the sand. The shell is outwardly white, transversely wrinkled, and annulate; the inside is separated by imperforated convex and concave divisions, making it appear as if it consisted of numerous united tubes.

**Arearia.** Shell jointed, entire, distinct, flattish beneath. It is found in India, and divers parts of the coast of Africa. It is probably a teredo, hereafter to be des- cribed. The shell is white, with pale brown undulate rays, or whitish; the outside cancellate, within it is smooth; spirally twirled: there are about a hundred siphes, which are sometimes nodular.

**Anguina.** Shell roundish, sub-spiral, with a longitudi- nal jointed cleft. It inhabits the Indian ocean; varies much in figure, being sometimes round and sometimes angular; it is more or less flexuous, glabrous or rough, with the joints of the cleft often obsolete. There is a variety of this species.

**Vermicularis.** Shell round, tapering, curved, wrinkled. It inhabits the European seas, and is from two to three inches long. The shell is whitish, ending in an obtuse point; the inhabitant is of a bright scarlet, with elegantly feathered tentacula, from the middle of which arise a trumpet-shaped tube, and a leffer simple one.

**Penis.** The shell of this is round, straight, taper, with a dilated radiate larger extremity; the diske is covered with cylindrical pores. This is denominated the *watering-pot.* It is found chiefly in the Indian ocean. The shell is white or cinereous, with a faint shade of red; smoothish, tapering, and open at the small end; the dilated margin at the larger
end terminating in numerous small tubes; the disk is convex, and covered with round perforations, with a longitudinal one in the middle.

Echinata. Shell roundish, flexuous, rosy, with numerous rows of prickles, obtuse at the end. It is the size of a crow's quill; the aperture is marginated.

Oreia. The shell of this is roundish, flirate, brown. It inhabits the Indian ocean, usually affixed to corals.

Protenta. Shell polished, smoothish, with annulate plates, a little tapering towards the end. It is found in the Indian and American seas, and is the size of a quill. The shell is ivory, whitish or blueish, either straight or partly bent.

Decussata. Shell round, with decussate flirates, slightly wrinkled, flexuous, red, within smooth and white.

Proscidea. The shell is smooth and white; the broader part is straight and transversely plaited. The shell is from two to four inches long, white, or of a dusky brown.

Afra. Shell sub-flirate, yellowish-brown, round, twisted into three whorls, with a central tip. It is found about the coasts of the island of Goree.

Cerolus. Shell round, smooth, yellowish, many times twisted. It inhabits America. The shell is long and narrow.

Cornucopia. Shell conic, spirally twisted, yellowish, with brown bands; the middle is round and twisted; the aperture is orbicular. The shell, as to its form, is obtuse at the tip.

Goreensis. The shell is round, cancellate, yellow, within horny. It is found at Goree, fixed to tesselaceous substances and wood; is from eight to nine inches long, with elevated flrases; the longitudinal ones are crowded.

Intestinally. Shell triangular, twisted, fragile, tuberculate, with hollow dots. This is found on the African coast. The shell is whitish, angularly twisted, sub-umbilicate, within glabrous.

Infundibulum. The shell is round, white, transversely flirate, and three twisted; the first bend appearing as if composed of five funnels placed on each other.

Pyramidalis. Shell crenose, above convex, beneath flat, pyramidal, hence its specific name; and it is many times twisted, the bends decreasing inwardly. It is found in the Indian sea, adhering to tesselaceous substances about an inch long, open at the narrower end; sometimes it is straightish, or a little bent.

Denticulata. The shell of this is white, round, subulate, straight, toothed at the fides, with a longitudinal glabrous rib in the middle; the tip is a little incurved and glabrous. It is found adhering to the Lepas tationsulum, and is about three-quarters of an inch long.

Melitensis. Shell roundish, twisted, umbilicate, with decussate flirates, and longitudinal nodulated ribs, within smooth, with numerous divisions. It is found fossile in Malta. The two first bends are placed on each other.

Norwegica. The shell of this is round, smooth, incurved, with a nearly obsolete undulate base: the mouth is obliquely truncate. It is found, as its specific name denotes, in Norway.

Porrecta. Shell round, smooth, polished, ascending in a flexuous manner from the spiral base. It inhabits the North seas. The shell resembles the S. spirillum, but is whiter, pellucid, and not rugged; the inhabitant is short, with a red back and paler sides.

Vitrea. The shell is round, regular, spiral, orbicular, pellucid, shining, wrinkled, with a thickened aperture. This species is found in the Greenland seas, on tesselaria, frunci, thones, and divers marine substantias. It resembles the S. glomerata; the shell is thick, umbilicate, not a line in diameter, and sometimes it is of a reddish colour.

Cancellata. Shell spiral, glomerate, with three grooves, the lower groove interrupted by transversely lines. It inhabits the Greenland seas, and resembles the S. granulata. Shell white, grey or greenish, the aperture is two-toothed.

Stellari. Shell sub-orbicular, umbilicate, convex, radiate with wrinkles. This also is found in the Greenland seas, on tesselaria and thones. The shell is scarcely larger than a needle, violet, reddish-brown, or yellowish radiate with white; beneath it is flat, with a single whorl or bend; the aperture is very minute.

Gigantea. The shell of this is somewhat triangular, with a little bend, gradually tapering, violet, within smooth, pale yellow, the aperture is white, with undulate flirates, and armed with a conic tooth. It inhabits Africa and America, attached to rocks and corals. The shell is six inches high, and as thick as the little finger. The inhabitant is whitish.

Cinerea. The shell is filiform, glabrous, congoulerate, perforated. It inhabits the shores of Madagascar; it is glabrous, of a greyish-white, and flexuous.

* Sulcata. Shell with two whorls, deeply and spirally grooved. It inhabits the coasts of Pembrokeshire, on the roots of the Fucus digitatus. It is a minute shell, of a greenish colour.

* Ovalis. Shell sub-oval, imperforated. It is found at Tenby. The shell has two bends, which form an oval; it is never perforated, and is minute.

* Reflexa. The shell is regular, rounded, with a reflected margin at the aperture. This is found on the Pembrokeshire lands. It is a minute; shell glossy, white, perforated; the aperture is above the plane of the spire.

* Cornea. The shell is regular, rounded, and pellucid, with three whorls. This also is an inhabitant on the Pembrokeshire coast. It is brown and horny.

* Bicornis. Shell semilunar, ventricose, white, opaque, glossy. It is found at Sandwich and Reculver, and is minute.

* Perforata. Shell semilunar, perforated, white, opaque, glossy. It inhabits Sandwich, as do all those that will hereafter be described. This is, however, as well as the next, very rare and minute.

* Lacera. The shell is ovate, thin, smooth, pellucid, with milky nerves.

* Lacina. Shell rounded, flirate, grooved, with a narrow neck. This is decribed, as are all those which are found in this country, in Adama’s work on the Microscope. The shell of this is exactly shaped like an oil-leaf, and is whitish.

* Retorta. Shell rounded, margined, with a slender recurved neck. The shell is white, opaque, shaped something like the retort used by chemists.

Incurvata. The shell is straight, with three close whorls at the smallest end. The shell is white and transparent, and resembles, in some respects, the Nautilus semilunatus.

Serpillum, in Botany, sometimes written Serpillum, so called from its humble creeping mode of growth. See Thymus.

Serequeux, in Geography, a town in France, in the department of the Upper Maine; 3 miles N. of Bourbounne.
SERRA, PAOLO, in Biography, author of an elaborate treatise on foliation, published at Rome in 1768, small folio, entitled "Introduzione Armonica Sopra la nuova fiera de' Suoni modulati oggidì e modo di rettamente e più facilmente intonarli," or, "Harmonical Introduction to a new series of modulated sounds, and a method for accurately, and with greater facility, learning to name and produce them with the voice."

The author begins, cap. 1, with the origin of music, its utility, and the different modes of naming the notes in fingering. After endeavouring to rob Guido of the invention of the hexachord, and foliation, and condemning its use, he proposes a new method of naming the notes in learning to sing, assigning a specific name to every found in the scale ending with the vowels A, E, I; as ca for a flat note, ce for a natural note, and ci for a sharp note; beginning each found with the letters now in use in the Septenary, by which means the student is disembarassed from all mutations, and every found in the scale has a specific and invariable name appropriated to it.

This method had the approbation of several of the best masters in Rome, who have signed a certificate of its effect upon the studies of a young finger of the name of Benedetti, who was rendered capable by it, in less than a year, of singing at sight any vocal music that was put before him, even without accompaniment. Benedetti has since sung the first man's part in the operas of several of the principal cities of Italy; and, perhaps, his genius may be such, as would have enabled him to have done the fame by any other method, with equal facility and practice. Instrumental performers, at present, are not plagued with the ancient names of the notes and mutations, but learn them by the simple letters of the alphabet; and yet we have never heard of one that has been able to play at sight in a year's time.

Upon the whole, the alphabetical names of the notes seem the most simple and useful for every purpose but that of exercising the voice, which is best done by the vowels; and it may be said, that to syllabize in quick passages is little more than to speak, but to vocalize is to sing. However, we were told by a scholar of the famous Durante, that while he was in the conservatorio of St. Onofrio, at Naples, when the boys used to be tormenting themselves about the mutations, and the names of notes in transfused keys, with double flats and sharps, Durante cried out, "Quelle note intonatele, chiamatele poi anche diavole ve volete, ma intonatele." Meaning, that if they did but hit the intervals right, and in tune, he did not care what they were called. And, perhaps, what Pope says of different forms of government, may be more justly applied to these several methods of fingering:

"What'er is best admitter'd is best."

And seconds his instructions with the greatest degree of intelligence and industry, will be the most likely to succeed. And when we recollect the great abilities and enchanting powers of many fingers of past times, who have been obliged to articulate every note of their "solfeggi" in the most rapid movements, we may apply to the new systems what M. Rousseau said with respect to his own: "That the public has done very wisely to reject them, and to send their authors to the land of vain speculations." For innovators will always find, that a bad method, already known, will be preferred to a good method that is to learn.

SERRA, in Botany, a genus of plants, so called in the Flora Peruviana, after a Spanish botanist of the same name, who has studied the plants of Minorca. De Theis.

SERRA, in Geography, a town of France, in the department of the Jemappes, and chief place of a canton, in the district of Corté. The canton contains 2,717 inhabitants.

SERRA, a town of Corseca; 11 miles S.S.W. of Cervione.

SERRA de Azenho, mountains of Portugal, in Alentejo; 4 miles N. of Monfort.

SERRA d'Alcoba, mountains of Portugal, in the province of Braga, between Vifeu and Bragança Nova.

SERRA de Bouzeno, mountains of Portugal, in Alentejo; 4 miles S. of Portalegre.

SERRA de Caldeirao, mountains of Portugal, between Algarve and Alentejo.

SERRA da Eferica, mountains of Portugal, in the province of Entre Duero e Minho; 18 miles N. of Bragança.

SERRA Falhera, a town of Portugal, in Tras los Montes; 15 miles W. of Mirandela.

SERRA de Maram, a mountain of Portugal, in the province of Tras los Montes; 10 miles S. of Chaves.

SERRA de Monchique, mountains of Portugal, between Alentejo and Algarve.

SERRA de Monfim, mountains of Portugal, between Mirandela and Torre de Moncorvo.

SERRA de Querera, a town of Africa, in Lower Guinea, on the river Camarones.

SERRA de Rebearados, mountains of Portugal, south of Braganza, in Tras los Montes.

SERRA de St. Miguel, mountains of Portugal, in Alentejo, on the south side of the Tagus; 15 miles N.N.W. of Castello de Vide.

SERRA de Salvador, mountains of Portugal, in Alentejo; 8 miles E. of Arronches.

SERRA Pifitas, in Ichthyology, a name given by many authors to the pifitas, or feco-fish.

SERRA is also a name given by Pliny to a species of the balaenidae, called by the generalities of writers foldopas. It is distinguished by Artedi by the name of the balaenidae, with two spines in the place of the belly-fins, and one behind the anus. See TRUMPET-fish.

SERRAE, in Geography, a town of European Turkey, in Macedonia, the fee of a Greek archbishop; 36 miles E.N.E. of Saloniki.

SERRAIN, a town of Arabia, in the province of Hedjas; 40 miles S.W. of Mecca. N. lat. 21° 5'.

SERRANA, or Pearl Island, a small island in the Caribbean sea, so called from Serrana, the commander of a Spanish vessel in the time of Charles V., who was shipwrecked on the coast. N. lat 14° 5'. W. long. 78° 50'.

SERRANILLA ISLANDS, a cluster of small islands in the bay of Honduras. N. lat. 16° 10'. W. long. 86° 10'.

SERRAPETRONA, a town of Italy; 7 miles S.W. of Ancona.
SERRATA, a name given by some of the Roman authors to the plant which the Gauls, according to Pliny, had named betonica, and which the Greeks called *systerin-fuchstropon* and *priorites*. This was evidently the same plant with our *ferrata*, or *faw-word*; but besides this there was another plant called by this name, and which, according to Pliny, was the chamaedrys or germander of the Greeks.

 Dioscorides says nothing of the chamaedrys, but that its leaves were small. And it is much more probable, that the world should take the idea of a faw from the leaves of the *ferrata* than from those of this plant, they being much leaves nicely denticulated than those. So that those who have been influenced by Pliny, to suppose the germander and ferra of the ancients to be the same plant, are in the wrong, though they have the coextensity of this so generally reputed authentic author for it.

SERRATE FLIES, in *Natural History*, a name given by authors to certain flies, distinguished from all the other kinds by their having a weapon resembling a double faw, placed at the hinder part of the body; this serves several species of them to make holes in the branches of trees, in which they deposit their eggs; but there are some of them which do not communicate the name of this curious insect, though they have it. See ROSA-FLY.

The fly of this kind that lays its eggs on the gooseberry-bush, deposits them only on the surface of the middle rib of the leaf; and the other-fly, which is one of this genus, produced from a bastard capperpillar of the other, lays its eggs on the intermediate surface of the leaves between the ribs.

There appears to be no use made of this curious instrument in the depositing of these eggs, since they are only laid in rows upon the leaves, and fixed to them by means of a viscid fluid which covers them. It is a very remarkable property in the eggs of this genus of flies, that they grow much longer after they are laid. This is observable in the eggs of the common rose-fly, which are at first buried in the wood, and by their growth force out the surface into tumours of an oval figure; but in those of the other-fly it is more beautifully feen, and the whole growth of the fly in them is clearly seen, on examining them at different times of their growth, which may be easily done without disturbing them, as they are left upon the surface of the leaf.

There seems a plain proof that the egg receives some sort of benefit, and that a very essential one to its preservation, from the juices of the plant on which it is deposited, since, if these leaves be pulled off from the plant, and left to dry, the eggs always dry up with them, and perish; whereas, if the ends of these leaves be put into water, and the leaf be by that means preserved fresh and juicy, the creature hatches from it as well as if it was left upon the tree.

SERRATED LEAF, in *Botany*. See LEAF.

SERRATI, in the *History of Coins*, a name anciently given to Syrian, Roman, confular, and some few other coins, which were ornamented by cutting out regular notches on the edges. Tacitus says, that the Germans preferred these to other Roman coins. But the old forgers imitated this kind of incision, which was intended to prevent forgery, by using the inside of the metal.

Gen. Ch. *Common Calyx* oblong, nearly cylindrical, closely imbricated, with numerous, lanceolate, erect, unarmed scales. *Cor.* compound, tubular, uniform. Flores numerous, equal, all perfect, of one petal, funnel-shaped; the tube forked; limb subulate, five-eleft. *Stam.* Filaments five, capillary, very short; anthers united into a cylindrical tube. *Fyl.* German obovate; fyll thread-shaped, the length of the filaments; ligaments two, oblong, revolute. *Peric.* none, except the unchanged calyx. *Seeds* solitary, obovate. Down soft, toothed or feathery. *Recept. calyx* hairy.

Obs. *Carduus* and *Cnicus* are distinguished from this genus by their more swelling, or nearly globoso, calyx, with spinous scales. We know not what Germain has procured for the *Cardus cyanoides*, which he represents with unarmed scales, and therefore properly refers to *Serralula*; but the true Linnaean plant has spinous scales. This learned author would remove to the present genus a number of species from *Cnicus*, *Carduus*, and *Centaurea*, of which he names but two, *Cnicus centauriae*, and *Centaurea Rhoecamum*, certainly very remarkable plants, and strictly akin, but in our opinion they answer very imperfectly to the idea of a *Serralula*. We content ourselves with following Widdenow in the main, though well aware of the ambiguity of some of the species, too prone to approach *Cardus* in their calyx, or *Centaurea* occasionally in their marginal florets. We prefer, however, in excluding *S. arvenfis*, which is, in character and habit, a most evident and certain *Cardus*, or rather *Cnicus*, as Mr. Curtis long ago demonstrated. Widdenow could scarcely have been acquainted with this common species, for he marks it as biennial, though no weed is more notorious for its deeply creeping, almost indestructible, roots. See Fl. Brit. 851, and Curt. Lond. f. f. 1827. Two genera, with a naked receptacle, and other differences of character, are properly separated by Schreber, Widdenow, and others, from *Serralula*. See *Liatris* and *Vernonia*.

2. *S. coronata*. Siberian Saw-wort. *Linn. Sp.* Pl. 1144. *Ait.* n. 2. *(S. praecarpa centauriae montana italic*; *Bocc.* *Mul.* 45. t. 37? *Carduus* n. 41; *Gmel.* *Sib.* v. 2. 499. t. 20.)—Leaves sharply serrate, somewhat ciliate, deeply pinnatisect. *Corolla* level-topped. Flores of the circumference female, longer than the rest.—Native of mossy parts of Siberia, flowering in the end of June. If Boccuno's synonym be right, the plant grows also on mountains in R.
SERRATULA.

Leaves cottony and white beneath, toothed, pointed, ovato-lanceolate, undivided; the radical ones somewhat ovate or heart-shaped. Flowers corymbose. Calyx clothed with soft hairs.—Native of the highest mountains of Europe, particularly Siberia, while, Scotland, and Switzerland, flowering in July and August. There can be no doubt that all the synonyms here cited belong to one species, nor is it easy to mark the limits of even its varieties. The root is perennial, tough, and woody. Stem from three to twelve inches, or more, in height, simple, leafy, furred, cottony, crowned with a level-topped tuft of elegant flowers, on stalks of various lengths. Calyx of many soft, brown, hairy scales. Flora pink, with blue or violet anthers. The leaves are excessively variable in shape, from lanceolate to broadly heart-shaped; their margin toothed, sometimes wavy; their footstalks long and slender, short and thick, or altogether wanting. The upper surface of each leaf is green, smooth, and nearly or quite naked; the under covered with dense, white, cottony down. The narrow-leaved specimens grow in rich ground, amongst other plants.

8. S. angustifolia. Narrow-leaved Saw-wort. Willd. n. 9. (S. alpina, angustifolia; Linn. Sp. Pl. 1145; Cirrimum n. 50; Gmel. Sib. v. 2. 278. t. 32. Herb. Linn. from the author.)—Leaves linear, revolute, entire; rather hairy beneath. Flowers somewhat racemose. Bracteas awl-shaped.—Gathered by Steller, on the banks of rivers in the eastern part of Siberia. A much more slender plant than any variety of the preceding. The stem is eighteen to twenty-four inches high, erect, slender, hairy, almost smooth. Leaves furred, hardly a line broad, quite entire, paler, and a little hairy, but not cottony beneath. Flowers few, on long, simple, distant, rather racemose than corymbose, flaky. Scales of the calyx ovate, pointed, purplish or brown, hairy within.

9. S. falicifolia. Willow-leaved Saw-wort. Linn. Sp. Pl. 1145. Willd. n. 15. Ait. n. 5. (Cirrimum n. 55; Gmel. Sib. v. 2. 69. t. 27.)—Leaves linear-lanceolate, entire; white and cottony beneath. Corymb compound, leafy. Scales of the calyx elliptical, ribbed, downy.—Native of Siberia, in dry open rocky places, where it flowers towards the end of July. Mr. Joseph Buth is said to have brought this species into the English gardens in 1796. It is an elegant hardy perennial, distinguished by the snow white whiteness of the back of its leaves, whose edges are fearlessly, if at all, revolute; their base tapering down into a bordered footstalk. The flowers rather more refulible those of S. tinctoria than of alpina, but the calyx is slightly cottony.

11. S. multiflora. Many-flowered Saw-wort. Linn. Sp. Pl. 1145. Willd. n. 12. (Cirrimum n. 54; Gmel. Sib. v. 2. 71. t. 28.) — Leaves lanceolate, rough, somewhat decurrent, nearly entire; woolly beneath. Stem repeatedly corymbose, many-flowered. Scales of the calyx lanceolate, keeled.—Gathered by Gmelin in mountainous parts of Siberia. Dr. Flitcher has sent us a less luxuriant specimen from Mount Caucans. Th. stems are said to be decumbent. The leaves vary in breadth, and are sometimes revolute; the radical ones coarsely toothed. Their green upper surface is rough like a file;
the under clothed with loose white cottony wool. Flowers more or less numerous, corymbose, rose-coloured, with an elegant, slender, purplish, slightly downy, calyx. Gmelin himself fully says that the flowers in his plate are too large; yet Linnæus on that account doubts the certainty of his synonym, for which there can be no reason.

14. S. amarit. Bitter, Saw-wort. Linn. Sp. Pl. 1148. Willd. n. 15. (Asciunum n. 55; Gmel. Sib. v. 2. 72. t. 20.)—Leaves lanceolate, round-edged, naked, somewhat deciduous. Flowers corymbose. Scales of the calyx dilated and rounded at the extremity. — Native of dry open fields in Siberia, on a saline soil, abundantly. Gmelin. Root as thick as the little finger, perennial, bitter, with a saline flavour. Stem from a sap to one or two cubits high, simple or branched, leafy, angular, and furrowed. Leaves four or five inches long, and one broad, coriaceous, tapering at each end, naked and nearly smooth on both sides, except the edges and midrib; the lower ones flaked, toothed; the upper generally deciduous, and entire. Flowers several, purple, the size of Centaurea nigra or Jacob, but in the aspect and hue of their calyx most resembling the latter, except that the round apex of each scale, though jagged, is not fringed.

15. S. centauroid. Centaur-like Saw-wort. Linn. Sp. Pl. 1148. Willd. n. 16. Ait. n. 6. (Cardus n. 38; Gmel. Sib. v. 2. 44. t. 17.)—Leaves deeply pinnatifid, acute, smooth, unarmured. Stem branched. Flowers foliaceous. Scales of the calyx partly pointed; the inner ones dilated and membranous. — Native of Siberia. Sent by Sir Joseph Banks to Kew, in 1804. A hardy perennial, flowering in July and August. This has the habit of several Centaureas, but wants the neutral margin of flowers. The stem is a foot or more in height, alternately branched, leafy, angular, smooth. Leaves rigid and coriaceous, with deep, entire, deciduous segments. Flowers foliaceous at the top of each branch, large, purple. Calyx ovate, of many ovate acute scales, several of the middlemost of which bear a short spine, while the inner ones are much elongated into a linear, membranous-tipped appendage. The genus of this plant cannot but be considered as very doubtful, nor can we refer it without scruple to Scirtatula or Centaurea; perhaps we should, like Gmelin, remove it to Cardus or Centaurea, the calyx answering very nearly to that of the arvensis.

17. S. ciliata. Fringed Saw-wort. Vahl. Symb. v. 1. 69. Willd. n. 18.—Leaves sessile, lanceolate, undivided, fringed with minute spines; downy underneath. — Gathered by Forskål, in gardens at the village of Bujuchtar, near Constantinople. Willdenow erroneously makes this species a native of Egypt. Forskål took it for the Linnæan S. arvensis. Vahl, who had examined his original specimemens, describes the stem as herbaceous, branched, fringed, hoary in the upper part. Leaves sessile, an inch and a half long, tapering at the base, obtuse, finely serrated, with spiny teeth; the upper side green, flaggy; the under hoary and downy. Flowers smaller than a hazel-nut, flaked, two or three at the end of each branch. Calyx-scales smooth; the outermost ovate, keeled at the summit, and pointed; the inner ones lanceolate. Seed-down feathery. This may possibly, like the following, belong to Cinclus.

18. S. tetofa. Brilly Saw-wort. Willd. n. 19— "Leaves oblong, smooth, finely serrated, fringed with bristles, obtuse, pointed. Stem corymbose." — Native of Sileia; observed by the Rev. Mr. Seeliger. Root biennial. Stem furrowed, smooth, corymbose and level-topped. Leaves copious, alternate, an inch long (or broad?) green on both sides, smooth, undivided, very minutely serrated, each serration tipped with a brilly point. Flowers flat; hoary. Calyx glitly downy, with ovate, acute, obscurely-serrated scales. Willdenow, from whom we borrow this description, says the plant is like Sileia (his Scirtatula) arvensis, except in the form of its leaves, and smallness of the flowers. If so, it perhaps is likewise a real Cinclus, and perennial; see our observations under the generic character.

SERRATULA, in Gardening, contains plants of the tall, hardy, herbaceous, perennial kind, of which the species cultivated are the long-leaved faw-wort (S. noveboracensis); the tall faw-wort (S. pratetia); the glaucous-leaved faw-wort (S. glauca); the rough-headed faw-wort (S. australis); the ragged-cupped faw-wort (S. scariflora); and the spiked faw-wort (S. scirpeta).

Method of Culture. — These plants may all be increased by parted the roots, and planting them out in the autumn, when the stems decay, or in the spring; but the former is the better season. The old plants should not be parted oftener than every third year, and then not too small.

They are likewise all capable of being increased by seeds, when they can be had good, which should be sown in the autumn or early spring, in a border to the east, in flight drills. When the plants are a few inches high, they should be pricked out in nursery-rows to remain till the following autumn, and then planted out where they are to remain.

They afford ornament in the borders, clumps, &c. being planted to the middle or the back parts.

SERRATUM, and Serratula, Folium, in Botany, so called from ferra, a faw, the teeth of which are imitated in their margins. See leaf.

SERRATUS, in Anatomy, a name given to different muscles attached to the ribs, and arising by several distinct portions, so as to have a serrated edge. In French they are called dentelé.

SERRATUS Anticus, the name under which Albinus describes the pectoralis minor. It is also called ferratus minor antiquus.

SERRATUS Magnus, ferratus major antiquus; le grand dentillé; faculo collum), a large muscle of the shoulder, broad and flat, lying between the scapula and the clavicle, and extending
extending from the nine upper ribs to the bไข的 of the scapula. It is irregularly four-furred, broader below and in front than above and behind. It arises from the eight or nine upper ribs by as many distinct pointed portions, which are first tendinous, then flabby. The first, which is broad, very thick, short, and distinct from the rest, arises from the outer edge of the first rib, towards its back part, from the second, and from an intermediate aponeurosis. The second, third, and fourth, broad and thin, arise from the external surfaces of the second, third, and fourth ribs, in oblique lines directed from above and behind, downwards and forwards. The fifth or sixth, narrower and increasing in length downwards, arise from the upper edge and external surface of the corresponding ribs, and are placed between the digitation of the obliquus externus abdominis. From the origins just enumerated, the fibres of the muscle proceed, divided, particularly below, into faciculi corresponding to each digitation, separated by cellular lines, and soon forming three distinct portions. The superior division is thick, narrow, and short, extends from the two first ribs to the superior angle of the scapula, affending a little, and covering the upper edge of the second portion, to which it is united. The middle division, broad and thin, goes from the second, third, and fourth ribs to the upper third-fourths of the bases of the scapula; its fibres proceed horizontally from before backwards, except the inferior ones, which descend a little. The inferior portion of the muscle passes from the fifth, sixth, seventh, and eighth ribs to the inferior fourth of the bases of the scapula, and the inferior angle of the bone. This part is thick, radiated, broad in front, and narrow behind. The superior fibres of this portion go nearly horizontally from before backwards, the inferior ones are directed at the same time from below upwards, and are more oblique in proportion as they are lower: they are united towards the inferior angle of the bone.

The external surface of the serratus is covered, towards its lower and anterior part, by the skin, at the lower and posterior part by the latissimus dorsi. Above and towards the front it is covered by the pectoral muscles, by the axillary vessels, and the brachial plexus. In the rest of its extent it is in contact with the sub-fascial. The external surface covers the seven or eight superior ribs, the external intercostal muscles, and behind a portion of the serratus posterior inferior. The upper edge of the muscle is the shortest, extending from the margin of the first rib to the superior angle of the scapula: the inferior, much longer, reaches from the eighth or ninth rib, or about two inches from its cartilage, obliquely to the inferior angle of the scapula. The anterior edge is the longest, and fixed to the external surface of the eight or nine first ribs, by the distinct pointed serrae or digitated portions, from which the name of the muscle has been derived: the posterior is fixed to the front edge of the bases of the scapula, and of the superior and inferior angles of the bone.

The action of the serratus anterior produces two different effects, according as the scapula or the ribs are the fixed point. In the first case, the scapula being fixed by the trapezius, rhomboïd and levator muscles, it draws the ribs outwards, elevating those to which it is fixed by its lower digitations; in this respect it is a powerful agent of inspiration, concurring with the pectoral muscles. In the second case, it carries the scapula forwards, antagonizing the rhomboïd, trapezius, &c. But it moreover draws the inferior angle forwards, and consequently moves the upper and anterior angle of the bone, forming the shoulder, upwards. Thus the serratus anterior is an important muscle in supporting burdens carried on the shoulders. In this case the diaphragm and abdominal muscles are put in action to draw down the ribs, fix them, and prevent them from yielding to the efforts of the serratus.

Serratus Major Anticus. See Serratus Anticus.

Serratus Posticus Inferior, (denté postérieur inférieur ; lombocollien) is a broad, thin, and flat muscle, situated at the lower part of the back, and extending from the spinous processes of the vertebrae to the ribs. It arises from the spinous processes of the two last dorsal vertebrae, of the three first, and the intervening inter spinous ligaments, by a broad aponeurosis, comprising one half of the muscle, common to it and the latissimus dorsi, composed of parallel fibres, directed obliquely upwards and outwards. This aponeurosis is connected in front to that of the transversus abdominis, and by its lower edge to the obliquus internus. The muscular fibres, passing with the same obliquity as those of the aponeurosis, form four faciculi or pointed serrated portions, of which the first and broadest is fixed to the lower edge, and near the angle of the second last rib; and the three others, which are successively smaller, are also attached, by aponeurotic fibres, to the lower edge of the three succeeding ribs, farther from the angle. The posterior surface of this muscle is covered by the latissimus dorsi. The anterior surface covers the three last false ribs, the external intercostal muscles, the longissimus dorsi and facrualbalius, and the transversus abdominis. The upper edge is continuous with the thin aponeurosis, which immediately covers the longissimus dorsi and facrualbalius.

By drawing downwards the lower ribs, this muscle affairs in expiration. It cannot produce any effect on the spine; it will confine the muscles lying at the side of the spine, and thus has the fame effect as the serratus posterior superior and the fascia extended between them.

Serratus Posticus Superior, (denté postérieur supérieur ; dorso-costéen,) is a very small and thin muscle, flat and four-sided, placed at the upper part of the back. It arises from the ligamentum nuchae, the last cervical spinous processes, and the two or three upper dorsal ones, by a thin aponeurosis, composed of parallel fibres, directed obliquely downwards and outwards. The fleshy fibres follow the same direction, forming a thin frattum, which terminates in four small faciculi or serrated portions, ending in aponeurotic fibres, which are inserted in the upper edges of the second, third, fourth, and fifth ribs, near their angles. It is covered externally by the rhomboïd; and it covers the splenius, transversalis, collis, the vertebral muscles, the ribs, and the corresponding intercostal muscles.

It will have the effect of elevating the ribs, and thereby of enlarging the chest, or assisting in inspiration.

Serravalle, in Geography, a town of France, in the department of Marengo, on the Serina; 12 miles S. of Turin.—Also, a town of France, in the department of the Seine; 18 miles N. of Vercelli.—Also, a town of Italy, in the duchy of Mantua; 24 miles S.E. of Mantua.—Also, a town of Italy, in the Trevisan, 25 miles in circumference, partly on a plain between two mountains, and partly on the mountains near the river Mafchio, which runs through the middle of the town, and has its source in a small lake in the higher part of the town. At the extremity of the marketplace is the public palace, and at the lower end the cathedral church, containing some good paintings. The town and its suburbs comprehend two parishes, and 30 churches, that of St. Augustine, built by its noble architecture, and its long noble staircases. Here are also two monasteries, and two nunneries. The inhabitants are industrious, and trade particularly
particularly in cloth, woollen and silk manufactures, and carry on an extensive commerce in wine, corn, and honey, both with the adjacent provinces and with Germany; 2 miles N. of Genoa.

SERRE, L. A., in Biography, a miniature painter of Geneva, who had been in England, and seemed well acquainted with Gemmian, and the state of music in our country in the middle of the last century. He has analysed the "Guida Armonica" of Gemmian, the "Balle fondamentale" of Rameau, and the Treatises of Tartini, with his discovery of the "Terzo Suono." These celebrated works M. Serre has critically examined in two ingenious essays, published in 1755 and 1765, in which there are likewise many curious remarks on disputable points in the theory and practice of harmony, which will both amuse and instruct musical students.

Serre, Fr., close intervals in music, such as the enharmonic quarter tones in the ancient Greek music; and in French music, short and quick. See Soprus.

SERRI, La, in Geography, a river which runs into the Oise, near La Fère, in the department of the Aine.

SERRI, a town of France, in the department of the Hère; 12 miles N. of Romans.

SERRIS, JOHN DE, in Biography, a Protestant minister, was born in the south of France, and studied at Lauffeune. We find him in 1572, serving a country church in the neighbourhood of Geneva. Having made himself known by various works, he became rector of the college of Nîmes, and a minister of that city, and was employed on several important occasions by Henry IV.; that prince having asked Serre if it were possible for a perfon to be faved in the communion of the church of Rome, he answered in the affirmative, and that he had been secured of promoting Henry's change of religion. Notwithstanding this declaration, he was a warm controversialist against the Catholics, and made a very severe attack upon the Jesuits, entitled "Doctrina Jesuicis præcipuæ capita." As a learned author, he is chiefly known by an edition of Plato in three volumes folio, printed by Henry Stephens in 1578, with notes and a new Latin version, which however is not remarkable for correctness; and the style of those parts which Serre composed is very unequal to the majesty of the original. He was author of a number of works in history, and had the title of Historiographer of France; but his compositions are paid by the Catholics to be partial and full of misrepresentations. The principal of them are as follows: "Commentarius de Ritu Religionis et Republicæ in Regno Franciæ," comprising the events from 1557 to 1576; "Memoire de la Troisiçme Guerre civile sous Charles IX."; "Recueil des Choffe memorable avens in France sous Henri II., Francois II., Charles IX., et Henri III."; and "Inventaire Général de l'Histoire de France." Serre, towards the end of his life, engaged in the hopeless design of uniting the Catholic and reformed churches, which brought on him the contempt of one party and the enmity of the other. He died in 1598.

SERRIS, OLIVIER DE, an eminent agriculturist, was born in 1539, at Villeneuve de Berg, in the Vivarais. During the civil tumults of his time, his property was pillaged, and his house demolished, and after it had been rebuilt, it was again destroyed by fire. He is said to have borne these misfortunes with great equanimity, and to have forgotten them by engaging his mind in study and rural occupations. By his talents he became so advantageously known to Henry IV., that he went for him to Paris, and employed himself in several improvements about his domains. Serre wrote works, which rendered him the oracle of the cultivators in that age, and many of his ideas have been copied by later writers without acknowledgment. The chief of these, in which he collected the results of long experience, is entitled "Théâtre d'Agriculture, et Ménage des Champs," 1630, and has been several times reprinted. It has been described by Haller as "a great and valuable work, written by an experienced man, fond of simplicity, and not at all attached to expensive methods." Some of the economical precepts of Mr. Serres have been thrown into verse, in order that they might be more easily remembered. He published treatises on the management of silk- worms, the collection of the silk, and the culture of the white mulberry-trees, which he introduced into France. This able man died in 1619, at the age of four-score, after having had the satisfaction of witnessing the happy effects of the improvements suggested by him.

SERRE, in Geography, a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Gap; 24 miles W.S.W. of Gap. The place contains 1219, and the canton 4249 inhabitants, on a territory of 170 kilometres, in 10 communes. N. lat. 44° 26'; E. long. 5° 8'.

SERRET, a town of Asiatic Turkey, in Natalia; 30 miles W. of Caftamena.

SERRIERES, a town of France, in the department of the Ardèche, and chief place of a canton, in the district of Tournon; 15 miles N. of Tournon. The place contains 1524, and the canton 9416 inhabitants, on a territory of 115 kilometres, in 17 communes.

SERRIS, a town of Hindostan, in Bahar; 15 miles S.E. of Saferam. N. lat. 24° 51'; E. long. 84° 26'.

SERRO, a small island belonging to the cluster of Papuan isles. See PAPA.

SERROPALPUS, in Entomology, a genus of insects, of the order Coleoptera, whose generic character is as follows: antennæ facetous; four unequal feelers; the anterior ones are longer, and deeply serrated, composed of four joints, the last very large, truncate, compressed, patelliform; the posterior ones are sublative; thorax margined, concealing the head, with a prominent angle on each side; the head is deflected; and the feet formed for digging. There are two Species.

STRIATUS. The body of this insect is brown; the shells bileate. It inhabits the island Runfale, and is described in the Stockholn Transactions for the year 1786; where it is said to be found chiefly on old wooden buildings, in the evening in autumn, and is about the size of the Elater aterrimus.

LAVIGATUS. This species is characterized by a black body, and smooth shells. It inhabits different parts of Europe, and is likewise described in the volume of the Stockholn Transactions already referred to.

SERRURIA, in Botany, a name rightly altered by Mr. Salisbury and Mr. Brown, from the Serraria of professor John Burmann, who, in his Planter Africænsis, 266, establishes the latter appellation, in honour of Dr. Joseph Ser- rurius, Professor of Botany at Utrecht; but it is not easy to discover the above author's meaning in thus perverting the word; for Serrurius is a locksmith, and has no reference to a saw, or sawyer.—Brown, Tr. of Linn. Soc. v. 111. Art. Hort. Kew. v. 1. 198 — Clade and order, Tetrameria Monegenia. Nat. Ord. Aggregate, Linn. Protonem. Jull. Brown. Eff. Ch. Coreollia in four deep segments. Stems of the concave tips of the segments. Nectary four buds beneath the
SERRURIA.

A genus of rigid Cape shrubs, of which Mr. Brown describes thirty-nine species, eight of which find a place in the Hortus Kewensis. The leaves are thread-shaped, pinnatifid or three-cleft, rarely undivided. Heads of flowers either terminal, or from the bobsoms of the uppermost leaves, either simple and solitary, or composed of several fistulous partial heads, or corymbose. Bracteas imbricated, membranous, most commonly shorter than the flowers, in a few instances longer, in some wanting. Flowers always fesille, purple. Petal the length of the corolla, with a club-shaped, rarely cylindrical, stigma. Nut oval, finely downy, sometimes bearded, sometimes nearly smooth. We select the following examples, among which are included all the species known in the gardens of England.

Sec. 1. Heads fimple; the flower-flalks undivided or wanting.

S. pinnata. Wing-leaved Serruria. Brown. n. 8. Ait. n. 1. (Protea pinnata; Andr. Repof. t. 512.)—Heads falked, somewhat aggregat. Bracteas lanceolate, villous, nearly as long as the flowers. Corolla bearded. Leaves pinnatifid or three-cleft, longer than the heads. Stem procumbent, hairy.—Gathered by Mr. Niven, on dry hills at the Cape of Good Hope, particularly in ascending Paarlberg. It flowered in Mr. Hibbert's garden, in the summer of 1807. In a natural state the ftem is said to be perfectly prostrate, dividing from the base into branches about a foot long, round, downy, leafy. Leaves above an inch long, turned upwards, confiding of three or five awl-shaped fegments. Heads of flowers red, about as big as a walnut, either solitary and terminal, or partially axillary; the young buds enveloped in the white silky hairs, which clothe the fips of the corolla externally.

S. cyanoides. Trifid-leaved Serruria. Brown. n. 10. Ait. n. 2. (Protea cyanoides; Linn. Maff. 188. Willd. Sp. Pl. v. 1. 507. Cyanus aethiopicus, rigidis capilascens tenuiflissim foliis trisidiis; Pluk. Maff. 61. Phyt. t 345. f. 6.)—Heads terminal, longer than their flalks. Bracteas roundish, pointed, villous. One segment of the corolla nearly smooth. Leaves spreading; the lower ones three-cleft; upper subdivided. Stem nearly upright.—Native of hills about the Cape. Mr. Brown gathered it on the sides of mountains, near Simon's bay. A shrub of humble growth, flowering with us in June or July. The branches are scarcely pubescent. Leaves not an inch long, rather hairy while young. Flower-flalks foliary, downy, generally but half the length of the heads of flowers, which are the fize of a large cherry, rising above the upper leaves, and accompanied by membranous silky bracteas.

S. petersiana. Woolly-headed Serruria. Brown. n. 13. Ait. n. 3. (Protea petersiana; Ait. Repof. t. 264.)—Heads terminal, falked. Bracteas ovate, downy. Corolla curved, fathery; its inner segment ficky. Leaves twice or three pinnatifid, hairy, as well as the upright ftem.—Found in various filly situations at the Cape of Good Hope, where the soil is rather fertile. Meffrs. Lee and Kennedy are recorded as having first raised this species, in 1789, from seeds obtained from Vieuina. It flowers in fummer, and makes a handsome appearance, with its copious many-cleft leaves, and large heads of light reddish brown flowers, clothed with fine white plummy down. The anthers are yellow. Stigma blackish.

S. hirsuta. Hairy Serruria. Brown n. 15. (Protea phylloides; Thunb. Diff. n. 9. Prodr. 25. Willd. Sp. Pl. v. 1. 510, excluding the reference to Bergius.)—Heads terminal, longer than their flalks. Bracteas linear-lanceolate, hairy. Corolla fathery. Leaves doubly pinnafeate, about as long as the heads. Branches hairy. Stem erect.—Native of ftony hills at the Cape. Mr. Brown observed it near Simon's bay. It feems unknown in our gardens. This fbrub is two or three feet high, with ftraight umbellate branches, rough with spreading permanent hairs. Leaves copious, moderately spreading, an inch, or sometimes an inch and half, long, hairy when young only; their segments very sharp-pointed. Flower-flalks often more than one at the top of each branch, half the length of the heads, with lanceolate-awl-shaped, spreading bracteas. Heads as big as a walnut, rising above the upper leaves. Corolla slightly curved; the hairs on its inner segment shorter than those of the other three. Stigma cylindrical, somewhat club-shaped.

S. Niveni. Niven's Serruria. Brown. n. 17. Ait. n. 4. (Protea decumbens; Andr. Repof. t. 349.)—Heads terminal, fesille. Bracteas lanceolate; the inner ones ficiary. Corolla bearded. Leaves doubly pinnatifid; the uppermost longer than the head, fomewhat smooth. Stem decumbent.—Discovered by Mr. James Niven, on Swartberg, a rocky mountain at the Cape of Good Hope, and fent by him to Mr. G. Hibbert in 1800. It blooms in the summer, and is of a small stature, and decumbent habit. The flowers are of a dull red, clothed externally with white silky hairs; and each fotaly head, smaller than a hazel-nut, is encompafied with numerous, crowded, radiating leaves. Each leaf of the general foliage is about an inch long. Stigma hardly thicker than the fyle. Mr. Andrews's plate represents the branches as somewhat downy.

S. pflvicoidea. Phyllica-flowered Serruria. Brown. n. 24. Ait. n. 5. (Leucadendron phylloides; Berg. Cap. 29. Protea phyllochefta; Linn. Maff. 188. P. abrotanifolia; Ait. Repof. t. 507.)—Heads terminal or axillary, on fcaly flalks. Bracteas half as long again as the head, lanceolate, fomooth; the outer ones narrowfelt. Tips of the corolla bearded. Leaves twice compound, longer than the flower-flalks.—Native of the Cape, from whence it was fent to Kew, by Mr. Maffon, in 1788; flowering there in July and Augulf. This is a smooth upright fbrub, with redifh leafy branches. Leaves generally bipinnatifid, an inch or two long, moderately spreading. The flower-flalks, clothed with several lanceolate fcales, and either fotaly, or aggregate in a corymbose manner, are longer than the heads, but usually shorter than the foliage. Heads above half an inch in diameter, subtended by many longifh, deflexed, green, red-pointed bracteas. Corolla whitifh and fomooth, except the ends of the segments, which are red, and definely bearded. Stigma red, cylindrical.

S. florafa. Large-flowered Serruria. Brown. n. 25. (Protea florafa; Thunb. Diff. n. 2. t. 1. Prodr. 25. Willd. Sp. Pl. v. 1. 506.)—Bracteas longer than the flalked heads; the outer ones elliptic-oblanc, pointed, fomooth; inner concealed, linear-lanceolate, fringed. Leaves once or twice pinnatifid.—Thunberg and Maffon gathered this species on the mountains of Franche Hoek at the Cape. It has not as yet found its way into our green-houses, which is much to be regretted, no other Serruria being comparable to it in beauty. The leaves are three or four inches long, fomooth, as well as the branches, which are of a puifh hue. Flowers many together, on corymbose fcaly flalks at the ends of the branches, large, remarkable for their beautiful red external bracteas, which are each an inch in length and half long, attended by smaller ones, of the same kind, flacked down the flalk, while the innermost bracteas, coming into view by the spreading of the former, are linear, fringed with
with yellow hairs. This is a very rare plant, even in dried collections.

Sect. 2. Heads compound; partial ones crowded.

S. decumbens. Trailing Serruria. Brown. n. 27. (Protea decumbens; Thumb. Diff. n. t. 1. Prodr. 25. Wildl. Sp. Pl. v. t. 506. P. procumbens; Linn. Suppl. 196.)—Stem prostrate, smooth, as well as the three-leaved leaves, whose segments are undivided. Each partial head of about four flowers.—Native of the flaky stones of mountains, at the Cape of Good Hope; not as yet known as a garden plant. It is smooth, dividing from the root into several prostrate, leafy, wavy branches. Leaves ascending, about two inches long, in twos or threes, thick, linear segments. Flower-flasks axillary and terminal, slender, flaky, each bearing a small roundish head, enveloped in ovate, pointed, rather silky bracts, and composed of four to fix smaller heads. Corolla flaky, very slightly curved. Mr. Brown remarks that some of the heads are, apparently from starvation or abortion, simple.

Sect. 3. Flower-flasks divided. Heads simple, corymbose or racemose.

S. burniana. Burmann's Serruria. Brown. n. 36. Ait. n. 7. (Protea serraria; Linn. Mant. 188. Wildl. Sp. Pl. v. t. 508. Leucadendron serraria; Linn. Sp. Pl. 137. Serraria folis tenuifilmindivis, floribus rubris apetalis; Burm. Afr. 265. t. 99. f. s.)—Abrotanoides arboreum, &c.; Pluk. Mant. t. 329. f. 1.)—Heads corymbose, each of about ten flowers. Corolla level-topped, more or less flaky, shorter than the partial flasks. Leaves doubly pinnatifid, bristle-shaped, longer than the flower-flasks. Native of low barren spots, about the sides of hills at the Cape, very frequent. Mr. Maslin sent it in 1786 to Kew garden, where it blossoms from May to July. A humble corymbose flower, with very slender acute leaves, which are slightly hairy. The heads are small, reddish, crowned with the long prominent styles. Mr. Brown mentions a variety, or possibly distinct species, whose leaves are rather flaky, heads more obtuse at their base, and bracteas, as well as flowers, altogether flaky.

S. triflora. Silvery-flowered Serruria. Brown. n. 37. Ait. n. 8. (Protea triflora; Thumb. Diff. n. 7. Prodr. 25. Wildl. Sp. Pl. v. t. 509. P. argentiflora; Andr. Repof. t. 447.)—Corymbs compound. Heads globose, many-flowered. Bracteas and partial flower-flasks flaky. Leaves three truncate, smooth as well as the stem.—Gathered by Mr. Niven, near the river at Roode Zant, Cape of Good Hope. Mr. Masson and Kennedy are said to have first raised this elegant species, about the year 1802. It blossoms from June to August. The leaves are five or four inches long, and as thick as a crow's quill, being larger, as well as more compound, than in most other species. Heads of flowers of a silvery white, flaky, numerous, each rather above half an inch diameter. Stigma obovate, yellow.

SERSALISIA, so named after a Neapolitan ecclesiastic, much commended by Fabius Columna (though in what part of his writings we are not informed), is a genus separated by Mr. Brown, in his Prodr. vol. 1. t. 529, from the Linnaean Sideroxylon; but the character does not seem to us very clear. One species of this new genus is Sideroxylon fericum, Ait. Hort. Kew. ed. 1. t. 526. ed. 2. t. 153; another is called Mr. Brown Sideroxylon, Linnaean. Both are natives of the tropical parts of New Holland. See SAPOTE and SIDEROXYLON.

S.R. T.S. in Geography, a town of Hindustan, in Oude; 25 miles E. of Bareit.

SERTA, GARLANDS, among the Ancients. See GARLAND.

SERTAM, in Geography, a town of Portugal, on the river Pera, in Estremadura; 24 miles N.E. of Thomar.

SERTINO, a river of Sicily, which runs into the sea, on the east coast.

SERTORIUS, QUINTUS, in Biography, a distinguished Roman commander, was a native of Naris, in the Picentine regions of Italy. His father died in his infancy, but by the care of his mother he received a most excellent education; and even in his youth he gained a considerable reputation as a pleader at Rome. He had, however, a decided turn for the duties and glory attached to a military life, and made his first campaign under Servilius Capio, against the Cimbrians and Teutones in Gaul. In an early engagement he was severely wounded, and would have lost his life, if he had not possessed sufficient vigour to swim across the Rhone, when encumbered with his armour. He next served under Marius, and exhibited proofs of valor and talents, which much ingratiated him with that general. Spain was the next great theatre of his exertions, where he served under Didius, and acquired much reputation in the campaign. On his return to Rome, he was made quaestor in Cisalpine Gaul; and when the socal war broke out, he brought a well-timed reinforcement to the Roman army. In a battle that ensued, he lost an eye, a mark of bravery in which he always gloried, and which pointed him out to the plaudits of the people, whenever he appeared in the theatre, and other public places. He was candidate for the tribunship, but was disfitted in his hopes by the overbearing interdict of Sylla: he accordingly joined the party of Marius in the succeeding civil war. He commanded one of the three armies which invested Rome, and honourably distinguished himself by abstaining from all acts of cruelty which disgraced the arms of Cinna and Marius. When Sylla gained the ascendency in Italy, Sertorius withdrew to Spain, of which country he had been appointed propraetor. Here he hoped to be able to revive his cause, and with this view he detached a body of troops to seize the palaces of the Pyrenees; but the murder of their commander induced them to abandon their spoil, and consequently left Spain open to Sylla's officers. After some various adventures, chiefly of the disfavour kind, Sertorius went into Africa, and affinity the Mauritanians to throw off the yoke of a tyrannical king; defeating one of Sylla's generals, by whom he was supported. His reputation now caused him to be invited to Lusitania; and failing thither with a small body of Romans and Africans, he obtained such an ascendency over the natives, that he soon had the command of the whole Lusitanian nation. He exerted them in the arts of warfare, and introduced a rigid discipline among them; but Roman tactics being unfavourable to them, he adopted a service better suited to the nature and circumstances...
stances of the country. He defeated, with his new-trained armies, several Roman generals, who were sent against him, and inflicted a defeat in competition with that of Rome, and illuminated all the arms of the republic. He foiled the attempts of that eminent commander, Metellus, to reduce him; continually harass'ing his troops by sudden attacks and skirmishes, and intercepting his convey. He adopted the liberal policy of civilizing the Lusitaniacs and neighbouring Spaniards, and familiarizing them with Roman letters and customs. For this purpose he established a great school in the city of Oe
cs, at which the sons of men of distinction were gratuitously educated, and at the same time kept as hostages for the fidelity of their parents. Feeling that his power was not sufficiently firm, without the aid of super-
fition, which ever captivates the ignorant and uncivilized, he trained a white fawn, that had been presented to him, to such a degree of tameness, that it followed him whitherto he went, and was his constant companion; and he en-
couraged the belief that the animal was the gift of Diana, and intended by that goddess to convey information of the designs of his enemies. At length the famous Pompey was nominated to the command against him; and when he arrived, he found that all the Roman troops, which, after the death of Lepidus, had been carried to Spain by Per-
enna, with the design of setting up there for himself, had joined Sertorius, who was now at the head of a considerable army. Pompey proceeded against him with a superior force; but Sertorius took a town in his presence, and afterwards defeated him at the battle of Sucro. He gave him a second defeat; but Metellus routed a separate division, and Sertorius was glad to take to the mountains. He then of-
ered to lay down his arms, provided the proscription against him might be taken off, and he were permitted to return to Rome. Soon after he received an embassy from Mithri-
dates, the formidable foe of the Romans, offering him an advantageous alliance, provided he were suffered to re-
possess the provinces from which he had been expelled by Sylla. But Sertorius would not agree to more than his re-
coverry of Bithynia and Cappadocia, without touching upon the Roman province of Asia; and upon these terms the treaty was concluded. A conspiracy was formed against Sertorius by the Roman patricians in his army, and they succeeded in exciting a revolt in several Lusitaniac towns. Incensed at this defection, he caused several of the children, whom he kept as hostages at Oe
cs, to be slain, and others to be sold as slaves. This is said to have been the only act of cruelty by which his memory is tarnished. In revenge for the loss of their sons, the conspirators formed a plot against the life of Sertorius; in conseqnece of which he was kept in close confinement, while he was at a feast. This event took place in the year 73 B.C. "The great qualities and military talents of this eminent person would undoubtedly have raised him to the first rank among the chiefs of his country, had he not been a leader of a party, instead of a commander for the state. With nothing to support him but the resources of his own mind, he created a powerful kingdom among strangers, and defended it a long time against the arms of Rome, although wielded by the ablest generals of his time; and he displayed public and private virtues, which would have rendered a people happy under his rule at a less turbulent period."” Univer. Hist.

**SERTULA CAMPANA**, in Botany, a name given by some authors to melilot.

**SERTULARIA**, in Natural History, a genus of the class Vermes, and order Zoophytes. The generic char-
acter is this: the animal grows in the form of a plant; the stem is branched, producing polypes from cup-shaped den-
ticles, or minute cells. There are nearly four-score species, divided into two divisions, A and B, of which the following is the description.

A. Stem hairy, tubular, fixed to the base, base with cup-shaped den-
ticles, and furnished with vesicles, or ovaries, containing polypes, eggs, or living young.

Species.

*ROSAE*. This species is paniced, with opposite, tubular, truncate denticles, and alternate branches; the ves-
icles are crowned with pines. It inhabits the European seas, and our own coasts, growing on shells, or creeping up other corallines; it is white; the vesicles resemble the blossom of the pomegranate.

*PULINA*. The denticles of this species are opposite, pointed, and recurved; the vesicles are obovate; the branches loose and irregular. It is found in the ocean, on fuci, particularly on the ferratus.

*OPERCULATA*. Denticles opposite, pointed, and nearly erect; the vesicles are obovate, covered with a lid; the branches are alternate. It inhabits the European and American seas, on fuci and shells. The twigs are about five inches long; the denticles are bicuspidate, with a short bristle on each side.

*TAMARISCA*. Denticles nearly opposite, truncate, three-toothed; vesicles ovate, two-toothed, with a short tube in the centre; the branches are alternate. This is found in most of the European seas, and is the largest of its kind. It is about four inches long, and is found adhering to shells.

*ABRETINA*. Denticles nearly opposite, tubular, oval; the vesicles are oval, and the branches alternate. It is found in the British and other European seas, the Mediterranean, growing to shells. It is five inches long, and often covered with small fperula; the branches are frequently pinnate.

*NIGRA*. Denticles nearly opposite, minute; vesicles large, placed all on one side, oval, quadrangular; the branches are pinnate. This is found on the Cornish coasts, adhering to the Mytilus margaritiferus. It is four inches long, blackish.

*FUSCESCENS*. Denticles nearly opposite, tubular; the vesicles are numerous, placed all on one side, minute, with three tubercles on each; the branches are pinnate. This is also an inhabitant of the Cornish coast. It resembles the last, but is of a greyish-brown colour.

*OBSELETA*. Denticles generally placed in eight rows, ovate, slightly heart-shaped, and disposed in a quincunx form; the branches are alternate and pinnate. It is an inhabitant of the Frozen ocean, is about five inches high, and of a horn colour, with the joints becoming more and more obsolete towards the top.

*PINUS*. Denticles sub-spinous, generally disposed in six rows; the vesicles are bottle-shaped, turgid, subdiphaceous, with a simple mouth; the branches are pinnate, nearly al-
ternate. It inhabits the White sea, fixed to shells.

*CUPRESSOIDES*. Denticles simple, obliquely truncate, with a slightly protruberant mouth; the vesicles are oval, with a subtubular mouth; the branches are dichotomous, loose, and with the trunk joined with two rings at the junctures. This is found in the White sea; is subdiphaceous, yellowish, and nearly half a foot long.

*CUPRESSA*. Denticles nearly opposite, obliquely truncate, and a little pointed; vesicles obovate, two-
toothed; branches paniced, and very long. It is common in all the European seas, and is found in a long pointed loose panicle.

*ARGENTEA.*
* Argentea.* Denticles nearly opposite, pointed; vessels oval; branches alternate, panicked. This is an inhabitant of the European and American seas; very much resembles the last, but the branches are shorter and looser, and the panicle is more obtuse.

* Rugosa.* Denticles nearly opposite, obsolete; vessels much wrinkled, and three-toothed; the branches are furred. This species inhabits the European seas, and is found growing on the Fuflra foliacea, and other fterulariae.

* Halecina.* Denticles alternate, tubular, and two-jointed; the vessels oval, each united along the side to a small tubular flake; the stem is alternately branched and pinnate. This is found in the European and Mediterranean seas. It is horned, and of a yellowish-grey; the denticles are nearly obsolete.

* Thulia.* The denticles in this species are arranged in two rows, closely adhering to the stem; the vessels obvate, margined; stem waved and fiff, with a tuft of dichotomous branches near the tip. It is found on the northern coasts of England, and in the Mediterranean, and is about half a foot long.

* Myriophyllum.* The denticles are truncate, all leaning one way on the stem; the stem itself is gibbous on the side opposite the branches; the branches lean all one way. This is found in most European seas, and in the Mediterranean; it is about three inches long, pale and forny; the stem is rather angular, with arched proteruberances opposite the branches; the denticles are fcelled in a focket furnished with a short spine on the lower part.

* Hypnodes.* Denticles pointing one way, campanulate, toothed, and beaked; stems with pinnate branches, and very crowded subdivisions. It inhabits the Indian ocean, is fix inches high; in colour it is brown, with yellowish imbricate radicles.

* Speciosa.* Denticles campanulate, effuse, toothed, and fipulate; the stem is pinnate, rigid, with incurved branches, mostly pointing one way. It is found in the Indian ocean, adhering to the tubular radicles of gorongize; it is brown, forny, and from three to four inches long.

* Punctata.* The denticles of this species point all one way; they are imbricate and truncate; the vessels are ovate; the branches are pinnate and alternate. There is a variety of this species described by Ellis, in his work on Coralines. It inhabits the European and Indian seas, and is from three inches to a foot long; the stem is a little flexuous; the denticles in a fingle row.

* Pluma.* In this the denticles point one way, they are imbricate and campanulate; the vessels are gibbous and crefied; the branches are pinnate, alternate, and lanceolate. It is found on most European coasts, climbing up fucis; the branches are jointed; the denticles are ferrate at the margin, and supported in front by a small hollow spine; the vessels have a denticate margin, and generally five oblique crefed ribs.

* Echinata.* Denticles opposite, pointing one way, campanulate; the vessels are crefed; the branches pinnate, alternate, and lanceolate. It inhabits chiefly the fhores of Sweden, on fucis.

* Antennaria.* The denticles are vermiculate, in fours, fetectaceous; vessels obliquely truncate, vermiculate; the stems are generally fimple. There is a variety which is branched. They are both found on the British coasts, often nearly a foot high; it is yellow, with very fine capillary yellowish radicles; the stem is surrounded with small incurved fetectaceous branches, on the upper fides of which are rows of small cup-shaped denticles; the vessels are placed on pedicles obliquely open towards the stem, and placed round it at the ferrition of the branches.

* Verticillata.* The denticles in this are obsolete; the vessels campanulate, toothed round the rim, on long twisted pedicles, and placed in fours round the stem; the branches are alternate. It is found on the British coasts; stem ribbed, very loosely branched; the denticles are not visible; the vessels are nearly ecret, and glutinous; the ovaries are oval, ending in a tubular mouth.

* Gelatinosa.* Vessels campanulate; stem with numerous decomposite spreading branches. It is found on the coasts of the Netherlands; is half a foot long, and of a grey-brown colour.

* Volubilis.* The denticles in this are obsolete; the vessels are alternate, campanulate, toothed round the rim, on long twisted pedicles; the branches are alternate. It inhabits European seas, climbing up other fterulariae; it is whitish and minute; the stem is loosely branched; the ovaries are egg-shaped and smooth, or tranfverfely wrinkled.

* Syringa.* Denticles obsolete; vessels cylindrical, mostly alternate, and placed on short twisted pedicles.

* Cuscata.* Denticles obsolete; vessels oval, axillary; branches opposite and simple. It is found in the European seas, adhering to fucis.

* Postulosa.* Stem with alternate dichotomous branches, obsolete denticulate on the upper part. It inhabits the shores of the Ife of Wight, and is four inches long. The stem is feen rising into alternate dichotomous joints, with small denticles, having a circular rim, with a point in the middle of each towards the upper part of each joint.

* Frutescens.* Denticles cylindrical, campanulate, placed in a fingle row on the inside of the branches; the branches are alternate, and pinnate. This is chiefly found on the British shores; rather hard, blackish with brown branches; the stem is composed of small united tubes.

* Pinaster.* In this species the denticles are opposite, fimple, with an incurved tubular tip; the vessels are large, ovate, quadrangular; the angles terminating in a spine, and furnished with a tubular mouth in the centre, placed in a row along the branches; the branches are alternate.

* Penatula.* The denticles in this are in a fingle row, crefate on the rim, and supported by a flender, truncate, incurved horn; the branches are opposite. It is found in the Indian ocean; is five or six inches long; yellow-brown; the denticles have two opposite fpines on the rim.

* Filicula.* Denticles opposite, ovate, with a fingle crefed one at the junctures of the branches; vessels ovate, with a tubular mouth in the centre; the stem is zig-zag, with alternate branches. It inhabits the British fhores, is very tender, and the stem is much branched.

* Quadridentata.* Denticles in fours, opposite, at the joints of the stem; the stem is fimple, with the joints tapering and twisted towards the base. It inhabits the African fhores on the Fucus lengerus.

* Spicata.* Denticles in three, cylindrical, terminal, and nearly closed at the mouth; vessels ovate, axillary; stem tubular, panicked, annulate, with trihromous branches defcribed in whors round the rings.

* Evansii.* The denticles are short and opposite; the vessels are lobed, arifying from the branches which are opposite. It inhabits the British coasts, and is found on fucis; it is two inches high, very flender, and yellow, with fulvous vessels.

* Mutica.* The denticles of this species are pedicled, proceeding alternately from the joints of the branches; vessels oval, fipinous; the stem is jointed. It is found on the fhores of Scotland; the vessels are nearly globular,
placed on pedicles, and full of pointed spines from crested ribs.

Sertularia. Denticles in a single row, campanulate; the vehicles are axillary; the stem is minute, white, and incurved. This species is found in the Mediterranean: it is scarcely three lines high, and not thicker than a fine brittle.

Misenexis. The denticles are alternate, very thin, spreading; the vehicles are ovule, peduncles axillary; stem much branched, dichotomous. It inhabits the Mediterranean, is very slender, pellucid towards the tip, and sometimes covered with the Cancer linearis.

Racemosa. Denticles scattered, pellucid; vehicles clustered; stem straight, round; opaque, horny, with finely curved branches. It inhabits the Mediterranean.

* Uva. Denticles oblonge; vehicles ovate, clustered; stem slightly branched, with alternate subdivisions. It inhabits the shores of this country and Holland, adhering to other zoophytes; vehicles transparent, with a white nucleus.

* Lendigeria. Denticles oblonge; vehicles cylindrical, arranged in a single row along the branches, and growing gradually less towards the top; the stem and branches arc jointed. This is found on the European coasts, on other zoophytes. The branches are subdivided and irregularly interwoven; the vehicles are placed in parallel ranks along the sides of the branches, and growing gradually shorter towards the top of the joints.

* Gexiculata. Denticles alternate, twisted; vehicles ovate, with a tubular mouth in the center; the stem is branched, jointed, flexuous. It inhabits the European coasts, adhering to fucil.

* Dichotoma. Denticles oblonge; vehicles ovate and axillary, on twisted pedicles; the stem is dichotomous, with twisted joints. It inhabits the British and Dutch coasts, and is nearly a foot long; it is white, but becomes tesselaceous with age.

* Spinosa. Denticles oblonge; vehicles ovate, tabulate; the branches are dichotomous and pinnate. It is found on most European coasts, as well as on those of this country, and is about eight inches long. The stem is composed of interwoven tubular fibres; the branches are flexuous, lofe, forked, with pointed tips.

* Pinna. The denticles of this species are oblong; the vehicles are oblong, and surrounded with a coronet of tubercles at the rim; stem simple, pinnate, and lanceolate. It is found in Europe and in India, and is about three inches high. The stem is pinnate, with alternate subdivisions; the vehicles are placed in clusters round the stem.

* Setaea. Denticles oblonge, remote, placed in a row on the upper side of the branches; vehicles oblong, axillary; the stem is pinnate, with alternate bent divisions. It inhabits the European coasts, and is about an inch and half high.

* Polyxenia. Denticles alternate, slightly toothed; vehicles oblonge, transversely wavy; the stem is lofe, branched. It inhabits mott sear, adhering to marine substances.

Pennaria. The denticles are placed in a row on one side the branches; the vehicles are oval; the stem is twifed, and doubly pinnate. It inhabits the Mediterranean sea, growing in tufts on rocks; the stem is straight, ascending, flexible, and almost white with whitish branches.

* Lichenastrum. Denticles alternate, obtuse, in two imbricate rows along the stem; the vehicles are ovate, in two parallel rows along the branches; the stem is pinnate, alternately pinnate. It is found in the Irish, Indian, Asiatic, and Armenian seas. The stem is erect, jointed, compressed, and denticulate; the branches are alternate, denticulate, and straight.

Cedrina. Denticles subcylindrical, tubular, in four imbricate rows; the branches are irregular, quadrangular, and thicker upwards. Inhabits the seas of Kamtschatka; the branches are dichotomous, subulate, with four rows of vehicles.

* Imbricata. The vehicles of this species are subulate, irregularly imbricate upwards; the stem is slightly branched. This species is described and figured in the 5th vol. of the Linnæan Transact. It inhabits the western coast of Britain, on the Fucus nodosus; it very much resembles the alga, but the vehicles are not placed in any regular series; it is about three inches high; the smaller branches have the vehicles placed bifurcately, but towards the tip they become imbricate.

Purpurea. Denticles subovate, tubular, in four imbricate rows; the vehicles are ovate and campanulate; the branches are dichotomous and square. It inhabits the sea around Kamtschatka, and is of a blackish-purple.

Articulata. Denticles pressed together; the vehicles are ovate, rather large, covered with a lid, and placed in a single row; the stem is jointed and pinnate. It is found in the Atlantic ocean, creeping on shells, and is about two inches long; pale yellow.

Fulicina. Denticles imbricate, placed on one side only; vehicles jointed; stem granulate, branched and pinnate, the subdivisions alternate. It inhabits the Indian ocean, is pale, and about three inches long.

Furcata. The denticles of this species are in a single row on one side; semi-campanulate; the stem is granulate, woody, with alternate fleshy subdivisions. It inhabits the American seas, like the fup. It is six inches long, and of a yellowish-grey.

B. The species of this division have a compound stem, including to fust, and composed of rows of cells; they have no vehicles, but in the place of these there are small globules.

* Dorsaria. Denticles opposite, compressed and truncate; the stem is branched, and dichotomous. It is found on the British coasts, adhering to fuel; it is minute, flexible, yallow; the denticles are carinate, with a small clavate tube at the top.

* Lorica. Denticles opposite, obliquely truncate, and nearly oblonge; the branches are erect and dichotomous. It inhabits the British coasts, on old furturiae.

* Fastigiata. Denticles alternate, pointed; branches dichotomous, eret. This is found in the British seas; the denticles are marked with a black spot in the middle.

* Articulata. The denticles all point one way, nearly opposite, and furnished with two mucronate appendages; the globules appended; the stem is branched and dichotomous. It is found in the European seas; is from one to two inches long; in colour it is of a dirty green. It is very brittle.

* Nebitina. The denticles are alternate, acute, and pointing one way; the branches are dichotomous, unequal, and straight. It is found in the European and American seas. It is soft; the globules have an opening surrounded by a dark-coloured margin.

* Scurra. Denticles alternate, angular, xpinous; the branches are dichotomous and creeping. It inhabits most seas; is very brittle, linear, and pale, with a double row of cells.

Pilosia. The denticles are alternate, oblique, with a long mouth; the branches are dichotomous, fastigiate, and strong.
strong. It is found in the Mediterranean, and is not half an inch long.

*CRISPUS.* This species is very much branched, dichotomous, elongated, and cripped, with depressed ovate joints, furnished with cells on one side. It inhabits the East, is large, flexible, and of a pale-grey colour.

*FLOCCOSA.* This is very much branched, dichotomous, fusiiforme, with wedge-shaped joints, having cells on one side. This is found chiefly in the Indian ocean; is large, whitish, with greyish flexible joints.

*REPTANS.* Denticles alternate, two-toothed; the branches are dichotomous and creeping. This is found in the European seas, adhering to the Flustra foliacea; it is not an inch long; white or pale-grey.

*PARASITICA.* The denticles of this species are vertical, turbinate, ciliate, and parafatical. It is found in the Mediterranean and North seas, adhering to other furticolor and corallines; in colour it is dull red, with terminal denticles.

*CILIATA.* Denticles alternate, ciliate, funnel-form; branches dichotomous and erect. It inhabits the European seas, on marine substances; not half an inch high; it is whitish; the cells have wide mouths.

*EBURNEA.* The denticles are alternate, truncate, a little prominent; the vessels are gibbous, with a tubular beak on one side; the branches spreading. This inhabits the European and Mediterranean seas, and is found growing upon other furticolor and fuci; is about an inch high, and white.

*CORNUTA.* The denticles are alternate and truncate, with a single hair on the top of each; the vessels are gibbous, with a tubular beak; the branches are alternate. This inhabits, like the last and two following, the European and Mediterranean seas, on fuci; it is fomy, clear white, and not half an inch long. The denticles are curved, tapering towards the base, and placed on each other.

*LORICATA.* Denticles in a cuneate row, pointing one way, with a margined mouth, horned beneath; the branches are alternate. It is found on fuci. The denticles are like inverted horns placed on each other, with a short hair on the top.

*ANGUINA.* The item is very simple, without denticles, but befet with very simple, obtuse, clavate arms, each with a lateral opening. This is found climbing up marine substances; it is white, soft, flexible, varying in form, and appears to connect the furticolor and hydras; the arms are tesselate.

*CEREHOIDES.* Denticles imbricate, with somewhat prominent mouths; the item is branched, jointed, and cylindrical. It inhabits the coast of Africa; is three inches high; whitish, fomy, aggregate, with short joints.

*TULIPIFERA.* Cells in threes on the upper part of the joints, and united together; item branched, with clavate joints. It inhabits the West Indies, adhering to fuci, about half an inch high, and clear white; the item is fomy and subepithanous; the cells are terminal.

*FLAGELLUM.* This species is fomy, branched, jointed, dichotomous; the joints are somewhat wedge-shaped, and have cells on one side. It inhabits the Bahama islands, is about two inches high, white, growing in tufts; the joints are convex and filiate on one side; the others are flat, with a triple row of cells.

*TERRATA.* Branched, dichotomous, jointed, creeping; the joints are angular at their sides, with three cells in the front of each. It inhabits the shores of Scotland; it is fomy, semitransparent.

*CHRATA.* Stony, jointed, flat, dichotomous, incurved, the joints are subciliate, ovate, truncate, flat, and having cells on one side. It inhabits the Indian ocean, is about two inches high, and is white; the joints are convex, and filiate on one surface; the other is flattened, with a double row of cells.

*OPUNTIOIDES.* Branches in threes, with cylindrical joints, covered with slightly prominent pores. It inhabits the Eastern ocean; is about half an inch high, erect, very much branched, white, fomy, with the pores disposed in a quincunx form.

*SERVA,* in Geography, a town of Persia, in Szigeti; 180 miles S.S.W. from Zareng.

*SERVAGE.* See Service.

*SERVAL,* in Zoology. See Felis Serval.

*SERVAN,* in Geography, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of St. Malo. The place contains 8836; and the canton 10,617 inhabitants, on a territory of 50 kilomètres, in 4 communes.

*SERVANDONI,* John Nicholas, in Biography, an eminent architect, was born at Florence in 1605. He was employed by several of the sovereigns in Europe on occasions of magnificent public spectacles, in which he displayed a very fertile invention, with nobleness of ideas, and a correct taste. At Paris he had the direction of the theatre during 18 years, and was architect, painter, and decorator to the king; and was admitted member of the several academies of arts. He gave a number of designs for the theatres of Dresden and London, and was sent for to the latter capital on the rejoicings for peace in 1749. He preceeded at the grand festivals exhibited at the court of Vienna, on the marriage of the archduke Joseph and the princes of Parma. The king of Portugal frequently employed him, and honoured him with the order of Chrift. He died at Paris in 1766, having acquired the reputation of being the first artist of the period in which he flourished. As an architect he has left a fine specimen of his taste in the portico and front of the church of St. Sulpice.

*SERVANT, SERVUS,* a term of relation, signifying a person who owes and pays a limited obedience for a certain time to another, in quality of master; in contradistinction to slave, over whose life and fortune the master claims an absolute and unlimited power. See Slave.

The first sort of servants, acknowledged by the laws of England, comprehends mental servants; to be called from being intra mania, or domestics. The contract between them and their masters arises upon the hiring; if the hiring be general, without any particular time limited, the law concludes it to be hiring for a year (Co. Lit. 42. F. N. B. 168.); but the contract may be made for any larger or smaller term. All men between twelve years of age and sixty, and married ones under thirty years of age; and all single women between twelve and forty; not having any visible livelihood, are compellable by two justices to go out to service in husbandry, or certain specific trades, for the promotion of homel industry; and no master can put away his servant, or servant leave his master after being so retained, either before or at the end of his term, without a quarter's warning, unless upon reasonable cause, to be allowed by a justice of the peace (flat. 5 Eliz. e. 4.); but they may part by consent, or make a special bargain.

Another specie of servants includes those called apprentices (which fee); a third sort belongs to that class denominated labourers. See Labour and Labourers.

And there is a fourth species, if they may be called servants, being rather in a superior capacity of service; such as managers, factors, and bailiffs, whom, however, the law considers
SERVANT.

Much depends upon the fobriety, integrity, and diligence of servants; and the ease with which they obtain characters, or procure employment with such characters, real or fictious, as they gain, is very injurious both to their employers and to themselves. Characters are given with so little re-
servce and veracity, “that I should as soon depend,” says the author of the Rambler, “upon an acquittal at the Old Bailey, by way of recommendation of a fervant's honesty, as upon one of these characters.” At the same time an-
other extreme should be avoided, which is that of obstruct

What the Christian scriptures have delivered concerning
the relation and reciprocal duties of masters and servants, breathes a spirit of liberality, very little known in ages
when servitude was slavery; and which flowed from a habit
of contemplating mankind under the common relation in
which they stand to their Creator, and with respect to their interest in another existence. (Ephef. vi. 5—6.) “Servants be obedient to them that are your masters, according to the flesh, with fear and trembling; in singleness of heart, as unto Christ; not with evil-service, as men-pleasers, but as the servants of Christ, doing the will of God from the heart; with good will, doing service as to the Lord, and not to men: knowing that whatsoever good thing any man doth, the fame shall he receive of the Lord, whether he be bond or free. And ye masters do the same thing unto them, for-
bearing threatening; knowing that your master also is in heaven; neither is there respect of persons with him.” The idea of referring their service to God, of confidering him as having appointed them their task, that they were doing his will, and were to look to him for their reward, was new; and affords a greater security to the master than any inferior principle, because it tends to produce a steady and cordial obedience in the place of that constrained service, which can never be trusted out of sight, and which is justly enough called eye-service. The exhortation to masters, to keep in view their own subjection and accountability, was no less feasible.

The Romans, besides their slaves, whom they also called
freyi, had another kind of servants, whom they called uexi and aditi, who were such as being in debt, were delivered
up to their creditors by the prince, to work out the debt, after which they were again at liberty.

The pope, out of his wonderful humility, calls himself in
his bulls, the servant of the servants of God, servus serv-
vorum Dei. The first who used the appellation, as Dion-
cusus tells, were pope Damatus, and Gregory the Great, which last is said to have used it to check, by his modesty, the arrogance of John, patriarch of Constantinople, who took the title of ascenital. Du-Cange adds, that the title servant has been assumed by some bishops, by some kings, and some monks.

SERVANT, in Agriculture, a person employed in the
performing of some part of the busines of a farm, of
whatever kind it may be. On this subject, the following
judicious hints have been thrown out by the author of the
"Landed Property of England," for the direction of those
servants who have the conducting of the management of
farming
farming business. Nothing, he contends, contributes more to facility and satisfaction in this fort of business, than a forecast towards works to be done. A miscarriage is ever to be dreaded as a mischief; and when it is brought on by a want of forethought, it brings with it a degree of discredit, and a train of unpleasant reflections, which, for every enjoyment. This kind of servant should, he thinks, have a forecast towards crops for three or four years; toward team-labour for as many months; and should look forward with a view to hard labour for some weeks, according to the season of the year. And to bring it to a degree of certainty, it is necessary to make out a list of the fields, or parcels of land, of which the farm consists; with the crops which each has borne for some years back; together with the manurings which they have severally received, in order that the future treatment of each may be decided upon with sufficient accuracy. And to prepare every autumn, by the assistance of such list, an arrangement of the crops that are intended for the ensuing year; clashing the fields, or pieces, according to the purposes for which they shall be intended: thus ascertaining the quantity of each crop, whether arable or grazing, as well as the quantity of ground intended for pasture; in order that the quantity of team-labour may be distinctly foreseen,—the required strength be estimated from time to time,—and the several crops be sown in due season; and in order that the flock of the ensuing summer may, in due time, be properly apportioned to the intended quantity of pasture ground; as well as that the works of summer and harvest may be constantly before the eye; and proper hands be engaged, in time, to perform them in season, and with the necessary dispatch and certainty. And he further advises a fort of memorandum list to be kept of business to be done,—immediately,—or in immediate succession; whether it relate to crops or to any other concerns of the farm; that nothing may escape the memory; and that the most requisite may be brought forward first; or another which is more suitable to the state of the weather, or other circumstances. In this, as well as other business, the great object to be aimed at is that of enuring success; which is not only profitable to an employer, but satisfactory to the person employed. Whereas a miscarriage injures at once the property of the one, and the character, as well as peace of mind, of the other. Hence a farm manager ought to engage in a work, whether of improvement or ordinary practice, with caution; and to proceed in it with attention and firmness. A standing rule, respecting this main object of management, is not to attempt too much, and never to begin a work without a moral certainty of being able to finish it in due season.

Further; but besides the common work of a farm, as the culture and husbandry of crops, the rearing and fattening of live-stock, and the business of markets; there are various other objects of attention which ought to be constantly kept in the mind, or in the mind's way, of a manager; as on them the difference between good and bad, between correct and slovenly management, very much depends; such as keeping the home-fall in repair, and free from impediments; attending to private roads and driftways; keeping up fences, every where, in thorough repair; attending particularly to young hedges, and to the rearing of hedge-row timber; the fitting that gates swing clear, and catch with certainty; equally to preserve them from injury, and to prevent loose stock from going astray; the attending to drains and water-courses; to see that superfluous waters have free passages to their proper outlets, and be readily discharged. And it is advised, that in summer strict attention be paid to drinking-pools and other watering places of stock, as well as to the state of pasturing, and the shifting of pasturing stock. Likewise to weeds, as well in grazing grounds as in arable lands, to see that not a chaff blows, nor any other weed manures its seed, either in the arable, or on the borders of fields, as great injury is done by their shedding their feeds.

Also in winter, much care is necessary to the cattle-flock, not only to see that they are regularly supplied with proper fodder; but that sufficient shelter and comfortable refuges, and that the watering of the fields should be attended to as much as the nature of the situation will admit. And to the accumulation of manure an unremitted care should be bestowed the year round, as upon it much depends. And on the whole, to perform these and other objects with propriety, repeated examinations of every part and particular under his care; and committing to his memory whatever requires his more immediate attention; so that whether he is on the spot, or arranging his plan of operation, in the hour of leisure, it may be prevalent to his mind, and take its proper course in the routine of work which is to be carried forward.

It may be noticed, that in the time of work the business of a managing servant lies in the field, in executing the plans he has formed, in passing from one set of work-peo-ple to another: not more to see that the different operations are rightly executed, with proper dispatch, than to order any required assistance, (to the teams most especially,) in order that every part of the machine may be kept in profitable motion. And that in the ordinary operations of husbandry, and on common occasions, a steady even pace be recommended; equally for the good of working animals, and the work which they are performing. Nevertheless, there are times when quick dispatch is necessary; and then it is his duty to encourage good speed; by his example, and by promises of reward, if the occasion require it. That at all times, and on every occasion, idleness is a crime which ought not to be suffered to pass with impunity. It is a direct fraud; and a manager should guard against it with the same care and affluence as against pillaring. A day labourer who idles away an hour, robs his employer of an hour's wages; and thereby injures him as much as if he were to steal a faggot of equal value. This truth requires to be deeply imprinted on the minds of labourers. He has known the impression to have a good effect. But he properly remarks, that the right ordering of servants and work-people is a difficult branch of moral duty; and forms an important part of that of the managing servant. They require to be treated according to their respective merits; encouraging good ones by extra wages, or other rewards. Some men are worth double the wages of others, as day labourers. Yet custom makes no distinction between them in this respect! Hence the propriety of engaging the best workmen the country affords; and retaining them, by civil treatment, and suitable encouragement. The managing servant should keep his work people at a proper distance, without destroying that free communication of opinion respecting the work in hand, which, on ordinary occasions, every intelligent workman should be allowed. And a standing rule of conduct, in the ordering of workmen, is never to find fault without occasion; nor to commend, without reason. Good fellows will not brook the former, nor will bad ones be endured by the latter. But it is right to habituate workmen in general to be told of their faults; first, in the mildest terms the occasion will admit of; referring the warmth of temper for extraordinary occasions;
and it is prudent to fling them with keen, rather than to load them with heavy, words: to endeavour to stir up their pride, rather than their malice or resentment. And much of the smoothness and uniform success of business depends on the manner of communicating orders to workmen. If orders are inaccurately or loosely given, it is unreasonable to expect that the execution of them should be faultless. It is difficult to explain business in words with sufficient accuracy to rustic workmen; and if a third person is suffered to intervene, errors are inevitable. The servant who has the management ought therefore to make a point of giving orders, in person, and if possible on the spot, to the men whom he means shall execute them. There he can explain himself to them intelligibly and fully; or affix them in marking out their work. There is always danger in merely verbal orders; and, in a message, certain mischief. It should be an irrevable rule for him to set his men to a fresh work, in person; and if it is out of the common way of husbandry, to stay by them, or direct them with his own hands; and return to them, again and again, until he finds them completely in their work. In this view, this sort of servant, as well as for various other reasons, ought to be matter of every implement, tool, and operation belonging to his profession; and if he find himself deficient in any particular, he should practice it day by day, until he make it familiar to him; or how is he to correct a bad workman; or to know when to be satisfied with a good one; who, knowing when he is right, will not bear the reproaches of ignorance? He has no other way of securing the eftem and attachment of good workmen, and of finifhing in a workman-like manner every thing he undertakes, than by making himself master of his busines; without which little satisfaction will arise from it to himself, or profit to his employer. And in the general principles of conduct, in his dealings and intercourse with other men, punctuality is one of the most effential. Method is the bell assistant of punctuality; and clear accounts are one of the best results of method. These should always be kept with exactness, and be fent, when required, to the proprietor, in weekly, monthly, and annual periods, so as to shew the daily income of the work; the monthly fiate of receipts and payments; and, lastly, the whole state of accounts and balances.

Besides, it is extremely necessary for the farmer to be careful in providing his servants, not only to see that they are proper for the work, but that there be not more than are necessary for executing it, as the expense of them is now become extremely great. It has long since been recorded by the above writer, in his "Minutes of Agriculture," that on the matured calculation he found the yearly expense of a man servant in the house to be 35l., and that of a boy 23l., supposing the man's yearly wages to be 100l. and the boy's 35l. Now the expense of a day-labouring man for a whole year (if he works every day) is but 27l. 10s., which is 7l. 10s. difference against keeping a man in the house by the year, and hiring one by the day. But that of a boy is still more in proportion, viz. the expense of a day-labouring boy for a whole year, if he works every day, is but 13l., which makes a difference of 10l., or more than three-fourths of a boy's day-wages. In the above account, no deduction in the daily pay is made for rainy days. The impropriety, therefore, of keeping plough-boys in the house is very visible; and though it may be convenient to have the carters about the house, the conveniency is not worth 7l. 10s. a-year. He therefore recommends putting a woman into a cottage, within about two hundred paces of the farm-yard, to take in lodgers; and to keep in the house no more farming servants than a buffer and a yardman. Indeed he says it is absolutely necessary to have somebody about a farm-yard in cases of emergency; but the above two are sufficient, as the carters in the adjoining cottage will be nearly as handy as if they were in the house. This measure, it is observed, like many others, is merely local, but the hint is universal.

But perhaps the farmer, who keeps no accounts, imagines he saves money by boarding his servants in the house; however, if he keeps them in the luxurious manner which farming-servants in general expect to be kept, he will be mistaken. A farmer, indeed, who fits at the head of his kitchen-table, may no doubt feed his men considerably cheaper, than a person who eats in a separate apartment. It is a just observation, that one fed by his master costs the community as much as two who provide for themselves; for discharge a grumbler, one who pretends to be dissatisfied, though in fact only fattated, and who will return to his bread and cheese with perhaps equal health and equal happiness. He fits down to his master's table with a resolution to eat voraciously of the belt, to do himself justice; but at his own table eats sparingly of the meanest, to save his money. His motive in both cases is the same; self-interest. The plan here inculcated is at this time still more necessary than it was at a former period.

And it is added, that in some counties, particularly in Surrey, it is an established custom for every man, in harvest, to work by the acre, or by the month, not by the day. If a labourer be constantly employed through the year, he expects during harvest to be constantly employed in mowing, reaping, &c. by the acre, or to have his harvest-month; that is, to have an advance of wages certain, wet or dry, during one month; which month commences when it belt suits his employer. This is very convenient; they are always at command in cases of emergency; and nothing but a continuance of rains while the barns are empty can make them burden-some. He strongly recommends the employing of active young men; for one invalid or fluggish fellow will spoil the whole set; and this holds generally. Mix two or three old women, or two or three boys, with a company of men, and the effect will be very soon visible; for the men will soon conform to the ways of either the old women, or the playfulness of the boys. It is not prudent to employ many women with the men; and nothing but necessity can excite them. Two women after the first or second day, will do as much work as half a dozen, alone. If it be necessary or convenient to employ a number of both men and women, it is but common good management to keep them separate; with this exception, which may be laid down as a maxim, viz. one man among women, and one woman among men. A truly conceited old fellow will check the goolipping of the women, and it has been remarked that raking after a young wench has animated more than a gallon of ale. Two are dangerous; they breed contention, and rather retard than accelerate. The most valuable servant in harvest is a good carter. It is necessary to common management that he should be able, willing, and careful. Every pitch of hay and corn, generally speaking, passes twice through his hands; he loads and unloads, which are the two most laborious tasks of harvest; he drives the team backwards and forwards; if he losers by the way, the field-men or black-men must stand idle; if he spill or overturn his load, or if he breaks his waggon, or let his horses, the arrangement of the day is broken; and, perhaps, the damage done by the loss of time rendered irrepairable by the next day's rain. A good carter will not suffer
fuffer his waggone to be overloaded. The field-men, too, that is, the pitcher and affilant-loader, should be young and active, and well matched with the carter.

But since the above was written, the prices of servants have considerably increased in every district of the kingdom, and the expences of keeping them been very greatly augmented. This has led to fewer being kept, and especially in the house. It is rated, that in Hertfordshire the annual wages of a carter or ploughman was formerly from fix to nine guineas, boys from two to four guineas; and maid-servants about five guineas; but they have since risen to nearly double these sums. And formerly in Norfolk farm-work was particularly distinguished by the cheapness as well as expedition with which it was performed; which, it is said, arose not merely from the cheapness of labour, but the greater exertions of servants and labourers than in most other districts; but this is considerably diminished at present. In some parts of that district the custom of allowing board-wages to farm-servants, instead of the old plan of feeding them in the house, is coming into use; and 8s. a-week are given. This is a bad, immoral regulation, which should be discontinued. In Yorkshire the wages of servants have also been greatly increased. In the West Riding the wages of a house servant (of which kind most of the ploughmen are) may be estimated from 25/- to 30/- yearly, including maintenance. There is a practice which prevails over a considerable part of this district, of giving them drink both forenoon and afternoon, to be the work what it will; which is a ridiculous custom, and ought to be abolished without loss of time. What can be more absurd than for to a ploughman slopping his horfes half an hour, in a cold winter day, to drink ale? But the practice is so deep rooted, that it will not be easily removed without a compensation. It is suggested that the proper remedy is to let the value of the ale be paid to the servant in money, which probably would be as much for his interest, and certainly more advantageous to the farmer. In those places where long yokings are taken, say seven or eight hours, it may be necessary to feed both men and horfes on the ground; but this practice cannot be recommended unless in urgent cases, it being very injurious to their health. In the belt regulated agricultural counties, five hours labour in the morning and four hours in the afternoon, when the season allows, and five hours, or four hours, and a half, in short days, is considered to be as much as horfes are capable of sustaining, and yokings of this duration require no refreshment on the ground. And it is added, that the hours of labour for men are generally in summer from six to six, with the usual time for rest and refreshment, which gives between nine and ten hours labour each day, and in winter from light to dark. Much of the farm-labour is such as ditching, hedging, threshing, &c. is done by the piece, but the prices vary greatly in different places. And it may be added that when the farmer is a proper judge of his business, piece-work is not only most to his advantage, but the only way by which an active diligent servant can be properly rewarded for his labour.

In Berkshire, and many other counties, great care is taken to keep no more servants in the house, by the farmers, than are just sufficient for performing the ordinary business to be done. The pay of a carter is ther from nine to twelve guineas the year; an under carter from four to seven guineas for the same length of time; a shepherd from eight to ten guineas, and the run of a few sheep; a boy from two to three guineas; and a dairy-maid from five to ten guineas, in proportion as he may be qualified.

In the manufacturing districts of Chefhire and Lancashire, the wages of house-farming servants run in this way:

They have lately been considerably on the increase in both of these districts.

In the county of Essex, and many other districts which are principally agricultural, the work of the farms is in a great measure executed by hired daily or weekly labourers, very few yearly servants being kept by the farmers. This is supposed, in many instances, to be not only the cheapest, but the most convenient method of having such forts of work performed; and the farmers are, at the same time, the most free from trouble in their houfes and families. In the southern agricultural districts of Devonshire and Cornwall, the wages of the farm servants, kept in the house, with washing and lodging, are, in the former, for a carter or head man ten pounds the year, the inferior forts of farm bafines being often accomplished by parish apprentices; and in the latter, from eight to twelve guineas, with their board, for men, and from three to four pounds, with the fame, for maid servants during the year. These rates, however, vary a little, according to the qualifications of the servants, and the nature of the situations and farms.

In the county of Herefordshire, where the hours of labour are from light to dark in the winter, and from fix in the morning to the fame hour in the afternoon, in summer, the following are the average prices of wages now given to servants kept in the house by the farmers.

Likewise in East Lothian, in Scotland, the wages are mostly from ten to fourteen pounds per annum; but this class of servants is but small. The female servants have from four pounds to four pounds ten shillings, or five pounds. And in Clydesdale, the greater part of the agricultural labour is performed by servants hired by the half year, and living in the farm-houses. In many parts of the county the women servants work along with the men, at almost all kinds of out-work. But as more hands than ordinary are needed for cutting down the corn in harvest, many husbandmen, to secure a fixed number for that purpose, when they can be got, contract with villagers to affill during the time of reaping. All these labourers have no fixed hours, but continue their labour while light and weather admit, and circumstances require. The poor girls, when light is gone and the men fit down by the fire, refume their household labours.
The labourers, both men and women, are sometimes hired by the day, particularly in the time of planting, sowing, and hoeing turnips and potatoes, hay-making, and harvest, when a fixed number is not provided. These work only ten hours in the day, beginning at six in the morning and stopping at six at night, and taking an hour to rest at breakfast, and another at dinner. Hired labourers, in winter, take breakfast before they go out in the morning, make a short pause to eat a little at mid-day, and quit when light fails in the evening. The following are the prices of wages.

But in Perthshire, a man servant, who is master of all the operations in farming, only receives, in the corn country, between eight and twelve pounds, for twelve months. In the grazing districts, more remote from the seat of manufactures, their wages, and the price of all kinds of labour, are about one-fourth lower. But in many cafes the servants are maintained in the farmer’s family; but the practice of giving them fix and a half rolls of meal, together with a houfe, garden, and a cow’s grate, free of rent, and some fuel, is daily becoming more general. These farmers, who keep any married servants, have them all on this establishment of livery meal. The maid servants live all in their master’s family, and are engaged for between eight and twelve pounds, and three cafes five pounds of yearly wages, according to their expertness, and the nature of their work. But common labourers earn between one shilling and one shilling and three-pence a day; and if able-bodied and handy, they demand one shilling and sixpence, without victuals. The various denominations of artificers charge according to the nicety of their art. The hours of labour from the vernal to the autumnal equinox, are from six to eight, allowing an hour for breakfast and another for dinner; and during the other half year, from the dawn of day till the light fails at night, with an allowance of one hour for breakfast. Household servants are not so exact with respect to hours; in the long days, they continue to work after six at night; and in short days they get out of bed before day light, where there is much grain to thresh. But in many of the large farms, threshing machines have been erected; and they are such a great saving, by the abridgment of labour, that more of them are set up every year, in different parts of the county.

And in Argyleshire, within these 30 years, the price of labour is somewhat more than doubled. It still varies in different parts of the county, but may be estimated in general at the following rates: A man servant’s wages, per annum, with victuals, from 6l. to 8l. A maid servant’s, from 5l. to 4l. And that since 1795 the wages and the price of labour have been advanced more than one fourth, or from 25 to 50 per cent., and are still rising.

Further, in regard to regulating the rate of wages, it has been suggested in the Agricultural Survey of the West Riding of Yorkshire, that the only mode of making them proportional to the rise or fall on the value of money and provisions, is to pay the labourer in kind, that is, with a certain quantity of corn, as parties shall agree, which infures him, at all hazards, a comfortable subsistence, and prevents him from a daily or weekly visitation of the markets. When the labourer is paid in money, it exposes the thoughtless and inattentive to many temptations; whereas, when paid in kind, he cannot raise money to gratify the whim of the moment. In those counties where this mode of payment has been long established, we believe the ploughmen and labourers are, in the whole, better fed, live more comfortably, and rear healthier children than in those parts where, from being paid in money, the currency of the article facilitates the expenditure, and prevents them from laying by a stock of provisions for his support, when laid off work by casualties or distresses. In the part of the kingdom where the writer resides, nearly all farm-servants are paid in this manner. They have a certain quantity of grain, maintenance for a cow summer and winter, a piece of ground for planting potatoes and raising flax, and whatever fuel they require, given gratis. They, with the privilege of keeping a hog and a few hens, enable them to live, and bring up their families in a comfortable manner; and, while their income is considerably less than people of their station in other parts, they are, in the whole, better fed, better drested, and enabled to give a better education to their children. Placed under these circumstances, they are a respectable set of men; and, for frugality, faithfulness, and industry, they will bear a comparison with their brethren in any quarter. The introduction of a similar mode of paying farm-servants into the West Riding, is therefore recommended, which, although it might at first be attended with some difficulties, would contribute to the public good, and to the advantage of the farming peasantry in many respects. And it is remarked in the Herefordshire Agricultural Survey, that if a certain proportion between the price of labour and the average price of wheat could be fixed by law, so as to render the applications for parochial aid necessary only in cafes of very large families, of unusual ilnesses, of scanty scawns, or any other real emergency; the measure, it is presumed, would stimulate industry and fidelity, would check dishonesty, and endeavour to a numerous classes their native taste.

The advance in the rate of farm-servants’ wages who live in the houses of the farmers, has, within the last twenty-five years, been probably not less than from a third to a fourth of the whole, according to the nature and situation of the district, over the whole country; but how far the agricultural and manufacturing state of the nation may thereby be affected, is difficult to determine.

It is a matter of very great consequence to farmers, to have good, tractable, intelligent, able, and honest servants, and no sort of good farm-work, or improvements, can be properly carried on without them.

Servants’ Rooms, in Rural Economy, the lodging places for farm-servants, which should always, if possible, be distinct from the house upon farms of considerable size. And in cafes of very extensive farms, and of course where many servants are required, especially if they be unmarried, proper and convenient accommodations for sleeping, and where they find their own provisons, for preparing and dressing them in, are not only requisite, but highly advantageous, both to the farmer and the men, as having much time, which would otherwise be lost in going to their meals, and keeping them together sober, steady, and ready for their different employments. And in this way the servants are much more comfortable, and live considerably cheaper than where it is the custom to go to public houses, or other such places for their meals, which is too much the case in many of the more southern districts of the kingdom, by which their manners often become depraved, and their constitutions enfeebled by the great use of spirits, and other intoxicating liquors, which they are almost necessitated to take under
under such circumstances. But these inconveniences are perhaps the most effectually guarded against by such servants being provided for, where it can be done, from the tables of the farmers. But where this last method is followed, the eating rooms should be so situated, that they may be overlooked with facility. Their lodging rooms, in all cafes, are the most proper and the safest, when made in a building quite detached and distinct from the other houses and offices; as per sons of this description are often extremely negligent of their fires, candles, &c., as well as irregular in other parts of their conduct. It has been advised, that whatever situation may be fixed upon for these conveniences, the ground-floors should always be of stone or brick, and the upper ones made with plaster, as is done in some of the midland counties, or brick, which is more easily laid. See Plaster Floors.

Molt kinds of farm labour may, however, probably at present be performed more cheaply by other sorts of workmen, than servants provided for in any of these ways.

SERVE, in the Sea Language. To serve a rope, is to lay spun-yarn, rope-yarn, Jennit, a leather, a piece of canvas, or the like upon it, which is rolled fast round about the rope, to keep it from fretting or galling in any place.

SERVERETTE, in Geography, a town of France, in the department of the Lozere; 12 miles N.N.W. of Mende.

SERVETISTS, in Ecclesiastical History, a sect said to be the disciples or followers of Michael Servetus, the ring-leader of the Anti-Trinitarians of these late ages. See his article.

It is impossible (says the translator of Moseheim's Eccl. Hist.) to justify the conduct of Calvin in the case of Servetus, whose death will be an indelible reproach upon the character of that great and eminent reformer. The only thing that can be alleged, not to efface, but to diminish his crime, is, that it was no easy matter for him to divest himself at once of that persecuting spirit, which had been so long nourished or strengthened by the popish religion in which he was educated.

Servetus, in reality, had not any disciples, as being burnt, together with his books, before his dogmas had time to take root. But the name Servetists has been given to some of the modern Anti-Trinitarians, because they follow the footsteps he had marked out.

* However, those who were denominated Servetists, or Servetians, by the theological writers of the sixteenth century, not only differed from Servetus in many points of doctrine, but also varied widely from him in his doctrine of the Trinity, which was the peculiar and distinguishing point of his theological system.

Sixtus Senenis calls the Anabaptists Servetists, and seems to use the two terms indifferently. The truth is, in many things, the ancient Anabaptists of Switzerland, &c. coincide in opinion with Servetus.

As the books that he wrote against the Trinity are very rare, his real sentiments are but little known: M. Simon, who had a copy of the first edition, delivers them at large in his critical history.

Though Servetus uses many of the same arguments against the Trinity as the Arians, yet he professes himself very far from their sentiments. He also opposes the Socinians in some things; and declares his different from the opinions of Paulus Samofatenus; though Sandius mistakenly charges him with having the same sentiments.

In effect, he does not seem to have had any fixed regular

Vol. XXXII.
of the church, condemned in private the reigning super-

ofitions, to which, however, they readily conformed in public. Whether Servetus was instructed by any of these, or whether his own opinions were the result of investigation, cannot be ascertained: it is certain, that he did not think it prudent to divulge them in France, and therefore retired to Germany, where a much greater liberty of con-

science was allowed and afforded, and where several princes secretly favoured the bold attacks on the popedom. He went through Lyons and Geneva to Switzerland, and fixed his residence at Basle in the year 1530. Here he was on a footing of friendly intimacy with Oeolampadius, with whom he often conversed about various religious topics, but to whose peculiar opinions he would not yield, in the smallest degree, any notions which he had previously adopted. The unbending disposition with regard to mat-

ters of small moment, alienated many persons from Servetus who had formed a high opinion of his talents and integrity. While he was at Basle, he put into the hands of a book-

feller a manuscript, "De Trinitatis Erroribus," which was printed in the year 1531. Servetus now went to Straffburg, in which city he became acquainted with two reformers, viz. Capito and Bucerus. Here he searched for opportunities to communicate his religious tenets to his new acquaintances, and here he learned that his work had excited a considerable sensation among people of all classes. He was aware that he had, in many respects, treated the subject too imperfectly; and had made use of expressions that were liable to give offence; he accordingly, in the following year, endeavoured to soften the unfavourable impres-

sion, and to avert a storm that seemed threatening to fall upon him, by publishing a work entitled "Dialogorum de Trinitatis Libri duo," in which he explained and de-

fended his opinions. The confessions of this second piece was, that many were exasperated against the author, while a few adopted his doctrines and spread them abroad. Oeol-

lampadius requested his friend Bucer to inform Luther, that Servetus's book had been published without their knowledge, in order that it might not be supposed they had given any countenance to the propagation of the offen-

sive tenets. And Melanchthon, in speaking at this time of Servetus, says, "He wants neither acuteness nor cunning in disputing, but I cannot allow him energy. He has, moreover, as it appears to me, confused imaginations, neither is he able sufficiently to explain his thoughts with precision. He unorthodoxly speaks like a madman about justification; about the Trinity, ἡ τριαδής, you know that I have been always apprehensive that similar things sooner or later would break out. Good God! what trage-

dies will this quizzion excite among posterity?"

The circumstances of Servetus being now, he engaged for some time with the Frellons, eminent bookfellers at Lyons, as corrector of the press. From Lyons he went to Paris, where he studied physic under the celebrated Sylvius, Fernelius, and other professors; and, as we shall have occasion to remark hereafter, he carried into that science the same penetrating spirit and love of improvement which distinguished him in theology. He graduated at Paris, and being invested with this honour, he delivered public lectures in geography and some branches of mathe-

matics, while he followed the profession of a physician.

At Paris he quarrelled with the faculty, and wrote an "Apology," which was suppressed by the parliament. After quitting that capital he practiced physic at Charlevue, near Lyons, whence, at the invitation of the archbishop of Vienne, he removed to that city, and had apartments near

the palace. He had, previously to this, viz. in 1544, superintended the printing of a Latin Bible at Lyons, to which he added marginal notes, under the name of Villanovanus.

During this time, Servetus was in constant correspond-

ence with Calvin, with whom he discussed various points of controversy, and to whom he opened himself freely and without reserve concerning his particular notions, and con-

sulted him respecting his writings. Calvin afterwards made a base use of this confidence, by actually producing his let-

ters and manuscripts as matter of accusation against him on his trial. It must not, however, be concealed, that Calvin does not appear to have encouraged Servetus to this exposition of his sentiments, for he frequently sent him in reply angry and severe letters. In 1553, Servetus published his matured theological system under the title of "Christianissimi Refutatio."

Conscious of the danger to the author of such a work in a Catholic country he concealed his name, but Calvin took care that the magistrates of Vienne should be informed of it. He was in consequence thrown into prison, and his death would have added an example to the num-

berless cruelties of Roman Catholic persecutions, had he not made his escape. His effigy and his books were con-

demned to the flames. Servetus, purposing to go to Naples to practice in his profession, imprudently went through Geneva. Calvin, who was acquainted with the plans of the traveller, and who was on the watch to entrap him, gave information to the magistrates the moment he arrived within the gates of the city. He was accordingly feized, thrown into prison, and a charge of blasphemy and heresy was preferred against him by Calvin's own servant. In order to ensure conviction and condemnation, no less than thirty-eight articles of accusation were brought against him, for which not only his last work, but all his other writings were ransacked. As a proof of the malice and unfairness with which he was treated, it is mentioned that one of the charges was extracted from his preface to an edition of Ptolemy's Geography, published twenty years before, in which he had asserted that Judea had been falsely extolled for its beauty and fertility, since modern travellers had found it to be sterile and unfavourably. That no doubt might be left whence the prosecution came, one of the main articles against the prisoner was, that in the person of Mr. Calvin, minister of the word of God in the church of Geneva, he had defamed the doctrine preached in it,uttering all imag-

inable injurious and blasphemous words against it.

Servetus, in the first examination, repelled with firmness every accusation, though he avowed that he published in Germany his book "De Trinitatis Erroribus;" in France his "Refutatio Christianissimi," together with Ptolemeus, and the edition of Pagnini's bible. At the second exami-

nation, he acknowledged, when urged to confess the truth, some of the articles brought against him in regard to his publications, denied others, and hesitated to explain himself more plainly upon others. But when he was again questioned, "why he had slandered Calvin, and lacerated the Christian doctrine?" he protested that Calvin had been the aggressor, and that if he had recompensed it was done in self-defence; which plea was deemed by his judges as an aggravation of his offence.

The magistrates of Geneva were, however, sensible that many eyes were upon them in this extraordinary proceed-

ing, with respect to one who was no subject of their's, nor a resident in their city, nor could he be accused of having committed any offence in their territory, and within their jurisdic-

tion. He was, in truth, kidnapped in his passage.

Moreover,
Moreover, it could not but appear strange, that men should
be associates in perfection, with those very people who
would infallibly burn them as heretics, should they fall into
their hands. They therefore thought it advisable to con-
front the magistrates of the Protestant cantons of Switzerland,
to whom they sent Servetus's book, with Calvin's reply.
The Helvetie divines, to whom the matter was referred,
unanimously declared for his punishment: they said that
Servetus's errors ought to be detested; and that great care
ought to be taken that the infection spread no farther, and
that the man ought to be retrained; but they, none of
them, said a word respecting capital punishment, nor do
they allude to the kind of coercion that should be chosen.
Their meaning was, however, readily inferred from their
own practice; for the capital punishments of heretics had
not been abolished in Switzerland; they had been frequent-
ly practised at Zurich against the Baptists.

Servetus was for some time kept ignorant of all the pro-
cedings against him; at length he discovered the inten-
tions of his enemies, and drew up, and caused to be pre-
rented, two petitions to his judges; in the first he endeavoured
to exculpate himself; in the second he complained that a fair
trial had not been allowed him. As he refused to retract
his opinions, he was, notwithstanding his plea, condemned
to the flames as an obstinate heretic, which cruel sentence
was carried into execution on the 27th of October 1553,
when he was in the forty-fourth year of his age. His
sufferings were particularly severe, and the fire was so
managed, that the unfortunate man lingered in excruciating
pain more than two hours.

That this bloody persecution was disapproved by many
at the time, is rendered very probable by the apology for
the Genevan magistrates published by Calvin, in which he
undertook to prove that it was lawful to punish heretics
with death. The mild and otherwise moderate and benevolent
Melanchthon functioned the deed by a congratulatory letter
addressed to the magistrates of Geneva. The conduct of
Calvin in this business, as instigated not only by bigotry,
but personal hatred, has impregnated an indelible stain on
his memory; and the only possible excuse now offered for it
arises from the provocation given by Servetus, "who ex-
ceeds all reason," according to Mosheim, "was accompa-
nied with a malignant and contumacious spirit, and an in-
vincible obstinacy of temper."

The theological fablem of Servetus is decried as singular
in the highest degree. The greatest part of it was a neces-
sary consequence of his peculiar notions concerning the
universe, the nature of God, and the nature of things,
which were equally strange and Chandler. See the article
Servetists.

Servetus is numbered among those anatomists who made
the nearest approach to the doctrine of the circulation of
the blood. The passage cited to this effect is contained in
his latest and fatal work, "De Rerstitutione Christianisi." It
clearly states the circulation of the blood through the
lungs. He purified, in his medical studies, anatomical re-
searches with the greatest ardour.

Servetus was a man of great erudition and unfeigned piety:
his mind was stored with a variety of knowledge, and
he stood very high, in the estimation of his contemporaries,
for his talents and for his discoveries in the profession
of medicine. Whatever might have been his errors as a
theologian, it is certain he never preached them to the vulgar,
but communicated them freely to Calvin, Oecolampadius,
Cephalic, Bucerus, and other reformers, with an eagerness
to discover truth which has never been surpassed.

The atrocious murder committed on him will not ad-
mit of a single excuse. His imprisonment was scandalous
and unjust. The senate of Geneva had no right to lay
violent hands upon a traveller, who had no intention of
remaining in their city, and who probably never uttered
within the precincts of their dominions one syllable of his
obnoxious opinions. Here Geneva stands condemned by all
citizens.

The affability of the manners of Servetus, and his vaft
learning, had procured him numerous friends in France, in
Germany, and in Italy; and his name will be handed down
to the latest posterity with compliment and respect. See
a life of Servetus, in a series of letters to Jedidiah Morle,
D. D., by Fr. Adrian Vanderkemp: in vol. v. of the
Monthly Repository.

SERUG, in Geography, a town of Asiatic Turkey, in
the province of Diarbekir; 12 miles S. of Urfa.

SERUGNANO, a town of Italy, in the Veronese;
8 miles E. N. E. of Verona.

SERVIA, a province of Turkey in Europe, part of
the ancient Panonia, or of Turkish Illyria, deriving its name
from its inhabitants, is bounded on the N. by Bosnia and
Slavonia, on the E. by Walachia and Bulgaria, on the S.
by Macedonia and Albania, and on the W. by Bosnia and
Dalmatia. It was formerly divided into Proper Servia, or
Serbia, and Rascia, and the inhabitants were distinguished
into Servians, and Rascians or Reitzes; and the former,
which constitutes the upper part, towards the Danube,
resembles the banat of Mafovia. The capital of Servia is
Belgrade; (which see). The Turks call it Lafi Vilayeti,
or Lazarus-land, because in the year 1365, when they
subdued it, Lazarus was prince of Serbia. See Ser-

VIAN.

SERVIAN, a town of France, in the department of
the Herault, and chief place of a canton, in the district of
Beziers; 6 miles N. E. of Beziers. The place contains
2200, and the canton 7319 inhabitants, on a territory of
1176 kilometres, in 9 communes.

SERVIAN, or SERBES, a branch of the Illyrian Slav,
who gave name to the province called Servia or Serbia.
In the Kuffian empire the Servians and Reitzes are colonists,
whom, in the year 1754, a considerable district was allotted
on the Dnieper near and upon the possessions of the Zaporagians.
This country, which got the name of New Servia,
was for the most part an uninhabited desert, extending to
what were then the Polish borders, by which it was sur-
rounded on three sides. The Serbians, who voluntarily
settled here in great numbers, were formed into a military
association, in order to protect the frontiers of the
Zaporagians. In the year 1764, the whole of this
tract of country was erected into the government of New
Ruthia, and at present forms a considerable part of the
province of Ekeenomofal.

SERVICE, or SERVAGE, Servitum, in Law, a duty
which the tenant, by reason of his fee, owes to the lord.
This is a pure, proper, and original feuds, was only two-
fold: to follow, or to do suit to, the lord in his courts in
time of peace; and in his armies, or warlike retinue, when
necessity called him to the field.

Ancient law-books make several divisions of service, viz.
into personal, real, and mixt; military and bafe, intrinsic and
extrinsic, &c. But, since the statute 12 Car. II., by which
all tenures are turned into free and common socage, much
of that learning is yet asid. Yet it may not be amiss to
mention how the several kinds of service are described in
our ancient law-books.

SERVICE, Personal, is that to be performed by the per-
corn. Such is that due from a slave to his master.
Personal service is a disagreeable sort of tenure, under which lands were formerly held, and in which the tenant did various sorts of work for the lord, and provided him with a variety of different articles. It is a custom which has long been abolished in this part of the kingdom, as being highly injurious and improper; but which, Mr. Donaldson remarks, is not wholly discarded in Scotland. "In the north of Scotland," says he, "the rents are to a certain extent paid in personal services; the tenants being bound to plow and harrow a certain proportion of the proprietor's farm; to reap, carry home, thresh, dres, and kill a certain quantity of his crop at their own charges; and that they are also bound to pay poultry, eggs, cheese, sheep, swine, fish, linen, yarn, &c." It might, continues he, have been unavoidably necessary, from the want of a circulating medium in the early periods of the history of this country, to oblige the tenants to pay their rents in personal services, and in the various articles of produce which their farms afforded; but it must be considered a singular circumstance in the history of Great Britain, that in the end of the eighteenth century, and at a period when the introduction of improvements in agriculture is the chief topic of conversation, there should exist proprietors, who are so loth to every sentiment regarding what is due to the community of which they are members, to the people whom Providence has placed under their protection, and to the improvement of their native country, as to perfic in demanding from their tenants a species of rent, which no farmer, who is entitled to the name, would submit to pay, nor any proprietor, who regarded the good of his country, or his own interest, think of requiring. These disagreeable services should of course be done away with in every situation, as being incompatible with all sorts of improvements in husbandry, or the introduction of spirited agriculture into any part.

This sort of service is not only hostile to all kinds of farming improvements, but highly distasteful and ruinous to tenants at particular feasons, as during the feed-time, the harvest, and the time of getting in the hay, by being often under the necessity of neglecting their own operations and busineses, in order to perform the various works of their lords, or superiors. The sooner these services are wholly abolished in every part of the kingdom, the better it will be for the interest of agriculture.

Service, Real, is either urbane or rustic; which two kinds differ, not in the place, but the thing. The first is that due from a building or house, in whatever place situate, whether in city or in country, as keeping a drain, a ville, or the like.

Services, Rustic, are those due for grounds, where there is no building; such is the right of palleage through ways, &c.

Service, Mijt, is that due from the person, by reason of the thing, as an usufruit, &c.

Our ancient law-books tell us of lands held of the king, by the tenant's letting a part before the king on New Year's Day; others, by furnishing the king with horses, whenever he travelled that way; others, by bringing the king a mels of potage at his coronation-feast, &c.

There are also natural services. For instance, if a man cannot gather the produce of his lands, without passing through his neighbour's grounds, the neighbour is obliged to allow a palleage, as a natural service.

Service, Forensic or Extrinsic, Servitium forensicum, &c. was a service which did not belong to the chief lord, but to the king.

It was called forensic and extrinsic, because done feris, out of doors; and extra servitium. We meet with several grants, in the Monasticon, of all liberties, with the appurtenances, falvo forensi servitio.

Service, Intrinsec, Servitium intrinsecum, that due to the chief lord alone, from his vassals within his manor.

Service, Frank, Servitium liberum, a service done by the feudatory tenants, who were called liberi homines, and distinct from vassals: as was likewise their service; for they were not bound to any base services, as to plow the lord's lands, &c. but only to find a man and horse to attend the lord into the army or court.

Service, Bafe. See Villenage.

Service, Bord. See Bondage.

Service, Foreign, Honorary, Knights, Rent. See the adjectives.

Service, Herit. See Heriot.

Service, Overly of. See Overly.

Service, Suit of. See Suit.

Service, Choral, in Church History, denotes that part of religious worship which consists in chanting and singing. The advocates for the high antiquity of singing, as a part of church music, urge the authority of St. Paul in its favour: Eph. 5. chap. v. ver. 9. and Coloss. chap. iii. ver. 16. On the authority of which passages it is asserted, that songs and hymns were, from the establishment of the church, sung in the assemblies of the faithful; and it appears, from un-doubted testimony, that singing, which was practiced as a sacred rite among the Egyptians and Hebrews, at a very early period, and which likewise constituted a considerable part of the religious ceremonies of the Greeks and Romans, made a part of the religious worship of Christians, not only before churches were built, and their religion established by law, but from the first profession of Christianitv. However, the era from whence others have dated the introduction of music into the service of the church, is that period, during which Leontius governed the church of Antioch, i.e. between the year of Christ 347 and 356. See Antiphony.

From Antioch the practice soon spread through the other churches of the East; and in a few ages after its first introduction into the divine service, it not only received the sanction of public authority, but those were forbidden to join in it who were ignorant of music. A canon to this purpose was made by the council of Laodicea, which was held about the year 372; and Zonaras informs us, that these canonical fingers were reckoned a part of the clergy. Singing was introduced into the western churches by St. Ambrose, about the year 374, who was the instituttor of the Ambrosian chant, established at Milan about the year 386; and Eusebius (lib. ii. cap. 17.) tells us, that a regular choir, and method of singing the service, were first established, and hymns used in the church at Antioch, during the reign of Conftantine; and that St. Ambrose, who had long refrained there, had his melodies thence. This was, about two hundred and thirty years afterwards, amended by pope Gregory the Great, who established the Gregorian chant; a plain, unisonous kind of melody, which he thought consistent with the gravity and dignity of the service to which it was to be applied. This prevails in the Roman church even at this day: it is known in Italy by the name of canto fermo; in France, by that of plain chant; and in Germany, and most other countries, by that of the cantus Gregorianus. Although no satisfactory account has been given of the specific difference between the Ambrosian and Gregorian chants, yet all writers on this subject agree in saying, that St. Ambrose only used the four authentic modes, and that the four plagal were afterwards added.
added by St. Gregory. Each of these had the same final, or key-note, as its relative authentic; from which there is no other difference than that the melodies in the four authentic, or principal modes, are generally confined within the compass of the eight notes above the key-note, and those in the four plagal, or relative modes, within the compass of the eight notes below the fifth of the key. See Mode.

Ecclesiastical writers seem unanimous in allowing, that pope Gregory, who began his pontificate in 590, collected the musical fragments of such ancient psalms and hymns as the first fathers of the church had approved and recommended to the first Christians; and that he selected, methodized, and arranged them in the order which was long continued at Rome, and soon adopted by the chief part of the western church. Gregory is also said to have banished from the church the canto figurato, as too light and dissonant; and it is added, that his own chant was called canto fermo, from its gravity and simplicity.

It has been long a received opinion, that the ecclesiastical tones were taken from the reformed modes of Ptolemy; but Dr. Burney observes, that it is difficult to discover any connection between them, except in their names; for their number, upon examination, is not the same; those of Ptolemy being seven, the ecclesiastical eight; and, indeed, the Greek names given to the ecclesiastical modes do not agree with those of Ptolemy in the fifth instance of key, but with those of higher antiquity. From the time of Gregory to that of Guido, there was no other distinction of keys than that of authentic and plagal; nor were any female tones used but those from E to G, B to C, and occasionally A to B.

With respect to the music of the primitive church, it may be observed, that though it consisted in the singing of psalms and hymns, yet it was performed in many different ways; sometimes the psalms were sung by one person alone, whilst the rest attended in silence; sometimes they were sung by the whole assembly; sometimes alternately, the congregation being divided into separate choirs; and sometimes by one person, who repeated the first part of the verse, the rest joining in the close of it.

Of the four different methods of singing now recited, the second and third were properly distinguished by the names of symphony and anaphony; and the latter was sometimes called responsaria, in which women were allowed to join. St. Ignatius, who, according to Socrates (lib. vi. cap. 8.), converted with the apostles, is generally supposed to have been the first who sung to the primitive Christians in the East the method of singing hymns and psalms alternately, or in dialogue; and the custom prevailed in every place where Christianity was established; though Theodoret, in his History (lib. ii. c. 24.), tells us, that this manner of singing was first practiced at Antioch. It likewise appears, that almost from the time when music was first introduced into the service of the church, it was of two kinds, and confined in a gentle inflection of the voice, which they termed plain song, and a more elaborate and artificial kind of music, adapted to the hymns and lection offices contained in its ritual; and this distinction has been maintained even to the present day.

Although we find a very early distinction made between the manner of singing the hymns and chanting the psalms, it is, however, the opinion of the learned Martini, that the music of the first five or six ages of the church consisted chiefly in a plain and simple chant of unisons and octaves, of which many fragments are still remaining in the canto fermo of the Roman missals. For with respect to music in parts, as it does not appear, in these early ages, that either the Greeks or Romans were in possession of harmony or counterpoint, which has been generally ascribed to Guido, a monk of Arezzo, in Tuscany, about the year 1022; though others have traced the origin of it to the eighth century, it is in vain to seek it in the church. The choral music, which had its rise in the church of Antioch, and from thence spread through Greece, Italy, France, Spain, and Germany, was brought into Britain by the fingers who accompanied Austin the monk, when he came over, in the year 596, charged with a commission to convert the inhabitants of this country to Christianity. Bede tells us, that when Austin and the companions of his mission, had their first audience of King Ethelbert, in the aisle of Thanet, they approached him in procession, singing litaniæ; and that afterwards, when they entered the city of Canterbury, they sung a litany, and at the end of it, Alleluia. But though this was the first time the Anglo-Saxons had heard the Gregorian chant, yet Bede likewise tells us, that our British ancestors had been instructed in the rites and ceremonies of the Gallican church by St. Germanus, and heard him sing Alleluia many years before the arrival of St. Austin. In 680, John, precentor of St. Peter's in Rome, was sent over by pope Agatho to instruct the monks of Wescomuth in the art of singing; and he was prevailed upon to open schools for teaching music in other places of Northumberland. Benedict Biscop, the preceptor of Bede, Adrian the monk, and many others, contributed to disseminate the knowledge of the Roman chant. At length the successors of St. Gregory, and of St. Austin his missionary, having established a school for ecclesiastical music at Canterbury, the rest of the island was furnished with masters from that seminary. The choral service was first introduced into the cathedral church of Canterbury, and, till the arrival of Theodore, and his settlement in that see, the practice of it seems to have been confined to the churches of Kent; but after that, it spread over the whole kingdom; and we meet with records of very ample endowments for the support of this part of public worship. This mode of religious worship prevailed in all the European churches till the time of the Reforma'tion: the first deviation from it is that which followed the reformation by Luther, who being himself a lover of music, formed a liturgy, which was a musical service, contained in a work, entitled, "Psalmodia, h. c. Cantica Sacrae Veteris Ecclesiae," printed at Norimberg in 1553, and at Wittenberg in 1561. But Calvin, in his establishment of a church at Geneva, reduced the whole of divine service to prayer, preaching, and singing; the latter of which he restrained. He excluded the offices of the antiphon, hymn, and motet, of the Roman service, with that artificial and elaborate music to which they were sung; and adopted only that plain metrical psalmody, which is now in general use among the reformed churches, and in the parochial churches of our own country. For this purpose, he made use of Marot's version of the Psalms, and employed a musician to set them to easy tunes of one part. In 1553, he divided the Psalms into panes or small portions, and appointed to them to be sung in churches. Soon after they were bound up with the Geneva catechism, from which time the Catholics, who had been accustomed to singing, were forbidden the use of them, under a severe penalty. Soon after the reformation commenced in England, complaints were made by many of the dignified clergy, and others, of the intricacy and difficulty of the church music of those times; in consequence of which it was once proposed, that organs and curious singing should be removed from our churches.
Latimer, in his diocese of Worcester, went still further, and issued injunctions to the prior and convent of St. Mary, forbidding in their service all manner of singing. In the reign of Edward VI. a commission was granted to eight bishops, eight divines, eight civilians, and eight common lawyers, to compile a body of such ecclesiastical laws as should in future be observed throughout the realm. The result of this compilation was a work, first published by Fox the Martyrologist, in 1571, and afterwards in 1640, under the title of "Reformatio Legum Ecclesiasticarum." These thirty-two commissioners, instead of reproducing church music, merely condemned figurative and operose music, or that kind of singing which abounded with fugges, responsive psalms, and a commixture of various and inordinate proportions; which, whether extempore or written, is by musicans termed decant. However, notwithstanding the objections against choral music, and the practice of some of the reformed churches, the compilers of the English liturgy, in 1548, and the king himself, determined to retain musical service. Accordingly the statute 2 & 3 Edw. VI. cap. 1. though it contains no formal obligation on the clergy, or others, to use or join in either vocal or instrumental music in the common prayer, does clearly recognize the practice of singing; and in less than two years after the compiling of king Edward's liturgy, a formula was composed, which continues, with scarcely any variation, to be the rule for choral service even at this day. The author of this work was John Marbecke, or Marbeke; and it was printed by Richard Grafton, in 1550, under the title of the Book of Common Prayer, noted. Queen Mary laboured to re-establish the Romish choral service; but the accession of Elizabeth was followed by the act of uniformity; in consequence of which, and of the queen's injunctions, the Book of Common Prayer, noted by Marbecke, was considered as the general formula of choral service. In 1660, another musical service, with some additions and improvements, was printed by John Day; and in 1565, another collection of Offices, with musical notes. Many objections were urged by Cartwright, and other Puritans, against the form and manner of cathedral service, to which Hooker replied, in his Ecclesiastical Polity. In 1664, the statutes of Edward VI. and Elizabeth, for uniformity in the common prayer, were repealed; and the directory for public worship, which allows only of the singing of psalms, established. But upon the restoration of Charles II. choral service was again revived, and has since uniformly continued. The Quakers object to singing as a part of public worship, and accordingly it is never practised in their meetings. To this respectable body we here make an apology for a jeu d'esprit of our learned coadjutor, Dr. B., who compiled part of the article Liturgy, which escaped him, notwithstanding his well-known liberality and candour, and which was undoubtedly unobjectionable introduced, in an account of their public worship. Religious serpents, though in some respects unfounded and unwarrantable, when seriose avowed, are not fit subjects of ridicule. See on this subject Hawkins's Hist. of Music, vol. i. p. 404. vol. ii. p. 264. vol. iii. p. 58—468. &c. vol. iv. p. 44—347. Burney's Hist. of Music vol. ii. ch. i. pf. 11.

SERVICES OF THE CHURCH. (See CATHEDRAL SERVICES.) These have been collected, and splendidly and accurately published in score, by doctors Green, Boyce, and Arnold. These valuable publications appeared in the following order, and are reputable monuments of the abilities of our old masters in the ecclesiastical style of composition, equal, at least, to contemporary productions by the greatest contrapuntists on the continent.

CATHEDRAL MUSIC; being a collection in score of the most valuable and useful compositions for the service by the several English masters of the last 200 years, the whole selected and carefully revised by Dr. William Boyce, organist and compositor to the royal chapels, and master of his majesty's band of musicians. Vol. i. 1760.

The second volume was published in 1768, and the third in 1773. These were both dedicated to his majesty.

In 1782, Dr. Samuel Arnold, organist and compositor to his majesty's royal chapels, published, in the same splendid manner, a first volume, in continuation of this collection of services and full and service anthems of old masters; and in 1790 a second and third volume, all dedicated to the king.

There is likewise, in the British Museum, Bibl. Harley 7337, Plut. VI. B. a collection of English church music, in five volumes. All transcribed for and dedicated to the right hon. Edward lord Harley, by Dr. Thomas Tudway, music professor of Cambridge. In these volumes, among some compositions of no great merit, there are many valuable productions by Tye, Tallis, Bird, Morley, Gibbons, Child, Blow, Purcell and Crofts, that have never yet been published.

SERVICE, CATHEDRAL. See CATHEDRAL SERVICES.

SERVICE, FREE, in Botany, a corruption of the Latin Sorbus; see that article, as well as PYRAUS and MESPLUS.

SERVICE, FREE, WILD. See CRATAGUS.

SERVIENTES VIRGATORUM. See VIRGATORES.

SERVIERE, in Geography, a town of France, in the department of the Lozere; 15 miles N. W. of Mende. SERVIERES, a town of France, in the department of the Correze, and chief place of a canton, in the district of Tulle; 13 miles S. E. of Tulle. The place contains 1115, and the canton 8567 inhabitants, on a territory of 265 kilometres, in 13 communes.

SERVILE, in Hebrew Grammar, the denomination of a class of letters used in contradistinction to radical. The last constitute roots (which see), and the former constitute derivatives, or branches from these roots, and are employed in all the different flexions. Of all the twenty-two letters of the alphabet, any of which may be radicals, there are properly only eleven letters that can claim this title, because they never can be serviles. The serviles are the other eleven letters, by means of which the whole universe of flexions is derivable, numbers, genders, persons, and tenses, is accommodated. But even these letters are somewhat limited in their servile power. For only two of them, viz. and , can be interposed or ingrafted between radical letters; the others must be either prefixed or suffixed to the root. The eleven servile letters are the following; , , , , , , , , , , , .

SERVIN, Louis, in Biography, a celebrated lawyer in France, who flourished at the sixteenth and beginning of the seventeenth centuries, was defended of a good family in the Vendomais. He cultivated polite literature with success while he was young, and at an early period became the correspondent of several eminent men of letters in different parts of Europe. In 1589 he was appointed advocate-general to the parliament of Paris, being then, according to Vendome, "a young man of great learning, and much attached to the interests of his majesty Henry III." He distinguished himself in that station by his zealous support of the liberties of the Gallican church, and his opposition to the pretenions of the court of Rome. His printed pleadings were honoured with the censure of the Sorbonne, and with a virulent attack by a Jefuit of Provence. The title of his work was "Actions notables et Plaidoyes." In
1590 he published a work in favour of Henry IV., who had succeeded to the crown, entitled “Vindicæ lecundam Libertatem Ecclesiæ Gallicane, et Defenso Regii Status Gallo-Francoorum sub Henrico IV. Rege.” In 1598, being joined in a commission for the reformation of the university of Paris, he delivered “a remonstrance” on the subject, which was printed. To live also is attributed a work in favour of the republic of Venice in the affairs of the Interdict. In the reign of Lewis XIII., at a bed of justice held in 1620, he made strong and animated remonstrances in favour of the right of parliament to regisler royal edicts. On another similar occasion, for the purpose of compelling the registry of foreign financial edicts, he was firmly but respectfuily making fresh remonstrances to his majesty, he suddenly fell and expired at the king’s feet, a memorable death, and such, says his biographer, as may in a measure entitle him to be enrolled among the martyrs to liberty. The particular character of this excellent magistrate was worthy his high public reputation, and few men of his time flowed in more general reputation.

SERVING, encircling a rope with line or spun-yarn, &c. to preserve it from the wet getting to it; also to prevent its being chased. Riggins, Plate I. fig. 48.

SERVING the Riggins. See Mallet.

SERVING-Mallet, a cylindrical piece of wood with a handle in the middle. It is used for serving rope, and has a groove along the surface, opposite to the handle, which fits the convexity of the rope to be served. Riggins, Plate I. fig. 49, a short board with grooves in it, is used for laying on small service.

SERVISTAN, in Geography, a town of Peria, in the province of Farfallan: 25 miles S.E. of Schuras.

SERVITES, an order of religious, so denominated from their wearing a peculiar attachment to the service of the Virgin.

The order was founded by seven Florentine merchants, who, about the year 1233, began to live in community on Mount Senar, two leagues from Florence. In 1239, they received from the bishop the rule of St. Augustine, with a black habit, in lieu of a grey one, which they had worn before. In 1251, Bonifacio Monaldi, one of the seven, being simple prior of Mount Senar, was named general.

This order was approved of by the council of Lateran, and again by cardinal Raynarius, legate of pope Innocent IV., who put it under the protection of the holy see. The succeeding popes have granted it a great many favours. It is become very famous, in Italy, by the council of the council of Trent, of P. Paolo, a Venetian, who was a religious Servite. M. Hermant gives this order the name of the Annunziata, doubtless from this mistake, that in some cities of Italy they are called religious of the Annunziata, because in those cities their church is dedicated under that name. F. Archang. Giani derives the name Servites, servants of the holy Virgin, from hence; that when they appeared for the first time in the black habit given them by the bishop, the flunking children, as they say, cried out, Behold the servants of the Virgin. There are also nuns of this order.

SERVITIA, Per Quiz. See Per Quiz.

SERVITIS Acquiudantis, a writ judicial that lies for a man detained for services to one, when he owes and performs them to another, for the acquittal of such services.

SERVITIS Consuetudinibus. See Consuetudinibus.

SERVITOR, in the university of Oxford, a scholar or student, who attends and waits on another for his maintenance there.

Servitors of Bills, denote such servants or messengers of the marshal of the king’s bench, as were sent abroad with bills or writs, to summon men to that court. They are now commonly called tip-flower.

SERVITUDE, the condition of a servant, or rather slave. Under the declension of the Roman empire, a new kind of servitude was introduced, different from that of the ancient Romans: it consisted in leaving the lands of subjects to the first owners, upon condition of certain rents, and servile offices, to be paid in acknowledgment. Hence the names of servi consulis, aetipotitatis, and additatis: some of which were taxable at the reasonable discretion of the lord; others at a certain rate agreed on; and others were immemorially, who, having no legitimate children, could not make a will to above the value of five-pence, the lord being heir of all the rest; and others were prohibited marrying, or going to live out of the lordship. Most of which services still subsist in one province or other of France; though they are almost abolished in England. Such, however, was the original of our tenures, &c. See Slave.

SERVIUS, MAURUS-HONORATUS, in Biography, a grammatic and critic, who flourished in the reigns of Arcadius and Honorius, is principally known by his Commentaries on Virgil, which, however, are considered rather as a collection of ancient remarks and criticisms on that poet than as made by himself. They contain many valuable notices of the geography and arts of antiquity. The Commentaries of Servius were first printed separately at Venice in 1471, and have frequently been reprinted since. In 1532 they were annexed to Stephen’s Virgil, but they are most correctly given in Burman’s edition in 1756. A tract on profody by this author, entitled “Centimetrum,” is printed in the collections of the ancient grammarians. Servius is mentioned with respect and honour by Macrobius, who makes him one of the speakers in his Saturnalia.

SERVIUS, Sulpicius Rufus, an eminent Roman jurist and statesman, was descended from the illustrious patrician family of Sulpicii. He was contemporary with Cicero, and born probably about a century before the birth of Christ. He cultivated polite literature from a very early period, especially philosophy and poetry, and wrote some pieces in the latter clas, which were marked with the licentiousness of the time. He bore arms in the Maric war; but finding himself better pleased with the arts of peace, he appeared a pleader at the bar in the 25th year of his age. The professions of advocate and lawyer were then of distinction, that the former were accustomed to consult jurists upon all difficult points. Servius having once applied for that purpose to Quintus Macius, a very eminent lawyer, the latter perceiving that Servius did not comprehend his explanations, afflicted him if it were not a shame that he, a patrician and pleader, should be ignorant of the law upon which he was frequently called to speak. This reproof is said to have had such an effect upon him, that Servius quitted the bar, and gave all his attention to legal studies; and such was his success, that Cicero said of him, “If all, in every age, who in this city have acquired a knowledge of the law, were brought together, they would not be to be compared with Servius Sulpicius;” and he farther adds, that “he was not less the oracle of justice than of the law; he always referred to principles of equity and obvious interpretation what he deduced from the civil code, and was less diffident of finding grounds for actions than of settling disputes.” There was a great intimacy formed between these two personages, and there are several letters extant from Cicero to Sulpicius, and two from Sulpicius to Cicero, of which
one is a well-known consolatory epistle on the death of Tullia.

Servius passed through the usual gratitudes of honour among Romans of rank. He was first questor, then edile and praetor. When the troubles of the republic were impending, he was created interrex, in which quality he nominated Pompey sole consul. He was himself consul with Marcellus, in the year 51 B.C., and opposed the motion of his colleague to remove Caesar from his command, left it should immediately bring on a civil war. After the battle of Pharsalia he declared for Caesar, and was appointed governor of Achaea. When that chief was taken off he returned to Rome, and acted with the party who aimed at the restoration of public liberty. During the siege of Modena by Mark Antony, he was urged by the senate to undertake a legation to him, which, after pleading his age and infirmities, he accepted: but he forewarned it would be fatal to him, and he died in Antony's camp in the year 43 B.C. Cicero's ninth Philippic is entirely employed in pleading for a brazen statue to the memory of this excellent man, as for one who had left his life in the service of the republic, which was voted by the senate. Servius was author of a great number of volumes on legal topics, none of which have been preferred; but quotations from some of them are extant in A. Gellius.

Servius Tullius, the sixth king of Rome, was the son of Oenomaus, a native of Cornovium, who was made a captive when the Romans took that place. Tarquin the Elder presented Oenomaus to his queen Tanaquil, and having a son born while she was in a state of servitude, he was named Servius. It is not at all known who the father of this king was, and it was probably not till after his elevation to the regal dignity that he was represented as having been a prince of rank who was killed in the defence of his country. Young Servius was brought up in the palace, and became a great favourite of the king and queen. He distinguished himself both in a civil and military capacity; was raised to the patrician order; had an important command in the army given him; and was at length united in marriage to Tarquinia, the king's daughter. On the assassination of Tarquin, Servius took possession of the throne, which event is dated in the year 577 B.C. As the sons of Ancus Marcius, who were the authors of the conspiracy against Tarquin, had a strong party among the patricians, Servius pursued the policy of attaching the people to his interest, by paying off their debts, and making several regulations in their favour; and having added to his reputation by a defeat of the revolted Etruscans, he strengthened his title to the crown by procuring a legal election from the curia. He then applied himself to the improvement of the public police, and several of the most useful institutions of the Roman state took origin in his reign. Servius enlarged the city by taking two more hills into its limits: he added four tribes to the three old ones; he divided the whole Roman territory into tribes, with a pagus, or fortified poilt to each, and instituted a census, by which all the Roman citizens were distributed into fixed classes, according to their property. He also gave to the freedmen the privileges of citizens; and finding the duties of the regal office under the augmented population too numerous, he committed to the senate the determination of ordinary causes, referring to himself only the cognizable crimes against the state. Aware that he was still looked upon by the nobles as an intruder on the throne, he endeavoured to add consequence to his family by marrying his two daughters to the grandsons of the late king. He now created a closer connection between the Romans and their allies, the Latins and Sabines, by the erection of a temple of Diana at Rome, at their common expense, in which they were to join in annual sacrifices, and in the amicable division of all disputes among them. Servius, in many respects, was fortunate as a man and a monarch; but his greatest calamity was in his youngest daughter, who was continually urging her husband Aruns to criminal attempts against her father, but he nobly rejecting her infamous solicitations, he attached herself to the other brother, her sister's husband, Tarquin, a prince of a character and disposition very similar to her own. They got rid of their partners by poison, and then, having formed an incestuous union, they boldly and openly declared Servius an usurper, and Tarquin laid claim to the throne before the senate. The patriots generally came over to his interest; but the great masses of the people were determined to support their king, who, whatever might have been his defects, had shewn himself worthy of the crown which his infamous relations wished to tear from his head. Tarquin, however, continued to intrigue with his party, and at length took the daring step of affuming the royal robes and insignia, and seated himself on the throne at the temple in which the senate assembled. He there pronounced a violent invective against the perfon and government of Servius, who arrived while he was speaking, and approached to pull down his son-in-law from the throne; but Tarquin seized the venerable monarch by the waist, and threw him down the steps of the temple. He was fortunate in his antagonist, and moving away the help of some by-standers, when his unnatural daughter Tullia arrived, who, having falsified her husband as king, suggested it him the necessity of dispossessing her own father. Tarquin sent perons to perpetrate the foul deed, and Tullia sealed her cruelty and impiety by driving her chariot over the dead body. Servius was murdered in his 74th year, after a reign of forty-four years, during which he had done enough to merit the title and character of one of the best kings of Rome.

Serula, in Ornithology, the name of a web-footed sea-bird, a kind of mergus, very common about Venice, and called by Mr. Ray mergus cirratus jubatus, the brown-crested, or lesser-crested diver, and supposed to be the anas longirostris, or long-beaked duck of Giphorn. This is the red-breasted merganer of Pennant.

It is very nearly of the size of the duck; its head and throat are of a fine changeable black and green; on the first there is a long pendent crest of the same colour; the upper part of the neck and of the breast, and the whole belly, white; the lower part of the breast ferrugious, spotted with black; the upper part of the back black; near the setting on of the wings some white feathers, edged and tipped with black; the exterior scapular black; the interior white; lower part of the back, the coverts of the tail, and feathers on the sides, under the wings, and over the thighs, grey, marked with waving lines of black; covers on the ridges of the wings dusky, succeeded by a broad bar of white; the quill-feathers dusky, the tail short and brown, and the legs orange-coloured; the head and upper part of the neck of the female are of a deep rust colour; the crest short, the throat white, and distinguished by some other varieties of colour from the male. These birds breed in the northern parts of Great Britain. Pennant.

Serum. See Blood.

Serum, Alumifum, Suln-whey, a form of medicine prescribed in the late London Pharmacopoeia, made of a pint of milk boiled to whey with a quarter of an ounce of alum.

Servong, in Geography, a town on the N. coast of Sumatra. N. lat. 5° 31'. W. long. 96° 18'.
SESAMOID, in Anatomy, a name given to some small bones of the thumb and great toe. See Extremities.

SESAMOIDES, in Botany, a name first published by Clusius, as applied to Salamanca to two very different plants, neither of them bearing any evident resemblance to Sesamum. These are Silene Otites and Reseda Sesamoides; see Reseda and Silene. Tournefort has founded on the last-mentioned species, along with R. canescens and purpurascens, his genus Sesamoides, Linn. 424. t. 238, whose character depends on the deep divisions of the ripe fruit, each of which embraces a seed, and seems a distinct capsule. But this is only one instance, amongst others, of the proteine-like nature of the very peculiar genus of Reseda.

SESAMUM, an ancient Latin name, σεσαμοες in Greek, for which some vague derivations have been proposed, but which appears, as professor Martyn observes, to have been taken from Sesamum, the Egyptian name of the same plant, or grain, the use of which, as food, has been, from the most remote antiquity, common in the East. Those who have read the Arabian tales, will not forget the magic power of the word sesame.—Linn. Gen. 323. Schreb. 422. Willd. Sp. Pl. v. 3. 358. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 52. Juss. 138. Lamarck Illust. t. 528. Gärtn. t. 110.—Clas and order, Didynamia Angio/permia. Nat. Ord. Luriz. Linn. Bignasia, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, erect, short, permanent, in five deep, equal, lanceolate segments, of which the upper one is slightly shorter. Cor. of one petal, bell-shaped; tube roundish, as long as the calyx; throat inflated, spreading, bell-shaped, very large, declining; limb in five segments, four of which are spreading, and nearly equal, the fifth, which is the lowest, ovate, obtuse, twice as long as the rest. Stam. Filaments four, originating from the tube, shorter than the corolla, tapering, ascending, the two interiormost shorter; anthers oblong, acute, erect; there is an imperfect filament bidentate. Pist. Germin superior, ovate, hairy; style thread-shaped, anthering, rather longer than the filaments; stigmac lanceolate, deeply divided into two parallel plates. Peric. Capsule oblong, obscurely quadrangular, compressed, pointed, of two valves and four cells. Seeds numerous, nearly ovate.

Obf. Linnaeus remarks that the flower agrees with Digits, but the fruit is widely different.

1. S. orientale. Common Sefamum or Oily-grain. Linn. Sp. Pl. 883. Wild. n. 1. Ait. n. 1. (Sesamum feu Semplem; Alpin. Egyptian. 68. t. 190. S. five Sifamum; Ger. Em. 1232.)—Leaves ovate-oblong, undivided; the lower ones somewhat serrated.—Native of the East Indies.

Vol. XXXII.
Sesamum is also a name given by some authors to the myrrhus, or gold of pleasure.

Sesban, a barbarous and inadmissible generic name, even when altered by Mr. Pursh into Sesbania, in his flora of North America, v. 2. 460, 485. This name is given by Poiret in Lamark's Dictionary, v. 7. 126, to a genus erected by him out of Eichynomeones, see that article; and continuing the Linnaean Ac. grandiflora, coccinea, and Sesan, with several others more recently discovered. These plants are mostly referred by Wildenow to Corollis, with which they do not all accord. They certainly cannot remain with the original species of Eichynomeones, which scarcely differ from Smith's, see that article.

Sesel, Poiret in Lam. Dict. v. 7. 130, the Ambonya name of a tree, which, according to Rumphius, assumes a very different appearance on the coast to what is usual in the adjacent plains; the leaves, always strongly three-rubbed and entire, lanceolate in the latter situation, being roundish-ovate, and much shortened, in the former. He speaks of this plant as allied to Metrosideros, the wood being so hard as to spoil the tools used in cutting it down. Nothing is known of the fruitification, except that the flowers form small whitish heads, subessentially brown, and the fruit seems a globose yellow berry, or drupa. See Rumph. Amboin, v. 3. 64. t. 36. 37.

Gen. Ch. General Umbel rigid; partial very short, of many rays, globoso. General involucre of very few leaves, or none; partial of several pointed leaves, about the length of the partial umbel. Perisianfs greatly dircernible. Cor. Universal uniform; florets all fertile; partial nearly flat, of five petals, whose inflexed points render them heart-shaped. Stam. Filaments five, awl-shaped; anthers simple. Pila. Germen inferior; styles two, distinct; stigma obtuse. Petio. Fruit ovate, small, fringed, separable into two parts. Seeds two, ovate, convex and fringed at the outer side, flat on the inner.

Ell. Ch. Umbels globoso, rather rigid. Flowers regular, all fertile. General involucre of one or two leaves; partial of several. Fruit ovate, fringed.

Obf. S. Hippomarathrum offers a remarkable exception to the above generic character, having a partial involucrum of one leaf, orbicular and toothed, like the wheel of a clock. That of S. gummiferum is nearly similar.

1. S. filiformum. Thread-leaved Meadow-faxifrage. Thunb. Prodr. 51. Willd. n. 1.—Leaves linear-threaded. Stem zigzag. Erect. Perianth awl-shaped. Gathered at the Cape of Good Hope, from which we have an authentic specimen. The stem is a foot high, slightly branched, round, furrowed, smooth. Leaves two or three, one of which only remains perfect, an inch long, undivided, very narrow, acute, ribbed, smooth, somewhat channelled. Umbel terminal, of four rigid fringed rays, with a general involucre of as many unequal, lanceolate, ribbed, smooth leaves, the longest but half the length of the rays. Partial umbels level-topped rather than globose, of ten or more short flat angular rays, and several Lanceolate partial involucre leaves, of the same length. The halfripe fruit is oblong, about as long as the flowers which support it, furrowed, crowned with a very evident calyx, of five awl-shaped, sharp, permanent, somewhat spinous, teeth, finally recurved at the points. We have been the more particular in our description, as there is no figure of this plant extant, and few botanists would recognize it for a Sefal.

Native of the south of Europe. Cultivated by Linnaeus at Upsal. Perennial. Stem a foot high, slightly leafy, round, finely fringed, smooth, decumbent at first, but firmly erect as the flowers come to perfection, and bearing about three rather large umbels, which in a young flat droop, like those of Pinpinella Saxifraga. Radical leaves stalked, a span long, smooth, of a light glaucous green; their segments spreading, acute, entire, veiny, very uniform. Flowers white. Partial involucrum of one or two, almost capillary, leaves. Seeds a quarter of an inch long, nearly oval, with five elevated ribs, three of which are central, two marginal, and dark intermediate furrows.

3. S. montanum. Mountain Meadow-faxifrage. Linn. Sp. Pl. 372. Willd. n. 3. Ait. n. 1. (S. multicaule; Jacq. Hort. Vind. v. 2. 59. t. 129. Carvifolia; Vail. Paris. t. 5. f. 2.)—Footstalks under the branches oblong, entire, with a membranous edge. Stem-leaves with linear very narrow segments. Seeds downy. Native of hillocks in Italy and France. Cultivated at Oxford in the middle of the 17th century. A hardy plant, flowering in summer. Root perennial, tapering, crowned with the fibres of decayed footstalks. Stems erect, from one to three feet high, round, fringed, smooth, branched, leafy. Leaves doubly pinnate, three-leaf; the segments of the upper one longish, narrow, and most glaucous; their footstalks sheathing, close, fringed, with more or less of a membranous border, entire at the summit. Umbels smaller than in the preceding, erect, white, of many rays, sometimes accompanied by a general involucre leaf. Seeds obovate, one-fourth of the former, ribbed, minutely downy.

5. S. glaucum. Glaucous Meadow-faxifrage. Linn. Sp. Pl. 372. Willd. n. 5. Ait. n. 2. Jacq. Aurtur. t. 144.—Footstalks under the branches oblong, entire, with a membranous edge. Branches spreading. Leaflets linear, channelled, smooth, glaucous, longer than their footstalks. Seeds ovate, downy. Umbels lax. Native of France. To define the difference between this plant and S. montanum is very difficult. The glaucum has longer leaflets, and the primary divisions of its radical leaves seem to be always forked, not fitting close to the mid-rib. The branches are more divaricated.
cated, and umbels more lax. Seeds rather shorter. In Jacquin's figures these plants appear very different, but the glaucum of most authors is merely montanum. Jacquin does not notice the hairy seeds.

A hardy perennial, flowering in June and July. Miller says the root is biennial. Leaves doubly pinnate; lobes very narrow, and finely divided. Stems strong, a foot and half high, furnish'd with hissing winged leaves, and terminated by pretty large umbels of white flowers. A specimen sent by Gouan for S. annum, which it certainly is not, seems to be the plant under consideration. The figments of its leaves have callous tips. The leaves of the partial involucrum are ovate, with broad white membranous edges, their points extending beyond the flowers.

Foot tapering, wooly, crowned with fibres of decayed leaves, and having all the appearance of being perennial. Stem twelve or eighteen inches high, erect, stiff, somewhat zigzag, round, fringed, leafy, often purplish; its branches very little spreading. Leaves flat, varying greatly in the length of the leaflets and their divisions, green rather than glaucous; occasionally purplish; their segments linear-oblong, narrow, keeled. Umbels white or purplish, of many general as well as partial rays, all more or less downy. Partial involucrum of many lanceolate membranous-edged leaves, whose tapering parts reach beyond the flowers. Seeds elliptic-oblong, very convex, with three dorsal ribs, deliitute of pubescence in every part. We have this species from M. Du Cros as Haller's n. 762, to which it seems well enough to answer, but if so, Gouan mistakes Haller's plant.

9. S. Amnoides. Milfoil Meadow-faxifrage. Linn. Sp. Pl. 373. Wild. n. 9. Ait. n. 4. Jacq. Hort. Vind. v. 1. 20. t. 52. (Amnoides; Bauh. Pin. 159. Ammi; Matth. Valg. v. 2. 120. A. Mathiilii; Dalech. Hift. 695.)—Leaflets of the radical leaves imbricat; those of the upper ones a little capillary. Stem spreading. Rays of the umbel capillary, very unequal. Seeds smooth.—Native of Greece, Portugal, Italy, Sicily, and the south of France. A slender annual plant, about a foot high, its stem generally branched from the very bottom. Lower leaves on long slender flanks, pinnate, their leaflets in many narrow-lanceolate, channelled segments, lying over each other; upper usually twice ternate, with much longer, and very slender, undivided leaflets; their footstalks short, flattening, furrowed, and membranous. Umbels terminal, very delicate and lax, of about seven or eight extremely unequal capillary rays; the partial ones of more numerous, but like wife unequal, much shorter, spreading rays. Involucral leaves bristle-shaped. Flowers white. Fruit minute, roundifoliate, inflated, smooth.

10. S. tortuosum. Crooked Meadow-faxifrage. Linn. Sp. Pl. 373. Wild. n. 10. Ait. n. 5. (S. maflillifera, fenzici folio, quod Dioecoris censetur; Bauh. Pin. 161. Funiculum tortuosum; Bauh. Hift. v. 3. p. 2. 16.)—Stem much branched, divaricat, rigid, furrowed and angular. Leaves of the partial involucrum ovate, membranous at the edges, somewhat combined at the base.—Native of the south of Europe. Root biennial, rather than perennial. This species is known by its remarkably rigid, repeatedly branched, trailing spikes, bearing great numbers of rigid, clumpy, spreading umbels, each frequently accompanied by a general involucrum of one leaf. The felif leaves are commonly very small, with a large, broad, abrupt, membranous-edged footstalk. Whether the leaflets of the radical leaves vary greatly in length and breadth, or whether Linnaeus has, under this, confounded several different species, we have not sufficient information to decide. The whole herbage is glaucous, of a thick rigid habit.

11. S. gummiferum. Gummy Meadow-faxifrage. Sm. Exot. Bot. v. 2. 121. t. 120. Ait. Epit. 374.—Stem furrowed, rigid, leafy. Partial involucrum of many linear leaves, united by a broad base. Flowers almost entire. Leaflets wedge-shaped.—Gathered by professor Pallas in the Crimea. It was observed by Mr. Lambert in the Oxford garden, about the year 1803, and communicated by him to his friends. The plant is biennial, hardy, flowering in summer and autumn. Stem three or four feet high, erect, branched, leafy, very flinty and rigid, furrowed, minutely downy; when wounded exuding a copious, yellow, fetid resinous gum. Leaves a span long or more, triplicate, glaucous, somewhat downy; their leaflets oblong or wedge-shaped, flat, decurrent, acute. Umbels terminal, erect, finely downy, flattish, from three to fix inches broad, of very numerous rays. General involucreus usually of one short frappshaped leaf; but in the large primary umbel of several: partial with a broad, simple, oblong-like base, fringed with copious, horizontal, linear, acute leaffetls, nearly equal to the flowers. Each partial umbel is flat when young, partly coloured with purple and white, but afterwards convex, confluent of insinmeraul almost lellife flowers, powdered over, as it were, with the white anthers. Petals red and white, inflexed, nearly regular. German furrowed, fefid. Fruit elliptical. The flowers have a faint smell, not unlike thoie of the Barberry. In Haller's letters, v. 2. 516, is one from Dillenius, dated Dec. 1746, in which he speaks of an umbelliferous plant, sent under the name of Sefeh from Siberia, which, being fown in the spring, flowered, but perished on the approach of winter, without producing seed. He conceived it to be allied to the Hippoparathrum of Rivinus, (see our next species,) on account of the simple-leaved partial involucrum, cut into fix or eight teeth. The general umbel had a felif frapp-like leaf to each ray. The seeds resembled thoie of Caraway, and were not winged. Might not this be our S. gummiferum? If so, Dillenius ought to be recorded as its original introducer.

SESELI.

high, nearly upright, rigid, round, smooth, roughy, somewhat branched above, bearing several oblong, sheathing, membraneous-edged footstalks, with only very short or abortive leaves. The proper leaves are radical, very numerous, stalked, two or three inches long, doubly pinnate and cut, linear, glaucous and smooth like the rest of the herbage. Umbels terminal, solitary, small and cloe, rigid, minutely downy, with several principal rays, and sometimes a sheath-like leaf at the base; the partial ones of many white, nearly sessile, flowers, chiefly remarkable for the simple, cup-like, partial involucre, whose membranous downy edge is variously jagged and toothed. Dillenius rightly observes, in the letter to Haller, quoted under our last species, that this singular part is not shown in the figure of Clusius and Gerard. It indicates an affinity to our gummiferum, which obliges us to place these two species together, next to tortuosum, with which they accord greatly as to habit.

13. S. Turbith. Turbith Meadow-faxifrage. Linn. Sp. Pl. 374. Amoen. Acad. v. 4. 310. Willd. n. 11. (S. que ferulce facie, Thapsia, five Turbith, gallorum ; Bauh. Hilt. v. 3. p. 2. 45. Boer. Lugd. Bat. v. 1. 50. Thapsia Dios; Lob. p. 779. T. tetonifolia ; Ger. Em. 1050.)—Leaves recurved three-clawed, divided, awl-shaped. General involucre of one or two awl-shaped leaves; partial of many short, pointed, membranous ones. Seeds villous, the length of the permanent lylles.—Native of Spain, and the south of France. The root is perennial, thick, discharging a milky juice, which, according to John Baulhin, to whom it was pointed out by his preceptor Rondelet, possesses a valuable purgative quality. Stem erect, branched, round, smooth, not so clumsy as in Baulhin's figure. Leaves chiefly opposite, with broad sheathing footstalks, spreading, repeatedly subdivided into divided, slender, awl-shaped segments, crossing each other, and much resembling fennel. Umbels terminal, large, of many slender, downy, spreading, general as well as partial, rays. General involucre of very few and short, tapering, scarcely membranous-edged leaves; those of the partial ones more membranous, lanceolate, fringed, half the length of the flower-stalks, quite distinct at their base. Petals white. Fruit ovate, covered with fine hoary dense brilly hairs, and crowned with the long spreading flutes, very timid at their base. Stigmas obtuse, but hardly capitate.

14. S. pyrenearum. Pyrenean Meadow-faxifrage. Linn. Sp. Pl. 374. Willd. n. 13. Alt. n. 7. (Selium pyrenearum, Gouan. Illit. v. 2. 316. Carvi alpinum ; Bauh. Prodr. 84. Lachenal Act. Helvet. v. 7. 352. t. 12.)—Leaves doubly pinnate, with many linear, acute, deciduous, flat segments. Partial involucre fetaeuse, equal to the flowers. Seeds smooth, nearly orbicular, with three cloe central ribs.—Native of the Pyrenees. Miller appears to have cultivated it in 1731. The root is perennial, the fize of the finger. Stem a foot high, erect, furrowed, smooth, scarcely branched, moss leafy at the lower part. Footstalks long, dilated and sheathing at the base. Leaves three or four inches in length, light green, smooth, their leaflets uniform, with linear, alternate, pointed, deciduous, veiny segments. Umbels of six or eight unequal rays, without any general involucrum; the partial ones convex, dense, many-flowered, with a partial involucrum of many smooth, slender leaves, almost capillary, distinct at the bottom. Petals yellowish, with a purple tinge externally. Seeds with a broad, flat, even margin, their centre marked with three cloe prominent ribs.

15. S. faxifragum. Slender Meadow-faxifrage. Linn. Sp. Pl. 374. Willd. n. 14. (Pimpinella faxifragia tetonifolia ; Bauh. Prodr. 84.)—"Stem thread-shaped, divaricated. Leaves doubly ternate, linear. Umbels of about six rays."—Plentiful about the lake of Geneva, according to C. Baulhin, who describes it with an oblong root. Stem a foot high, green, smooth, frutiated, bent, divided from the base, and subdivided into slender branches. Leaves in slender, afterwards almost capillary, segments. Flowers few, minute, whitish, in a small umbel. It is not possible to determine any thing from this description, nor have we seen an authentic specimen. Linnæus saw this species in Burfer's herbarium only. His account agrees with the above, only adding that the partial involucral leaves are bristle-shaped.

16. S. clatum. Tall Meadow-faxifrage. Linn. Sp. Pl. 375. Mant. 357. Willd. n. 15. Alt. n. 8. Gouan II.II. 16. t. 8.—Stem much branched, round, rigid, very smooth. Leaves twice ternate, with linear, feely, diffuse leaflets. Fruit smooth, ovate, with diffuse obtuse ribs. Partial involucrum awl-shaped, shorter than the flowers. Partial involucrum awl-shaped, shorter than the flowers. Native of Italy and the south of France. Specimens are in the Linnæan collection from Arduins and Gouan, as well as the garden plant alluded to in the letter to Linnæus, cited by Gouan. Théle, as well as Gouan's figure, prove the present species to vary greatly in luxuriance. The stems are from eighteen inches to fifty feet high, much branched from top to bottom, very smooth, pale at the joints, leafy, the upper part greatly divaricated. Lower leaves twice ternate; upper quite simple; all linear, very narrow, feely, smooth; each leaf, or leaflet, from one to two inches long. Footstalks linear, channelled, sheathing, close, with an evident, though narrow, membranous edge. Umbels numerous, terminal, of from two or three to ten rays, smooth, without an involucre; partials of many short unequal rays, their involucral leaves slender, but membranous, rarely equal to the flowers. Petals white. Seeds ovate, gibbous, smooth, by no means tuberculated, though Gouan describes them dotted; each is marked with three slightly prominent ribs, but not bordered. The synonym of Magnol, quoted in Sp. Pl. was afterwards referred by Linnæus to his Pimpinella glauca.

17. S. triternatum. Yellow Meadow-faxifrage. Pursh v. i. 197.—"Leaves triply ternate; leaflets linear, elongated. Umbels hemispherical. Partial involucrum of many linear leaves, as long as the flowers."—About the waters of Columbia river, where it was found by governor Lewis, flowering in April and May. The spindled-shaped perennial root is one of the grateful vegetables of the Indians, who use it baked or roasted. Flowers deep yellow. Pursh.

18. S. junceum. Rushy Meadow-faxifrage. Sm. Prodr. Fl. Græc. Sibth. n. 698.—Stem much branched, divided. Footstalks of the stem-leaves very short, and spreading. Umbels solitary, simple, of few flowers.—Found in the Greek herbarium collected by Dr. Sibthorp, but without any name, or mention of the place where it was gathered. The root appears to be perennial. Here a fain high, rigid, smooth, rather glamous. Radical leaves twice ternate, with keeled three-pointed leaflets; those of the stem very small, and as if abortive. Umbels small, white.

19. S. capitojum. Tufted Meadow-faxifrage. Sm. Prodr. Fl. Græc. Sibth. n. 699.—Stem simple, nearly naked. Radical leaves tufted, flat, pinnate, cut; the terminal leaflet three-claw, deciduous. Gathered by Dr. Sibthorp, and his companion Borone, on the summit of the Bithynian Olympus. The root is thick, perennial, dividing at the crown into many heads. Stems from four to eight inches high, simple, scarcely ever divided, erect, straight, stiff and smooth, bearing a solitary leaf only. Radical leaves forming a dense tuft, smooth, rigid, of various sizes. The footstalk of the stem-leaf has a membranous edge. General umbel
of about five rays. Fruit cylindrical, obscurely iri-ated, smooth.

Seseli-Seed, in the Materia Medica, the name of the seed of a plant, called also by some Libanotis, and growing three or four feet high, with leaves like fennel, but of a paler green. It is a native of warm climates. The seed ought to be chosen moderately large, of a longish shape, heavy, clean, and of a greenish colour, fresh, and of a graceful smell. It affords, by distillation, a very large quantity of an essential oil, and is hot and dry. It incides, opens, and discusses, and is cephalic, neurotic, pectoral, and nephritic. It is good against epilepsy, apoplexies, vertigo, and all disorders of the head and nerves. Lemery's Diet. of Drugs.

The seeds of the fejfei Cretum, or hart-wort of Crete, are diuretic, uterine, and good in all disorders of the breast and lungs. They are given in infusions of urine, and of the menes, and in all kinds of flatulencies; and are, among the German physicians, a common ingredient in medicines, intended to promote expectoration.

The seed of the French hart-wort, or fejfei Maffiflense, has been esteemed of great virtue in diseases of the head and nerves, in convulsions and epilepsies, and in weaknesses of the sight. It is also given in electuaries, intended against all disorders of the breast and lungs, in coughs, catarrhs, and apheresis, and in obstructions of the liver. Some have recommended it chiefly, as a medicine of great efficacy against obstructions of the menes; and Schruder tells us, that it has the credit of being an antidote to the poison of hemlock.

The common hart-wort is poissled of the fame fort of virtues with the other two, but its seed is more warm and acute than that of either of them. It is esteemed a very efficacious remedy in obstructions of the menes, and in all disorders arising from indigestion, crudities, and flatulencies. See Sermountain.

Seseli Pratense. See Saxifrage.

SESEME-QUIAN, in Geography, a river of the N.W. territory, in the United States of America, which runs into the Illinois.

SESEN, or Sesem, a town of the principality of Wolfsenbuttle; 12 miles S.W. of Goslar.

SESERINUS, in Ichthyology, a name given by Rondeletius, and some other authors, to a broad and short sea-fish, seeming the same with the lampgusa of Italian siftermen; and describ'd by authors in general, and by this very author in another place, under the name of stromatus.

Sesha, in Hindoo Mythology. Images of Naga, or Seraphs, in brahs, are said to be invoked in cases of ill-health, with appropriate ceremonies, and according to the author of the Hindoo Pantheon, they are very common in India, where the idea of the medicinal virtues of snakes appears to be of very old date. A Hindoo, attacked by a fever, or other disease, makes an image of a Naga in brahs, clay, or wax, and performs appropriate ceremonies in furtherance of his recovery. Such ceremonies are particularly efficacious when the moon is in the nakhapatra, or alterfin, called Sarpa, or the serpent. We have observed that the snake, in all mythological language, is an emblem of immortality; its endless figure, when its tail is inserted in its mouth, an astrological mysticm common to Asia and Europe; and the annual renewal of its skin and vigour afford symbols of continued youth, of duration, and eternity; and its supposed medicinal virtues, or life-preserving qualities, may also have contributed to the famed honours of the serpent tribe. In the mythological machinery of India, Egypt, and Greece, these coincidences are numerous. Some learned writers attribute this universality of serpent-forms to the early and all-pervading prevalence of sin, its first shape on earth. For some notice of fabulous relations connected herewith, see Kusa and Superflum. With the Hindoo, serpents are not always of ill omen. A day in the Indian calendar, called "nagapanchami," is sacred to the demi-gods in the form of serpents, who are enumerated in the Padasa and Garuda Puranas." Cities, towns, mountains, rivers, men, women, &c. are commonly, among the Hindoos, named after mythological personages. Nagpur, the capital of the rajah of Berar, properly Nagappuri, is after one of the common names of Sesha, as is also a town in My-fore, Naugmungalam, properly Naiga-mangala. See Man-gala.

One of the fables most commonly alluded to in Hindoo writings, is Vifiunu repos'd on Sesha, and it is a favourite subject with painters. In a beautiful ode, by Sir W. Jones, addressed to Lakshmi, the Magna mater of her sectarries, (see Laksimali,) her union with Vifiunu is introduced. On this occasion the bride roves from the churned seas, like our Venus, and choosing Vifiunu for her husband, the subject of this article formed a nuptial couch for her reception; thus poetically deserib'd.

"—Love bade the bridegroom rise:—
Straight o'er the deep, then dimpling smooth, he rush'd:—
And tower'd th'unmeasur'd snake — a stupendous bed:—
The world's great mother, not reluctant, led:
All nature glow'd where'er the smiled or blush'd:—
The king of serpents rush'd:
His thousand heads, where diamond mirrors blaz'd,
That multiplied her image as he gaz'd."

The operation of churning the ocean, alluded to above, is described under the article Kurmapatara of this work, and a poetical allusion to the reflecting gems or mirrors on the heads of Sesha, will be found under Siiaakotha. See also Loto.

Seshnaga, a name of a mighty mythological serpent among the Hindoos, otherwise called Sesha; which see.

Seshthi-Matriya, a name of Kartikya, the mytho-
logical commander of the celestial armies of Hindoo fable. The name means having six mothers. Shan-matriya has the same meaning, and is another of his names, and Shan-
matura. Shanmuka is another, and means with six faces or mouths. For the origin of these appellations, and for particulars of the hero to be distinguished, see Kartiya, and Skanda, another of his names.

Sesia, in Geography, a river in Italy, which rises in the Alps, on the borders of the Valais, and runs into the Po, a little below Cuzal.

Sesa, one of the six departments of France, into which Piedmont was divided, when it was united to the French republic, Aug. 26, 1802; it is composed of Vercell and Mafrans, in N. lat. 45° 25', E. of Doire; and contains 140 square leagues, and 210,445 inhabitants; it was divided into three circles, viz. Vercell, comprising 79,391 in-
habitants; Sannia, with 36,014; and Biele, having 89,040 inhabitants. The climate of this department is unhealthy; the eminences and hills are favourable for the culture of the vine; and the cultivated plains yield abundance of grains, fruits, and pastures.

Sesiala, a town on the N.W. coast of Timor. S. lat. 8° 55'. E. long. 125° 26'.

Seskara, a small island in the N. part of the gulf of Bothnia. N. lat. 65° 38'. E. long. 23° 39'.—Allo, a small island in the gulf of Finland. N. lat. 59° 57'. E. long. 28° 28'.
SESLERIA, in Botany, received that appellation from Scorpius, who in the first edition of his excellent Flora Carolina, says, he could never forget the delightful garden, so rich in scarce plants, which he often used to visit, while at Venice, in the year 1745. It was formed in the island of St. Helen, by Dr. Leonard Seller, whose great diligence in observing and cultivating plants justly entitled him, in Scorpius's opinion, to this botanical commonnoration. A letter of his, describing a supposed new genus, under the name of Vitaliana, is subjoined to Donati's Storia Naturale del Adriatico, but Limmeus reduced the plant to Primula.—Scop. Carn. ed. i. 180. Sm. Fl. Brit. ii. Prodr. Fl. Grec. Beith. v. i. 52. Ait. Hort. Kew. v. i. 153. Julit. 31. Lamarck Dict. v. 7. 138. Illust. t. 47.—Clasf and order, Triandria Digynia. Nat. Ord. Gramina.

Gen. Ch. Cal. Glume of two, nearly equal, ovato-lanceolate, conceave, pointed valves, containing about three flowers. Cor. of two unequal, erect parallel, acute, valves; the inner folded, two-ribbed, closer, outer rather the longest, entire or three-cleft. Stam. Filaments three, capillary, longer than the flower; anthers pendulous, oblong, cloven at each end. Pfil. German superior, ovate; hyaline two, various in length, capillary, more or less combined; stigmas oblong, cylindrical, feathery. Peric. none, except the corolla, which embraces the seed, but is not attached to it. Seed solitary, ovate, smooth.

Eff. Ch. Calyx of two valves, containing about three florets. Corolla of two valves; the inner cloven; the outer variously pointed. Styles united at their base.

2. S. alba. White Moor-grafs. Sm. Fl. Grec. Beith. v. i. 56. t. 72. v. 2. 2. (Carex dubia; Sibth. MSS.)—Spike ovate-oblong, imbricated. Bractes alternate. Outer petals lanceolate, acute, undivided.—Discovered by Dr. Sibthorp, in woods about the village of Belgrad, near Constantinople. The general aspect of this grass, so like some of our common species of Carex, with compound androgynous spikelets, easily led its learned discoverer to refer it to that genus. He was, at the same time, too accurate to overlook the differences of its generic character; though not sufficiently acquainted with Sceliria, to perceive its agreement herewith. This species is somewhat larger in every part than the foregoing, and has a creeping root, sheathed with the wrinkled bases of old leaves. The spikelets are twelve or fifteen inches high, and the foliage nearly as tall. Spike of a greenish-white, rather shining, faintly branched. Spikelets two or three together, filked. Calyx three or four-flowered, membranous, taper-pointed; the middle florets filked. Petals membranous, whitish, with green roughish keels; the outer one lanceolate, pointed, undivided; inner cloven a little way down into two sharp-pointed lobes, each of which has its own folded rib or keel. Stamens white, considerably longer than the flowers; anthers pale yellow, drooping. Styles smooth, united throughout, the length of the corolla; stigmas divericate, awl-shaped, clothed with short pubescence. This Sceliria serves greatly to confirm the genus, and to indicate its true essential character.

3. S. sphaerophila. Round-headed Moor-grafs. Arduin. Spec. 2. 20. t. 7. Poiret in Lam. Dict. n. 2. Lamarck Iluiftr. t. 47. f. 2. (Cynorurus sphaerophila; Jacq. Mifc. v. 2. 71. Ic. Rar. t. 20. Wild. Sp. Pl. v. 1. 414. C. microsphora; Hoffm. Germ. 49.)—Spike capitata, globose, bracteate at the base. Outer petals with three teeth; the middle tooth awned.—Native of the lofty alps of Carinthia, Austria, the Tyrol, &c. A very much more slender plant than either of the former. The root is fibrous. Stem four or five inches high, somewhat quadrangular, bearing one leaf only, at the lower part, which is flat, short and broad, with a long filiated sheath, and a more elongated filipula than that of the other species. Radical leaves larger and narrower, folded, numerous. Spike almost globular, the size of a common currant, subtended by two or three opposite, broad, concave, notched, membranous, colour'd bractes, not half its own length. Spikelets imbricated every way, of a blueish-purple, nearly fiddle. Each calyx contains two or three florets. The petals are divided as in S. carulea, but the middle segment of the outer one is lengthened out into an awn, of a dark hue, twice or thrice as long as the rest. Wulffen, who communicated this species, and its description, to Jacquin, observed what he supposed a variety, with white flowers, in rather larger spikes, four or five florets in each calyx, and a shorter central awn to the corolla. This seems to be represented in Jacquin's plate, and Hoffmann, after Haenk and Hopp, has made it a distinct species, by the name of Cynorurus sphaerophila, calling our's microsphora. We do not fee sufficiently permanent characters to authorize this. Haller makes another Sceliria, at his n. 1447, which is Poa disticha, Jacq. Mifc. v. 2. 74. Ic. Rar. t. 19. Wild. Sp. Pl. v. 1. 400. Allioni has given it the barbarous appellation of P. microsphora. This plant is unquestionably a true Poa, see that article.

SUSOSTRIS, in Biography, king of Egypt, of whom the accounts are so mixed with fable, and so obscured by antiquity, that it has been found extremely difficult to form a confident and probable story. Historians are even divided as to the identity of the name Sesostris with that of some other resembling names in the Egyptian history, and several hold him to be the same with the Sesac or Shehmac of the Hebrew scriptures. The following is regarded as the most probable account of this monarch. He is generally placed by chroniclers in the 15th century B.C., and is by some thought to have been the son of Amenophis. Educated in many exercises with a number of companions, he is said to have been sent, by his father, at an early age, upon an expedition into Arabia; and after subduing that country, into Africa. While engaged in the conquest of the latter, his father died; and his successes having inflamed his ambition, he resolved to grasp at universal empire. Before his
his departure from Egypt, he ingratiated himself with the people by many acts of kindness, and made a division of the country into thirty-six departments, to each of which he assigned a governor. Then having constituted his brother Armais regent, he marched with a numerous army into Ethiopis, which he rendered tributary, penetrating near to the straits of Babemaneb. As he now perceived that he could not carry on his great designs without a navy, he fitted out two fleets, notwithstanding the aversion of the Egyptians to maritime occupations, one in the Mediterranean and the other in the Red sea. By means of the former he reduced the courts of Phcenicia, Cyprus, and several of the Cyclades, and with the latter he sailed into the Indian gulf, and made himself master of its coasts. Then, pursuuing his conquests by land, he is represented as having overrun all Asia, and even as having crossed the Ganges. On his return, he invaded the country of the Scythians and Thracians, in which, however, he lost a great part of his army. It is commonly thought that he left an Egyptian colony at Colchos, but Thrace was his farthest progresl wellward. On his arrival at Pelusium, after an absence of nine years, laden with spoils, and attended with a vast number of captives, he was received by his brother Armais with pretended joy and submifion, though he had formed a plot against him. For this traiterous attempt he expelled Armais from Egypt, and then, difbanding his army, he set down to the improvement of his country. He erected magnificent temples in all the cities of Egypt, in the building of which none but his captives were employed. He raised obelisks, with inscriptions recording his conquests and revenues. He built a wall of great length, on the eastern boundary of Egypt, to protect it from the incursions of the Arabians, and he dug a number of canals, branching from the Nile in all directions, for the purposes both of commerce and navigation. He is said, in the height of his pride, to have harforded tributary kings to his chariot, till one of them, pointing out to him the rotation of the wheels, by which each part was successively at top and bottom, brought him to reflection. Becoming blind in his advanced years, he finished his course by a voluntary death.

It may be observed that Sir Ifaac Newton has endeavoured to prove that Sphinxis is the Ofiris of the Egyptians, and the Bacchus of the Greeks, as well as the Serac of scripture. Univer. Hilts.

SESQUI, a particle often used by old masters and theoricsts, in Myfics, in the composition of words to express different kinds of measure. They called sesqui-alterate measures those which contain notes equal to one-third more than their usual value; that is, when equal to three notes of less value, instead of two. This happened in what was called perfect time, before the use of points or dots, when the breve was equal to three semibreves, the semibreve to three minimi, &c.

In Indian treatises by old theoricsts, sesqui is much used to express a kind of ratio, particularly in different species of triples; that is, when the greater term contains the less once, and some small quantity more; as 3:2, when the first term contains the second, and unity over, which is the half of 2. So that if the part remaining be just half the less term, as 4:3, the ratio is called sesqui terza, or tertia; if a fourth, or 5:4, the ratio is sesqui quarta, and so on to infinity; still adding to sesqui the ordinal number of the less term.

SESQUIALTER is a flop in the organ, implying a whole and a half. In large organs this flop has usually five ranks of pipes, each note having one found in unison with the diapason, one with the principal, one with the twelfth, and one with the fifteenth.
Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, with five angles, each angle terminating in an oval tooth, permanent. Cor. of one petal, funnel-shaped; tube as long again as the calyx; throat globular; limb plaited, in five deep, straight, oval segments, revolute at their margin. Stam. Filaments five, inserted towards the middle of the tube, curved and downy at their base, as long as the tube; anthers oval, of two cells. Pet. German superior, small, oblong; style terminal, thread-shaped, the length of the stamens; stigma of two unequal lobes. Peric. Capsule cylindrical, slightly curved, as long again as the calyx, of one cell, and two cleft valves. Seeds numerous, imbricated, oblong, compressed, each enfolded with a membranous border.

1. S. stipulata. "Fl. Peruv. v. 2. 9. t. 115. f. B."—
"Leaves lanceolate, or heart-shaped. Clusters panicked."—
Native of cool situations, on the mountains of Peru, flowering in June and July. A folid shrub, five or six feet high, having the aspect of a Cestrum. The branches are straight, leafy, alternate. Leaves alternate, flaked, mostly lanceolate, heart-shaped at the base; others, especially the upper ones, narrower, oval, oblong, entire, pointed, from three to five inches long, and one or two broad, smooth above, white and downy beneath. Siphules at the base of the footstalks, equal to them in length, opposite, large, oval, obtuse, sessile, a little heart-shaped at the bottom, deflected at the fides, deciduous. Panicles terminal, composed of straight, downy clusters, with corymbose flanks, of yellow downy flowers, accompanied by small, awl-shaped, deciduous bracteas.

2. S. dependens. "Fl. Peruv. v. 2. 9. t. 116."—
"Leaves oblong, heart-shaped. Clusters very long, pendulous."—
Native of the banks of rivers in Peru, flowering in November, December, and January. A tree, twenty-five or thirty feet high, agreeing in many respects with the foregoing, but the leaves are very powdery at the back, and the clusters very long, simple, and pendulous, slightly zigzag. The flowers are usually placed three together, in alternate sessile tufts. Calyx powdery. Corolla with a black tube, and yellowish limb, externally downy. Capsules black.

Both species are esteemed emollient anodyne. Poison.

Sessei, in Geography, a town of Bengal; 5 miles N.E. of Doela. N. lat. 23° 40'. E. long. 84° 58'.

Sesnenhorth, a town of Germany, in the principality of Cuimbach; 10 miles N. of Bayreuth.

Sessery, a town of Hindoostan, in Oude; 13 miles S. of Lucknow.

Sesile, in Botany, a term applied to any part of the herbage or flowers of a plant, that is not elevated on any kind of stalk; from the Latin sessilis, sitting close. Many plants bear flores sessiles, sessile flowers, on the branches; very few at the root, like Crocus, Colchicum, and Amarys. It is not unusual for the fruitification, though sessile at the flowering period, to become flaked as the fruit advances toward maturity. The germs are so usually sessile, as seldom to require to be so described, it being sufficient to notice a flaked germ, whenever such occurs, as affording most an important generic character. For folia sessilis, sessile leaves, see Leaf.

Sesile Roots, such tuberous roots as adhere to the base of the flalk. See Root.

Session, Sesio, denotes each fitting, or assembly, of a council.

In quoting councils, we say, in such a session, such a can-
non, &c.

Session of Parliament, is a session, or space, from its meet-
ing to its prorogation, or dissolution. See Parliament.

Session, in Law, denotes a sitting of justices in court, upon their commission. As the session of oyer and terminer, of gaol-delivery, &c. See Assizes, Justices of Assize, Justices of Gaol-delivery, Justices of Oyer, &c.

Sessions of Wales, Great. See Courts of Wales.

Quarter-sessions, called general sessions, or open sessions, stand opposite to special, otherwise called petty sessions, which are procured upon some special occasion, for the more speedy dispatch of justice. See Quarter-Sessions.

Statute-sessions, are those kept by a high-committee of a hundred, for the placing of servants, &c. See Statute.

Sessions for Weights and Measures. In London, four justices from among the mayor, recorder, and aldermen, (from whom the mayor or recorder is to be one,) may hold a session to enquire into offences of selling by fall weights and measures, contrary to the statutes; and to receive indict-
ments, punish offenders, &c. Char. K. Cha. I.

Session, The Court of, otherwise called the college of jus-
tices, is the supreme court in Scotland for all civil causes.

It consists of one confant president, who has an annual salary of 1300l. and fourteen other judges, at 700l. per annum each, who are lords by their office, which they hold by patent quamdiu je bene geferiet. The lord high chancellor presides here when present. The king names several other extra-
ordinary lords, who sit, but are not obliged to give attendance, because they have no salaries; but they may vote among the rest.

The court sits from the first of November, old style, to the last of February, and from the first of June to the last of July, all inclusive; which holds of all the inferior courts or judicatories in Scotland. In time of session, or term, they sit from nine o'clock to twelve in the forenoon, every day in the week but Sunday and Monday; sometimes they sit in the afternoon, to end concluded causes, or to hear such long debates as the forenoon was too short to hear, which gives a great dispatch to causes that come before them.

The lords, both ordinary and extraordinary, when in the inner house, sit on a semicircular bench in their robes; where the advocates debate their clients' causes before them. There are six principal clerks belonging to this court. Nine of the lords make a quorum in the inner house, otherwise they cannot vote in any case, except such as are referred to one or more of the whole lords; and one of the ordinary lords (the president being always excepted) is weekly appointed judge in the outer house, for discharging of ordinary actions, and has fix under clerks to attend him. He meddles with no extraordinary causes, except where it is remitted to him by all the lords, to be discharging in the outer house for dispatch.

That the lords may have time to read informations, pe-
titions, &c. and the suitors be eaid of the trouble of going with them to their houses, every lord has a box standing upon the table in the waiting room in the inner house, from two to four o'clock in the afternoon, every day; wherein all who have papers to offer, may put them by a slip in the cover. Each of the principal clerks has also a box, and parties must put in their bills, answers, or informations of causes to be reported, into the clerk of the proces's box.

The rolls of the court bring in all causes in their due order. Causes of the greatest confluence are at first ad-
viced by the whole lords in the inner house. Other causes are called of course before an ordinary in the outer house, who decides the controversy, if clear, without further trouble or expense; and, in case of difficulty, takes some little time
to advise itself, or to advise with the whole lords upon it. And if any of the parties think themselves wronged by the sentence of the ordinary, they may complain to the lords, and get their answer upon a bill.

An appeal lies from this court to the house of lords.

The lords of session were first appointed by James I. of Scotland, who selected, among the elates of parliament, a certain number of persons, and distinguished them by this appellation. They were empowered to hold courts for determining civil causes three times a-year, and forty days at a time, in whatever place he pleased to name. James IV. on the pretense of remedying the inconveniences arising from the short terms of the court of sessions, appointed other judges, called lords of daily council. The session was an amelioratory court, and met seldom; the daily council was fixed, and sat constantly at Edinburgh; and though not composed of members of parliament, the same powers which the lords of session enjoyed, were vested in it. At last, James V. erected the new court that still subsists, and which he called the college of justices, the judges or senators of which were called lords of council and session. Robertson's Hist. of Scotland, 1776, vol. i. p. 40.

Sessions, Kirk. See Kirk.

Sessach, in Geography, a town in the duchy of Wurzburg; 50 miles N.E. of Wurzburg.

Sesoo, a town of Bengal; 21 miles S. of Doesa.

Sesta, a town of the Ligurian republic; 5 miles N.W. of Brugneto.

Sesta, ItaL, the interval and conflation of the sixth, in Manic. See Hexachord, and Hexachordon.

Sesterce, Sesterctus, a silver coin, in use among the ancient Romans, called also simply nummus, and sometimes number foliarius.

The sesterce was the fourth part of the denarius, and originally contained two as and a half.

The sesterce was at first denoted by LLS; the two L's signifying two libra, and the S half. But the librarians, afterwards converting the two L's into an H, expressed the sesterce by HS.

The word sesterctus was first introduced by way of abbreviation for sestertius, which signifies two, and a half of a third, or, literally, only half a third; for in expressing half a third, it was understood that there were two before. Hence sesterctus came to be the great estimate of Roman money. Some authors make two kinds of sesterces: the lea, called sesterceus, in the masculine gender; and the great one, called sesterctus, in the neuter: the first, that which we have already defined; the latter containing a thousand of the other. Others will have any such division of great and little sesterces unknown to the Romans: sesterctus, lay they, was an adjective, and signified as sesterctus, in two as and a half; and when used solely, as in quinuagesima sesterctus, or sesterctus, it was only by way of abbreviation, and there was always understood centena, millia, &c.

This matter has been accurately stated by Mr. Raper, in the following manner. The sesterctus to which sesterctus referred is either as, or ponctus; and sesterctus is, in two as and a half; sesterctus ponctus, two ponders, and a half, or two hundred and fifty denarii. When the denarius passed for ten as, the sesterce of two as and a half was a quarter of it; and the Romans continued to keep their accounts in these sesterces long after the denarius passed for sixteen as; till, growing rich, they found it more convenient to reckon by quarters of the denarius, which they called nummi, and used the words nummus and sesterctus indifferently, as synonymous terms. And sometimes both together, as sesterctus nummus; in which case, the word sesterctus having lost its original signification, was used as a substantive; for sesterctus nummus was not two nummi and a half, but a single nummus of four as. They called any sum under two thousand sesterces so many sesterctus in the masculine gender; two thousand sesterces they called duo or bina sesterctus, in the neuter; so many quarters making five hundred denarii, which was twice the sesterctus; and they said dena, vicena, &c. sesterctus, till the sum amounted to a thousand sesterces, which was a million of sesterces. But, to avoid ambiguity, they did not use the neuter sesterctus in the singular number, when the whole sum amounted to no more than a thousand sesterces, or one sesterctus. They called a million of sesterces, decies nummum, or decies sesterctus, for decies centena millia nummorum, or sesterctorium (in the masculine gender), omitting centena millia, for the sake of brevity. They likewise called the same sum decies sesterctus (in the neuter gender) for decies centes sesterctus, omitting centes for the sake of brevity; or simply decimals, omitting centena millia sesterctus, or centes sesterctus; and with the numeral adverbs, decies, vicena, centes, millia, and the like, either centena millia, or centes, was always understood. These were their most usual forms of expression; though for bina, dena, vicena sesterctus, they frequently said bina, dena, vicena millia nummum. If the confinal denarius contained sixty five grains of fine silver, it was worth somewhat more than eight pence farthing and a half pence; and the as, of sixteen to the denarius, a little more than a halfpenny. To reduce the ancient sesterces of two as and a half, when the denarius passed for sixteen, to pounds sterling, multiply the given number by 5427, and cut off six figures on the right hand for decimals. To reduce nummi sesterctus, or quarters of the denarius, to pounds sterling; if the given sum be confinal money, multiply it by 5772, and cut off six figures on the right hand for decimals; but for imperial money, diminish the said product by one-eighth of itself. Phil. Trans. vol. li. part ii. art. 48. See Denarius and Drachm.

To be qualified for a Roman knight, an estate of four hundred thousand sesterces was required; and for a senator, of eight hundred thousand.

Authors also mention a copper sesterce, worth about one-third of a penny English.

Sesterce, Sesterctus, was also used, in Antiquity, for a thing containing two wheels and a half of another: as was taken for any whole, or integer.

Sestini, La Signora, in Biography, engaged as a prima buffa in the comic opera, arrived in England from Lisbon in 1774; and her first performance was in Auffoli's comic opera, entitled "La Marchesa Giardimier." Her face was beautiful, her figure elegant, and her action graceful. Her voice, though by nature not perfectly clear and sweetly toned, had been well directed in her studies, and the song with considerable agility, as well as taste and expression.

She was married to a young man of family at Lisbon, by which imprudent step he had totally lost all parental favour, and even support; so that, instead of being an auspicious match for herself, she had him and a large family to maintain by her talents; which not being of the first class, were soon disregarded by the public. And after languishing some years unemployed, she went with her helpless husband and family to Italy, where, it is to be feared, they suffered all the melancholy mortifications of extreme indigence.

Sesto, Cesare, known by the name of Cecco Milanese, was a native of Milan, and flourished about the year 1500. He is one of those painters by whom probably were executed some of the many pictures attributed to Lionardo da Vinci; and in the Ambrosian library was a head by him often attributed to Lionardo. In some of his works he also

Xx

imitated
imitated Raphael, to whom he was known. He died at Milan in 1524.

Sesto, in Geography, a town of Italy, in the Milanese; 28 miles W.N.W. of Milan.—Alfo, a town of Italy, in Friuli; 5 miles N. of Concordia.

SESTOLA, a town of Italy, in the department of the Panaro; 17 miles S. of Modena.

SESTOS, a fortress of European Turkey, in the province of Romania, opposite to Abydos; 34 miles S.S.W. of Gallipoli. N. lat. 40° 6'. E. long. 26° 25'. Abydos (which fec) and Sestos were two towns, opposite one another at the most narrow part of the Hellespont: they were famous for the love-adventures of Leander, who lived at Abydos, and Hero, a priestess of Venus, at Sestos. Leander swam across the Hellespont to visit his mistress, guided by a torch, which she lighted on the top of a tower; but, in a tempestuous night, Leander, having too imprudently committed himself to the waves, could not reach the other shore, and was unfortunately swallowed up by the agitated waters. Hero, in true despair, threw herself into the sea, in order to share the fate of her lover. Procopius places Sestos in the cove nearest to Abydos; and he adds, that the emperor Julianus caufed a citadel to be built near that city: the remains of this citadel are still to be seen close to the sea-shore. On the declivity of the hill, the walls of the ancient city may very easily be traced. Four miles from Sestos, on ascending the channel, is another harbour, near which is seen only a single habitation of dwarves, occupied by three or four Mussulman monks.

SESTOS, a river which rises in the mountains of Sierra Leone, traverses the Grain Coaft, and runs into the Atlantic, N. lat. 5° 30'.

SESTRE, Grand, or Great Paris, a town of Africa, on the Grain Coaft, being one of the largest commercial towns of the country. N. lat. 4° 16'. W. long. 8° 20'.

SESTRE, Petit, or Little Paris, a town of Africa, on the Grain Coaft, near Grand Sestre.

SESTRE-KRO, or SETTRA-KRO, a town of Africa, being the chief town of the Kroo country, which extends along the Grain Coaft, between Cape Mount and Cape Palmas, from 5° 54' to 5° 7' N. lat. The chief town is in long. 7° 48'. This district, though small, is extremely populous, and the natives are of a migratory disposition. Above 800 are employed as labourers at Sierra Leone; and they are to be found at every factory and town along the coast for a space of 350 miles. They are employed as factors or intermediate merchants, boatmen and sailors; and while the slave trade was carried on upon this coast, they had their share of its occupations. After the age of forty, they return and settle at home. Their country produces grain, particularly fine rice, pepper, and cattle; but their staple article is their own labour, with which they purchase goods, and return to their homes with the produce. Wars are rare among this people; they never fell one another, nor kill their captives; nor do they punish any offence by slavery, though witchcraft among them is a capital offence, and the only one that is invariably fo among them. One of the most singular parts of the character of the Kroomes, is their extreme love for their own country, and their confident belief in its vall superiority over all others. Every action of their lives bears a reference to it. With regard to their talents and acquirements, they are sufficiently acute and observant, where the occasion calls their minds into action. They have not the afe of letters, nor will they permit their children to learn; their language in conversation is very bad; and as they live by daily labour, which is paid for in European goods, they have no occasion for manufactures of their own, and of course no opportunity for displaying their talents. They make their own canoes, some implements of agriculture, and a few musical instruments.

SESTRI, di Levante, a town of the Ligurian republic; 12 miles W. of Brugnetto.

SESTRI, di Ponente, a town of the Ligurian republic; 4 miles W. of Genoa.

SESTUPLA, Ital. in Music. See SEXTUPLA.

SESVAH, or RAMBUR, in Geography, a town of Hindoothan, in Bahr; 22 miles E.S.E. of Bettiah.

Gen. Ch. Cal. Perianthe inferior, of one cell, bell-shaped, deeply cleft into five, ovate, acute, withering segments, coloured on the inside. Cor. none. Stamus. Filaments numerous, awl-shaped, shorter than the calyx and inserted at its base; anthers roundish. Pet. Germ. superior, oblong, at the bottom of the calyx, triangular at the upper part; stigmas three, capillary, erect, the length of the flaments; styleg simple, Peric. Capsule ovate, of three cells, bursting all round. Seeds rounded, flat, with a base at the margin.

1. S. Portulacaorum. Purflane-leaved Seufvium. Linn. Sp. Pl. 684. Jacq. Amer. t. 95. (Portulaca aizoides mari- tima procumbens, flore purpureo; Sloane Jam. v. 1. 204. Crithmus indicus; Rumph. Amboin. v. 6. 165. t. 72. f. 1.)—Stem round. Leaves opposite, oblong. Flowers stalks solitary, much shorter than the leaves.—Native of the Weft Indies, in maritime situations; flowering in July and August.—Root perennial. Stems succulent, four or five inches long, round, thick, diffuse, branched, at first procumbent, then erect. Leaves on short stalks, fleshy, bright green; their stalks sheathing, with membranous edges. Flowers solitary, axillary, green on the outside, white and blood-red or purple on the inside, inodorous. Seeds black.—The whole plant is very succulent, and abounds with a neutral-alcalafeant falt, which is easily extracted, and would probably serve as a substitute for Kali.

SET, a term used for a pole or shaft, ufed to fhoat boats along a canal, &c.

Set is also a term signifying to let, as land.

Set, in Agriculture and Gardening, a term used in Ireland to signify a fort of ridge. It alfo signifies a cutting of any fort of fleshy root, shrub, or tree of the fruit kind. Likewise any fort of young plant from the seed-bed to be planted out.

Set-off, in Law, is an act, by which the defendant ac- knowledge
knowledges the justice of the plaintiff's demand on the one hand; but, on the other, sets up a demand of his own, to counterbalance that of the plaintiff, either in the whole, or in part; as, if the plaintiff sues for ten pounds due on a note of hand, the defendant may set-off nine pounds due to himself for merchandise sold to the plaintiff; and, in case he pleads such set-off, must pay the remaining balance into court. This answer very nearly to the condemnation, or stoppage, of the civil law, and depends upon the statutes 2 Geo. I. cap. 22, and 8 Geo. II. cap. 24.

SET-off, in Inland Navigation, is a reeves, as I K (Plate I. Canals, figs. 3 and 6.), on the bank of a canal, and has the same meaning with bench or bern.

Set-Bolts, in a Ship. See Bolts.

To SET fail. See SAIL, and SETTING.

SETACEUS VERMIS, in Natural History, a name given by Dr. Lister to that long and slender water-worm, which so much resembles a horse-hair, that it has been supposed by the vulgar to be an animated hair of that creature. These creatures, supposed to be living hairs, are a peculiar sort of insects, which are bred and nourished within the bodies of other insects, as the worms of the ichneumonflies are in the bodies of the caterpillars. See AMPHIBESA.

SETAH, in Botany, a name used by the oldest writers for the acacia. It is an original Hebrew word, and is explained by the lexicographers, by a thorn growing in the desert. It is rendered by Theodotion acantha, one of the names of the acacia.

SETAPOUR, in Geography, a town of Hindoostan, in Golconda; 30 miles N.N.W. of Rachore.

SETARIA, in Botany, from sata, a bristle, a name given by Acharius, in his Prodromus Lichenographicus, to the 27th tribe of the great genus Lichen. It comprehends several species, of what have usually been termed filamentous lichens, as jubatus, chalybeformis, &c. See LICHENES.

SE-TCHEOU, in Geography, a city of China, of the first rank, in Koei-tcheou, in a mountainous country, yielding cinnabar and quicksilver; 982 miles S.S.W. of Peking. N. lat. 27° 10'. E. long. 103°.

SE-TCHIN, a town of China, of the second rank, in Quang-fi; 1157 miles S.S.W. of Peking. S. lat. 22° 48'. E. long. 136° 31'.

SE-TCHING, or Se-TCHIN, a city of China, of the first rank, in Quang-fi; 1100 miles S.S.W. of Peking. N. lat. 24° 17'. E. long. 105° 54'.

SE-TCHUEN, a province of China, bounded on the N. by Chen-fi, on the E. by Hou-quang, on the S. by Koei-tcheou, and on the W. by the kingdom of Thibet and some other neighbouring countries. This province comprehends, besides a great number of forts and strong places, 10 cities of the first class, and 88 of the second and third. The great river Yang-tse-kiang traverses Se-tchuen, which is opulent, not only on account of the abundance of silk it produces, but also for its mines of iron, tin, and lead; its amber, fugar-canes, loadstone, lapis lazuli, musk, and horses, which are in great request; also for its rhubarb, and the root fui-lin, which the Chinese physicians introduce into all their prescriptions; and for a thousand other useful productions, which would be tedious to mention. This province, which is at a great distance from the sea, obtains the salt which it consumes from its mountains, where the inhabitants dig pits, that furnish them with it in great abundance. Its capital is Tching-tou; which see. The population of this province, according to Sir John Staunton, is estimated at 27,000,000.

SETEEF, a town of Africa, anciently called Suipha and capital of a part of Mauritania, which made a stout resistance against the Saracens. There is scarcely one fragment left, either of the ancient walls, pillars, or cisterns of the Romans; the few remaining structures being obviously the work of the later inhabitants. The fountains, which continue to flow very plentifully near the centre of the city, are equally delightful and convenient; and without doubt gave occasion formerly for many ingenious and useful contrivances in the distribution of the water; 50 miles S.W. of Constantina. N. lat. 35° 58'. E. long. 5° 30'.

SETERRA, or SETRES, a town of Africa, on the Grain Coast.

SETHIANs, SETHIDiANS, Sethians, or Sethinians, in Ecclesiastical History, a branch of the ancient Gnostics; thus called, because of their pretending to deduce their origin from Seth, son of Adam, whom they called Jesus and Chrift; from an opinion, that Seth and Jesus were the same person, who came down from heaven at two several times.

As the Sethians had the same philosophy with the other Gnostics, they had numerous other fables in their faith. They pretended to have several books of the ancient patriarchs; particularly, seven of their great master Seth; besides one of Abraham, which was full of manifold fallacies, which yet they called Apocalypfe, or Revelation. The book called the "Little Genesis," very anciently common in the churches of the East, was borrowed from them. From this book they learned the name of Seth's wife, who, they say, was called Horaa. Some imagine, they borrowed a great many of their fictions from the Helleniff Jews.

SETHRON, in Geography, a town of Egypt, on the S. coast of the lake Menzalah; 16 miles W. of Tinh.

SETICAUDAE, in Natural History, a term used to express such flies as have one or more hairs growing out at their tails. There are many species of these distinguished by their having one, two, or three hairs.

SETER, See SEPTER.

SETINES, in Geography. See Athens.

SETIO, a mountain in the E. part of the Tyrolese.

SETIANA, a town of Hindoostan, in the circuit of Siroy; 35 miles N.W. of Siroy.

SETLE, a town of Turkifh Armenia; 30 miles S.W. of Aklaziké.

SETLEDGE, a river of Hindoostan, which rises in the mountains of Thibet, and runs into the Indus, near Veh, anciently called Hysudrus.

SETON, a river of Spain, which runs into the Gallege, in the province of Aragon.

SETON, Setaceum, denotes, in Surgery, a skein of silk or thread, introduced through a part of the flesh by means of a needle, and left there so as to keep up a continual discharge of matter, and a degree of counter-irritation, with a view of relieving or curing a variety of diseases. In a few cases, setones are employed on another principle. When sinuses and fistulae have lost all disposition to heal, in consequence of a want of action in the parts affected, a seton, passed through the track of the disease, will sometimes excite a salutary kind of inflammation, which brings on the healing process. Great judgment, however, is necessary in the application of a seton to this purpose; for, unless the sinus be prevented from healing merely by the caufe above specified, namely, a want of action in the parts, no success can be expected to attend the practice, and the patient will be put to much unnecessary pain and inconvenience.

A seton is also sometimes employed as a means of dif-
charged the contents of large chronic abscesses. It is thought by some practitioners that this method has the advantage of letting the matter escape very gradually, a circumstance, by which the dangerous effects, often arising from emptying the abscesses all at once, are in a great measure avoided. Many surgeons even suppose that fets hinder the external air from getting into the cavity of the abscesses, and, as prejudice and exaggeration have filled their minds with serious apprehensions upon this subject, they are perhaps more attached to the practice than any recommendations which it really possesses would justify.

Formerly, fets were frequently used for accomplishing the radical cure of the hydrocele. The celebrated Mr. Pott was an advocate for this method, which he certainly brought to great perfection. It is scarcely necessary for us to remark here, that the feton excited the requisite degree of inflammation in the cavity of the tunica vaginalis tesi, and the adhesion of its opposite surfaces to each other. See HYDROCELE.

The common mode of making a feton is with a flat broadish needle, which is somewhat curved towards the point, and furnished with cutting edges. This form enables the surgeon to bring the needle out of the part again without any difficulty. The integuments are pinched up into a fold, of which the operator raises one end with the fore-finger and thumb of his left hand, while an assistant raises the other. The needle, armed with the filk or thread dipped in sweet oil, is then to be pushed through the skin thus lifted up. It is only necessary to draw the end of the filk or thread a little way out of the second aperture: the needle may now be removed. The next object is to fix the ends of the filk, which is usually done with adhesive plaster.

The wounds are then to be covered with plastes, and a retentive bandage. The oil prevents the skin from adhering to the flesh, and facilitates its passage through the wound; for, as soon as suppuration has taken place, that part of the skin which is in the wound is to be drawn out and cut off. The same method is to be repeated every day, and the same plan of dressing continued. When the skin of the fik is exhausted, a new one, oiled in the above manner, is to be introduced by means of an eye-probe.

Fetons, unless kept exceedingly clean, and dressed with much tendernefs, sometimes excite a great deal of irritation, and prove very troublesome to the patient. The thread is also apt, with the leaf neglect, to cut its way out, and leave an ugly sore.

When a feton is made in a cafe of large chronic abscesses, a puncture is first made in the upper part of the tumour; an eye-probe, armed with a skin of filk, is introduced downwards; and the end of the instrument being felt against the infide of the lower part of the swelling, an incision is made upon it, so that the end of the filk can then be drawn out.

The manner of making a feton for the cure of hydroceles has been described in a former volume. See HYDROCELE.

The like operation is frequently practiced on horfes, &c. and called, by the farriers, rowelling.

SETOSCH, in Geography, a town of Bohemia, in the circle of Chrudim; 8 miles S.S.W. of Chrudim.

SETRA-JETA, the name, in Hindoo romance, of the father of one of the favourite wives of the popular deity Krishna. Her name was Satyavama; and she is sometimes said to have been an incarnation of Lakshmi, confof of the god Vishnu. See those articles.

SETS, in Agriculture and Gardening, a term applied to the cuttings or planted parts of potatoes, hops, liquorice, lavender, &c.

It has lately been found to be of material advantage for the fets which produce the plants, in some cafes, to have a large substance for their early nourishment and support, as in the case of the potato; as though the small parts, called "eyes" or "buds," will grow and produce crops, they are far from being equal to those where the fets are of a large size. In short, the result of various experiments has shown that crops of this fort prove, ceteris paribus, abundant or otherwise, nearly in proportion to the size of the fets. Therefore, as there is no material saving produced by the use of small fets or cuttings of this root, while the difference in the quantity of produce is from one hundred to one hundred and fifty bushels the acre, the practice of employing such small fets in planting should be discontinued in all situations; and for the very reason that heavy well-fed corn, when otherwise in good condition, should, in all cafes and circumstances, be preferred to that which is light. See POTATOES and SEED.

SETSE, in Botany, the name of a Chinese tree, called also chufs, and much esteemed by the people of that country for its beauty, and for the goodness of its fruit. In the provinces of Cantong and Honan there are whole plains covered with these trees, many of which grow to the size of our walnut-tree. The fruit ripens every where in the East, where the tree grows, but it is of a much more delicious flavour in some places than in others. The leaves are of the colour and shape of the walnut-tree, only that they are more round at the ends. The fruit is sometimes round, sometimes pointed at one end, sometimes oval, sometimes flat, and not frequently composed of two pieces, as it were, and resembling two apples, cut and joined together. The rind is always green, never changing yellow or red, and the fruit keeps its freshness all the winter. They are about the size of the orange, and the skin is very tender and thin, and the fruit has a mixed taste of the sharp and the juicy. It is very wholesome and good.

SETTE, in Geography, a town of Africa, and capital of a country of the same name, subject to Loango, on the river Sette; 160 miles north of Loango.—Allo, a country of Africa, south of cape Lopez Gonfalvo, watered by a river of the same name. This country is governed by a mani, who is subject to the king of Loango.—Alfo, a river of Africa, which runs into the Atlantic, S. lat. 2° 15'.

SETTE, in Sea Language, a vessel, very common in the Mediterranean, with one deck, and a very long and sharp prow. They carry, some two, three, some three, without top-masts. They have generally two masts, and are rigged and navigated like xebecs or galleys, with fettees, instead of lateen sails. The lenth of them are of forty tons burden. They ferve to transport cannon, and provisions for ships of war, and the like. These vessels are peculiar to the Mediterranean sea, and are usually navigated by Italians, Greeks, or Mahometans.

SETTEFRA TRI, in Geography, a town of Naples, in Abruzzo Ultra, 10 miles N. of Teramo.

SETENIL, a town of Spain, in the province of Grenada; 8 miles N. of Ronda.

SETTER, among Farmers. A fetter, is to cut the dew-lap of an ox, or cow, and into the wound to put the root of the hellebora; by which an illume is made, for ill humours to vent themselves.

S E T T E R - Wort, in Botany. See HELLEBORE.

SETTIA, in Geography, a province of the island of Candia, occupying the whole eastern part of the island; it is the most extensive, but the least peopled, and the least productive,
productive, though in a great measure susceptible of culture, and though most of its lands are very fertile. But distance from the capital, want of harbours, and the incon- siderate injustice of the agas, and almost every other circumstance, contribute to render the inhabitants of this part of the island more indolent than the others. Contented with gathering corn and fruit for their subsistence, oil for paying their taxes, and procuring for themselves a few clothes, and the utensils necessary for their family, they are not eager to seize from the earth a surplus of productions, which would render them more subject to the oppression and spoliation of the agas. The town is situated on a flat shore, which with a cape not much advanced, and three islets placed at upwards of a league’s distance, protect it feebly from the N. and N.E. winds. When the Venetians were masters of the island, it was tolerably well fortified, and sufficiently peopled. They constructed a mole, in order to shelter the vessels which came thither to load with the productions of the province, or which brought thence that which was necessary to supply the wants of the inhabitants. At this day none but small boats may be seen at Settia. The population has diminished considerably, and the fortifications are in the greatest disorder. It is the see of a Greek bishop; 44 miles E.S.E. of Candia. N. lat. 35° 3’. E. long. 26° 3’.

SETTIAVARAM, a town of Hindoostan, in the cir- cuit of Cicascole; 30 miles S.W. of Collimottta.

SETTIMA, Ital., in Mufic, the interval of the seventh; which fee.

SETTIMANA SANTA, Ital., passion-week, during which holy time, the sacred mufic of the highest clafs used to be performed in the most perfect and imprefive manner in the pontifical chapel. See Miserere and Allegri.

SETTIMO, in Geography, a town of France, in the department of the Po; 8 miles N. of Turin.—Also, a town of Italy, in the department of the Tefino; 5 miles N.E. of Pavia.

SETTING, in Astronomy, the withdrawing of a star or planet; or its sinking below the horizon.

Alphornmen and poets make three different kinds of fetting of the stars: cosmical, acroical, and heliacal.

To find the times of the setting of the fun and stars, fee Globe.

SETTING, in Navigation. To set the land, or the fun, by the compas, is to observe how the land bears on any point of the compas, or on what point of the compas the fun is; likewise the act of observing the situation of any distant object by the compas, in order to discover the angle which it makes with the nearest meridian: as at feven poll meridian, we set the tower of Arabia near the port of Alexandria, and it bore S.S.E. distant four leagues by estimation. (See BEARING.) Also, when two ships fall in fight of one another, to mark on what point the chafed bears, is termed setting the chaf by the compas.

SETTING also denotes the direction of the wind, current, or sea, but particularly the two latter; as, the tide, which sets to the south, is opposed to a turning sea, setting to the north-west.

SETTING, when applied to the falls, is the loosening and expanding them, so as to give the ship motion, or to accelerate her velocity, when she is already moving, and perhaps give a new direction to her motion. It is used in contradiftinction to taking-in the falls, as loosening or heaving-out is opposed to furling or lowering them.

SETTING, in the language of Sportmen, a term used to express a manner of attacking partridges, in order to the taking of them by means of a dog peculiarly trained to that purpose. The setting-dog generally used is a long hafl-spaniel, taught by nature to hunt partridges more than any other game, and in his utmost range running over the fields in search of them, with an acnility that is truly wonderful; yet by art this creature is brought under a fuch excellent command, that he will, in the midft of his highest career, attend to the left hem from his master, and fand still to look in his face, and take his orders by the flighteft signals; and when he is fo near his game, that it is almost in his mouth, he will fand still, or lie down on his belly till his master arrive, and he receives his directions.

The setting-dog being taken to the haunt of the partriges is to be call’d off, and sent to range; but he muft be made to keep near the sportman, and not to run wildly on, but to beat all the ground regularly. On being reproved for ranging too widely and too far, he will keep close the whole day, and at times look up in his master’s face, to know if he does right or wrong. If in the dog’s ranging he fpot of a sudden, the sportman is to make up to him, and as there is certainly game before him, he muft be ordered to advance; if he refuses this and look back, and shake his tail, it is a signal that they are clofe before him, and the sportman is then to take a circumference, and look with a carelcss eye before the dog’s nofe to see where they are, and how they lie; then going up, and flaking down one end of the net, he is to command the dog to lie still, and to draw the net gently over the birds; then making in with a nofe, he is to spring them, and they will be en- tangled and taken as they rife. It is a rule with fair sport- men, when they take a covert in this manner, always to let the cock and hen go.

SETTING, among Cock-Majfers, is the placing a cock that has fought fo that he cannot fland, beak to beak against the other cock, and if he does not strike, the battle is won.

SETTING-down, in Falconry, is when a hawk is put into mew.

SETTING-dog, one trained up to find out and discover to the sportman whereabout fowls are. See SPANIEL and DOG.

SETTING-up, in Ship-Building, is raising a ship by fhores and wedges from her blocks, the act of extending the throns, itays, and back-irays, to secure the masts, by the application of tackles, &c.

SETTING, or Setting-to, the act of making the planks, &c. hay or fet close to the timbers, by driving wedges between the plank, &c. and wain-iraff. Hence “let, or let away,” means to exert moreifhrent. The power or engine used for this purpofe is fimple, and called a jetf, and is compofed of two ring-bolts, and a wain-iraff, cleats and lathing, or fhores.

SETTING, in Agriculture and Gardening, the buifines of putting fets of different kinds into the ground, as thofe of the potatoe, hop, madder, liquorice, lavender, and many other kinds.

SETTING out Plants, the praticife of thining and reducing them; in the former, to their proper diftances, in order to fland for crops, as in the turnip, cabbage, and many other forts of plants; and, in the latter, the buifines of putting them into the ground as crops; it being praticied for a great many different forts of plants that are raifed on feed- beds, as all the cabbage kind, lettuces, endives, heets, and many other plants of a fimilar nature. It is ufually performed as foon as the plants have acquired a proper state of growth in the feed-beds, and molly when the weather is cloudy and rather moist, as it can then be done to the greateft
greatest advantage, in so far as the plants are concerned. They are commonly put in this way to the proper distances for growing as crops, and the work is for the most part done by means of a line and dibble. See Thinning out Crops, and Transplanting.

Setting of Wheat, is a method of cultivating wheat, which was probably first suggested by planting grains in a garden from mere curiosity, and first attempted on a larger scale by a farmer near Norwich, about the year 1768. His example was followed by some of his neighbours, and particularly by one of the largest occupiers of land in the county of Norfolk, who set fifty-seven acres in one year. His lucres, from the visible superiority in his crop both in quantity and quality, was so great, that the following autumn he set three hundred acres, and afterwards continued the practice. The method of setting was generally introduced, in consequence of this experiment, among the intelligent farmers, in a very large district of land. And it has been observed, in recommendation of it, that, although the set crops appear very thin during the autumn and winter, the plants tiller and spread prodigiously in the spring. The ears are indifferently larger, without any dwarfish or small corn; the grain is of a larger fathom, and specially heavier per bushel than when fown. It furnishes employment for aged persons and children, at a leaven when they have nothing else to do; it leaves to the farmer fix pecks of feed-wheat in every acre; the expense is already reduced to about five shillings an acre; and a drill-plough has been invented, by which one man may set an acre a day.

The lands on which this method particularly succeeds, are either after a clover rubbish, or those on which trefoil and grafs-feed were fown the spring before the laft, and on which cattle have occasionally pastured during the summer. These grounds, after the usual manuring, are once turned over by the plough in an extended flag or turf, at ten inches wide; along which a man, who is called a dibber, with two setting-irons, somewhat bigger than ram-rods, but considerably bigger at the lower end, and pointed at the extremity, dips backwards along the turf, and makes the holes about four inches asunder every way, and an inch deep. Into these holes, the droppers (women and children) drop two grains, which are quite sufficient. After this, a gate, bushed with thorns, is drawn by one horse over the land, and closes up the holes. By this mode, three pecks of grain are sufficient for an acre; and being immediately buried, it is equally removed from vermin, or the power of frost. The regularity of its sowing affords the best opportunity of keeping clear from weeds, by weeding or hand-hoeing.

Setting, a term used in sheep-management, which signifies the picking, choosing, and selecting those which are the best formed, and most perfect for the purposes of breeding, forming the flock, and keeping as flock; the others, or the refuse ill-formed sheep, being sold off, or sent to be fattened in the proper pastures. The practice is extremely useful and necessary, where good flock of this kind is aimed at, as it cannot be well obtained without it. See Sheep, and Sorting Sheep-Stock.

Setting Lamb-Stock, a term made use of to signify the practice of culling and removing those lambs, which are any way improper for being kept as flock. It is an excellent custom in sheep-management, which should be as seldom as possible neglected.

Setting of Farms, the business of letting them to tenants of different kinds. Much care and attention are necessary in the management of this business. See Letting Farm.
forth end is an entrance down into a small cave, which communicates with the larger one by a subterraneous passage, "where the delphinous visitant fees, influing from a large aperture in the rock, an immense cataraft, falling above 20 yards in an unbroken sheet, with a noise that flutes the ear. The water disappears as it falls from the rocks and pebbles, and runs about a mile under ground. The whole cave is filled with the spray that arises from the cataraft, and sometimes a small vivid rainbow appears, which for colour, size, and situation, is scarcely any where else to be equalled."

But the most sublime features of this romantic district are the mountains of Ingleborough, Pennington, and Wharfedale. The summit of Ingleborough is level and horizontal, and, from its great elevation, commands extensive prospects on all sides. To the east, the picturesque country of Craven presents a confused assemblage of hills, gradually diminishing in height till they vanish in the horizon. Pennington, at the distance of four miles, appears to be almost within a leap; as do also the rocks of Settle and Pendlehill. The northern and north-western prospect exhibits a mass of mountains. Wharfedale is within the distance of six miles, and Snowdon and Crof mell are clearly visible in the back ground. Towards the west the flat country of Lancashire lies as in a map, and the prospect extends far into the Irish sea, the nearest point of which is 24 miles from Ingleborough. Beauties of England and Wales, vol. vi. by John Bigland, 8vo. 1814.

SETTLEMENT, Aa of, in Britsh History, a name given to the statute 12 & 13 W. III. cap. 2. by which the crown was limited to his present majesty's illusrious house; and some new provisions were added, at the famine fortunate era, for better securing our religion, laws, and liberties; which the statute declares to be the birth-right of the people of England, according to the ancient doctrine of the common law. See Right of Crown.

SETTLEMENT, Marriage. See Marriage.

SETTLEMENT of the Poor. See Poor.

SETTLING a Deck, at Sea, a term for taking a deck lower than it was at first.

SETTLING the Land, denotes sinking it lower, by failing farther out to seaward, and is used in the same sense with laying the land.

SETTORE, in Geography, a town of Bengal; 56 miles N.W. of Burdwan.

SETTOVITONE, a town of France, in the department of the Dora; 4 miles N. of Irea.

SETTS, powers made use of, where force is required, to bring or unite two or more pieces together. The operation is performed by screws, shores, crofs-letts, or cleets.

SETTS, Crofs, are made by two short pieces of spars, about four or fix feet in length; one is laid across on the upper side, and the other on the under side, of any two pieces that are to be brought together, and their ends lathed together on each side with several turns of rope, taken round each end alternately: wedges are then driven in between the upper crofs-piece, and the side or part of the milt.

SETTS for Saws, instruments for setting their teeth, when out of order.

SETUNA, in Geography, a town of Africa, on the Grain Coast.

SETUVAL, or St. Ubes, a strong sea-port town of Portugal, in the province of Estremadura, situated in a bay of the Atlantic, at the mouth of the river Sandao, with a good harbour, capable of receiving any ships of burden. This town was founded on the ruins of the ancient Codo-

briga, which was destroyed by the Moors. The environs abound in corn, wine, and oil. Besides the old walls and towers, it is strengthened with eleven whole and two demi-bastions, with several other out-works. It has likewise a strong citadel, called "St. Philip," in which is a spring of excellent water, and the strong fort of Outao, near the harbour, which also serve for a light-house, exclusive of which it has two smaller forts. It contains four churches, two hospitales, ten convents, an academia problematica, founded by John V., and about 10,000 souls. In 1796, the number of vessels which entered this harbour was 558; and the same number failed from it; 15 miles S.S.E. of Lisbon. N. lat. 30° 20'. E. long. 8° 53'.

SEWELL, in Botany, a name sometimes used for a species of valerian.

SETZINI, in Geography, a town of Poland, in the pa-
latinate of Sandomirz: near it are some silver mines, and some lapis-lazuli; 16 miles W. of Malogocz.

SEV, a river of Russia, which runs into the Dnina, near Trubeckov, in the government of Orlov.

SEU, a river of Malacca, which runs into the Chinefe sea, N. lat. 6° 45'. E. long. 10° 19'.

SEVAJEE, in Biography, a distingisht person in the history of Hindoostan, the founder of the modern Mahratta empire, was the son of Shawjee, who, from an humble situation, had raised him by his talents to be guardian to a minor of the house of Nizam Shah. On a Mogul invasion of the country, being closely pursued by the troops of his father-in-law, Jadoo Row, with whom he was at enmity, Shawjee escaped with an infant son, and left his pregnant wife to fall into the hands of her father. She was kindly received, and was delivered of her second son, Sevajee, the subject of this article, in the month of May 1626, and finally separated from her husband.

Sevajee, at the age of 17, placed himself at the head of a body of banditti, who pillaged all the neighbouring dis-

tribets, which so affected the person who had beenentrusted with the care of his education, that he put an end to his life. Upon this, Sevajee took possession of the property accumulated from his father's estate, and increased the number of his followers, so as to become a most formidable free-booter. His exploits soon rendered him dangerous to the government of Vifiapour, which sent a powerful army against him, and brought him to submission. Sevajee asked pardon for his offences, and, by the humility of his deport-

ment, threw the general, sent against him, off his guard, till he found an opportunity to stab him to the heart with a concealed dagger: in consequence of which the army dif-

persed. Shawjee, the father of this desperate young man, was now high in office at Vifiapour, and though he pre-
tended entirely to have renounced his son, a correspondence between them was suspected, and a plan was formed for feizing his person, and putting him to death. He was,

however, saved by the intercession of a patron, and at length restored to office. But he was resolved to have ample revenge for the affront, and caused Sevajee to murder the chief who had feized him, and his whole family. After this Shawjee paid a visit to his son at Poona in great state, and manifester much affection and respect for him.

Sevajee now proceeded in a career of successful predatory war, and in 1664 pillaged the rich city of Surat. Having, in 1672, laid the king of Golconda under a heavy com-

tribution, he afterwards entered into an alliance with a potent-

tate against the Mogul and the king of Vifiapour, the object of which was the expulsion of all the Mahometan powers from the Deccan; and marching with a great army, in 1677, towards Golconda, he took possession of many fortresses,
fortresses, and pillaged the whole country. His half-brother, Eccojees, was now king of Tanjore; and the different branches of the people were pillaged by a large portion of the south of India.

The principal dominions of Sevaze were in the tract called Concan, extending from the south of Surat to the south of Goa, which rendered him completely master of the western Guts; from which he was, at all times, able to infude and ravage the plains country, while it was impossible to force him from his fastnetes; hence he was denominated by Aurungzebe the mountain rat. Sevaze continued this course of action till his death in 1680, when he was succeeded in his conquests by his son Sambajee.

SEVANI, in Geography, a town of Persian Armenia, on a lake; 40 miles E. of Erivan.

SEVASTOPOL, a sea-port town of Russia, in the province of Tauris, on the coast of the Black sea, with an excellent harbour for men of war; 80 miles S. of Pereltop. N. lat. 44° 43'. E. long. 33° 24'.

SEUBELS DORF, a town of Germany, in the principality of Culmbach; 6 miles N. of Culmbach.

SEUBITZ, a town of Germany, in the principality of Culmbach; 8 miles S.S.E. of Bayreuth.

SEUCKENDORF, a town of Germany, in the margravate of Anfach; 4 miles E. of Langenzien.

SEUDRE, a river of France, which runs into the sea, opposite the isle of Oleron, N. lat. 45° 49'. W. long. 1° 5'.

SEVE, a town of France, in the department of the Seine and Oife, celebrated for its manufacture of china; 14½ pole S.W. of Paris.

SEVEKTI, or SEVIKTE, a town of France, in the department of the Lys; 10 miles S.W. of Bruges.

SEVEN, a river of Yorkshire, which runs into the Derwent.

SEVEN AGES, rocks in the Caribbean sea, near the S.E. coast of the island of Blanca.

SEVEN BROTHERS, a cluster of small islands near the north coast of Hispaniola. N. lat. 19° 53'. W. long. 72° 35'.

SEVEN CATES. See SEBIA Rous.

SEVEN HEADS. See CORK.

SEVEN ISLANDS, a promontory of the county of Cork, Ireland, well of Courtmaferry bay, and 6 miles W.S.W. of the old head of Kinfale. N. lat. 51° 34'. W. long. 8° 41'.

SEVEN ISLANDS, a cluster of small islands in the East Indian sea. S. lat. 1° 9'. E. long. 105° 21'.

SEVEN ISLANDS, a cluster of islands near the west coast of Sumatra, lying off Padang.

SEVEN ISLANDS, a cluster of small islands in the English Channel, near the coast of France. N. lat. 48° 54'. W. long. 3° 23'.

SEVEN ISLANDS, a republic so named, lately formed by the union of the islands of Zante, Cephalonia, Corfu, Cep, Curzola, St. Maura or Leucadia, and Teaki, constituted about the year 1799, acknowledged by the Ottoman Porte, and by the French and Great Britain, at the peace of Amiens, 1802.

SEVEN ISLANDS, small islands of Virginia, in James river. N. lat. 37° 40'. W. long. 78° 32'.

SEVEN ISLANDS, a cluster of small islands near the coast of Canada, in the gulf of St. Lawrence. N. lat. 50° 10'. W. long. 66° 5'.

SEVEN ISLANDS' BAY, a bay of Canada, on the north side of the river St. Lawrence. N. lat. 50° 5'. W. long. 66° 25'.

SEVEN PACODAS, a town of Hindoostan, in the Carnatic; 30 miles S. of Madras.

SEVEN ROCKS' POINT, a cape in the English Channel, on the coast of Dorsetshire; 3 miles S.W. of Lyme Regis.

SEVENNAER, or SEVENNAER, a town of Germany, in the duchy of Cleves; 10 miles N. of Cleves.

SEVENBERGEN, a town of Dutch Brabant; 8 miles N.W. of Breda.

SEVENNES, or SEVENNES, mountains of France, crossing the department of the Lozere, particularly memorable as being the strong hold of the Protestant in the 17th century, and beginning of the 18th.

SEVENOKS, or SEVENOAKS, a market-town, in a parish of the same name, hundred of Cosseheath, lathe of Sutton at Hone, and county of Kent, England, is situated on high ground at the distance of 16 miles W. by N. from Maidstone, and 33 miles S.E. from London. In the Textus Roffensis, the name is written Seuanacea, and is said to have been suggested by the circumstance of a cluster of seven large oaks growing on the site of the town, at the time of its foundation. The principal building here is the church, which forms a conspicuous object for several miles round the country. It formerly contained a chantry chapel, founded by Sir Henry Gawdy, who was buried within it. The only monument of note is that of William Lambard, the celebrated Kentish antiquary, whose family had a seat in this parish. Here are an alms-house and free-school, originally built and endowed by Sir William de Sevenoaks, in the beginning of the 15th century. They were subsequently incorporated under the title of the free grammar-school of queen Elizabeth, and now possess a revenue of nearly 1000l. a-year. The school-house was rebuilt in 1727, at which time the alms-house was substantially repaired. The former has six exhibitions to either university, and the latter affords an asylum to thirty-two elderly trades-people, who have a weekly allowance in money. This town consists chiefly of two wide streets, in one of which stands the ancient market-house, where the affairs were frequently held during the reign of queen Elizabeth, and where the petty sessions for the lathe of Sutton at Hone are still held. Many of the houses are large and respectable mansions, inhabited by independent families. The market-day here is Saturday, weekly; and there are two annual fairs on the 10th of July and the 22d of October. Sevenoaks town and parish constitute a liberty, governed by a warden or bailiff and four assiduous, who are not, however, empowered to hold any court of record for pleas. According to the parliamentary returns of 1811, this liberty contains 638 houses and 3444 inhabitants, of whom about 1500 reside in the town. History and Topographical Survey of Kent, by Edward Halsted, £vo. 1797, vol. iii. Beauties of England and Wales, vol. viii. by E. W. Brayley, £vo. 1805.

SEVENTH, Septima, in Music, an interval, called by the Greeks heptachordon; of which there are four kinds.

The first, called by Zarlino, and the Italians, semiditaino con diapason, or setimo minor, is composed diatonically of seven degrees, and six intervals, four of which are tones, and the rest greater semitones, as from ut to fis; and chromatically of ten semitones, six of which are greater, and the rest minor: it takes its form from the ratio quadruplaria quintas, 9 to 5.

The second, called by Zarlino, and the Italians, semiditimo con diapente, or setimo minore, is composed diatonically of seven degrees, and six intervals, four of which are tones, and the rest greater semitones, as from ut to fis; and chromatically of ten semitones, six of which are greater, and the rest minor: it takes its form from the ratio quadruplaria quintas, 9 to 5.
of the octave; as from $\frac{1}{2}$ to $\frac{5}{6}$; and chromatically of eleven semitones, five of which are greater, and five lesser. It takes its origin from the ratio of 15 to 8.

The fourth is the redundant seventh, composed of five tones, a greater semitone and a lesser, as from $\frac{5}{6}$ to $\frac{1}{2}$: so that it only wants a comma of an octave; that is, so much as it wants to render its second semitone a greater. Hence many confound it with the octave itself; maintaining, with good reason, that only the three first sevenths can be of any use.

In thorough basses the seventh, whether double, simple, major, or minor, is marked by a figure of $\frac{7}{5}$ if it be accidentally flat, or minor, thus, $b \frac{7}{5}$, or $\frac{7}{5}$. If sharp, major, thus, $a \frac{7}{5}$, or $\frac{7}{5}$. Again, if it is naturally minor, it must be marked with a flat, it must be diminished.

See **FUNDAMENTAL**.

**SEVERAC le Chateau**, in **Geography**, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Millau; 21 miles E. of Roses. The place contains 2,113, and the canton 6,051 inhabitants, on a territory of 212 square kilometers, in 7 communes. N. lat. $46^\circ 19'$. E. long. $3^\circ 19'$.

**SEVERAL**, in **Agriculture**, the same as dole. See **DOLE**.

**SEVERAL Tail**, or **Inheritance**, in **Law**. See **INHERITANCE**.

**SEVERAL Tenancy**, Tenura separata, a plea, or exception taken to a writ that is laid against two persons as joint tenants, who are several.

**SEVERALTY**, **Estates in**. He that holds lands or tenements in severalty, or is sole tenant of them, is he who holds them in his own right only, without any other person being connected with him in point of interest, during his estate therein.

**SEVERALTY Land**, in **Agriculture**, such as is in an open field flat, and divided amongst many. It is a bad situation or tenure of land, and ought to be done away as soon as possible

**SEVERANCE**, in **Law**, the singling or severing two or more that join, or are joined, in the same writ or action.

As if two join in a writ, **de libertate probanda**, and the one be afterwards non-fitted; here severance is permitted, so as, notwithstanding the non-fit of the one, the other may severally proceed.

There is also **severance of the tenants in affriff**; when one, two, or more diffuse appear upon the writ, and not the other.

And **severance in debt**, where two executors are named plaintiffs, and the one refuses to prosecute. We also meet with **severance of summons, severance in attainants**, &c.

An estate in joint tenancy may be severed and restored by destroying any of its unities. 1. That of time, which respects only the original commencement of the joint estate, cannot indeed (being now past) be affected by any subsequent tranflation. But, 2. The joint-tenant's estate may be destroyed, without any alienation, by merely diminishing their possession. 3. Thejointure may be destroyed, by destroying the unity of title. And 4. By destroying the unity of interest. Blackett. Comm. book II.

**SEVERANCE of Corn.** The cutting and carrying it from the ground; and sometimes the setting out the tythe from the eld of the corn, is called severance.

**SEVERIA**, or **SIEVERINZ**, in **Geography**, a town of Auerian Poland, in Galicia, capital of a duky held by the duke of Teschen to the bishops of Cracow; 4 miles N. W. of Cracow.

**SEVERIA**, a town of European Turkey, in the Morea; 14 miles N. E. of Mistra.

**SEVERIANS**, or **SEVERIANI**, in **Ecclesiastical History**. There were two sects of heretics thus called: the first, who are as old as the beginning of the third century, were an impure branch of the Gnostics; thus called from their chief, Severus.

The second, by some called Severites, were a sect of Monophysite, or Eutychians; their leader, Severus, was preferred to the see of Antioch in 513, where he died his untimely to set aside the council of Chalcedon.

**SEVERIK**, in **Geography**, a town of Asiatic Turkey, in the government of Diarbekir; 50 miles W. of Diarbekir.

**SEVERIN**, or **SZEZYNY**, a town of Walachia, on the Danube, founded by the emperor Severus; 12 miles E. of Orfova.

**SEVERINUS, pope**, in **Biography**, a Roman, was elected soon after the death of Honorius, in 638, but was not consecrated till May 640, when the papal see had been vacant nearly two years. This delay was owing to the refusal of the emperor to confirm the election till the clergy of Rome had promised that their bishop should sign the declaration of faith relative to the one will of Christ, drawn up by Sergius, the patriarch of Constantinople, and published by Heraclius. During the vacancy of the see, the Lateran palace was plundered of all its treasures by the exarch of Ravenna. At length the confirmation of the election of Severinus arrived, but he enjoyed his elevation only about two months, which afforded opportunity for no remarkable act, except that he refused to receive the declaration, and even published a decree condemning it.

**SEVERINUS, Marcus Aurelius**, a distinguished physician, was born at Tarra, in Calabria, in the year 1580. His early inclination led him to the study of law; but he subsequently abandoned that pursuit for the profession of medicine, and received the degree of doctor in the university of Naples. He became ultimately one of the most celebrated professors of that school, and taught anatomy and surgery with such reputation, as to attract a crowd of students to the university. His method of treating surgical subjects in his writings was highly commended by Bartholin. He was, however, a harsh practitioner, and cenured the inerths of his contemporaries for neglecting the cautery and the knife, as employed by the ancients, and himself carried the use of the actual cautery to a great extent. He died at Naples, on the 15th of July, 1656, at the age of seventy-six. He was a man of bold and original mind, but somewhat attached to paradox; and was the author of several publications, of which we have the following catalogue. "Historia Anatomica, Observativa medica eiviscerata hominis;" 1629. "De recitanda abscissu naturae Libri octo;" 1630, which passed through many editions. "Vesper Pythiæus, id est, de Vesper natura, venen, et medicina;" 1643. "Zoologiæ Democritae, id est, Anatomie generalis totius animantium opificii, Lib. v.;" 1645, containing the result of his dissection of a great many animals. "De efficaci Medicina, Libri iii;" 1646. In this work he extols the advantages of fire and blood in the cure of diseases. "De Lapide fungifero, de Lapide funginappa, Epipoloe duæ;" 1649.
SEVERN, in Geography, the second most important river in England, is supplied by some antiquaries to derive its name from the Britishe word, sibrin, sandy, or muddy; but others, with greater probability, consider it as a corruption of the Saxon term, sifere, which signifies seaflowing. This river has its source from a large bog on the top of Plimlinnon-hill, in Montgomeryshire, North Wales, whence running down with a swift current, and being joined by many lesser torrents, it presently appears considerable; and passing by Llandyfas and Newtown, becomes navigable near Welsh-Pool, where the river Veren joins it with a stream little inferior to its own. From thence proceeding gently to Shrewsbury, which it almost surrounds, it flows on to a rich vale, with many extensive windings, to Benthall Edge; by the way receiving into it the river Tern, which waters all the north of Shropshire. Here the Severn begins to be rapid, being pent up from thence, to Bridgenorth and Bewdley, by high woody banks and rocky cliffs, which afford a variety of beautiful prospects. Afterwards it again glides pleasantly on through the fertile plains of Worcestershire, visiting in its course the city of Worcester itself, near which it receives the waters of the Teme. At Tewkesbury it forms a junction with the Avon, and thereafter pursues its course to Gloucester, about fifty miles below which city the name of Severn is lost in that of the Bristol channel.

The Severn is a river of great importance, being navigated by vessels of large burthen for more than 150 miles from its mouth, without the assistance of any lock. Upwards of 100,000 tons of coal are annually shipped by the collieries about Madeley and Brokeley, for the cities and towns situated on its banks, and thence conveyed into the adjacent counties. Great quantities of grain, pig and bar iron, iron manufactures, and earthen-ware, as also wool, hops, cider and provisions, are likewise sent to Bristol and other places, whereas various kinds of goods are brought in return. This traffic is carried on with vessels of two sorts, the larger ones being called trows, and the lighter ones barges, or frigates. In May 1756, the number of these vessels navigating from Welsh-Pool, in Montgomeryshire, to Bristol, amounted to 376; but in consequence of the addition of the inland canals from the Trent, the Mersey, and the Thames, into the Stroud navigation, it may be fairly calculated that more than double that number are now employed. This river is peculiarly remarkable for its tide, which rolls in with a head of three or four feet high, foaming and roaring in its course, as if enraged by the opposition it meets with from the strong defending current of fresh water, which seems to contend with it for the superiority. They clash in such a manner as to dash the waters to a considerable height.

This contest is called the higre, or eage, as Rudder supposes, from the French eau-guerre, i.e. water-war. Drayton, in his Poly-Albion, describes it in these words.

"With whose tumultuous waves,
Shut up in narrow bounds, the Higre wildly raves,
And frights the raggling flocks, the neighbouring shore to fly.

Afar, as from the main it comes with hideous cry,
And on the angry foam the hideous foam doth bring.

The billows gainst the banks when fiercely it doth fling,
Hurling the slimy ounce, and makes the sealy brood
Leap maddening to the land, afrighted from the flood;
O'turns the toiling barge, whose steerer doth not launch,

And thrills the furrowed barge into her ireful paunch."

Rudder, in his "History of Gloucestershire," remarks that the bailiwicks of the Severn are vested in the crown; that John Arnold obtained a lease of it in 1669 for 31 years, at 10l. a-year, and that the bailiff in 1779 was a Mr. Edward Baylis. From the rapid and boisterous character of this river, its waters are extremely muddy, a circumstance which renders it unfavourable as an abode for fish. It is, however, well furnished with salmon in some of the calmer spots, and is particularly famous for lampreys. For an account of the local circumstances of this river, and the scenery on its banks, see the articles MONTGOMERYSHIRE, SHROPSHIRE, WORCESTERSHIRE, and Gloucestershire, also Welsh-Pool, Shrewsbury, and Worcester.

SEVERN, a river of America, in Maryland, which runs into the Cheapeak, a little below Annapolis. —Alfo, a river of North America, which runs into Hudson's bay, with a settleament at its mouth, called "Severn Houfe." —N. lat. 56°. W. long. 88°. —Alfo, a river of North America, which runs from lake Simcoe to lake Huron. —Alfo, a river of Virginia, which runs into the Cheapeak bay, N. lat. 37° 23'. W. long. 7° 27'.

SEVERNDROOG, a fea-port town and forrefts of Hindooftan, in Concan, taken by the English in 1756; 68 miles S. of Bombay. N. lat. 17° 55'. E. long. 72° 30'.

SEVERUS, LECIUS-SEPTIMIUS, in Biography, a Roman emperor, was born at Leptis, in Africa, in the year 146 of the Christian era. His father, Septimius Geta, was of a Roman equinquant family, and his two paternal uncles were raised to the confular dignity. Severus was liberally educated, and made a proficiency in rhetorical studies. He came to Rome in the reign of Marcus Aurelius, by whom he was raised to the offices of advocate of the treafury, and feator. His youth was licentious; he however palled with credit through the offices of quaefitor, tribune of the people, and praetor, in consequence of his active and regular performance of his public duties. After his quaefitorship, he went into Africa, as lieutenant of the proconful, where he shewed his fene of the dignity of office, and the importance of strict discipline, by cauling an old acquaintance of ordinary rank to be scourged for greeting him familiarly, as he was walking, preceded by lictors. After he had completed the praetorian year, he was sent to Spain with the command of a legion. He palled some time in retirement at Athens, at the beginning of the reign of Commodus; after this, however, he was raised.
SEVERUS.

raised to the highest honours, being successively appointed governor of the district of Lyons, confid, and commander of the legions posted on the banks of the Danube.

At the death of Commodus, Severus acquiesced in the elevation of Pertinax to the throne; but when, after the murder of that prince, the empire was purchased by Didius Julianus, he procured himself to be declared emperor by his Pannonian legions, in the year 193. Sensible that nothing was so essential to his success as celerity, after preparing his troops, he immediately commenced his march, which he performed on foot, at the head of a select body of guards, sharing with the meanest soldier all the hardships of his rapid advance.

He entered Italy without meeting with any re- sistance, Julianus being incapable of any confidient and effective measures. On his approach to Rome, his competitor was deposed and put to death, and Severus received the decree of his election to the empire. His first act of power was to inflict a just punishment on those of the praetorian guards who were immediately concerned in the murder of Pertinax, which was the only blood that his elevation hitherto cost. Though he spared the lives of the rest of that mutinous and diffident body, he determined to disband them, and with this view he summoned them on a plain near the city, ordering them to come without arms. He now re- proached them for their want of discipline, stripped them of their ornaments, and ordered them, on pain of infall death, to depart to the distance of one hundred miles from the capital. Severus was not secure on his throne, having to contend with two formidable rivals, Pefcanius Niger, governor of Syria, and Clodius Albinus, commander in Britain.

Niger being the more powerful, Severus made the first attack upon him; and in the mean time, to secure himself against the attacks of Albinus, he flattered his vanity, conferring upon him the title of Cæsar; and in a letter conceived in terms of apparent respect and friendship, he requested him to partake with himself the toils of government, which age and infirmity rendered him unable to undergo without an absorb.

In this manner he disarmed the unfurtupecting soldier. Severus now marched out to encounter Niger, whom he defeated in several battles, of which the last was at Iffus, in Cilicia. Severus was now freed from further contest by the death of his rival, who was slain in his flight to the Euphrates, but he ued his victory with great rigour; he banished and afterwards put to death the sons of Niger, severely fined all the towns which had taken his part, and executed all the senators who had been officers in his army.

Taking Byzantium after a long siege, he dismantled and reduced it to the condition of a village, confiscating all the property of the inhabitants. He remained in Asia some time after the victory over Niger, and made an expedition into Meopotamia, where he obliged the Parthians to raise the siege of Nisibis, and gained other advantages over the Barbarians on the frontiers.

Severus was now too great to think of sharing his power with a partner: he accordingly deprived Albinus of the prerogatives attaching to the title of Cæsar, while Albinus laid claim to the rank of Augustus. An open rupture ensued, and each prepared to decide the contest. They met at Lyons, each at the head of 150,000 men, equal in valour and discipline. Severus was the conqueror, and his rival destroyed himself. This event took place in 197. Severus being now undisputed master of the empire, indulged without restraint his disposition to cruelty. After putting to death the family of Albinus, and all the prisoners of rank taken in the battle, together with many citizens in the towns of Gaul, which had favoured his rival, he extended his severity to the Roman senate, which had displayed an inclination towards the caufe of Albinus. By way of inflict to that body, he conferred divine honours on the tyrant Commodus, whose memory they had declared to be detestable and infamous; and when he returned to Rome, he made a reproachful and menacing speech to the assembled senate, followed by the execution, without trial, of twenty-nine, or, as another account says, of forty-one of the most distinguished members, whom of his own accord he pronounced guilty of favouring the enemy. Conscious of having thus made himself odious to the superior classes, he endeavoured, by all the means in his power, to ingratiate himself with the people at large by public exhibitions, and by exemptions from certain duties; and it has been affirmed that, notwithstanding his tyranny, peace and prosperity were generally prevalent throughout the empire during the reign of this emperor. Severus studiously cultivated the affection of the soldiery, by the augmentation of their pay, and by privileges and indulgences which he granted them, and which have been considered as materially tending to introduce that relaxation of military discipline which in the end put a period to the Roman empire.

He supplied the place of the praetorian guards, whom he had disbanded, by a more numerous body, selected from all the legions, and confiding, in great part, of the natives of barbarous nations; and he conferred unusual authority on his commander Plautianus. To his reign is chiefly attributed the introduction of those maxims of imperial prerogative which entirely put an end to all ideas of a republic, and placed the government upon the footing of an absolute and unlimited monarchy. The indolence of the capital did not suit the disposition of Severus. Learning that, while he was engaged with Albinus, the Parthians had made an irruption into Meopotamia, and threatened Nisibis, he hastened into the East, and not only relieved that city, but took Seleucia and Ctephphon. He then marched towards Armenia, the king of which country sued for peace, and obtained it. Some successful incursions into Arabia concluded his eastern expedition, from which he returned in the year 203, after an absence of five or fix years. He celebrated his victories by many splendid spectacles; and in the same year he married his son Caracalla, whom he had some years before created Augustus, to the daughter of Plautianus; his second, Geta, had been elevated to the rank of Caesar, and both those princes had received their honours at a very early age. This union, which seemed likely to exalt the favourite minister Plautianus to the summit of fortune, was the cause of his destrication, for Caracalla, who had acquired a great ascendancy over his father, divorced his bride, and hated her father, and procuring an accusation against him of having formed a conspiracy to take away the emperor’s life, he caused him to be killed in the presence of Severus. His death drew after it that of many of his relations and adherents, and the cruelty of the emperor increased with his years. The reciprocal hatred between his two sons, and the ferocious character of the elder, who was sources of the utmost disquietude to him in the midst of his external prosperity. He in vain employed every argument to reconcile them, and at length he placed them on a perfect equality, by razing Geta, as well as his brother, to the rank of Augustus. It was chiefly with a view of removing these princes from the licentiousness of the capital, and keeping them under his own eye, that in the year 208 he undertook an expedition to the northern part of Britain, the uncivilized tribes of which had made incursions into the Roman provinces. He took his sons with him, and at the head of a powerful army proceeded beyond the walls of Adrian and Antoninus, and penetrated to the northern extremity of the island.
nland. He was harassed by the natives, who did not dare to meet him in the field, and he suffered much from the severity of the climate. At length the Caledonians purchased peace by surrendering all the country south of the Clyde and Forth, which he secured by raising a rampart between these forts. The attempt against his life by his son Caracalla, joined to age and a declining state of health, so reduced him, that he died at York in the year 209, in the 66th year of his age. In his last moments he recommended concord to his sons, and his sons he recommended to the protection of the army. Gibbon speaks of Severus ending a glorious and successful reign, but other historians have doubted whether Severus ought to be reckoned among the good or the bad emperors; for while his perjury towards his competitors, his cruelty to vanquished enemies, and the general severity of his administration, justified a very unfavourable view of his moral character, it is not denied that he possessed in a high degree the virtues of industry and vigour, the love of order, attention to correct abuses, strict and impartial administration of justice, and simple and frugal habits of life. He was a good judge of the characters of men, and the empire was in general well administered and prosperous during his reign.

He is supposed to have been favourable, in the early part of his reign, to Christians, but the rapid increase of their number seems to have alarmed him, and he is reckoned the author of the fifth persecution, which took place in the tenth year of his reign, and which caused more or less violence, according to Dodwell, two years, and according to Bagnette, six years and upwards. See Lardner's Works, vol. viii. ed. 1790. ch. 23.

SEVERUS, CORNELIUS, a Roman poet, who lived in the reign of Augustus, was author of a poem entitled "Aetna," which has sometimes been attributed to Virgil. He is reported by Quintilian to have given a relation in verse of the Sicilian war, and some lines of his on the death of Cicero are quoted by Seneca the orator. It is to him that Ovid is supposed to have addressed one of his Pontic elegies, in which he is termed "Vates magnorum maxime regum." An elegant edition of the remains of this writer, was published with notes at Amsterdam in 1703, by Le Clerc; and they are printed in Mattaire's "Corpus Poëtarum."

SEVERUS, SANCTUS, a Christiain rhetorician and poet, was a native of Aquitaine, and flourished in the fourth century. He wrote an eclogue, which is still extant, where, in a dialogue between a Pagan and a Christian, he treats of the mortality of cattle. It was first printed in the "Poemata Veneris" of Pitheus, and has been several times republished. Gronovius gave an edition of it, with a preface, under the title "Severi Sancti five Endleichei Rhetoris de mortibus Baum Carmen, ab Elia Vineto et Petro Petheo iertatum, cum notis John Weitzii et Wolfgang. Lug. Bat. 1715." Another edition was published by D. Richter, with a preface, in 1747.

SEVESE, in Geography, a town of Italy, in the Milanese; 8 miles N.W. of Milan.

SEVIMALLY, a town of Hindoostan, in the Carnatic; 19 miles W. of Trichinopoly.

SEVIER, a county of Tennessee, Hamilton district, containing 3449 inhabitants, of whom 162 are slaves.

SEVIERVILLE, a post-town and capital of the above county; 555 miles from Washington.

SEVIGNAC, a town of France, in the department of the Lower Pyrenees; 9 miles N. of Morlaas.

SEVIGNE, MARIE RABUTIN, Marquise de, in Biography, a distinguished lady, was born in 1626. Her father, baron of Chantel and Bourbilly, died while she was very young, leaving her heirefs of the house of Bulk Raboutin. Her rank, and the graces of her person and conversation, procured her many admirers, and in 1644 she married the marquis de Seignié, who in 1651 was killed in a duel. She from this time devoted herself to her children, and to the cultivation of her own mind. She had an extraordinary affection for her daughter, who, in 1669, married the count de Grignan, and accompanied him to his government of Provence, and this separation gave rise to the greater part of the letters which have gained her so high a reputation, though she had many other correspondents. Many of M. de Seignié's letters are of a domestic nature, but others are enlivened with court anecdotes, remarks on men and books, and topics of the period in which they were written, which render them very amusing; and in point of style, they are models of epistolary writing, which, perhaps, have never been surpassed. In her letters to her daughter, the reader sometimes is hurt with the excess of flattery on her talents and beauty, which latter quality appears to have been a principal source of her maternal tenderness, and the preservation of it the great object of her anxiety. This lady died in 1696, at the age of 70. Though endowed with much penetration, and, to a certain degree, with a cultivated understanding, she did not rise much above the level of her age and sex in taste and principles. She was attached to rank and splendour, loved admiration, and was apt to be taken with frivolous accomplishments in preference to solid worth. She had a deep sense of religion, but wished to conciliate it with the polite world, the manners and maxims of which, according to the rigid system of the Catholics, were entirely at variance with it. She has been cenured for want of taste in her inflexibility to the poetical merit of Racine, but this has been imputed to her propensities in favour of Corrville. The best editions of her letters are that in 8 vols. 1775; and that in 10 vols. 1801.

SEVIGNY, in Geography, a town of France, in the department of the Ardennes; 12 miles N.W. of Rethel.

SEVIL, in the Manche. The sylv of the branches of a bridge is a nail turned round like a ring, with a large head, made fast in the lower part of the branch, called gargonelle. See BANQUET.

SEUIL, in Geography, a town of France, in the department of the Ardennes, on the Aifne; 12 miles S.E. of Rethel.

SEVILLE, a province of Spain, commonly called the kingdom of Seville, is now exclusively, but improperly, denominated Andalufsia, and occupies the western part of ancient Bactica. Its size is irregular, 58 leagues long from E. to W., and 27 broad from N. to S.; a point of it bending towards the Straits of Gibraltar, 14 leagues long from N. to S. and 9 from E. to W. It is bounded to the E. by Cordova; to the E. and S.E. by Grenada; to the S. by the Atlantic and the Straits of Gibraltar; to the W. by the kingdom of Algarva, &c.; and to the N. by Estramadura. There are two sea-ports in this province, the one in the Mediterranean at Algeciras, and the other on the Atlantic at Cadiz; the latter is spacious and beautiful, the best known, and the most frequented in Spain; its bay is eight leagues round. The principal towns of the kingdom of Seville are its own capital, Seville, an archiepiscopal see; Cadiz, an archiepiscopal see, fortified, and sea-port; Santa-Maria, a sea-port; Xeres, Cordova, and Alcañiz, inland towns. Its rivers are, the Saltes, Guadiana, Tinto, Odiel, Chanza, Verde, Barbate, Guadix, Guadaliquivir, Xeni, Guadiano, Guadaira, Las Fuegos, Cendon, and San-Pedro.
SEVILLE.

SEVILLE, in Spanish Sevilla, and in Latin Hispaniae, the capital of the above kingdom, is a large handsome city, one of the first in Spain, and so ancient, that it is mentioned by Strabo, Pomponius Mela, Pleyte, and Ptolemy, as being ancient even in their time. Fabre ascribes its origin to Hercules, Bacchus, to the Hebrews, to the Chaldeans, and to the Phenicians; but its real founder is unknown. From the Romans it obtained the privilege of a Roman colony, and it was called "Julia Romula," or Little Rome. This town has often changed its sovereign and its form of government. It was formerly subject to the Gothic kings, who made it the place of their residence; and in 582 it took part in the rebellion of Ermenegild, son of king Leudigill. In 711, it opened its gates to the Moors; and in 1027 it supported the rebellion of the Moor, who was its governor, in favour of the king of Cordova, whom it proclaimed king of Seville. Restored to the empire of the sovereigns of Cordova, it again raised the standard of rebellion in 1144, and chose itself a king, whose descendants united Cordova to their new dominions. Aben-hut, the last of those kings, being assassinated at Almeria, and Ferdinand II., king of Castile and Leon, having seized upon Cordova and Jaen in 1236, it threw off all authority, formed itself into a republic, and was governed by its own laws. In its turn, however, it experienced the power of a conqueror. Ferdinand II. assembled his forces before Seville in 1247, and compelled it, after a year's resistance, to surrender 23d of Nov. 1248. From the period of this memorable siege Seville has always made a part of the dominions of the kings of Castile.

Seville is situated on a beautiful and extensive plain, on the banks of the Guadalquivir. Its shape is circular, and its circumference, as it was left by the Romans, is surrounded by a wall more than a league in circuit, flanked by 176 towers; the number of gates is 12, that of Triana being of Doric architecture, and ornamented with columns and statues. Over one of the gates is the following inscription:

"Considit Alcides, renovavit Julius Urbem,
Relluitu Christianus Tertius, Heros."

The town is badly planned, the streets being narrow, crooked, and ill-paved; the houses, however, are tolerably well built, and, including those of the fuburbs, amount to 11,820 in number. The number of inhabitants is stated by Mr. Townshend at 80,268, contained in 30 parishes, 84 convents, and 24 hospitals. Larobe estimates the present population, since the decline of its commerce, at 96,000. Many of the houses have large courts, surrounded by galleries or columns, with fountains in the middle. In summer the families live in the galleries, or courts, where they spread tents. In Seville there are many squares, the best of which are La Lonja, or the Exchange; the Hotel de Ville; the Arsenal, at the entrance of the harbour, with the Cuflom-house and the Gold-house, in which the gold and silver brought from the Indies are deposited; here are also several fine fuburbs, and a handsome promenade, called Alameda, having three walks planted with trees, and ornamented with seats and fountains. This city is the seat of an archbishop; and of the public celfedifical edifices, the first that demands attention is the cathedral, chiefly admired for its tower, constructed by Guever the Moor; originally, in A.D. 1568, 350 feet high, and afterwards raised 100 feet. It is so lofty, as to admit, and at the same time so spacious, that two horsemen may ride up abreast; and on the top is the Giralda, or brazen image, which, with its palm-branch, weighs near 1½ ton, and yet turns with the slightest variation of the wind.

The dimensions of the cathedral are 420 feet, by 263; and the height is 126 feet. It was built A.D. 1501. It receives light by four core windows with painted glase, the work of Anio of Flanders, each of which cost 1000 ducats.

The treasures of this church are inestimable; one altar is wholly silver, with all its ornaments, as are the images, large as life, of S. Ifidore and S. Leonor, and a cufmodia or tabernacle for the host more than four yards high, adorned with forty-eight columns; yet these are trifling in value, when compared with the gold and precious stones deposited by the piety and zeal of Catholics, during the period in which all the wealth of a newly-discovered world flowed into this city. The profusion of gold, of silver, and of gems, would be more striking, were not the attention occupied and lost in admiration of innumerable pictures, the works of those Spanish masters who flourished immediately after the revival of the art in Seville. Every chapel prefers some monuments of their superior skill. Of these, the most conspicuous are of Luis de Vargas, and of Fr. Zurbaran, but chiefly of Murillo. By the latter is a Nativity in the chapel of the Conception, and, near the baptismal font, S. Anthony of Padua, with the Baptism of Christ. In the principal sacristy, are his much admired pictures of S. Ifidore with his brother S. Leander; and in another sacristy his Holy Family, and an Electric Homo by Morales. The chapter-house is wholly devoted to Murillo, and the chapel of S. Peter is given up to Zurbaran. The works of Luis de Vargas are dispersed in various places; but his famous picture called de la Gamba, is in a chapel near the gate of S. Christopber, and merits particular attention.

To the cathedral belongs a library of 20,000 volumes, collected by Hernando, fon to Chrofbob Colon, the first discoverer of America, a man of taste, and much admired in his day for learning. It is to be lamented, that modern publications have not been added to complete what was so well begun by him.

The construction of the organ is peculiar; it contains 5300 pipes, with 110 stops, being, as it is said, 50 more than those of the famous one at Haerlem, yet so ample are the bellows, that when stretched they supply the full organ fifteen minutes. The mode of filling them with air is singular; for instead of working with his hands, a man walks backwards and forwards along an inclined plane of about fifteen feet in length, which is balanced in the middle on its axis; under each end is a pair of bellows of about five feet by three and a half. These communicate with five other pairs united by a bar; and the latter are so contrived, that when they are in danger of being overtrained, a valve is lifted up, and gives them relief. Falling ten times along the inclined plane fills all these bellows.

In the cathedral are eighty-two altars, at which are said daily five hundred masses. The annual consumption is fifteen hundred arrobas of wine, eight hundred of oil, and wax about one thousand.

The wealth belonging to this chapter may be estimated by the numbers that are supported by it.

The archbishop, with a revenue of three hundred thousand ducats; or, in Sterling, nearly thirty-three thousand pounds a year.

Eleven dignitaries, who wear the mitre on high festivals, amply, but not equally, provided for.

Forty canons, of forty thousand reals, or about four hundred pounds each per annum.

Twenty
Twenty prebendaries, with an income of thirty thousand reals each.

Twenty-one minor canons, at twenty thousand reals each.

Befide thefe, there have twenty chanters, called Vienteneros, with three affiliants, called Sochantres, two beadles, one matter of the ceremonies, with a deputy, three attendants to call the roll and mark the absentees, thirty-fix boys for singing and for the service of the altar, with their rector, vice-rector, and music-masters; nineteen chaplains, four curates, four confellors, twenty-three musicians, and four supernumeraries; in all, two hundred and thirty-five.

Many of the convents are remarkable for the beauty of their architecture; but, in Seville, the eye covets only pictures, and amidst the profusion of thefe, it overlooks works, which in other situations would rivet the attention, and every where fixes on the pencil of Murillo. His most famous performances are in the Hospital de la Caridad, and, suited to the institution, express some acts of charity; such as the Miracle of the Loaves and Fishes; the miftaking of the Rock in Horcle; the Pool of Bethsaida; the Reception of the returning Prodigal; Abraham adreftring the three Angels, and prefuming them to enter his habitation; the Deliverance of Peter from the Prifon; and Charity, in the perfon of Elizabeth, washing the wounds and curing the difeafes of the poor. Befide thefe, in the fame hospital, is the Anunciation of the bleffed Virgin; and two little pictures, the one of the infant Jesus, the other of John.

The church of the Capuchins is richly furnished with his works; and although in thefe the composition is more simple than in the former, yet they may be confidered as fome of the best of his productions. Eleven of his pictures are to be seen in a chapel called de la Vera Cruz, belonging to the Francifcans. Thefe do much credit to his pencil; and not inferior to them, are many preferved in other convents, fuch as, an Ecce Homo, and the bleffed Virgin, with the infant Jesus, in the church of the Carmelites; the Flight into Egypt, in that of La Merced Calzada; a rich variety of fubjects in S. Maria de la Blanca; and S. Augustin writing, with S. Thomas of Villanueva, ftriping himfelf to clothe the poor, in the convent of the Augustin Friars, near the gate of Carmona. In the opinion of Mr. Townend, the moft matterly of all his works is in the refefitory of an hospital defigned for the reception of supernumerary priets. It represents an angel holding a ballet to the infant Jesus, who, standing on his mother's lap, takes bread from it to feed three venerable priets. No representation ever approached nearer to real life, nor is it possible to fee more effraction, than glows upon that canvas. In the parochial church of Santa Cruz are two pictures in a superior style, a Stabat Mater Dolorofa, which excels in grace and softnefs; and the famous Defcent from the Cross, of Pedro de Campana, which Murillo was accustomed daily to admire, and opposite to which, by his own directions, he was buried.

This great painter was born A.D. 1618, and died in 1682.

His name stands high in Europe; but to form an adequate idea of his excellence, every convent should be visited, where he deposited the monuments of his superior skill.

In exacts of imitation he was equalled; in claro obfcuro, and in reflected lights, he was surpassed by Velazquez; but not one of all the Spanish artists went beyond him in tendernefs and softnefs.

Of the convents, which is upon the moft extensive scale belongs to the Francifcans. It contains fifteen cloifters, many of which are elegant and spacious, with apartments for two hundred monks; but at prefent they have only one hundred and forty in their community. These, like all their order, are fed by charity, and are much favoured by the people. Their annual expenditure is more than four hundred thousand reals, or initering about four thousand pounds, amounting to twenty-eight pounds eleven flillings and five-pence for each. But then out of this must be deducted the expence of wine, oil, and wax, with the alms distributed daily to the poor, which altogether is coniderable.

Among all the hospitals, Mr. Townend was most pleased with that of La Sangre, designed for the reception of female patients. The front is elegant, and the sculpture is much to be admired, more especially the three figures of Faith, Hope, and Charity. The wards are spacious, and the whole is remarkable for neatness.

Our limits will not allow our introducing particular descriptions of other public buildings; fuch as the Torre del Oro, the Plaza de Toros, the Aqueduct with its four hundred and ten arches, and especially the Exchange. The latter, planned by Herrera (A.D. 1598), and worthy of its great architect, is a quadrangle of two hundred feet, with a corridor or spacious gallery round it, adorned with Ionic columns, and supported by an equal number of Doric.

The university was founded in the year 1502, and soon rose into confideration. The name of Arias Montanus, who lies buried at the convent of St. Jago, is alone fufficient to give celebrity to this feminary. His translation of the holy scriptures will be valued by the learned, as long as the scriptures themselves shall be the objects of veneration to mankind. The number of undergraduates here is about five hundred.

We meet at Seville with the favourite institutions of count Campanones, his academy for the three noble arts of painting, sculpture, and architecture, and his economical society of the friends of their country. Both these have been attended with success, and have given affifance not only to the arts, but to agriculture, to manufactures, and to commerce. About two hundred pupils attend the former.

The alcazar, or royal palace, built by the Moors, is very spacious. The principal article of manufacture in Seville is snuff; and it furnishes also cigars to a very coniderable amount. The silk manufacture was formerly very flourishing in this place; fo that in the year 1248 it employed 16,000 looms, and 130,000 persons; and fuch was then the population of the city, that the Moors who left it, when it was surrendered to the Christians, were 400,000, besides multitudes who died during a fifteen months' siege, and many who remained after their fellow-citizens were gone. But in confequence of the accumulation of taxes and other circumftances, the number of looms has been very much diminished; fo that A.D. 1740, the looms for wide silks amounted to 462, and for other purposes to 1856.

The country round the city to a coniderable distance lies fo low, that it is frequently overflowed, and upon some occasions the water has been eight feet high, even in their habitations. The foil is rich, and being at the fame time very deep, its fertility is inexhaustible. The produce is corn, leguminous plants, hemp, flax, lemons, oranges and liquoric. The quantity of this exported from Spain is said to be annually not less than four thousand quintals, or nearly two hundred tons, a coniderable part of which
is supposed to be purchased by the porter-brewers in London.

In consequence of vapours and misfurnace, occasioned by
flaming water, and by frequent floods, the inhabitants of
Seville and its neighbourhood are subject to tertians, to
putrid fevers, and to hystericai disorders. The predisposi-
tion to such diseases may be likewise sought for in the
quantity of cucumbers and melons consumed by them all
the year, in consequence of which they are likewise in-
fecked with worms, accompanied with epilepsies, especially
in the more youthful subjects. Other diseases arise from
heat, whenever they have the Solano wind, that is, when-
ever the wind blows from Africa, they become liable to
pleurisy, and also a very pernicious irritability of nerves.
N. lat. 37° 12'. W. long. 6° 8'.

**SEVILLA del Oro.** See MACAS.

**SEVILLE Plantation,** a place on the N. coast of Jamaica,
W. of Mammea bay, where are the ruins of an ancient town,
called "Sevilla Nueva," founded by Efigival on the spot
where Columbus refitted after his shipwreck in the year
1503.

**SEVILLET A,** a town of New Mexico; 100 miles S.
of Santa Fé.

**SEVIN, Francis,** in Biography, a man of letters, born
in the diocese of Sens, was educated at Paris, where he
pursued, with great ardour, the study of the learned lan-
guages, in company with the abbé Fourmont the elder.
He became an associate of the Academy of Belles Lettres
in Paris in 1714. He was lent in 1728, by the king's com-
mand, with the abbé Fourmont the younger, to Constan-
tinople, in search of MSS., of which he brought back a
considerable number, and was, in 1737, presented with the
device of keeper of MSS. in the king's library. His letters,
descriptive of this journey, were published in 1801, in one
vol. 8vo. These contain several interesting details concerning
Turkey, Egypt, &c. Sevin died in 1741. Several of his
papers are published in the "Memoires de l'Acad. des
Inscriptions."

**SEVION,** in Geography, a river of North Wales, which
runs into the Clyde; 3 miles N.W. of St. Aphant.

**SEVIR,** among the Romans, an officer who, according
to Peticus, commanded a whole wing of horse; though
others make him only the commander of a troop, turnis,
and division answering to our regiments.

**SEVIRI** were also magistrates in the colonies, so called,
from their being fix in number.

**SEURAH,** in Geography, a town of Hindoostan, in
Bundesland; 18 miles N. of Callinger.

**SEVRE,** or Severe Nantofe, a river of France, which
rises about eight miles W. from Parthenay, passes by Mor-
tagne, Tiffauges, Clifton, &c. and runs into the Loire,
opposite to Nantes.

**SEVRE Nantofe,** a river of France, which rises near
St. Maixent, passes by Niort, Marance, &c. and runs into
the sea; 7 miles W. of Marance.

**SEVRES,** a town of France, in the department of the
Seine and Oise, and chief place of a canton, in the dioces
of Verfailleux. The place contains 2643, and the canton
3485 inhabitants, on a territory of 50 kilometres, in eight
communes.

**SEVRES,** two, one of the nine departments of the western
region of France, formerly Lower Poitou, between Vendée
and Vienne, in N. lat. 45° 30', containing 6337½ kilometres,
or 305 square leagues, and 242,658 inhabitants. This
department comprehends 4 districts, 30 cantons, and
563 communes. The districts or circles are, Thouars,
including 43543; Parthenay, 53,020; Niort, 84,923; and

Melle, 61,167 inhabitants. Its capital is Niort. According
to Haffenrath, the extent is 32 French leagues in
length, and 12 in breadth; the number of circles in 6, and
of cantons 50, and the population is 259,122. The con-
tributions in the 11th year of the French era amounted to
2,556,115 francs; and the expenses for administration,
j ustice, and public instruction, to 233,694 francs 66 cents.
The soil of this department, in general, is fertile, yielding
grain, wine, fruits, and pastures. The S.W. district is
marshy.

**SEVRI,** a river of Natolia, which runs into the Sa-
karia, near Sevrilar.

**SEVRIHI SAR,** a town of Asiatic Turkey, in Natolia,
at the conflux of the Sevri and Sakaria; 60 miles W. of
Angora. N. lat. 39° 53'. E. long. 32° 2'.

**SEURRE,** a town of France, in the department of
the Côte d'Or, and chief place of a canton, in the dioces
of Beaune; 21 miles S. of Dijon. The place contains 2777,
and the canton 11,546 inhabitants, on a territory of 280
kilometres, in 23 communes. N. lat. 46° 58'. E. long-
5° 12'.

**SEVSK,** a town of Russia, in the government of
Orel, on the Sev; 56 miles S.W. of Orel. N. lat. 52° 15'.
E. long. 34° 44'.

**SEUTZACH,** a town of Switzerland, in the canton of
Zurich; 17 miles N.N.E. of Zurich.

**SEVYNVEY,** a river of South Wales, which runs into
the Clethy, in Pembrokehire.

**SEW,** in Sea Language, the situation of a ship when the
water first leaves her resting on the ground, or blocks in a
dock. Thus, if a ship runs a-ground on the tide of ebb,
or by the reflux of the tide she rests on her blocks; and if
it be required to know she hasfewed, or how much she has
fewed, the mark the water-line has made on her bottom
when afloat is examined, and as much as is the difference
above the surface of the water and this mark, so much she
is said to have fewed.

**Sew** is also a term applied to a cow, signifying to go dry.

**SEWAD,** or SOWIAD, in Geography, a province of
Candahar, situated on the W. side of the Indus, which
separates it from Puckholi; 40 coffes long and 15 broad.
This province, as well as Bijore, is very mountainous, and
abounds with pails and strong situations; so that their
inhabitants have not only held themselves generally
independent of the Mogul emperors, but have occasionally
made very furious inroads into their territories. The country
of the Asf раге, or Asf раге, answers to Sewad; Afsagenur
being the ancient name of Sewad; or rather Sewad was one
of the subdivisions of Afsagenur. At present Sewad in-
cludes the three provinces of Sewad proper, Bijore, and
Bener.

**SEWAD,** the easternmost and largest of the four rivers
that unite successively with the river Cabul, before it falls
into the Indus; the other three being that which palls by
the town of Bijore, the Penjakoresh river, separating Bijore
on the W. from Sewad on the E., and the Chendoul river,
which is a branch of the Bijore river.

**SEWALICK,** or SEWA-LUCK, a chain of mountains
forming the northern boundary of Hindooistan, and sepa-
rating the country of Lahore from Thibet.

**SEWAN,** or ALLIJUGNE, a town of Hindooistan, in
Babar; 32 miles N.N.W. of Chaprah. N. lat. 26° 11'.
E. long. 84° 32'.

**SEWARD, Thomas,** in Biography, an English divine
of the church of England, was born in 1708. He became
rector of Eym, in Derbyshire, and prebendary of Litchfield,
where he died in 1790. He was a man of taste and learn-

ing.
ing, and of considerable talents for poetry and polite literature. He published an edition of Beaumont and Fletcher's works, and was author of a treatise on the "Conformity between Popery and Paganism." Some of his poems are in Doddley's collection.

Seward, Anna, daughter of the preceding, a poetess of distinguished elegance, was born about the year 1745. Her infant mind was nourished by her father with the vivid and sublime imagery of Milton, and her early education amidst the wild and alpine scenery of the Peak, enhanced the enthusiasm of feeling to which she was naturally disposed. In her seventh year, his father being appointed canon refiendary of Litchfield, she removed with the family to that city, which thenceforth became her residence during the whole of her life. The fruit of her father's instructions appeared in some early efforts at poetical composition, which, however, met with discouragement from her mother; and Mr. Seward was afterwards induced to withdraw the countenance he had given to her literary pursuits; so that several years of her youth elapsed with its if open and interrupted attempts to cultivate an art of which she had so strongly imbued the rudiments. As she advanced in life, she of course followed more freely the bent of her genius, and in 1780 she published an "Elegy on Captain Cook," a performance of great merit, as well from the harmony of its construction, as the beautiful and appropriate imagery with which it abounds, and the force and delicacy of its sentiments. The contrast between the different manners on this event, queen Oebera, and the wife of the great navigator, is peculiarly striking. In the following year she gave the world a "Monody on Major Andre." With this lamented young officer she was intimately acquainted: she accordingly wrote with peculiar pathos on the occasion, and expressed a glowing, and we fear not to say, a just indignation against the actors in that tragedy: the laws of what are called civilized war do not and ought not to supprave the feelings of humanity. Mis s Seward made herself known as a writer on many other topics; in 1790 she published "Llangollen Vale," with other poems; and in 1804 she gave the public "Memoirs of the Life of Dr. Darwin." This is a defunctary performance, but it contains much entertaining matter, enriched with some judicious criticism on Dr. Darwin's poetical character. Miss Seward died in March 1809. A collection of her letters has been published since her decease, in six volumes. Athenaeum. Monthly Mag.

Seward, William, was the son of a brewer in London, and born in 1797. He received his education at the Charter House, which he completed at Oxford; this place he left without taking a degree. Having a good fortune, he devoted his life to literary cafe, and antiquarian researches. He is known as an author by five volumes of "Anecdotes of Distinguished Persons," extracted from curious books, to which he added a supplement, in two volumes, under the title of "Biographiana." Europ. Mag.

Sewary, in Geography, a town of Hindooftan, in the circuit of Surgooja; 22 miles E. of Surgooja.

Sewee, a country of Asia, between Peria and Hindooftan, on the W. side of the Indus.

Sewee, Bay, or Bull's Harbour, a bay of the Atlantic, on the coast of South Carolina. N. lat. 32° 58'.

Sewestan, a country of Hindooftan, between Sewee and the Indus, about 110 miles long and 50 broad.

Sewel, among Sportsmen, denotes any thing that is fast or hung up, to keep a deer out of any place.

Sewel, Coronde, a name given by the natives of Ceylon to a species of cinnamon, which, when chewed, is of a mucilaginous nature, like the cashia: this dries well, and is very firm and hard, and has the appearance of a very fine cinnamon; but it has very little taste, and a disagreeable smell. The natives take advantage of the circumstance of this kind of cinnamon, and are very apt to mix it with the good kind, to the great detriment of the buyer. Phil. Trans. N° 499.

SEWEB, formed from the French seubier, esquire, gentleman, or usher, in the Houehold, an officer who comes in before the meats of a king, or noblemans, to place and range it on the table. Of these officers there are four in the king's household, and eight, called fewers of the great chamber.

Sewers, in Building, are shores, conduits, or conveyances, for the suillage and filth of a house.

Sewers, Clerk of the. See Clerk.

Sewers, Commission of. See Commission.

Sewin, in Ichthyology. See Grey.

Sewl, in Agriculture, provincially a plough. It is sometimes written sole. See Plough.

Sewnady, in Geography, a town of Hindooftan, in the circuit of Ruttunpore; 35 miles N. of Ruttunpore.

Sewn, a town of Hindooftan, in Goondewar; 60 miles N. N. E. of Nagpore.

SEX, Sexus, something in the body, which distinguishes male from female. See Generation.

The number of persons, of the two sexes, are exceedingly well balanced; so that every man may have his wife, and every woman her husband.

Hermaphrodites have the apparent marks of both sexes. It is expressly forbidden by the law of Mofes, to disguise the sex.

SEXAGENERY, Sexagennarius, something relating to the number fixity: more particularly a person arrived at the age of fifty years.

Some caluils depend on sexagenerians for not falling: the Papian law prohibits sexagennarius from marriage; because at that age the blood and humours are frozen.

SEXAGENERY Arithmetic. See Sexagesimal.

Sexagenerary Table, are tables of proportional parts, shewing the product of two sexagesimaries that are to be multiplied; or the quotient of two to be divided.

Sexagesima, the second Sunday before Lent, or the next to Shrove Tuesday; so called, as being about the sixtieth day before Easter.

Sexagesima is that which follows Septuagesima, and precedes Quinquagesima.

Sexagesimal, or Sexagenerary Arithmetic, a method of computation, proceeding by fixties.

Such is that used in the division of a degree into fixty minutes; of the minute, into fixty seconds; of the second, into fixty thirds, &c. See Arithmetic.

Sexagessimals, or Sexagenerary Fractions, are fractions, whose denominators proceed in a sexagene ratio; that is, a prime, or the first minute = 1/60; a second = 1/3600; a third = 1/21600.

Anciently there were no other than sexagesimals used in astronomical operations, and they are still retained in many cafes; though decimal arithmetic is now much used in astronomical calculations.

In these fractions, which some also call astronomic fractions, the denominator being always 60, or a multiple of it, is usually omitted, and the numerator only written down: thus, 4° 59', 22° 50', 16°, is to be read, 4 degrees, 59 minutes, 22 seconds of a degree, or 56 parts of a minute, 50 thirds, 16 fourths, &c.

SEXANGLE, in Geometry, a figure having fix sides, and consequently fix angles.
SEX

SEXDRA, in Geography, a town of Sweden, in Wett Gothland; 38 miles E. of Goteborg.

SES of Plants, in Vegetable Phylogony. See Fecundation, and Fructification.

SEXTA, in Geography, a town of France, in the department of Mont Blanc; 2 miles S.E. of St. Maurice.

SEXTA Pars Lat. a fixation vocal part in the metotti and madrigals of old masters.

SEXTAN, Sextant, a fixation part of certain things. The Romans divided their as, which was a pound of brass, into twelve ounces: the ounce was called unica, from unum; and two ounces extant, as being the fixation part of a pound. See As.

Sextant was also a measure which contained two ounces of liquor, or two cyathi. Hence, “Sextantes, Calitae, duo infundi Falerii.”

Sextan, the Sextant, in Astronomy, a constellation of the southern hemisphere, made by Hevelius out of uniform stars. In Hevelius's catalogue it contains 11, but in the Britanic catalogue 41 stars. See Constellation.

Sextant, in Mathematics, denotes the fixation part of a circle, or an arc comprehending sixty degrees.

Sextant is more particularly used for an astronomical instrument, made like a quadrant; excepting that its limb only comprehends sixty degrees.

The use and application of the sextant is the fame with that of the quadrant.

In the observatories of Greenwich and Pekin, there are very large and fine sextants.

Sextarius, an ancient Roman measure, containing two cotyle, or two hemina. See Cotyla.

Sextery-Lands, are lands given to a church, &c. for maintenance of the sexton.

Sextile, Sextis, the position or aspect of two planets, when at sixty degrees distance; or at the distance of two signs from one another. It is marked thus (*).

See Aspect.

Sextilis, in Chronology. See August.

Sexton, a church-officer, thus called by corruption of the Latin sacerdote, or Saxon, Sagerplane, which denotes the fame. His office is to take care of the vesels, vestments, &c. belonging to the church; and to attend the minister, churchwarden, &c. at church. He is appointed by the minister or others, and receives his salary according to the custom of each parish.

Sextons, as well as parih clerks, are regarded by the common law as persons who have freehold in their offices; and, therefore, though they may be punished, yet they cannot be deprived, by ecclesiastical censures.

The office of sexton in the pope's chapel, is appropriated to the order of the hermits of St. Augustine. He is generally a bishop, though sometimes the pope only gives a bishopric, in partibus, to him on whom he confers the pall. He takes the title of prefect of the pope's sacristy, and has the keeping the vesels of gold and silver, the relics, &c.

When the pope's mass is, the sexton always takes the bread and wine first. If it be in private he says mass, his holmens, of two wafer, gives him one to eat; and, if in public, the cardinal, who affords the pope in quality of deacon, of three wafer, gives him two to eat. When the pope is dangerously sick, he administers to him the sacrament of extreme unction, &c. and enters the conclave, in quality of first conclave.

Sexton's River, in Geography, a river of America, in Vermont, which runs into the Connecticut, N. lat. 43' W. long. 72' 25' Vol. XXXII.

SEXTULA, a word used by some pharmacuetic writers to express the fixation part of an ounce, that is, four scruples, or one drachm and one scruple.

Sextupla, Ital. Sexta, Fr. and Eng. in Musiv, implies a compound time of triplets, mixed with binary time. Sextuple time is never properly used but in the farandol, consisting of six even crotchets, or quavers, expressed by 3, or 3; where triplets are out of the question. All other indications of compound measure, or, as formerly called, jig time, are at present the following: 4, 4, 4, 4, 4, 4; all which measures confit of triplets.

Old authors mention five different species of sextuple time: as,

Sextuple of the Semi breve, by the French called triple of 6 for 1, as being denoted by those two numbers 6; or because here are required six semibreves to a measure, in lieu of one, viz. three rising, and three falling.

Sextuple of the Minim, called by the French triple of 6 for 2, as being denoted by 2; which flew, that six minims are here required to a measure, instead of two.

Sextuple of the Crotchet, called by the French triple of 6 for 4, because denoted by 4, or 4, which flew, that there must be fix crotchets to a measure, in lieu of four.

Sextuple of the Chroma, by the French called triple of 6 for 8, as being denoted by 8; which flew, that fix quavers here make the measure, or semibreve, instead of eight.

Sextuple of the Semibreve, or triple of 6 for 16, so called, because denoted by 16; which flew, that fix quavers are here required to a measure, instead of sixteen.

Sextus, Sextilis, in the Canon Law, denotes a collection of decreets, made by pope Boniface VII. usually thus called from the title, which is “Liber Sextus;” as if it were a fixth book added to the fixe books of decreets, collected by Gregory IX.

The Sextus is a collection of papal constitutions, published after the collections of Gregory IX. containing those of the fame Gregory, Innocent IV., Alexander IV., Urban IV., Clement IV., Gregory X., Nicholas III., and Boniface VIII., by whose order the compilation was made. The persons employed in making of it were Will. de Mandegot, archbishop of Ambrun; and Berenger, bishop of Beziers; and Richard of Sienna. See Canon Law.

Sextus, in Biography, an ancient philosopher of the hystorical sect, was a native of Choronea, and the nephew of Plutarch. He is celebrated as the preceptor of the emperors Lucius Verus and Marcus Aurelius.

Sextus, Empiricus, in Medical History, a Roman physician, of the empiric sect, who followed Heraclides and others in the adoption of that system which Serapion and Philinus began. He is said to have been the pupil of Herodotus, the physician, and the preceptor of Saturninus. There are two works extant, with the name of Sextus attached to them; but Le Clerc believes, that they are not both the production of this physician, who only composed that which is entitled “Sexti Placitum;” and that the other work, which contains six books, treating of the doctrines of Pyrrhonism, and ten books relative to all the sciences, was the production of another Sextus, of Choronea, who was of the Platonic school, a nephew of Plutarch, and preceptor of the emperor Marcus Aurelius. See Le Clerc, Hist. de la Med. p. ii. chap. 8.

Sextus Oculi, in Anatomy, a name given by Fallopius to one of the muscles of the eye, called by Albinus, and others, the obliquus oculi inferior, and by some, the obliquus oculi brevis.

Sextus Thoracis, a name given by Fallopius, and others,
SEX

to a muscle, now generally known by the name of the tria-
ngularis fterni.

SEXUAL System, in Botany, denotes that sys-
tem, which is founded on a discovery, that there is in vegetables, as well as in animals, a distinction of the sexes; or that plants propagate themselves by means of male and female organs, either growing upon the same tree, or upon different trees of the same species. This system is suggested and confirmed by the analogy observable between the eggs of animals and the seeds of plants, both serving equally to the same end; viz. that of propagating a similar race; and by the remarks which have been made, that when the seed of the female plant is not impregnated with the prolific powder of the male, it bears no fruit; insomuch that as often as the communication between the sexual parts of plants has been intercepted, which is the cause of their fecundity, they have always proved barren. The authors of this system, after exactly anatomizing all the parts of the plant, assign to each a name, founded on its use and analogy to the parts of an animal. Thus, as to the male organs, the filaments are the spermatic vessels, the anther is the stigmatic, and the duft of the anther correspond to the sperm and seminal animalculae; and as to the female, the stigma is the external part of the female organ, which receives the duft; the style answers to the vagina; the germ to the ovary; and the pericarpium, or fecundated ovary, to the womb. See Vegetation.

The sexual system was not wholly unknown to the ancients, though their knowledge of it was very imperfect. Accordingly we find in the account given by Herodotus (lib. i.) of the country about Babylon, where palm-trees abounded, that it was a custom with the natives, in their culture of these plants, to affift the operations of nature, by gathering the flowers of the male trees, and carrying them to the female. By this means they secured the ripening of the fruit; which might else, on account of unfavourable fesions, or the want of a proper intermixture of the trees of each sex, have been precarious, or at least not to have been expected in equal quantities. The ancients had also similar notions concerning the fig. Theophratus (Hist. Plant. lib. iii. cap. 9.) observes, that the characteristic and universal difference among trees is that of their gender, whether male or female. And Aristotle (De Plantis, lib. i. cap. 23.) says, that we ought not to fancy, that the intermingling of sexes in plants is the same as among animals. However, there seems to have been a difference of opinion among the ancients as to the manner in which plants should be allowed to have a difference of sex. Some apprehended that the two sexes existed separately; and others thought that they were united in the same individual. Empedocles thought, that plants were androgynous or hermaphroditical, or that they were a composition of both sexes. Aristotle expresses his doubt upon this head. Empedocles (vide Arit. de Generat. Anim. lib. i. c. 23.) called plants oviparous; for the seed or egg, according to his account, is the fruit of the generative faculty, one part of which serves to form the plant, and the other to nourish the germ and root; and in animals of different sexes, we see that nature, when they would produce, impels them to unite, and like plants to become one; that from this combination of two, there may spring up another animal.

As to the manner in which fruits were impregnated, the ancients were not ignorant that it was by means of the pro-
lific duft contained in the flower of the male; and they re-
marked, that the fruits of trees never come to maturity till they had been impregnated with that duft. Upon this subject Aristotle says (De Plant. lib. i. cap. 6.) that if one shakes the duft of a branch of the male palm-tree over the female, her fruits will quickly ripen; and that when the wind sheds this dust of the male upon the female, her fruits ripen apace, just as if a branch of the male had been suspended over her. And Theophratus (Hist. Plant. lib. ii. cap. 9.) ob-
erves, that they bring the male to the female palm, in order to make her produce fruit. The manner in which they pro-
ceed, says he, is this: when the male is in flower, they selec
t a branch abounding with that downy dust which re-
fides in the flower, and shake this over the fruit of the fe-
male. This operation prevents the fruit from becoming abortive, and brings it soon to perfect maturity. Pliny also informs us (Nat. Hist. tom. i. lib. xiii. c. 7.) that naturalists admit the distinction of sex, not only in trees, but in herbs, and in all plants. Yet this is no where more observable, he adds, than in palms, the females of which never pro-
igate, but when they are fecundated by the dust of the male. He calls the female palms, deprived of male affluteness, barren widows. He compares the conjugation of these plants to that of animals; and says, that to generate fruit, the female needs only the abscision of the dust or down of the flowers of the male.

Zaluziækii seems to have been the first among the mo-
derns who clearly distinguished from one another the male, the female, and the hermaphroditical plants. About a hundred years after him, Sir Thomas Millington, and Dr. Grew, communicated to the Royal Society their observations on the impregnating dust of the ilamina. Grew's Anatomy of Plants, published in 1682.

Camerasius, towards the end of the last century, observed, that upon plucking off the ilamina of some male plants, the buds that ought to have produced fruit came not to maturity. Malpighi, Geoffroy, and Vaillant, have also carefully considered the fecundating dust; the latter of whom seems to have been the first eye-witness of this secret of nature, the admirable operation that paffes in the flowers of plants, between the organs of different sexes. Many authors afterwards applied themselves to improve this system; the principal of whom were Murland, Logan, Van Royen, Bradley, Ludwig, Blair, Wolius, &c. But Linnaeus had the honour of applying this system to practice, by reducing all trees and plants to particular classes, distinguished by the number of their ilamina, or male organs. See Dutens' Inquiry into the Origin of the Discoveries attributed to the Moderns, 1769, chap. vii. Phil. Trans. vol. xxvii. art. 25.

The sexual hypothesis, on its first appearance, was re-
cieved with all that caution which becomes an enlightened age; and nature was traced experimentally through all her variations, before it was universally attented to. Taurine
tort refuted to give it a place in his system; and Pontedera, though he had carefully examined it, treated it as chimerical. The learned Dr. Alton, professor of botany in the university of Edinburgh, violently opposed it; but the proofs which Linnaeus has given amongst the aphorisms of his "Fundamenta Botanica," and farther illustrated in his "Philosophia Botanica," are so clear, that the mind does not hesitate a moment in pronouncing animal and vegetable conception to be the same; but with this difference, that in animals fruition is voluntary, but in vegetables necessary and mechanical. The impregnation of the female palm by the farina of the male, related by Mylius, in his letter to Dr. Watfon (Phil. Trans. vol. xviii. art. 25.) establishes the fact attested by the ancients con-
cerning the palm-tree; and as the fructification in other vegetables, though it may differ in particular circumstances, has nevertheless a general conformity to that of the palm-tree, with respect to the parts supposed to be the organs of ger-
eration, which are discoverable either on the same or in a sep
cate flower, we may, from this single experiment, deduce
an argument by analogy for the confirmation of the whole sexual hypothesis. Besides, a very striking proof of the analogy between plants and animals may be drawn from observations made in their infant states, at which early period they seem nourished and protected in a similar manner. Those who desire farther satisfaction, may see the several demonstrations collected, and methodically connected, in the "Spongia Planatarum" of J. G. Walkborn, published in the "Amoenitates Academicae," at Leyden, in 1749. See Botany, Classification, Fruktification, Plants, and Vegetation.

SEXUALISTE, among Botanical Authors. See Botany, Fruktification, and Sexual System.

SEXUNX, in Pharmacy, the weight of six ounces, or half a pound troy.

SEYBO, or SEYVO, in Geography, a settlement in the southern part of Hispaniola; 70 miles N.E. of St. Domingo.

SEYBORSWORP, a town of Prussia, in the province of Oberland; 6 miles S. of Liebfat.

SEYCELLEWS, an island in the Indian ocean, N.E. of Madagascar; high and mountainous, and estimated at 72 miles in circumference. The soil appears to be rich and good, and the island is covered with trees, many of which would serve for masts and yards for ships, as they are large and straight; among the trees are great quantities of rose-wood, and cocoanut trees. Wild goats, land-tortoises, and Guiana-fowl, are found in plenty; and in the harbour abundance of good fish.

The harbour is well sheltered from the south-east wind. When the winds are from the north and north-west, it is rather an open road, but the ground seems to hold well. The tide runs about six feet, and sets about S.S.W. High water full and change, thirty minutes past live. S. lat. 4° 34'. E. long. 55° 35'.

SEYIWA, or SEDAU, a town of Saxony; 10 miles E. of Wittenberg. N. lat. 51° 55'. E. long. 12° 59'.

SEYDE. See Saino.

SEYDEWITZ, a river of Saxony, which runs into the Elbe, near Pirna, in the margravate of Meissen.

SEYER. See Pulo Seyer.

SEYER. See Seyer.

SEYER, an island of Denmark, in the Cattegat, about eight miles long, and hardly one broad; about five miles from the coast of Zealand. N. lat. 53° 53'. E. long. 11° 11'.

SEYFFERSWORP, a town of Silexia, in the principality of Groetkau; 3 miles N.N.E. of Groetkau.

SEYFERTESWORP, a town of Prussia, in the province of Ermeland; 9 miles S. of Heilberg.

SEYGR, in the Materia Medica, a name used by some authors for the wormwood.

SEYGER, in Geography, a town of Prussia, in the province of Oberland; 4 miles N.E. of Salcfeld.

SEYFOLNE, a town of Hindoostan, in Oude, seated on a river which runs into the Goomty; 15 miles S.E. of Barely.

SEYMAN, an island in the Red Sea. N. lat. 15° 20'. E. long. 57° 30'.

SEYMORE, Edward, in Biography, brother of Lady Jane Seymour, in Henry VIII. (see his article), and uncle to Edward VI., was created viscount Beauchamp, earl of Hertford, and duke of Somerset. On the accession of his nephew to the throne he became his guardian, and protector of the kingdom. Not thinking that the vote of the executors of Henry VIII. was a sufficient foundation for the high authority which he partly assumed by the influence which his relationship to the king gave him, he procured a patent from Edward, by which he overfed the meaning and intent of the late king's will. In this patent he named himself protector, with full regal power, and appointed a council entirely of those persons whom he thought he could trust. The protector became the warm friend of the reformation, and consulted Cranmer on the best means of promoting the object he had at heart. He appointed a general visitation to be made in all the dioceses in England, the visitors confining of a certain number of the clergy and laity, and they had their different circuits assigned them. The chief purport of their instructions was, besides correcting the immoralities and irregularities of the clergy, to abolish, but with a very lenient hand, ancient superstitions, and to bring discipline and worship somewhat nearer the practice of the reformed churches. Somerset made war upon Scotland, and upon his return in Nov. 1547, he called a parliament, and being elated with the success which he obtained over the Scots, he procured from the young prince a patent, appointing him to sit on the throne, upon a floor at the right hand of the king, and to enjoy the same honours and privileges that had usually beenpolled by any prince of the blood, or uncle of the kings of England. In this patent the king employed his dispensing power, by setting aside the statute of precedence enacted during the reign of his father. If, however, the protector gave offence by affirming too much flate, he devolved high praise on account of the laws which were passed during this session, by which the rigour of former statutes was much mitigated, and some security given to those principles of freedom which seem to make a part of the constitution. All laws were repealed which extended the crime of treason beyond the statute of the twenty-fifth of Edward III.:

"By these repeals," says Hume, "several of the most rigorous laws that were ever passed in England were annulled, and some down, both of civil and religious liberty, began to appear to the people."

A bout this time, most violent differences subsisted between the protector and his brother, Thomas Seymour, admiral of England. The ambition of the latter was inestimable: he was besides arrogant, assuming, and implacable; and though exalted to the highest capacity to the protector, he did not possess the fame degree of confidence and regard of the people. By his flattery and addresses, he had so far impartially himself into the favour of the queen-dowager, that she married him almost immediately upon the demise of the king. The credit of this alliance supported the ambition of the admiral, and gave great offence to the dukes of Somerset, who, uneasy that the younger brother's wife should have the precedence, employed all the credit she had with her husband, first to create, and then to widen the breach between the two brothers. Matters, at length, were carried so far, that the admiral was attainted of high treason, and executed by a warrant, which was signed by the hand of his brother, whose own disgrace was at no great distance.

After the death of Somerset had obtained the patent, investing him, as it were, with full regal authority, he thought every one was in duty bound to yield to his sentiments. Besides his general hauteur, he gave great offence to the higher ranks of society, by the attention with which he evidently courted the applause of the people at large. For the relief of the latter he had created a court of requets in his own house, and he interposed with the judges in their behalf, a circumstance that could not but be deemed illegal. Though the protector had thus courted the people, to the displeasure and disgust of the nobles, whom Hume represents as "the
Sureft support of monarchical authority," the interest which he had formed with them was in no degree answerable to his expectations. The Catholic party, who retained influence with the lower ranks, as might be expected, were his declared enemies, and took advantage of every opportunity to decay his conduct. The attainer and execution of his brother bore an odious aspect: the introduction of foreign troops into the kingdom was represented in invidious colours: the great estate which he had suddenly acquired at the expense of the church, and of the crown, rendered him obnoxious; and the palace which he was building in the Strand served, by its magnificence, and still more by other circumstances attending it, to expose him to the cenfure of the public. The parish church of St. Mary, with three bishops' houses, were pulled down, in order to furnish ground and materials for this structure. Not content even with this, which, at that period, was regarded as great sacrilege, an attempt was made to demolish St. Margaret's church, Welling- 

minter, and to employ the stones for the fame purpose, but the parishioners role in a tumult, and chafed away the protector's tradesmen. He then laid his hands on a chapel in St. Paul's church-yard, with a cloister and charnel-house belonging to it, and these edifices, together with the church called the St. John of Jerusalem, were made use of to raise his palace. All these improprieties were remarked by Somer- 

sset's enemies, who revolved, when an opportunity offered, to take advantage of them to his ruin. A conspiracy was soon formed against him, and he resigned his office, hoping that with this concession his foes might be satisfied, but he was mistaken, they determined to pursue him even to the scaffold. He was committed to the Tower, with some of his adherents, and articles of indictment were exhibited against him, of which the chief was his usurpation of the government, and his taking into his own hands the whole administration of affairs. The clause of his patent, which invested him with absolute power, unlimited by any law, was never objected to him, because, says Mr. Hume, "according to the sentiments of those times, that power was, in some degree, involved in the very idea of regal authority." Somer- 

set was prevailed upon to confess on his knees, before the council, all the articles laid to his charge, and he imputed these misdemeanors to his own rashness and indiscretion, not to any malignity of intention. He even subscribed a paper which contained a full confession of his guilt; he was accordingly fined two thousand pounds a-year in land, and depriving of all his offices, and here the matter for the present ended; the fine was remitted, and he recovered his liberty. After this, he was re-admitted into the council, and soon obtained a considerable portion of popularity, which rendered him an object of jealousy to the duke of Northumberland, who planned his destruction. Under pretence of an intended insurrection, he had him feized, with his friends, and committed to the Tower. He was now brought to trial before a jury of twenty-seven peers, some of whom were his avowed enemies, and was of course found guilty, and condemned to death. Care was taken to prepossess the young king against his uncle, and left he should relent, no accesse was allowed to the duke of Somerset's friends, and the prince was, by a continued series of occupations and amusements, kept from reflection. The prisoner was executed on Tower-hill, much to the regret of the great body of people, who entertained the hopes of pardon to the last. A vast multitude of those friendly to him were the witnesses of his death. Many of them dipped their handkerchiefs in his blood, which they preferred as a precious relic; and some of them, when Northumberland, his great enemy and one of his jurors, met with a like doom, upbraided him with this act of his cruelty, and displayed to him these symbols of his crime. "Somer- 

set, indeed," says Hume, "though many actions of his life were exceptional, feems in general to have merited a better fate, and the faults which he committed were owing to weaknesses, not to any bad intention. His virtues were better calculated for private than for public life; and by his want of penetration and firmness, he was ill-fitted to extricate himself from those cabals and evictions to which that age was so much addicted."

Somer set left three daughters, Anne, Margaret, and Jane, who were distinguished for their poetical talents. They composed Latin dittics on the death of Margaret de Valois, queen of France, which were translated into the French, Greek, and Italian languages, and printed in Paris in 1551. Anne, the eldest of these ladies, married first the earl of Warwick, the son of the duke of Northumberland, already mentioned, and afterwards Sir Edward Huntson. The other two died single. Jane was maid of honour to queen Elizabeth.

SEYMOUR, ARABELLA, better known in history by the name of the Lady Arabella, was daughter of Charles Stuart, earl of Lennox, youngest brother of Henry Dundie, husband to Mary queen of Scots. Her mother was daughter of Sir William Cavendish of Chatsworth, in Derbyshire. Her affinity to the crown was the cause of her misfortunes. Several projects were formed for placing her on the English throne, so that she was kept under confinement in the reign of queen Elizabeth. At the beginning of that of James, a conspiracy, or rather a project of a conspiracy, was formed to raise her to the crown. She was first cousin to the king, being the daughter of a younger brother, which shews how rash the project was, supposing it to have been real; because James did not ascend the throne of England by the right of his father but that of his mother, consequently Arabella, though of the Stuart family, stood in a very remote degree of relation to the late queen Mary, had no claim to the crown of England, and the more so, as James had three children. The authors of this conspiracy were lords Grey, Cobham, Sir Walter Raleigh, and others, who were tried, convicted, and condemned, but none were executed at the time, except a brother of lord Cobham, and two priests. The others were remanded to the Tower. (See RALEIGH.) Arabella died in the year 1615, in prison, to which place she had been committed some time before, for having contracted marriage, without the knowledge of the crown, with William Seymour, grandson to the earl of Hertford. Hume. Acta Regia.

SEYMOUR'S Canal, in Geography, an inlet on the S.E. coast of Admiralty Island, extending from Point Hugh, about 28 miles N.N.W. of the entrance between Point Hugh and Point Gambier.

SEYM, among Farriers. See SEAMS.

SEYNE, in Geography, a town of France, in the de- 

partment of the Lower Alps, and chief place of a canton, in the district of Digne; 15 miles N. of Digne. The place contains 2557, and the canton 5227 inhabitants, on a territory of 307½ kilometres, in 8 communes.

SEYNE, a town of Lithuania; 38 miles N.N.W. of Greudno.

SEYPOUR, a town of Hindooistan, in Oude; 40 miles N.E. of Fyzabad.

SEYSSÉL, CLAUDE DE, in Biography, an historical and political writer, who flourished in the beginning of the sixteenth century, was brought up to the law, which he practised with great applause at Turin. He obtained the places of master of requests and counsellor under Lewis XIII. of France. He attended in the name of that prince at the council
council of Lateran, and was promoted to the bishopric of Marfelles in 1510, and to the archbishopric of Turin in 1517. He died in 1520, leaving behind him a great number of works, on theological, juridical, and historical subjects. He also translated into the French language Eufebius's Ecclesiastical History, Thucydides, Appian, Diodorus, Xenophon, Justin, and Seneca. He is said to have been the first who alleged the Salic law as influencing the succession to the crown of France. His "Grand Monarchie de France," published in 1519, and translated by Seilhan into the Latin language, maintains that the French constitution is a mixed monarchy, and that the king is dependent on the parliament. In his "Histoire de Louis XII. Pere du Peuple," he is the perpetual panegyrist of that prince, but gives some curious facts respecting the reign of Lewis XI., whose vices are exposed by way of contrast.

SEYSSEL, in Geography, a town of France, in the department of the Ain, and chief place of a canton, in the district of Belley, situated on the Rhone, which here becomes navigable, and divides it into two parts; 13 miles N. of Belley. The place contains 2260, and the canton 6632 inhabitants, on a territory of 1231, kilometres, in 5 communes.

SEZANE, or CEZANE, a town of France, in the department of the Oise, on the Dour; 7 miles E. of Briandou.

SEZANNES, a town of France, in the department of the Marne, and chief place of a canton, in the district of Epernay; 45 miles W. of Vitry-le-Francais. The place contains 4749, and the canton 12,203 inhabitants, on a territory of 350,000, kilometres, in 30 communes. N. lat. 48° 42'. E. long. 3° 48'.

SEZARNIK, a town of Hungary; 4 miles W. of Kaposdor.

SEZENEA, a town of Ruffia, in the government of Viatka; 16 miles N.N.E. of Glazov.

SEZULFE, a town of Portugal, in the province of Tras los Montes; 7 miles N.E. of Miranda.

SEZZA, a town of the Campagna di Roma; 15 miles E.S.E. of Roma.—Alfo, a town of Naples, in Lavora, the seat of a bishop, suffragan of Capua; 29 miles N.N.W. of Naples. N. lat. 41° 19'. E. long. 13° 34'.

SFACCIA, a town of European Turkey, in Albania; 8 miles N. of Duecigno.

SFACHIA. See SPIACHIA.

SFALASSA, a river of Naples, which runs into the sea; 4 miles E. of Cape Scglio.

SFASACCA, a town of Japan, on the S.W. coast of Nippon; 18 miles E. of Amanguc.

SFAX, or El Sfaxiff, a town of Africa, in the kingdom of Tunisia, surrounded with walls. The trade of the inhabitants in oil and cloth is considerable; 45 miles S.E. of Cairo. N. lat. 34° 49'. E. long. 10° 56'.

SFORZA, GIACOMEZZO, in Biography, named also Attendolo, founder of the illustrious house of Sforza, was born in 1360 at Cotignola, in Romagna. He is said to have been originally a peasant, and, according to a traditionary report, being one day at work, he was solicited to enlist for a soldiery, when throwing his spade on a tree, he said he would enter if the spade did not fall down again, which proving to be the case, he immediately engaged in that military life which rendered him famous. He first served under general Albéric de Barbiano, and had for his comrade in arms the celebrated Braccio. Thence, in the early part of their career, were as intimate as brothers, but as they advanced in the profession, jealousy intervened, and they became at length such determined enemies, that when one engaged in the service of a prince or state, it was a sufficient motive for the other to engage on the opposite side. Sforza was soon distinguished for his bravery, and for a disposition to seize by force whatever booty fell in his way. Braccio and he perfectly agreed in selling their services as dearly as possible, and in considering war as a trade which was to be kept up for their benefit. From the command of 100 men he rose to that of 7000; he obtained the office of gonfalonier to the holy see, and by pope John XXIII. he was created count Cotignola, an honour that was given by way of payment of a sum of money due to him. He commanded in the kingdom of Naples against Alphonso of Aragon, and was made countable of the kingdom. In marching to the relief of Aquila, he was drowned in the passage of the river Aterno or Pescara, in the year 1424. He is represented to have been robust in body, and when elevated to his highest rank, that he preferred the peafant's disregard of luxury, and frankness of manners.

SFORZA, FRANCESCO, first duke of Milan of that family, natural son of the preceding, was born in 1401. In 1421 he was viceroy to Louis, duke of Anjou, who had been adopted by queen Joan II. of Naples, and in 1424 he defeated the troops of Braccio; but his father, as we have seen, being drowned, he could make no advantage of his successes. Although an illegitimate son, Joan conferred upon him all his father's estates, and he served successfully against the Aragonese commanders. He afterwards entered into the service of the duke of Milan, and defeated a fleet of the Venetians in the Po, in 1431. After the death of the queen, in 1435, he attached himself to her heir, Rene, duke of Anjou, and made himself master of several places in the Marche of Ancona. He even feized some of the pope's possessions, which brought on him an excommunication from Eugenius IV., whom he had formerly served. He had long wished to marry Bianca, the natural daughter of Philip-Maria Vifconti, duke of Milan, and being in the Venetian service against that prince, he gained such advantages as induced Philip, who had often deceived him, to enter into a treaty in 1414, by which he made peace with the Venetians, and gave his daughter to Sforza, with Cremona and its territory for her portion.

The father and son-in-law did not long continue united, and Sforza commanded, as general, the troops of the pope, Venetians, and Florentines, in a war against Philip. He was, however, at length, induced to go over to the party of the duke of Milan, who, in 1447, died without legitimate issue. Sforza was now ambitious of succeeding him, and took a commission, as general of the troops of Milan, against the Venetians. But he soon made a treaty with the latter, and then led an allied army to the gates of Milan, to which he laid siege. The dfficres of the city occasioned a popular commotion, the leaders of which proposed the execting of Sforza for their duke. The majority concurred in the proposal; and in February 1450 he was received with great acclamations in that quality. Sforza remained in possession of the duchy, and in 1464 made himself master of Genoa, Lewis XI. of France having made over to him all the right of France to that city. Sforza died in 1466, and transmitted the sovereignty to his son. He had shown himself a brave and skilful commander; but with several traits of grandeur in his character, he was not a man of principle, and was ready to change sides as suited his interest. Mod. Univ. Hift.

SFORZA, CATHERINE, an heroine of the same family, the natural daughter of Galeazzo Sforza, duke of Milan, who was aUiliated in 1476. She married Jerome Riario, lord of Forlì and of Imola, which was her own dowry; but she was left a widow at the age of twenty-two, with several children. In 1500 Forlì was besieged by the duke of Valentinois, son of pope Alexander VI. but the defended the
the fortresses with the greatest bravery, though the besiegers threatened to put her children to death, who were in their hands. At length the place was taken, and Catherine sent prisoner to Rome, but the soon recovered her liberty, and was married to John de Medicis, to whose family she rendered very eminent services.

Sforza, Isabella, an ingenious lady of the same family in the sixteenth century. Her letters were printed at Venice in 1549, by Hortensiö Landi.

Sfrondati, Francis, a senator of Milan, and counsellor of state to the emperor Charles V. On the death of his wife he entered into orders, and was elevated to the cardinalship. He died in 1550, aged 56. A poem of his, on the "Rape of Helen," was printed at Venice in 1550. His son Nicholas became pope by the name of Gregory XIV: there was another cardinal of this name and family, who wrote several works against the liberties of the Gallican church. He died in 1600.

Sfuggito, It. in Musie, to flun, avoid, go out at the common way: as canzana sfuggito, a disappointed cadence. This happens when the base seems preparing for a full close; instead of falling a 5th or rising a 4th, it rises only one tone or semitone, or falls a 3rd; or in other words, when all parts avoid their natural and expected conclusion.

Sfumberg, in Geography, a town of Bohemia, in the circle of Chrudim; 5 miles S.S.E. of Chrudim.

Sgigata, Stgizata, or Stora, a town of Africa, in the country of Algiers, anciently called Ruscada; situated near the coast of the Mediterranean. A few cemeteries are the only remains of its ancient splendour; 30 miles W. of Bona. N. lat. 36° 48'. E. long. 6° 40'.

Sgigatcche, or Shigatcehe, a town of Thibet, situated in a narrow valley, on a ridge of rock, fo 35 to command the road near the river Painam-tchieu; 130 miles W.S.W. of Lassa. N. lat. 25° 5'. E. long. 88° 52'.

Sgraffita, or Sgraffiata, in Painting. See Scratchwork.

Shaab al Yadzun, in Geography, a dry shelf in the Red sea, extending from N.E. by E., deriving its name from its supposed resemblance to two arms wide open with their hands, situated at the end of a great bay, far out to sea. There is a secure harbour on the tide towards the land.

Shaal Stone, in Mineralogy. See Tabular Spar.

Shab, in Agriculture, a disease of sheep. See Scab.

Shan, or Shek, in Geography, a town of Africa, in the country of Nubia; 450 miles S.S.W. of Cairo. N. lat. 23° 35'. E. long. 30° 30'.

Shabadpour, a town of Hindeoosl, in Oude; 50 miles W. of Kairabad.

Shabala, a name of a wonderful boon-granting cow, often spoken of in Hindoo romance; but more commonly under the name of Surabhi; which see.

Shabale, in Geography, a mountain of Turkifhan; 70 miles N.N.E. of Toncat.

Shabamoushwon Lake, a lake of Canada; 210 miles N.N.W. of Quebec. N. lat. 49° 10'. W. long. 75°.

Shabat, a town of the kingdom of Chasraim; 95 miles S.S.E. of Urgheuz.

Shabaygan, a river of Canada, which runs into lake Michigan. N. lat. 48° 30'. W. long. 86° 45'.

Shabazpour, a town of Hindeoosl, in Allahabad; 16 miles S.E. of Corab.

Shabran, a town of Perifia, in the province of Shirvan; 40 miles N.E. of Schamachie.

Sha bury, a town of Peria, in the province of Irak; 6 miles S.W. of Calbin. Also, a town of Egypt, on the west branch of the Nile, thought to be the ancient Andropolis; 50 miles N.N.W. of Cairo. N. lat. 30° 47'. E. long. 31°.

Shack, in Ancient Cufions, a liberty of winter-pasturage. In the counties of Norfolk and Suffolk, the lord of the manor has shack, i.e. a liberty of feeding his sheep at pleasure, in his tenants' lands, during the six winter months.

In Norfolk, shack also extends to the common for hogs, in all men's grounds, from the end of harvest till feeding-time. Whence to go a shack, is to feed at large.

Shack, in Agriculture, provincially to shed as grain at harvest. See Harvesting Grain.

Shack, or Shack-corn, a provincial term applied to the waffe corn left in the fields at harvest: also the flock turned upon the stubble after harvest, and likewife to such grounds as lie open to common fields. Pigs are the flock usually employed in gathering this, and in some parts flocks of geese and turkeys. Where pigs are clovered through the hummer, they are filled with the shacks and the acorns; but some farmers are so provident, as neither to feed their clovers in that advantageous way, nor even keep pigs enough to pick up the waffle corn, which is sometimes absolutely suffered to rot in the fields. Young pigs answer well in this use, as they thrive greatly, especially when bred upon the farm.

Shack-Fork, provincially a wooden fork for shaking straw off the barn-floor, made of forked willow, &c.

Shackleford, in Geography, a poft-town of America, in Virginia; 143 miles W.S.W. of Washingto.

Shackles, in Ship-Building, the small ring-bolts driven through the ports, or scuttles, and through which the lashings or an iron hook passes when the ports are barred in. There are also shackles put upon billow-bolts, for confining feamen, &c. who have deferved corporal punishment.

Shacora, in Geography, a town of Egypt, on the coast of the Red sea; 67 miles S. of El Colter.

Shad, Alada, in Ichthyology, the name of a sea-fish, called also the mother of herrings, and by some authors clupea and triphos, by the ancients trichis, or trichias, and the clypeus alofis of Linnaeus. See Clupea.

It very much resembles the herring in its general form, but it is flatter and broader, and grows to a cubit long, and four inches broad. The head slopes down considerably from the back, which at the beginning is very convex, and rather sharp; the body from thence grows gradually less towards the tail; the under jaw is rather longer than the upper; the teeth very minute; the dorsal fin is placed very near the centre, is small, and the middle rays are the longest; the pectoral and ventral fins are small; the tail very forked; the belly extremely sharp, and strongly serrated; the back is of a dusky blue; above the gills begins a line of dark spots, which mark the upper part of the back on each side; the number of these spots is different in different fish, from four to ten.

It is very common in many seas, and in some of our large rivers which lie near the sea. They run up thefe in great numbers, and are then very fat; they afterwards become lean, and then go down to the sea again. They usually swim in large shoals together.

In Great Britain the Severn affords the shad in higher perfection than any other river; where it first appears in May, but in very warm feasons in April, and continues about
about two months. The shade at its first appearance, especially near Gloucester, is esteemed a very delicate fish, and sells dearer than salmon. The London fishmongers deliver it from that of the Thames, by the French name of alof. Whether they spawn in the Severn or Wye is not determined, as their fry has not yet been ascertained. The old fish come from the sea in full roe. The fishermen erroneously imagine that the bleak, which appears in multitudes near Gloucester in July and August, are the fry of the shad. Many of these are taken in those months only, but none of the emaciated shads are ever caught in their return. The Thames shad does not frequent that river till the month of July, and is esteemed a very inipid coarse fish. About the same time, the twaite, a variety of the shad, makes its appearance near Gloucester, and is taken in great numbers in the Severn, but held in as great disrepute as the shad of the Thames. The true shad weighs sometimes eight pounds, but their general size is from four to five. The twaite, on the contrary, weighs from half a pound to two pounds, which it never exceeds. The twaite differs from a small shad only in having one or more round black spots on the sides; if only one, it is always near the gill, but commonly there are three or four, placed one under the other. Pennant.

No shad is to be taken in the Thames or Medway, except from May 10 to June 30. 39 Geo. II. cap. 21.

SHADDOCK, in Botany. See Citrus.

SHADE, in Agriculture, any sort of protection employed for preventing the heat, cold, and rain, from affecting and injuring any kind of stock, whether of the nature of building or plantation, of the woody kind, &c. See Screen-Plantation, and Shelter.

SHADE, in Gardening, any thing that intervenes to obscure or protect plants from the rays of the sun. It is effected in various ways by the gardener; as by mats, covers, &c.

SHADE, provincially a shed for fuel, or house for sheltering live-stock, &c.; it also signifies to shed as grain, as used in some places.

SHADE Mountain, in Geography, a mountain of Pennsylvania, N.E. of Lewitown.

SHADENDORFF, a town of Austria; 4 miles N.E. of Brugg.

SHADING of Plants, in Gardening, the art of protecting plants of young and tender growths in feed-beds, &c., from the sun: It is a necessary work on many occasions, in warm, dry, sunny weather in spring and summer, &c., in pricking out various sorts of small young plants from feed-beds, into nursery-beds, pots, &c., as well as small cuttings, slips, above-ground off-sents, pipings, &c., as likewise occasionally in transplanting any kind of more advanced plants, flowers, &c., into beds, or pots, in a hot, dry season, and sometimes to feed-beds of particular sorts of small or curious seeds, in hot sunny days; also to plants in hot-beds, under frames and glasses, both of young and more advanced growths. It is the most commodiously and effectually performed by garden mats in a sort of awning over the beds, to plants in the full ground, or to those in pots placed close together, or sometimes to feed-beds, either in that way, or by being spread on the surface; in the latter method, being occasionally watered over the mats; or sometimes, in hot dry weather, by some loose litter sifted in over feed-beds, which by screening the surface from the parching sun, and preserving the moisture in the earth, promotes a more quick, regular, and free germination in the seed; and when the plants are come up, the covering is soon drawn off lightly with a wooden or other rake. To plants under glasses in frames, &c. the occasional shading is effected either by mats spread thinly over the glasses, or sometimes by a little loose, long litter, shaken lightly over them, till during the fierce heat of the sun. In all cases the shade should not be made too thick, so as to darken the plants too much.

Also in the business of occasional shading, it is in general only to be continued in the warmest time of sunny days, generally longer to plants, cuttings, &c., which have not fructified, than those that are in a growing state; and in common with all plants in the full ground, or others designed for placing in the open air, where occasional shading is necessary, it should be discontinued on evenings, mornings, and nights, that they may enjoy the benefit of the full bright air at these times; as also the tender sorts, striking or advancing in growth under glasses, having occasional shading when the sun is powerful, in the warmer part of the day, should remain unfadened before and after that time, that they may receive the necessary beneficial influence of light and air in a proper degree. But in plants, cuttings, slips, &c. that have had occasional shading till they have fructified good root, and begin to advance a little in a renewed growth, the shading should be mostly discontinued gradually, especially for those in beds, pots, &c. in the open ground, or others designed for transplantation, or for placing in pots, in the full air for the summer, according to their kinds: but in some small tender plants of slender growth, the occasional shading may probably be neccesary in longer continuations, till they acquire more strength; and to plants remaining all summer in hot-beds, or under frames and glasses, the continuance of occasional moderate shading in hot sunny days will be proper; but in most young plants, cuttings, &c. pricked out or planted as above, and designed for the full ground or open air, not continued under glasses, the having the benefit of occasional shade till well fruct is all they require.

The sorts of plants which require this kind of management are very numerous; but it is constantly mentioned in their culture where necessary.

SHADMAN, in Geography, a town of Grand Bucharia; 36 miles N.N.E. of Termed.

SHADOW, in Shade, in Optics, a certain space deprived of light, or where the light is weakened by the interposition of some opaque body before the luminary.

The doctrine of shadows makes a considerable article in optics, astronomy, and geography; and is the general foundation of dialling.

As nothing is seen but by light, a mere shadow is invisible: when, therefore, we say, we see a shadow, we mean partly, that we see bodies placed in the shadow, and illuminated by light reflected from collateral bodies; and partly, that we see the confines of the light.

If the opaque body, that projects the shadow, be perpendicular to the horizon, and the plane it is projected on be horizontal, the shadow is called a right shadow. Such are the shadows of men, trees, buildings, mountains, &c. If the opaque body be placed parallel to the horizon, the shadow is called a vertical shadow; as the arms of a man stretched out, &c.

SHADOWS from opaque Bodies, Laws of the Projection of.

1. Every opaque body projects a shadow in the same direction with the rays of light; that is, towards the part opposite to the light. Hence, as either the luminary or the body changes place, the shadow likewise changes its place.

2. Every opaque body projects as many shadows, as there are luminaries to enlighten it.

3. As the light of the luminary is more intense, the shadow
The intensity of the shadow is measured by the degree of light that space is deprived of. In reality, the shadow itself is not deeper, but it appears so, because the surrounding bodies are more intensely illuminated.

4. If a luminous sphere be equal to an opaque one, which it illuminates, the shadow this latter projects will be a cylinder; and, of consequence, will be propagated till equal to itself, at whatever distance it extends; so that, if it be cut in any place, the plane of the section will be a circle equal to a great circle of the opaque sphere.

5. If the luminous sphere be greater than the opaque one, the shadow will be conical. If, therefore, the shadow be cut by a plane parallel to the base, the plane of the section will be a circle; and that so much the less as it is at a greater distance from the base.

6. If the luminous sphere be less than the opaque one, the shadow will be a truncated cone; consequently it grows still wider and wider; and, therefore, if cut by a plane parallel to its base, that plane will be a circle so much the greater as it is farther from the base.

7. To find the length of the shadow, or the axis of the shady cone, projected by a less opaque sphere, illuminated by a larger; let the semidiameters of the two, as C G and I M, (Plate XX. Optics, fig. 1.) and the distances between their centres G M, be given:

Draw F M parallel to C H; then will I M = C F; and therefore F G will be the difference of the semidiameters G C and I M. Consequentially, as F G, the difference of the semidiameters, is to G M, the distance of the centres; so is C F, or I M, the diameter of the opaque sphere, to M H, the distance of the vertex of the shady cone, from the centre of the opaque sphere. If then, the ratio of PM to MH be very small, so that M H and P H do not differ very considerably, H M may be taken for the axis of the shadowy cone; otherwise the part P M must be subtracted from it, to find which, seek the arc L K, which is the measure of the angle L M K, or M H I, and this angle is one of the angles of the right-angled triangle M H I, the sides of which, M I and M H, are known; for this, subtracted from a quadrant, leaves the arc I Q, which is the measure of the angle I M P. Since then, in the triangle I M P, which is rectangular at P, besides the angle I M Q, we have the side I M; the side M P is easily found by plain trigonometry.

E. g. If the semidiameter of the earth be M I = 1; the semidiameter of the sun will be F M = 1 11/10; and of consequence M H = 2 17/20; since then M P is found by calculation to be a very small ratio to M H, for the angle M I P = K M L, may be taken equal to the apparent semidiameter of the sun, because of the sun’s great distance, and its considerable magnitude, in proportion to the globe M; and therefore, M P : M I :: fine of 16° : radius, i.e. :: 217 : 1, nearly; and as M H is about 217 times M I, P M may be neglected, and P H may be taken to be 217 semidiameters of the earth. See Eclipse of the Moon.

Hence, as the ratio of the distance of the opaque body, from the luminous body G M, to the length of the shadow M H, is constant; if the distance be diminished, the length of the shadow must be diminished likewise. Consequentially, the shadow continually decreases as the opaque body approaches the luminary.

8. To find the length of the shadow projected by an opaque body T S (fig. 2.); the altitude of the luminary, e. g. the fun above the horizon, viz. the angle S V T, and that of the body, being given. Since, in the rectangular triangle S T V, which is rectangular at T, we have given the angle V, and the side T S; the length of the shadow T V is had by trigonometry.

Thus, suppose the altitude of the sun 37° 45’, and the altitude of a tower 178 feet; T V will be found 230 feet nearly.

9. The length of the shadow T V, and the height of the opaque body T S, being given; to find the altitude of the sun above the horizon.

Since, in the rectangular triangle S T V, rectangular at T, the sides T V and T S are given; the angle V is found thus: as the length of the shadow T V, is to the altitude of the opaque body T S, so is the whole fine to the tangent of the sun’s altitude above the horizon. Thus, if T S be 30 feet, and T V 45, T S will be found 41° 49’.

10. If the altitude of the luminary, e. g. the sun above the horizon T V S, be 45’, the length of the shadow T V is equal to the height of the opaque body, the triangle in this case being isecles.

11. The length of the shadows T Z and T V of the same opaque body T S, in different altitudes of the luminary, are as the co-tangents of these altitudes.

Hence, as the co-tangent of a greater angle is less than that of a smaller angle; as the luminary rises higher, the shadow decreases; whence it is, that the meridian shadows are longer in winter than in summer.

12. To measure the altitude of any object, e. g. a tower A B (fig. 3.) by means of its shadow projected on an horizontal plane.

At the extremity of the shadow of the tower C, fix a stick, and measure the length of the shadow A C; another in the ground of a known altitude D E, and measure the length of the shadow thereof E F. Then as E F is to A C, so is D E to A B. If, therefore, A C be 45 yards, E D 5 yards, and E F 7 yards; A B will be 324 yards.

13. The right shadow is to the height of the opaque body, as the cosec of the height of the luminary to the sine.

14. The altitude of the luminary being the same in both cases, the opaque body A C (fig. 4.) will be to the vered shadow A D, as the right shadow S B to its opaque body B D. Hence, 1. The opaque body is to its vered shadow, as the cosec of the altitude of the luminary to its sine; consequently the vered shadow A D is to its opaque body A C, as the sine of the altitude of the luminary to its cosec.

2. If D B = A C; then will D B be a mean proportional between E B and A D; that is, the length of the opaque body is a mean proportional between its right shadow and vered shadow, under the same altitude of the luminary.

3. When the angle C is 45°, the sine and cosec are equal; and, therefore, the vered shadow is equal to the length of the opaque body.

15. A right fine is to a vered fine of the same opaque body, under the same altitude of the luminary, in a duplicate ratio of the cosec to the sine of the altitude of the luminary.

Right and vered shadows are of considerable use in measuring; as by their means we can commodiously enough measure altitudes, both accessible and inaccessible, and that too, when the body does not project any shadow. The thin shadows we use, when the shadow does not exceed the altitude; and the vered shadows, when the shadow is greater than the altitude. On this footing is made an instrument called the quadrat, or line of shadows; by means of which the ratios of the right and vered shadow of any object, at any altitude, are determined. This instrument is usually
Let the scheme, No. 1. (Plate I. Shadows, fig. 1.) represent the vanishing plane, and No. 2, the plane of the picture.

In the vanishing plane, No. 1, let V 1 be the vanishing line, e the point of sight or place of the eye, A and B the intersection of the original vertical plane, inclined to the plane of the picture in the angle A G 1. Let A D be the base of the line, as given in position, to the horizon; make the angle D A F equal to the inclination of the line to the plane of the horizon; draw D F perpendicular to A D, and D B perpendicular to A B; produce D B to K; make B K equal to D F, and join A K, which is the feat of the line on the vertical plane. Draw e 1 parallel to A B, and draw I h perpendicular to V 1: in v 1, make 1 m equal to 1 e, and make the angle 1 m h equal to B A K, and h will be the vanishing point of the feat of the line. Draw e v parallel to D A, and v 1 perpendicular to v 1: make v n, in the vanishing line, equal to v e; make the angle v n i equal to the angle D A F, which the original line makes with the plane of the horizon. Draw e o perpendicular to v 1, meeting v 1 in g.

In the plane of the picture No. 2, let V L be the vanishing line answering to v 1, No. 1: in V L make choice of any convenient point, O, for the centre of the picture: make O L equal to 0 1, No. 1, and O V equal to v o, No. 1: draw L H and V I perpendicular to V L, then H is the vanishing point of the feat of the line, and I the vanishing point of the line itself.

The points H and I will be both on the same side of the vanishing line of the horizontal planes.

This problem is the same when the horizon and altitude of the picture are given, and the inclination of a vertical line to the plane of the picture; to find the vanishing point of a ray of light, and the vanishing point of the feat of the fun's rays.

When the fun is on the same side of the picture with the spectator, the vanishing point of the feat of the rays, and the vanishing point of the rays, will be below the vanishing line V L; but when on the other side of the picture, the vanishing point of the rays and the vanishing point of their feat will be above V L.

The following problem unites that of finding the vanishing points of the feat of a line, and the vanishing point of the line itself, with the vanishing point of the feat of the fun's rays and the vanishing point of the rays, as relating to the plane given.

Given the inclination of a plane to the plane of the picture, both being perpendicular to the original plane, the feat and inclination of a straight line, and the feat and inclination of the fun's rays, both to the plane of the horizon; to determine the vanishing point of the feat of the fun's rays, the vanishing point of the feat of the line on the vertical plane, as also the vanishing point of the fun's rays and vanishing point of the line itself.

It is evident, that the vanishing point of the feat of the fun's rays, and the vanishing point of the feat of the line, are both in the vanishing line of the plane, which is a straight line perpendicular to the vanishing line of the horizon; since the original of the feat of a ray, and the original of the feat of the line, are both in the original plane; and if the line be parallel to the original plane, the vanishing point of the feat of the line will be in the intersection of the vanishing line of the vertical plane with that of the horizon.

Join V S, (fig. 2.) and let it meet A B in s; draw b i and a S, cutting each other in e, and b e is the shadow of the line required.

For the vanishing point of the line that projects the shadow and the vanishing point of the fun's rays, are in the vanishing
vanishing line of the plane of shade; and because the plane of shade is supposed to cut the original plane, the intersection, which is the shadow, will be a line in the original plane, and therefore the vanishing point of the shadow will be in the vanishing line of the original plane; and as it has been shown that it is also in the plane of shade, it will therefore be in the intersection of the plane of shade, and the vanishing line of the plane on which the shade is thrown.

This problem is general for planes and lines in all situations, but in the following examples the centre and distance of the picture are supposed to be given, and the position of the picture is that of being perpendicular to the primary plane or first original plane: the objects themselves are solids, whose edges or planes are supposed to be perpendicular to the plane on which they stand. As absolute positions very seldom occur in practice, we shall suppose the vanishing line of the original plane, on which the object is placed, to be given.

To find the shadow of a prism placed on the primary plane.

Let AB (figs. 3, 4, and 5) be the vanishing line of the plane of the base, and since the picture is supposed to be perpendicular to the primary plane, the vanishing line of the plane of shade, occasioned by the vertical lines which form the concourse of the sides of the object, will be perpendicular to the vanishing line AB. Let S, therefore, be the vanishing line of a plane of shade, occasioned by any line of concourse, S being the vanishing point of the sun's rays, and s the intersection of the vanishing line of the plane of shade, with that of the plane on which the shadow is to be thrown.

Let g, d, ba, mn, be the edges of the solid: join bs and  

\[aS,\] cutting each other in e; and bc is the shadow, occasioned by the edge or line of concourse ba. Draw dc and ds, cutting each other in e; or, if necessary, produce them to cut in e, and ce is the shadow, occasioned by the edge ad, parallel to the plane of the original plane; also draw ce and sf, cutting each other in i; or, if necessary, produce them to cut each other in i, and ei will be the shadow of the edge df.

Lastly, draw is, which will complete the shadow of the prism, as required.

Fig. 3. shews the shadows of the object when the sun is before the picture: fig. 4. shews the shadow when the sun is behind the picture; and fig. 5. when the sun is in the plane of the picture.

To find the shadow of a building with a break. Let V L (fig. 6) be the vanishing line of the horizon, V the vanishing point of the horizontal lines, represented by ac and bd, that form the end of the building, also of ef, g, b, which represent the horizontal lines forming the sides of the break. Let the sun be supposed to be in the plane of the picture, or its rays parallel thereto, and let the lines ef, bgf, which are produced by the sun, and the plane egbf will throw a shadow upon the plane ablk, and the plane abde upon the horizon. As the sun's rays are parallel to the picture, they will have no vanishing point, but still the rule will hold in this case also. Through the vanishing point L, draw LM perpendicular to VL, then LM is the vanishing line of the plane ablk, on which the shadow is to be thrown; through V draw VM parallel to the sun's rays, or make the angle LVM equal to the angle which the sun's rays make with the plane of the horizon. Thus M is the vanishing point of the shadow of all lines vanishing in V, upon the plane ablk; therefore, to find the shadow of the line bg, join Mb, and produce it to m; and draw gm parallel to MV, then m will be the shadow of the point g, and bm of bg. Draw mn parallel to ge, and mn will be the shadow of ge; therefore hmnf will be the whole shadow of the plane bgfs, upon the plane ablk.

To find the shadow of the end abcde upon the plane of the horizon: draw ao parallel to LV, and bo parallel to MV; then ao is the shadow of the vertical line A B; join oV, and draw dp parallel to MV, and op is the shadow of bd; join pL, and draw ry parallel to MV, and pqr will be the shadow of the line dr, not seen: join ar, or draw it parallel to LV, then aopqr will be the shadow of the building upon the plane of the horizon.

Many more examples of shadows might be given, but if the principles here shewn are understood, the artist will not be at a loss to find the shadow of any right-lined object whatever: for to find the shadow of an object constituted by planes, and consequently terminated by straight lines, is no more than to find the shadow of these lines. If a circle be given, the circumstances may be divided by parallel lines into parts, and the shadows of the points of division may be found by finding the shadows of the intercepted lines, and drawing a curve round the extremities.

If it were required to find the shadows upon several planes, first find the shadow in the plane on which the object stands, and observe where the shadow meets the next plane; then having the vanishing line of this second plane, observe where the vanishing line of the plane of shade cuts the vanishing line of this second plane, then the point of intersection is the vanishing point of the shadow on the second plane.

The principles shewn under the article Projection, will apply equally to the representation of objects in perspective, particularly where the planes which throw the shadow intersect the plane on which the shadow is to be thrown; by continuing the line that throws the shadow, and the intersection of the plane to meet each other, you have the point where the shadow terminates; and therefore, if a point be given in the shadow, the direction of the shadow will be known. Thus in the last example, suppose the line ao obtained; and since the point a is the beginning of the shadow of the line bd, produce ac and bd to meet in V; join oV, and draw the ray of the plane dp, then op is the shadow of bd; produce dr and es to meet in L, and join pd; draw the ray r from r, then pq is the shadow of dr, not seen.

To find the vanishing line of a pole upon several planes.

Let A B C D E F G H I K, (Plate II. Shadows, fig. 1) be the outline of a building, with a lean-to or pent-houfe DE N P Q; V is the vanishing point of all horizontal lines, in the gable A B L I K of the main houfe, and also of the gable D M Q C of the pent-houfe; L is the vanishing point of all the horizontal lines in the parallel fronts B F G L and D E M N; and as all vertical planes have vertical vanishing lines, VR is the vanishing line of the parallel gables A B L I K and C D M Q; LU the vanishing line of the fronts B F G L and D E M N; I L G H is the representation of the roof of the main building, and O M N P that of the pent-houfe.

Produce LI to meet VR, its vanishing point, in S; draw SL, which will be the vanishing line of the inclined plane L G H I, for S and I are the vanishing points of two lines in that plane; produce MQ to meet VR in T; and draw TL; then TL is the vanishing line of the inclined plane M N P Q of the roof of the pent-houfe, because T and L are the vanishing points of two lines in that plane.

Let WX be a pole, rising upon the end of the houfe in the same plane with the gable A B L I K; and let \( \odot \) be the vanishing point of the sun's rays: produce the pole X W to meet VR in R, then R is the vanishing point of the pole, or of the line that throws the shadow; therefore by drawing \( \odot Y \odot R \), \( \odot \) R will be the vanishing line of the plane of shade, which let cut V I, the vanishing line of the horizon, in Y; and L,
L, U, the vanishing line of the vertical planes BFGI and DEMN of the walls, in U; VR, the vanishing line of the gables, in R; SL, the vanishing line of the main roof, in Z; and TL, the vanishing line of the pent-house, in Z'. We are now prepared for drawing the shadow of the pole WX upon the horizontal plane and upon the building.

Produce AB to meet WX in X, then X will be the point where the pole falls upon the ground or horizontal plane: draw XY, cutting DE in a; draw Ua, cutting DM in b; draw bH, cutting MQ in c; draw cZ, cutting PQ in d; draw Ud, cutting GI at I; and draw IZ, cutting the ridge LI at f; then Xabcdef will be the whole shadow of the pole.

For, since the shadow first begins at the foot of the pole or line in the plane of the horizon, and since the intersection of the vanishing line of a plane upon which the shadow is to be thrown, and the intersection of the vanishing line of the plane of shade, gives the vanishing line of the shadow upon that plane; now Y is the intersection of the vanishing line of the plane of shade with the vanishing line of the horizon; therefore Y is the vanishing point of the shadow of the line WX upon the plane of the horizon. The next plane on which the shadow is thrown is DEM; now LU is the vanishing line of the plane DEM; and U is the point where the vanishing line of the plane of shade cuts LU; therefore U is the vanishing point of the shadow upon the plane DEM. The next plane on which the shadow is projected is the plane CDMQ; now VR is the vanishing line of the plane CDMQ, and it intersects the vanishing line of the plane of shade in R; therefore R is the vanishing point of the shadow upon the plane CDMQ. The next surface on which the shadow is projected is the plane MNQP, of the roof of the pent-house; now Z is the intersection of the vanishing line of the plane of shade with the vanishing line of the plane MNQP; therefore Z is the vanishing point of the shadow on the plane MNQP. The next surface on which the shadow is projected is the plane BFGI of the wall; but U has already been thrown to be the vanishing point of the shadow. The plane of the roof is the last surface on which the shadow is projected: now SL is its vanishing line, and it meets the vanishing line of the plane of shade in Z, therefore Z is the vanishing point of the shadow upon the roof.

In carrying the shadow of a line across several planes, it will not be surprising if some little inaccuracy takes place from the obliquity of intersections: it might be a great chance, that when the part of the shadow falls upon the plane BFGI, drawn from the vanishing point U, through the point d, that it will meet the pole at 1, as it ought to do. To remedy this, begin with the shadow I d, and proceed in the reverse order, until it meets the line WX at X, which is most in principle, and will not be liable to vary much in practice.

The points which direct the shadows upon the several planes might also be found by the methods shewn in the article Projection.

The following observations will be useful in the practice of shadows.

When a straight line that throws a shadow is parallel to the picture, it is then represented parallel to the original. In this case it has no vanishing point; or, in other words, the vanishing point of the line may be said to be at an infinite distance; and, therefore, instead of the vanishing point of the line being joined to the vanishing point of the fun's rays, draw a straight line from the vanishing point of the fun's rays parallel to the projection of the line which throws the shadow, which will be the vanishing line of the plane of shade; and therefore the intersection of the vanishing line of the plane of shade with the vanishing line of the line on which the shadow is to be thrown, will give the vanishing point of the shadow on that plane, after the same analogy as lines which are inclined to the picture. This case is similar to that of the fun's rays being parallel to the picture: for here also the vanishing point of the rays is at an infinite distance; but as the plane of shade will still have a vanishing line, this line will be found by drawing a straight line through the vanishing point of the line that throws the shadow parallel to the fun's rays, as already shewn in a former example.

**Shadow projected from a given Point; as by the Light of a Candle Lamp.**—It is evident, if the representation of the luminous point be given, and its seat upon any plane, also the representation of any point in space, and its representation upon that plane, the shadow of the point will be found by drawing a straight line from the luminous point through the point in space, and by drawing another straight line from the seat of the luminous point through the seat of the point in space; and the intersection of the two lines thus drawn will represent the shadow of the point upon the plane. But when the relation of several planes represented in a picture, the representation of the light with its seat, and the representation of a point in space with its seat, are given, to project the shadow of the point on the other planes, other considerations become necessary.

For this purpose, let ABCD (fig. 2.) be the inside of a room, confiding internally of the vertical planes, AHI, EJ, FKI, GCI, and of the horizontal planes AEGFB and DHIKC; also, let L be the luminous point, and M its seat in the plane AEGFB. In order to form an idea of the point L, in respect of the other planes, it is neccesary to have the intersection of a line drawn through L, in a given position with one of the planes. Thus, if it is known that the straight line LA, parallel to the picture, cuts the plane of the wall BK, in the point a; the position of the point L to any of the other planes may be easily determined, as follows.

Through a draw ab parallel to the vanishing line NO of the plane BK; cutting BG, the intersection of the planes BK and AG, in b; through b draw bM parallel to PQ, the vanishing line of the floor, cutting AE, the intersection of the planes AG and AH, in c; also FE, the intersection of the planes AG and EI, in d. Draw ef parallel to NO, the vanishing line of the plane AH; and df parallel to RS, the vanishing line of the plane EI. Then, because the intersecting and vanishing lines of any plane are parallel to each other, and because a line drawn parallel to the intersecting line is parallel to the picture; therefore the representations of all the lines, ab, bc, or bd, cd, ef, and df, are all parallel to the picture, and in a plane passing through the luminous point L.

Given the representation of any straight line UT, and the points V and W, where the lines TV and UW, drawn parallel to the picture and to each other, meet the plane AG, whose vanishing line, PQ, is given, to find the vanishing point, X, of the line UT.

Draw WV, cutting PQ, the vanishing line of the plane AG, in Y; and draw YX parallel to TV or UW, meeting the line UT, produced in X, the vanishing point required.

To make this appear, it is evident that the vanishing line of a plane passing through W and V, must also pass through Y; and likewise the vanishing line of a plane passing through UW, must be parallel to it: whereas YX is the vanishing line of the plane, which passes through W.
Now let W Y cut the plane AX in Z; and in this example the vanishing line, Y X, is parallel to the vanishing line of the plane E F: therefore the planes, represented by F E and X U W Y, intersect each other in a line parallel to the picture; and, therefore, the representation of such an intersection is parallel to XY, or to RS, the vanishing line of the plane E F.

Given the vanishing lines, A B, C D, E F, (fig. 3.) of three planes, G H I K, L M N O, and M N I Q R, the common intersection, N O, of the planes G H I K and L M N O; also the intersections, N I and M N, of the planes G H I K and L M N O; the point of light, e; c d, a line parallel to the picture; and d, the point where it intersects the plane M N I Q R; to find the shadow of the line on the plane G H I K.

First, find the representation of a ray of light parallel to the picture, thus: draw d e parallel to A B, cutting M N at e; draw e f parallel to E F; then if a b be not parallel to e f, produce a b to f, and join f e, which is the ray required. Secondly, find the vanishing line of a plane of shade passing through the line a b, and the ray f e, thus: produce a b to meet C D in D, which is the vanishing point of a b; through D draw D F parallel to f e, and D F will be the vanishing line of the plane required. And, lastly, find the shadow of A B upon the plane G H I K, thus: produce O N and a b to meet in g; from g, through g, draw the line F h; and from the point of light, e, draw e b h and c a i; then h i will be the shadow of the line, as required.

For d e being parallel to A B, the vanishing line of the plane M N I Q R, d e will be parallel to the picture; and since e f is drawn parallel to E F, the vanishing line of the plane L M N O, e f will be parallel to the picture; and because a b meets e f in f, f e is a ray of light parallel to the picture, meeting the line a b; and because C D is the vanishing line of the plane L M N O, and a b is in the plane L M N O, therefore the vanishing point of a b is in C D, and consequently at D, where a b produced meets C D, and because D is the vanishing point of a b, the vanishing line of the plane of shade will pass through D parallel to f e; but F is the vanishing line of the plane of shade, with the vanishing line E F of the plane G H I K, on which the shadow is projected, therefore F is the vanishing point of the shadow on the plane G H I K; and because a is the intersection of a b with the plane G H I K, the shadow will commence at a, and consequently drawing F g h i gives the direction of the shadow; and lastly, because e is the luminous point, the rays c a i and e b h will terminate the shadow.

As D would be the vanishing point of all lines parallel to the original of a b in the plane represented by L M N O; and as different representations could not meet the line e f in the same point, the ray e f will have different positions, and consequently D F, which is drawn parallel thereto; and as the point D is stationary, the point F will be variable.

Given the representation of three rectangular planes, forming a solid angle, the representation of a point of light or candle, and the feet of the light on one of the planes; to find the feet of the light on the other two planes.

Let the three planes be A B C D, A B C F, A F E D, (fig. 4.) it is evident that every two adjoining planes have three edges parallel to each other, one common to both, which is their line of concurrence; these edges will therefore vanish in a point or be parallel to each other, according as the original planes are oblique or parallel to the picture: let the original planes be obliquely situated; therefore produce the edges C D, B A, G F, of the two adjoining planes A B C D, A B G F, and they will all meet in V, their vanishing point; and produce the edges D E, A F, B G, of the two adjoining planes D A F E, F A B G, and they will meet in W, their vanishing point; likewise produce the edges C B, D A, E F, and they will meet in X, their vanishing point.

Let L be a luminous point, and S its feat in the plane A B C D; draw S X, cutting A B in a; draw a W, and draw L X, cutting a W in S; then S is the feat of the luminous point in the plane A B G F; draw S V, cutting A D in b; draw b W, and L V, cutting each other in S; therefore S is the feat of the luminous point in the plane A D E F.

Because the plane A B C D represents a rectangle, and V is the vanishing point of the one side, and X that of the other, all the lines drawn to X will represent right angles with the lines which vanish in V; therefore S a and A B represent a right angle in the plane A B C D. For the same reason, a S represents a right angle in the plane A B G F, and since the planes A B G F and A B C D are at right angles, the angle S a S' will represent a right angle; and because S a represents a perpendicular to A B, a S' and S L will represent parallel lines; and since L S' and S a have the same vanishing point X, the original of L S' is parallel to the original of S a; but S a represents a perpendicular to the plane A B G F, therefore L S' also represents a perpendicular to the plane A B G F; and because the point S' is in the plane A B G F, S' is the feat of the luminous point L, in the plane A B G F. In the same manner it may be shown that S is the feat of the luminous point in the plane A D E F.

Given the representation c d of a line perpendicular to the original of the plane A B C D, and the vanishing point W of the line, and the point d, where the line meets the plane A B C D, a luminous point L, with its feat S, also upon the plane A B C D; to find the shadow of the line C D upon the said plane.

Draw S d and L c to meet each other in e, then d e will be the shadow of the line c d, as required. In the same manner, if f g represent a line perpendicular to the plane A B G F, and g the point where it meets the plane A B G F, g h will be the shadow of the line, by drawing L f and S' g to meet in b.

This method is general for any position of the original planes, with respect to the picture; and this position of the planes, in respect of each other, is that which most frequently occurs in practice.

Let A B C D (fig. 5.) be the inside of a room, showing five sides, one, E F G H, being parallel to the picture, and the other four perpendicular to it; C' is the centre of the picture.

Let L be the light of a candle, S its feat upon the floor; then to find the feet of the light on all the other four sides. Through S draw a b parallel to V L', the vanishing line of the horizon, cutting B F at a, and C G at b; draw a S' and b S' parallel to Y Z, the vanishing line of the two vertical planes; through L, the point of light, draw S' S, then S' is the feat of the light in the plane A B F E, and S' is the feat of the light in the plane C D H G. Produce C S to meet B C in c; draw c d parallel to Z Y, and join d C'; draw S S' parallel to Z Y; then S' is the feat of the light in the plane A E H D; let C S cut the line F G in e; draw e S' parallel to Z Y, cutting L C' in S, then S' will be the feat of the light on the plane E F G H. Then to project a prism standing perpendicular to any of these planes, suppose that
that which stands on the floor. From the feet S draw S, meeting CG in a; draw or parallel to ZY, and draw the ray Lm, and r will be the shadow of the point m; draw SH, cutting CG in p; draw p, parallel to YZ, and draw LN, cutting p at s; then s is the shadow of the point n; also draw SG, meeting CG in q; draw q, parallel to ZY, and draw LK, meeting q, at t, then t is the shadow of the point k; join rs and st, which complete the whole shadow of the prism upon the floor, and on the wall.

The principle of finding the shadows of the prisms on the other sides, is the same, and will be obvious on inspection. The truth of the method has already been flown.

Shadow, in Geography. The inhabitants of the globe are divided, with respect to their shadows, into Aequi, Amplificii, Heteroceri, and Periferici.

Shadow, in Painting. denotes an imitation of a real shadow, effected by gradually heightening and darkening the colours of such figures as by their disposition cannot receive any direct rays from the luminary supposed to enlighten the piece. The management of the shadows and lights makes what painters call the chiaro-oscuro, the laws of which lie under the article Clair-obscur.

Shadows, Genus of Curves by. See Curve. Shadows, Blue. See Blueness.

SHADWELL, Thomas, in Biography, a dramatic writer, and poet-laureat to King William III., was descended of an ancient family in Staffordshire, and was born about the year 1640, at Lanton-hall, in Norfolk, a seat belonging to his father, who was bred to the law, but having an ample fortune did not practice, choosing rather to serve his country as a magistrate. He was in the commission for those counties viz. Middlesex, Norfolk, and Suffolk, and discharged the duties of the office with distinguishing ability, and the most perfect integrity. In the civil wars he had been a considerable sufferer for the royal cause, so that having a numerous family, he was reduced to the necessity of selling and spending a considerable part of his estate to support it. In these circumstances he resolved to educate his son to his own profession. He was sent for preparatory studies to Caius college, Cambridge, and was afterwards entered at the Temple, but becoming acquainted with some of the wits of that time, he deserted his profession and devoted himself to literature. It was not long before he became eminent in dramatic poetry, and he appeared before the public as the writer of a comedy entitled "The fallen Lovers," or "The Impertinent," which was acted in the duke of York's theatre, and in 1668 it was printed. The success of this piece encouraged the author to proceed, and he from this period rapidly brought out plays, chiefly of the comic kind, till he had reached the number of seventeen. His model was Ben Jonson, whom he imitated in drawing humorous characters, rather from his own conceptions than from nature; and though his name has not been transmitted to posterity with much eulogium, and his works have long since disappeared from the stage, yet some of his delineations are said to display much real humour. Lord Rocheller has given him a respectable place among his contemporaries; he says,

"None feel to touch upon true comedy,
But ha'ly Shadwell, and flow Wycherly."

As every one in those days was of necessity a party man, Shadwell ranked himself among the Whigs, and in consequence of this he was set up as a rival to Dryden. Hence there grew a mutual dislike between them, and upon the appearance of Dryden's tragedy, entitled the "Duke of Guise," in 1683, Shadwell was charged with having the principal hand in writing a piece, entitled "Some Reflections on the pretended Parallel in the Play called the Duke of Guise, in a Letter to a Friend," which was printed the same year. Dryden wrote a vindication of the Parallel, and a contesterion was raised both against Shadwell and his friend Hunt, who himself in it, and who on this occasion was forced to fly into Holland. Dryden, by way of revenge upon Shadwell, wrote the bitterest satire against him that ever was penned; this was the celebrated Mac-Flecknoe.

In 1688 Shadwell was appointed to succeed his rival Dryden in the laureate ship, an honour which he did not enjoy many years. He died suddenly in the year 1692, in the fifty-second year of his age, at Cheltenham, and was interred in the church there. Dr. Nicholas Brady preached his funeral sermon, in which he affirms, "that the subject of his discourse was a man of great honesty and integrity, and had a real love of truth and sincerity; an inviolable fidelity and strictness to his word; an unalterable friendship wherever he professed it; and a much deeper sense of religion, than many others have who pretend to it more openly." The titles of Shadwell's plays are given in the Biographia Dramatica. An edition of his works, containing of those plays and miscellaneous poems, was printed in 1720, in four volumes.

The Earl of Rochester, in speaking of Shadwell, says, "If he had burnt all he had written, and printed all he spake, he would have had more wit and humour than any other poet."

SHADWELL, in Geography, a parish in the Tower division of the hundred of Offallton, and county of Middlesex, England, is situated about two miles and a half E. by S. from St. Paul's cathedral. It was formerly called Chadwell, as is supposed from a spring dedicated to St. Chad, and constituted a hamlet in the parish of Stepney, still separated from it, and made parochial, in 1669. The extent of this parish is very small, being only 910 yards in length, and 760 in breadth, and is wholly covered with houses, except a few acres, called Sun Tavern fields, which are appropriated as rope-walks. That portion of it which adjoins the Thames, and is called Lower Shadwell, is chiefly inhabited by tradesmen, and manufacturers connected with the shipping; such as ship-chandlers, biscuit-bakers, wholesale butchers, malt-makers, saw-makers, anchor-smiths, coopers, &c. A market which had been formerly held at Shadwell under the authority of a charter of King Charles II., but which was long disused, has been revived within the last few years. The church, dedicated to St. Paul, is a modern structure of brick. The living is a rectory in the gift of the dean of St. Paul's. In Shadwell's Place is a meeting-house for Presbyterian dissenters, opened only on Sunday evening, when sermons are delivered by diftinguishing ministers of different denominations, for the support of a charity-school, in which 50 boys and 30 girls are clothed and educated. Here are also a Calvinist meeting-house, and a chapel for Wesleyan Methodists, who have a Sunday-school attended by above 100 children. A third charity-school, founded in 1712, and partly endowed by queen Anne, provides clothes and education for 80 boys and girls.

The Shadwell water-works, which were established in 1669, and served a district containing 8000 houses, have been lately discontinued; the premises having been purchased by the East London Water-works' company, by whom this parish and its neighbourhood are now supplied with water. In Sun Tavern fields is a mineral spring, called the Shadwell Spa, which long sustained a high character for its medicinal qualities,
qualities, but it has lately fallen into disrepute. Barracks for the accommodation of the Chinese and Lascars, during their stay in England, have been recently erected here, and frequently lodge upwards of a thousand persons. According to the parliamentary returns of 1811, Shadwell parish contains 1694 houses, and 6855 inhabitants. Lyons' Environs of London, 140. 1795. Supplement, 1811. Stow's History of London, folio.

SHADWICKS, a town of America, in North Carolina; 10 miles W.S.W. of Hilliborough.

SHAFITEs, in the History of Mahometanism, the followers of Mohammed Ebn Edris al Shafei, the author of the third orthodox feets, who were formerly spread into Mawara'nahr, and other parts eastward, but are now chiefly of Arabia. Al Shafei was born either at Gaza or Afcalon, in Palestine, in the year of the Hijra 150, on the same day in which, as some fay, Aba Hanifa, the founder of the Hanefite, the first of the four orthodox feets, died; and was carried to Mecca at two years of age, where he was educated. He died in 204, in Egypt, whither he went about five years before, though Abulceda says he lived 58 years. This doctor was very highly esteemed for his excellency in all parts of learning, infomuch that his contemporary, Ebn Henbel, used to say that he was as the sun to the world, and as health to the body. Al Shafei is said to have been the first who discoursed of jurisprudence, and methodized that science; and accordingly it was wittily said of him, that the relations of the traditions of Mahomet were asleep, till Al Shafei came and awoke them. He was a great enemy to the feholatic divines. It is said of him, that he used to divide the night into three parts; one for study, another for prayer, and the third for sleep. It is also related of him, that he never so much as once swore by God, either to confirm a truth, or to afford a falsehood; and that being once asked his opinion, he remained silent for six months; and when the meaning of his silence was demanded, he answered, "I am considering first whether it be better to speak or to hold my tongue." The following saying is also recorded of him, "Whoever pretends to love the world and its creator at the same time is a liar." Sale's Koran, Int.

SHAFERS, in Geography, a town of Pennsylvania; 48 miles N.E. of Easton.

SHAFT, in Building. The shaft of a column is the body of it; thus called from its straightness; but by architects more frequently the flue. See the dimensions under COLUMN.

Shaft is also used for the spire of a church-tower; and for the flank or tunnel of a chimney.

Shaft, or Tunnel-Pit, is the well through which the flue, excavated from a tunnel, is drawn up to the surface.

Shaft of a Mine, is the hollow entrance or passage into a mine, fish or dug to come at the ore.

In the tin-mines, after this is sunk about a fathom, they leave a little, long, square, place, which is called a fiambique.

Shafts are sunk some ten, some twenty fathoms deep into the earth, more or less. Of these shafts, there is the landing or working-shaft, where they bring up the work or ore to the surface; but if it be worked by a horse engine or whim, it is called a whim-shaft; and where the water is drawn out of the mine, it is indifferently named an engine-shaft, or the rod-shaft. See MINE and QUARRY.

SHAFT, in Agriculture, a name provincially applied to a handle of a tool; as a spade, fork, &c.

Shafts of Cart and Wagons, the parts or poles be-
tween which the thill-horses draw. The manner in which the fore-horses are attached to these shafts, when there are more than the thill-horses in the teams, is a matter of great conformation; as the weight or pressure on them is more or less, according to its nature, and the way in which it is performed. See THILL-HORSES and WAGGON.
is supported by Camden, upon the evidence of an inscription mentioned by William of Malmesbury, which seems to point out Alfred himself as the founder, and is certainly much more probable than those which rest on the fanciful speculations of Jeffrey of Monmouth. There are circumstances, however, indicating Roman habitation on the site of Shaftesbury; and affuming this as a fact, some later writers contend that the words of the inscription, “Aelred rex fecit hanc urbem,” are only intended to denote that Alfred renewed or repaired this city. But whatever may have been its condition previous to that monarch’s reign, it was then only that it first attained any authenticated degree of celebrity, by the foundation of a monastery for nuns of the Benedictine order. This convent was indubitably the work of the great prince above-mentioned, as the charter of foundation, appointing his daughter Ethelgisa abbess, is yet extant. It was originally dedicated to the Virgin Mary, and became one of the richest and best endowed nunneries in England, occupied a great extent of ground, and possessed a vast number of offices and apartments within its precincts. The abbess was among the number of those who held a whole barony in capite, and was in consequence liable to serve in parliament, though excused on account of her sex. She wrote, however, directed to her, to send her quota of men into the field, according to her knight’s fees. On the translation of the body of Edward the Martyr hither, from Wancham, this monastery assumed the name of that saint, which it retained till the dissolution. Many miracles are said to have been wrought at its shrine, which was visited by an immense concourse of pilgrims, among whom was the illustrious Canute, who died here. After the Conquest, this convent was for some time neglected; but the patronage of succeeding monarchs soon restored it to celebrity, and conferred upon it such extensive donations in land, that it became proverbial to say, “that if the abbey of Glastonbury might marry the abbesses of Shaftesbury, their heir would have more land than the king of England.” At the dissolution, the nuns amounted to fifty-four in number, and enjoyed a revenue valued by Speed at £129l. 11s. 3d. The last abbess was Elizabeth Zouch, who had an yearly pension annexed to her of £53.

Shaftesbury is a very ancient borough by prescription, being mentioned as such in Domesday Book. It was not, however, incorporated by regular charter till the reign of queen Elizabeth, who confirmed all the privileges it enjoyed by custom, and vested the government in a corporation, consisting of a mayor, recorder, twelve aldermen, a bailiff, and common councilmen. That charter has since been confirmed by kings James I. and Charles II., with little variation. Henry VIII. made this town the seat of a suffragan bishop, but it did not retain its episcopal dignity above a few years. Shaftesbury has sent two members to parliament since the 25th year of Edward I. They are elected by the inhabitants paying tax and lot, who are estimated at about 300 in number, and are returned by the mayor. Shaftesbury has a weekly market on Saturday, and one annual fair; and according to the parliamentary returns of 1811, contains 515 houses, and a population of 2159 persons.

The town of Shaftesbury is most pleasantly situated, being built on a very lofty eminence, which commands an extensive prospect over the three adjoining counties of Dorset, Somerset, and Wilts. From the irregularity and narrowness of most of the streets, and the mean character of the buildings, however, it presents but an indifferent appearance. In ancient times it was more flourishing and important than at present; containing, besides the abbey-church, twelve others, several chantries and fraternities, and a priory or hospital of St. John the Baptist. Of these public structures only four churches remain, respectively dedicated to St. Peter, the Holy Trinity, St. James, and St. Rumbald. The principal of them is St. Peter’s, which is a building of considerable antiquity, and discovering much elegance in its symmetrical proportions and ornaments; but the greater part of it is defaced by modern alterations. Of the abbey scarcely a vestige is visible, the whole having been demolished soon after the dissolution, except the high embattled wall, supported by buttresses, which formerly inclosed the park, and is still in part standing on the site next the town. The other principal buildings of Shaftesbury are the town-hall, a free-school, two alms-houses tenements, and three meeting-houses, for Presbyterians, Methodists, and Quakers.

The manor of Shaftesbury appears from Domesday Book to have been very anciently divided into two moieties, one of which belonged to the crown, and the other to the abbey. The abbey manor was surrendered in the 30th year of Henry VIII., whose successor granted it to Thomas Wriothesley, earl of Southampton, together with the town, borough, feite, and precincts of the monastery. From him it passed to Sir Thomas Arundell, and afterwards to the earls of Pembroke, by one of whom, Philip, the royalty of the manor, and borough manor, were sold to Anthony Ashley Cooper, earl of Shaftesbury, in whose family they still continue.

Well from the town is an eminence called Castle Green, which is supposed to have received that appellation from its having been the feite of an ancient castle, though history is silent respecting any such structure belonging to Shaftesbury. On the brow of this hill is a small mount, surrounded by a shallow moat, which may have belonged to it, but it is commonly regarded as a Roman intrenchment. Tradition reports that the old town stood here, and it is certain that it occupied somewhat different ground from the feite of the present buildings. The immediate vicinity of Shaftesbury is noted as the birth-place of the Rev. James Granger, author of the celebrated Biographical History of England, Beauties of England and Wales, vol. iv., by John Britton and E. W. Brayley, 8vo. 1853. Hutchinson’s History of Dorsetshire, fol. 1776, 2d. edit. 1797. History of the Ancient Town of Shaftesbury, 12mo. 1808.

SHAFTESBURY, a considerable and flourishing port-town of America, in the county of Bennington, Vermont, having Arlington on the north, and Bennington on the south, and containing 1973 inhabitants.

SHAD ISLAND, an island near the entrance into Chatham Sound, on the S. coast of the island of Terra del Fuego; 4 miles N.E. of York Medical.

SHAGGE, or Shag, in Ornithology, a name by which we call a water-fowl common on the northern coasts, and called by Mr. Ray Cervus aquaticus minor, or the lesser corncrant, being properly a bird of the corncrant kind, or the pelicanu gracilis of Linnaeus.

It is somewhat larger than the common duck, and weighs about four pounds; its beak is straight and slender, and is not flattened, but roundish; it is four inches long, and is hooked at the end; its mouth opens very wide, and its eyes are small; the head is adorned with a crest, two inches long, pointing backward; the whole plumage of the upper part of this bird is of a fine and very shining green, the edges of the feathers a purplish-black; but the lower part of the back, head, and neck, wholly green; the belly dirty, and the legs black. It builds in trees as the common corncrant, swims with the head erect, and is very difficult to be shot;
SHAG, because, when it feeds the flesh of a gun, it tops under water, and does not rise but at a considerable distance.

SHAGR, in Geography, a town of Syria, in the pa-
chalic of Aleppo; 40 miles W. of Aleppo. N. lat. 35° 45'.
E. long. 36° 25'.

SHAGREEN, or CHAGREEN, derived from the Tartar
foghr, a kind of grained leather, prepared in Atra-
chan, chiefly by Tartars and Armenians, and mostly used in the
covers of cages, books, &c. It is very close and solid, and
covered with little roundish grains, or papille. It is
brought from Constantinople, Tunis, Tripoli, Algiers, and
some parts of Poland.

There has been a dispute among authors, what the animal
is from which the shagreen is prepared? Rauwolf affirms
us it is the onager, which, according to him and Bellonius,
p. 65.

It is added, that it is only the hard part of the skin which
is used for this purpose. Or, it is that part of the skin
that grows about the rump; that of horses is said to be
equally good. There are large manufactures of it at Atra-
chan, and in all Peria. Borel says, it is the skin of a fe-
calf; others, of a kind of fift, called by the Turks shagrain,
whose skin is covered with grains; and those so hard, that
they will rasp and polish wood.

There is also a sort of shagreen, which was formerly made
of the skin of the quaternia: in English, the monk or a-
gelfih, but now of that of the greater dog-fifh. Vide Wil-
lugby's lchth. p. 80.

SHAGREEN, Manner of preparing. The process for
making shagreen is as follows: of horse-hides and ass-hides
the hinder back-piece, cut off immediately above the tail in
nearly a semi-circular form about an arlaine and a half upon
the crupper, and rather less than an arlaine along the back,
is selected as the only part that is useful, and the rest is
thrown away. The back pieces thus cut out are laid in a
vat filled with clean water, and left in it several days suc-
cessively, till they are thoroughly soaked, and the hair comes
freely off. Then the hides are taken one by one out of the
vat, spread against a board let flapping against the wall, one
corner of it reaching over the edge of the board where it is
fasted; and in this position the hair is scraped off with a
blunt scper, urak, and with the hair the upper pellecie; and
the cleaned skin is laid again in clean water to soften. This
done, they take it a second time out, spread one piece after
another in the manner before described, scrape now the fleh-
side with the same fpering-iron, and the whole skin cleaned
again on the hair-side with great care, so that nothing now
remains of the softened skin but the clean finewy web which
serves for parchment, consisting of thick fiscenclous of mille
fibres, resembling a hog's bladder softened in water. After
this preparation they immediately take in hand certain
frames, palizi, composed of a strawberry piece and a fe-
cicular bow, forming therefore nearly the shape of the
skin, which is stretched in it with struts as even and uniform
as possible; and during this operation is sprinkled between
whiles with fair water, that no part of it can dry and occa-
sion an unequal extension. In like manner they finall
them when the whole flock of skins is stretched, and carry all
the thoroughly wetted skins into the work-room. There
the frames are one by one laid flat on the floor, so that the
flesh-side of the stretched skins is turned underneath.
The other side is now thick floored over with the black, very
smooth, and hard seeds of a species of the herb goose-foot,
or the greater orach (chenspodium album), which the
Tartars call alabuta, and which grows in great abundance,
and almost to man's height, about the southern Volga in farm-

yards and gardens; and that these may make a strong im-
pression on the skin, a felt is spread over them, and the seeds
fiod with the feet, by which means they are impelled
depthly into the very yielding skins. Then, without shaking
off these seeds, the frames are carried again into the open
air, and set leaning against a fence or a wall to dry, in
such manner that the hides covered with the seeds face the
wall and cannot be shown on by the sun. In this situation
the stretched skins must dry for several days successively in
the sun, till no trace of moisture is perceptible in them, and
they may be taken out of the frames. Then, when the
improved seeds are beaten off from the hair-side, it appears full
of little pits and roughfifhes, and has got that impression
which the grain of the shagreen ought to produce when the
true polish has been given to the skin by art, and the ley
now to be mentioned has been used previous to the basting of

The polish is done on a table, furnished on all trestles, and covered with
some thick felts or foldoks of sheep's wool, on which the
dried shagreen skin may lie soft. This is hung in the
middle, by a hole which has been occasioned by the basting in
the stretching, to the hook, and fastened at the end by a
basting with a weight or a stone, by means of which the skin
is allowed to move to and fro, but cannot easily be moved
out of its proper situation. This done, the polishing or
raping is performed by two several instruments; the first
is called by the Tartars tokar, being an iron hooked at one
end like a hook and sharpened, the other the shagreen
serated very sharply, in order to remove the most prominent roughfes, which from the horne hardkens of the dried skyn is no other matter, and in which great care
must be taken not to have awy too deeply the impression
of the alabuta seeds, of which there is imminent danger if
the iron is kept too sharp. As the blade of this iron is
very narrow, it will make the shagreen rather uneven, and
therefore after it, must be used the other fesper, or urak, by
which the whole surface acquires a perfect equality, and
only a slight impression remains of the seeds, exactly as it
ought to be. After all these operations the shagreen is laid
again in water, partly for rendering it supple and partly
to make the elevated grain appear; for the seeds having caused
pits in the surface of the skin, the interfaces of these pits have
left their prominent subtiance by the polishing or
shaving, and now the points that were pressed down, having
left nothing of their substance, spring up above the shaven
places, and thus form the grain of the shagreen. To this
end the pieces of shagreen are left to soften twice 24
hours in water, and are floated several times afterwards in a
strong and hot ley, which is obtained by boiling from an alkalefent
faine earth, fchora, found about Altrachan. From this ley
the skins are bundled warm one on another, and thus suffered
to lie some hours, by which they swell up and are softened in
an extraordinary manner. Again, they are left to lie
24 hours in a moderately strong brine of common salt, by
which they are rendered fine and white, and excellently
adapted to receive any agreeable colour, which the work-
man hantes to give them as soon as they are come out of
the pickle. The colour most commonly communicated to
the fine shagreen is the fea-green, as the most beautiful.
But the expert shagreen-makers have the art of making also
black, red, blue, and even white shagreen.

For the green dye, nothing more is necessary than fine
copper-filings and sal-ammoniac. As much of the latter
is melted in hot water as the water will admit. With this
sal-ammoniac water the shagreen skins, still moist from
the brine, are bruised over on the ungrained flesh-side, and
when they are thoroughly wetted, a thick layer of copper-filings

6
is spread over them, the skins doubled together, so that the dried side lies inwards, and then each, being rolled apart in a little felt or voil, they lay all these rolls orderly on one another, and press them equally by a considerable and uniformly pressing weight, under which they must lie twenty-four hours. In this time the fial-ammoniac water diffolves enough of the cupreous particles for penetrating the skin with an agreeable sea-green colour; and though it be not strong enough the first time, yet a second layer of copper-dust, wetted with fial-ammoniac water, with which the skins must lie again twenty-four hours, will be quite sufficient for staining them thoroughly; when they may be properly cleaned, spread out, and dried. For giving the blue colour to thugreen, they use only indigo, which to this end is not so prepared as for the silk and cotton-dyers, but entirely without bones, only by friction, is mingled and dissolved with the other ingredients. They put about two pounds of finely grated indigo in the kettle, pour cold water on it, and stir it till the dye begins to dissolve. They next dissolve in it five pounds of pounded ala-dar, which is a sort of barilla, or raw foda-falt, burnt by the Armenians of Kitzilzor, and a worfe kind by the Kal- mumyes, adding two pounds of lime and one pound of virgin honey, all thoroughly stirred, and left in the fun for several days, during which the stirring is frequently repeated. The thugreen skins which are to be made blue must be put only in the natron ley, schora, but not in the brine made of common salt. They are again folded up wet, and fewed close together round the edges, with the flesh-side turned inwards, and the thugreened hair-side outwards, upon which they are three times dipped in succeffion in an old store-dye kettle, at every time pressing out the superfluous dye; lastly, they are all brought into fresh dye, which must not be pressed out, and with which the skin is hung up in the shade to dry; they are, for the last time, cleaned, ornamented on the edges, and reduced to order. For the black thugreen they employ nut-galls and vitriol in the following manner: the skins, still moist with the brine, are thickly spread with finely powdered nut-galls, folded together, and laid one on another twenty-four hours. In the mean time a new ley of bitter earth-falts or schora is boiled and poured hot in little trowsers or trays. In this ley each skin is waved to and fro several times, is again spread with pulverized nut-galls, and again laid in heaps for some time, that the virtue of the galls may thoroughly penetrate the skins, which are then suffered to dry, and are beat out to clear them from the galls. When this is done, the skin is leared on the thugreen-fide with mutton fat, and laid a little in the sun, that it may absorb the fat. It is the custom, likewise, with the thugreen-makers to roll up each skin apt, and to squeeze and press it against some solid body, in order to promote the absorption of the cuticular particles. The surplus is again scraped off with a blunt wooden scraper. This done, and the skin having lain a little while, a sufficient quantity of iron-vitriol is dissolved in water, with which the thugreen is rubbed on both sides, by which it soon acquires a beautiful black colour; and now the edges and other defective parts are dried. To obtain white thugreen, the skin must first be steeped in strong alum-water on the thugreened side. Having imbied this, the skin is well rubbed on both sides with a paste of wheat flour, and left to dry with it; then all the paste is washed away with alum-water, and the skin is let to dry completely in the sun. As soon as the skins are dry, they are gently fmooed over with clean melted mutton fat, leaving them in the fun to imbibe it, and are worked and pressed with the hands to promote this effect. Afterwards the skins are fastened one by one on the above-mentioned stretching-bench, warm water is poured over it, and the superfluous fat scraped off with obtuse wooden instruments, to which the warm water just poured on has much afflighed. By this process the thugreen receives a fine white colour, and needs only, in conclusion, to be drelled and rubbed. This whiteness, however, is given to the thugreen, not so much that it may continue in that state, but in order to impart to it a beautiful high red hue, as this end could not be obtained to such perfection without that preparation. But the thugreens intended to be stained red must not be brought out of the natron better falt ley into the brine, but must be made white, in the manner above-described, and afterwards supplied with the brine, in which they are left to lie about twenty-four hours, or less, from the dye. The dye is made with cochenille or kirmis, as the Tartars call it. The operation is begun by boiling for a full hour about a pound of the dried herb fretsh, which grows plentifully on the falt steppe about Attrachan, and is a fort of kali, in a kettle large enough to contain about four common vedros of water, by which the water acquires a greenish colour. The herb is thun taken out, and about half a pound of grated cochenille put into the kettle, with which the above decoction must be boil another full hour, diligently flirring it on the fire, that the kettle may not boil over. Lastly, to this are added fifteen or twenty grains of the material which the dyers call litter (perhaps opium), let the dye boil a little more, and then take the fire from under the kettle. Then the skins taken out of the brine are laid separately in trays, pouring the dye upon them four times, rubbing it in with the hands, that it may be equally spread and imbied, pressing it out every time, which done, they are ready for drying and ornamenting, and fell much dearer than the others.

The best thugreen is that brought from Constaninople, of a brownish colour; the white is thinned. It is extremely hard; yet, when dipped in water, it becomes very soft and pliable; whence it is of great use among cafe-makers. It takes any colour that is given it, red, green, yellow, or black. It is frequently counterfeited by morocco, formed like thugreen: but this art is distinguished by its peeling off, which the first does not.

SHAGUM, in Geography, a river of America, which runs into lake Erie, N. lat. 41° 49′. W. long. 81° 27′.

SHAH, the Persian title corresponding to kia, and equivalent to khan. (See CHAM.) Nevertheless, the most absolute Persian monarchs, who have never assumed any other title than that of shah, have permitted the governors of provinces in their empire to take that of khan, which is its equivalent, and which they have ever affected. Even in our time, the governors of the provinces of Ghilan, Mazanderan, &c., who have no more authority in Persia than the pachas in Turkey, take the title of khan, the reason of which it is not easy to assign.

SHAHABAD, in Geography, a town of the kingdom of Candahar; 40 miles S.W. of Cabul. —Afzo, a town of Hindooftan, in the circle of Sirhind; 42 miles E.S.E. of Sirhind.—Afzo, a town of Hindooftan, in Oude; 45 miles W. of Kairaband. N. lat. 27° 40′. E. long. 80° 20′. —Afzo, a town of Hindooftan, in Oude; 25 miles S.W. of Mahomdy.

SHAHAMA, a name given to a colossal statue, cut in a mountain in the neighbourhood of the ancient city of Bamian, in the East Indies. This city, (which is described in our article BANIAN,) is eight days' journey north-westther from Cabul, and is rarely visited by Europeans, though highly deserving of examination. The statue in question is accompanied by another, called Salpala. Native travellers...
differ as to their height; from fifty cubits to eighty ells. Their origin, age, and sex, are also variously related. The few Hindoos who live in the neighbourhood, say, they are the statues of one of their heroes named Bhim, and his comfort. Bhim is one of the five famous Pandus. (See PANDU.) The followers of Buddha call them by the names first mentioned. The Mahomedans say, they are of Adam and Eve; and a third statue, half a mile distant, about twenty feet high, they say is of Seth, their son. The author of a celebrated Persian dictionary, entitled "Farhang Jahangir," says they existed in the time of Noah; but gives them other names. There can be little doubt but these statues, and the wonderful excavations of the city of Bamian, scooped, like Thebes, out of a mountain, were executed by the same indefatigable race of workmen, who in the more southern parts of India constructed the gigantic statues in the similar caverns at Kenera, on the island of Salsette, near Bombay, in the province of Kanara, and at Karly; all believed to be of Jaina or Buddhist origin. See JAINA, KARLY, and KENERA.

SHAHBUNDER, in Geography, a town of Hindoostan, in the province of Tatta; 45 miles S.S.W. of Tatta.

SHAHDOURAS, a town of Hindoostan, in the circle of Sirhind; 10 miles N. of Tannafar.

SHAHG, a town of Hindoostan, in Myfore; 18 miles S. of Venecathery.

SHAHJEEHAN, a town of Hindoostan, in Bahar; 18 miles N.W. of Bahar.—Also, a town of Hindoostan, in Rohilcund; 45 miles S. of Pilibhit.

SHAHJEEHANPOUR, a town of Hindoostan, in Malwa; 20 miles N.E. of Ougin, N. lat. 23° 26'. E. long. 76° 18'.—Also, a town of Hindoostan, in Oude; 30 miles S.E. of Fyzabad. N. lat. 26° 26'. E. long. 82° 40'.—Also, a town of Hindoostan, in Mewat; 20 miles W. of Alvar.—Also, a town of Hindoostan, in Bahar; 14 miles S.S.E. of Patna. N. lat. 25° 24'. E. long. 85° 30'.

SHAHIGIAN, a town of Persia, in the province of Khorasan, near Maru, which since is called Maru Shahigian.

SHAHJOLE, a circar of Bengal, bounded on the north by Raajehly, on the east by Mahmudj, on the south by Jelfore, and on the west by Kifsenagur; about 30 miles long, and from 5 to 10 broad.

SHAHISABI, a town of Persia, in the province of Khorasan, on the borders of Bucharia; 80 miles N. of Maru.

SHAHISHAK, a town of Persia, in the province of Khorasan, on the borders of Bucharia; 5 miles N. of Maru.

SHAHPOUR, a town of Hindoostan, in Lahore; 30 miles W. of Nagorcote.—Also, a town of Hindoostan, in Lahore; 27 miles E. of Scalcot.

SHAHR and VAN, the ancient Apollonia, a town of the pachalic of Bagdad, 27 miles from Bacoob, which is nine furings from Bagdad, peopled by about 4000 Turks and Kurds, and is, upon the whole, a handsome little town, watered by two canals drawn from the Dilia. At the distance of 18 miles is Kuzul Roobat, not so large as the former, situated in a sandy plain, about one mile from the river Dilia. Khanaikie is also a handsome little town, built on that branch of the Dilia, which has its source in the mountains of Kurzend, 18 miles from Kuzul Roobat; it occupies both banks of the river, over which is a handsome bridge, and is surrounded by numerous gardens and plantations. Mendell, about the same size as Solymania, is situated in one of the roads leading to Kermaiah; and four furings on the Bagdad side is a fountain of naphtha. Thirteen leagues from Mendell, and four from the foot of the mountains, is Bedri, the frontier town, in this quarter of the Turkish empire.

SHAIKI, a town of Nubia, on an island in the Nile; 130 miles E. of Dongala. N. lat. 20° 20'. E. long. 50° 45'.

SHAPIOL, a town of Persia, in the province of Khorasan; 10 miles S.W. of Maru.

SHAIMA, a town of Persia, in the province of Meidan, on the sea-coast; 200 miles W.S.W. of Kedge.

SHAINT, or HOLT, ISLES, three small islands of the Hebrides, or Western isles, are situated in the channel between the isles of Lewis and Skye, in the parish of Lochs and district of Lewis. These isles are well known to mariners, and are remarkable for their fine sheep pasturage. One of them, called St. Mary's island, has a small chapel upon it, dedicated to the Virgin, and bears marks of having been formerly better inhabited than at present. Sinclair's Statistical Account of Scotland, vol. xix. 8vo.

SHAINYMALY, a town of Hindoostan, in Combe- ton; 12 miles S. of Erroad.

SHAIZAR, a town of Syria, in the pachalic of Damascus, on the Orontes; 20 miles N. of Hamah.

SHAK, a town of Persia, in the province of Schirvan; 20 miles N.W. of Schamakche.

SHAKE, in Music, is a grace, an embellishment of melody, of which the indication is a ♮, or sometimes only †, the initial of the Italian term trillo, which implies the same thing. There are two kinds of shakes, the continued, and the transient. The continued shake, upon a long note, must be practiced at first by incipients, flow, and accelerated by degrees. The effect of a shake is a rapid motion of two adjoining notes: as dt, bc, &c.

In our didactic and elementary articles, we should not wish to confine ourselves to mere dry definitions of terms of art; but, having had some little experience, we would gladly affilt students, by pointing out the means of acquiring the practical use of what we describe.

With regard to a vocal shake, we can do young fingers no greater kindness, than in referring them to the 3d chap. of Tof's "Observations on florid Song," as admirably translated by Galliard, and illustrated with the notes of that able and experienced master.

Tofi, after informing the student of the importance of the shake to fingers, says, "Let the matter strive to enable his scholar to attain a shake that is equal, distinctly marked, easy, and moderately quick, which are its most beautiful requisites."

This excellent author describes the different kinds of shakes, and their preparation, that are worth cultivating, as well as those that are to be avoided. The free and open shake on the whole tone and the femiton, are certainly the principal.

The
The two tones or semitones that constitute the shake major or minor, should be equally loud and distinct; but above all, perfectly in tune with the notes of the general scale and particular key in which the performer is fingering. The Italians call a bad shake, or no shake at all, but a quivering upon the same note, toffe da capra, a goat's cough. If the finger is not polished of a true and good shake, he or she had better refrain from ever attempting it; and if accustomed to elegant melody, and polished of good taste and ornamental embellishments, the shake in fongs of expression and pathos may be avoided with advantage.

As the acquiring of a good shake in fingering is a work of time, difficulty, and uncertainty of success, several ingenious and elegant cadences have been invented in order to evade the shake. A good shake well applied is certainly a great ornament; but it is a matter of brilliancy more than expression; non discerente, it says nothing—according to modern Italian critics, and is seldom wanted except at the end of a formal close. Those who have a good shake, like persons with a fine set of teeth, are too ambitious of letting you know it. The different kinds of shakes are expressed in notes on the music-plates. The plain note and trill are at present thought more elegant, and are more frequently used than the sudden and long continued rapid motion of the common shake.

Close without a shake.

Shakes upon keyed instruments are best practised at first with the second and third fingers; holding down at the same time the fifth below with the thumb, to keep the hand and the wrist quiet. And we recommend, contrary to the usual practice and precepts, beginning the shake with the lowest note; otherwise, in rapid transient shakes on semi-quavers, there is not time for returning to the upper note; so that the shake is reduced to a mere appendage. See GRUPPO and TRILL.

SHAKER-Pigeon, in Ornithology, a kind of pigeons, of which there are two sorts, the broad-tailed, and the narrow-tailed.

The first is the finest, and most valued. It has a beautiful long thin neck, which bends like the neck of a swan, leaning towards the back. It has a full breast, a very short back, and a tail consisting of a great number of feathers, seldom less than four-and-twenty, which it spreads in an elegant manner, like the tail of a turkey-cock, and bends it up so, that it meets the head. It is commonly all white, but sometimes is red, yellow, or blue-pied. The longer the neck of this bird is, the more it is valued.

The second, or narrow-tailed shaker, has a shorter and thicker neck and a longer back. It is esteemed by many a different species, and seems only a mixed breed with some other pigeon. They are called shakers, from a tremulous motion which they have with their necks when courting.

SHAKERS, in Ecclesiastical History, a sect which originated in Lancashire, with some dissenters from the society of Quakers, or Friends, about the year 1747, and which continued for some time unconnected with every denomination of Christians. During this period, their testimony, derived, as they fancied and pretended, from what they saw by vision and revelation from God, was, "that the second appearing of Christ was at hand, and that the church was rising in her full and transcendent glory, which would effect the final downfall of Antichrist." From the shaking of their bodies in religious exercises, they were denominated Shakers, and by some persons they were called Shaking Quakers. The sect seems to have made no great progress until the year 1770, when the testimony originally announced was fully opened, according to the special gift and revelation of God through Ann Lee, who was born of obscure parentage, at Manchester, about the year 1736; and who, having joined the society in 1758, became afterwards a distinguished leader among them. Her exercises, both of body and of mind, were singularly trying and severe for about the term of nine years; but she was thus prepared for receiving the testimony of God, against the whole corruption of man, in its root and every branch. Accordingly, her testimony was in the power of God, attended with the word of prophecy, and such energy of the Spirit, as penetrated into the secrets of the heart, and was irresistible, especially in those with whom she was united.

And from the light and power of God which attended her ministry, and the certain power of salvation transmitted to those who received her testimony, she was received and acknowledged as the first Mother, or spiritual parent in the line of the female, and the second heir in the covenant of life, according to the present display of the gospel. Hence among believers, she hath been distinguished by no other name or title than that of Mother, from that period to the present day. To such as addressed her with the customary titles used by the world, she would reply, "I am Ann the Word;" signifying that in her dwelt the Word.

In 1774, Ann Lee, with some of her followers, having been thought mad, and fearfully persecuted, settled their temporal affairs in England, and left from Liverpool for New York. James Wardley and his wife remaining behind, were removed into an alms-house, and there died. The others, we are told, "being without lead or protection, left their power, and fell into the common course and practice of the world!" Ann Lee and the brethren reached New York, after working a sort of miracle, for the ship sprang a leak on the voyage, and it is more than hinted, that had it not been for their exertions at the pump, the vessel would have gone down to the bottom of the ocean! She, however, left New York, and fixed her residence up the Hudson river, eight miles from the city of Albany. In this retired spot, her followers greatly multiplied, but she was not without bitter reproaches and manifold perfections. She and the elders would delight in missionary journeys, being out for two or three years, and returning with wonderful accounts of their success.
After Mother and the elders were released from prison, they again collected together at Water-Vilet, where they were visited by great numbers from distant parts of the state of New York, Massachusetts, Connecticut, New Hampshire, and the district of Maine, who received faith; and through the power and gifts of God, which were abundantly manifested for the destruction of sin, and the salvation of souls, many were filled with joy unspeakable and full of glory, and increased in their understanding of the way and work of God.

Ann Lee died on the eighth day of the ninth month 1784. From the year 1780 to 1787 the credit of this fact revived in America, and the number of its adherents considerably increased.

The creed of the Shakers is very obscurely and mystically expressed. They seem to be believers neither of the Trinity nor of the Satisfaction. They deny also the imputation of Adam's sin to his posterity, as well as the eternity of future punishment. The tenets on which they most dwell are those of human depravity, and of the miraculous effusion of the Holy Ghost! Their leading practical tenet is the abolition of marriage, or indeed the total separation of the sexes. This circumstance of course attracts great attention, and they pride themselves on their superior purity. The essence of their argument is, that the resurrection spoken of in the New Testament means nothing more than conversion; our Saviour declares that in the resurrection they neither marry nor are given in marriage, therefore, on conversion or the resurrection of the individual, marriage ceases!!! To speak more plainly, the single must continue single, and the married must separate. Every passage in the gospel and in the epistles is interpreted according to this strange and unnatural hypothesis.

The system of the Shakers is thus very plainly described.

"In the fulness of time, according to the unchangeable purpose of God, that same Spirit and Word of power, which created man at the beginning—which spake by all the prophets—which dwelt in the man Jesus—which was given to the apostles and true witnesses as the Holy Spirit and Word of promise, which crowned them in waiting for the day of redemption—and which was spoken of in the language of prophecy as a woman travelling with child, and pained to be delivered, was revealed in a woman.

"And that woman, in whom was manifested that Spirit and Word of power, who was anointed and chosen of God, to reveal the mystery of iniquity, to stand as the first in her order, to accomplish the purpose of God, in the restoration of that which was lost by the transgression of the first woman, and to finish the work of man's final redemption, was Ann Lee.

"As a chosen vessel, appointed by divine Wisdom, she, by her faithful obedience to that same anointing, became the temple of the Holy Ghost, and the second heir with Jesus, her Lord and Head, in the covenant and promise of eternal life. And by her sufferings and travail for a loft world, and her union and exaltation to Christ Jesus, her Lord and Head, she became the first born of many sisters, and the true mother of all living in the new creation.

"Thus the perfection of the revelation of God in this latter day, excels, particularly, in that which respects the most glorious part in the creation of man, namely, the woman. And herein is the most condescending goodness and mercy of God displayed, not only in redeeming that most amiable part of the creation from the curse, and all the sorrows of the fall, but also in condescending to the lowest estate of the los of mankind.

"So that by the first and second appearing of Christ, the foundation of God is laid and completed, for the full restoration of both the man and the woman in Christ, according to the order of the new covenant, which God hath established in them for his own glory, and the mutual good and happiness of each other.

"And in this covenant, both male and female, as brethren and sisters in the family of Christ, jointly united by the bond of love, find each their correspondent relation to the first cause of their existence, through the joint parentage of their redemption.

"Then the man who was called Jesus, and the woman who was called Ann, are verily the two first foundation pillars of the church of Christ—the two anointed ones—the two first heirs of promise, between whom the covenant of eternal life is established—the first father and mother of all the children of regeneration—the two first visible parents in the work of redemption—and the invisible joint parentage in the new creation, for the increase of that seed through which all the families of the earth shall be blessed."

The Shakers record several cates which they pretend to be miraculous, but it is needless to enlarge on a system that is wholly founded in delusion.

SHAKERTOWN, in Geography, a town of Kentucky, in Mercer county, containing 256 inhabitants.

SHAKES, in Ship-building, a name given to the cracks or rents in a plank, &c. occasioned by the sun or weather.

SHAKING, a disease in sheep, consisting of a weakness in their hind quarters, so that they cannot rise up when they are down. There has not hitherto been found any remedy for this disease. It is probably of the nature of palsy, and to be removed by strong nervous stimulant remedies.

SHAKLES, on board Ship. See Shackles.

SHAKRA, in Geography, a town of Arabia, in the province of Nedsjed; 120 miles N.E. of Pad.

SHAKSPEARE, WILLIAM, in Biography, an English dramatic poet, is justly esteemed the most eminent and most interesting author of the ancient or modern world. His writings have progressively risen in popular estimation in proportion as they have been studied and analyzed. Some of his dramas are continually acted on the London and provincial stages; many critics and commentators, both English and foreign, have employed their pens, and exerted their faculties, in dissertations on the merits and defects of his productions. From the most trying and��itious ordeal of investigation he has risen in glory and greatness; and may, at the present time, be justly pronounced pre-eminent and unrivalled as a dramatic poet.

To Englishmen his writings are singularly estimable; for they have conferred on the country a literary immortality, which nothing less than the dissolution of "the great globe itself" can annihilate. Nor is he exclusively endeared and valuable to the man of letters; but all classes of artists, and even many artisans, have derived both fame and emolument through the medium of his works. It has been often remarked, that the prophet is never honoured in his own country, or appreciated by his contemporaries. Although this maxim is now merely considered as figurative, and the age of, and confidence in, prophecy is past, yet it may be fully and strictly applied to the meritorious author. After death, his whole merits are gradually unfolded; his talents and genius command admiration, and every reader and commentator seem eager to discover new beauties, and to point out hidden excellencies. Among the literary "worthies" of the world, from the days of Homer to Milton, no one has attained equal celebrity with Shakspeare. He now flames as the sun of the intellectual hemisphere, and every other poet seems to derive a reflected light from him, or moves in a less circumsterted orbit. Like divine nature, which was at once
his guide and goddefs, his writings excite admiration and
delight, the more intensely they are studied. Prompted by
inspiration, and impelled with profound knowledge, with
the keen and acute "poet's eye," he commanded every re-
gion of the terrestrial globe, penetrated the hidden thoughts
of man, gave to "airy nothing a local habitation and a
name," and aligned to every passion and sentiment "its true
form and feature."

--- "'Tis wonderful,
That an invisible instinct should frame him
To poetry unlearned; honour untaught;
Civility not seen in other; knowledge
That wildly grew in him, yet yielded crops
As though it had been sown; for he could find
"Tongues in trees, books in the running brooks,
"Sermons in fountains, and good in every thing."—
Do not smile at me that I boast him off.
For ye shall find he will outstrip all praise,
And make it halt behind him. — Dovaston.

Heaven has him now: let our idolatrous fancy therefore
fancify his reliques. Despairing to be his equals, let us
profit by his precepts; seek to acquire his wisdom; emu-
late his gentleness, talents, and honours. Conscions of the
comparative frigndnrs of our own faculties, let us warm our
hearts at his celestial fire, and kindle our fous at his unex-
tinguishable flame! If enthusiasm be justifiable on any sub-
ject, the writer of the present article hopes to fland execed
in giving this latitude to his feelings and expressions. He has
to regret, with thousands of others, that the subject of this
memoir is only known in his writings, and that his personal
history is as obscure as that of Heren or Archimedes. In-
deed, before we proceed farther, it is necessary to premise,
that a singular and unaccountable mystéy is attached to
Shakespeare's private life; and, by some strange fatality, almost
every document concerning him has either been destroyed, or
still remains in obscurity. The first published memoir of him
was drawn up by Nicholas Rowe, in 1709, nearly 100 years
after the decease of the poet; and the materials for this were
furnished by Betterton, a player. It should be remembered,
that the age in which he lived was not the age of minute in-
quiry. From Rowe's account, and from other evidence, it is
clear that our poet was not ambitious of posthumous fame;
that he disregarded the estimation of after ages; that he was
unconsciously the highermént of his own writings; and that,
though he was much in the public world, and died in com-
parative affluence, his private life and character were fiercely
noticed by the biographer or critic. To the man of taste
and refined sensibility, he has, however, bequeathed an ex-
haustless treasure in his dramatic productions; and these
constitute an essential part of the well-stored library, it is
equally essential to record every fact, and investigate every
problematic statement, relating to the ineludable author.

That he was born at Stratford-upon-Avon, in Warwick-
shire, on the 23rd of April 1564, is well ascertained; and
that he was baptized on the 26th of the same month, appears
by the parish register. He is there described as the son of
John Shakespeare, who, according to Rowe, and most sub-
sequent biographers, was "a considerable dealer in wool,"
and whose "family were of good figure and fashion." Oppo-
posed to this statement is that of John Aubrey, who entered
himself as a student in the university of Oxford, 1642, only
26 years after our poet's death, who derived his information
from "some of the neighbours" of Shakespeare, and who
appears to have made a practice of writing down every fact
and tradition that he heard relating to public characters.
His account is entitled not only to recital, but to cautious
consideration.

"Mr. William Shakespeare was born at Stratford-upon-
Avon, in the county of Warwick; his father was a butcher;
and I have been told heretofore by some of the neighbours, that
when he was a boy he exercised his father's trade, but when he
kill'd a calf, he would do it in a high style, and make a
speech. There was at that time another butcher's son in this
towne that was held not at all inferior to him for a
natural wit, his acquaintance and countenance, but dyed
young. This Wm. being inclined naturally to poetry and
acting came to London, I guess about 18, and was an actor
at one of the play-houses, and did act exceedingly well.
Now B. Jonson was never a good actor, but an excellent
instructor. He began early to make eflays at dramatic poetry,
which at that time was very lowe, and his plays tooke well. He was a handfome well-fap'd man, very
good company, and of a very ready, and pleafant Smooth
witt. The humour of — the confable in A Midsummer
Night's Dreame he happened to take at Grondon in Bucks,
which is the roadc from London to Stratford, and there
was living that confable about 1642, when I firll came to
Oxon. Mr. Jos. Howe is of that parih, and knew him."—
(See Warton's Life of Sir Thomas Pope.) — Ben Jonson
and he did gather humour of men dayly wherevhere they
came. One time, as he was at the tavern at Stratford-upon-
Avon, one Combes, an old rich ufurer, was to be bured;
he makes there this extemporary epitaph:

Ten in the hundred the devil allows
But Combes will have twelve, he sweares and vowes:
If any one affkes who lies in this tome,
"Hoh!" quoth the devill, "tis my John o'Combe.

He was wont to goe to his native country once a yere.
I thinke I have bee informed that he left 2 or 300 lib. per annum
there and there about to a filter. I have heard fir Wm.
Davenent and Mr. Thomas Shadwell (who is counted the
bell comedian we have now) fay, that he had a moft pro-
digous wit, and did admire his natural parts beyond all
other dramaticall writers. He was wont to fay that he
never blotted out a line in his life: fayd Ben Jonson "I
wish he had blotted out a thousand." His comedies will
remain wat as long as the English tongue is understood,
for that he handles mores hominum; now our present writers re-
lect so much upon particular persons and coxcombities,
that twenty yeres hence they will not be understood.

"Though, as Ben Jonson fayes of him, that he had but
little Latin and leffe Greek, he understood Latin pretty
well, for he had been in his younger yeares a schoolmater
in the country." The latter fact was communicated by Mr.
Beefon.

In another memorandum Aubrey notes that
"Mr. William Shakespeare was wont to goe into War-
wickshire once a yere and did comunely in his journey lyt
at this house in Oxon" (i.e. the Crowne tavern, kept by
the father of sir William Davenant,) "where he was exceed-
ingly respected. * * * * Now fir Wm. would some-
times, when he was pleafant over a glaffe of wine with his
moll intimate friends,— e.g. Sam. Butler (author of Hu-
dibras) &c. fay, that it femed to him that he writ with
the very spirit that Shakespeare, and feemed contented
enough to be thought his fon * * * *"—These anecdotes
are now published in "Letters written by eminent Perfonns
in the Seventeenth and Eighteenth Centuries," three vols.
8vo. 1813.

This account is truly curious and interesting; and in
spite of the scepticism of Dr. Farmer, in his “Effay on the Learning of Shakspere,” and of some other writers, the impartial reader must admit that it affumes the air of probability, candour, and truth. Aubrey might have erred in some points; particularly in saying, Shakspere visited London at the age of eighteen, when the registry of his own baptism, and that of his twin-children, shewed that he must have remained at home till the age of twenty. Again, it is very probable that he met with a confable at Grendon, or Long-Crendon, in Buckinghamshire, whose character he dramatized, not in “A Midsummer Night’s Dream,” but in “Much ado about Nothing,” or in “Love’s Labour’s Lost.” The extempore epitaph on John o’Combe is represented by Rowe, who gives it different to the above, as having been made during the life-time, and in the presence of the person commemorated, who is also said never to have forgiven the poet. In Aubrey’s relation there is nothing improbable, nor unreasonable, in a poet producing such lines sportively over his cups, and among convivial friends: it is a smart epigram on an unuruous character. Instead of leaving 300. per annum to a sister, he bequeathed as much to his daughter, as will be shown in the sequel. If there be any lurking prejudice against the profession of a butcher, let it be remembered, that the proud and ostentatious cardinal Wolley was the son of a butcher; and that the parentage of a Homer, a Milton, and a Shakspere, cannot be honoured or degraded by their ancestors.

“Honour and fame from no condition rise; Act well your part, there all the honour lies.”

The house in which our poet was born has been occupied by a succession of butchers from time immemorial. Besides, it is not at all improbable that the butcher and the wool-stapler were united in one person. Admitting this, we shall find Rowe and Aubrey in harmony, and one great difficulty removed.

The early education of Shakspere, as well as his parentage, is not ascertained: on this topic all the biographers and commentators have supplied us with conjectures and opinions. Chalmers, in his “Apology,” is at once ingenious, intelligent, and learned on this subject. Rowe observes, and many of his followers repeat the fame, that he “was bred for some time at a free school, where it is probable he acquired what Latin he was master of.” They proceed to remark, that “on leaving school, he seems to have given entirely into that way of living which his father proposed to him.” About the age of eighteen he married Anne Hathaway, daughter of a substantial yeoman, then residing at Shottery, a hamlet at Stratford. In the parish register we find that “Susanna, daughter of William Shakspere, was baptised May 26, 1583.” By the same record we learn that his wife produced him twins in 1584; and on the 2d of February in that year, the names of Judith and Hamnet are entered in the register. It must have been soon after this event that our poet visited the metropolis; but the cause of leaving his native place, as well as his object, connection, and prospects in London, are alike unknown. Rowe relates, and others have adopted the opinion, with some variation as to sentiment and inference, that, “falling into ill company,” he was induced, “more than once,” to afflict his associates in stealing deer from a park belonging “to Sir Thomas Lucy, of Charlecote, near Stratford. For this he was prosecuted by that gentleman so severely,” that he was first impelled to write a satirical ballad on him, and afterwards fly from his home to avoid arrest and imprisonment. This story, however, is not entitled to full credence; for though our young poet might have associated with some idle youths, and have accompanied them to the neighbouring park, either for the sake of catching deer, or for some less difficult and less hazardous enterprise, yet the circumstance appears improbable, and comes in such a questionable shape,” that before it be admitted as historical evidence against an amiable man and super-eminent author, it should be supported by “confirmations strong as proofs of holy writ.”

Without relying on this circumstance, or crediting another absurd story, of his holding horses at the door of a theatre for his livelihood, we shall find a rational motive for his visiting London, and resorting to the theatre, by knowing that he had a relative and townsman already established there, and in some estimation. This was Thomas Green, “a celebrated comedian.”

We now come to that era in the life of Shakspere, when he began to write his immortal dramas, and to develop those powers which have rendered him the delight and wonder of successive ages. At the time of his becoming, in some degree, a public character, we naturally expected to find many anecdotes recorded of his literary history: but, strange to say, the fame delusion of authentic incidents marks every stage of his life. Even the date at which his first play appeared is unknown; and the greatest uncertainty prevails with respect to the chronological order in which the whole series were written, exhibited, or published. As this subject was judiciously confided by Malone to be both curious and interesting, he has appropriated to its examination a long and laborious essay. Chalmers, however, in his “First Part of King Henry VI.” published in 1589, and commonly attributed to Shakspere, was not written by him, though it might receive some corrections from his pen at a subsequent period, in order to fit it for representation. “The Second Part of King Henry VI.” this writer contends, ought therefore to be considered as Shakspere’s first dramatic piece; and he thinks that it might have been composed about the year 1591, but certainly not earlier than 1590. The other dramas are placed in the following order of time by him and by Mr. George Chalmers.

According to Malone.

Troilus
SHAKESPEARE.

According to Mone.  
According to Chalmers.

Troilus and Cressida - 1602 1600
Measure for Measure - 1603 1604
The Winter’s Tale - 1604 1601
King Lear - 1605 1605
Cymbeline - 1605 1606
Macbeth - 1606 1606
Julius Caesar - 1607 1607
Antony and Cleopatra - 1608
Timon of Athens - 1609 1601
Coriolanus - 1610 1609
Othello - 1611 1614
The Tempest - 1612 1613
Twelfth Night - 1614 1613

Besides the above thirty-five plays, Shakspeare wrote some poetical pieces, which were at first published separately, viz.: “Venus and Adonis,” printed in 1593; “The Rape of Lucrece,” 1594; “The Passionate Pilgrim,” printed in 1599; “A Lover’s Complaint,” not dated; and a Collection of Sonnets, printed in 1609. The first and second of these poems were dedicated, as “the first heir of my invention,” to Henry Wriothesley, earl of Southampton; who, according to Sir William d’Avenant’s statement, presented the poet with the sum of 1000l. to make some purchase. If this be a fact, it is honourable to the liberality and good taste of the nobleman, and shows that the “poor Warwickshire lad” met with a munificent patron in an early stage of his literary career. Other circumstances tend to prove that his merits were known to, and admired by, some illustrious personages. Queen Elizabeth, whose ear was perpetually affayed by fullsome panegyric, and who encouraged all sorts of silly shows, May-games, and buffoons, was not insensible of Shakespear’s talents; for the commanded several of his plays to be acted before her; and having been much delighted with the character of Falstaff, as delineated in the first and second parts of “Henry the Fourth,” recommended, or perhaps commanded, thebard to portray the fat knight in love. Hence originated “The Merry Wives of Windsor”; some incidents in which may have pleased the daughter of Henry VIII., although they are justly repulsive to modern taste and delicacy. King James I. also attended the representation of many of our author’s plays. Sir William d’Avenant told Sheffield, duke of Buckingham, that the monarch wrote the poet “an amiable letter” with his own hand; probably to thank him for the compliment contained in the play of Macbeth.

Shakspeare, as already hinted, was an actor, as well as author of plays, and performed some of the characters in his own dramas. As late as the year 1603, only 13 years before his death, his name appears among the players of Ben Jonson’s tragedy of Sejanus. Thus it is evident that he continued to perform many years; but of his histrionic merits we have no satisfactory evidence. Hence on this point there is much diversity of opinion; some contending that he was an excellent actor, and others that he was only equal to the perfonication of his own character of the ghost in Hamlet. Some passages in his own writings prove that he was well qualified to appreciate and to describe the essentials of good acting. See Hamlet’s admirable advice to the players; the scene between Hamlet and his mother; and also the description of a tragedian in “King Richard III.” Aubrey states that Shakspeare visited his native town periodically; but we do not learn when he finally returned home. From a document in the possession of Mr. R. B. Wheler, the historian of Stratford, it appears that he was in London in November, 1614. At that time Mr. Thomas Green, a professional gentleman of that town, and a relative of Shakspeare’s, visited the metropolis, to obtain an act of parliament, or to settle some business relating to the inclosure of an open field, in which our poet was a party concerned. His memoranda are:

“Rec. 16. No. 1614, at 4 o’clock afr. noon, a letter fr. Mr. Bayli & Mr. Alderman, [the bailiff and chief alderman of Stratford-upon-Avon] dated 12. No. 1614, touching the inclosure busynes. Jovis 17. No. [1614] my coven Shakspeare comings yesterday to town, I went to see him how he did. He told me that they [the parties wishing to inclose] affurred him they meant to inclose no further than to Godspel bush, & so uppy straight (leaving out pt. of the Dungelys to the field) to the gate in Clapton heig & take in Salibury’s pce; & that they mean in April to fvey, the land & thyn to gyve fatisfaction & not before: & he & Mr. Hall [Shakspeare’s fon-in-law, probably present] say they think yr. [there] will be nothing done at all.” It appears that Mr. Green, after his return to Stratford, made the following entry, which is partly illegible. “23 Dec. [1614] a Hall Innes, wryt ten, one to Mr. Manyring—another to Mr. Shakspeare, with almost all the company’s hands to eyther. I also wryt myselfe to my cni. [cousin] Shakspear, the coppyles of all our . . . . . then also a note of the inconveniences wold. . . . . . by the inclosure.” Another part of the memorandum states, that the town of Stratford was then “lying in the ashes of desolation.”

We find that Shakspeare had purchased a house, called “New-place,” at Stratford, about three years before his death, where he resided in the style and character of a private gentleman. Here he died on the anniversary of his birth-day, April 23, 1616, and was interred on the second day after his death, in the chancel of Stratford church, where a monument still remains to his memory. It is constructed partly of marble and partly of stone, and consists of a half-length bust of the deceased, with a cushion before him, placed under an ornamental canopy, between two columns of the Corinthian order, supporting an entablature. Attached to the latter is the Shakspeare arms and crest, sculptured in bold relief. Beneath the bust are the following lines:

Judicio Pylivm, genio Socratem, arte Maronem,  
Terra tegit, populus xacet, olympus habet.

Stay, paller, why gosst thou by so faft,  
Read, if thou canst, whom envoyes death hath plaff  
Within this Monument, Shakspeare: whit whom  
Ovick natvr dde; whole name doth deck ys tombe  
Far more than cote; fish all yt he hath wright  
Leaves living art, but page to serve his witt.

On a flat flone, covering the grave, is this curious inscription:

Good fred for Jesvs’ sake forbeware,  
To digg the deat encoafed heare;  
Blest be ye man yt Spres these flones,  
And croid be ye yt moves my bones.

The common tradition is, that the four last lines were written by Shakspeare himself; but this notion has perhaps originated solely from the use of the word “my,” in the last line. The impression, says Mr. Malone, was probably suggested by an apprehension “that our author’s remains might share the same fate with those of the rest of his countrymen, and be added to the immense pile of human bones deposited in the charnel-house at Stratford.”
Mrs. Shakfpeare, who survived her husband eight years, was buried between his grave and the north wall of the chancel, under a stone inlaid with braies, and inscribed thus: “Here lyeth interred the bodye of Anne, wife of Mr. William Shakspere, who departed this life the 6th day of Avgust, 1623, being of the age of 67 yeares.”

Verea, tv Mater, tv lac vitamq. dedili,
Vae mihi; pro tanto mevne faixa dabo!
Qvam Mallem, amovest lapidem, bonus angel’ore
Exept vt Christus Corpus, imago tva,
Sed nil vota valent, vinias cito Christe refyrget,
Clavfs licet tvmvel mater, et altra petet.

The family of Shakspere, as already mentioned, consisted only of one son and two daughters. The son died in 1596; but both the daughters survived their father. The eldest, Susanna, married Dr. John Hall, a physician of Stratford, who is said to have obtained much reputation and practice. She brought her husband an only child, Elizabeth, who was buried, hrft to Thomas Naihe, esq. and afterwards to Sir John Barnard, of Abingdon, in Northamptonth: but had no issue by either of them. Judith, Shakspere’s second daughter, married Thomas Quercy, a gentleman of good family, by whom she had three children; but as none of them reached their twentieth year, they left no posterity.

Hence our poet’s last descendant was lady Barnard, who was buried at Abingdon, Feb. 17, 1669-70. Dr. Hall, her father, died Nov. 25, 1635, and her mother July 11, 1649; and both were interred in Stratford church under flat stones, bearing inscriptions to their respective memories.

Shakspere, by his will, yet extant in the office of the prerogative court in London, and bearing date the 25th day of March, 1616, made the following bequests.

To his daughter Judith he gave 150l. of lawful English money; one hundred to be paid in discharge of her marriage portion, within one year after his decease, and the remaining fifty upon her giving up, in favour of his elder sister, Susanna Hall, all her right in a copyhold tenement and appurtenances, parcel of the manor of Rowington. To the said Judith he also bequeathed 150l. more, if she, or any of her issue, were living three years from the date of his will; but in the contrary event, then he directed that 100l. of the sum should be paid to his niece, Elizabeth Hall, and the proceeds of the fifty to his sister, Joan, or Jane Hart, for life, with residue to her children. He further gave to the said Judith a broad silver gilt bowl.

To his sister Joan, besides the contingent bequest above-mentioned, he gave twenty pounds and all his wearing apparel; also the house in Stratford, in which she was to reside for her natural life, under the yearly rent of twelve pence. To her three sons, William Hart, — Hart, and Michael Hart, he gave five pounds apiece; to be paid within one year after his decease. To his grand-daughter, Elizabeth Hall, he bequeathed all his plate, the silver bowl above excepted.

To the poor of Stratford he bequeathed ten pounds; to Mr. Thomas Combe, his sword; to Thomas Ruffell five pounds; to Francis Collins, esq. thirteen pounds of shilling and eight-pence; to Hamlet (Hamnet) Sadler twenty-six shillings and eight-pence; to buy a ring; and a like sum, for the same purpose, to William Reynolds, gent., Anthony Nath, gent., John Hemyng, Richard Burbage, and Henry Condell, his “fellows;” also twenty shillings in gold to his godson, William Walker.

To his daughter, Susanna Hall, he bequeathed New-place, with its appurtenances; two meallouses or tenements, with their appurtenances, situated in Henley-street; also all his “barns, stables, orchards, gardens, lands, tenements, and hereditaments whatsoever, situate, lying, and being, or to be had, received, perceived, or taken within the towns, hamlets, villages, fields, and grounds of Stratford-upon-Avon, Old Stratford, Bishopton, and Welcombe, or in any of them, in the said county of Warwick; and also all that meallage or tenement, with the appurtenances, wherein one John Robinson dwellth, situated, lying, and being in the Blackfriars, London, near the Wardrobe; and all my other lands, tenements, and herediments whatsoever; to have and to hold all and singular the said premises, with their appurtenances, unto the said Susanna Hall, for and during the term of her natural life; and after her decease, to the first son of her body lawfully issue, and to the heirs male of the body of the said first son, lawfully issue; and for default of such issue, to the second son of her body lawfully issue, and to the heirs male of the body of the said second son lawfully issue; and for default of such issue, to the second son of his body lawfully issuing, and the heirs male of the body of the said second son lawfully issuing; and for default of such issue, to the second son of his body lawfully issuing; and for default of such issue, to the right heirs of me the said William Shakspere.”

To the said Susanna Hall and her husband, whom he appointed executors of his will, under the direction of Francis Collins and Thomas Ruffell, esqrs. he further bequeathed all the rest of his “goods, chattels, leaves, plate, jewels, and household stuff whatsoever,” after the payment of his debts, legacies, and funeral expenses; with the exception of his “second bed with the furniture,” which constituted the only bequest he made to his wife, and that by inheritance after the will was written out.

Among the mysteries connected with our poet’s private life and actions is one, which has hitherto escaped the invertebrate researches and countless opinions of his biographers and commentators. We have already seen, that his wife bore him three children in less than two years after marriage. In the Stratford register is an entry of “Thomas Greene, alias Shakspere,” in 1589-90, which excites some speculation respecting the fidelity of our bard’s wife; and it may be inferred from his will, that his lady could not have enjoyed much of his affection, to have been put off with only the bequest of a “second bed with the furniture;” besides, we do not hear of any other children by the poet.

The first collection of Shakspere’s plays was published in 1623, with the following title: “Mr. William Shakspere’s Comedies, Histories, and Tragedies. Published according to the true original copies. London, printed by Izaac Jaggard and Ed. Blount, 1623, folio.” This volume was edited by John Hemyng and Henry Condell, and was dedicated to “the most noble and incomparable pair of brethren,” William, earl of Pembroke, and Philip, earl of Montgomery. In the title page, prefixed to the list of the author, with the engraver’s name, “Martin Droeshout, sculptor, London,” and on the opposite page are these lines by Ben Jonson, addressed to the reader:

“Thus figure thou here from put: It was for gentle Shakspere cut, Wherein the graver had a fire With nature to outdo the life: O, could he but have drawne his wit As well in brasse, as he hath hit His face; the print would then surpass All that was ever writ in brasse. But, since he cannot, Reader, looke Not on his picture, but his Booke.” B. I.
SHAKESPEARE.

The above volume was carefully reprinted, in close imitation of the original, a few years back, by J. Wright, for Vernor and Hood, London. A second edition of Shakespere's plays was published, in folio, in 1632, a third in 1664, and a fourth in 1665. These several impressions are usually denominated "ancient editions," because published within the first century after the death of the poet, and before any comments or elucidations were employed to expand the original text. Some of his dramas were published, in 4to., during his own life.

Of those editions which are distinguished by the title "modern," the earliest was published by Nicholas Rowe, in 1709, in 7 vols. 8vo. This was followed by an edition in 9 vols. 12mo. by the same author, in 1714; and to both were prefixed a biographical memoir of the illustrious bard. In 1725, Pope, who first introduced critical and emendatory notes, published his edition in 6 vols. 4to. with a preface, which Johnson characterizes as valuable alike for competition and justness of remark. A second edition by the same editor was published in 10 vols. 12mo., with additional notes and corrections, in 1728. The successor of Pope was Theobald, who produced a very elaborate edition in 7 vols. 8vo. in 1733; and a second, with corrections and additions, in 8 vols. 12mo. in 1745. Sir Thomas Hanmer next turned his attention to the illustration of Shakespere, and in 1744 gave the world an edition of his plays in 6 vols. 4to. Warburton published his edition in 8 vols. 8vo. in 1747; from which time no critic attempted the task till the year 1765, when Dr. Johnson's first edition made its appearance in 8 vols. 8vo. It was preceded by an able and ingenious preface, in which the character of Shakespere's writings are commented on in a powerful style of eloquence, but with a severity far removed from accuracy and justice. Indeed Johnson did not fully understand the varied merits of his author, but in 1766, Steevens published the twenty "Old Plays," in 4 vols. 8vo. This was followed, in 1768, by an edition in 10 vols. crown 8vo. by Mr. Capell. Next came out, in 1771, a second and improved edition in 6 vols. 4to. by Sir Thomas Hanmer, which was succeeded by an edition in 10 vols. 8vo. in 1773, by John and Steevens, conjointly. Of this last, a second edition was published in 1778; a third, revised and corrected by Reed, in 1785. In the year following was produced the first volume of the dramatic works of Shakespere, with notes by Joseph Rams, A.M. which work was completed in 6 vols. 8vo. in 1794. In 1784, was published, in 1 vol. royal 8vo. an edition by Stockdale, with a very copious index of passages, by the Rev. Mr. Ayseough. Bell's edition appeared in 1788, in 20 vols. 18mo.; and in 1790 Malone's was ushered into the world in 10 vols. crown 8vo. In 1793, a fourth edition, "revised and augmented," in 15 vols. 8vo., was produced by Mr. Stevens. A fifth edition, in 21 vols. 8vo., was published in 1825, from the text and with the notes of Johnson, Steevens, and Reed; and another edition of 21 vols. with corrections, &c. appeared in 1831.

Many other impressions of our author's plays have been published by different booksellers, in different sizes, and of various degrees of typographic merit. Most of them, however, are unauthentic reprints: but many have the popular attraction of embellishments. The most splendid of this class was published by Boydell, in 9 vols. folio, embellished with 100 engravings, executed by and from artifs of the first eminence. The same work was also printed in 4to. In 1805 was published an edition of Shakespere's plays in 10 vols. 8vo., with a prefatory effay by Alexander Chalmers, F.S.A. and a print to each play from a design by Henry Fuseli, efq. R.A. The last edition of this kind has just appeared in 7 vols. 18mo. with 250 engravings on wood, from the tasteful press of Whittingham.

Steevens estimated, at the time he published his notes on Shakespere, that "not less than 35,000 copies of our author's works" had been then dispersed; and it may now be confidently said, that nearly 100,000 of them have been printed and sold.

From what has been already stated, it is evident that the writings of Shakespere have progressively acquired considerable popularity; and that they now rank as chief, or the first thing, of British classics. This high celebrity is to be attributed to various secondary causes, as well as to their own intrinsic merits. To players, critics, biographers, and artists, a large portion of this popularity is to be ascribed; for had the plays been represt by Garrick, Kemble, &c. as originally published by Condell and Hemyng, or reprinted verbatim from that text, the specta tors to the one, and readers of the other, would have been comparatively limited. It is talent only that can properly represent and appreciate talent. The birth and production of one man of brilliant genius, will stimulate the emulation, and call into action the full powers of a creative mind.

Hence the British theatrical hemisphere has been repeatedly illuminated by the corruptions of Garrick, Henderson, Pritchard, Kemble, Siddons, Cooke, Young, and Kean; and these performers have derived no small portion of their justly acquired fame from the exquisite and powerful writings of the bard of Avon. Whil s the one may be considered as the creator of thought and inventor of character, the others have perfected and given "local habitation" and existence to the poetical vision. The painter has also been usefully and honourably employed in delineating incidents, and portraying characters from the poet; while the engraver has translated these designs into a new language, and given them extensive circulation and permanent record.

The confummate acting of Garrick tended, in a great degree, not only to revive the fame of Shakespere, but to augment and extend it. The peculiar powers of Betterton, and of his other dramatic predeccessors, have not been sufficiently defined to enable us to estimate their real talents; but those of the English Roscius have been commented on and described by so many able critics, that we are certain they were of the most accomplished kind. He was therefore amply qualified to personify, and give life and effect to the characters of Macbeth, Hamlet, Lear, Richard the Third, Romeo, &c.; and by his exquisite representation of these historic personages, the public were additionally delighted and astonished with the amazing genius of the author. Since Garrick's time other actors have judiciously chosen some of Shakespere's characters, as best calculated to their own talents; and as the most certain touchstone of passion. A Kemble and a Siddons have enwreathed their brows with never-fading laurel by diligently studying and successfully personating many of our poet's great characters. As the former has acquired a well-earned fame in portraying Macbeth, Lear, Coriolanus, Prospero, Cardinal Wolsey, Richard, Hamlet, and Otello; the latter has astonished and gratified many thousand spectators by her horrifying representation of lady Macbeth, her dignified playing of the queen in Henry VIII., and the queen in Hamlet; by her commanding powers in Portia; and in her pathetic eloquence of Ophlemon. Cooke displayed the characters of Richard the Third, Iago, and Shylock, with great skill and excellence; and in the present day, Kean has personated these characters, with that of Richard II. and Hamlet, so as to command the approbation of the most acute and intelligent critics.

Vol. XXXII.
The number, variety, and versatility of commentaries that have been successively published on the text of Shakespeare's plays almost exceed credibility; and a foreigner, or stranger to the subject, would be more than astonished, were he to be told that the whole of one mass before him. The number, variety, and versatility of commentaries that have been successively published on the text of Shakespeare's plays almost exceed credibility; and a foreigner, or stranger to the subject, would be more than astonished, were he to be told that the whole of one mass before him. It is true, that many of them are unimportant and useless, but it is equally true, that several of his critical annotators have displayed much research, learning, and acuteness; and to such the philologist and poetical antiquary are much indebted. It was our intention to have given a concise account of the whole, but the whole would be too vast and repellant to the poetical mind. The chief editors of his plays have been already noticed, as well as the respective eras of their different writings. Rowe was the first to add any thing to the original text, by prefixing a memoir of the author. This memoir has been reprinted with almost every succeeding edition, and without any alteration or comment, until Malone accompanied it with notes to his edition of 1790. Mr. Alexander Chalmers, in an edition of 1805, has prefixed a "Sketch of the Life of Shakespeare," in which he has adopted most of the statements of Rowe, with the additional and corrective remarks of Malone and Steevens. "The whole, however," he remarks, "is unsatisfactory. Shakespeare's private characters, in his friendships, in his amusements, in his cloths, in his family, is no where before us."

The plays of Shakespeare are divided into three classes, and called in the first edition 4 comedies, histories, and tragedies. Each is of a distinct character; but in some of them there is a mixture of the three in one. "The Merry Wives of Windsor," "The Comedy of Errors," and "The Taming of the Shrew," are all comedies; but they have something of both kinds. It is not easy to determine in which way of writing he most excelled. His Falstaff is universally allowed to be a master-piece: the character is always well fullamed, though drawn out into three plays; and even the account of his death, given by his landlady, Mrs. Quickly, in the last act of Henry V, is as natural and diverting as any part of his life. "If there be any fault," says the critic, "in the draught he has made of this aged fellow, it is, that though he has made him a thief, a liar, and a coward, and, in short, every way vicious, yet he has given him so much wit, as to make him almost too agreeable; and I do not know whether some people have not, in remembrance of the amusements which he had formerly afforded them, been sorry to see his friend Falstaff come to be curiously when he comes to the crown, in the end of the second part of Henry IV. Among other extravagancies in the "Merry Wives of Windsor," he has made him a dcer-streaker, that he might have the opportunity of remembering his Warwickshire precursor under the name of Justice Shallow." The whole play is admirable, the humours are various and well opposed; the main design, which is to cure Ford of his unreasonable jealousy, is extremely well conducted.

Another of the characters which has been fixed on, as one of Shakespeare's fine delineations, is that of Shylock, the Jew, in "The Merchant of Venice," in which there appears such a deadly spirit of revenge, such a savage fierceness, and such a bloody designation of cruelty and mischief, as cannot agree either with the fyle or character of comedy, though usually ranked as such. Taken altogether, it is perhaps one of the most refined of Shakespeare's pieces; the tale indeed is improbable in some of its parts; but taking the facts for granted, the story is beautifully written. There is something in the friendship of Antonio and Belfanio very great and generous. The whole fourth act is extremely fine, but there are two passages that are universally known and applauded, the one is in praise of mercy, and the other is on the power of music.

The melancholy of Jaques in the comedy of "As you like it," is as singular and odd, as it is amusing, and if, according to the maxim of Horace,

"Difficile est proprium communi dicere,"

it will be a hard task for any one to go beyond him in the description of the severer degrees and ages of a man's life. See the article Age.

His images are indeed everywhere so lively, that the thing he would represent stands out before you, and you possess every part of it. Rowe mentions his image of Patience in the person of a young woman in love, as one of the finest and most uncommon things ever written; it is as follows:

"She never told her love; But let concealment, like a worm 'tis bud, Feed on her damask cheek; she pin'd in thought, And fat like patience on a monument Smiling at grief."

The style of his comedy is, in general, natural to the characters, and easy in itself; and the wit most commonly sprightly and pleasing, except in those places where he runs into doggerel rhymes. But the greatness of this author's genius does nowhere so much appear, as where he gives his imagination the entire loofe, and raises his fancy to a flight above mankind, and beyond the limits of the visible world. Such are his attempts in the Tempest, Midsummer Night's Dream, Macbeth, and Hamlet. Of these, the Tempest is thought by able critics to be the most perfect in its kind of any thing that Shakespeare has left behind him. His magic hath something in it very solemn, and very poetical; and that extravagant character of Caliban is extremely well sustained, and shews a wonderful invention in the author, who could strike out such a particular wild image, and it is certainly one of the finest that was ever exhibited to the human imagination. It has been said by able judges, that "Shakespeare had not only found out a new character in his Caliban, but had also devised and adapted a new manner of language for that character."

It is the same magic that raises the fairies in the Midsummer Night's Dream, the witches in Macbeth, and the ghost in Hamlet, with thoughts and language so proper to the parts they sustain, and so peculiar to the talent of this writer. "If," says the author whom we have so often quoted, "one undertook to examine the greatest part of his tragedies by those rules which are established by Aristotle, and taken from the model of the Grecian stage, it would be no difficult task to find a great many faults; but as Shakespeare lived under a kind of mere light of nature, and had never been made acquainted with the regularity of those written precepts, so it would be hard to judge him by a law of which he was ignorant. We are to consider him as a man, that lived in a state of almost universal licence and ignorance; there was no established judge, but every one took the liberty to write according to the dictates of his own fancy. When one considers, that there is not one play before him of a reputation good enough to entitle it to an appearance on the present stage, it cannot be but a matter of great wonder, that he should have advanced dramatic poetry so far as he did.

"It is now a received article of literary faith in England, that notwithstanding the faults and defects with which Shakespeare abounds, and which were chiefly those of his age, no dramatist in any country has displayed such intimate
SHAKESPEARE.

intimate knowledge of the human heart; such extensive acquaintance with nature in its various forms, an imagination so powerful and poetical, and such a copiousness of moral sentiment expressed in the most forcible language." Dryden says, "he was a man, who, of all modern and, perhaps, ancient poets, had the largest and most comprehensive soul. All the images of nature were still present to him, and he drew them not laboriously, but luckily. When he desires any thing, you more than see it, you feel it too. He needed not the spectacles of books to read nature; he looked inwards, and found her there. I cannot say he is every where alike; were he so, I should do him injury to compare him with the greatest of mankind. He is many times flat and insipid: his comic wit degenerating into clenches, his ferious swelling into bombast. But he is always great, when some great occasion is presented to him. No man can ever say, he ever had a fit subject for his wit, and did not then raise himself as high above the rest of the poets,

"Quantum lenta solent inter viburna cupreli."

Shakespeare, like most men of pre-eminent talents, is said to have been much affailed by the attacks of envious rivals, notwithstanding that gentleness and good nature were the peculiar characteristics of his personal deportment. Among those who are said to have treated him with hostility was the celebrated Ben Johnson; but Dr. Farmer departs from the received opinions on this subject, and thinks that, though Johnson was arrogant of his scholarship, and publicly professed a rivalry of Shakespeare, he was in private his friend and associate.

Pope, in his preface, says, that Jonson "loved" Shakespeare "as well as honoured his memory; celebrates the honesty, openness, and frankness of his temper; and only distinguishes, as he reasonably ought, between the real merit of the author, and the silly and derogatory applauses of the players." Mr. Gilchrist, who has been the most profound and acute of the many who have treated him with hostility, has published a pamphlet, to prove that Jonson was never a harsh or an envious rival of Shakespeare; and that the popular opinion on this subject is founded in error. The following story respecting these two great dramatists is related by Rowe, and has not been generally credited by subsequent biographers. "Mr. Jonson, who was at that time altogether unknown to the world, had offered one of his plays to the players, in order to have it acted; and the perfons into whose hands it was put, after having turned it carelessly and superciliously over, were just upon returning it to him with an ill-tempered answer, that it would be of no service to their company, when Shakespeare luckily cast his eye upon it, and found something so well in it, as to engage him to read it through, and afterwards to recommend Mr. Jonson and his writings to the public."

The opposition or rivalry of Shakespeare and Jonson produced, as might naturally be expected, much contention concerning their relative merits, between their respective friends and admirers; and it is not a little remarkable, that Jonson seems to have maintained a higher place in the estimation of the public in general than our poet, for more than a century after the death of the latter. Within that period Jonson's works are said to have passed through several editions, and to have been read with avidity, while Shakespeare's were comparatively neglected till the time of Rowe. This circumstance is in a great measure to be accounted for on the principle that classical literature and collegiate learning were regarded in those days as the chief criteria of merit. Accordingly Jonson's charge against Shakespeare was the want of that species of knowledge; and upon his own proficiency in it, he arrogated to himself a superiority over him. That all classical scholars, however, did not function. Jonson's pretensions, is certain; for among the greatest admirers of Shakespeare, was one of the most learned men of his age, the ever-memorable Hales. On one occasion, the latter, after listening in silence to a warm debate between Sir John Suckling and Jonson, is reported to have interposed by observing, "That if Shakespeare had not read the ancients, he had likewise not stolen any thing from them; and that if he (Jonson) would produce any one topic finely treated by any one of them, he would undertake to shew something on the same subject, at least as well written, by Shakespeare." A trial, it is added, being in consequence agreed to, judges were appointed to decide the dispute, who unanimously voted in favour of the English poet, after a candid examination and comparison of the passages produced by the contending parties.

In September, 1769, was celebrated the Shakespeare jubilee, at Stratford, under the direction of Garrick.

Shakespeare was fond of music, and not wholly ignorant of the art. He not only frequently introduces masques for music in his plays, but singing almost all his fourteen comedies; and even in most of his tragedies, where this wonderful and exquisite dramatist has manifested the same predilection for music as poetry.

In the "Tempell," the use that he has made of it is admirable, as well as the description of its effects. Act 1. sc. 5. Ariel, invisible, playing and singing to Ferdinand, says,
Where should this music be, i' th' air or earth?
It founds no more; and sure it waits upon
Some god o' th' island.

And afterwards:

"This is no mortal busines, nor no found
That the earth owns: I hear it now above me."

Indeed, the serious part of this most fanciful play is very fortunately calculated for an opera. Shade-well, in the last century, made one of it, in the manner of what were then called operas on our stage. It has been performed of late years more as a musical masque, than opera or play, at Drury-lane, to the music of the late Mr. T. Linley, as it used to be to that of Dr. Arne, and others. The songs in this play, Dr. Wilton, who refelt and published two of them, tells us, in his "Court Ayres, or Ballads," published at Oxford, 1660, that "Full fathom five," and "Where the bee suckes," had been first set by Robert Johnson, a composer contemporary with Shakespeare.

Act ii. sc. 1. "Enter Ariel playing solemn music." We never could understand this indication: no music seems to be heard by the characters on the stage, nor do they take any notice of it through the whole scene. Afterwards, when with music and a long he acquaints Gonzalo of the danger he is in, his million has meaning. "While you here do firing live," &c.

Even Caliban talks well about music:

"The birds are full of notes,
Sounds and sweet airs, that give delight and hurt not."

Ariel never appears or is employed without music, which is sweetly described, and introduced with perfect propriety. Prospero calls for medicinal music:

"A solemn air, and the best comforter
To an unfetted fancy, cure thy brains."

Midsummer Night's Dream.

Act ii. sc. 5. "Come now a roundel, and a fairy song." If, as Dr. Gray says, a roundel is "a dance in a ring," a roundelay was the song and tune to such dance; as ballad, from ballata, Italian; &c. roundelay, from rondelet, old French, round, modern.

The ideas and language of fairyism are wonderfully imagined and supported in this play; and the use assigned to music happy and fitful.

Act iv. sc. 1. "Rural music, songs, &c." Poker and songs, narrow-bones and cleavers, falt-box, hurdy-gurdy, &c. are the old national instruments of music on our island.

Queen. "Music, ho! music: such as charmeth sleep."

Still music, meaning such soft and gentle music as tranquillizes, soothes, and lulls to music.

Act v. sc. 1. In the lift of sports ready for the nuptial feast of Theseus, is "the battle with the Centaurs; to be sung by an Athenian swain to the harp." This scene to imply a more ancient practice of castracion for the voice than can be found in opera annals.

Speaking of Quince, in the clown's prologue, Hippolita says, "indeed, he hath play'd on his prologue, like a child on a recorder; a found, but not in government."

Two songs alluded to in the last scene of this play are lost.

Oberon. "And this ditty after me
Sing and dance it trippingly."

Queen. "First rehearse this song by rote,
To each word a warbling note;
Hand in hand, with fairy grace,
Will we sing, and blest this place."

"Two Gentlemen of Verona.

Though this comedy furnishes fewer occasions for music than the two preceding dramas, yet musicians are employed in it as well as musical allusions. As Ben Jonson, in his masque of "Cynthia's Revels," speaks of the gamut or syllables of solmisation, ut, re, mi, fis, fol, la, which palfmifiers had made well known to his audience; so Shakespeare, in this play, act i. sc. 3. introduces all the musical terms then in use: as, a tune, a note, a light, a heavy tune, burden, melodious to reach high, keep in tune, sing out, too sharp, too flat, concord, harsh descant, the mean ehoen, &c.

Act iv. sc. 7, there is a laboured description of the powers of poetry and music; Orpheus's lute, concert, spelt as now:

"— to their instruments
Tune a depearing dump,"—
or lament (lamentation), sung by a wretched and forsaking lover in the dump.

Sec. 2. A serenade, or nocturno, is introduced:

"— nowplaint to her window,
And give some evening music to her ear."

Enter Musicians.

"— now, gentlemen,
Let's tune, and to it lustily."

Song. "Who is Sylvia? what is she?" &c.

"Measure for Measure."

Though this play has left music in it than the three preceding, yet at the beginning of act iv. a song, from his own Passionate Pilgrim: "Take, oh, take those lips away," is sung to Mariana by a boy, who is sent away on the arrival of the duke, in the character of a friar; when apologizing for the seeming levity of listening to music, the says:

"I cry you mercy, sir, and well could with
You had not found me here so musical."

To which the duke anwers:

"It's good; though music oft hath such a charm,
To make bad good; and good provoke to harm."

This is a heavy charge, which it would not have been easy for Shakspere to substantiate, and does not very well agree with what he says in the "Tempest," of the innocuous efficacy of music. "Sounds and sweet airs, that give delight, and hurt not." Music may be applied to licentious poetry: but the poetry then corrupts the music, not the music the poetry. It has often regulated the movements of lascivious dances; but such airs heard, for the first time, without the long or dance, could convey no impure ideas to an innocent imagination; so that Montesquieu's assertion is still in force: that "music is the only one of all the arts, which does not corrupt the mind."

"Merchant of Venice."

Act ii. sc. 1. A flourish of cornets when the Moorish prince comes in.

Act ii. sc. 6. "The vile squeaking of the wry-neck'd life."

SHAKESPEARE.

Act iii. sc. 2. “Let music found, while he doth make his choice; Then, if he lose, he makes a swan-like end, Fading in music. — he may win; And what is music then? then music is As are these dulcet founds at break of day, That creep into the dreaming bride-groom’s ear, And summon him to marriage.”

Music within.

A song while Baffano examines the caskets:

“Tell me where is fancy bred,” &c.

The passages in the fifth act of this interisting play are beautiful, numerous, and celebrated:

“And bring your music forth into the air,” &c.

“soft illincs and the night

Become the touchs of sweet harmony.”

Jellica. “I am never merry when I hear sweet music.”

This is the initial of a well-known, and now proverbial, eulogium on modulated found: “The man that has no music in his soul,” &c.

“As you like it.”

Act ii. sc. 1. A song:

“Under the green-wood tree,” &c.

Remarks on music by Jacques. Then another song:

“Blow, blow, thou winter’s wind.”

Music. Song: “What shall he have that kill’d the deer.”

Song: “’Twas a lover and his lady.”

Still music. Song: “Then is there mirth in heav’n.”

Another song: “Wedding is great Juno’s crown.”

“Love’s Labour’s lost.”

This is a most beautiful and comprehensive requost: none of the fine arts can subsist, or give rapture, without passion. Hence mediocrity is more intolerable in them than in other inventions. Music without passion is as monotonous as the tolling of a bell.

But no song is printed: though the author tells us there is singing. Dr. Johnson says, “here is apparently a song lost.”

Music as for a masquerade.

Songs for spring and autumn:

“When daisies pied.” — And, “When icicles hang on the wall.”

“Winter’s Tale.”

Two nonsensical songs, by the rogue Autolycus:

“When daffodils begin to peere.” — “Jog on, jog on, the lost pathway.”

“He’s main musical.” This Autolycus is the true ancient minstrel, as described in the old Fabliaux. See Gen. Hist. Mus. vol. ii. p. 208.

A three-part catch, ready planned by the poet, and another pedlar’s song: “Will you buy any tape?”

“Twelfth Night.”

Act i. sc. 1. This play opens with a beautiful eulogium on music:

“If music be the food of love, play on,” &c.

The use of Evirati, in the same manner as at present, seems to have been well known at this time (about 1600). For Viola says:

“I’ll serve thee the doctor;

Thou shalt pretend me as a eunuch to him,

It may be worth thy pains, for I can sing,

And speak to him in many sorts of music,

That will allow me very worth his service.”

And the duke’s sensibility to the power of music is disclosed in the first interview, when he says to Viola:

“thy small pipe

Is as the maiden’s organ, thrill and found,

And all its emotivat—a woman’s part.

I know thy constellation is right apt

For this affair?”

Fupposing her to be a eunuch.

Act ii. sc. 3. The clown is asked for a love-song, and sings:

“O wiltfrels mine, where are you roaming?” &c. And

“What is love? ’tis not hereafter,” &c.

Ibid. They sing a catch, beginning,

“Hold thy peace.”

Sc. 4. Scraps of songs and catches are roared out by sir Toby, sir Andrew, and clown, as “Three merry men be we.” — “Tilly, valley, lady!” — “There dwell a man in Babylon, lady, lady.” — “O the twelfth day of December.” — “Farewel, dear heart, since I must needs be gone.” — “His eyes do thwew his days are almost done.” — “Shall I bid him go? what, an’ if you do?” — “Shall I bid him go, and spare not? O no, no, no, you dare not.”

All these, probably, were well known in Shakspeare’s time.

Sc. 5. The duke, who is as constant in his passion for music, as for Olivia, says:

— give me some music now—

Now, good Cesario, but that piece of song,

That old and antique song, we heard last night;

Methought, it did revived my passion much;

More than light airs, and recollected terms;

Of these most brisk and giddy-paced times:

— how dost thou like this tune? —

It gives a very echo to the seat

Where love is thron’d.”

Ibid. — the song we had last night—

— it is old and plain;

The spinners and the knitters in the fun,

And the free maids that weave their thread with bones.

Do use to chant it: it is silly footh,

And dally with the innocence of love,

Like the old age.”

Song: “Come away, come away, death.”

Act iv. sc. 4. The clown, as elsewhere, is much addicted to singing. Song, by the clown:

“When that I was a little tiny boy,” &c.

Serves as an epilogue to this entertaining play.
In "The Taming of the Shrew," no other use is made of music than to introduce minstrels at the wedding, and disguise Hortensio in the character of a man well fen in music, to facilitate his admission to the presence and courtship of Bianca; an expedient, however, which was unsuccessful.

More fragments of old ballads are here quoted than in any other of Shakspere's plays; though, as Dr. Warburton said, "he seemed to bear the ballad-makers a very particular grudge, and often ridicules them with exquisite humour."

In "The Comedy of Errors," music has no admission or concern.

"Much ado about Nothing."

Music at the masquerade, Act ii. Sc. 2. And in Benedick's dainty description of such an all-accomplished woman as could ever incline him to wed, he adds to her qualifications, music: "of good discourse, an excellent musician, and her hair of what colour it shall please God." Sc. 8.

Act ii. Sc. 9. The song, "Sigh no more, ladies, sigh no more," is introduced by several reflections on music, and the affectation of fingers. Baltazar, the musician and servant to Don Pedro, was perhaps thus named from the celebrated Baltazarini, called "De Beaujolayaux," an Italian performer on the violin, who was in the highest fame and favour at the court of Henry III. of France, 1577. In the last act, Sc. 8, the epitaph and song are beautiful, and well calculated for music.

"All's Well that ends Well."

Historical plays. "King John."

No music but trumpets and the din of war.

"King Richard II."

Act i. Sc. 4. Military instruments are admirably described:

"—rous'd up with boift'rous untun'd drums,
And harf' refounding trumpets dreadful bray."

Ibid. Mowbray, duke of Norfolk, on being ordered into banishment, says:

"My native English, now I must forego;
And now my tongue's ufe is to me no more,
Than an unfringed viol, or a harp;
Or, like a cunning instrument cas'd up,
Or being open, put into his hands
That knows no touch to tune the harmony."

Act ii. Sc. 1. "—the tongues of dying men
Inforce attention, like deep harmony:
—more are men's ends mark'd, than their lives before;
The setting fun, and music in the clofe,
As the laft faple of sweets, is sweetest laft—"

Ibid. Sc. 3. Speaking of John of Gaunt's death:

"—all is faid,
His tongue is now a stringless instrument."

Act v. Sc. 10. Richard, in his prifon, fays:

"—Music do I hear?
Ha, ha! keep time: how low're sweet music is,
Where time is broke, and no proportion kept?"

Here he plays on musical terms for several lines.

All instruments played with the bow, in Shakspere's time, were frettet, except violins.

In "The Taming of the Shrew," Act ii. Sc. 3, he could not refit the temptation of quibbling on the term fret.

"Frets call you them? quot hfe: I'll fume with them."

"—then call'd I rafeal, filder,
And twangling Jack!"

alluding to a famous street musician of the time.

"First Part of Henry IV."

Act i. Sc. 2. Falstaff says he's as melancholy as the "drone of a Lincolnshire bagpipe."

Act ii. Sc. 3. "An I have not ballads made on you all, and sung to filthy tunes, let a cup of fack be my poifon."

Act iii. Sc. 3. "—thy tongue
Makes Welch as sweet as ditties highly pinn'd,
Sung by a fair queen in a fummer's bow'rs,
With ravifhing divifion to her lip's."

"Second Part of Henry IV."

Induction. "—Rumour is a pipe,
Blown by furnifes, jealousies, conjectures;
And of too eafy and too plain a flop,
That the blunt moniler with uncounted heads,
The fill discordant wavering multitude,
Can play upon it."

We advanced no farther in hunting through the pleafant wilds of Shakspere; but in dipping accidentally, the following paffages struck us as worthy of notice.

"Henry V."

Act i. Sc. 2. There is a manifest allusion to the different parts of music.

"For government, though high, and low, and lower,
Put into parts, doth keep in one content,
Congrening in a full and natural clofe,
Like music."

In "Othello," Act iv. Sc. 13. Desdemona says:

"My mother had a maid, called Barbara;
She was in love; and he, the lovd, prov'd mad (faffe),
And did forfake her: she had a song of willow,
An old thing 'twas, but it expres'd her fortune,
And she did finge it. That fong, to-night,
Will not go from my mind; I've much ado,
Not to go hang my head all o' one fide,
And finge it like poor Barbara."

"King Lear," Act i. Sc. 7. "O, these eclipses portend these divisions! fa, fol, la, mi."

None of the commentators have hitherto been sufficiently skilled in music to fay the meaning of these fyllables in folfatation, which imply a feries of founds fo unnatural, that ancient musicians prohibited their ufe. "Mi contra faeul disbolus," Shakspere, however, fews by the context, that he was well acquainted with the property of the musical intervals contained in the tritone, or sharp fourth, which confifiting of three tones, without the interversion of a femitone, is extremely difficult to finge, and difagreable when
when fung, if mi, or fa, is the last note of the phrase or passage.

Shakespeare’s Cliff, or High Cliff, in Geography, a lofty cliff on the E. coast of England, in the county of Kent; so called from the beautiful description of it given by that poet in the tragedy of King Lear; 2 miles S. of Dover.

Shaky, or Shaken, a natural defect in timber when it is full of splits or clefis, and will not bear the falling line, or when fawn into plank the creaking.

Shal, in Geography, a district of Persia, in Balouchistan, the country of the Balouches, which is confidered by some as a province distinct from Mekran (the ancient Gedroia), and which commences at Koohme (the hilly road), 25 miles N.E. of Bayla, or in N. lat. 26° 35', and extends to Noohky, 79 miles N.W. of Kelat, or in N. lat. 39°. This country is a confedent maze of mountains, through which the road generally leads in water-courses. Flocks of sheep and cattle abound in every part of this country, and it also produces great quantities of wheat. It is divided into the two mountainous provinces of Jhalawan and Sarawan, the low country of Cutch Gandava to the E., and the province of Zuhree and Anund Dijel; and to these may be added the small districts of Shal and Mulung, lying N. of Kelat. This is the most southern province of Balouchistan, and Sarawan (which see) is the most northern part of Cutch Gandava, situated at the bottom of the mountain lying S.E. of Kelat, is about 150 miles long, and 40 or 50 broad. Its soil is rich, black, and loamy, and produces every species of grain, as well as cotton, indigo, madder, &c. Cutch Gandava exports great quantities of grain to the sea-ports of Coraeean and Sonamay, whence it is shipped to Mufcat, the coast of Mekran, &c. Anund Dijel lies N. of Cutch Gandava: its climate is good, the soil excellent, and the productions abundant; so that the khan of Kelat derives a large revenue from this small district. Shal and Mulung are smaller than Anund Dijel, but they are remarkable for their fruits, which are excellent and cheap. The climate is warmer than that of Kelat; the soil is more sandy; but the grain and other products are the same. (See Zuhree.)

Of Balouchitan is Kelat, a town surrounded by a mud-wall, and containing 4000 houses, and about 7000 inhabitants, of whom about 500 are Hindus. The bazar of Kelat is well supplied, and the town appears opulent, being frequented by merchants, and carrying on a considerable trade. N. lat. 29° 6'. E. long. 67° 57'.

Shalberg, a mountain of Switzerland; 4 miles N. of Sargans.

Shalberis, a cirque of Hindoostan, bounded on the N. by Goragot and Bettoorah, on the E. and S. by Bettoorah, and on the W. by Bettoorah and Dinagepore; about 18 miles from N. to S. and nearly as much from E. to W. The chief town seems to be Carter. Shaldeah, a town of Hindoostan, in Bahar; 7 miles S.W. of Rotagur.

Shale, in Natural History, a variety of chelitose clay: the first variety is denominated flat black, the felcherion Then of Werner. (See Clay.) The second variety is bituminous slate, the brand felcherion of Werner, of a brownish-black, or blackish-brown, colour, appearing like bad coal; it is found in considerable stratified masses: lathre, or slices; transparence, 0; fracture flatly; fragments tabular; hardness, 5; sp. gr., about 2600; breaks somewhat glossy; effervescing, though very slowly, with the mineral acids: feeling rather greasy; placed on burning coals, it burns with a weak flame and fulphurous smell, the residuum being light-grey; it seems to differ from the former variety, in containing bitumen. Kirwan. See Tabular Spar.

The acid emitted from shale, during its calcination, uniting itself to the argillaceous earth of the shale, forms alum. About a hundred and twenty tons of calcined shale will make one ton of alum. The shale, after being calcined, is steeped in water, by which means the alum, which is formed during the calcination of the shale, is dissolved: this dissolved alum undergoes various operations, before it is formed into the alum of the shops. Watton's Chem. Eff. vol. ii. p. 315. See Alum.

This kind of slate forms large stratified in Derbyshire; and that which lies near the surface of the earth is of a softer and more shivery texture than that which lies deeper. It is also found in large stratified, generally above the coal, in most coal counties of this kingdom. Dr. Short informs us, that the shale wafles the lead ore near it, by its strong acid; and that it corrodes and destroys all minerals near it, except iron or coal, of whose vitriol it partakes. See Slate.

Shallop, Shallop, or Sloop, is a small light vessel, with only a small main-mast, and fore-mast, and lug-sails, to hale up, and let down, on occasion. Shallop vessels are commonly good failers, and are therefore often used as tenders upon men of war.

The French shallop is a large-decked sloop of burden, used in Holland and Flanders, having one mast, carrying a gaff-main-sail. On the fore-side of the mast, above the gaff, is a short spar projecting forwards; to which is bent a long narrow sail, the tack of which is made fast to the stem, and the sheet to the side near the shrouds. On the bowsprit are set two or three jibs, and a small main is often fixed abaft that carries a mizen.

Shallop, in Gardening, the common name of a very useful culinary plant. See Allium.

To what has been said under the above head, it may here be necessary to add some improvements, which have since been made, in the culture of these small bulbous roots. As the habits of growth in roots of this nature differ greatly in the different soils, some requiring to be nearly or quite on the surface of the ground, while others fland in need of being a considerable depth below it, which has not been well attended to in the garden culture of such roots; it may be readily supposed that these have considerable influence and effect on the growth of such root crops. In consequence of finding that crops of this root generally became mouldy and perished, and that they were usually planted, from the directions of garden cultivators, at the depth of two or three inches from the surface; the injury, failure, and destruction of such crops, were naturally ascribed to this cause. A few bulbs or bunches of this root were consequently divided, as far as possible, into single buds or bulbs, and planted upon or rather above the surface of the ground, some very rich soil being placed underneath them, and the mould on each side raked to support them, until they became firmly rooted. This mould was then removed by means of a hoe, and the use of the watering-pot, and the bulbs of course left wholly out of the ground. The growth of the plants had now to bear a resemblance to that of the common onion, as not readily to be distinguished from it, until their irregularity of form, the consequence of the numerous germs within each bulb, became evident. The forms of the bulbs, however, continued conflantly different from all those raised in the ordinary method, being much more broad, but of less length. The crop was a great deal better in quality, and at the same time much more...
more abundant in quantity. It may consequently not be unworthy of the gardener’s attention. See the Transactions of the Horticulural Society of London, vol. ii. p. 97.

Shallop Creek, in Geography, a river of North Carolina, which runs into the Atlantic, N. lat. 33° 53’. W. long. 78° 28’.

Shallow. See Shool.

Shaltoch Cairn, in Geography, a mountain of Scotland, in Aythire; 12 miles E. of Girvan.

Sham, Ei. See Damascus.

Shamade, in W. See Shamade.

Shamal Apaleam, in Geography, a town of Hindoostan, in Coimbetore; 15 miles N.E. of Coimbetore.

Shamarashup, a town of Hindoostan, in Coimbetore; 18 miles S.W. of Erroad.

Shame, a river of West Florida, which runs into Pentaclea bay.

Shamble, or Shammel, in Mining, a term used to express a fort of rich, or landing place, left at certain distances in the adits of mines, and formed by a lage of boards. The method of digg ing the tin-mines in Devonshire, and some parts of Cornwall, is this; they sink their way in such a breadth as is sufficient for them to land and work, and at every fathom they leave a square place vacant, to which the ore is to be thrown up with shovels as it is dug. This they do from call to call; that is, as far as a man can conveniently throw up the ore with his shovel. Thus the ore, as it is dug by the beartmen, is thrown up by the shovelers, who follow them from shamble to shamble, till it comes to the top of the mine. This, however, is but an inconvenient way, and the use of these shambles is generally supplied by a winder at the opening of the mine, which manages two buckets, the one of which is fent down empty, while the other is fent up full; and one man employed below to load, and another to empty. Phil. Trans. N°60. See Mining.

Shambles, or Shingles, in Geography, a bank of sand in the English Channel, near the coast of Dorsetshire, about four miles E. by S. from Portland Bill, with 14 feet at low water.

Shambrier, in the Manager, a long thong of leather, made fast to the end of a cane, in order to animate a horse, and punish him, if he refuses to obey the rider.

Shambypatam, in Geography, a town of Hindoostan, in the Carnatic; 36 miles S. of Tanjore.

Shamdara, a town of Allam, in the Burmanpo ter; 65 miles N.W. of Gerghonghe.

Shame, in Ethics. See Passion.

Shameran, in Geography, a town of Curdian; 18 miles S. of Sherezur.

Shammy, Chamy, or Chamois, a kind of leather, either dressed in oil, or tanned; much esteemed for its softness, pliability, &c.

It is prepared from the skin of the chamois, or shamoo, a kind of rupicapra, or wild goat, called also ifard, inhabiting the mountains of Dauphinie, Savoy, Piedmont, and the Pyrenees. See Chamois.

Besides the softness and warmth of the leather, it has the faculty of bearing soap without damage; which renders it very useful in many accounts.

In France, &c. some wear the skin raw, without any preparation. Shammy leather is used for the purifying of mercury; which is done by passing it through the pores of the skin, which are very close.

The true chamois leather is counterfeited with common goat, kid, and even with sheep-skins; the practice of which makes a particular profession, called by the French shamoi-
the mill, they undergo a particular preparation called 
romalling; the most delicate and difficult of all the others. It 
conflicts in this, that, as soon as brought from the mill, 
they are steeped in a fix liquid, taken out, stretched 
on a round wooden leg, and the hair is scraped off with 
the knife; this makes them smooth, and, in working, to 
call a kind of fine koap. The difficulty is in scraping them 
evenly.

SHAMOKIN, in Geography, a town of Pennsylvania, 
in Northumberland county, containing 2027 inhabitants.

SHAMOKIN Creek, a river of Pennsylvania, which runs 
into the Susquehanna. N. lat. 40° 51'. W. long. 76° 53'.

SHAMZANGU, a town of Peru, in the province of 
Larillan.

SHANCORI, a town of Persian Armenia; 12 miles 
W.N.W. of Kauja.

SHANDECAN, Big, a town of New York, in the 
county of Ulster, 14 miles N.W. of Kingston.

SHANDECAN, Little, a town in the same county; 12 miles 
N.W. of Kingston.

SHANDYMUNGULUM, a town of Hindoo, in 
Baramaul; 8 miles E. of Namacul.

SHANEDI, a town of Nubia, on the right bank of the 
Nile; 45 miles S.W. of Nubia.

SHANGOLDEN, a small post-town of Ireland, in the 
county of Limerick; 115 miles W.S.W. from Dublin.

SHANGRA, a country of Africa, W. of Mocaranga.

SHANGRAP, a town of Hindoo, in Marawar; 20 miles 
S.S.E. of Tramul.

SHANK, in Conchology, the Sanscrit name of that 
species of shell, which gives its name to Europe in this 
branch of natural history. French and other foreign writers 
spell the word shank. The easy substitution of a hard 
for a soft initial, has led to a supposition that conch may 
by early writers have been taken from the same source as 
shank, or even derived from it. The shank, or shank, or 
conch, is the large buccinum, and is often seen beautifully 
coloured like a pheasant's breast. With the Hindoos, the 
shank is an object of mytical reverence. It is seen in one 
of the four hands of their deity Vishnu, and is one of his 
commonest attributes. Images and pictures of him are 
indeed distinguished more by this than by any other mark. 
It has of course a fabulous or mythological origin; and we 
accordingly find it among the "fourteen gems" that were 
recovered from the ocean, after a general deluge, as related 
under the article Kuramvanah of this work, where the 
shank is said to be a shell conferring victory on 
any one who should find it." In the distribution of the 
precious articles, the shell seems to have fallen to the share 
of Vishnu.

Shells, as aiming implements, were much used in early 
Indian wars, as trumpets and drums are with us. In the 
terrible civil wars between the Pandus, and their kinmen 
the Kurus, as Homerically described in the Mahabarat, 
Krithuna used a shell named Panchajanya, obtained in 
the manner related under our article Kasya, from a sea-
monster named Sankagura, which fee. Each chief in the 
war was allowed to bone a shell, to which, like the swords 
of our chivalous knights, distinct and significent names are given. 
In the portion of the Mahabarat translated by Mr. Wilkins, 
called Bhagavat Gita, the following passage occurs: "The 
ancient chief, and brother of the grand fire of the Kurus, 
then shouting with a voice as roaring lion, blew his shell 
to raise the spirit of the Kurus chief; and importantly insu-
merable shells, and other warlike instruments, refounded on all 
shells—the changour was excelle. Krithuna and Arjun, 
standing in a splendid chariot drawn by white horses, 
found their shells of celestial form; that blown by Krithuna 
was named Panchajanya; Arjun's, Devata. Bhim, of 
dreadful deeds, blew his capacious shell Pundra; and 
Yudhitya, the royal son of Koini, founded Ananta-Vijaya.
Nakal and Sahadeva blew their shells also, the one called 
Sugriva, the other Manipushpak; so that their thrill 
shuffling voices pierced the hearts of the Kurus, and 
recheced with a dreadful noise from heaven to earth." P. 29.

The shells in question are articles of commerce in India, 
to no inconsiderable extent. A changour fishery on the 
island of Ceylon is noticed by Mr. Cordiner. It is in the neigh-
bourhood of Maanar, (see Maanar), and yields, Mr. Cor-
diner says, a considerable revenue to government.
The shells, he says, are brought from the depth of two fathoms 
by divers, who, in a calm day can, from a boat, see them 
crawling at the bottom. Such as are of a spiral form are 
chiefly exported to Bengal, where they are sawed into rings 
of various sizes, and worn on the arms, legs, fingers, and 
toes of the Hindoos, both male and female. A changour 
opening to the right, that is with its spiral line contrary to 
its usual direction, is rarely met with, and is highly valued 
by myrtics and zealots. They always sell, Mr. Cordiner 
says, for their weight in gold. History of Ceylon, vol. ii. 
p. 6.

Univalves of the forre here alluded to, called heterostrophous 
by conchologists, are very rarely of any species, and are looked 
on with admiration in all countries; but with the enthusi-
sastic Hindoo in a degree unequalled. A Yogi, or Saniaifi 
of the Vaithnava sect, deems himself extremely happy in 
such an acquisition. The shell in question is frequently seen in the 
hands of itinerant holy beggars, and it is found in some 
of the temples and religious ceremonies of the Hindoos.

SHANK of an Anchor, on board a Ship. See Anchor.

SHANK of a Horse, in the Manege, the name of that part 
of the fore-leg which is between the knee and the fetlock, 
or pattern joint. The larger and broader the Shank is the 
better. It is known to be fo, by the back finew being at a 
distance from the bone, or well separated from it, and hav-
ing no kind of swelling betwixt it and the bone, which may 
cauc the leg to appear round.

SHANK, or Shank-panther, in a Ship, is a short chain fas-
tened under the foremast-cribrous, by a bolt, to the ship's 
seeds, having at the other end a rope fastened to it. On 
this Shank-panther the weight of the aft-part of the 
anchor rests, when it lies by the ship's side. The rope by 
which it is hauled up, is made fast about a timber-head. See 
Painter.

SHANK, Sheep, a sort of knot made on backflays, &c. to 
shorten them.

SHANKER, in Medicine. See Shankre.

SHANKLIN CHINE, in Geography, a ledge of rocks on 
the E. coast of the Isle of Wight, N. of Ludecomb Chine.

SHANMUKA, a name of a celebrated hero in Hindoo 
Mythology, more commonly called Kartikya; which fee. 
The name Shanmuka means with six mouths or faces, he 
being so represented; the reason of which is given under 
the article referred to. See also Seshti-Matriya, another 
of his names.

SHANNON, in Geography, the chief river of Ireland, 
and the largest in any island in the world. The name is sup-
posed to be derived from the Irish words shum, old, and 
non, a river. Other derivations, however, are given, all of 
which seem equally fanciful and uncertain; as the names of 
rivers are in general more ancient than even the names of the 
states through which they flow. Prokemy calls the Shan-
non Srum; Orolius, Senn; and Æthicus, Steena. 
It is called by Girdalus Cambrenis Flumen Senufis; who
SHANNON.

The principal rivers that fall in from the right bank, or Connaught side, are the Key, Suck, Scariff, and Fergus. The confluence of the Key is at Carrick, and the Suck, which divides the counties of Roscommon and Galway, flows in at Clonfert above Banagher. Several smaller rivers fall in from the county of Galway; and from Clare flow the Scariff and Fergus; but the great weight of water comes from the other side by rivers running from eall to well, which, it may be remarked, is different to the usual course in other parts of the world. The Inny is the first great river on the left bank; it is the boundary between the counties of Longford and Westmeath, and falls into Lough Ree, where it forms a large estuary. The second river on this side is the Great Brolin, which forms a fine confluence with the Shannon above Banagher; and the Lefler Brolin, united with the Birr river, falls in a few miles below that town. From hence to Limerick many smaller rivers flow in on the Ormond side, and below that city there are some larger ones: the principal are the Maig, Deel, Ovan, Cummage, Feale, Oyle, and Callin. Several of the above are navigable to a considerable distance from the Shannon.

From such an accumulation of rivers, lakes, and springs, the mouth of the Shannon is increased to an immense magnitude, being nearly ten miles in breadth, for the last fifteen miles, and from twenty to thirty fathoms deep. It is not only larger than any other infular river, but discharges much more water into the ocean than any continental stream whatever, running to short a distance than two hundred miles. Camden seems to credit a tradition, commonly believed in his time, of a gradual increase in the number and size of the lakes and rivers of Ireland. The supposition is curious, and may not be wholly unfounded.

As the Shannon from Limerick to the ocean is of great and increasing importance to the commercial world, we shall here give some particulars of its navigation from an hydrographical survey lately made. The distance is above sixty English miles, and the bearing nearly W. by S. The breadth of the river is various. If the length be divided into three parts, the first will be found to measure from one to three miles broad; the middle division increases to about six, and the third to ten miles in breadth. The foundings of the mouth have already been mentioned: they decrease towards Limerick; but in all parts the river is of considerable depth, and is remarkable for its transparency.

The tides in the mouth of the Shannon rise from nine to fourteen feet perpendicular height; and they increase as the river becomes narrower, and is much that at the pool of Limerick, they are from twelve to twenty feet high. The current of the tide varies considerably in different parts of the stream, running at the rate of from two to five miles an hour. It is not, however, perceptible far above the city, owing to several cataracts.

There are many fine bays on the Clare side, which afford safe anchorage and good shelter for shipping. The principal are Kilbaha, Carigahault, Clonderlaw, and Laphabeda, besides the commodious harbour of Poulainish, near Kilruth, and Tarbert bay on the Kerry side. It may be mentioned, that Kerry Head, also called Ballyheigh Point, is a long and narrow promontory; and that Cape Lean, or Loop Head, on the other side, is still narrower; having at its extremity a light-houfe, in N. lat. 52° 20'. W. long. 10° 12'.

The navigation between the Upper and Lower Shannon was formerly impeded by the noted cataract near Callyconnel, called the Salmon's Leap, but of late years canals have been drawn round this rock as well as others called the Falls. An important communication has been likewise opened between the Shannon and Dublin by means of the grand canal, which
which forms its junction above Banagher. (See our article CANAL.) It may be observed, that the Shannon nearly imitates Connaught with the county of Clare; and that if a canal, of about four miles in length, were cut from Lough Ree to the river Bonnet, which falls into Sligo bay, the insular boundary would be complete, and the Shannon rendered navigable from sea to sea.

The bridges over this river are chiefly at the forementioned towns, but there are none below Limerick. In this city there are three, one of which, called Thomond bridge, contains fourteen arches; and about ten miles higher is O'Brien's bridge, which has nineteen arches.

The fisheries on the Shannon are numerous and productive, particularly for salmon, which is of the finest flavour. Mr. Arthur Young, in his Tour through Ireland, p. 359, oberves of this river, that "besides affording all sorts of wild fowl, the quantity and size of its fish are amazing. Pikes swarm and rise to the weight of 50lbs. each. Trout, bream, cel, gillaroo, &c. are large and abundant, and perch are so plentiful, that, in some years, the poor almost live upon them." It may be added, that not only river fish, but even such as are generally denominated pond and lake fish, abound there; so that what Spenser says of the Trent may be truly applied to the bounteous Shannon, which

——"Within itself enfeames,
Both thirty forts of fish, and thirty Candy streams."

The Shannon forms a very important subject in the ancient history of Ireland. Trollemy mentions three large cities on its banks, called Regia, Macolicum, and Regia Altera. But his editors, Mercator and Ortelius, do not exactly agree in their maps as to the situations, and no vestiges remain to settle the question. The general opinion is, that Regia was on the east side of Lough Ree, and the names correspond, as Regis signifies a King, in the Irish language. Macolicum is supposed, from the name, to have been at Melick, a village in the county of Galway, and Regia Altera at or near Limerick.

This river was of great political and military use before the English power was established in Ireland. It long served as a barrier between the territories of provincial kings, and not unfrequently was made the scene of naval engagements, particularly below Limerick. The following curious instance is recorded in the Annals of Mnundlé, and quoted by Archdall. "This year (1665), Hugh O'Kuark, king of Briefne, in company with Thady O'Kelly, king of Maine, were defeated by Hugh O'Connor, king of Connaught, who totally overthrew their whole army, and sunk and dispersed their fleet on the Shannon." (Monastic Hibernicum, p. 280.) Even in modern times this river has been occasionally found of great military importance. See our articles ATHLONE, and LIMERICK.

The islands on the Shannon add an interesting feature to the history of the early progress of Christianity in Ireland; particularly from the fourth to the eighth century, when that country enjoyed a repose unknown on the continent, and was famed by the "Infusa Sacra et Sanctorum," or, to use the words of Dr. Johnson, "the pious and hospitable school of the well." During that period many of those isles were dedicated to the service of religion, and numerous vestiges still are seen in the remains of churches, abbeys, and other monastic institutions. The holy isle in Lough Derg has already noticed, and there are many others of a similar description, which are still held in pious veneration by the multitude, and are much referred to on certain festivals. We shall mention only another, which is Inniscattery, in the mouth of the Shannon, about twenty mile

from the ocean, and which is thus described by Archdall. P. 49.

"On the rich and beautiful island of Scattery, are the ruins of a monastary dedicated to St. Senan, who founded here an episcopal see about the time of St. Patrick. There are likewise the ruins of seven churches, out of eleven which were here in queen Elizabeth's time. An ancient round tower of one hundred and twenty feet in height, and in complete repair, graces the scene." For a more particular account of these "Infusa Sacra et Sanctorum," see Gough's Camden; also Ware, Wilton, Archdall, &c.

The views of the Shannon are in many parts highly picturesque and sublime. We shall briefly notice three. The first is from a beautiful hill in Lower Ormond, called Knockshegowans, i.e. Oonagh's hill, so named as being the fabled residence of Oonagh, Spenser's Fairie Queen. From this eminence the river is seen to an extent of nearly twenty miles, apparently extending in its course. The second is from the admired ruins of Carrick O'Gunnel, beyond Limerick; and the third from Knockpatrick, a lofty hill in the same county, and much nearer to the sea. It is celebrated by several writers as commanding the most grand and interesting prospect that can be imagined both of the river and the ocean. Among these authors may be mentioned Neham, an English poet and divine of the twelfth century; whose verses on the Shannon are thought worthy of quotation by Camden, and which we shall here transcribe, annexing a free translation.

"Fluminibus magnis letatur Hibemia, Sineus Inter Connaught; Momoniame quin.
Transit per muros Limerici, Noc Patric illum
Oceanus datus sub ditione videt."

"Amid majestic streams, Hibernia's pride,
The noble Shannon bids her plains divide.
Leinster and Munster to the easterly bear,
With Connaught to the right, and lofty Clare;
By Linn'rick's walls he bends his lordly way,
While tributary streams their homage pay.
Till proud Knockpatrick views, from Delmond's coast,
This world of waters in the ocean loft."

SHANNON, a river of Canada, which runs into the N.E. part of lake Ontario.

SHANSCRIT, Sanscrit, Sanskrit, Sanscritam, or Shanfcrit language, is the original language of the Hindoos or Gentoos, in which their Shaffals, or Shafter, is written, &c.

The grand source of Indian literature, the parent of almost every dialect, from the Persian gulf to the China seas, lays the learned Hamled, in the Preface to his Gram.

mar of the Bengal Language, is the Shanfcrit; a language of the most venerable and unfathomable antiquity, which, although at present shut up in the libraries of Brahms, and appropriated solely to the records of their religion, appears to have been current over most part of the oriental world; and traces of its original extent may still be discovered in almost every district of Asia. It is astonishing to find the fimilitude of Shanfcrit words with those of Persian and Arabic, and even of Latin and Greek; and those not in technical and metaphorical terms, which the fluctuation of refined arts and improved manners might have occasionally introduced; but in the main ground-work of language, in monosyllables, in the names of numbers, and in the appellations of such things as would be first discriminated in the immediate dawn of civilization. The coins of Assam, Napaual, Cashmire, and many other kingdoms, are all Ramped

3D2 with
with Shanascrit letters, and mostly contain allusions to the old Shanascrit mythology: the fame conformity is also observable in the impressions of seals from Boonan and Thiibet. Besides, the arrangement of the Shanascrit alphabet is very different from that of any other quarter of the world. This extraordinary mode of combination still exists in the greatest part of the East, from the Indus to Pegu, in dialects now apparently unconnected, and in characters completely dissimilar; and affords a forcible argument that they are all derived from the same source. Moreover, the names of persons and places, of titles and dignities, which are open to general notice, and which are found even to the utmost limits of Asia, present manifest traces of the Shanascrit.

Another circumstance deserves to be mentioned, and that is, that the raja of Kifjenagur, a very learned and able antiquary of Bengal, affirmed, that he had in his own possession books which give an account of a communication formerly subsisting between India and Egypt, in which the Egyptians are described as disciples, and not as instructors; and as seeking that liberal education and those sciences at Hindooftan, which none of their own countrymen had sufficient knowledge to impart. But though these several proofs of the former prevalence of the Shanascrit are now thinly scattered over an immense continent, and interspersed with an infinite variety of extraneous matter, arising from every possible revolution in the manners and principles of the nations who have by turns cultivated or destroyed it; that part of Asia, between the Indus and the Ganges, still preserves the whole language pure and inviolate; and offers a thousand books to the perusal of the curious, many of which have been religiously handed down from the earliest periods of human existence.

H. T. Colebrooke, esq. has given us in the Asiatic Researches (vol. vii. p. 199, &c.), a literal translation of two passages cited from a treatise on rhetoric, compiled for the use of Maniycya Chandra, raja of Tirabhuuti, or Tirhubut, in which are enumerated the languages used by Hindoos poets. The first is as follows:—Sanferica, Pracrita, Paibachi, and Magadhi, are in short the four paths of poetry. The gods, &c. speak Sanferica; benevolent genii, Pracrita; wicked daemons, Paibachi; and men of low tribes and the reft, Magadhi. But fages deem Sanferica the chief of these four languages. It is used three ways; in prose, in verse, and in a mixture of both. Again, "Language, the virtuous have declared to be fourfold, Sanferica, or the polifhed dialect; Pracrita, or the vulgar dialect; Apabhranfa, or jargon; and Miura, or mixed. Sanferica is the fpeech of the celeftials, framed in grammatical inftitutes; Pracrita is similar to it, but manifelf as a provincial dialect, and otherwife; and thofe languages which are ungrammatical, are fpoken in their refpective diftricts." The Paibachi, says Mr. Colebrooke, feems to be giberifh, which dramatic poets make the daemons fpeak, when they bring thefe fantaflic beings on the stage. The mixture of languages, noticed in the second quotation, is that which is employed in dramas, as is expressly faid by the fame author in a subsequent verfe. It is not then a compound language, but a mixed dialogue, in which different perfons of the drama employ different idioms. Both the passages above quoted are therefore easily reconciled. They, in fact, notice only three tongues. 1. Shanascrit, a polifhed dialect, the defcifions of which, with all its numerous anomalies, are taught in grammatical inftitutes. This the dramatic poets put into the mouths of gods and of holy perfons. 2. Pracrita, confiting of provincial dialects, which are lefs refined, and have a more imperfect grammar. In dramas it is fpoken by women, benevolent genii, &c.

3. Magadhi, or Apabhranfa, a jargon deftitute of regular grammar. It is used by the vulgar, and varies in different diftricts: the poets accordingly introduce into the dialogue of plays a provincial jargon, fpoken by the loweft perfons of the drama.

Sanferica is the passive particle of a compound verb, formed by prefixing the preposition fam to the crude verb ceri, and by interpofing the letter s, when this compound is used in the fene of embellishment. Its literal meaning then is "adorned," and when applied to a language, it signifies "polifhed." Pracrita is a similar derivative from the same crude verb, with pra prefixed: the most common acceptance of this word is "outfit, or man of the lowest class:" as applied to a language, it signifies "vulgar." Apabhranfa is derived from ibraias, to fall down: it signifies a word, or dialect, which falls off from correct etymology. Grammarians use the Sanferica as signifying "duly formed or regularly inflected," and Apabhranfa for false grammar.

The languages of India are all comprehended in thefe three classes. The firt contains Shanascrit, a moft polifhed tongue, which was gradually refined until it became fixed in the classic writings of many elegant poets, moft of whom are suppos'd to have flourifhed in the century preceding the Christian era. It is cultivated by learned Hindoos throughout India, as the language of science and of literature, and as the repository of their law, civil and religious. It evidently draws its origin (and fome fteps of its progres may even now be traced) from a primeval tongue, which was gradually refined in various climates, and became Shanascrit in India; Pahlavi in Persia; and Greek on the fhores of the Mediterranean. Like other very ancient languages, Shanascrit abounds in inflexions, which are, however, more anomalous in this, than in the other languages here alluded to; and which are even more fo in the obfolute dialect of the Vedas, than in the polifhed fpeech of the classic poets. It has nearly shared the fate of all ancient tongues, and is now become almoft a dead language; but there feems no good reafon for doubting, that it was once universally fpoken in India. Its name, and the reputed difficulty of its grammar, have led many perfons to imagine, that it has been refined by the concerted efforts of a few priests, who fen themselves about inventing a new language; not like all other tongues, by the gradually improved praftice of good writers and polite fpeakers. The exquitely refined fystem by which the grammar of Shanascrit is taught, has been mistaken for the reinfalment of the language itelf. The rules have been suppos'd to be anterior to the praftice, but this fuppoftion is gratuitous. In Shanascrit, as in every other known tongue, grammarians have not invented etymology, but have only contrived rules to teach what was already eflabllifhed by approved praftice.

There is one peculiarity of Shanascrit compositions which may alfo have fuggested the opinion, that it could never be a fpoken language. Mr. Colebrooke alludes to what might be termed the euphonifh orthography of Shanascrit. It confifts in extending to syntax the rules for the permutation of letters in etymology. Similar rules for avoiding incompatible sounds in compound terms exift in all languages; this is often times effected by a deviation from orthography in the pronunciation of words, fometimes by altering one or more letters to make the spelling correspond with the pronunciation. These rules have been more profoundly investigated by Hindoo grammarians than by thole of any other nation, and they have completed a fystem of orthography, which may be juftly termed euphonifh. They require all compound terms to be reduced to this fandard, and Shanascrit authors, it may be observed, delight in compounds of inordinate
SHANSCRIT.

Ordinate length; the whole sentence too, or even whole periods, may, at the pleasure of the author, be combined like the elements of a single word, and good writers generally do so. In common speech this could never have been practiced. None but well-known compounds would be used by any speaker who wished to be understood, and each word would be distinctly articulated, independently of the terms which precede and follow it. Such indeed is the present practice of those who still speak the Shanfcrit language; and they deliver themselves with such fluency as is sufficient to prove, that Shanfcrit may have been spoken in former times with as much facility as the contemporary dialects of the Greek language, or the modern dialects of...Arabic tongue.

The father of Shanfcrit grammar, who first composed those grammatical institutions in which this language is formed, or by which words are correctly formed or inflected, was Panini, who lived in fo remote an age, that he ranks among those ancient sages, whose fabulous history occupies a conspicuous place in the "Puranas," or Indian theogonies. According to the Puranica legends, Panini was the grand-son of Devada, an inspired legislator; but whatever may be his history, to him the Sutras, or succinct aphorisms of grammar, are attributed by universal consent.

His system is grounded on a profound investigation of the analogies in both the regular and the anomalous inflexions of the Shanfcrit language. He has combined those analogies in a very artificial manner; and has thus composed a most copious etymology into a very narrow compass. His precepts are indeed numerous, but they have been framed with the utmost conciseness; and this great brevity is the result of very ingenious methods which have been contrived for this end, and for the purpose of afflicting the student's memory. In Panini's system the mutual relation of all the parts marks that it must have been completed by his author; it certainly bears internal evidence of its having been accomplished by a single effort, and even the corrections, which are needed, cannot be interwoven with the text. It must not be hence inferred, that Panini was unaided by the labours of earlier grammarians; in many of his precepts he cites the authority of his predecessors, sometimes for a deviation from a general rule, often for a grammatical casus which has universal cognizance. He has even employed some technical terms without defining them, because, as his commentators remark, those terms were already introduced by earlier grammarians. None of the more ancient works, however, seem to be now extant; being superseded by his, they have probably been diffused for ages, and are now perhaps totally lost.

The inaccuracies of the Paniya grammar were corrected by Catyaayana, an inspired poet and lawgiver, whose history is involved in the impenetrable darkness of mythology. The amended rules of grammar have been formed into memorial verles by Bhartrihari, whose metrical aphorisms, entitled "Carics," have almost equal authority with the precepts of Panini, and emendations of Catyaayana. Bhartrihari is said to have lived in the century preceding the Christian era. The text of Panini being concise and ambiguous, many commentaries were composed to elucidate it, of the chief of which Mr. Colebrooke has given an account. The best and most concise commentary now extant, is entitled the "Carics vyriti," or commentary composed by Varnasa. Within a few centuries past, a grammar, well adapted for aiding the student in acquiring a critical knowledge of the Shanfcrit tongue, has been compiled by Ramachandra, entitled "Pracriyacumudi."

When Shanfcrit was the language of Indian courts, and was cultivated not only by persons who devoted themselves to religion and literature, but also by princes, lawyers, sultans, physicians, and scribes; in short, by the first three tribes, and by many chales included in the fourth; an easy and popular grammar must have been needed by persons who could not waste the whole years of their lives in the study of words. Such grammars must always have been in use; though, however, which are now fluently are not, we believe, of very ancient date. The most esteemed is the "Saralwata," together with its commentary named "Chandrika." It seems to have been formed on one of the Cauumus, by translating Panini's rules into language that is intelligible, independently of the glosis, and without the necessity of adhering to a different context.

Another popular grammar, which is in high repute in Bengal, is entitled "Mug'dhabdha," and is accompanied by a commentary. It is the work of Vopadewa, and proceeds upon a plan grounded on that of the Cauumus; but the author has not been content to translate the rules of Panini, and to adopt his technical terms. He has, on the contrary, invented new terms, and contrived new abbreviations. The same author likewise composed a metrical catalogue of verbs alphabetically arranged. It is named "Cicalpadrлина," and is intended as a substitute for the "Dhatupata." The best and most esteemed vocabulary of the Shanfcrit is the "Amerca colha," which, like most other Shanfcrit dictionaries, is arranged in verse to aid the memory. Numerous commentaries have been written on this vocabulary; the chief object of which is to explain the derivations of the nouns, and to supply the principal deficiencies of the text. Shanfcrit etymologists scarcely acknowledge a single primitive amongst the verbs. When unable to trace an etymology which may be connective with the acceptance of the word, they are content to derive it according to grammatical rules from some root to which the word has no affinity in sense. At other times they adopt fanciful etymologies from Puranas or from Tantras. But in general the derivations are accurate and instructive.

Amerca's dictionary does not contain more than ten thousand different words. Yet the Shanfcrit language is very copious. The invention of derivatives, that do not at all deviate from their regular and obvious import, has been very properly deemed superfluous. Compound epithets, and other compound terms, in which the Shanfcrit language is peculiarly rich, are likewise omitted; excepting such as are especially appropriated, by a limited limitation, either as titles of deities, or as names of plants, animals, &c. In fact, compound terms are formed at pleasure, according to the rules of grammar; and must generally be interpreted in strict conformity with those rules. Technical terms too are mostly excluded from general dictionaries, and confined to separate nomenclatures. The "Amerca colha" then is left defective than it might be inferred from the infallibility of the number of the words explained in it. Still, however, it needs a supplement. The remaining deficiencies of the Amerca are supplied by conflicting other dictionaries and vocabularies, which are very numerous.

The Shanfcrit language is very copious and nervous; but the style of the best authors wonderfully concise. It far exceeds the Greek and Arabic in the variety of its etymology, and, like them, has a prodigious number of derivatives from each primary root. The grammatical rules are also numerous and difficult, though there are not many anomalies. "The Shanfcrit language," says Sir William Jones (Afr. Ref. vol. i. p. 422), "whatever be its origin, is of a wonderful structure, more perfect than the Greek, more copious than the Latin, and more exquisitely refined than either; yet bearing to both of them a stronger affinity, both
both in the roots of verbs, and in the forms of grammar, than could possibly have been produced by accident; so strong, indeed, that no philologer could examine them all three without believing them to have sprung from some common source, which, perhaps, no longer exists. There is a similar reason, though not quite so forcible, for supposing that both the Gothic and the Celtic, though blended with a very different idiom, had the same origin with the Shanfcrit, and the old Persian might be added to the same family."

The fundamental part of the Shanfcrit language is divided into three classes; viz. dhaut, or roots of verbs, jibbd, or original nouns, and avya, or particles. The latter are always indeclinable, as in other nations; but the words comprehended in the two former classes must be prepared by certain additions and inflexions to fit them for a place in composition. Here the art of the grammarians interposes, as not a syllable, nor a letter, can be added or altered but by regimen, nor the most trifling variation of the tone in the minute subdivision of declension or conjugation can be effected without the application of several rules, and all the different forms for every change of gender, number, case, person, tense, mood or degree, are methodically arranged for the assistance of the memory; resembling, though on an infinitely more extensive scale, the compilations of proprias que maribus and as in profeni.

In the Shanfcrit language, the three distinctions of genders, viz. masculine, feminine, and neuter, are preferred in their common number and order. A Shanfcrit noun, in its first formation from the general root, exists equally independent of case as of gender. It is neither nominative, nor genitive, nor accusative, nor is it impregnated with any of those modifications, which mark the relation and connection between the several members of a sentence. In this state it is called an imperfect, or crude noun. To make a nominative any noun, the termination must be changed, and a new form supplied. Thus we see that, in the Shanfcrit at least, the nominative has an equal right with any other inflexion to be called a case. The Shanfcrit has seven declensions of nouns, which are all used in the singular, dual, and plural number, and differently formed, as the terminations, whether for gender or number, and with a long or short vowel; and also as they are of different genders. The seven changes of inflexion are exclusive of the vocative, and therefore the Shanfcrit comprehends two more than even those of the Latin; they are as follows, viz.: 1. The nominative or agent in a sentence; 2. The passive case, or subject of the action; 3. The causal case, pointing out the cause by which a thing is done; or the instrument with which it is done; or the subject in or by which it is fulfilled; 4. The dative, with the sign to or for; 5. The ablative, implying the subject from whence any thing proceeds; 6. The pujfet case, called by us the genitive; 7. The locative case, definitive of situation, and generally known by the sign in.

The vocative is excluded from the number of cases, as no inflexion is employed in its formation.

The Shanfcrit, the Arabic, the Greek, and the Latin verbs are furnished with a set of inflexions and terminations so comprehensive, and so complete, that by their form alone they can express all the different distinctions both of person and time. Three separate qualities are in them perfectly blended and united. Thus by their root, they denote a particular act, and by their inflexion, both point out the time when it takes place, and number of the agents. Every Shanfcrit verb has a form equivalent to the middle voice of the Greek, used through all the tenses with a reflective tense; and the former is even the most extensive of the two in its use and offices; for in Greek the reflective idea can only be adopted intrinsically, when the action of the verb descends to no extraneous subject; but in Shanfcrit the verb is both reciprocal and transitive at the same time. The verb substantive of the Shanfcrit very nearly resembles those of the Greek and Latin; but perhaps it would not be suspected that all the verbs in mi are formed exactly upon the same principle with the Shanfcrit conjugations, even in the minute particulars. All the terms which serve to qualify, to distinguish, or to augment either future or action, are clasped by the Shanfcrit grammarians under a head, literally signifying increase or addition. According to this arrangement, a simple sentence consists of three numbers: the agent, the action, and the subject; which, in a grammatical sense, are reduced to two, viz. the noun (whether agent or subject) and the verb. All such words as tend to particularize or to amplify the noun, are denominated by a term which signifies predicatives or epithets; and such as are applied to denote relation or connection, are called connectives of nouns, and by European grammarians, prepositions; those particles which in any manner affect the verb are denominated attributes of verbs. The Shanfcrit alphabet contains fifty letters; and it is one boast of the Brahmins, that it exceeds all other alphabets in this respect. But when we consider that of their thirty-four consonants, nearly half are combined sounds, and that five of their vowels are merely the correpodent long ones to as many which are short, the advantage seems to be little more than imaginary. The Shanfcrit character, used in Upper Hindoo, is said to be the same original letter that was first delivered to the people by Brihma, and is called Devnagur, or the language of angels; whereas the character used by the Brahins of Bengal is by no means so ancient, and is evidently a corruption of the former. In the four bees, or vedas, which constitute the original and sacred text of the great Hindoo creator and legislator Brihma, the length of the vowels is expressed by a musical note or sign placed over every word; and in reading the bees, these inflexions of tone and time must be nicely observed; so that they produce all the effect of a laboured recitative. It is remarkable, that the Jews in their synagogues chant the Pentateuch in the same kind of melody, and it is supposed that this usage has descended to them from the remotest ages. Some writers have erroneously asserted, that the four bees are in verse; whereas they are written in a kind of measured prose; and they are now scarcely intelligible to the most learned pundits or lawyers; they are also scarce, and difficult to be found. However, comments have been written upon them from the earliest periods; of which one of the most ancient and approved was composed by Biskhi Mhamomé, or the Wise Wolf, a great writer and prophet, who is said to have lived in the sutter joges, or firm age of the world. See Halhed's Preface to his translation of the Code of Gentoo Laws, printed in 1776.

Dr. Leyden, in his account of the languages and literature of the Indo-Chinese nations, (Asiatic Researches, vol. x.) has shewn, that the "Pali," as it is generally written, or "Bali" language, as it is commonly pronounced, occupies the same place among the Indo-Chinese nations, which Shanfcrit holds among the Hindoos, or Arabic among the followers of Ilami. Throughout the greater part of the maritime countries, which lie between India and China, it is the language of religion, law, literature, and science, and has had an extensive influence in modifying the vernacular language of those regions. La Louvere, on the authority of d'Hébelot, has stated that the ancient Persian language was termed Pahalevi (Pahlavi), and that the Persians do not distinguish in writing between Pahali and Bahali. P. Paulinus, however, applies this term Bali inaccurately to the fquare Bali character, instead
of the language. This language, notwithstanding its extensive use among so many nations, and the degree of cultivation which it has received from the different tribes by which it is employed, has hitherto attracted little attention among Europeans. The Bali alphabet, according to Dr. Leyden, seems, in its origin, to be a derivative from the Deva-nagari, though it has not only acquired considerable difference of form, but has been also modified to a certain degree in the power of the letters, by the monosyllabic pronunciation of the Indo-Chinese nations. The form of the Bali character varies essentially among the different nations by which it is used.

The Bali is an ancient dialect of Sanscrit, which sometimes approaches very near the original. When allowance is made for the regular interchange of certain letters, the elision of harsh consonants, and the contraction of similar sylables, all the vocables which occur in its ancient books, seem to be purely Sanscrit. In Chentas and later compositions, however, some words of the popular languages of the country sometimes infuse themselves, in the same manner as Tamul, Telinga, and Canara vocables occasionally occur, in the later Sanscrit compositions of the Dekhin. The Bali, while it retains almost the whole extent of Sanscrit flexions, both in nouns and verbs, nevertheless employs this variety rather sparingly in composition, and affects the frequent introduction of the participial particle, and the use of imperonal verbs. It also uses the cases of nouns in a more indeterminate manner than the Sanscrit, and often confounds the active, neuter, and passive tenses of verbs. Like other derivative dialects, it occasionally uses Sanscrit nouns and particles in an oblique sense; but notwithstanding all these circumstances, it approaches much nearer the pure Sanscrit, than any other dialect, and exhibits a closer affinity to the Prakrit, and the Zend.

These three dialects, the Prakrit, the Bali, and the Zend, are probably the most ancient derivatives from the Sanscrit. The great mass of vocabularies in all the three, and even the forms of flexions, both in verbs and nouns, are derived from the Sanscrit, according to regular laws of elision, contraction, and permutation of letters. Sometimes, in pursuing these analogies, they nearly coincide, sometimes they differ considerably, sometimes one, and sometimes another of them approaches nearest to the original Sanscrit. Their connection with this parent language was perceived, and pointed out by Sir W. Jones, and has also been alluded to by P. Paulinus, who derives his information, concerning the Bali, from Carpanius and Mantegatius. The fate of these three languages is also, in some degree, similar. The Prakrit is the language which contains the greater part of the sacred books of the Jains; the Bali is equally revered among the followers of Buddha; while the Zend, or sacred language of ancient Iran, has long enjoyed a similar rank among the Parsees or worshippers of fire, and been the depository of the sacred books of Zoroaster. It is perhaps, however, more accurate to consider all the three, rather as different dialects of the same derivative language, than as different languages; and comformably to this idea, the Bali itself may be reckoned a dialect of Prakrit. The term Prakrit, both in books, and in common use among the Bramins, is employed with some degree of latitude. Sometimes the term is confined to a particular dialect employed by the Jains, as the language of religion and science, and appropriated to females, and respectable characters of an inferior class, in dramas. Sometimes it includes all the dialects derived immediately from the Sanscrit, whether denominated Prakrit, Magadhi, Surafeni, Paishachi, or Apabhrastra; and sometimes it is even extended to the Dasi-bhahlas, or popular tongues of India, as Mahrafi or Mahrrata, Canara, Telinga, Udia and Bengali. According to the extended use of the term Prakrit, it may certainly include both Bali and Zend; and if more extensive research should justify the idea derived from an imperfect investigation, Dr. Leyden apprehends that the Bali may be identified with the Magadhi, and the Zend with the Surseni, of Sanscrit authors.

The learned Mr. Colebrooke has published in the 10th volume of the Asiatic Researches, an elaborate essay on Sanscrit and Prakrit poetry. He observes, that the profody of Sanscrit will be found, from the examples which he has adduced, to be richer than that of any other known language, in variations of metre, regulated either by quantity or by number of syllables, both with and without rhymes, and subject to laws imposéd in some inferences rigid restrictions, in others allowing ample latitude. The rules relative to Prakrit profody, are applicable, for the most part, to Sanscrit profody also; since the laws of verification in both languages are nearly the same.

Sanscrit profody admits of two sorts of metre; one governed by the number of syllables; and which is mostly uniform or monoschematic in profane poetry, but altogether arbitrary in various metrical passages of the Vedas. The other is in fact measured by feet, like the hexameters of the Greek and Latin; but only one sort of this metre, which is denominated Arya, is acknowledged to be so regulated; while another sort is governed by the number of syllabic initials or matras.

The most common Sanscrit metre is the flanaz of four verbs, containing eight syllables each; and denominated from the name of the clafs "Anuflubh," for an account of which, and of other kinds of metres, we refer ubi fibra.

The Sanscrit writers notice different species of prose. They discriminate three and even four sorts, under different names. 1. Simple prose, admitting no compound terms. It is denominated "Mufcasa." This is little used in polished compositions; unless in the familiar dialogue of dramas. It must undoubtedly have been the colloquial style, at the period when Sanscrit was a spoken language. 2. Prose, in which compound terms are sparingly admitted. It is called "Culaca." This and the preceding sort are by some considered as varieties of a single species named Charnica. It is of course a common style of composition; and, when polished, is the most elegant as it is the chaste. But it does not command the admiration of Hindoo readers. 3. Prose abounding in compound words. It bears the appellation of "Utsala Praya." Examples of it exhibit compounds of the most inordinate length; and a single word exceeding a hundred syllables is not unprecedented. This extravagant style of composition, being suitable to the taste of the Indian learned, is common in the most elaborate works of their favourite authors. 4. Prose modulated so as to frequently exhibit portions of verse. It is named "Vrittawardhi." It will occur without study, and even against design, in elevated compositions; and may be expected in the works of the best writers.

Some of the most elegant and highly wrought works in prose are reckoned among poems, as already intimated, in like
like manner as the "Telemache" of Fenelon and "Tod Ables" of Giffier. The most celebrated are the "Valavada" of Subandhu, the "Dafa Cumara" of Dandi, and the "Cadambari" of Vana.

For a further account of the Shanferit, see Language of Bengal, or Bengalese.

Exclusive of the Shanferit, there are three different dialects in the kingdom of Bengal, viz., the Persian, the Hindoostanee, and the proper Bengalee. See Persia and Persian Language, Hindostanee, and Bengalee.

SHA, in Geography. See Shanferit.

SHAONA, a town of Egypt, on the W. coast of the Red sea; 90 miles S.S.E. of Coffer.

SHAOUME, a town of Arabia, in the province of Hedsjas; 25 miles from Calaza el Mohsh.

SHAOUN, a town of Arabia, in the province of Hedsjas; 45 miles S. of Jambo.

SHAPARY, a town of Hindoostan, in the circuit of Gangour; 30 miles S.W. of Pads.

SHAPE, Inflammation of, among neat cattle, an affection in cows, arising in hot weather after taking the bull, and which is shown by a swelling of the parts with boils or eruptions. It is observable by the animal rubbing her hind parts in the hedges, &c. In the cure Mr. Dugald Morison advises, after free bleeding, the following: Nitre in powder, two ounces; cream of tartar, three ounces; Calico soap, one ounce; and aniseed powder, one ounce; which are to be mixed for a dose, and to be given in a quart of warm whey, repeating them as there may be occasion.

To SHAPE the Course, in Sea Language, is to direct or appoint the track of a ship, in order to prosecute a voyage.

SHAPINSAY, in Geography, one of the Orkney islands, Scotland, is situated to the N. of the Mainland of Orkney, at the distance of three miles from Kirkwall, the capital of all the islands. It measures about seven miles in length and five in breadth, and formerly constituted part of the temporalities of the bishopric of Orkney. Almost the whole of it is capable of cultivation; but a great part yet remains in an neglected state, to the detriment, as well as to the disgrace of the proprietors. Nevertheless, sufficient grain is raised for the supply of the inhabitants. Kelp is produced in great abundance, and is much used as a manure. Lead ore is likewise abundant in the south-west corner of this island, and was for some time wrought, but the work is now entirely abandoned.

In common with most of the Orkney islands, Shapinsay exhibits some monuments of antiquity: among these may be reckoned, besides several Popish chapels, a numerous collection of Picts-houses ranged along the shores, like so many forts, together with tumuli, or barrows, in various situations. A monument stone of large dimensions raises its venerable head in a plain near its eastern extremity; and on the northern shore is the stone Odin.

To the south of Shapinsay, at the distance of a furlong, is situated the beautiful islet of Elgar or Ellerholm, which bears evident traces of former habitation, and of having been, at no very distant period, attached to the principal island. At present it furnishes pasture for a number of sheep and young cattle during summer, and serves to give, by its favourable position, the utmost secularity to the harbour of Elwick, which is one of the finest in the Orkneys. Barry's History of the Orkney Islands, 2d edit. by J. Headrick, Lond. 1806.

SHAPLEY, a post-town of America, in Massachusetts, in the province of Maine, incorporated in 1785; 108 miles N. of Boston.

SHAPOTA HILLS, a mountainous ridge of Hindoostan, between the Merbuddah and Taptee; 60 miles E. of Surat.

SHAPORA, a town of Hindoostan, in the circuit of Rantapour; 45 miles W. of Rantapour.

SHAPOUR, a city of Persia, in the province of Farsit, is said to have been originally founded by Taimuras Deevand, who called it Deen Dar; it was destroyed by Alexander the Great, and subsequently built by Sapor, the son of Artaxerxes Babegan, who named it after himself. The ruins of this ancient city are distant about 16 miles from Kazerovers; and if we may form an idea from the breadth and circumference of the ramparts, and the remains of some other public buildings, it must have been a city of great extent and magnificence. It is situated immediately under the eastern range of mountains, on the banks of a small but rapid river, and in a wild, romantic spot, amid rocks and precipices, many of which are decorated with pieces of sculpture similar to those near Persopolis, for a description of which we refer to Kinneir's Memoir of the Persian Empire, p. 66. The hills in the immediate vicinity of these ruins appear to have been formerly fortified; and an extraordinary cavern, further up the river, has given rise to many fabulous stories.

SHAPS, an island in the Chefsepeak; 27 miles S.S.E. of Annapolis. N. lat. 38° 46'. W. long. 76° 25'.

SHAR, or SHER-HOG, in Agriculture, a term signifying a yearling sheep, which has been once thorn. The same as lamb-hog. See Sheep.

SHARAF BENI GATEI, in Geography, a town of Arabia, in the province of Hedsjas; 25 miles N. of Madian.

SHARBASHI, a town of Turkish Armenia; 18 miles S.E. of Mouch.

SHARBIN, a town of Egypt; 16 miles S.S.W. of Damietta.

SHARD, in Agriculture, a term applied to a fragment of an earthen vessel, or the gap in a hedge.

SHARE of a Plough, that part which enters, cuts, and breaks up the ground, the extremity forward being formed with a sharp-pointed iron, called the point of the share; and the end towards the wood behind, the tail of the share. This part constituted a portion of what is usually denominated the throat, which is of very great importance in the construction of this implement. (See Plough.) The dimensions are: the length of the whole share from point to tail, according to Tull, should be three feet nine inches, but in modern ploughs much shorter; at the top of the iron it hath sometimes an upright piece called the fin; and near the iron, at the other end, there is an oblong-squared hollow called the socket; the use of which is to receive the bottom of the share. Near the tail there is a thin plate of iron, well rivetted to the wood; by means of this plate, the tail of the share is held firmly to the hinder flat of the plough by a small iron-pin, with a ferev on the end, and a nut screwed on it, on the inner or right side of the share. But shares are made in different forms.

The point of the share is that part in which it does not run up to the fin; this point is generally made three inches and a half in length, and should be flat underneath, and round at the top, and the lower part of it must be of hard steel. The edge of the fin should also be well steel, and should make an acute angle with the share. The socket is a fort of mortise; it should be a foot long and about two inches deep; the fore-end of it must not be perpendicular, but oblique, conformable to the edge of the share which enters into it. The upper edge of the fore-part must be always
always made to bear up against the heat; but if this end of the socket should not be quite so oblique as the heat, it may be helped by paring off a small part of the wood at the point.

However, in modern ploughs, the shares, as has been seen, are very different, according to their contructions and the uses for which they are intended.

Lately, improved cast-iron plough-shares have been made by R. Ramfome, of Ipswich, Suffolk, for which he has obtained a patent. These shares are made hard on one side and soft on the other, which affords the great advantage of wearing them, as it is found by farmers that those made in the common way wear thick, with a baffle on the under side, which obstructs their entering into hard or strong soils, and at the same time increases the labour of the team, as well as pars over weeds without cutting or eradicating them. The same person also makes plough-ground, which are so contrived, as that by turning a screw the plough is made to work more or less to the land with the greatest ease and facility. And both these contrivances are said to be capable of being applied to all sorts of ploughs which have been already constructed, and are in use upon farms.

The broad share, which is used in Suffolk, is said to be a capital contrivance, whether invented in that district or in Kent. It serves to cut over pea and bean rubbles, or such weedy fallows as do not require ploughing. It consists of an oblong share two feet long, and four or five inches wide, fixed to the fock or front of the ground rif, by an iron shank in the middle, and occasionally bolted to the side of the fame rif of a wheel-plough. It is pitched with an inclination into the ground, capable of being raised or sunk at pleasure, by the elevation or depression of the beam on the gallow, anfwering the purpofe of the great skim of the ifle of Thanet, defcribed in Young's Eastern Tour. When the rubbles have been cut over with this tool, they are harrowed, raked, and burnt, the land being left in excellent order for wheat.

On cast-iron plough-shares a very simple and beneficial improvement has lately been made by a perfon of the name of Morland, in Berkshire. It is well known that when the point, or fock, of wrought-iron plough-shares wears out, they are capable of being renewed; but that, in cast-iron, the fufe is otherwise. By this invention and improvement, however, which is much approved of in the above county, the blunt point is capable of being dipped or defcribed in fuch a manner as to produce every effect which is wanted by the ploughman, when the share mufl have become quite useless without it. The cheapness and durability of castiron plough-shares render them highly defirable in all farming concerns where there is much ploughing to be done.

The whole is accomplished by the share having a fort of joint, and the top part taking in and out, and by a tuck that goes through the beam of the plough, which tralles or falls the point of the share.

SHAKE. Genus, principally a fort of ledge.

SHAREMAN'S CREEK, in Geography, a river of Pennsylvania, which runs into the Susquehanna, N. lat. 40° 26'. W. long. 72° 6'.

SHARK, in the Linnean fystem of Ithology, is a species of the fqualus. Pennant makes it a diftinct genus, the characters of which are thefe; the body is fender, and grows lefs towards the tail, it has two fins on the back, a rough skin; five orifices on the fides of the neck; the mouth generally placed far beneath the end of the nose; and the upper part of the tail longer than the lower. We know two different fih under the fame name of fhark, with the addition of their colour, blue and white.

Vol. XXXII.

The blue fhark is that species of fqualus called glaucaus, and galus glaucaus, by authors, and diftinguifhed by Artedi by the name of the fqualus with a triangular dent, or furrow, in the extremity of the back, and with no foramina about the eyes. It is of a fine deep blue colour on the back, and of a bright silver white on the belly; the skin is smoother than that of the white fhark, and the nose long pointed, and somewhat flattened, and extending far beyond the mouth; the nostrils are long, and placed tranverfely; the tail is bifid, and one portion of it is much larger than the other; it is very voracious of human flesh, and will follow close under the fhor if there be depth enough, and a man is walking there. It is sometimes found on the English fhores, and has been caught on the Cornwall coalt, during the pelagif fefion, with large iron hooks, made on purpofe. Afin informs us, that this fih will permit the fmall brood, when in danger, to swim down its throat, and take fhelet in its belly; and the fact has been confirmed by Rondeletus. Mr. Pennant apprehends that this care of their young is not peculiar to this species, but common to the whole genus of fhark.

The other is the lamia, or canis carechosus, of authors, the fqualus carechosus of Linnaeus, commonly called by us simply the fhark. This is diftinguifhed by Artedi by the name of the fqualus with a flat back, and with numerous teeth, ferrated at the edges.

The white fhark, or lamia, is a very dreadful and voracious fih, the largest of all the fharfs. They have been feen of four thousand weight, with throats capable of swallowing a bulky man whole; nay, men have been found whole in them when opened. Some have, for this reafon, imagined this, and not the white, to have been the fih in whose belly the prophet Jonah lay. Swimmers very often peril by them; sometimes losing an arm or leg, and sometimes being bit quite afunder, and ferving only for two morfels for this ravenous animal. Its teeth are very fharf and terrible; they are difpofed in fix rows, and are all triangular, and notched like a faw on their edges; there are, in the whole, a hundred and forty-four in number, and are placed in various directions; their number is not exactly determinate; their teeth, when the fih is in a state of repofe, lie quite flat in the mouth, but when he fizes his prey, he has power of crefting them, by the help of a fet of mufcles that join them to the jaw; the mouth is placed far beneath; on which account these fihes, as well as the refl of the kind, are faid to be obliged to turn on their backs to fize their prey; which is an obfervation as ancient as the days of Pliny; its back is fhort and broad, in comparifon of the other fih of this kind, and its tail, which is of a femilunar form, compofed of two fins of a cubit in length each. This fih has furprifing ftrength in its tail, and can strike with great force; fo that the failors infantly cut it ofi with an ax, as soon as they draw one on board. The pectoral fins are very large, which enable it to swim with great fwiiftnefs; the colour of the whole body and fides is a light alf; its fkin is rough, and its eyes large and round. It is found both in the ocean and in the Mediterranean, and is of all fihes the most voracious of human flesh.

It has its name from the Greek λυχος, a voracious feeder, or gluton. The foffile bodies, called glaficopetra, or terps' tongues, and fupposed to be real fhorres, are the teeth of this fih.

SHARK. Fufking, Squalus maximus of Linnaeus, the name given by Mr. Pennant to a fih which inhabits the northern seas, as high as the arctic circle, and which was taken for a species of whale, till he pointed out the branchial orifces in the fides, and the perpendicular fite of the tail,
This species has been long known to the inhabitants of the south and west of Ireland and Scotland, and those of Caernarvonshire and Anglesea; they quit the bays of those Welsh counties about Michaelmas, and the frith of Clyde, and the Hebrides, about the latter end of July. They have nothing of the fierce and voracious nature of the shark kind, but are so tame as to suffer themselves to be fished; lying motionless on the surface of the water, commonly on their bellies, but sometimes on their backs, as if to sun themselves; whence they are called basking sharks. Their food seems to consist entirely of fish-plants. Linnaeus says they feed on medusas. At certain times they are seen sporting on the waves, and leaping with great agility several feet out of the water; they swim deliberately, with the dorsal fins above water; their length is from three to twelve yards, and they are sometimes longer; their form is slender; the upper jaw much longer than the lower, and blunt at the end; the mouth placed beneath, and each jaw furnished with numbers of small teeth; those before being much bent, and those more remote in the jaws being cone, and sharpened; on the sides of the neck there are five large transverse apertures to the gills; on the back two fins; the first very large, nearer the head than the middle; the other small, and situated near the tail; on the lower part there are five others; viz. two pectoral fins, two ventral fins, and a small anal fin; near these, the male has two gonites, as in other sharks; and between these fins was fixed by the pudendum of the female; the tail very large, having the upper part much longer than the lower; the colour of the upper part of the body a dark leaden, and the belly white; the skin rough, like flagueen, but less so on the belly than on the back; within the mouth, towards the throat, was a very soft fore of whalebone; the liver is of a great size, that of the female being the largest, and is melted into a pure and sweet oil, fit for lamps, and much used by the people, who take it to cure bruises, burns, and rheumatic complaints. A large fish will yield eight barrels of oil. These fishes are viviparous, a young one, a foot in length, having been found in the belly of one of them. When they are struck with a harpoon, and wounded, they swim up their tails, and prison end to the bottom, coiling the rope round them, and attempting to disengage themselves from the harpoon, by rolling on the ground. They swim away with such rapidity and violence, that there has been an instance of a vessel of seventy tons having been tossed away against a fresh gale; and they will employ the fishes for twelve, and sometimes twenty-four hours, before they are subdued. Pennant's British Zoology, vol. iii. p. 101, &c.

Shark, Hammer-headed, Squatius zigyna, a fish of the shark kind, called also the balance-fish. It is an extremely singular and remarkable fish, and differs not only from all the other sharks, but from all the fish in the world, in the figure of its head: this is not placed, as in all other fishes, longitudinally, or in a line with the body, but is set on transversely, as the head of a hammer or mallet upon the handle. This is semicircular at the front, and runs to fo thin and sharp an edge, that as the fish swims forward with violence, it may cut other fishes, and is terminated at each end by an eye; these are very large, and so placed, that they more conveniently look down than either upward or sidewise. In the farther part of the forehead also, near the eyes, on each side, there is a large oblong foramen, serving either for hearing or smelling, or perhaps for both; the mouth is very large, and placed under the head, and armed with four rows of extremely sharp and strong teeth, flat, and serrated at their edges; the tail is composed of two fins, one vastly larger than the other; the body is rounded and very long, and is not covered with scales, but a thick skin; the back is ash-coloured, and the belly white. Rondel, de Aquat. p. 549.

It is caught in the Mediterranean, and sometimes in different parts of the ocean. Some authors have called it zigyna, and others bhera; which last answers to the English name of the balance-fish.

Shark, Pickerel. See Acantias and Squalus. Shark, Long-tailed. See Sea-Fox and Squalus Vulpes. 

Shark, Spotted, Squatius Canicular of Linnaeus. See Squalus Canicular.

Shark, After Spotted, called the morgaen, or rough bound-fish, Squatius Canicular of Linnaeus. See Squalus Canicular.

Shark, Smooth, Squalus Mystus of Linnaeus. See Squalus Mystus.

Shark, called the tope, Squalus Galeus of Linnaeus. See Squalus Galeus.

Shark, called the angel or monk-fish, Squatius Squatina of Linnaeus. See Squalus Squatina. 

Shark River, in Geography, a river of New Jersey, which runs into the Atlantic, N. lat. 40° 10'. W. long. 74° 4'.

Sharkind, a town of Sweden, in East Gotland; 9 miles S.S.W. of Nordkoping.

Sharkstown, a town of Maryland, on the island of Kent; 28 miles S.E. of Baltimore.

Sharm el-Kiman, or Sharm el Kaman, a port on the Red Sea, on the coast of Egypt. N. lat. 24° 44'.

Sharma, a town of Arabia, in the province of Hadramaut; 30 miles E.N.E. of Sahar.

Sharmagoel, a town of Persia, in the province of Choralian; 12 miles S. of Nea.

Sharmalik, a sea-port of Africa, on the Gold Coast; 13 miles W. of Commando.

Sharokee. See Shon.

Sharon, a town of the province of Maine; 40 N. of Portland.—Also, a town of Connecticut; 12 miles N.W. of Litchfield.—Also, a port-town of the state of New York; 23 miles W. of Albany.—Also, a township of Massachusetts; 10 miles S.W. of Bolton.—Also, a township of Vermont, on the White river; 6 miles N.W. of Norwich.

Sharp, Abraham, in Biography, an eminent mathematician, mechanist, and alfronomer, was descended from a family of Little Horton, near Bradford, in Yorkshire, where he was born about 1651. After he had received a good education, he was put apprentice at Manchester, but being steadily attached to mathematical pursuits, he quitted his business and removed to Liverpool. Here he applied with great diligence to his favourite study, and procured a sufficient knowledge of languages, which he taught writing and the elements of arithmetic. He next went to London, with the view of associating with Mr. Flamstead, by whose interest he obtained a profitable employment in the dock-yard at Chatham, where he remained till he was invited to become the assistant of Flamstead at the Royal Observatory at Greenwich. In this situation he continued to make observations, and had a large share in forming a catalogue of 3000 fixed stars, with their latitudes and magnitudes; their right ascension and polar distance, and the variations of the same, while they change their longitude by one degree. In this employment he injured his health, and was obliged to retire to
to his native air, at Horton, where he fitted up an observatory of his own, having constructed a very curious machine for turning all kinds of work in wood and brass. He constructed most of the tools used by joiners, clock-makers, opticians, and mathematical instrument-makers. He manufactured entirely his own telescopes and other astronomical instruments.

He next materially assisted Mr. Flamsteed in calculating most of the tables in the second volume of his "Historia Celestis," and made curious drawings of the constellations, which were sent to Amsterdam to be engraved, and though executed by a masterly hand, the originals were said to have exceeded the engravings in beauty and accuracy. In 1689 Mr. Flamsteed completed his mural arc at Greenwich, in which he had been greatly assisted by his friend Mr. Sharp, who had been some time in the observatory as his assistant. Mr. Smeaton, in a paper published in the Philosophical Transactions for the year 1786, speaking of this mural arc, says, it may be considered as the first good instrument of the kind, and that Mr. Sharp was the first person who cut accurate and delicate divisors upon astronomical instruments.

In 1717, Mr. Sharp published a work entitled "Geometry Improved," in which he engraved the figures as well as compiled the work. This treatise contains 1. A large and accurate table of segments of circles, with the method of its construction, and various uses in the solution of difficult problems. 2. A concise treatise of polyedra, or solid bodies of many bales, both the regular and irregular ones, to which are added twelve new ones, with various methods of forming them, and their exact dimensions in words or species, and also in numbers. In the year 1699 he undertook, for his own private amusement, the quadrature of the circle, deduced from two different series, by which the truth of it was demonstrated to be 72 places of figures. Mr. Sharp maintained an epistolary correspondence with the most eminent mathematicians and astronomers of the day; among these were the illustrious Newton, Dr. Halley, and Dr. Wallis. It appears from a great variety of letters which remained after his death, written to him by these celebrated men, that he spent neither pains nor time to promote the interests of real science. But it is justly reckoned one of the ablest calculators of his time, his assistance was required by, and freely given to Flamsteed, Sir Jonas Moore, Dr. Halley, and others, in all difficult calculations. When he quitted Mr. Flamsteed, he retired to Little Horton, in Yorkshire, where he spent the remainder of his days, and where he died in July 1742, in the 91st year of his age. He was of very retired habits, and admitted few visitors, excepting two gentlemen, at Bradford, one a mathematician and the other an ingenious apothecary. Many of his singularities are recorded in the General Biography, and also in Hutton's Mathematical Dictionary, to which the reader is referred.

Sharp, John, archbishop of York, a celebrated divine of the church of England, was the son of a respectable tradesman at Bradford, in Yorkshire, where he was born in 1644. He was admitted of Chrift's college, Cambridge, in 1660, and in 1667 he commenced master of arts, and was ordained. He was now appointed private tutor to the four sons of Sir Henage Finch, a family which he occupied about five years, when he obtained, through his patron's recommendation, the archdeaconry of Berkshire. When Sir Henage was raised to the post of keeper of the great seal, he manifested such confidence in the fidelity and judgment of his friend, as to commit to him the scrutiny of the characters of applicants for church livings in the gift of the crown. A sermon which he preached in 1674, reflecting upon those who differed from the church, gave rise to a controversy, in which Dodwell, Baxter, and others engaged. In 1677 he was instituted to the rectory of St. Giles-in-the-Fields, in which parish he resided ten years. Among his parishioners was Richard Baxter, who, though he was himself a preacher on Sunday evenings, was a constant hearer of the rector in the mornings; and these two excellent men, notwithstanding their differences in some points, lived together upon the most friendly terms. In 1679 Mr. Sharp commenced D.D., and in 1681 he was promoted to the deanship of Norwich. On the death of Charles II., to whom he had been a chaplain, he drew up the address of the grand-jury of London to his successor, to whom he was also nominally chaplain. After this he preached against popery, and thus exciting the royal displeasure, he was obliged to quit the metropolis, and reside altogether at his deanship. He employed himself in forming a cabinet of coins, chiefly British, Saxan, and English. Being wearied with his exclusion from his function in London, he presented a very humble petition to the king, in consequence of which, he was allowed to return to his duty in the metropolis, and he was extremely careful never after to give offence, as he had done before. After the abdication of the monarch, Dr. Sharp irritated the adherents to William, by some offensive allusions in a prayer and sermon, which he delivered before the house of commons, who at first refused him their accumulated thanks, which, however, were voted afterwards. In 1689, Dr. Sharp was appointed the successor to Dr. Tillotson in the deanship of Canterbury, and he was nominated one of the commissioners for revising the liturgy. At this period several bishops had been deprived of their fees for refusing to take the oaths to William and Mary, and Dr. Sharp might have succeeded to almost any of them, but he refused, not through any scruple of conscience, but on account of his friendship for the persons deprived. When, however, the archbishopric of York became vacant in a different way, he readily accepted the high office, and he was consecrated in July 1691. He filled this exalted station in a manner, which has cauied him to be represented as a model of prelatical virtue, and which procured him general respect and esteem. He died at Bath in 1714, in the 69th year of his age. His only writings were sermons, of which were published two volumes, containing of such occasional discourses as he had printed during his life-time, and five others, that were selected after his decease. He was reckoned an excellent preacher, and his style and doctrine are said to be equally of the standard purity. Biog. Brit.

Sharp, Thomas, younger son of the preceding, was born in Yorkshire, and admitted to Trinity college, Cambridge, about 1703, when he was of the age of 15. He obtained a fellowship in 1729, and took his doctor's degree the same year. Archbishop Davvcs appointed him his chaplain, and in 1730 he was collated to the rectory of Royston, in Northumberland, and was afterwards prebend in Durham cathedral, and also to the archdeaconry of Northumberland. He died in 1758. Dr. Sharp wrote two dissertations concerning the etymology of the Hebrew words Elohim and Berith—"Discourses on the Antiquity of the Hebrew Tongue and Character." He left a son, Granville, to whom fine character as a genuine English patriot, we shall endeavour to do justice in the next article.

Sharp, Granville, son of the preceding, a most distinguished philanthropist and friend to the liberties of mankind, was born in the year 1734. He was educated for
the bar, but did not practice at it. When he quitted the legal profession, he obtained a place in the ordnance office, which he resigned at the commencement of the American war; the principles of which were abhorrent from his mind. He now took chambers in the Temple, and devoted himself to a life of study; at the same time, laying himself out for public utility. He first became known to the public in the case of a poor and friendless Negro, of the name of Somerset. This person had been brought from the West Indies to England by a master, whose name we should gladly hand down to the execution of polety, if it were in our power; and falling into bad health, was abandoned by him as a useless article of property, and turned into the streets, either to die, or to gain a miserable support by precarious charity. In this deplorable state, almost it is said, on the point of expiring on the pavement of one of the public streets of London, Mr. Sharp chanced to see him. He instantly had him removed to St. Bartholomew’s hospital, attended personally to his wants, and in a short time had the happiness to see him restored to health. Mr. Sharp now clothed him, and procured him comfortable employment in the service of a lady. Two years had elapsed, and the circumstance almost, and the name of the poor Negro, had elapsed the memory of his benefactor, when Mr. Sharp received a letter from a peron, signing himself Somerset, confined in the Poultry Compron, flating no cause for his commitment, but intreating his interference to save him from a greater calamity even than the death from which he had before refor led him. Mr. Sharp instantly went to the prison, and found the Negro, who in sickness and misery had been discarded by his master, sent to prison as a runaway slave. The excellent patriotism went immediately to the lord mayor, William Nath, esq., who caused the parties to be brought before him; when, after a long hearing, the upright magistrate decided that the master had no property in the person of the Negro, in this country, and gave him his liberty. The matter instantly concurred him, in the presence of Mr. Sharp and the lord mayor, and informed on his right to keep him as his property. Mr. Sharp now claimed the protection of the English law, caused the matter to be taken into custody, and exhibited articles of peace against him for an assault and battery. After various legal proceedings, supported by him with moli undaunted spirit, the twelve judges unanimously concurred in an opinion that the matter had acted criminally. Thus did Mr. Sharp emancipate for ever the race of blacks from a state of slavery, while on British ground, and in fact banished slavery from Great Britain. Such an incident could not fail deeply to impress a benevolent mind; and slavery, in every shape and country, became the object of his unceasing hostility. In 1769 he published a work, entitled "A Representation of the Injustice and dangerous Tendency of tolerating Slavery, or of admitting the least Claim of private Property in the Persons of Men in England." Having succeeded in the case of an individual Negro, he interred himself in the condition of the many others, who were seen wandering about the streets of London, and at his own expense collected a number of them, whom he sent back to Africa, where they formed a colony on the river Sierra Leone. He performed a still more essential service to humanity, by becoming the instigator of the "Society for the Abolition of the Slave Trade," which, after contending against a vast mass of opposition, at length gloriously succeeded, as far as this country was concerned in the horrible traffic.

Mr. Granville Sharp is mentioned in connection with this business, in terms of the highest commendation, by Mr. Clarkson, in his "History of the Abolition of the Slave Trade." (See vol. 1. p. 63—70.) The following short account of him is extracted from the Edinburgh Review, vol. xiii.

"We think it a duty to mention the name of Mr. Granville Sharp. Regardles of the dangers to which he exposed himself, both in his person and his fortune, Mr. Sharp stood forward in every case as the courageous friend of the poor Africans in England, in direct opposition to an opinion of York and Talbot, the attorney and solicitor-general for the time being. This opinion had been acted upon; and so high was its authority, that, after it had been made public, it was held as the settled law of the land, that a slave, neither by baptism, or arrival in Great Britain or Ireland, acquires freedom, but may be legally forced back to the plantations. Discouraged by judge Blackstone, and several other eminent lawyers, Mr. Sharp devoted three years of his life to the English law, that he might render himself the more effectual advocate of such friendless strangers. In his work, entitled "A Representation of the Injustice and dangerous Tendency of tolerating Slavery in England," published in the year 1769, and afterwards in his learned and laborious "Inquiry into the Principles of Villanages," he refuted the opinion of York and Talbot by unanswerable arguments, and neutralized their authority by the counter opinion of the great lord chief justice Holt, who many years before had decided, that as force could be used against no man in England without legal process, every slave coming into England became free, insomuch as the laws of England recognized the distinction between person and property as perpetual and sacred. Finally, in the great case of Somerset, which was argued at three different sittings, in January, February, and in May, of the year 1772, (the opinion of the judges having been taken up on the pleadings,) it is at last ascertained and declared to be the law of the land, that as soon as ever any slave set his foot upon English territory, he became free. Among the heroes and sages of British glory, we can think of few whom we should feel a greater glow of honest pride in claiming as an ancestor, the man to whom we owe our power of repeating with truth,

"Slaves cannot breathe in England; if their lungs Receive our air, that moment they are free: They touch our country, and their shackles fall."

Similar principles led Mr. Sharp to use his endeavours to restrain the arbitrary practice of marine imprisonment; and a citizen of London having been carried off by a press-warrant, Mr. Sharp obtained a habeas corpus from the court of king’s bench, to bring him back from a vellum at the Nore; and by his arguments obliged the court to liberate him. In his political principles he was always the ardent and zealous friend to liberty, and he neglected no opportunity to defend its principles, and affright the rights of the people. He was the warm advocate of "parliamentary reform," and published, in 1778, the second edition of an excellent little work, full of constitutional knowledge and sound reasoning, entitled "A Declaration of the People’s natural Right to a Share in the Legislature, which is the fundamental Principle of the British Constitution of State." He was, in 1794, as zealously attached to the cause as he had been twenty years before; though, perhaps, he did not feel himself sufficiently active to engage in it as a partisan, when it was a subject of obloquy. He was not, however, an unconcerned spectator of the dreadful tyranny, which, but for the intervention of an honest English jury, would have overwhelmed the land. He lent, to one of the persons at that time confined in the Tower of London, a copy of the work..."
work referred to, with assurances of a readiness to do anything in his power to reme the torrent setting in against the liberties of the country.

Mr. Sharp's plan of reform recommended to the public, was founded on the earliest principles and practices of the British constitution. He proposed to reform the ancient tithings, hundreds, &c.; and the whole body of the people were to form a national militia, each hundred to constitute a regiment, the alderman or magistrate to be the colonel; and each hundred to constitute a company, the capable of each for the time being to be their captain. So many of the thousands to be summoned once in every year, by their magistrate, as would have a right to vote in their respective hundreds, before the capable, in the choice of their part of the representative legislature. Mr. Sharp has shown that the division of this kingdom into tythings and hundreds was instituted by the immortal Alfred; that such a division is consistent with the most perfect state of liberty that man is capable of enjoying, and yet fully competent to answer all the purposes of mutual defence, to secure the due execution of the laws, and maintain public peace.

Mr. Sharp was educated in the principles of the estabished church, and through life shewed a warm attachment to them. He always, even at the close of his life, had a thorough dread of Popery, but was candid and liberal to Protestant dissenters of all parties. His zeal for the established religion of the country led him to recommend an episcopal church in America; and he introduced the first bishops from that country to the archbishop of Canterbury for consecration.

Mr. Sharp died in July 1813, and like Cato, though advanced to the age of 79, he pursued his studies with all the ardour of youth. He was an able linguist, deeply read in theology, and was well acquainted with the scriptures in the original tongues. He was pious and devout, without gloom, strictly moral and temperate, a great lover of music, and cheerful in conversation. His services to humanity were very distinguished, and few persons in private life have deserved a higher or more honourable commemoration.

As a writer, his pieces are very numerous. From these we learn that he was a believer in the doctrines as set forth in the articles of the church, as that of original sin, the existence and operations of the devil on the human mind, and of the Athenian mystery of the Trinity. He also, from studying the book of Revelation, fully expected the commencement of the Millenium, or personal reign of Christ on earth, in the spring of 1811; but he lived long enough to see his error. He posseesed a very extensive library, in which the theologian, lawyer, classical scholar, politician, antiquary, and orientalist, might find almost every thing of which they could stand in need; and his collection of bibles was esteemed the belt in the kingdom.

The principal works of Mr. Sharp, besides those already mentioned, are: Remarks on several very important Prophecies, Remarks on the Ufes of the definitive Article in the Greek of the New Testament, containing many new Proofs of the Divinity of Christ, &c. This occasioned Six Letters to be addressed to him, in vindication of his theory; and also Six more Letters, &c. by Gregory Blunt, esq., which is a work of great talent, profound learning, and masterly wit. It has long since been out of print, and the author is probably known only to two or three persons; the designation Blunt being alluded to conceal the real name. Mr. Sharp's last work was entitled Remarks on the 68th Psalm, addressed to the Consideration of the House of Israel. Monthly Mag. Gentleman's Mag. Edin. Rev. Clarkson's Hist. of the Abolition of the Slave Trade.

SHARP, Samuel, an able and distinguished surgeon in the middle of the last century, was a pupil of the celebrated Chevalier, and afterwards studied his profession with great zeal at the hospitals of Paris. He is said to have commenced his profession rather late in life; nevertheless, after settling in London, and obtaining an appointment as surgeon of Guy's Hospital, his genius and affinity soon obtained for him a high degree of celebrity, and extensive practice. He was elected a fellow of the Royal Society, and a foreign member of the Academy of Surgery at Paris; and he contributed to the improvement of his art by two valuable publications, which passed through many editions, and were translated into several foreign languages. The first of these was "A Treatise on the Operations of Surgery, with a Description and Representation of the Instruments; and an Introduction on the Nature and Treatment of Wounds, Abscesses, and Ulcers," first printed in 1739. Our edition, printed in 1751, is the fourth. The second work was entitled "A critical Inquiry into the Present State of Surgery," first printed, we believe, in 1750. Our edition of 1761 is the fourth. See Eloy Dict. Hist. de la Med., and Sharp's Works.

SHARP, in Muse, is a chromatic sign, marked thus, \( \sharp \), and elevates the note before which it is placed half a tone, without changing its name or place on the staff.

A sharp on a line or space, at the beginning of a movement, affects all the notes of the same name throughout the piece, contradicted by a natural, \( \flat \). See NATURAL.

An accidental sharp affects no note beyond the finger bar in which it occurs; but it always, when accompanied by a flat or lower part, implies a new modulation, except in minor keys, the sharp to the seventh of the key, which is a thing of course.

In the key of C with a sharp third, there are seven sharps at the clef, which implies that every note in the scale is elevated a semitone above its usual pitch.

\[ \begin{align*}
\text{C} \quad & \text{C} \\
\sharp \quad & \sharp \\
\sharp \quad & \sharp \\
\sharp \quad & \sharp \\
\sharp \quad & \sharp \\
\sharp \quad & \sharp \\
\sharp \quad & \sharp 
\end{align*} \]

In this key, an accidental sharp is marked by a double sharp \( \# \), usually called a "flat", or enharmonic sharp; which is.

SHARP the Bow-lines, in Sea Language. See BOWLING.

SHARP Nails. See NAIL.

SHARPE, Gregory, in Biography, a learned divine, was born in Yorkshire in the year 1713. He received his education first at Wellminton school, and afterwards at Aberdeen, under the learned Blackett. Upon his entering orders he became minister of St. Margaret's chapel, Wellminton; after this, he was appointed chaplain to the king, and master of the Temple. He was also elected a fellow of the Royal and Antiquarian Societies; and died in 1771. He united to great learning a taste for the fine arts, and etched several plates in the edition of Dr. Hyde's Syntagma. His own works are: 1. A Review of the Controvery about the Meaning of the Demonicis in the New Testament. 2. A Defence of Dr. Clarke against Leibnitz. 3. Two Disquisitions upon the Origin of Languages, and the Power of Letters; with a Hebrew Lexicon. 4. A Dissertation on the Origin and Structure of the Latin Language. 5. Two Arguments in Defence of Christianity. 6. Translation of Holberg's Introduction to Universal History. 7. Sermons.
To which is prefixed a biographical preface, from which the foregoing facts have been extracted.

SHARPING CORN, a customary present of corn, which, at every Christmas, the farmers in some parts of England make to their smith, for sharpening their ploughing-irons, harrow-tines, &c.

SHARPING, in Ichthyology, the English name of the gatterofleus. See Stickle-Back.

SHARPSBURG, in Geography, a town of America, in Maryland; 69 miles N.W. of Baltimore.

SHARUM, a town of Arabia, in Hadramaut; 15 miles S.W. of Kefehim.

SHARUT, Sainrat, or Sharoot, a small town of Peria, in Alterabad, called also Balin, is surrounded in some parts with a flight earthen wall. The houses, from a want of wood, are built of unburnt brick; and covered with a flat arch of the same materials. In its vicinity are seen many people, whose noses, fingers, and toes have been destroyed by the frost, which is said to be severer at this place than in any part of Peria. This town, with its dependencies, yields a revenue of 1560 tomans. The position of the town is determined by two routes, one from Tehraun and the other from Tarshih.

SHASAD, or Shazadder, a town of Hindooftan, in the circcar of Sumbul; 16 miles S. of Sumbul.

SHASAVA, a town of Hindooftan; 18 miles S. of Agra.

SHASH, At. See Tassikund.

SHASHTI, in Mythology, a name of the Hindoo goddess Parvati; which see.

SHASK, in Geography, a town of Hindooftan, in Bagh- 

SHASSAIR, a town of Africa, in Biledulgerid; 7 miles N. of Fighig.

SHASTAH, Shaster, or Saffra, which latter is laid to be the correct spelling and pronunciation, the name of a facred book, in high estimation among the idolaters of Hindooftan, containing all the dogmas of the religion of the Bramins, and all the ceremonies of their worship, and serving as a commentary on the Vedam.

The word is derived from a root signifying to ordain, and means generally an ordinance, and particularly a facred ordinance delivered by inspiration: properly, therefore, the word is applicable chiefly to facred literature.

The term Shaster denotes science or system; and is applied to other works of astronomy and philosophy, which have no relation to the religion of the Indians. None but the Bramins and rajas of India are allowed to read the Vedam; the priests of the Banians, called Sudderers, may read the Shaster; and the people, in general, are allowed to read only the Paran or Pouran, which is a commentary on the Shaster.

The Shaster is divided into three parts; the first containing the moral law of the Indians; the second, the rites and ceremonies of their religion; and the third, the distribution of the people into tribes and classes, with the duties pertaining to each class.

The principal precepts of morality contained in the first part of the Shaster, are the following: that no animal be killed, becaufe the Indians attribute fouls to brute animals as well as to mankind; that they neither hear nor speak evil, nor drink wine, nor eat flesh, nor touch any thing that is unclean; that they observe the feats, prayers, and washings, which their law prescribes; that they tell no lies, nor are guilty of deceit in trade; that they neither opprefs nor offer violence to one another; that they celebrate the

solemn feasts and feafts, and appropriate certain hours of ordinary sleep to cultivate a disposition for prayer; and that they do not feal, or defraud one another.

The ceremonies contained in the second part of the Shaster, are such as these: that they wash often in the rivers, hereby obtaining the pardon of their sins; that they mark their forehead with red, in token of their relation to the Deity; that they perform offerings and prayers under certain trees, set apart for this purpose; that they pray in the temple, make oblations to their padogas, or idoles, fing hymns, and make procelfions, &c.; that they profcribe pilgrimages to diftant rivers, and especially to the Ganges, there to wash themselves, and make offerings; that they make vows to particular fants, according to their refpective departments; that they render homage to the Deity, at the firft light of the fun; that they pay their refpect to the fun and moon, which are the two eyes of the Deity; and that they treat with particular veneration, thofe ani- mals that are deemed more pure than others, as the cow, buffalo, &c., because the fouls of men have tranfmi grated into these animals.

The third part of the Shaster records the distribution of the people into four claffes; the firft being that of the Bramins, or priests, appointed to inftitute the people: the second, that of the Kutteris, or nobles, who are the ma-giftrates: the third, that of the Shudderis, or merchants; and the fourth, that of the mechanics. Each perfon is required to remain in the clafs in which he was born, and to pursue the occupation affigned to him by the Shaster. According to the Bramins, the Shaster was imparted by God himfelf to Brahma, and by him to the Bramius, who communicated the contents of it to the people.

Modern writers have given us very different accounts of the antiquity and importance of the Shaster. Mr. Holwell, who had made a confiderable progress in the translation of this book, apprehends, that the mythology, as well as the coignomy of the Egyptians, Greeks, and Romans, were borrowed from the doctrines of the Bramins contained in it, even to the copying of their exteriors of worship, and the distribution of their idols, though grofsly mutilated and adulterated. With refpect to the Vedam and Shaitah, or feriptures of the Gentoons, this writer informes us that Vedam, in the Malabar language, signifies the fame as Shaitah in the Shancon; and that the firft book is followed by the Gentoons of the Malabar and Coromandel coasts, and also of the land of Ceylon. The Shaitah is followed by the Gentoons of the provinces of Bengal, and by all the Gentoons of the reit of India, commonly called India Proper, along the course of the rivers Ganges and Jumna to the Indus. Both these books, he fays, contain the inftinuates of their repective religion and worship, as well as the history of their ancient rafts and princes; often couched under allegory and fable: their antiquity is contended for by the partifans of each; but he thinks, that the fimilitude of their names, idols, and great part of their worhip, leares little room to doubt, nay, plainly evinces, that both these feriptures were originally one. He adds, if we compare the great purity and chaffe manners of the Shaitah, with the great aburdities and impurities of the Vedam, we need not hefitate to pronounce the latter a corrup- tion of the former.

With regard to the high original of these feriptures, the account of the Bramins is chiefly as follows. Brahma, g. d. Mighty Spirit, about four thoufand eight hundred and fixty- 

fix years ago, affirmed the form of man, and the government of Hindooftan. He translated the divine law (designed for the reftoration of mankind, who had offended in a pre-exi- dent
SHASTAH.

and who are now in the last scene of probation, to the dignity from which they were degraded,) out of the language of angels into the well-known Sanscrit language, and called his translation the “Chartah Bhade Shafta” of Birmah, or the Six Scriptures of the Divine Words of the Mighty Spirit. He appointed the Brahmans, deriving their name from him, to preach the word of God; and the doctrines of the Shafta were accordingly preached in their original purity a thousand years. About this time there was published a paraphrase on the Chartah Bhade; and about five hundred years afterwards, a second exposition, called “Aungtorrah Bhade Shafta,” or eighteen Books of Divine Words, written in a character compounded of the common Hindoo lan and the Shanfric. This innovation produced a schism among the Gentoos; on which occasion, it is said, those of Coromandel and Malabar formed a scripture of their own, which they pretended to be founded on the Chartah Bhade of Birmah, and called it the Vedam of Birmah, or Divine Words of the Mighty Spirit. The original Chartah Bhade was thrown aside, and, at length, wholly unknown, except to a few families, who can still read and expound it in the Shanfric character. With the establishment of the Aungtorrah Bhade, and Vedam, which, according to the Gentoo account, is three thousand three hundred and sixty-six years ago, their polytheism commenced; and the principles of religion became so obscure, and their ceremonies so numerous, that every head of a family was obliged to keep a Brahmin, as a guide both in faith and practice. Mr. Holwell is of opinion, that the Chartah Bhade, or original scriptures, are not copied from any other system of theology, promulgated to, or obstruded upon mankind. The Gentos do not attribute them to Zoroaster; and Mr. Holwell supposes, that both Zoroaster and Pythagoras visited Hindoostan, not to instruct, but to be instructed.

From the account of Mr. Dow we learn, that the books which contain the religion and philosophy of the Hindoos, are distinguished by the name of Bedas; that they are in number, and, like the sacred writings of other nations, are not penned by the divinity. Bedas, he says, in the Shanfric language, literally signifies science; and these books treat not only of religion and moral duties, but of every branch of philosophic knowledge. The Bramins maintain, that the Bedas are the divine laws, which Brimage, at the creation of the world, delivered for the instruction of mankind; but they affirm, that their meaning was perverted in the first age by the ignorance and wickedness of some princes, whom they represent as evil spirits, who then haunted the earth. The first credible account we have of the Bedas is, that about the commencement of the calling, of which era the year 1768 was the 488th year, they were written, or rather collected, by a great philosopher, and reputed prophet, called Beafs Muni, or Beafs the Inpired.

The Hindoos, says Mr. Dow, are divided into two great religious sects: the followers of the doctrine of Bedang, which is the original Shafta, or commentary upon the Bedas; and those who adhere to the principles of the Ne- adiren. The original Shafta is called Bedang, and is a commentary upon the Bedas. This, he says, is erroneously called, in Europe, the Vedam. It is ascribed to Beafs Muni, and said to have been revised some years after by one Sorider Swami, since which it has been reckoned sacred, and not subject to any further alterations. Almost all the Hindoos of the Deccan, and those of the Malabar and Coromandel coasts, are of this sect. The followers of the Bedang Shafta do not allow any physical evil exits; they maintain that God created all things perfectly good, but that man, being a free agent, may be guilty of moral evil, which may be injurious to himself, but can be of no detriment to the general system of nature. God, they say, being perfectly benevolent, never punished the wicked otherwise than by the pain and affliction which are the natural consequences of evil actions; and, therefore, is no other than a consciousnes of our evil.

The Neadiren Shafta is said to have been written by a philoopher called Goutam, near four thousand years ago. The Bramins, from Mr. Dow’s account of their sacred books, appear to believe invariably in the unity, eternity, omniscience, and omnipotence of God; and the polytheism, of which they have been accused, is no more than a symbolic worship of the divine attributes, which they divide into three classes. Under the name of Brimage, they worship the wisdom and creative power of God, under the appellation of Bhishen, his providential and preserving quality; and under that of Shishah, that attribute which tends to destroy.

According to M. de Sainte-Croix, the Shafta, however extolled in Europe with respect to its antiquity, is posterior to the Vedam, being no more than the explication of it. Holwell’s Interesting Historical Events, &c. 8vo. Dow’s History of Hindoojtan, 4to. 1766. L’Ezour Vedam, &c. by M. de Sainte Croix, 12mo. Paris, 1779. See Gentoos, Shanscrit, and Vedam.

Six Sastras are commonly described as of superior sanctity, and are called the proper Sastras:—in these are comprised the four Vedas, the eighteen Puranas, commentaries on the Vedas, called Upaveda, and others. (See Veda, and Purana.) The Sudra, or lowest of the four classes of Hindoos, are not permitted to study these fix Sastras, as being too holy for such prophane contemplation. (See Sudra.) As noticed under the article Ramayana, that book is reckoned too sublime for the perusal of the inferior classes. The Sudra may bear it read. An ample field, however, remains for them in the study of prophane literature, comprised in a multitude of popular books, which correspond with the several Sastras, and abound with beauties of every kind. All the tracts on medicine must indeed be studied by the Vaidyas, or those who are born physicians; and this profession is confined chiefly to the Sudras. The Vaidyas are said to have often more learning than many Bramins, with far less pride than any. They are usually poets, grammarians, rhetoricians, &c. and may be esteemed in general among the most amiable and virtuous of the Hindoos. See Vaidya.

The word Sastra is, however, applied more extensively than the above account may seem to imply. For instance, a collection of tracts on arts and manufactures, is called Silpi Sastra. The name of Niti Sastra is given to a system of ethics. The Derdana Sastra is indeed one of the fix superior, and comprises an explanation of the principles of the fix philosophical schools; a brief notice of which is given under the article Philosophy of the Hindoos. An analysis of this work would shew that many of its theories are either the source of similar doctrines propounded in later times in Greece, or borrowed from the same source with them. Other collections of tracts, and some separate works, bear also the denomination of Sastra; and it is sometimes rather vaguely applied. A Brahman deeply versed in sacred literature has the honourable title of Sastra added to his name; equivalent to our clericus. Sometimes he is distingished by it alone, and called the Sastra. There is also the Dharma Sastra, a body of ethics and ritual observances; the Agama Sastra, or occult ordinances. This latter has been suspected to have some reference to the Ogham of the west. See Ogham, and Omal.
Saffri, which was omitted in its proper place, is a name for the Hindoo deity Budha, or Boosh. The name signifies wisdom, or a wise man; and is still applied to, or alluded by, individuals, especially Brahmins, who are supposed to have acquired an extraordinary degree of learning or wisdom. As all profitable wisdom is presumed to be comprized in the Saffri, or sacred books, the title of Saffri is thence derived. It is sometimes appended similarly to the scholar's name; and he is at others called the Saffri, or Saffri falsib.—Mr. Saffri.

SHAMUN, in Geography, a town of Persia, in the province of Mavanderan; 30 miles E. of Eterabad.

SHAT-EL-AMAR, a name given by the Arabs to the Tigris.

SHAT-EL-DEAL, a river which runs from the north, and enters the Tigris near Bagdad.

SHAT-EL-DEGELA, a river or canal, so called by the Arabs, which communicates with another named Shat-el-Biez, which is a branch of the Tigris.

SHAT-EL-FRAATE, a name given by the Arabs to the Euphrates.

SHAT-EL-KRATU, in Mythology, one of the names of the Hindoo Indra, regent of the firmament. It means the hundred sacrifices; that is, he to whom a hundred sacrifices are offered; or rather, perhaps, he who has offered them. Indra, it is faided, obtained his present dignity by the great sacrifice of a hundred horses. An offering of a horse is called Afwamedha, and is attended with infinite trouble and expense, as laid down in the Hindoo rituals. See Indra, Nakhedia, and Riemha.

SHATNUT, in Geography, a town of Egypt, on the right bank of the Nile; 9 miles N. of Cairo.

SHATOOR, a town of Hindooftan, in Madura; 20 miles N.N.W. of Calpetta.

SHATORE, a town of Hindooflan, in Madura; 12 miles N.E. of Calpetta.

SHAT-UL-ARAB, one of the noblest rivers in the Eait, formed by the combined streams of the Euphrates and Tigris. The union of these streams takes place near Korna, or Corvy, which is one of the three Apameas, built by Seleucus in honour of his first wife, Apama. On the western bank of this river, and 70 miles from its mouth, in N. lat. 31° 30', is situated the city of Bulflora or Bafra; and the river is navigable as far as the city for ships of 500 tons burthen. The city is sometimes so completely deluged by the river, that it appears like an island in the middle of a lake. The combined stream of the Shat-ul-Arab has generally been thought to enter the Persian gulf by a variety of mouths; but the fact is, that this noble river has, at this time, only one mouth, and probably never had any other. The island, or delta, between the Shat-ul-Arab and the Bamiishna (the ancient Mefena) was formerly included in the pachalie of Bagdad; but having been conquered by Sheik Solymas from the Turks, has remained in the possession of his successors. This is a low and fertile tract: the northern parts of which, towards the Hafur, are interfaced by a number of canals, and are in a tolerable state of cultivation. Extensive ruins are visible in many places, and the borders of the Shat-ul-Arab, as far down as Chuba, are covered with date-trees. The river Shat-ul-Ajew, signifying in Arabic a river of Persia, discharges itself on the Persian side into the Shat-ul-Arab, near Margil.

SHATZAM, a town of Persia, in the province of Mekran; 210 miles S.E. of Arokhage.

SHAVAKAT, a town of Turkeftan, on the Surr; 20 miles S. of Taphkund.

SHAUBACO, a town of Egypt, on the left bank of the Nile; 16 miles S. of Cairo.

SHAVE GRASS, in Botany. See Equisetum.

SHAVING-IRONS, among Gardiners, tools to keep a garden free from weeds, otherwise called edging-irons.

SHAVINGS, Horn, in Agriculture. See Manure.

SHAW, or SHAW, an article of female drefs, much prized in the East, and now well known in England. As the shaws all come from Cashmere, or Cachemir, it was generally concluded, that the materials from which they were fabricated was of the growth of that country. It was said to be the hair of a particular goat, and the fine under hair from a camel's breast; but we now certainly know that it is the produce of a Thibet sheep. Bernier relates, that in his time, shaws made for the great omrals of the Thibetian wool, cost a hundred and fifty rupees; whereas those made of the wool of the country never cost more than fifty. For an account of their manufacture and value, see Cashmere.

SHAYOYA, or CHAYOYA, in Geography, a province of the empire of Morocco, situated to the S. of the kingdom of Fez, and W. of Tedla; inhabited by mountaineers addicted to robbery and violence. Towards the latter end of the last century refusing to pay tribute to the emperor, Muley Ismael, he marched an army, which, surrounding their strong holds on the mountains, compelled them to flight, leaving their wives and children, who were put to the sword, and the plunder distributed among the soldiers.

SHAUR, a small island in the Red Sea. N. lat. 27° 20'. E. long. 34° 58'.

SHAUS. See CHAUS.

SHAVUNGUNK, a mountain of New York; 20 miles S. of Kingston.

SHAW, THOMAS, in Biography, was born at Kendal in 1692. He was educated at the grammar school of that town, and in 1711 was admitted of Queen's college, Oxford. Soon after he had taken orders, he was appointed chaplain to the English factory at Algiers, in which station he remained several years, making use of the opportunity which it afforded of travelling into various parts of Barbary, and into Egypt. In 1727 he was elected fellow of his college, in 1733 he commenced D.D., and in the following year he was elected a member of the Royal Society in London. In 1738 he published his “Travels, or Observations on several Parts of Barbary and the Levant,” to which a supplement was added in 1746; and about ten years afterwards the whole appeared in a second edition, with considerable improvements. Few books of the kind lend higher in reputation than Dr. Shaw's Travels, which contain many learned dissertations respecting the countries which he had visited, with divers remarks on their manners and customs, and valuable observations in natural history. They have been regarded as particularly useful in illuminating the scriptures by comparisons between the ancient and modern state of the eastern regions. Dr. Shaw, on his return from his travels, brought back a large collection of dried plants. He presented to the university of Oxford some relics of antiquity which he had collected, of three of which engravings were made in the “Marmora Oxoniensis.” In the year 1740 he was chosen principal of St. Edmund's Hall, and was at the same time prefented to the vicarage of Bramley in Hampshire. Soon after the regius professorship was conferred upon him, which he held till his death, in 1751. His Travels have been translated into various modern languages. An attack was made on them by Dr. Pocock, which led the author to defend them in his supplement, and in a letter of Dr. Clayton, bishop of Clogher.
SHAW.

SHAW, Peter, a physician, and contemporary of the former, was the author of several works, which enjoyed a considerable reputation in their day. His first publication was entitled "New Practice of Physic," in two volumes, and first printed in 1726; it contained a brief description of diseases and the methods of treating them. His next work was an "Enquiry into the Virtues of Scarborough Spaw Waters," which he visited during the season; it was printed in 1734. In the same year he published also "Chymical Lectures publicly read in London 1731, 1732, and Scarborough 1733." This was deemed a scientific and valuable work, and was translated into French. He published some minor works, "A Portable Laboratory," 1731; "On Scurvy," 1736; "Essays in Artificial Philosophy," 1731; "On the Juice of the Grape," 1724; and he edited the "Dipensatory of the College of Physicians of Edinburgh," in 1727. See Eloy Diet. Hist. de la Méd.: and the works mentioned.

SHAW, George, the younger of two sons of the reverend Timothy Shaw, was born December 16th, 1751, at Birton, in Buckinghamshire, of which place his father was vicar. He flourished, at a very early age, a great propensity to study, and when he was only four years old, instead of following the amusements common to young children, he usually entertained himself with books, or by the side of ditches and rivulets catching insects, and taking them home, and would spend all his leisure time in watching their motions and examining their structure. He was educated entirely by his father, and before he was fourteen years of age, his proficiency was such as allowed him to enter with great advantage upon a course of college studies. In 1765 he was entered at Magdalen-hall, Oxford, where he was no less distinguished by the regularity of his conduct, than by an uncommon diligent application to his studies. In 1769 he was admitted to the degree of B.A. and in May 1772 to that of M.A. In order that he might assist his father in his clerical duties, he took orders, and was ordained deacon in 1774, at Buckden, by Dr. Green, bishop of Lincoln, and regularly performed the duty at Stoke and Buckland, two chapels, each three miles apart from the mother church. As soon as an opportunity offered, he laid aside his theological career, which was never quite congenial to his mind, and went to Edinburgh, to qualify himself for the profession of physic. Having attended the lectures of Black, Cullen, and other eminent professors for three years, he returned to Oxford, where he was appointed deputy botanical lecturer. In this office he acquired much celebrity. He had been appointed to his office by Dr. Sibthorp, the botanical professor, who was then upon the eve of setting out upon his travels into Greece. (See Sibthorp.) Upon the death of this gentleman, Dr. Shaw became candidate for the vacant professorship, in which he would unquestionably have been successful, had not an old statute been found, which prohibited a person in orders from filling the office. In 1787 he was admitted to the degrees of bachelor and doctor of medicine: it appears that at this time he had removed from Magdalen-hall to Magdalen college. In the same year he removed to London, where he practised as a physician. Shortly after this, several gentlemen, distinguished for their attachment to the study of, and eminent for their acquirements in natural history, established a society for the advancement of this science, under the denomination of the Linnean Society. Dr. (now Sir James) Smith was elevated to the presidency, and Dr. Shaw was nominated one of the vice-presidents. To the Transactions of this Society Dr. Shaw contributed the following papers. "Description of the Stylephorus Cordatus," which see; "Description of the Cancer Stagnalis;" "Remarks on the Scolopendra Electrica and Scolopendra Subterranea;" "A Note to Mr. Kirby's Description of the new Species of Hirudo;" "Account of a minute Ichneumon;" "Description of the Species of Mycteris;" "Description of the Mus Bursarius, and Tubularia Magnifica;" "C poet, Dr. Shaw at this period delivered a course of lectures at the Leverian Museum, and never failed, as well before, as after, that rich and magnificent collection was removed from Leicester Fields, to attract very large and scientific audiences. In 1780 Dr. Shaw began to publish "The Naturalist's Miscellany," which came out in monthly numbers, and continued to his decease, when 286 parts had been published, and, according to the biography of the author given in the Gentleman's Magazine, a posthumous number, with an index, was to terminate the work, which is described as a most beautiful and extensive production, comprising, in 1064 plates, figures of the more curious and remarkable productions of the three kingdoms of nature, more particularly of the animal kingdom, with descriptions in Latin and English. In this year Dr. Shaw was elected a fellow of the Royal Society, and in 1790 he projected a work in 4to. entitled "Speculum Linneum; or Linnean Zoology," but it probably did not promise success, as a single number only appeared. In 1791 Dr. Shaw became a candidate for the office of a librarian in the British Museum, and his qualifications, which were of the first order, procured him the appointment of assistant keeper of the natural history. He now quitted the duties of physician, and devoted himself entirely to researches in natural science. Between the years 1792—6, appeared the following work; "Musei Le- verniani explicatio Anglica et Latina, opera et studio Georgii Shaw, M.D. F. R. S. Adduntur figuræ elegantur sculptæ et colorata. Impenis Jacobii Parkinson." In 1794 Dr. Shaw, in conjunction with Dr. Smith and Mr. Sowerby, engaged in a splendid publication, illustrative of the accidents which had been made to natural science on the shores of New Holland. The animals peculiar to that country were described by Dr. Shaw in a work entitled "The Zoology of New Holland," the figures were delineated by Mr. Sowerby, and the botanical part was written by Dr. Smith, and published under the title of "The Botany of New Holland." Sixty large plates published by Miller, the editor of the Gardener's Dictionary, under the title of "Various Subjects in Natural History, wherein are delineated Birds, Animals, and many curious Plants," being judged defective from want of letter-pens, Dr. Shaw supplied the deficiency in a work entitled "Cimelia Physica: Figures of rare and curious Quadrupeds, Birds, &c., together with several most elegant Plants, engraved and coloured from the Subjects themselves: with Descriptions by George Shaw, M.D. F. R. S."

In the year 1800, Dr. Shaw began his great work, entitled "General Zoology, or Natural History, with Plates from the best Authorities, and most exact Specimens." This work had proceeded to the eighth volume during the life-time of the author, and a ninth was left ready for the press. In this work he intended to comprise the whole of the history of the animal world. It began with quadrupeds, and had proceeded through fishes, amphibious, insects, and part of the birds. The Linnean arrangement, with occasional variations, has been pursued throughout.

In the years 1806 and 1807, Dr. Shaw delivered a course of zoological lectures, which were published in 1809 in two large volumes 8vo. In the first nine lectures the author has comprehended the substance of what he had delivered in the General Zoology, and in the three remaining lectures is a sketch...
a sketch of what, had his life been spared, he intended to accomplish in completing the General Zoology. In 1807, upon the death of Dr. Gray, keeper of Natural History in the British Museum, Dr. Shaw was promoted to that office. An abridgment of the Transctions of the Royal Society was begun in 1809, of which the department of natural history fell to the lot of Dr. Shaw. It is said he bridged 1500 distinct articles, which he rendered still more interesting than the originals, by the insertion of Linnean and specific names, and by occasional annotations, and considerable references to subsequent authors of note, who had treated on these subjects. This was the last work in which he engaged. His time was wholly occupied upon the "Naturalist's Miscellany" and the "General Zoology," when death terminated his active and very useful life on the 22d of July, 1813, in the 62d year of his age. His illness was but of a few days' continuance: his fenes and his recollection only forsook him with his breath. He died, as he had lived, with philosophic composure and serenity of mind, which neither the acute pains which he endured, nor the awful change which he was well aware he was about to experience, could in any degree disturb.

"As few men have left behind them a character more estimable, his name will be transmitted to posterity among those who give tribute to their age and country, who do honour to human nature by their virtues, and who contribute to the advancement of science, and the interests of literature, by their superior talents. Endowed by nature with considerable intellectual parts, and these improved by affuluous cultivation, he acquired a vast flock of general knowledge. His extensive information was treasured up without confusion, applied in his works with discernment, and communicated to every enquirer with cheerfulness and freedom." Gentlemen's Magazine, 1813, p. 290.

SHAW, Sydney, a divine and antiquary, was born at Stowe, in Staffordshire, in 1762, and educated first at Repton school, and afterwards at Queen's college, Cambridge, where he took his degrees and obtained a fellowship. In 1787 he made a tour in the Highlands of Scotland, of which he published an account without his name. In the following year he made another tour in the west of England, an account of which he also published. In 1789 he commenced, in conjunction with a friend, a periodical publication, called The Topographer, chiefly consisting of extracts made from curious books and MSS. in the British Museum. This work was discontinued in about two years. He next undertook the "History of Staffordshire," of which the first vol. in folio, was published in 1793: in 1801 the first part of the second volume was given to the public, and he died in 1803.

SHAW, in our Old Writers, a grove of trees, or a wood. Shaw Fowl, an artificial fowl made for fowlers to shoot at.

SHAW'S ISLAND, in Geography, a small island in the North Pacific ocean, at the entrance of Cook's Inlet. N. lat. 50° 16'. E. long. 205° 16'.

SHAWABAD, a town of Hindoostan, in the circle of Rantampos, 35 miles S. of Sultanpoor.

SHAWANEE, a town of America, in the county of Randolph, and territory of Illinois, containing 830 inhabitants.

SHAWANEESE, the denomination of a tribe of Indians who inhabit Louisiana, on the Mississippi and St. Francis. The number of warriors is 300; that of the inhabitants 800; their trade requires 1000 dollars of merchandise; the value of their returns is 3000; their commerce is carried on in their villages or settlements. The Indians of this tribe have four towns on the Tallapoosie river. By the treaty of peace, Aug. 3, 1795, the United States agreed to pay this tribe a sum in hand, and 1000 dollars annually for ever in goods. They inhabit on the Scioto river, and a branch of the Muskingum, and have their hunting grounds between Ohio river and lake Erie. They are generally of a small size, rather handsome in their features, and a cheerful, hardy people. Counselling among the elder, and dancing among the young men and women, take up a great part of their time.

SHAWANGUNK, a post-town in Ulster county, New York; containing 2809 inhabitants; 7 miles from Goshen and 12 from New Paltz.

SHAWGUNGE, a town of Hindoostan, in Allahabad; 32 miles N. of Gazypour.

SHAWI, in Botany, received its name in honour of the celebrated oriental traveller, Dr. Thomas Shaw, who has given a catalogue, in alphabetical order, accompanied with rude plates, of the rarer plants, observed by him in Barbary, Egypt, and Arabia. The species amount to 632, and the catalogue is enriched with several synonyms, as well as occasional descriptions and remarks. His dried specimens are preserved at Oxford. The orthography of the name is attended with difficulty to foreigners, our泽 being as unmanageable to them, as their multiplied confonants are to us. Some of them blunder into Shaweis, Shawoia, or Shaweia. Perhaps the latter might be tolerated, were it not for the ludicrous ambiguity of Shawin itself, applied by facetious Oxonians to the above famous traveller and his namesake.—Forster, Gen. t. 48, Prodr. 58, Schreb. Gen. 595, Mart. Mill. Dict. v. 7, Juff. 182, Lamarec. Dict. v. 7, 148. Clas. and order, Synonyma Monogynia, Forster. S. Polygynia-fegrae, Schreb. Nat. Ord. Compositae Nidiflora, Linn. Corymbiarefa, Juff.

Gen. Ch. Cal. Periathanum incirrillated, cylindrical, of five or six oblong scales; the three innermost longest, and nearly equal. Cor. of one petal, funnel-shaped, short; limb in five linear spreading segments. Stam. Filaments five, capillary; anthers united into a cylindrical tube. Pet. Gèmen oblong, below the corolla, superior with respect to the calyx; style thread-shaped, longer than the corolla; stigma divided, spreading. Peric. none, except the unexpanded perianth of calyx. Seed solitary, oblong. Down capillary, woolly at its base. Recept. naked.

1. S. paniculata. Forster, Prodr. n. 1.—Native of New Zealand. We have seen no specimen of this plant. The younger Linnaeus, in his copy of Forster's book, has made a note of its being referred by Banks and Solander to Solidago, under the name of undulata. Perhaps this is the most natural way of disposed of it; though if the calyx never contains but one floret, and is not in any way aggregate, the genus should stand in Pseudoria Monogynia, along with Corymbium, at least according to the strict laws of artificial arrangement; but we should hardly, in either case, recommend such a measure.

SHAWLE, in Agriculture, a name applied to a shovel used in winnowing corn, in some places.

SHAWINGUNGE, in Geography, a town of Bengal; 18 miles W. of Rungpore. N. lat. 25° 27'. E. long. 88° 46'.

SHAWNAWAZ, a town of Hindoostan, in the subah of
of Moulton; 70 miles N.E. of Moulton. N. lat. 30° 40'.
E. long. 77° 38'.

SHEAP, a town of Bengal; 12 miles S.E. of Moorschabad.—Also, a town of Bengal; 30 miles S. of Calcutta. N. lat. 20° 57'. E. long. 88° 26'.—Also, a town of Hindooftan, in the circuit of Surgooga; 28 miles N. of Surgooga. N. lat. 23° 55'. E. long. 83° 25'.—Also, a town of Hindooftan, in Bener; 45 miles N.W. of Maltoy.

SHEA, a town of Hindooftan, in the circuit of Chandere; 45 miles W. of Chandere.

SHEAVERN, a considerible stream of America, in Massachusetts, which rises in Bedford county, Middlesex, and passing through Billerica, Tewkbury, and Andover, discharges itself into Merrimack river.

SHAYE, a town of Hindooftan, in Guzerat; 33 miles N.E. of Junagur.

SHAYSHAR, a town of Syria, anciently called Larije, on the Orontes; 10 miles N. of Hamah.

SHAZADABAD, a town of Hindooftan, in Allahabad, on the right bank of the Ganges; 30 miles N.W. of Allahabad. N. lat. 25° 42'. E. long. 81° 43'.

SHADAPOUR, a town of Hindooftan, in Bengal; 25 miles S.E. of Nattore. N. lat. 24° 12'. E. long. 89° 43'.

SHEARING, a riding, tything, or division, in the Isle of Man; the whole island being divided into six sheadings, in every one of which is a coroner, or chief constable, appointed by the delivery of a rod at the annual convention.

SHEAF, in Agriculture, a bundle of corn, as bound up in the field. Sheaves are made of very different sizes in different places, but they are belt when not made too large.

SHEAF-CORN, such grain as is in the flake or ear in the straw before being threshed out. It is sometimes employed in this stage as fodder for different sorts of live stock.

SHEAF of Arrows, a bundle consisting of 24 in number.

SHEAGUR, in Geography, a town of Hindooftan, in Myfore; 4 miles W.N.W. of Vaniambaddy.

SHEALLINGS, in Rural Economy, the portions of rich grass-land in the more hilly and mountainous parts of the country, which were fixed upon, and taken possession of, by the farming inhabitants at an early period of society, for the purpose of retiring to, and grazing their cattle-stock upon, at certain feasons of the year. Some fine well-feltered spot in such hilly ranges was always fixed on in this intention, which was removed from one to another whenever the cattle had consumed the grass of it; huts or city being provided for the companioning persons to live in, who had the care of the animals, &c.; a trusting servant being usually sent before hand to secure the spot, and drive away any wandering and tree-passing cattle from it. This person was denominated the poudler, perhaps because he was authorized to pound or confine troublesome stock, and fix the fine established for the trespas. In some eases there were more than one such spots, and where they were very rich, as near lakes, brooks, or in vallies, the grass was consumed in common by two or more of them associating together. The sheallings were by no means, as
SHEARING, another term commonly applied to a sheep that has been once thorn by sheep-masters.

SHEARPOR, in Geography, a town of Hindoostan, in Bengal, on the Burhampooter; 82 miles W.N.W. of Dacca. N. lat. 24° 53'. E. long. 89° 55'.

SHEAR, or Sheets, a name by which men call a young hog.

Sheet, or Sheets, in a Ship. See Sheet.

If the main-fall sheets are haled aft, it is in order to make a ship keep by a wind, but when the fore-sheets are haled aft, it is that the ship may fall off from the wind; and if she will not do it readily, then hale the fore-fall, by the sheet, flat in, as near the ship's sides as they can; and this they call flatting in the fore-fall. When they say, cafe the sheet, they mean veer it, or let it go out gently; but when the word is, let fly the sheet, they mean let it go all at once, and run out as fast as it can; and then the fall will hang loose, and hold no wind. The Lemmen say, when they would have the sheets of the main or fore-fall haled aft, hastily the sheets.

Sheets, in a Ship, also, are those planks under water which come along her run, and are clefted into the forecastle; so also that part within board, in the run of the ship, is called the flem-sheets.

Sheet, False. See Sheet.

Sheet, Overhale the, in Sea Language, a word of command to hale upon the standing part of the sheet.

Sheet-Anchor, in a Ship. See Anchor.

Sheet of a Plough, in Agriculture, that part of the plough which passes through the beam, and is fastened to the share. It is sometimes called sheet.

And the sheet, or as it is sometimes called, the fore-sheet, there being another piece of timber behind it, which is called the hinder-sheet, should be seven inches wide, and fastened to the beam by a rathe (a piece of iron with two legs), and by a wedge driven by it into the hole of the beam. But in the modern construction of this tool, the sheet is fastened without having recourse to these means. The angle contained between the sheet and the beam of the plough should be about forty-two degrees.

SEATH, in Botany, is synonymous with spath, perichetium, and vagina. In the first instance it belongs to the single-leaved covering, turfing longitudinally, which Linnaeus reckons a kind of calyx, differing from a perianthium in being more or less remote from the flower. Such occurs in Galanthus, Narcissus, Allium, and others of the Hexandrous class; as also in Arum; and more especially in the natural order of Pala. The pericheium, fee that article, is the fcaly sheet, or calyx, of Mosses. Vagina, which will be further explained in its place, is the sheathing part of a leaf.

SHEATHING of a Ship, is the casing that part of her hull which is to be under water with something to keep the worms from eating into her planks.

It is usually done by laying tar and hair, mixed together, all over the old plank, and then nailing on this new boards. But this hinders a ship's falling; and therefore, of late, some have been sheathed with milled lead, which is much smoother, and consequently better for falling; and also more cheap and durable than the other way. It was first invented by Sir Philip Howard, and major Watton.

The sheathing with copper is a still later invention, and answers better than any other.

It is very well worth the trying what the new fline pitch will do in this case; if it will defend from the worm, as perhaps it may, a ship might be paid with it cheaper than with the crown pitch; and it will not crack nor scale off, as that will do, but keeps always soft and smooth. It has been found to continue on thirteen months, and to remain very black and soft all the time.

SHEAVE, a cylindrical wheel, made of hard wood or metal, moveable round a pin as its axis in a mortice, as being used to raise or decrease the mechanical powers, as a pulley, applied to remove or lift weighty bodies. Sheaves are either fixed in blocks, to form tackles, or let through the ship's sides, for affisting to lead the tacks and sheets on board, or in mortices cut through the masts, yards, caps, &c. to facilitate the working of the rigging, and outer ends of the cat-heads, to form the cat-tackle to raise the anchor to the bow.

SHEAVES, in Rural Economy, provisionally the broken parts of the stems of flax which come away in dressing. Also the small bundles of grain in the straw.

SHEB, in Geography, a town of Nubia, on the borders of Egypt, on the route from Carje to Cobbe; 175 miles N. of Carje. This place is occasionally infested by a tribe of the wandering Arabs, called Abodé, who come from the neighbourhood of the Nile. Sheb is marked by the production of a great quantity of native alum, as the name imports. The surface, from which the alum is found, abounds with a reddish stone; and in many places is seen argillaceous earth.

SHEBAT, in Chronology, the eleventh month of the Jewish ecclesiastical year, answering to part of our January and February.

SHEBBY, or SHELBY, as Morse has it, in Geography, a county of Kentucky, in the United States, containing 14,453 inhabitants, of whom 2906 are slaves.

SHEBBYVILLE, a town of the forementioned county, containing 424 inhabitants, of whom 118 are slaves; so that the total in the county and town includes 14,877 inhabitants.

SHEBSHIR, a town of Egypt; 9 miles S. of Amrus.

SHEBUSTER, a town of Perfa, in the most picturesque, and, at the same time, the most flourishing division of Azerbaijan, which lies along the N. and W. borders of the lake of Uremea, from the Tabreez to the confines of Armenia. Shebuster is a large and flourishing town.

SHECATICA BAY, a bay on the S. coast of Labrador, N. lat. 51° 20'. W. long. 58° 20'.

SHECHALLION, or SHICALLION, a lofty mountain in the parish of Fortingall, district of Rannoch, and county of Perth, Scotland, is situated in the immediate vicinity of Loch Rannoch. It rises in a conical form, and hence derives its name, which signifies the maiden's breast. According to mensuration, its height is 3564 feet above the level of its base, which nearly coincides with that of the ocean. This mountain is rocky and barren; but is particularly remarkable from the circumstance of its having been chosen by Dr. Malkeflure, late altronomer royal, for ascertaining the powers of mountains in attracting the pendulum. Sinclair's Statistical Account of Scotland, vol. ii. 1792. See Attraction of Mountains, and Mountains.

SHECHINAH, in the Jewish History, the name of that miraculous light, or visible glory, which was a symbol of the special presence of the Deity. This shechinah, after it had conducted the Israelites through the wilderness, had its more flated residence in the tabernacle and the temple. See Ark of the Covenant.

For a farther account of this miraculous phenomenon, the
the reader may consult part ii. chap. 2. of Mr. Lowman's Rationale of the Hebrew Ritual.

Toland, in his "Tetradymus," has attempted to prove, that this appearance had nothing miraculous in it, but was only a kind of beacon, used by the Israelites for their direction in their journey.

SHED BUILDING, in Agriculture, a term applied to any fort of flight temporary building.

SHED, Open, a fort of flight open building, for containing cattle, and various other uses in the farm-yard. See Cattle Shed.

SHED, in Rural Economy, a term signifying to part, with the fingers and thumb, wool, hair, &c. as in salving sheep.

SHEDDING of the Hair, in horses, is the cutting of the coat. See Moulting.

SHEDDIE, in Geography, a harbour on the E. coast of New Brunswick.

SHEDMA, a province of Morocco, containing 550,000 inhabitants. This province produces wheat and barley; its fruits are not so rich as those of the north, or of Sufe; it abounds however in cattle. Of goats it furnishes annually an incalculable number, the skins of which form a principal article of exportation from the port of Mogodor; and such are often the animosity and opposition among the merchants there, that they have sometimes given as much for the skin, as the animal itself was sold for. Honey, wax, and tobacco are produced in this province; the two former in great abundance; also gum arabic, called by the Arabs "Alk toh," but of an inferior quality to that of the Morocco district.

SHEDUAN, an island in the Red sea, about nine miles long and six broad. It is high and craggy, without wood or water; it is situated at about an equal distance between the two coasts of Egypt and Arabia. N. lat. 27° 34'.

SHEDWOOD, in Rural Economy, provincially rough poles of top wood. See Wood.

SHEEY MOUNTAINS, in Geography, the name of a range of mountains in the barony of Mulkerry, and western part of the county of Cork, in Ireland. Of these and other mountains along the confines of Kerry, it is observed by Mr. Townend, in his Statistical Survey, that though sometimes high, they generally want grandeur, and that the intermediate hollows are seldom marked with striking or romantic scenery. The adjoining lands are rude, rugged, and fanny in the extreme, with a very scanty intermixture of anything fair or fertile to relieve the eye amidst such a dreary waste.

SHEELIN, or, as Arrowmith spells it, Shillia, a lake on the south of the county of Cavan, Ireland, situated between it and the counties of Meath and Westmeath. The river Inn flows from this lake, of which Mr. Edgeworth has said, in his report to the Bog Commissioners, that it is in many places a fine deep river, and capable of being rendered navigable at a small expense, and to great national advantage.

SHEEP, in Zoology. See Ovis.

SHEEP, in Agriculture and Rural Economy, a well-known species or kind of live-flock kept by the farmer. The sheep belongs to the class of ruminant animals, or such as chew the cud, and of which there are different species, and varieties or breeds. And in its generic character it is distinguished by being with or without horns, which are hollow, wrinkled, turning backward, or inserted in a spirall manner. Eight front teeth in the lower jaw, in the upper none.

It is evident that sheep are animals of the utmost importance to mankind, whether considered in the light of affording food and clothing, or in that of the vast improvement and profit which they produce in the various systems of management to which they are subjected by the farmer; in some instances constituting a very large proportion, and in others nearly the whole of his dependence and support. There is also another point of view in which they appear equally advantageous and interesting, which is that of their becoming thus beneficial in situations and upon lands that might otherwise be nearly if not wholly useless. Also in the view of affording the raw material for one of the most extensive staple manufactures of the kingdom, the advantages which they afford are almost incalculable.

But besides the wool, the skins and other parts of these animals afford a variety of other equally useful and important articles and products, such as those of parchment, leather, glue, fuel, and many others, which are of great value for different intentions and purposes in the arts and other ways, and which employ a great number of labourers in forming and preparing them. In short, there is hardly a part of the sheep that does not afford an useful and valuable product of some sort or other. In usefulness they may, of course, be placed at least next to, if not before, the cow. In disposition, almost all the improved breeds are extremely mild, tame, and gentle, which is a proof of their value as grazing flock: but those which have been less attended to, or which continue more in their native or original state, are much less tractable, as those which inhabit the downs, heaths, and mountains in different parts of the island.

The character of stupid, want of sagacity, and of some other valuable properties, which the naturalist Buffon has given these animals, seems by no means well-founded. It is probably the offspring of prejudice, and the improper examination of the subject.

The increase or growth of the sheep continues to advance till at least three years old, when it is in general considered as in the most proper state for the purposes of the grazier, though it is employed in this way till a much later period, sometimes even till five or six, and also with the view of breeding; but an early maturity is a property of much consequence, especially for the grazier. Of sheep, the breeds or varieties that are dispersed over the globe are almost endless; even in this country they are so extremely numerous as scarcely to be desribed with any correctness.

The characteristic circumstances by which they have been chiefly distinguished, are those of their poll-plucking horns, or being wholly without them, and from the length or shortness and fineness of the wool or coat, as well as the situation in which they are chiefly found. It has been stated by lord Somerville, in his "System of the Board of Agriculture," that all the breeds of sheep in this kingdom may be arranged into two classes; those which shear the short or clothing, and those which shear the long or combing wool. And that the quality of the fleece in each class follows the character of the wool; the short-woollen sheep being close in the grain as to fleece, consequently heavy in the scale, and highly-flavoured as to the table; the polled long-woollen sheep more open and loose in the grain, and larger in size. And by the author of "The present State of Hulbandry in Great Britain," they have been distributed under three general divisions, as below:

1. The mountain breed;
2. The short-woollen breed; and
3. The long-woollen breed.

And among the first are comprised several varieties, as the black-faced, which range on the mountains of Wales, Wellow-
SHEEP.

Welbmoreland, Cumberland, Yorkshire, and those in the south, west, and north of Scotland, and in the Shetland islands; the Cheviot hills, in the south of Scotland and north of England; and the forest and common sheep of the last-mentioned country. In the second division are included those of Hereford, Dorset, Sulles, Norfolk, and some parts of Cumberland. And the third division comprehends all those varieties that are dispersed over the more rich and fertile parts of England, and which are distinguished under the titles of the Durham or Teeswaters, the Lincolnshires, the old and new Leicestershires, &c. But others divide them into long, short, and middle-wooled kinds.

And a still more clear and concise view of the various breeds of British sheep, is afforded in the tabular form given by Mr. Culley, as enlarged and corrected by the author of the "General Treatise on Cattle," and others.

Table of the Breeds or Varieties of Sheep in England.

</table>

There are a few other breeds met with in different districts, as noticed below.

Since it is found by the grazer that the more an animal approaches towards perfection in its form, the better, in general, it is adapted to the purpose of fattening; it is obviously a matter of much importance to be well acquainted with the peculiar disposition and constitution of parts which constitute such excellence or perfection of form; these have been already fully explained in speaking of the nature and principles of breeding animals, as well as in considering the nature and management of cattle. And the same thing is to be aimed at in sheep-flock; as the more any breed may approximate to such an excellence of shape, the more perfect it must be. A form of model to be aimed at, in so far as shape is concerned, in the improvement of these animals, due attention being always had to other properties, has been given by Mr. Culley, in his description of a ram, and which may be seen under that head. (See RAM.) The nature and combination of the various points and parts should, of course, be well understood and impressed on the mind of the breeding and grazing farmer, in order that he may always rear or procure these animals to the greatest advantage.

The varieties of this most useful animal are endowed with different particular qualities, properties, powers, and propensities, which is necessary to ascertain, in order for the farmer to draw and produce the utmost advantage possible from the combining, crossing, and rearing of them. All the breeds of sheep are the most distinct while they are kept or left in the state of nature.

The common and usual descriptions of the several breeds are the following:

Teeswater Breed or Variety.—This is a breed of sheep said to be the largest in the island; it is at present the most prevalent in the rich, fine, fertile, inclosed lands on the banks of the Tees in Yorkshire. In this breed, which is supposed to be from the same stock as those of the Lincoln, greater attention seems to have been paid to size than wool. It is, however, a breed only calculated for warm rich pastures, where they are kept in small lots, in small inclosures, and well supported with food in severe winter seasons. The produce in weight of mutton is large, but then from their requiring so much longer time and richer keep, and being admitted in so much smaller proportions on the acre, they are probably not, upon the whole, so profitable, even in situations where they can be kept with the greatest chance of success, as the smaller more quick-feeding breeds. In the ewes there is, however, a property which is of much consequence, which is, that in general they are very prolific, bringing two and frequently three lambs, and in some cases a greater number each, according to Mr. Culley. He gives the following description of the breed. The legs are longer, finer boned, and support a thicker and more firm and heavy carcase than the Lincolnshires; the sheep are much wider on the backs and sides, and afford a fatter and finer grained mutton. The weight per quarter in two-years old
old wethers is from 251bs. to 35lbs., and in particular
inances to 55lbs. or more. The wool is shorter and less
heavy than in that breed. However, the writer of the
"Treatise on Cattle," thinks that the breed is nearly worn
out; but he adds that there is a similar breed in Ireland.
This is a sort of sheep that has been little attended to,
but which, when improved by proper crossing, it is supposing,
would answer, and pay well in districts where it would be
well supported. In the Corrected Report of the State
of Agriculture in the Well Riding of Yorkshire, Mr. Par-
kinson supposes that an useful kind is capable of being
bred by crossing the ewes of this fort with Dibbly rams, in
a careful manner. And it is added, that by the use of
these, and those of the Northumberland kind, the quality
of the wool and the mutton has not only been greatly
improved, but the quantity of bone and offal much increased;
and, at the same time, the fattening property considerably
increased; they becoming fatter at two years old than the
others are at three. The wethers of this improved fort
generally fall unhorned, at two years old, from 45s. to 5s.
a-piece, and weigh from twenty-four to thirty pounds the
quarter. They fell a great deal higher at the present time.

Lincolnshire Breed or Variety.—This is a breed of sheep
which is characterized by their having no horns; white faces;
long, thin, weak carcasses; thick, rough, white legs; bones
large; pelts thick; slow-feeding; mutton coarse-grained;
the weight per quarter in ewes from 12lbs. to 20lbs.; in
two-year old wethers from 20lbs. to 30lbs.; the wool
from 10 to 18 inches in length. And it is chiefly prevalent
in the districts which gives the name, and other rich grazing
places. But the writer of the work on Live-stock supposes
that this breed is now so generally improved by new Leice-
ter tupps, that they are probably, in a great measure, free
from those defects of the old breed, of which Mr. Culley,
with much reason, complained, namely, slow feeding, from
a looseheads of form, and too much bone, and coarse-grained
flesh. It must not, however, be denied, that a good old
Lincoln has ever been, and the same, at least, ill continues
great favourite at Smithfield, and the flavour of the Lin-
coln mutton has been generally held superior, as more
favour than the Dibbly. The new or improved Lincolns
have now finer bone, with broader joints and trussed carcasses,
and are among the best, if not actually the best, long-wooled
stock we have. Many will recollect the ridiculous and
indecorous squabbles, some years ago, between two eminent
breeders concerning these two breeds of sheep. About
this time, they attempted to feed Lincoln sheep on the
Effex marshes, and pretented the Dibbly degenerated, which
might happen from insufficiency of winter keep, or, if they
were feeding with cows, from cross with other breeds, an
overlasting and undervalued practice in those not professedly
breeding counties. This has been suggested as a breed only
capable of being made fat on the richest grazing lands;
but that in such cases it may probably be kept till three
years old, with greater profit than the new Leicesters.
The proportion of bone to mutton is considerable, and the
latter not very fine in quality. But the principal excel-
ence of the breed is in the large quantity which it affords,
which pays for their being kept longer before they are
fatted. Such breeds as feed quicker should however be
preferred by the farmer on moist lands of.

New Leicesters, or Dibbly Breed or Variety.—This is an
improved breed of sheep, which is readily distinguished
from the other long-wooled forts, according to Culley, by
having fine lively eyes; clean heads, without horns; straight,
broader, flat backs; round or barrel-shaped bodies; fine
small bones; thin pelts; and a disposition to make fat at
an early age; to which may be added a superiority in the
fineness of the grain and the flavour of the mutton to that
of other sheep of the long large-wooled kinds. The
weight per quarter in ewes three or four years old from
18lbs. to 20lbs.; in two-year old wethers, from 20lbs.
to 30lbs.; the length of wool from ten to fourteen inches.
But the author of the "Treatise on Live-Stock," char-
cterizes them as having a fulness of form and substan-
tial width of carcase, with a peculiar plainness and meekness
of countenance; the head long, thin, and leaning backward;
the neck projecting forward; the ears somewhat long, and
falling backward; great fulness of the fore-quarters;
legs of moderate length, and the finest bone; tail small;
fece well covering the body, of the shortest and finest
of the combining wools, the length of staple fix or seven
inches. The fore-foot, a term of the old school, current in the time
of Lisle, or that flap of skin and fat appended to the
ribs, and the inferior part of the shoulder, is remarkably
capacious in this breed. New Leicesters mutton, it is
believed, is the most finely grained of all the large long-wooled
species, but of a flavour bordering on the trivial. And it
is added, that it is reported, and with the largest probability,
from the appearance of the flock, the fineness of the wool,
and the grain of the mutton, that a Ryeland croft is a
prime instrument in the Dibbly improvement of sheep.
Probably the root or foundation was the Lincoln. In the
ordinary and gradual course of improvement or alteration
of form, it must have taken, it is thought, a long time and
vast pains, to mould the animals into that arthritic and
peculiar shape which distinguishes this remarkable variety,
unless indeed something nearly similar was suddenly
and fortuitously chopped upon, as will occasionally happen
when the rickle deity is good-humouredly disposed to spare
our labours.

It must be observed, that the great advantages of this
fort of sheep have been stated to consist in producing a better
profit to the farmer, in proportion to the quality of food
consumed, than most others; in being more perfectly formed,
and consequently more disposed to fatten quickly; in con-
taining a much larger proportion of meat on an equal weight
of bone; in thriving well on such pastures, as would not
support other forts of the same size and in being capable of
being kept or fattened in larger proportions to the other
breeds of the same size and in being capable of

The author of the "Treatise on Cattle," who seems
to object to the Leicesters breed, from its too great
propensity to fatten, which, he supposes, also abates the
procr
procreative and lactiferous powers, says, "Pure Difhley sheep are by no means the most prolific, nor the best nurser." And adds, that the heads of the improvers having had time to cool, it is no longer boasted, that new Leicesters are able to sufficit, and even thrive, on the shortest commons. In fine, it is contended, the merits of this flock as an improving crop, (their grand point of utility,) being so undeniably great, their disadvantages have been overlooked, and comparisons have been usually made with such only as had a strong need of improvement, in which the new Leicesters in course were sure to triumph. And further, that though the Difhley crop has made its way into every part of this island, to the Land's End, to the bottoms of the Welsh mountains, and of the Soocifh Highland, to Ireland, and even to Russia, its general success has been attended with various particular instances of failure, a remarkable one of which is given by lord Somerville, in his Facts, in respect to the Bampton or Wefhern long-woofed sheep. The crop is sometimes very injudiciously tried with short or carding wool flock, excepting where the intention is only for ord lamb. On flock naturally good and improvable, this peculiar effect of the new Leicesters has resulted, the improved have considerably surpassed, in the most valuable properties, their improvers. Of this many examples may be seen, it is supposed, in the improved Lincoln, Northumberland, and Midland county sheep.

The following is a table of the value of new Leicesters, sheep, at various ages, as given on the authority of different eminent breeders in the Lincolshire Agricultural Survey:

<table>
<thead>
<tr>
<th>Wether lambs, at 6 months, worth</th>
<th>£</th>
<th>s.</th>
<th>d.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>17s. 10d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>at 12 months</td>
<td>30s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>at 18 months</td>
<td>35s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>at 24 months</td>
<td>45s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>at 30 months</td>
<td>45s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>at 36 months</td>
<td>55s. 0d.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

But others, in different parts of the district, state it thus:

<table>
<thead>
<tr>
<th>Leicesters, at six months old, worth</th>
<th>£</th>
<th>s.</th>
<th>d.</th>
</tr>
</thead>
<tbody>
<tr>
<td>at twelve ditto</td>
<td>22s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>at eighteen ditto</td>
<td>28s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>at twenty-four ditto</td>
<td>35s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>at thirty ditto</td>
<td>45s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>and, if kept to thirty-six, would be</td>
<td>50s. 0d.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If a three-shear falls for 3/., it will be worth,

| At 6 months, 28s. | | | |
| At 12 months, 35s. | Wool 9 lbs. | | |
| At 18 months, 40s. | | | |
| At 24 months, 48s. | Wool 9 lbs. | | |
| At 30 months, 56s. | | | |
| At 36 months, 60s. | Wool 9 lbs. | | |

According to the first of these tables, the scale of receipt is:

<table>
<thead>
<tr>
<th>For the first summer</th>
<th>£</th>
<th>s.</th>
<th>d.</th>
</tr>
</thead>
<tbody>
<tr>
<td>For the first winter</td>
<td>0 17 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>For the second summer, including 8 lbs. wool at 9d.</td>
<td>0 11 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>For the second winter</td>
<td>0 10 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>For the third summer, including wool</td>
<td>0 6 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>For the third winter, including wool</td>
<td>0 16 0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Three fleeces | 3 13 0 |
As above | 0 18 0 |

At 7s. they pay, per annum, 24s. 4d.

And it is remarked, that, at these prices, the last half year pays better than any; if this is just, there is a great loss, by selling at 23 years old; for it is just at the conclusion of the worst half year there is.

Mr. Dawsom of Berthorp, who has an excellent flock bred from Mr. Dalby's rams, last year sold 200 two-shear wethers at 3/., round. The following is his table of sales for four years, of wethers of that age.

<table>
<thead>
<tr>
<th>1790 Average</th>
<th>£</th>
<th>s.</th>
<th>d.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1791</td>
<td>35s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1792</td>
<td>43s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1793</td>
<td>38s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1794</td>
<td>44s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1795</td>
<td>50s. 0d.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1796</td>
<td>60s. 0d.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

He sold threes. Average 2l. 3s. 6d.

And, at this average, he would thus divide it, by supposing the proportion to be,

<table>

</tbody>
</table>

The advantages and disadvantages of the Lincoln and new Leicesters of sheep have been very fully considered in the Agricultural Survey of the former county; and the results stated as below in the different districts of it.

Circumstances of comparison between the Lincoln and Leicesters breeds of sheep.

Bolton. Lincoln better than Leicesters, on general experience and particular experiment.

Brothertoft. In experiment, very little difference.

Ewerby. Leicesters tenderer than Lincoln. Lincoln pay belt for keeping to three-shear.

Hacketton. Last year of Lincolns pay bet.

Ewerby. Old sheep stand the winter better, and pay better than young.

Owerby. Shearling Leicesters have, at Wakefield, fold as high as two-shear Lincolns. Difference of wool has been as 8 to 16 Leicesters tenderer in winter.

Normanby. Lincoln fleeces 2lbs. heavier than Leicesters. Leicesters get more wool from two-shear Lincolns. Difference of wool has been as 8 to 16 Leicesters tenderer in winter.

Walcot. Leicesters fleeces, though not so heavy as Lincoln, fold in one instance, for as much money.

Barton. Leicesters not tenderer in winter than Lincoln. Old breed of Lincoln used to go lean at two years old.

Now, Leicesters fat at the same age.

No difference in number on the same land. Wool the same.

Bonby. Leicesters come to sale sooner, but will not bear cold, wet land in winter so well, nor heat or cold after shearing, as the Lincoln.

Five Leicesters are one Lincoln; and Leicesters have refined hardships on the worst land better. Brocklesby.
Brocklesby. Lincoln more profitable than Leicesters.
Lumber. Where a man can keep, by means of marsh, to three-shear, Lincoln most profitable, but not otherwise. Not more Leicesters kept on the same land. Leicesters wool is a tod more than Lincoln. Leicesters more liable to the fly.
Cadney. Leicesters will feed a little fatter, and run a little thicker.
Beefby. Leicesters one in six more on the same land, but both do at the same age. Leicesters harder, and have less offal. Tallow equal; wool higher priced. Gives corn to Leicesters, but did not to Lincolns.
Aleby. Leicesters feed quicker, and have less offal; wethers and hogs less wool, but wool equal, and on the whole more per acre; hardier, and bear driving better. Go off at the same age, but Leicesters fatter. Five kept instead of four. Lamb easier; necessary to give corn.
Humberston. More pride than profit in the new fort. Leicesters 2 lbs. less wool than Lincolns, and not better; but run one in ten thicker.
Louth. Leicesters feed quicker, and have lighter offals. No difference in hardines. Lincoln best.
Tathwell. Lincolns and Leicesters being put together into the marsh, and sent thence at same time to Smithfield; the former yielded 4 a.-head more, and 5 a.-head more wool.
Cookswold. Marsh graziers all prefer Lincoln. No difference in number kept.
Tathwell. Lincoln wool 4 lbs. heavier than Leicesters. At two-shear, Lincoln heavier by 2 lbs. a quarter; at three-shear, 5 lbs. In tallow, 6 lbs. at three-shear, in favour of Lincoln. In number per acre no difference. In hardines, Lincoln best. Leicesters less wool, and less mutton per acre.
Driby. No difference in number kept.
Spilsby. Leicesters as fat at Lady-day, coming two-shear, as Lincolns at Lammas. Same number per acre. No difference in hardines; Leicesters have corn.
Horncastle. Three-shear better than two, as fure to find more tallow.
Asgarby. Leicesters bred too fine; fine-headed ones do not yield wool enough.
Frampton. As many of one as the other per acre. Lincolns travel bet, and pay bet.
Raiby. Leicesters thicker on land, as five to four.
Alderkirk. In an experiment of the two breeds on the same land, of the same weight and age, the Lincolns conferably superior.
Thoresway. True Lincolns most faleable, and most profit to breed.
Sudbrook. One-third more Leicesters on the same land.
Rigeholm. Bolton graziers not judges, for they can get good Lincolns, but not Leicesters, as the breeders of these can fat them themselves. Leicesters ran one-fourth thicker on the land. From six to twelve months old, rather tenderer than Lincolns; Leicesters travel bet.

Claypool. Leicesters as fat at one year as Lincolns at two, and with less trouble, and one-tenth thicker. Do as well as Lincolns in winter on wet land.
Marlton. Leicesters fatter, and run one-sixth thicker.
Woolthorpe. Leicesters by far the best; but more apt to be barren than Lincoln. Drape ewes far more valuable.
Grimithorpe. Leicesters travel bet, and are the bet; and much less loss in lambing; run one-third thicker.

A clear distinction is to be drawn, as the writer remarks, between the rich south-eastern district and inferior soils; for, upon the former, the information is strong in favour of Lincoln. However, in general, he should observe, that the new Leicesters are spreading very rapidly over the country, probably faster than they have done in any other, one or two only excepted, which may be attributed to the general goodness of the soil; for this breed makes a much more respectable figure here than it has done in various trials made in counties inferior to it in soil; and the breed driving out the Lincolns so much as it has done in the poorer parts of this county, is a fact that unites with this circumstance. The true Lincoln is a large sheep, and with a longer wool, and therefore demands better pasturage; where it finds such, there the old breed remains; subject, perhaps, to little more change than fashion can cause. Upon inferior land the Leicester establishes itself; and upon land still inferior in other counties, experiments prove unsuccessful for the same reason; that of the necessity of having a smaller size and shorter wool.

But some of the original pure long-wooled polled breed of sheep, are still to be met with in the midland districts, which are a larger boned, longer formed, deeper coated, and more coarse flock than the improved f-ort. And that, from the coaritenss and larger size of the head and neck in the old fort, the ewes lamb with more difficulty than in the true Difeley breed.

The new Leicester fort of sheep is found a very advantageous breed on some kinds of land in the county of Oxford, as on the Itone-brass; there are some farmers indeed, who think that no other fort comes nearly up to them, when all their valuable properties are taken into the account.

_Cotswold or Gloucester Breed or Variety._—This is a breed of sheep which, according to a late writer on them, is of the fine combing wool fort, deriving the finestness of their fleece from the same source as the new Leicesters. This part of that county formerly, and in memory, bred, it is said, small fine-wooled sheep of the Ryeland kind, which in past times had been cotted, but the practice was discontinued. These sheep, being judged too small for the improving state of the country, have been, by gradual crossings with Midland long-wooled rams, chiefly Warwicks, completely changed from short to large long-wooled flock. The writer finds a picked lot of Cotswolds last year, he says, which answered the following description: long coarse head, with a particular blunt, wide nose; a top-knot of wool on the forehead, running under the ears; rather long neck; great length and breadth of back and loin; full thigh, with more substance in the hinder than fore-quarters; bone somewhat fine; legs not long; fleece soft, like that of the Difeley, but in clovenefs and darknes of colour, bearing more resemblance to short or carding wool. Although very fat, they had all the appearance of sheep that were full of solid flesh, which would come heavy to the scale. It is added, that it is said, none of these sheep have reached 40, and even 50 lbs. a quarter.
a quarter, at two years and a half old, giving 11 lbs. to 14 lbs. of wool each sheep, and being fat, they are indubitably among the largest breeds in England. A single dip, continues he, of new Leicesters gives the Cotswolds a fulness in the fore-quarter; but any farther crofs of that kind, it appears, diminishes their size. The strange crofs of Wiltshire horned sheep has been recurrent to in some parts, for no possible good purpose, he should apprehend, either to the carcass or wool; and it is probable, supposing such large stock profitable, that the chief alteration required by the Cotswolds, is to encourage length of staple in their fleece or wool.

In this breed the ewes are usually put to the tup, so as to have lambs at two years old, mostly producing two lambs each, in the proportion of nearly one-third of the whole, where kept well, which must always be done. They may be kept for breeding till three or four years old, if they are of the proper improved sort. But it is said that the wethers afford most profit when killed so early as at two years old, as they are apt to become too fat when kept longer.

The Cotswolds or Gloucesters, and the half Leicesters and half Gloucesters, and other mixtures of these breeds, are considered as very excellent sorts of sheep flock in many parts of Oxfordshire; they are of a good size, bear plenty of wool, and stand, penning well. But penning or folding is not thought beneficial by some farmers, as more and better sheep may be kept without it.

The native Cotswolds, if they are anywhere to be found, would be, it is said, at two-feet from twenty-eight to thirty-two pounds the quarter; they are a long sort of sheep, not full in the sides, sharp in the chine, not full in the fore-flank, coarse in the bone, not straight but good in the hind-quarters; will not fatten so early as when croffed; and of wool, the two-feet wether affords three and a half fleeces to the tod. The new Leicesters, it is contended, is calculated to correct every one of the deficiencies which have been noticed, and to bring a greater disposition to fatten. Between all Cotswold and all Leicester, the average difference of wool, it is said, is three pounds.

In Devonshire, it is said, have succeeded in the crofs of new Leicesters upon the Cotswold, the equal breed of which is attempted to be preserved as much as possible. Wethers of this kind, at eighteen months old, will average nineteen pounds the quarter, and seven pounds of unwashed wool the fleece. When kept on for another twelvemonth, the age at which they are mostly killed in this county, this crofs will attain the size of twenty-five pounds the quarter, and yield nine pounds of wool to the fleece. This wool is allowed by the flappers to be one penny the pound superior to that of the Exmoor, Bampton, South Devon, and Dartmoor sheep, yet still the common price of 10d. the pound is only allowed for it. In the young wethers of this breed, the loose fat is slat to be nine pounds, with nearly three pounds of kidney fat on each side. The larger wethers are said to produce thirteen pounds of rough fat, and four pounds of kidney fat on the side.

Romney-Marsh Breed or Variety.—This is a kind which is described by Mr. Young, as being a breed of sheep without horns; white faces and legs; rather long in the legs; good size; body rather long, but well barrel-shaped; bones rather large; and it is said that the weight per quarter, in fat wethers at two years old, is usually from 22 lbs. to 28 lbs. In respect to the wool, it is fine, long, and of a delicate white colour, when in its perfect state. On this Marsh 28 lbs. of wool are supposed to be produced per acre. In this breed there is a property of arriving at the state of fatness at an early age, as well as that of producing a large fleece of fine long combing wool, of course it is a valuable sort; however, from the size, and great weight of the coat, it is only capable of being supported and fattened on the rich kinds of marsh pasture; and on those which extend from Haulings to Rye, in Kent, according to the Suffex Agricultural Report, the graziers find it much more beneficial than the South Downs; the marsh wethers fattening more quickly. The wool afforded by such fat wethers averaging five pounds, and breeding ewes five pounds, but not equal in quantity to the wool clipped from shearings. And the author of the "Synopsis of Husbandry" remarks, that a convincing proof of the great value of this breed of sheep, as well as of the land on which they are fed, is seen in the manner of flocking, which in tens is from four to seven per acre, in fattening wethers from six to eight, in barrows from two to three, and in couples three; which is certainly a great flock. And this is a breed that probably undergone much improvement without crossing, by proper care and attention, and being left exposed in the winter. In the old Romney-Marsh breed, the sheep were remarkable for having large heads; for being large, long, and tubby; also for being large in their bone, long in their legs, and coarse in their wool; which form is still held in estimation by some, in consequence of improper prejudices, to the great injury of the grazier and community in general; but the pure breed of this fort, Mr. Price says, is distinguished by a thickness and length of head, a broad forehead, with a tuft of wool upon it, a long thick neck, a great length and thickness of carcase; being flat-sided, and having a sharp chine, tolerably wide on the loin, but the breast narrow, not deep, the fore-quarter not heavy or full, a good chest; the thigh full and broad, the belly large and tubby; the tail thick, long, and coarse, the legs thick with large feet, the muleco coarse and the bone large; the wool long and not fine; coarfelt on the breech, the sheep prove good, and are great favourites with the butchers. But this description is not now, it is said, so applicable as it was some time ago, when most of them had horns.

The same writer, in his account of the sheep management in this marsh district, has remarked, that the introduction of the Leicester breed has very perceptibly altered the form and properties of the original breed or flock of this tract, so that in a few years it will scarcely be discernible. And it is probably the general opinion that it has been injurious to it, in reducing the size and value of the animal, as well as the quality and quantity of its wool, though it has still many advocates, and has certainly contributed much to its improvement. The principal objections which the graziers of this Marsh seem to have to the mixing of the Leicesters with their own breed, are, that they have seldom or ever twin lambs, which are very desirable and beneficial in this situation; that the lambs are more tender, and, of course, a greater loss liable to be sustained, especially in an open exposed tract of this fort; that their lambs do not winter so well as those of the native breed upon the uplands: they are much less hardy, consequently cannot stand cold and hardships so well, which is very disadvantageous; that their wool is not in such abundance, or so valuable, which is a great defect; that there is a want of proof in them, which renders them a very great deal less saleable to the butcher; this may, however, be no disadvantage to the breeder or grazier, as it shews other more valuable properties and dispositions; and that they are too short in their bodies and legs, so as to stand too low in their pens at the market. These are, however, probably improved valuable properties, which must be rather beneficial than hurtful. Some improvement has, however, been given to the Marsh breed by the Leicesters crofs, as the
SHEEP.

those of smaller and less coarse heads, a greater depth of carcase, and shorter and less coarse legs, better symmetry or form of several different parts, as well as of the whole animal.

There can, therefore, be no doubt but that this breed has been greatly benefited by the introduction of the new Leicestfer fort; and it is probable that it has not depended so much upon selection as the use of this new variety, as though the cry in the market is for the marsh kind, that form is carefully improved, and by no means preferred, although something of it may still exist. Something of the South Down fort is likewise discernible in this breed, it is said.

This breed of sheep is thought to be highly valuable for cold exposed situations, as being easily bred, and standing in need of no artificial food in the most severe winters, except a little hay; they are very hardy for their size, have now many improved qualities, and may probably be made the most profitable of any for rich pastures, as affording the largest proportion of meat at the least expense. In wethers, the general average is now from ten to twelve stone weight each; and in ewes, when fat, from nine to eleven.

Dartmoor, Devonshire, Bampton and Nott Breed or Variety.-This is a breed or sort of sheep, which is chiefly distinguished by having no horns; white faces and legs, thick necks, backs narrow, and back-bones high; sides good; legs short, and bones large; and probably without any material objection, being a variety of the common horned sorts. According to Mr. Culley, the weight of ewes on the average about 20lbs. a quarter; in wethers, at two years and a half old, 30lbs. Length of wool much the same as in the Romney-Marsh breed. It is a breed found to be prevalent in the districts from which it has derived its name. And it is supposed to have received considerable improvement by being crossed with the new Leicestfer or Disley improved fort within these few late years.

Besides the forest from which it takes its name, this breed is met with in some other parts of the county. The Dartmoor wethers at five years old will average about 16lbs. per quarter, and produce from four pounds and a half to six pounds and a half of unwashed wool to the fleece. This breed of sheep, though they do not feed so quickly, when put to good keep, as the new Leicestfer fort, yet, when fat, they constantly prove the very best mutton, and never fail to command a superior price. They also stand the climate in a favourable manner, and the ewes are good nursety.

The old Devonshire dun-faced nott sheep were formerly held in high estimation, as a native breed of some parts of this county. It is, however, a crooked-backed, flat-sided, coarsely boned and woolled animal, but which has been much improved by crossing with the new Leicestfer fort; its principal defects are by these means removed, and a greater disposition to fatten at an earlier period given; while at the same time, however, the fleece, as well as the weight of the carcase, has been lessened, the former from ten to eight pounds of unwashed wool the fleece, and the latter from twenty-two to nineteen pounds the quarter. In order to recompose which, the animal comes to market four months earlier; the wethers at two years old, with advantage; that is, after being twice shorn as sheep, and once as lambs, equals the average already stated. This fibre once more crossed with the new Leicestfers, will arrive, it is said, still earlier to the same perfection.

In the Bampton nott breed, the wethers will, at twenty months old, weigh twenty-two pounds the quarter, and have six pounds and a half of wool to the fleece; also the same sheep, well wintered, and kept on for another twelvemonth, will average twenty-three pounds the quarter, and yield eight pounds of unwashed wool to the fleece. The price of the wool at present is about 1s. the pound.

The first crofs of this breed with the new Leicestfer is fast growing into great esteem in this district, in consequence of its improving the form, and bringing the animal three months sooner to market; but though so far useful and desirable, any more of that blood is thought disadvantageous, as rendering them too tender while young, and to require too much care and nursing.

The Bampton nott crossed with the new Leicestfer is also a breed much approved of in several parts of the county, especially when carried to the fourth degree, or four parts of the Leicestfer to one of the native nott. This crofs, it is said, comes earlier to market, and at two years old will generally average twenty pounds the quarter, and eight pounds of yoke wool to the fleece, which is worth about 1od. the pound. And the old Leicestfer crofs upon the Bampton makes a large and handsome animal, which feeds kindly and tallow well within. The wethers of two years old will average, with advantage, thirty pounds the quarter, and have ten pounds of yoke wool to the fleece. It is much valued in some places. But the new Leicestfer crofs upon the same fleece, will in some situations bring forward wethers at twenty months old, weighing twenty-two pounds the quarter, with a sheaf of eight pounds of yoke wool to the fleece, both of which are at this time worth 1od. the pound, weighing, according to the custom of unwashed wool, twenty-one pounds for every score. This fort is highly valued by some in different parts of this county. The half Bampton crofs is more hardy than the new Leicestfer fort, and suits some places better.

In most cases of a croff with the new Leicelte upon long full fleeced sheep, a deficiency of wool is observably under the belly and breast of the animal.
Exmoor Breed or Variety.—This is a fort of sheep which is
caracterized by having horns, white faces and legs; by
being very delicate in the bone, neck and head, or what is
sometimes denominated deer-necked; by the form of the
carcase being indifferent, narrow, and flat-sided. Accor-
ding to Mr. Culley, the weight per quarter in wethers at two
years and a half old, is from 13 lbs. to 18 lbs.; and the weight of
wool much less than in the Devonshire breed. It is a
small breed of long-wooled sheep, principally produced on
or in the neighbourhood of the moor from which it takes its
name, which is in the northern extremity of the above county.

Mr. Lawrence supposes that in their present state they are by
no means to be considered as a profitable fort of sheep-
flock, either in what relates to flesb or wool; on which ac-
count it would be for the interest of the county to change
them for the bell fine-wooled breed. It is remarked by Mr.
Billingfley, that this breed of sheep is frequently kept two
or three years, merely for the annual profit of their fleeces,
which often do not exceed more than four pounds in weight;
and that from their being kept upon so bare and indiffer-
ent pastures while young, they are fed up by many sheep-
farmers to be a very profitable fort of flock.

This horned breed has a moderately long staple of wool,
which formerly, before the cloths manufacture of the county
of Devon fled into Yorkshire, was much in demand by the
clerks of several different places. The fattened wethers
of this breed, at three years old, will usually weigh about
75 lbs. the quarter, and average 84 lbs. of washed wool to the
fleece; which is worth at present about 15d. the pound.

Attempts have been lately made in different places to im-
prove the wool of this breed or fort of sheep, by a cross
with the Merino or Spanish ram, and the results of the trials
thus made are as follows:

In which improvement of the fleece the carcase is said to
be rather advanced than the contrary.

In the crosses of the old Leicefter upon the Exmoor breed,
the wethers, which are the produce at three years old, av-
erge about 24 lbs. the quarter, and carry 66 lbs. of woal
wool to the fleece. The Exmoor sheep have also been crossed
with the new Leicefter; the wether produce of which, at two
years old, will weigh 18 lbs. the quarter, and yield 66 lbs.
of unwashed wool to the fleece; the price of the two latter
sold the pound. Much loss is often, it is said, sustained in this
last crosses at the time of yeasting, in consequence of the great
size of the shoulders of the lambs retarding or preventing
their exclusion. This will, however, be remedied in the
productions of this cross.

The Exmoor breed is a hardy fort of sheep on wet ex-
pended land while young. The ewes under such circum-
stances, in lambing, are also superior to the Bampton not.
kind.

Cornish Breed or Variety.—The true breed of this fort is
daed to have grey faces and legs, coarse short thick necks,
flapping lower behind than behind, narrow backs, flat-
shaped, a fleece of coarse wool, weighing about two or three
pounds, of eighteen ounces each; their mutton, which is
delicious, from eight to ten pounds the quarter.

However, from the various crosses which have been intro-
duced into the county at different times, in consequence of
the use of rams of the Exmoor, Dartmoor, North and
South Devon, Dorset, Gloucester, and Leicefter kinds, the
pure breed of this description is, it is said, now become rare,
but that, from the inferior nature and value of its proper-
ties the total extinction of it need not be lamented. The dif-
tinct is now capable of supporting a much better and more
improved breed of this fort of animal.

Black-faced Heafh Breed or Variety.—This is a kind or
breed of sheep which, according to Mr. Culley, have large
spirals horns, black faces and legs, a fierce wild-looking eye,
short tight carcases, from 12 lbs. to 16 lbs. per quarter, covered
with long, open, coarse flagged wool, fleeces 46 lbs. or 48 lbs.
each, wool worth at present about 8d. per pound. They are
an active hardy flock, running with amazing agility, and belt,
adapted, of all other breeds, to exposed, healthy, and moun-
tainous districts; seldom fed until three, four, or five years
old, when they feed well, and make the finest mutton, having
a high-flavored gravy. The sheep of this wild-looking
breed are natives of the north-west of Yorkshire, and of
that mountainous tract of country adjoining the Irifh sea,
from Lancashire to Fort William; they have been of late
years introduced into the Western Highlands of Scotland.

And the writer of the "Treatife on Live Stock," supposes
the black-faced Linton, or short sheep of Scotland, to be a
variety of the Heafh sheep. They have been crossed with
the Cheviot breed, and Mr. Culley, it is noticed, recom-
ends a Dishley crofs, meaners, doubfeles, for the use of the
low lands. If he may be allowed to give an opinion, he
would, for upland situations, recommend a Spanish crofs,
with good winter management, in preference to all others.
It is disgraceful, he contends, to the rural economy of
Britain, that so excellent a breed of sheep should be need-
lessly compelled to brace the rigour of the seafons, in fuch
loos, ragged, and beggarly clothing, when they might, with a
few years' pains, and without any deterioration of the car-
cases, produce a fleece of high value and consequence to
the manufactures of the country. And he adds, that Mr. Henry
King, faleman of Newgate market, and an eminent gra-
zier, informs him, that he once fed a lot of these northern
heafh sheep, and made excellent mutton of them, about
66 lbs. a quarter; but that their wool hanging down their
quarters like goat's hair, was so excreably bad, that it could
be folded only for mop yarn.

But what are termed black-faced, or short sheep, are said to
be originally short-wooled, the present length of it
having proceeded from crossing; and it is not well ascertained
whether they are a native Scotch breed, or have been intro-
duced from the moor-lands of Yorkshire. Besides the ob-
jection to these black-faced sheep, on the ground of the coarse
loos nature of their wool, they are said to be fubjeft to the
brawy, a disease that was unknown in the Highlands be-
fore their introduction. And it is remarked, in the able
Agricultural Survey of Earl Lothian, that the kind of sheep
bred and most generally kept in Lammermuir, is the black-
aced, or more properly, what is called the brocked faced, a
fort of dirty-looking mixture of black and white; they are for
the most part horned; when they are fed, the wethers weigh
from 10 lbs. to 12 lbs. per quarter, and the ewes from 8 lbs. to
10 lbs. on an average. It will take eight or nine fleeces of the
ewes and hogs, and six or seven of the wethers, to make a
tone of seventeen pounds (twenty-one ounces to the pound);
the quality, and consequently the price, vary much. The
difference of quality may result from various circum-
tances; it is owing partly to the quantity of tar put upon the sheep
in salting; partly, it is suppos'd, to the situation in which
they poulter, as those fed on high grounds, and coarse molly
herbage, are thought to have inferior wool; and partly to the
general
general attention and care which farmers bestow upon their flocks, in which some are greatly superior to others. But the black-faced sheep seem, the writer thinks, to be capable of very considerable improvement; it does not, indeed, appear, that much has been done for improving that breed, which certainly places them in an unfavourable situation, when their merits come to be discussed in opposition to others which have received great attention. There can hardly be a doubt that the weight of the carcase and the quantity and quality of the wool might all be increased, by sufficient care to select the strongest, healthiest, and best feeding among them for the purpose of breeding. It has been observed, that those which feed best have the greatest quantity of wool, and generally of the best quality; and it is natural to suppose that it should be the case, as they must be the healthiest and strongest.

**Herefordshire, Roofs, or Ryeland Breed or Variety.**—This is a fort of sheep which is distinguished by the author of the “Treatise on Live Stock,” by the want of horns, and having white legs and faces; by being small in size; and the wool growing close to the eyes; by the carcase being pretty well formed; and by the excellence of the mutton. Weight per quarter from 10 lbs. to 18 lbs. Wool long and short, the lean poor-fd sheep producing the finest. It is the true breed of this fort of sheep which is properly denominated Ryelands. In the Agricultural Report of that district, they are said, in symmetry of shape, and the flavour of the meat, to be superior to most flocks in the country. They lamb in February and March. It is a breed which, Mr. Knight says, is found to be remarkably easy in respecting food, but which, in its management, requires constant in the winter season, and being fed with hay or peas-haulm. In some cases they are hauled all the year round in the night-time. The cots are low covered buildings, proportioned to the extent of the flocks. In the Herefordshire Agricultural Report, it is observed that the cotting materially contributes to the health of the animal and the fineness of its fleece. The quantity horn from each of the small original breed does not average more than two pounds; but the quality is such as almost to rival that imported from Spain. The price has often been as high as thirty-three shillings the stone of twelve pounds and a half untrinned, when the coarse wool has brought but ten or twelve shillings. They are said, by Culley, to fatten the best at four years old. The Archensfield, or true Herefordshire breed, is said to afford the finest wool, except the Spanish. It is suggested by Mr. Knight, that the disposition of sheep to fatten in the north-west part of that district is in the proportion to the fineness of the wool; but he is not certain of its being so in this breed; however, it seems to him that where the wool is close and fine, there are many advantages; less nourishment is drawn from the body in its support than in the contrary case. The long coarse-wooled fleece admits the rain more freely, and by dividing on the back lets it down to the skin. It also takes in a larger weight of water, which must more inconveniently the animal already heavily loaded. The fine close fleece of this breed admits the water with difficulty, even when it is moistered in it, and is never wet through by rain. On account of the fineness of the texture, it only lodges on the outside, and is easily removed by the animal shaking itself. Besides, a fleece of this kind is much more warm and light. For these reasons it is supposed that no breed of sheep in the island is capable of subsisting on so small a proportion of food as this.

This animal, in Mr. Knight’s opinion, appears to be much more patient of hunger, and to keep itself in better condition on a less quantity of food than any other which he has had an opportunity of observing. To the great finenesses of the pelture on which it is usually condemned to feed, is to be attributed the fineness of its fleece; for the quality of this becomes immediately impaired by a copious supply of food; and this circumstance should be attended to, in every county where these sheep are introduced.

Some attention has lately been paid to its improvement, and although the wool is somewhat less fine in its quality than it formerly was, it is still the finest in the island, with the exception of the Spanish sheep recently imported; and the animal must be allowed, on the whole, to have been considerably benefited. The quantity of wool afforded by the improved fort of Ryelands, although increased, is still far from large; a three-years old wheather rarely yielding more than three pounds and a half. But as a large number of sheep will subsist on a small portion of ground, and the wool is still worth two shillings and sixpence the pound, its value, compared with the quantity of food consumed by the animals, is probably much greater than that afforded by any other breed.

And the Ryeland sheep readily acquires, on a very moderate pasture, that degree of fatness which renders its flesh more acceptable, but it is wholly incapable of being loaded with fat in the manner of Mr. Bakewell’s. It appears to him to fatten somewhat more quickly than those he is seen of the South Down breed.

In the Agricultural Survey of Herefordshire it is suggested, that a crofs between the Ryeland and real Spanish seems the most probable mode of adding to the fineness and value of the wool; and amongst many spirited breeders who are now making the experiment, colonel Scudamore of Kentchurch holds the fleeces of a crofs so crofted at forty shillings per stone, in the fair at Roofs, in the course of last year. The first stage of the crofs materially detracts from the beauty of the Ryeland’s form, but by continued attention, this objection will probably be removed, and the flavour of the mutton is uninjured. Lord Somerville has found that they feed quickly, and weigh heavily, although their form be not attractive; but perhaps form in this animal is of little comparative consequence. An ox rarely fattens well, or has flesh of good quality, unless it be in one particular shape; but sheep fatten well, and the meat is of prime quality in those of very different forms. Two Leicesters which were fed by Mr. Hewer, of Abergavenny, and slaughtered before the Agricultural Society of this county in March last, weighed less than fifty-one pounds in each fore-quarter, and forty-five in each hind-quarter. But notwithstanding this great weight, the Leicesters are often found less heavy than they appear to be, whilst the half Spanish weighs more than is generally expected from its fize.

A crofs of the Merino on the Ryeland breed has been tried in some parts of Devonshire with an appearance of success. The three-years old wethers of this crofs, when fattened to their frame, being, it is said, is, estimated to run from fourteen to fifteen pounds the quarter, and to throw off from three pounds and a quarter to four pounds of washed wool to the fleeces. In experiments made by some of these crofs in other parts, it appears that two-years old wethers of the first crofs will weigh about fifteen pounds the quarter, and shear from four to five pounds of washed wool to the fleeces, which is worth 32. 9d. the pound. The sheep are, however, greatly exposed to the foot rot.

The crofs between the Ryeland and the Spanish sheep has been made in some other parts, which has completely succeeded as a fleece, as the produce of the third crofs of this breed readily sells for 32. 6d. the pound; it is, however, objected to by many on account of its not affording an equal acreage proportion of mutton with the native sheep.
In crossing this breed with the Dihley, an useful kind of sheep has, however, been produced, both the wool and carcase being increased in weight, but much injured in respect to fineness; and it is contended by some, that the breed is rendered much less hardy by it.

Warton Cragg Breed or Variety.—This is a fort or variety of sheep which is principally met with in the district of the above name, and that of Silverdale, in the northern part of the county of Lancashire. These cragg sheep are greatly esteemed for the fine flavour of their mutton, their ready disposition to fatten, and the fineness of their wool. They are a close compact well-made breed of sheep, commonly with white or mottled black and white faces and legs. Their fleeces are short and close in the wool, which usually sells high. Their quality is chiefly that of the poor short rocky lime-flint kind. They are deferving of more attention than has hitherto been bestowed upon them by the farmers of the neighbourhoods where they prevail.

The Shropshire or Moor Breed or Variety.—This is a fort which, according to the writer on live flock, has small horns, with speckled dark or black faces and legs; they have the full character of red fine woolled sheep, and have been, for centuries, bred in Shropshire, Staffordshire, Worcestershire, and the vicinity. Their fleeces are nearly all fine, but it is said, superior to the Ryeland wool for the crossing which has taken place in that flock. Mr. Pitt of Pendeford, in a letter to lord Somerville, dated 1776, estimates the extent of Moor common, or walk, at 3,600 acres, and the number of sheep furnished thereon, at 15,800, to the annual profit of fifteen Figlings per acre in wool only, on a moderate calculation, eight fleeces and a half to the stone of 14 lbs.

Nothing is reckoned on account of carcase, as the sheep have some extra keep during winter. It is added, that the Shropshire commons produce good fine wool, but none equal to Morf by fixpence a pound.

The Dorsetshire Breed or Variety.—This breed is known by having the face, nose, and legs white, head rather long, but broad, and the forehead woolly, as in the Spanish and Ryeland farts; the horn round and bold, middle-sized, and standing from the head; the shoulders broad at top, but lower than the hinder quarters; the back tolerably straight; carcase deep, and joins bross; legs not long, nor very fine in the bone. Weight per quarter in wethers, at three years and a half old, from 15 lbs. to 20 lbs. Mr. Billingdale says, that the wool is fine and short. It is a breed which has the peculiar property of producing lambs at any period in the season, even to as early as September and October, so as to suit the purposes of the lamb-fuckeler. It has been found to answer well in some of the midland districts, and, from its close make, to be equally advantageous with almost any other. It is, however, suppos'd capable of improvement by being crossed with rams of a larger size. There are varieties of it met with in several districts. And it is said by some, that the Dorset breeders pay great attention to preserve the colour of their fleeces from mixture, since white lambs are the most esteemed in the London markets, from a presumed superior delicacy in the meat. It is believed this is one of the best breeds in England, if not superior to all others, considering its various qualifications. Their property of bringing twins, and making our highest priced house lamb, must be considered first; they are both good hill sheep and pasture sheep, and their flesh is an excellent medium between the delicate mutton of the hills, and the rich and juicy meat of the best lowland sheep. The latter Dorset lambs, when fattened, make the earliest farina lamb. By the practice of this county, the lambs which the breeders retain are born at Midsummer, having been taken from the ewes in May; produce of wool, one pound to a pound and a half each, the price a penny per pound nearly, under the price of sheep's wool. A three-lamb sheep may produce four or five pounds of middling fine wool, which it would be highly advantageous to improve to the utmost, on this excellent breed.

This is a breed, or fort of sheep, which seems to prevail among the generality of farmers in the high lands, and some other parts of the county of Devon, which border on the above, in which they are found to answer very well.

And there is a breed or variety nearly connected with thee in the Mendip hilly district. They are smaller than that breed, having smaller horns, more deer-headed, the wool less in weight; the mutton excellent in its flavour. It has been observed by the author of the "General Treatise on Cattle," that in the West Riding of Yorkshire, and in the adjoining parts of Westmorland, they have a breed of horned and white-faced sheep, bearing a strong affinity to the Dorfets; they are called Cheviot, and Wensleydale sheep, but more generally Penffion, from the market town where they are fold. They are a good breed or hill sheep, in their pure state, and give a fleece of coarse short wool, weighing between two and three pounds, the carcase good mutton, about fifteen pounds per quarter. They are variously crossed in this riding, with Cheviot, Dihley, and Northumberland tups; with the two half, for the purpose of making pallare sheep, in which case the weight of carcase is increased to twenty or thirty pounds per quarter. In the north, this breed is commonly crossed with the Heath sheep, which gives them black or grey faces and legs, with sometimes a black spot on the top of the neck, the wool coarse and open, instead of being close and thick set upon the skin, as a defence against the severity of the climate of that hilly and exposed country in which they are fed; defects for which the remedy is obvious. Ryeland tups have been tried with the Penffion ewes, a cross which made a considerable improvement.

The Welsh Breed or Variety.—This is a fort which has sometimes the title of horned-crofs. The writer on live flock distinguishes the breed, as having a large head and eyes, Roman nose, wide nostrils, horns bending down the cheeks, colour all white, wide boseom, deep greyhound breast, back and legs straight, carcase sublateral, legs long, bone coarse, fine middie wool, very thin on the belly, which is sometimes bare. He supposes, with Culley, that the basis of this breed is doubtless the Dorfet, enlarged by some long-woolled crofs; but how the horns come to take a direction so contrary is not cazy, he thinks, to conjecture; he has sometimes imagined it must be the result of some foreign, probably Tartarian, crofs. The old Hertford were, he says, suppos'd a kindred breed with the Wilts, but at present, the few of this kind bred in Herts are of smaller size, longer and coarser wool. These large and leggy Wilts' sheep work well in the fold, and have always had the character of good thrivers at corn, oil-cake, and the best meat, making very large mutton, and very deep in flesh, which is high-flavoured, yielding the dark-coloured gravy. The breed is, be adds, every where on the decline, generally supplanting by the South Downs, of which the farmers find they can, on the same quantity of land, keep more than one and a half, for one of the Wilts, the farmer, moreover, producing both better mutton and better wool. The difease called the giggle, is said to be peculiar to the Wilts sheep. It is flated, that this breed has been long used, more or less, in the counties bordering on Wilts, and in Surrey, Kent, Herts, Essex, and Middlesex. But that it is a breed not worth preserving; perhaps the only thing to be done with it to advantage, is to crofs it with the Merino. The Hampshire variety of this breed is said, for what reason he knows not, to be more hardy. It is a breed, however, which is esteemed in some places.
The Berkshire Breed, or the Variety called Notts.—This is a fort which the same writer describes by having considerable length and bone, straight made like horset, full fore-flank, Roman faced, with distinct black spots, high on the leg, thick fleece, of considerable length. He supposes them to clafs with the long-woolled breeds, and to probably bear some affinity to the breed of Oxfordshire, which is, he is told, a peculiar variety.

The peculiar qualities of the Berkshire nott breed seem to be its great fize, height on the legs, and weight when fattened. It would appear, contrary to the opinion of some, that this breed is well suited for the strong low lands of its native district, though the South Down are fall supplanting it in many places, probably without sufficient experience of them in such situations. In contrasting them with the horned Wiltshire sheep, it is found by some that the polled Berkshire or nott fort are as certainly more properly adapted to the low and cold lands, as they are proved to be more hardy for the fold, to fat sooner, and to be less liable to injury from the fly, than the horned sheep. When fat, the sheep vary as much as from fourteen to forty pounds the quarter, in weight. The polled or nott sheep are, however, not of so large a fize as the horned fort of the same district. The fleece of this breed of sheep is not fine, and on the average it will take eight of them to a tow of wool. The mutton is rather coarse, as in all large breeds of animals. The utility of crossing this breed is by no means defined. Some advise to breed from the belt of this fort, but to cross for fattening. Crottes are, however, very common between many different forts, as between the notts and the Wiltshires, the Cotswolds, the Leicesters, and different mixed breeds.

The Berkshire nott breed is much valued in some parts of Oxfordshire, especially for regular breeding as well as flanding the fold. They are strong, active, and able to travel, and fold unusually well; against which good qualities they are, however, long in fattening, &c. The crofts with the Leicesters improve them considerably, still they are fat giving way to the South Down and some other breeds.

And it is observed in the Norfolk Agricultural Report, that the Wiltshire sheep have proved, in various trials, an improitable breed, as well as the Norfolk sheep, but it is remarkable that for turnips, so sheep are had, by many practical and experienced husbandmen, to pay better, if so well. In Hertfordshire, many who turnip-feed adhere to that breed, who admit the South Down to be a superior fort for grass-feeding.

Heath-Croppers or Windsor Forest Breed or Variety.—This is a small ill-shaped breed of little value, found abundantly in the parishes which lie within the precincts of the forest of Windsor in Berkshire. It is a breed which affords a very sweet kind of mutton. A quarter of it will weigh about twelve or fourteen pounds. And in regard to the wool, about thirteen fleeces will make a tow. It is of equal value with that of the South Down breed. The term heath-croppers is very commonly, though vulgarly, applied to sheep of this breed.

The South Down Breed or Variety.—This is a very valuable fort of sheep, which Culley has distinguished by having no horns, grey faces and legs, fine bones, long small necks, and by being rather low before, high on the shoulder, and light in the fore-quarter, fides good, loin tolerably broad, back-bone rather high, thigh full, twid good, mutton fine in grain, and well-flavoured. Wool short, very close and fine, in the length of the staple from two to three inches. Weight per quarter in wether at two years old 12 lbs. It is a breed which prevails on the dry chalky downs in Sulux, as well as the hills of Surrey and Kent, and which has lately been much improved both in carcase and wool, being much enlarged forward, carrying a good fore-flank; and for the short legs fertile hilly pastures is an excellent fort, as feeding close. The sheep are hardy, and disposed to fatten quickly; and where the ewes are full kept, they frequently produce twin lambs, nearly in the proportion of one-third of the whole, which, are, when dropped, well-woolled. The wethers are capable of being disposed of at an early age, being seldom kept longer than two years old, and often fed at eighteen months; which is a very valuable property. But according to the Suflex Agricultural Survey, the ewes are commonly kept till between four and five, and found to answer well to the graziers in the neighbourhood, as well as the farmers in Norfolk and the adjoining counties, in the place of home-bred sheep, as being more expeditious feeders, and equally adapted for the purpose of the fold. It has been observed, that it is in fact a breed of sheep which, from the compactness of their form, and their legs being shorter, considerably outweigh both the Dorset and Norfolk breeds, in proportion to the size of the carcase, being heavy in a small compass. Their hardiness is estimated according to the darkness of the colour in the face and legs; but as there is inconvenience in the produce on this account, from the wool, especially about the head and neck, becoming spotted with black, and thereby thrown aside by the Rapier, as only of half the full value, a middle degree of colour may be the best. As an open country breed, they are sufficiently gentle and tractable. They are capable of travelling well, and of withstanding the effects of exposure to cold. The wool is fiercely, if at all, inferior in fineness to that of the Herefordshire kind; as the practice of fowing, which is common in that district, is not in use on the Downs. The excellent properties of this breed have been brought fully to the notice of the farmer, by the great patrons of improvement in Bedfordshire and Norfolk, and its superior merits on trial have been such as to have induced the sheep-farmers in various districts to introduce them in preference to other breeds. It is stated, in the Annals of Agriculture, that they have been found to confume less food, in proportion to their weight, than the Norfolk sheep, yet keeping in better order. Young sheep produce the belt lambs; the cranes are of course constantly fold at four or five years old; and it is observed, that it is fupposed, it would be more profitable. The author of the "General Trefiate on Cattle" fuggests, that the most noted variety is that of Mr. Elliman, of Glynd, in Suflex, who, he believes, first enlarged the Down breed, by the aid of polled or nott Berkshire tops. From this enlarged crofts, he understands, originated the flocks of the Duke of Bedford and Mr. Coke; the South Downs of Mr. Coke being generally acknowledged the largest and finest in England, a very pregnant proof of which was given at Lord Somerville's cattle show, in a two-hander Holkham South Down wether, which weighed more than 60 lbs. per quarter. Although quick and early feeders, they wallow within remarkably. And in answer to the complaints of those who knew the old Down sheep, that their wool is become so much coarser than formerly, from the modern habit of feeding the sheep with rape, cabbage, and oil-cake, they seem totally to forget the middle and long-woolled crofts, by which the carcasse of the South Downs of the present day has been enlarged, and their weight of wool increased, and rendered more coarse. The mutton is still excellent, although probably not so high-flavoured as the old Down mutton. It is also further fuggestes, that it would be difficult to point out any part of the island for which this breed would be unfit, but extremely easy to name a vast number of districts where it would be a most advantageous substitute for the native flocks. It is supposed, that all the South
SHEEP.

South Downs want is the noble covering of a Spanish fleece, and how little their carcase would suffer by the crof, has, it is said, been demonstrated by lord Somerville, in the exhibition of a very fine ewe, large enough for any purpose, half Spanish and half South Down. But in order to form a comparison between the Norfolks and South Downs, Mr. Overman of Norfolk, on March 27th, 1799, took from turnips twenty-two years old Norfolk wethers, and ten South Down of the same age, having always lived together from the time they were lambed, and two hours afterwards they weighed as follows:

Norfolk superior by 0 3 11 0

Besides, these Norfolk sheep losing 11 lb. 10 oz. more of their respective weight (taken full and empty) is a strong circumstance against them. The Downs are run much thicker on the land than the Norfolks. And Mr. Hill of the fame district estimates the difference of flocking between Norfolks and South Downs, at one-third in favour of the latter, in number, in better condition, and of greater weight, both in wool and carcase; all fairly attributable to the superiority of the breed, and free from any charge of defecating cattle, &c. When his flock was of Norfolks, scarcely one in a score had a whole fleece; but now they are South Downs, scarcely one in a score is broken. And Mr. Blyth of Burnham had, four years ago, a flock of between five and six hundred Norfolks: he has now one thousand South Downs on the same land, and has likewise double the wool from his land, flocking with South Downs, to what he clipped when under Norfolks. Also Mr. Duriglane, who has had South Downs for six years, is clear that, free from all change in habitation, or other circumstance that would unfairly affect the comparison, the number kept, compared with the Norfolks, has been as five to four. The carcase is as heavy as the Norfolks, more wool, and a better price. He does not fold; but the South Downs would bear it better than the Norfolks. At Palgrave he feds the South Downs, because there is a sheep-walk; a Norfolk flock changing gradually.

Some think that the South Down are much superior to the Norfolk, Cambridgshire, and well country sheep, both in point of form, hardiness, fineness of wool, and disposition to fatten. Crofles of the South Down with other sorts are likewise much approved of in many places; as that of the South Down ram with the Norfolk ewe, the lambs of which crofs are sometimes greatly admired. Some suppose it equally beneficial when done with several other breeds, according to the circumstances of the different districts. But this sort of crofing is very sparingly practised in the native district of this breed of sheep.

It has been tried with Spanish rams, and the wool has been considerably improved by the attempt; but two great defects, not to be compensated by any improvement in the wool, are paid to be produced, which are tenderness of constitution, and badness of shape. In other places this has not, however, been noticed to take place. In Oxfordshire, and several other counties, the South Down breed is fast supplanting the Berkshire, Norfolk, and many other kinds.

And it is stated, in the Staffordshire Agricultural Survey, that the Cannock Heath are a sort of sheep that has much resemblance to this breed, and is believed to have originated from the same. It is stated to have been much improved in the form, thickness, and weight of the carcase, as well as the fineness of the wool, by crofing with rams of the Herefordshire breed. They are polled with grey faces and legs; long before; wool fine and thickly fett, weighing two or three pounds the fleece; the mutton good; they weigh from 15 lbs. to 20 lbs. the quarter. In Mr. Edward Littleton's improvement of this breed, by crofing with Herefordshire tup's, the carcase and wool were both bettered, the latter being rendered worth nearly 2s. the pound.

The Norfolk Breed or Variety.—In this sort of sheep, the face is black; the horns large and spirally; the carcase long, small, weak, and thin; narrow chine; large bones; very long black or grey legs; mutton fine-grained and high-flavoured, but does not keep well in hot seasons. The weight per quarter from 16 lbs. to 20 lbs. The wool in the best part short and fine, but part coarse. This breed is chiefly prevalent in Norfolk and Suffolk, where folding is much the practice, as they have the property of travelling well. They are found in disposition to be given to beeffeaks, which renders them unfit stock, except in good inclusions. And it is stated, in the nineteenth volume of the Annals of Agriculture, that this sort of sheep, from possessing few valuable properties, in addition to that of stand-

Total difference in favour of Norfolk sheep 5s. 8d.

It is noticed, that neither of these ewes had any lambs, but at the time of trial, the Norfolk was more than half gone with lamb, and the South Down had but just taken the ram.

In short, the leading and characteristic qualities of the high and full-bred Norfolk and South Down sheep, seem upon comparison to be chiefly these, the wool of both is found to be of the finest quality, but the larger quantity is produced by the South Down: the mutton of both is equally delicious. But the quiet genteel South Down in the pastures must be opposed to the wild impatient ramblings of the Norfolk, whose constant exercise not only excites continual appetite, but at the same time occasions considerable waste in the pastures, by treading down and unnecessarily spoiling a great deal of food they do not eat. For this extraordinary exertion on the part of the Norfolk sheep in this respect, as it were, wantonly destroying a large portion of food which is prepared for its sustenance, there does not appear, from the trial already noticed, to be the smallest occasion at least, to put it on an equal footing with the South Down in that particular; for it is evidently demonstrated by that trial, that in an equally fed sheep, the heavier, and most capacious stomach, and consequently requiring the greatest quantity of food, is found to appertain to the Norfolk sheep. The hardness of the South Down, enduring wet and cold lodging, and a greater degree of abstinence and fatigue than the Norfolk in the field, is a superiority of much moment; and only to be equalled by another, which they possess in a very superior degree, which is that of doing well upon coarse four pastures. These are fairly to be contrasted with the delicate constitution, and the tender aromatic herbage, required by the Norfolk; to all which it may be added, that the South Down is an equally good turnip sheep; and for every possible purpose, whether for its fleth, for its wool, for breeding, for folding, or for the butcher, they demand a less supply of food, and of an inferior quality to that which, in every situation, would appear indispensable to the well doing of the Norfolk. On the score of the first cost of these sheep, an objection may, it is said, be very justly stated as to their general use; but when the South Down are more generally bred and increased through the country, in that proportion will the present objection be done away; and though they may continue in equal estimation, they will nevertheless, by their being more generally diffused and increased every where, be brought to a more equal level, in point of price, with the Norfolk, Welsh, and all those breeds so justly held in recoinutation for the fineness of their wool, and the superior excellence in the flavour of their mutton.

The value of the crosses which have been made between the Norfolk and Welsh sheep, by the South Down rams, are far from being decided, some sheep-farmers thinking them...
they highly beneficial, while others strongly reprobate them.

**Dalhorne Forest Breed or Variety.**—This is a breed or sort of sheep, which is found about the forest of that name, in the county of Chester. In point of shape, the animals are said not to be unlike those of a diminutive Norfolk sort, having the faces and legs black, grey, brown, and white, generally with small horns. The breed is small, the wethers not weighing more than from 8 lbs. to 12 lbs. the quarter, at four years old. The mutton is in common much esteemed, and the wool is valuable, selling about the year 1828 at 2l. 12s. 6d. the stone of 20 lbs.; the fleeces are, however, small, often not weighing more than 2 lbs. The wool is commonly purchased by the manufacturers of cloth in Yorkshire.

**The Herdwick Breed or Variety.**—This is a breed which is characterized by Mr. Culley by having no horns, and the face and legs being speckled; the larger the portion of white, with fewer black spots, the purer the breed; legs fine, small, clean; the lambs well covered, when dropped; the weight per quarter, in the ewes, from 6 lbs. to 8 lbs.; in the wethers of four years and a half old, from 9 lbs. to 12 lbs.; the wool short, thick, and matted in the fleece. It is a breed peculiar to the elevated mountainous tract of country at the head of the river Elk, and Duddon in Cumberland, where they are let in herds, at an annual sum: whence the name. At present they are said to possess the property of being extremely hardy in constitution, and capable of supporting themselves on the rocky bare mountains, with the trilling support of a little hay in the winter season; scratching down to the heath, during the snows, for their subsistence; and by their constantly moving about, not being liable to be drifted over by snow. From the nature of the climate, the ewes produce their lambs late, and are generally kept as long as they produce lambs. But the wether flock is usually disposed of from the mountains, without being put in the pastures, at from four to five years old. It is observed, that the fleece in this breed is finer than that of the Heath sort, but coarser than any of the short-wooled breeds. It is a breed that stands in need of a crofs with some of the finer-wooled breeds, and the Spanihs has been suggested as proper for the purpose. The property of the fleeces, as well as of the mountainous, is in lord Muncaiter, the lord of the soil; and the farmer of the principal flock is now Mr. Tyron, whose family, it is said, has inhabited this wild and forsaken spot through four centuries. Mr. Tyron is a tiner breeder, and sells a number of Herdwick tups yearly, some at several guineas each, to the adjoining districts, where their known hardy qualities are desirable.

**The Cheviot Breed or Variety.**—This breed of sheep is known by the want of horns; by the face and legs being mostly white, and the eyes lively and prominent; the belly long; little depth in the breast; narrow there and on the chine; clean, fine, small-boned legs, and thin pelts; the weight per quarter, when fat, from 12 lbs. to 18 lbs.; the wool partly fine, and partly coarse. Mr. Culley considers this as a valuable breed of mountain sheep, where the herbage is chiefly of the natural grass kind, which is the case in the situations where there are found the most prevalent, and from which they have obtained their name. It is a breed which has undergone much improvement within the last few years, in respect to its form and other qualities, and has been lately introduced into the most northern districts; and from its hardiness, its affording a portion of fine wool, and being quick in fattening, it is likely to answer well in such situations. The Spanish and South Down have been advised as proper crosses for this sort of sheep.

And it is observed by the writer of the Argyleshire Report, that the Cheviot sheep are in every respect superior to the black-faced kind, and found to be equally fit for a mountainous situation. They are hardy, fine-wooled, and well-shaped. They are long-bodied and long-limbed, which fits them for climbing steep mountains, and for travelling, either for seeking their food, or going to a distant market. Their fleeces, too, is finer, closer, and warmer. They have every property that should be sought in a mountain sheep, and accordingly they have been found to thrive in every part of the Highlands in which they have been tried, and are said to be less subject to diseases than the black-faced kind. Some of these have been lately introduced into the county by the duke of Argyle, and by Mr. Campbell of Auch, in the highest parts of Glenurchy, and found to answer exceedingly well. And lord Breadalbane, a few years ago, made a present of some Cheviot wethers to several of his tenants in Glenurchy, in order to try how they would fare on the same pasture with the black-faced kind; and the writer was informed by some of the fore-masters, that they perceived no difference in their thriving. Indeed no part of this county is more inclement than that from which they came, where the hills are sometimes covered with snow for three or four months in a year, and where many of the lower walks consist of peat-bogs and deep morasses; so that with us their situation would be mended, a circumstance which will always ensure success.

It is likewise stated in the twelfth volume of the Statistical Account of Scotland, that the following experiment, made in the parish of Barr, in Ayrshire, shews the comparative hardness and value of the Cheviot breed. In June, 1792, a ram and two score of ewes, of the Cheviot breed, were put upon one of the highest and coldest farms in the parish. The harvest was wet, the winter and spring stormy, and the lofs of the native sheep, through poverty and disease, was considerable; yet all the rest, though strangers, and in such a situation, did well. The wool of the native sheep, taking ten fleeces to the roane (24 lbs.), sold at 7s. 6d.; the wool of the Cheviot kind, taking only seven and a half to the roane, sold at 15s. The profit here was great; but how much more, if the wool had fetched its real value of 20s. the roane! And in "The Observations on different Breeds of Sheep," it is stated that in 1792, the Cheviot wool sold from 18s. to 20s. the merined, and from 20s. to 22s. the white; from six to eight fleeces of the first, and from eight to nine of the last, going to the roane. Some went as high as 23s.; and it is thought it will soon be improved to fetch 30s., if not 40s. Draft ewes sold from 12s. to 16s., and three-years old wethers from 18s. to 22s. In Etterick, Ewefeld, and Liddefdale, they are now converting their fleeces as quickly as possible into the Cheviot breed. The Roxburgh Agricultural Report also says, that Liddefdale is the worst district, yet the Cheviot breed thrive in it. The writer of the first of these Reports remarks, that it is difficult for those who have already got another kind to change the breed; but new beginners ought undoubtedly to flock with the Cheviot kind. It is said that the Yorkshire graziers have a prejudice against this kind; probably because they would then have more rivals in the trade, which is now few hands; as the carcass, and not the wool, is the principal object of attention. Whatever there may be in this, the introduction of the Cheviot, which would treble the price of wool, would more than balance it. And he adds, from the same volume of the Statistical Account of Scotland, that even they who have another flock, and cannot conveniently change it, might at least cross it with the Cheviot breed, which might
be done with little trouble, and to great advantage. In the years 1787, 1788, and 1789, an intelligent farmer, in the parish of Moffat, put Cheviot rams to his black-faced ewes. In 1792 he sold the wool of the sheep produced by that cross at 12s. the fix fleeces; and the wool of his other flock of the black-faced kind, which went exactly on the same pittance, only at 6s. 3d. the seven fleeces. The sheep thus produced were as healthy as his other sheep, the carcase not materially altered, and the weight of the wool increased a seventh part, and its price more than a third. The farm on which they were is as high ground as almost any in Scotland.

And the sheep which are at present known by the title of Long Hill sheep, by the northern farmers, are a hornless, white-faced, boote-shaped breed, having a coat of ordinary short or fine wool, perhaps raised by crovelling, through time, the old country breed with those of the Cheviot kind. They are said to be more tender than the short or black-faced breed, but to answer well with good care and keep. However, from the practice of milking ewes of this breed, for the purpose of making cheefes, being found to be prejudicial, it has lately been much left off by the bell sheep-farmers in those districts.

**The Dun-faced Breed or Variety.**—This is a fort which Culley says has no horns; the face in common of a dun tawny colour; the size small; the tail short; the mutton fine in texture; the weight often only 6 lbs. or 7 lbs. the quarter; the wool varially streaked and blended with different colours, some of which is very fine. He supposes it to partake of the Spanish breed, but it is not so hardy as the Cheviot breed. The mutton of this breed is excellent in flavour. They are supped by some to have had a Spanish origin; but they have been naturalized, for a great length of time, on the Grampian and other hilly districts in Scotland.

**The Shetland Breed or Variety.**—This is a small breed, and moftly without horns; but what more particularly distinguishes it from other breeds, is the uncommon smallness and shortness of the tail; the weight per quarter from 7 lbs. to 10 lbs.; the wool very fine, and of various colours. The breed is very hardy, but much too wild in its disposition to be confined in inclosed pastures, and of course less proper for the purposes of the grazer. There is a fort of this breed of sheep, which, according to Mr. Johnbon, carries coarse wool above, and fine soft wool underneath; and the sheep have three different fuccesions of wool annually, two of which resemble long hairs rather than wool, and are by the common people termed *fors* and *fudda*. As soon as the wool begins to loofen at the roots, which is mostly about February, the hairs or *fudda* spring up; and when the wool is cautiously pulled off, the tough hairs continue fall, until the new wool grows up about a quarter of an inch in length, then they gradually wear off; and when the new fleece has acquired two months’ growth, or thereabouts, the rough hairs, termed *fors*, spring up and keep root, until the proper season for pulling it arrives, when it is plucked off along with the wool, and is separated from it, at the time of dressing the fleece, by an operation called *forfing*. The *fudda* remains upon the skin, as if it were a thick coat, a protection against the inclemency of the season. But the native or kindly breed, that bear the soft cottony fleeces, according to Mr. Culley, are rather delicate; though the fact of their eating the sea-weed greedily, when the ground is covered with snow, and often during long and severe snows, when they have little elfe to live on, seems to prove the contrary. Nature, he says, seems to have imparted to them a perfect knowledge of the times at which this food may be procured; for immediately upon the tide beginning to fall, they in one body run directly down to the sea-shores, although feeding on hills several miles distant from the sea, where they remain until the tide returns, and obliges them to seek their usual haunts. They are very hardy, and the wildest of all the breeds of these animals.

But in respect to the wool of these *beaver* sheep, as they are sometimes termed, it is short and open, and delitute of a covering of long hairs. These fine short fleeces are liable to be rubbed off during winter, or early spring, which, if supposéd, might be prevented, by clipping the sheep in the usual way, instead of the absurd mode of pulling them off, which tends to weaken the sheep, and decrease the length of the staple of the wool. In regard to colour this wool is various, as *silver grey*, which is the finest and softest; the pure *walnut*, which is mostly of the greatest value for all the purposes of the finest combing wool; the *black*, and the *mourn* or *brown*, which are very little inferior; the whole of the softest texture, fit for the finest manufactures, and in some instances rivaling even Spanish wool, than which it is somewhat longer in the staple, and not so elastic. And it is flated to have been manufactured into focking of extraordinary fineness; and that the fleece attached to the skin affords a fur of great value. This breed was formerly a native of the higher parts of Aberdeenshire, and in the districts to the northward of it; but it has been since much crovelled, and it is now mostly confined to the Orkney and Shetland iles, the purest breed being to be found in the latter. The number of the *beaver* sheep in these iles amounted to ninety thousand, some years since; and five or six of them are said to be capable of being fed with the food required for one English sheep. In the Welf Riding of Yorkshire, Mr. Beaumont is said to have made a trial of these sheep; the result of which was, that they did not fatten, but grow, which shews that their fibre would improve with that of the wool; their wool also improved in length. But the original old breed of the Highlands are said to partake of the nature of the goat and deer; their coat consisting of a fort of fur or down, covered by a long, straight, rigid hairs, like those of the beaver, rather than wool; tail short, slender, tapering, not larger than that of the deer or goat, and thinly covered with strong, glossy hairs; the face covered with fleshy hairs, like the face of the deer, with his prominent eyes. They are tame, delicate of frame, and requiring to be housed in winter; they are of the highest quality in flavour. The breed is found in its original purity, in the central Highlands, on the southern banks of Strath Tay, and between the Lochs of Loch Faskell, and on the banks of Loch Nef, in the northern Highlands, as well as in the Shetland islands.

**The Merino or Spanish Breed or Variety.**—In this breed of sheep the males have horns, but the females are without them. They have, according to lord Somerville, white faces and legs; the body not very perfect in shape; rather long in the legs; fine in the bone; a degree of thoroughness, or production of loose pendulous skin under the neck; and the pelt fine and clear; weight, when tolerably fat, per quarter, in the rams about 17 lbs., in the ewes 11 lbs.; the wool very fine. It is a breed that is attired by force to be; tolerably hardy, and to posses a disposition to fatten readily; but others maintain the contrary opinion.

His majesty took the lead in the introduction of the Merino breed into this country, and his first flock was imported in 1792; but other nations seem to have got the flart in this respect, as Sweden had them even in 1729, where they have since greatly increased; and in France, Germany, and some other
SHEEP.

other rates, they were probably known long before. They have lately spread much in this country, and been greatly improved in different respects, by judicious crossing with other breeds. The horns in the true Merino rams are now of a middle size; the faces and legs darkish-white, the latter rather inclined to be too long. The wool is uncommonly fine, and weighs about 34 lbs. to the fleece, not being liable to deteriorate in this climate. The fleeces have a dark brown tinge in their surfaces, formed by dust fixing on the greatly yolky property of its pile; the contrast between which and the rich white coloured wethers, and the rosy hue of the skin, is very striking on the first view.

Some crosses the Merino rams with Devonshire ewes, but the Ryelands are more commonly preferred. They consider five crofses as necessary for reaching perfection; and on that ground properly conclude, that the wool of the first crofs may only be supposed to be worth about 7d. the pound more than that of the maternal flock, on the idea that it will, in five crofses, be of the value of 3s. above that of the Ryeland ewe; making an improvement of 7d. in each crofs. And that if the wool, when this fort is mixed with the most valued native breeds, does not gain its necessary degree of fineness in less than five crofses, it is unreasonable to expect the full price for it at one crofs. It is, however, certain that the animal is improved by a mixture with the Ryelands, and that the wool will not ultimately be found inferior to that of the Spanish flock. The Spanish crofs with the South Down and Ryeland, in several degrees, is diffusing itself in many districts with great benefit.

With the latter, in Devonshire, the wether produce, at two years old, weigh 15 lbs. the quarter, and afford a fleece of 5 lbs. each, worth 3s. the pound. In other cafes, the weight of mutton is greater in the first crofs; and the fleece of wool from 6½ lbs. to 7½ lbs. in the wool to the fleece, at the same age. Crofses with some other fine-wooled breeds are likewise made with great utility.

But according to Dr. Parry, who has had great experience of this breed, they are, as stated in a late work on Live-stock, entirely enveloped in wool, which grows under the jaws, down the forehand to the eye, under the belly, and down the leg to the very feet. It is not without reason that his hearth is so thickly it covers the skin; it will scarcely give way to the prehure of the hand, but yields as it were by arts, like the close short hair of an extremely fine clothes-brush. In washing them, the water penetrates to the skin with great difficulty. The fleece is heavier, in proportion to the carcase, than that of any other known breed in Europe. In the raw state (unwashed on the sheep’s back or afterwards), the fleeces of the two years old ewes average at 4½ lbs. avoirdupois, and the weight of the living being about 60 lbs.; the proportion of wool to that of carcase is about 11b. to 12½ lbs. The fleece of a fat wether of the same age will be from 5½ lbs. to 7½ lbs. In eight shearing rams, weighed alive, after having been clipped, the weight of the fleece to that of the living animal, was as one to about twelve and three quarters. The wool from the head and behind the ears, and the rest of the refuse, generally called doglocks, had been previously taken away. It is added, that had these sheep been washed before shearing, their fleeces would have left about a ninth part. And that the length of the staple or filaments varies. In a shearing ram, thorn when a lamb, a sample of the wool cut close to the skin above the shoulder, was three inches and a half in length; and that of the breeze, or middle of the back part of the thigh, three inches and three quarters; of an ewe of the same age, about a quarter of an inch shorter; the average according very exactly with the specimens taken from newly imported Spanish sheep.

An instance of the extraordinary length of staple, of four inches and three quarters, is related, which from the fourcooled fleece produced a sample more than five inches long. The proportion of fine wool in the fleeces of the Spanish sheep is much greater than those of any pure English breed.

Thus, while in the Ryeland, which is probably divided into four or five forts, the finest wool from the neck and shoulders does not make above one-eighth part of the whole fleece in that of his majesty’s flock, the fine wool formed near four-fifths of the whole. It is farther observed, that of Dr. Parry’s wool, consisting of whole fleeces taken from sheep which had not more than three or four crofses of the Spaniard, and divided into three forts (R. F. T.), according to the Spanish method, 156½ lbs. produced of R. or Rhinos, or superfine, 104 lbs. more than two-thirds of the whole. And the uniformity of fineness in the improved wool is such, that in sheering specimens from these different parts of the same animal, (the shoulder and the breech,) which are generally considered as producing the best and the worst wool, the doctor never met with any three persons who could agree which was the finest, and many good judges actually decided in favour of the latter. This wool contains a great deal of yolk, or oil, which is apt to entangle the dust of the fields, so as often to form a kind of mat of nearly an inch in thickness; it is remarkably, or rather wholly free from frizzles or k应急管理. Brownings in the wool of any particular sheep is an indication of superfine fineness (and which is the colour of the ancient fine-wooled sheep, and we need not look for the cafm in any peculiar quality of oil or composition mixed with the wool); it will nevertheless soon whiten. But according to Dr. Parry’s wool, from the wool of any particular sheep is an indication of superfine fineness (and which is the colour of the ancient fine-wooled sheep, and we need not look for the cafm in any peculiar quality of oil or composition mixed with the wool); it will nevertheless soon whiten. But according to Lord Somerville, this dark-brown tinge on the surface of the bell fleeces amounts almost to a black, which is formed by dust adhering to the greasy yolky properties of its pile; and the contrast between it and the rich white colour within, as well as that rosy hue of the skin, peculiarly denoting high proof, suprime at first sight. The harder the fleece is, and the more it refits any outward pressure of the hand, the more clove and fine will be the wool. Here and there a fine pile may be formed with an open fleece, though but rarely. And in Mr. Tollet’s Spanish flock, purchased from Lord Somerville, the average weight of each Spanish fleece in the grease was 5½ lbs. in oz., and the eighties ewe fleece 3½ lbs. 4 oz., and the heavy ram fleece 1½ lbs. 1 oz. of very good quality. This ram was not quite three months old at shearing, and was adjudged to weigh 20 lbs. per quarter. Mr. Tollet declined the price of two hundred guineas for him, likewise that of one hundred for the use of him during the tapping season: he does not wash his Merino sheep before shearing, since, from the filaments of the fleece, it is not much liable to the intrusion of dirt: as it does not lose quite half its weight in scouring by the manufacturer, an estimate may be made after that rate of the value of the fleece in the yolk. The fleece of the young ram produced upwards of 3½ lbs. and the average produce of the whole unwashed Merino wool 18½ d. each fleece. The price of the superfine more than four-fifths of the whole, 6s. 3½ d. and 6s. per pound of the third fort, or frieze, which was about about one pound in the whole quantity. Mr. Bartley has somewhere mentioned, that four wethers of this breed produced the quantity of 35½ lbs. of wool; and of several ewes which produced 8 lbs. each, and of a wether which gave 10½ lbs.

In the introduction of this breed his majesty, as has been seen, has taken the lead, and from his flock a great number of the improvers of it have been supplied in the different
different tales that have been made since its first establishment. In the sale of 1803, in Kent Lane, under the direction of Sir Joseph Banks, the numbers sold, according to some, were twenty-four shearing rams, which produced the sum of 40l. 9s.; seven full-mouthed and four toothed rams, 17l. 13s. 6d.; fourteen ewes, 11l. 8s.; amounting in all for the forty-five sheep to 69l. 10s. 6d. The highest price of the shearing was 42 guineas, the lowest 6l. 7s. Of the full-mouthed rams, 28 guineas were the highest, and 11 the lowest price. Of the ewes, 11 guineas the highest, 6 the lowest. The rams were put up at six guineas, the ewes at two guineas; the former prices at which they were allowed.

The wool has been sold this year unscored at 4s. 6d. per pound. The size of the ewes somewhat under our pure Ryelands, but above several of our small breeds; heads sharp and well-shaped, with occasionally a black spot or two; wool externally having a dirty tinge, but without that red-brown hue which has been before mentioned; ears pendulous; perfect ewe-neck, with the sinking or cavity both before and behind the shoulder, the top of which is generally higher than the rump; capacious belly, the animal standing wide and well upon the legs; the rams generally of good size, some of them large enough for any purpose whatever, and of a great bone, but flat and symmetrical; several of them were of as good and useful form as need be seen, having compact loins and shoulders, and straight backs. Two or three individuals resembled very strikingly our Dorset and Hampshire flock; the characteristic velvet or flagen gloss on the horn faces of the rams was remarkable, and their countenance put one in mind of the fair-haired human complexion. Mouths by no means fine.

And it has been observed, that the large tuft of wool covering the face of Merino sheep is extremely inconvenient in northern countries, where they have frequent heavy drifts of snow. And that it is lord Somerville's practice to clip this and the leg-wool two or three times a year, beginning about six weeks after shearing. But that in winter, and in very rigorous climates, it may not be proper to leave the head too bare and exposed, as it may produce disease. These clippings may be proper for inferior purposes, and the fleece be rendered more pure and valuable without them. The tuft on the head, and even the throatiness, or protuberance in the throat, characteristic of the Spanish fort, are, as it is asserted, discoverable, in degrees, in some of the native breeds, particularly the Ryeland, shewing its origin. And a good judge, Mr. Knight, contends, that the produce of a croft with this breed, and the Archenfield or true Ryeland fort, is extremely ugly, and, according to his information, subject to the foot-rot. On some rich pastures in Middlesex this has also been found to be the cafe in both the true and croffed breed.

The Mugged Breed or Variety.—This is a singular breed of sheep, which formerly prevailed throughout all the low lands of Northumberland. They had a short, coarse, curled wool, covering their heads, faces, and legs, and grew down to their feet; in form they resembled hill sheep; their shoulders low and sharp; sides flat; back rather arched; loins thin. It has been suggested, that this mugged appearance may have been the result of a Spanish croft. This fort of sheep has extended to Yorkshire; and traces of them are still visible, although they have long since given place to sheep of the long-woolly kinds. They are now chiefly met with in the northern counties.

The Welsh Sheep or Variety.—These, which are the most general breed in the hill districts, are small-horned, and all over of a white colour. They are neat compact sheep. There is likewise a polled short-wooled fort of sheep in those parts of the country, which are esteemed by some. And the genuine Welsh mutton, from its smallness and delicate flavour, is commonly well-known, highly esteemed, and sold at a high price. But the fattening of the small Welsh sheep has not in general been found to answer in the southern districts of the kingdom. In short, this is a breed which stands in need of much improvement, and which is capable of admitting of it with much advantage to the sheep-farmers of that district.

The croftes of it should be with the larger finer woolled breeds, that afford good mutton, and be made with great care and attention. It is suppos'd by some, that the Welsh are the original of all the different breeds of sheep in the island.

The Irish Breed or Variety.—This is a breed of sheep, which is described in this way by Culley. These sheep are supported by very long, thick, crooked, grey legs; their heads long and ugly, with large flagging ears, grey faces, and eyes sunk; necks long, and set on below the shoulders; breasts narrow and short, hollow before and behind the shoulders; flat-fided, with high, narrow, herring-backs; hind-quarters drooping, and tail flet low. In short, they are almost in every respect contrary to what is apprehended a well-formed sheep should be. The spirit of improvement in sheep-flock has however extended itself to Ireland, and there can be no doubt, therefore, but that they will soon improve this as well as other forts of live-flock.

Indeed, since the period in which the above account of Irish sheep was given, many useful and important alterations and improvements have been produced by judicious selection and crossing in this fort of flock, in several different parts of that country.

However, independent of these numerous breeds or varieties of sheep, which are inhabitants of this island, there are in other countries many other kinds, which may be just noticed for the sake of curiosity, as they are occasionally seen in parks and pleasure-grounds in this intention. The more cold districts of Iceland and Russia afford a many-horned breed of sheep, mostly from four to seven or eight, having a coat of dark-brown coloured hairy wool, weighing about four pounds, and covering an interior one of short soft fur. Also in Russian Tartary, a large long-eared, polled aquiline-nosed breed of sheep, somewhat resembling the Wilshire and Dorset breeds in their shape, are produced, and which have a long thick wool, of a black and white mixed or roan colour, and in the place of a tail, a large cullion of fat occupying the rump; hence some naturalists have called them fat-rumped sheep. This and the broad-tailed breeds are sometimes called the Kalmuck and Altrachan breeds. The projection of fat, in this, has an exquisite delicate marrowly taste. Some say the wool is rather short, not coarse, but having hair growing through it. They are said to be so prolific as to bring two or three young at once. And in Walachia, Crete, and through most of the Archipelago islands, there is a breed of sheep which have singular horns, twisted in a spiral or screw-like manner, standing in a perpendicular or diverging extending manner from the fore-part of the head, to some height. In size and shape tolerable, bearing a long shaggy, but not coarse coat. Likewise in the extended districts of Persia, Syria, Egypt, and Barbary, the broad-tailed sheep are met with, the tail in some of which grows to the breadth of a foot, and to a length to bring them to the weight of from twenty to fifty pounds, on which account the shepherds are sometimes under the necessity of supporting.
Sheep.

ing them on a carriage to prevent them from gallowing and exhausting the animal. These appendages are mostly also esteemed a great delicacy, being of a nature between fat and marrow. Further, some of this breed of sheep, especially those of the mountainous forts, have a wool of extraordinary length and fineness, from which are made the expensive Indian shawls, and some other fabrics.

And the Guinea breed of sheep, paid to be common in tropical climates, is large, strong, and swift, and though domesticated, are often found in a wild state; having coarse, hairy coats, short horns, pendulous ears, and a fort of dewlap under the chin.

What is called the Madagascar breed of sheep, is also of a good size, and well covered with a close pile of smooth glossy hair in the place of wool.

The Bashkarian breed of sheep is also hairy, and kept in large flocks in Great Tartary. The island of Antigua has likewise a breed of the same kind. Sheep of this fort were imported from Spain by Sir Joseph Banks, with coats as sleek and smooth as those of a horse, and which never at any season exhibited the least appearance of wool or down, or any thing of a similar kind.

It may be noticed, that it has been well fitted in a late practical work, that in the breeds of sheep there are evident differences in their sizes, forms, fleth, wool, and other properties, that admirably adapt them for different forts of pastures, situations, and uces of the farmer. And that the large long-woolled breeds, from their being more flow, heavy, and tame in their dispositions than most other kinds, are in general the most proper for the rich inclosed pasturage districts; the breeds which possess greater length in the legs, more activity in walking, and a less burthen of wool, are suited to the more elevated lands, such as the downs, moors, and heaths in different parts of the island, where the pasturage is less fertile and luxuriant; and that the small light haired hardy breeds are most adapted to the exposed mountainous situations, where the food is more sparing, and obtained with greater difficulty and expense. And in the Rural Economy of the Midland Counties, it has been observed, that a very long-woolled breed of sheep, as the old Lincolnshire or Teeswater fort, is necessary also in the view of our finest woollen manufactures; and another, such as that of the new Leicesters, for the inferior kind of grass lands, and the rich inclosed arable lands, where the folding system is not in use; for the supplying the materials of the coarser forts of worsteds, stockings, baize, coarse cloths, blankets, carpets, and other articles of the same kind; while a middle-woolled breed, as the Wiltsire, the Norfolk, or the South Down, is wanted for the well-fooled arable lands, where the practice of the fold is in use, in the view of making cloths of the narrow medium kinds; a very fine-woolled breed, as the Herefordshire Ryeland, for the finest cloths; and the Shropshire, or some of the more hardy breeds, for the healthy mountainous situations. The Spanish and Chievot forts may also be proper in the last intentions.

What is therefore chiefly necessary to be regarded in the introducing of new breeds of sheep, is to consider with attention the nature and situation of the pastures on which they are to be supported, and to carefully avoid making use of larger or finer breeds than can be properly fullained; as upon due management in this respect, much of the success in the improvement of sheep-flock must necessarily depend. Where bettering the form of the animal, and improving the quality of the wool or coat, are the principal objects, they may be effected by judicious croffing with proper breeds for the particular purpose, on the principles that have been explained in speaking of the nature of breeding, and which is farther shewn below. (See Breed, Breeding, and Livestock.) Indeed this last circumstance is one which should particularly engage the notice of the farmer in the business of stockling his lands with sheep, as it Seems from numerous statements, that wool of the finest quality may be produced in this country by means of Spanish sheep, and their being properly crossed with our fine-woolled breeds, which is a matter of the greatest national importance, as affording a probable means of rendering us independent of the foreign supply of this expensive but indispenisible article. The breeding sheep-farmer should therefore be particularly interested in promoting this sort of improvement, in all situations where the nature of his land will admit of it, which lord Somerville has shewn may be the case in most instances where the short-woolled breeds of sheep can be properly kept, or probably on more than one-half of the pasture-lands of the island. And he has remarked that there is one inducement to this, which is that of its not interfering with the production of the most valuable fort of mutton, a point to which the sheep-breeders of this country have till lately been particularly attentive, almost without regarding the quality of the wool; as it has been found that the quality of the flesh in the different divisions of sheep inclines to the nature of the wool, the short-woolled sheep being cleare in the grain of their fleth, of course heavy in the scale, and in the talle high-flavoured; while the polled long-woolled fort are more open and loose in this respect, larger in size, and the mutton more coarse, and in general less saleable in the different markets in the kingdom.

In sheep there are certain good or bad qualities, properties, or dispositions which mark their value and importance in the view of the farmer, grazier, and breeder. That such certain peculiar properties and dispositions prevail, is well known to experienced persons of these descriptions, by sheep in exactly similar circumstances in every respect becoming more or less quickly in the state of fatness, &c.; as an improved disposition in them signifies an aptitude to convert their food or nourishment into flesh and fat. Thus, in a number of sheep of the same kind and age, under the very same management, when handled, a vast difference will be found in their condition and state of fatness, &c. Some will be in a state to go off many months before the others are ready, although put on the same land in equal flesh; and others, though kept far beyond the usual period of time, will never get into sufficient condition. The disposition of the former must, of course, be very beneficial and desirable to such sheep-farmers, as well as advantageous to the community, while that of the latter is quite the reverse. This is likewise the case in the breeding of ewes, as those which have it most are in the best state at the lambing time. But there are, it is supposed, some instances of exception in this and other descriptions of sheep, which poffefs good qualities, that have bad properties, which such sheep improves as the above should also be careful in detecting, otherwise they may be liable to sustain considerable injury and loss; and it is frequently seen on killing different kinds of sheep, that there is great difference in individuals of the same breed and variety.

There are several circumstances which are supposed to form or contribute to this goodness of disposition in those animals; they must be well bred, or come from such as have good properties; they must not be permitted ever to be in a state of want of food, or be reduced in flesh; they must have constantly good food in sufficient abundance, the richer, to some extent, the better; they must have their...
frame or bone not too large for the quality of their keep; they must have a due relative proportion of parts; they must handle free and mellow in their flesh; they must have a peculiar appearance of countenance; and they must be perfectly tame and quiet. There are also other causes which in some measure conduce to this end, but they are of less certainty in their operation, such as the rate and action of the blood in their yflems, &c. The external forms and qualities of sheep which flew a good disposition are, a smallness of the head, a thinness and shortness of the neck, a deep wide breast, a wideness over the shoulders, a broad, straight and deep carcase or barrel, a smallness of bone and feet, the joints moderately short, the muscles or flesh plump and full, with a thinness about the intestine: the skin middling thin and mellow, of a fine texture, and a clear red and white colour; the wool of a yellowish-white appearance, a curly nature, and neither too long nor too short, but thickly set, the fat and flesh soft, with some port of firmness in handling, and the countenance pleasant, and inclined to quietness.

The improved disposition or quality of sheep is promoted by taking them from poorer or inferior keep or fofs, to such as are of a better and more rich kind, as in the cafe of feeds: but the removing of them from rich feeds or keep, to such as are of a worse nature, has directly the contrary effect. The quality of the flesh, in one cafe, becomes soft and mellow, while in the other it gets more close and hard.

The nature and quality of the land or foil, when any breed of sheep are kept upon it for a length of time, will, if it is benevolent, throw out the ufual fize for it, and certain accidental qualities will occur according to its fort, which, when properly managed by the breeder, will afford an improved disposition in the animals. In fuch a cafe improvements may have a probability of being produced, by having the male smaller in fize than the female, and by changing him from too good or rich keep, fo that his constitution may be in some measure delicate, by the female having her nourishment regular, and fo as at no time to be lowered in fpirit; and when a more full supply of food may be obtained, by the increafe being moderate, fo as to preserve rich keep for the lambs when young, in its advancing growth; by breeding from such sheep as are the most kindly, threw the best disposition, and allow the fufcient profit, on the particular foil or land on which they are bred and fattled; by choofing and selecting the middle fized sheep of the flock to breed from, and not the largeft, as it is favourable to be rather under than over the quality of the foil or land for forming good disposition; by refraining to breed from fheep defplaying a bad disposition, or which have defects; and by cautiously fwing for this pur- pose ewes which have had lambs, and are not too old, as disposition is fuppofed more likely to be produced from the second than the ftrait lamb: and laftly, by the mode of breeding that is called in and in, or in the fame line, which greatly contributes to form disposition.

In the degenerated form of sheep, the reverse of all this will, of course, moftly take place; they will have these qualities or properties in a larger or smaller degree; their heads will be generally short and thick, though occa- fionally rather long, and of a coarse nature; the neck, for the moft part, long, thick, and concave in the higher part; the carcase long and thin, and the ribs flat, ufually termed "flat-fid-d," while in improved sheep they bow out almost at right angles with the spine, in somewhat the barrel manner. Narrow shoulders, the loin not wide, the back not straight, and the belly goutly; the breast or chest contracted, without being deeply let down; the legs long, and thigh

not full or fleghy; the flefth thin, of a clofe texture, and thick about the intestine of the fucular parts; the feet large and coarfe; the flefth hard in handling, or what is sometimes denominated "ficky;" the countenance far from pleasant, and the nature wild; the wool coarfe and humpy; but capable of improvement by attention; difficult, or requiring time in fattening; the mutton often of good quality for eating, of a firm grain, sweet flavour, and abounding in gravy.

Sheep of this kind in general require a much greater quan- tity of food for their growth and support, and for fattening, than the improved fort, which is a confluence that molt evidently be difadvantageous to the breeder, graizer, and the whole community.

All such perfonas are in the habit of breeding and fattening sheep, and have fufficient experience, find that they depend on the qualities or properties of their breeds for growth and improvement: some will not fatten at all, or be as long again in fattening as others, and this molt commonly occurs in fuch as are not of the individual's own particular breed or kind. The degeneracy of sheep is readily seen and easily proved in the management of them. And some confider almost the whole of the breeds or varieties of this country to be more or less in this flate, or that there is not probably more than one which can be faid to be truly in an improved condition, on the exact principles of improved forms.

This degeneracy is in a great measure the confluence of neglect or error in the breeders and managers of sheep, as when they thrive and fatten well, that is to be attributed to proper refega, fitteable keep, and a due regard to the true and exact principles of management; but when, on the contrary, they do not go on to fatten well, but decline into a flate of degeneracy, it proceeds from neglect, harvation, and the want of fuch true principles in their regulation and management. As though a lamb may posfeft good proportions, yet from neglect and other caufes, it may be reduced to a flate of poverty; which, when it takes place, its degeneracy may be dated from that period, as its constitution is injured, and an unfavourable action is given to the fystem. The longer it is kept in this flate, and the more frequent the change it may undergo, the more confpicious will be a degeneracy be. Nature, then, it is fuppofed, will throw out indications in conformity to this decline; the head will increafe in fize in a greater proportion than the other parts. The body will become thin and long; the bones will be irregular in their growth; and there will be a want of symmetry in the whole fystem. The caufes which are the foundation of fuch degeneracy are believed to be thefe; the rams being too large in fize, and kept in too high a manner; thefe and the ewes not being well adapted to the foil, but too large; the lambs being kept in an occluial flate of want or harvation; the neglect in not breeding a proper number for the pofufe of fegation; the ignorance of breeders in regard to the true principles, in refpeft to the forms of sheep or their management; the frequent crossings of varieties of the fame breed; the prefence of dry fummers and hard winters, which tend to incline the constitution to an unfavourable action, and confequent degeneracy; and the want of good water, which is very prejudicial to sheep.

It is fuggeted, that it is to be lamented, that almost all the breeds, in every fitation, are found to have one or other of the bad properties or qualities already noticed. However, of all sheep, the shape or form of that of the Indian fort is probably the worft which is produced; and the Wilthire, the Welsh, and many other breeds, are not without partaking of too many of the properties and imperfections of the fame kind, in addition
SHEEP.

to their other defects. It is to be hoped, however, that a
more active exertion, and investigation of the matter, in sheep-
farmers, will in a short time be productive of the requisite
improvement in this fort of live-stock, and that by having
recourse to superior modes of breeding, rearing, and man-
gement, an equal pace will be kept in their advancement with
that of any other branch of the farmer’s art.

It may be noticed, notwithstanding what has been already
said, that it is flated to be almost universally and unanimously
the practice of the breeders on the South Down hills, to ex-
change the rams every third, fourth, or fifth year, as it is
conceived essentially necessary to the preservation of the
health, the size, and the bone of the flocks, though quite
contrary to the maxims laid down by some eminent sheep-
farmers, who are itenary promoters of the method of breed-
ing in and in, or in the same line, continually, when there
is a good breed or fort of sheep. Flocks that are flated to
have been nearly ruined in constitution and habit by this
means, are said to have had a wonderful improvement by
the change of the rams. See BREEDING.

The question concerning the belt and most profitable size
of sheep for the purpose of the grazing farmer, and for
producing the largest acriable quantity of food and other
products for the use of the community, is a matter of very
great interest and importance. Though it cannot probably
be disputed but that different sized animals of this fort must
be had recourse to for different situations, forts, and qualities
of land, &c. yet the confiderate sheep-farmer will, perhaps,
mostly perceive the propriety of having his ground stocked
with not too large a fort of sheep. It will most likely be
the belt way for such farmers to fully confult the nature
and properties of the foils of their pature or other lands,
previously to their fixing upon the size of their sheep-flock
which will be the most suitable and advantageous for them,
as where their pature or other grounds are inferior in their
nature and riches, the size, of the live-flock of this fort,
which is admitted, cannot with propriety be so large as in the
contrary circumstances, even where light floocking is prac-
tified, for hard and pinching feafons will reduce the flock to
the quality of the land. Though many are advocates for
very large-sized sheep, probably from want of sufficiently
considering the nature of the subject, it is never found that
those who flock with such animals, ever produce fo
much mutton on the acre, or gain fo great a profit on it, as
those who make use of a middling-sized flock. Some indeed
think that four small-sized sheep may be kept on the same
extent of land which is required for three large ones; and
that in some cases, allowing the sheep to be equal in dispo-
sion, the fame number of small ones, of about nine (the
each, may be fattened on the land that will barely be suffi-
cient to feed three of from ten to eleven (none. Small-sized
sheep-flock have also many other advantages attending them.
Many make complaints against sheep with improved forms,
such as the new Leiceliter, as being too small, from the mis-
taken idea of their close form, as although they may be
short and compact, there is a greater width and depth of car-
cafe in them; by which they do not come much, if any thing,
short of the weight of the more apparently large breed.

It is unquestionably a great error and defect in the sheep-
grazing practice to choose sheep of too large a size for the
constitution of the soil, and the quality of the keep which
it affords. The nature of keep will indeed itself be the
cause of different sizes in sheep-flock, if they be readily
maintained on the same fort of land for some length of time,
and this in some measure has produced the differences of size
in the different breeds of this animal.

The particular advantages of the different sizes of sheep
Vol. XXXII.
as are the cloths flocked, are found in common to afford sheep that give the best proof, but it has probably less effect in this way than is generally imagined, as particular breeds give a superiority of proof on poor lands, to that of others on very rich. Time has considerable effect in giving proof to sheep, as by it fat is enabled to be collected and formed internally; but disposing of the animals at short periods constitutes the great advantage of the grazing farmer, and he has no reason to breed and fatten his flock for the benefit of the butcher and other dealers in tallow. The management in regard to breeding and cropping, as well as the nature of the wool, are said to influence the proof in these animals, as where the more ordinary forms are adhered to, the proof will be greater than in the contrary circumstances, as they have a greater tendency to form tallow and loose inside fat. And though some think long white watery wool favourable to proof, others suppose it the contrary, as denoting a disposition to fatten quickly, and as preventing inside fat by taking away the nourishment, thereby concluding fine short-woolled sheep more disposed to afford good proof. The good or bad forms and feel of particular parts of the head, the neck, the back, the breadth, the barrel, the bone, the skin or pelt, and the fleece, often afford indications of proof, though not always such as are certain; as when the head is large, the second long and thin, the third narrow, thin, and high, the back thin and straight, the carcase thin and not well rounded, the bone long and large, the hide or skin ficky and hard, and the flesh hard. But these different indications of proof cannot, it is evident, always be wholly depended on, as sheep may have one or more of the marks or properties which denote good proof, but which may be counteracted by others that favour disposition and other similar qualities to the contrary; consequently where two sheep are similarly formed, that which has the largest head and firmest fleece may most likely be concluded to give the best proof. The opinions on proof ought, in fact, constantly to be formed from the greatest combination of the marks of it met with in the particular animals examined.

Perhaps, so far as proof is capable of being judged of before the animals are killed, it may be known by the feel of the fat glandular part, which extends from the bottom part of the neck to the shoulder, which, in lean sheep is so very small as scarcely to be felt, while in those that are properly fatted by sufficient time, or pastured, as it is sometimes termed, there is a different sized cushion or projection of the fat glandular part extending to the thick portion of the shoulder; by the feel on the ribs and tail or dock, which, when it is thick, fat, and mellow, the sheep will commonly, it is thought, die well for proof. A thick loin is sometimes also thought a mark of proof in the kidney and weight. The feel of the fore-dug of barren ewes and the cod of wethers, likewise shew, it is thought, proof. Many of these marks must, however, be allowed to be precarious and uncertain.

It cannot on the whole be doubted, from what has been stated on the subject of proof, that the interests of the butcher and the grazing farmer are at variance as matters stand at present, as what is the gain of one must be the loss of the other, where the thing is well under flood.

In the Agricultural Survey of the County of Norfolk, lately published, it is noticed, that the South Down breed is getting rapidly into the posession of all the country from Swaffham to Holkham; but that from Brandon to Swaffham many Norfolks remain. However, some mixture was observed even in that district. And it is stated that Mr. Coke is well satisfied of the advantage of the breed from Leicester ewes and Bakewell tups. His flock of 160 new Leicesters were produced, in 1802, 100 lambs; his flock of 630 South Downs produced 830 lambs living in June. The same farm, it is added, yields a most interesting comparison between Norfolks and South Downs: his former flock was 800 Norfolks, SELLING all the produce: he planted 700 acres, and now has 800 South Downs, KEEPING all the produce. Further, that his new Leicester hogs and sheaves produced 36s. of wool each in the same year, yet they had been kept hard kept on feeds fed very bare. And it is stated, that though he had a high opinion formerly of the crosses between the new Leicester tup and Norfolk ewe, now (1803) his opinion is changed from much experience; so that he prefers the crosses of a South Down ram on a Norfolk ewe to that of a Leicester ram. And it is added, that Mr. Coke has had the fame crosses, and they come to 32l. a quarter, at two-sheer. He put a Norfolk tup and a Bakewell tup at the same time to the same parcel of Norfolk ewes, and at St. Ives fair sold the lambs fat at six or seven months old, and the Bakewells brought just double the price of the Norfolks. In April 1799, Mr. Coke, on fending Norfolk, South Down, and new Leicester three-sheer wethers to Smithfield, that had been fed together, the return was:

And in May following above 100 going, the South Downs beat the new Leicesters by 2r. a-head. It is also observed, that at Waterden, Mr. Money Hill, with about 500 acres less land than at present, kept 27 score breeding Norfolk ewes, and sold the produce of lambs; now he has 35 score South Down ewes, and keeps their produce, selling his wool at 5r. a tod more than the Norfolk. And further, that Mr. Bevan, in 1792, had a South Down flock, of 30 score, on one farm, and having a flock of Norfolk ewes on an adjoining farm at Knattishall, he had an opportunity of comparing the wool exactly: 34 score of Norfolk ewes produced 43 tod at 28l. 6s. and 34 score of South Downs produced 61 tod; which 61, kept till November, became 64, but the summer very wet.

Also that in 1791, the shepherd would not let his own Norfolk ewes take the South Down ram; but in 1792 he was ready enough. He said they would eat harder than the Norfolks; and would eat what the Norfolks would not; that they are more quiet and obedient than the Norfolks; so that he has done with them what he could not do with the Norfolks; folded them almost to an inch without hurdles. And that a neighbouring farmer bought three rams of Mr. Bevan, at 5l. 5r. each; but afterwards repenting, because they would stain his flock, Mr. Bevan offered him 6d. a-head, for all their lambs, more than he sold his Norfolks for, in the same flock, at Ipswich fair. The offer was accepted; the price proved 6s. 3d. for the ewe lambs, and 9s. for the wethers. Mr. Bevan refold the ewes for 9s. and the wethers for 10r. 6d., or 2r. 13d. a-head in favour of the half-breds. Further, that when his sheep were Norfolks, he kept 500; but in 1794, he had 960 South Downs. That the produce

Actual profit: 120 1 0

Farther, it is also added, that he was early in trying South Down sheep, but finding them tender at lambing, went into a new Leicester cross; these he abandoned, and got back to the South Downs, but fell in love with a tender breed, and that they ought to have yards sheltered and littered for lambing in bad weather; remarking, that all the farmers he knows on the South Downs have these yards for that purpose. It is likewise stated, that Mr. Bircham, at Hackford, declares against having any favourites; he has generally bought Norfolks, and half-bred lambs; some few South Downs, but they did not answer: had some Leicesters; and often he can get worth his money. Little farmers, who keep a few sheep, find the polled breed very convenient from their quietness, and therefore prefer them. Norfolk lambs bred near Cromer, bought by Mr. G. Jones at 14s., were run on byphiles in the autumn, and put to turnips at Christmas, then to layers of the first year, probably as the best food for sheep, and fold shearers wethers at Michaelmas at 5s. each; 20lbs. to 24lbs. a quarter. And colonel Butler, at Haydon, is said to be convinced that Norfolk sheep answer better than South Downs; the Seaflax breed sometimes affording 20lbs. and 25lbs. a quarter, and 15lbs. of tallow; he has a breeding flock of 400, and sold his wethers lambs at 26s. and his ewe lambs at 24s. Mr. Johnson, of Thurning, has 40 head of South Downs, which he has been rearing these five years, having bought many ewes, and got good tops. He has, however, a good opinion of Norfolks, and would not be surprised to see them come into fashion again. In May 1792, he sold two-shear Norfolk wethers at Smithfield for 3l. each. He admits their straining disposition, but much against them; and he is clear that he cannot keep so many on his farm as of South Downs. The South Down wool is not, on good keep, so good as Norfolk wool, but the fleece is heavier. Five years ago he got a lot of Yorkshires from the Wolds, white faces, polled, and the wool very coarse, but they thrived wonderfully; never having had any sheep that did better, infamously, that he was forsy when he parted with them. Norfolks, he thinks, will bear folding better than South Downs. The latter will, however, come to hand rather sooner, but not on long: has had three-shear South Downs of 28lbs. a quarter. Also at Snetesham, Mr. Styleman, the waiter asserts, keeps 2000 of various breeds, South Downs, new Leicesters, and half and half; in number considerably more than when, on the same land, he kept Norfolks: his farm may, and probably does, produce more sheep-food than it did at that time; but he is perfectly clear in the great superiority of the number; this circumstance deducted, and that the profit is considerably greater; and he is clear also in the superior hardiness and kindliness of feeding of the new breeds. Of all cross-breeds, he thinks the first cross of the Leicester tup on the Norfolk ewe the best, and that wool now (1802) sells at 46s. a tod; fleeces 41lbs. And at Hillington, all are either Norfolk or half-breeds, a Leicester tup on a Norfolk ewe. Captain Beeforth thinks there are no sheep in the island which the Leicesters will not improve. He has grazed many Wiltshires, and thinks them the best of all for chase-grazing in the fens. But Mr. Beck, of Castle Rising, has had South Downs thirteenth years, beginning with some from Mr. Tyrrel, of Lamport, and has imported three or four times since. He has now 800, and is quite convinced of their superiority to Norfolks; when he was in that breed, he had not half the number; but after abating fully for improved husbandry, and every other circumstance, he is clear that there is a superiority of four to three. His fences are all made of his own making, and in such a farm quietness is a valuable object: his farm 486 acres. He gained the first prize for wethers, both last and this year at Swaffham, and also at Holkham. The surveyor examined his flock attentively, and it certainly is a very beautiful one. His wool now averages eight to a tod, equally of hogs and ewes; his Norfolks toed twelve: he is clear that, take the country through, they average half as much again as Norfolks. Before he took the farm there were fifty sheep on it, and a dairy of cows. What an improvement! However, in the vicinity of Downham are found all sorts of breeds: towards the river, Lincoln and Leicesters; higher up, Norfolks and South Downs. Mr. Saffory likes the South Downs best, but thinks that if as much care and attention had been exerted to improve the breed of Norfolks as the South Downs have experienced, they would by this time have been a very different breed. Norfolk three-shear wethers sold in April last at St. Ives, at from 4l. 4s. to 4l. 10s. each. At Brutenham, Mr. Twill keeps 68 head of breeding Norfolk ewes on 1800 acres of poor land. He had a South Down tup five years ago from Mr. Crow, but he could not perceive that the breed did better than Norfolks, though they did fold the full as well.

In the district called Marchland, Mr. Dennis, of Wigenhall, St. Mary, grazes only the best Lincoln wethers; he buys from May-day to Midsummer; keeps them over-year, clipping twice, average price 50s. to 60s. and sells at 65s. to 75s. getting 18lbs. in the two fleeces; he has good land will carry 4s. per acre, an average, in summer; in winter, on three acres, and thre has quite enjoy their flesh; if the season be favourable, you get something: he thinks that there is no other breed so profitable here; even a flax of the new Leicester is hurtful, as they will not stand the winter so well. Sheep the chief flock, though some Lincoln bullocks. He never gives hay to sheep, nothing but grays; 32lbs. a quarter his average of fat wethers. But Mr. Stanswell of Waterpole, prefers the crosses between Lincoln and Leicester: he buys them shearing-wethers, about Lady-day; the early year, 3l. to 3l. 10s. each, and has had them at 36s. and 34s. He clips the bell twice, three to a tod, which he likes better than heavier fleeces of sheep demanding more food. Some give 17lbs. or 18lbs. of wool. At Michaelmas he pulls the world, or buys cole for them, if reasonable; falls all by Midsummer, making 6s. or 10s. a-head, when bought in high, besides the wool. Very few beards are kept.

Also in Hertfordshire, some prefer the South Downs to Wiltshires, as the latter have the goggle over, but the South Downs never. But the long-legged Wiltshires tuffer lets in folding on wet land. But in other places the result of the comparison seems to be, that South Downs do better on...
Thefe had the dry South Downs. The Wiltfhi res are large sheep, and consequently require to be well kept. In the trials of Mr. Hale, of King’s Walden, for five or six years, nothing beats South Downs, where there is much graft; but on artificial grafts and turnips, without a breadth of natural grafts, they will not do like the Wiltfhi res; for which reason Mr. Roberts, on his own farm, keeps Wiltfhir eewes, and crosses them with South Down rams; so that they lamb in March. When put to grafts they are folded, and some lambs are fold at 34l. in the beginning of harvest; some twins at 3l. 6d.; and the best are kept. He approves so much of them, that he intends to continue them. Mr. Hale’s flock is a capital one, and the wool remarkably fine. And between thirty and forty years since, Mr. Calvert of Albury had Lincoln sheep, but fold them, from conviction that they did not answer: he was then, for about twenty years, in the Wiltfhi re breed; and lately, he changed these for the South Downs, which he has had for the last seven or eight years, and prefers them to all. He has no other but lord Pelham’s breed, both lambs and ewes, and considers the more modern attempts to raise a finer race, as likely to prove mischievous: he will not have anything to do with them. His six-toothed wethers weigh eleven stone and a half. He finds the breed extremely healthy; they very rarely die; and are subject to much fewer distempers than the Wiltfhi res. And Mr. Smith has changed Wiltfhi res for South Downs. He has about 400 in all, some of them Wiltfhi res; they are fed and worked together, and folded on wet lands. The South Downs in exceeding good order, but the Wiltfhi res very inferior. But about Barkway, South Downs are not yet introduced; Mr. Whittle, however, gave it as his decided opinion, that feed and work Wiltfhi res and South Downs together in the same manner, and the former will prove to be the most profitable; the latter are much injured by the dirt, as they are too thin in hair and legs; it was tried at Kimpton Hoo, and such was the result. He has fold Wiltfhi res wethers thrie thorn, at 7l. 15s. each. And Mr. Doe, of Bygrave, keeps Wiltfhi res, which he croses every year by new Leicel fer rams; but goes no farther than the first cros. These answer greatly, whether the fat be fat lambs or shearlings. He does not approve of South Downs, on account of their inferior weight.

However, from the high character which South Down sheep have lately attained, it may not be uninteresting to give Mr. Young’s account of their first introduction into Norfolk. Heremarks, that when once an improvement has spread so much as to become an object of importance, there are generally many claimants for the merit; and if such claimants are only heard of many years after, but little attention is due to them. With regard to the neighbouring county of Suffolk, he can speak with some accuracy, but should not mention it on this occasion, were not the fact connected with the introduction into Norfolk. In May, 1785, he published an account of an observation he had made in 1784, the year he brought them into Suffolk from Sulix; and it being printed at the time, the fact will admit of no doubt. He recommended them strongly to every gentleman and farmer he conversed with on the subject; and at his per- suasion, as many well know, the late Mr. Macro, of Barrow, purchased that flock which the earl of Orford, after his death, bought and established at Houghton. Mr. Macro died in 1789. And in a paper printed in the Annales, in 1790, he (Mr. Young) remarks, “I have had six and twenty years’ experience in Norfolk sheep, and once thought so well of them, as to carry them into Hertfordshire; but in the advance of my practice, I began gradually to doubt the superior merit of that breed. I thought that all of the sheep which I had examined particularly, none promised to answer so well for the general purpose of the counties of Norfolk and Suffolk as the South Downs. I began the import in 1784, and in 1790 had 350. I had too much friendship for the late Mr. Macro, to advise him to try any experiment that I was not clear would answer to him. I repeatedly urged him to try the South Downs; he listened to me with attention for some time, but would not determine, till having seen the number I kept proportionably to the quantity of land, and at the same time with some Nor- folks, it proved to him that the South Downs were worth attending to; and the journey I persuaded him to take into Suffolk, giving him an opportunity to converse with various noted sheep-masters there, he determined to make the ex- periment: he went over, previous to Lewis fair, and bought a flock of them. The lambs fold well at Ipswich fair. Mr. Le Blanc, at Cavenham, also turned South Down rams to 700 Norfolk ewes: he found no difficulty at Ips- wich; and his shep herd, after three years’ obdurate pre- ference to Norfolks, gave up his old friends, and actually set South Downs for his shepherd’s flock. Whether the breed should or should not, in the long run, establish itself, I have the satisfaction of feeling that I have done no ill office to my brother farmers by introducing it. From the daily accounts I receive, I have good reason to believe that it will be established.”

The farmers in Oxfordshire employ many different sorts of sheep, as the Wiltfhi res, Berkshire, and some others; but the South Down and new Leicel ter, and their croses, are fast driving the other sorts out of the county, as being more profitable in the number that can be kept on the same extent of land, in fattening more expeditiously, and at earlier periods of their growth, in folding equally well, and in the value of their wool. Some, however, think, that the long-wooll ed sheep are very profitable on farms of the fine-bra th kind, and have large flocks of that sort. In this district, in general, the quantity of sheep that is kept is large, in proportion to that of the extent of the farms. In Berkshire, the large Wiltfhi res and the breed of the county are giving way to the South Down, and other small- sized breeds, as yielding more profit, fattening quicker, and doing better in general. The new Leicel ter, so far as they have been tried in proper situations, have also answered well. Some croses of these smaller breeds have likewise been employed with considerable success.

In the county of Elles, several sorts of sheep-flock are made use of by the farmers, as the Norfolks, Wiltfhi res, Lincolns, new Leicel ters, South Downs, and different crosed kinds; but the superiority and advantage of the Downs are now almost everywhere admitted. The Dihley or new Leicel ter fort is also held in much estimation in many places, especially where the soil is of a dry light nature; as the wether lambs of this breed, and that of the Downs, on being constantly kept together on the same land, until they became fat, the former were invari ably drawn off the first, and were the fatter and heaviest. Besides, rams of this fort are preferred for being put to Norfolk ewes, to those of other breeds; as the produce is larger, and fatter fat. The new Leicel ters are by fome, however, thought inferior to the South Downs, as being such bad breeders; one hundred of them only producing eighty lambs, while the same number of the Downs will bring one hundred and twenty.
SHEEP.

In the district of Devonshire, many kinds of sheep, besides the native breeds, are had recourse to by the farmers, as the Dorset, new Leicelser, Cotswold, and South Down, with crofs of thefe and feveral other kinds, as may be feen by the table introduced above. The laft of these breeds feems to be falt making its way, in fome places where the land is dry, in this county too; but other forts and crofs are held in great favour for different purpofes and ufe, as for mutton, wool, feeding, and different others.

In many of the northern and other counties, as in Yorkshire, Lancashire, Cumberland, and feveral others, the new Leicelser, South Down, and different improved breeds, are now beginning to be had recourse to, and supplanting the old native or other kinds.

The trials have hitherto been fo few, in regard to the comparative advantages of different breeds of fheep, in what regards the relative proportion of food to mutton, offal, tallow, live and dead weight, and many other points, that the Rock-famer has been kept much in the dark. In order, however, to fully clear up and ascertain these effentially important matters, fo absolutely neceffary to the perfect knowledge of the fubjeét, the earl of Egremonl lately ordered the following experiment to be made. The wether lambs of the preceding fpring were ordered to be put up by themselves, into a paddock adjoining the Home-park.

There were of

South Down wether lambs
New Leicelser do.
Half-bred new Leicelser and South Down wether lambs,
from fame get as above
Romney-Marfh wether lambs,
out of Mr. Wall's ewes by his own ram, which, from the custom thare, of not having artificial food, were not lambed till May, being therefore nearly two months younger than any of the reft

Dedue fams

These fifty-five wether lambs, put into the paddock in the month of August, were brought up and examined on the 25th of the June following, when it was found that twelve of the South Down, and all the half-bred South Down and new Leicelser, were in a marketable condition; but that none of the true new Leicelser or Romney-Marifes were in any proper flate for fale.

Of the South Downs, ten out of the twelve were fent off to Smithfield market, fome days afterwards, and fetched per fheep

Of the half-bred new Leicelser and South Downs, ten of the twelve, fent a week before the fame market, brought per fheep

It is remarked, that the half-breeds were feemingly the better fheep; but they went to a bad market, when the prices were low.

The two of the half-bred fort that remained, and which were in equal condition for the market, were kept back, as forming part of the trial, detailed next column.

Here, however, it is neceffary to fay, it is faid, as the experiment is already defcife of one point, namely, that at this age of fix months, as noticed above, thofe two breeds were fo much more advanced than the others, that they might be profitably cleared from the land, and a frefh flock fent in. It will remain, it is faid, for the future progress of the trial, to asceroin whether fuch frefh flock would not pay better, than continuing the old; and for this purpofe it may be calculated, that the fheep now fold at the above market at 34s., with the addition of 32 for wool, pay for fixty-four weeks 7d. the pound from the time of their being lambid. This is noticed to be a very conliderable profit; and that if it fhould turn out, that keeping them much longer is not attended with an advantage somewhat proportionate, it will clearly prove the fuperior benefit of that breed, which may be got rid of at fo early an age. And it is thought worthy of remark, that not one of the true new Leicelser being in any condition fit to be drawn off in the firft lot for market, is a circumstance most strangely contradictory of affertions without end, that fattening at an early age is almost peculiarly a characteristic of that breed.

But to proceed with the trial.

It is noticed, that this result is not very different from what might have been expected; for as the Romney-Marfhes and new Leicelser were very much behind the South Downs and half-breeds ten weeks before, it was natural to fuppofe, that when they did begin to thrive, they would do it in a more rapid manner.

It is considered as very material, in all trials of this nature, to note the losses, as making fuch attempts double, by not only fhewing when the fheep thrive, and which do belt, but equally by marking when they go backward, and which breed is most capable of withftanding thofe circumftances which operate against them all. In the above fcale, the difference is not very material. In that lot which did the word, the lbs, it is faid, amounts to about 1d. per week; but that it is unfavourable to every lot, that in a period including the belt part of the autumn, as fheep fhould thrive, when the weather is fuitable, deep into the month of November, none of them fhould have gained, which they ought to have done conliderably. Their pailure, however, though good in quality, was bare.

The refult being found, the fheep were ordered to be flaved for twenty-four hours; and after which, to be turned out for other twenty-four hours; propofing, by thus weighing them, to asceroin the quantity of food eaten, and the quantity voided; it being rightly conceived, that if, upon the repetition of fuch trials, there existed any remarkable superiority, or any material difference, between the refpective breeds, it might throw fome light upon the general inquiry.
The sheep were then turned out, and twice weighed, after twenty-four hours eating each time.

The result of these weighings showed that the half-breeds lost most and gained most; that the Romney-Marshes lost least, and ate least; that the Leicesters lost more than the South Downs, and ate more. It is suggested, that such trials must be repeated many times, before conclusions can be fairly drawn. How the Romney-Marshes, in the first twenty-four hours, could gain nothing, is not to be accounted for, as the weighing was performed with accuracy.

Weighted again in the succeeding month of March, in the next year, which, as it will mark the loss sustained by the severe part of the winter season, deserves particular attention. They were at grass the whole of the time.

The result here shows that the Leicesters, which is remarkable, suffered the most; from which it is thought, that it may fairly be concluded, so far as one trial goes, that the great peculiarity of that breed is not by any means what has been contended for, a capability of supporting itself on little food; but that, on the contrary, it demands a very plentiful nourishment, and will bear the want of it worse than any of the other breeds.

The half-breeds are the next in the order of demerit; the South Downs are the best of all.

The period from the 30th of March to the 19th of June necessarily forms another interesting portion of the trial, as it takes in the whole flow of the spring growth of grass. Here the result, it is said, is also remarkable, and strongly in confirmation of the preceding observations on the Leicesters; for when in favourable circumstances in regard to food, as in the present case, from season, they exceed all the rest. The Romney-Marshes, however, approach near to them; and as these had lost, in pinching circumstances, much less, their superiority upon these two weighings seems to be clearly ascertained; and which will appear the plainer, by comparing the weight of December 11th with that of June 19th.

The merit of the Romney-Marshes, in this stage of the trial, is, it is said, conspicuous. The South Downs are next, the Leicesters and half-breeds being equal.

The Leicesters here, it is observed, continue to take the lead throughout the summer. So long as the food is plentiful, they beat all the others; and this part of the experiment goes to prove a most important point, which has indeed been long suspected, that in good situations no breed is so profitable to the grazier. The half-breeds are found the next to these.

The five remaining Romney-Marshes were sent to Smithfield on the 4th of July, and brought 48s. each; and on August the 7th, the remaining Leicesters went at 42s each, also seven at 40s each; so that the profit for two years and two months food, added to the value of the wool, is, it is said, 5d. and a fraction per week for the Romney-Marshes, and from 4d. to 4½d. for the Leicesters, from the time of their being lambed.

The former part of the experiment will shew that the South Downs and half-breeds in 64 weeks gave 7d. per week profit; and that the Romney-Marshes and Leicesters, kept until they were nearly twice the age of the others, namely, 108 weeks the former, and 117 the latter, only gave a profit of from 4d. to 5d. per week. This is, it is said, a most interesting circumstance, and which manifestly tends to ascertain how much better it would be to the grazier to get rid of these sheep at an earlier age, and re-stock his land with those which are most saleable at the earlist period.

November 21st to December 25th. Weighed again.

This, it is supposed, is perhaps the most striking period of the experiment. By the last weighing, if turned to, it will be seen that the Leicesters had outstripped all the rest, and that the superiority is still maintained.

The above details of the practices of different districts, experiments, and remarks, must place the profits and advantages of different breeds of sheep for the purposes of the sheep-farmer, in a clear, satisfactory, and striking point of view. With respect to the wool of different sheep, we refer to the next article, and Wool.

Different Kinds of Sheep-Management.—In the practice of sheep husbandry, different systems are had recourse to, according to the extent and nature of the farms on which they are kept, and the methods of farming that are adopted on them; but under all circumstances, the best sheep-masters constantly
constantly endeavour to preserve them in as good condition as possible at all seasons. With the paiture kinds of sheep this is particularly the case; and with the view of accomplishing it in the most complete manner, it is useful to divide them into different parcels or lots, in respect to their ages and fords, as by that practice they may be kept with greater convenience and benefit than in large flocks together, under a mixture of different kinds; as in this way there is not only less want of food, but the animals thrive better, and the pastures are fed with much more ease. The advantage of this management has been fully experienced in many of the northern districts, where they usually divide the sheep-flock into lambs, yearlings, wethers, and breeding ewes; and in this method it appears not improbable that a much larger proportion of flock may be kept, and the sheep be preserved in a more healthy condition.

The nature of the management with a breeding flock is that the sheep-miller must act according to his circumstances, situation, and the capital which he possesses, either selling the lambs to go to keep, fattening them for grasa-lamb, suckling them for house-lamb, or keeping them on to be grazed and fold as fore or fat wethers; the ewes being fold lean, as they are called, or fattened, as circumstances, profit, and convenience, may point out. Another practice, but which requires much capital, as well as knowledge, experience, and attention, is that of breeding and fattening off all lambs, both wethers and ewes, especially where markets for their sale, when fat, are conveniently situated. But where this system is too extensive, it may be partially acted upon, varying the plan according to capital, circumstances, and the nature of the times. In which case, whenever flock becomes extravagantly high, it is mostly a good way to sell. But a method which is attended with the least trouble and hazard, is that of purchasing a fore flock, as lambs, wethers, and what are termed crones, or old ewes; some of the last often proving with lamb, may be fattened off with them to good account. It is likewise often the case that ewes are disposed of in lamb, or with lambs by their sides, in what are termed couples, in which circumstances it is frequently a good practice to make annual purchases of them, in order to the fattening of both, and selling them in that state within the year. The system of breeding can only be had recourse to with effect and advantage in situations or on farms, where there are extensive tracts of land fit for the palling and support of these animals, but not the fattening of them; the more rich deep grassa-lands being adapted to their fattening, and thereby affording a better profit, especially when quickly performed with a proper fort of this kind of flock, as that of good wethers.

But in the purchasing of sheep, which is often done from very distant fairs and markets, much care and circum- spéction are necessary, whatever the fort or intention with which they are bought may be. In these cases much ad vantage, especially when at a considerable distance, may be derived by employing a halifax upon the spot.

And the appearances which shew the face to be in a proper found state of health, are a rather wild or lively briskness, a brilliant clearness in the eye, a florid ruddy colour on the inside of the eyelids and what are termed the eye linings, as well as in the gums, a fatness in the teeth, a sweet fragrance in the breath, a dryness of the nose and eyes, breathing easy and regular, a coolness in the feet, dung properly formed, coat or fleece firmly attached to the skin, and unbroken, the skin exhibiting a florid red appearance, especially upon the brisket. Where there are discharges from the nose and eyes, it indicates their having taken cold, and should be attended to by putting them in dry sheltered situations. This is a neccesary precaution also in bringing them from one situation to another while on the road.

It may be noticed that, with sheep-farmers, the common practice, except in particular instances, has been to leave the ewes for the purpose of breeding without any selection; but where good sheep-flock is the object, much attention should be paid in choosing such as are the most perfect, and that pellies, in the highest degree, those qualities or properties which are wanted, whatever the breed or variety of sheep may be; as it is only in this way that a good flock can be raised and preferred. And it is a business that should always be performed at the time they are turned to the ram, if it has not been done before; and this is equally necessary in regard to the rams, that they may be adapted to the ewes. The author of the Farmer's Calendar has observed, that the late duke of Bedford, in attending to this object, had every ram with the lambs got by him the preceding year put in distinct pens, that he might not only examine them but their progeny, previous to his deciding: "what ewes to draw off for him," which is certainly a method highly deserving of imitation by sheep-farmers in general. Such attention, united with a careful selection of cull lambs, mull, the writer thinks, keep a flock in a state of progressive improvement, proportioned to the accuracy of judgment, eye, and hand of the farmer who practises it. And it is observed in the Agricultural Report of Norfolk lately published, that Mr. Coke readily affirms, not only his tenants, but other neighbouring farmers, in forting and selecting their South Down ewes, &c. and distributing them in lots to the rams according to the shapes and qualities of each. He puts on his shepherds'smock, and superintends the pens, to the sure improvement of the flock; his judgment is superior and admitted. The writer has seen him, and the late duke of Bedford, thus accounted, work all the day, and not quit the business till the darkness forced them to dinner. See Sortirg Sheep-flock.

Further, it has been remarked in a late practical work, that the most advantageous and proper age for ewes taking the ram in the different breeds, has not been fully shewn: but from a year to a year and a half old may be sufficient, according to the forwardness of the breed and the goodnes of the flock. Some judge of this by the production of broad or sheep's teeth. It should not, perhaps, be done while too young in any case. And in regard to the featon of putting the rams to the ewes, it must be directed by the period at which the fall of the lambs may be most desirable, which must depend on the nature of the keep which the particular situation affords; but the most usual time is about the beginning of October, except in the Dorsetshire ewes, where the intention is sucking for house-lamb, in which case it should be much earlier, in order that the lambs may be sufficiently forward. But, by being kept very well, any of the breeds will take the ram at a much earlier period. Where the rams are young, the number of ewes should seldom exceed sixty for each ram; but in older rams a greater number may be admitted, without inconvenience, as from one to two hundred; but letting them have too many should be cautiously avoided, as by such means the farmer may fulfil great losses in the number of the lambs. It is found that the ewe goes with lamb about the space of five months, consequently the most common lambing-feaston is March, or the early part of April; but it has been observed, that in many of the more southern districts, where sheep-husbandry is carried on to a considerable extent, some parts of the ewes' flock are put to the rams at much earlier periods, so as to lamb a month or six weeks sooner; a practice which is attended with much profit and advantage in many situations where early grassa-lamb is in great demand. It is usual for the
the rams to remain with the ewes for a month or six weeks, and in some cases longer, in order to complete the business of impregnation, which in some districts is ascertained by smearing the fore-hoofs of the rams with some colouring substance. The method formerly in practice, and which is too commonly the cafe at present, of turning a number of rams among the flocks, is highly exceptional, as tending to prevent the main object, and injure the rams. A better way is to let each ram have a proper number of ewes, and with very choice flock to keep the ram in an inclosed small pasture, turning a few ewes to him, and as they are served replacing them with others. By this means there is more certainty, and more ewes may be impregnated. In such fort of fine flock, it is likewise of great utility to keep the rams during this season in a high manner. In this view a little oats in the straw, or a mixture of barley and pea-meal, are excellent. Where ewes are backward in taking the ram, the best means to be employed are those of good stimulating keep. The rams should always be continued with the ewes a sufficient length of time. It is stated in the General Treatise on Cattle, that the ewe will breed twice and even thrice a year, if it be made a point to produce some effect by attention and high keep, since the will receive the male indifferently at any season, and, like the rabbit, very soon after bringing forth. And that little gives an instance of three of his ewes, well kept, lambing at Christmas, fattening off their lambs at Lady-day, and producing lambs again the first week in June. It seems they fole the ram immediately after lambing, but brought the second time only single lambs, though a breed that generally produces twins. The former writer thinks there is no doubt the sheep would produce young three a year, were the bad practice reforted to, which has been so currently recommended with the rabbit, of allowing the male immediately after parturition; the ready way to render both the female and her progeny worthless. Could the lambs be advantageously weaned at two months, sufficient time would, he conceives, remain for the ewe to bring forth twice within the year; for example, suppose the young ewe tupped in August, the lamb would be dropped in the middle of January, and might be weaned in mid March, the ewe again receive the ram on the turn of the milk, like the fow, perhaps in or before April, the she would then bring forth within the twelve months, or in August. This plan would, he thinks, at least injure the dam infinitely less than fuckling during gestation.

And it is necessary, that during the time the ewes are in lamb they should be kept in parfures, and as free from disturbance as possible, being carefully attended to, in order to prevent accidents, which are liable to take place at this time, such as those of their being cast in the furrows, &c. Where any of the ewes flip their lambs, it is advised by Mr. Bannister that they should be immediately removed from the flock. They also require, under these circumstances, to be kept as well as the nature of the farm will admit, in order that there may be less los of lambing-time, from the ewes being stronger, and the lambs more healthy, and better capable of contending with the fate of the season at which they may be dropped. At lambing-time every possible attention is to be paid. The shepherd should at this period be particularly careful and attentive to afford his assistance where it may be necessary. He should constantly have regard to the fuckling of the lambs, and see that the udders of the ewes are not diseased. His attendance will often be required in the night as well as the day. At this season covered sheep-folds are often of very great advantage, in faving and protecting both ewes and their lambs. And in respect to the number of lambs, it is remarked by the author of the work on Live-stock, that the ewe brings off commonly one, next in degree of frequency, two, rarely from three to five lambs at a birth. This property of double birth is, he says, in some instances, specific; the Dorset sheep usually yielding twins; and the large-poll'd Belgic sheep, with their descendants, our Toffwater, doing the same, and producing occasionally more at a birth. Other breeds bring twins in the proportion of one-third of the flock, which is supposed to depend considerably on good keep. A certain number of ewes per centum prove barren annually: the cause very rarely, natural defect; sometimes over-fatness, a morbid rate of body, from poverty, or neglect of the ram; in other words, want of fylleum in the sheep.

Further, it has been recommended, that where rich pastures, or other forts of good grafs-lands cannot be reformed for their support, turnips, or other kinds of green food, should be provided for the purpose, and given them in a suitable manner; but where it can be done, it is always better to leave this fort of food untouched till about the period of lambing, when it should be regularly supplied, in proportion to the necessity there may be for it. The ewes also demand at this time much care, to see that they are put upon a dry sheltered pature, free from disturbance, and that neither they nor their lambs suffer injury from the too great severity of the season. Whenever this is the cafe, they should be carefully removed into a proper degree of warmth and shelter, until perfectly reforted. It is likewise necessary, as well as ufeful practice, as they lamb down, to take them and their lambs away from the common poflcock, putting them into a piece of turnips, or freh dry pature, where there is fheret when necefsary, as by this means much fewer lambs will be lost than would otherwise be the cafe. It is also found, that by a proper fupply of turnips, or other fimilar green food at this period, the milk of the ewes is much increased, and the growth of the lambs greatly promoted; which is of much future importance, as when they are finted at this early period of their existence, they never turn out so well afterwards for the farmer. With the green and root crops, and preferved after-grafts, hay, straw, corn, and oilcake, are in fome cafes made ufe of in the winter fupport of fheep-flock. With turnips, where the foil is not sufficiently dry to admit the sheep, it is the practice to draw them and convey them to a fround firm pature, that the ewes may be baiitated upon them once or twice in the day, as there may be occasion, care being taken that they are eaten up clean, as the circumstance of their being thus eaten may serve as a guide to the farmer for the fupply that may be daily necefsary. In this way this fort of food will be confumed with the greatefl economy. Where the land is perfectly dry, and the intention is to manure it for a grain crop, eating the turnips on the land, by means of portions hurried off as wanted, is a good practice; And with this fort of food, especially where it produces fouring in the ewes, green roots, hay, cut straw, or pea-fea-haulm, should conftantly be given, and also with rape, &c. Mr. Young has flated, that in fome parts of the kingdom, the bell farmers give their ewes and lambs bran and oats, or oil-cake, in troughs, while they are feeding on turnips; but he fuggcfs, at the fame time, that it must be a good breed for fuch a practice to repay. And it has been adved, when the weather is very wet, flormy, or there is much snow upon the ground, that the ewes and lambs should have hay given them in baits as may be necessary, which is mostly done in covered moveable racks, a portion being given fresh every day. It is, however, much better to have it cut into chaff, and given in troughs, as much less waste is made. There is still a higher practice of feeding made ufe of by fome farmers, with ewe-flock of the
the more improved kinds, and which is said to have been found to answer better than the common keep in particular cases; which is that of employing parnips, or carrots with hay of the green rhen kind, or a portion of pea, bean, or barley-meal, also malt-combs, with potatoes and hay, &c. These sorts of keep are, however, obviously much too expensive, except under particular circumstances, and for the more improved breeds. It is obvious, that where shelter can be provided, it will always be of much benefit to the sheep. But it has been observed, that the practice of letting them to the hay-flacks, which is common with some farmers, is flown and wasteful, and which, though it may afford a degree of shelter, should never be attempted when the other methods can be had recourse to. It has also been suggested by Mr. Young, as an excellent method, though not essentially necessary, to allow the sheep, whether the weather be bad or not, a small proportion of hay daily while at turnips. And it is supposed that by this careful management, and the use of hubble turnips when necessary, the ewe and lamb-flack may be well supported through the severity of the season, and be brought on in the best possible condition until the turnips are finished in March, which should always be the case when the preferred sorts of rye or rye-meal may be ready to receive them; which is considered by farmers as the most to be depended upon through this and the following months, which, with the first week in May, is the most difficult period of the year to the flock-farmer. On dry meadows and pastures it is invaluable in this view, though at first sight it may have an unpromising appearance, from the covering of decayed autumnal grass that is upon it; but which, when removed, presents a new growth of fresh green grafs, five or six inches in height, brought up by the shelter and warmth afforded by the covering of old grafs. This is found to agree remarkably well with the sheep, as they consume both together, having, as it were, both hay and grass in the same bite. It is, indeed, supposed impossible to keep a full flock of sheep so cheaply in April by any other method as by this. Tolerable roun will carry ten ewes an acre, with their lambs, through the whole month. Such roun may be worth in autumn ten or twelve shillings an acre; in April it is worth thirty or forty shillings; and if it be a backward season, a farmer that has it would not be tempted to sell it for much more. But in the support of his sheep and lamb-flack, if the farmer be provided with a sufficient extent of watered meadow, he may fully depend upon that without any other provision for this period.

But in cafés, however, where thefe cannot be fully depended on for the support of the sheep-flack at this difficult season, the most improved practice is, in place of depending on turnips and hay with rye fown for the purpose, young wheats, and the run of the pastures, to let the turnips continue, fo as that their shoots may become an object of sheep food, and to have annually a portion of tolerable good land, sufficient to the extent of the flock, under rye-grafs and clover, fo as to be ready in the spring to take the sheep from turnips, and support them till the time of turning upon the pastures. The same writer remarks, that this conduct is an improvement on the other, as it gets rid of three great evils: depending on rye, which is soon eaten; feeding on wheat, which is pernicious to the crops; and turning too foon into the general pastures. But at the same time that it effects this advantage, it is open to some objections, which make further improvement necessary. Keeping the turnips long in the spring is very bad husbandry. It damages greatly the barley crop, both in robbing the land, and preventing it from being fown in proper time; nor is the food of great confequences, for many acres of turnip-tops are requisite, the number of which must be in proportion to the flock of sheep; and as to the roots, they grow too fickly and hard after the tops are at all advanced, that their value is trifling. With respect to ray-grafs, the clover mixed with it is seldom above three inches high at this season; and a great breadth of ground to a given flock must be assigned to keep the sheep through April. The number of acres of that young growth necessary to keep a hundred sheep and lambs, is, it is said, surprising, so that these farmers, although they manage to spring-feed more sheep than the world of their brethren, yet effect it at a great expense, and at last not in any degree comparable to what might be done. A turnip should never be seen on the ground after March. For in the month of April the farmer should have a field of cabbages ready, which, yielding a great produce on a small breadth of ground, reduces the evil of a late spring fowing; and, if he manages as he ought, totally excludes it. The turnip-cabbage, and ruta baga, will last as long as wanted; and though they run the risk, yet the bulbs will not be sickly. The green borecole may be fed off several times in it is impenetrable to frost, and will make hoots in the winter. And another crop, continues Mr. Young, for feeding sheep in spring, which is of particular merit, is burnet. An acre of it managed properly, will at this season yield much more food than an acre of clover and ray-grafs. It should be four or five inches high in November, and left to the winter. Burnet has the singular quality of maintaining its green leaves through the winter; so that, under deep snows, you find some luxuriance of vegetation. From November to February the crop will gain two or three inches in growth in the young leaves, and then be ready for sheep. It will be better in March, and if kept, ready in April, not only for sheep, but horses, cows, or any other flock. These systeams of feeding and management are, however, in practice much varied according to the nature of the farm and the kind of sheep that are kept. In Norfolk, with Mr. Bevan’s flock, which consists of forty-five score of the South Down kind, the following is the arrangement. The turnips are put to the ewes about the 10th of September, for two months, being fed on the layers and pastures, and are folded on the old layers for wheat; after wheat-fowing they are fed on the pastures and layers till the time of yeaning, during which they lie on the pastures without fold, and have turnips thrown to them, with plenty of good hay. The fattening sheep are on turnips and hay, from Michaelmas to the end of March, followed by the hoggetts. In April the couples go to cole-feed in hurdles; from cole to rye; from rye to the new layers, if forward enough, otherwise to the water-meadows, till the beginning of May; and from thence to the new layers, being still in hurdles, with a good deal of room to fall back, and continue so on the layers till about the 10th of June, when the ewes are washed for clipping, and until the lambs are weaned; the ewes then go to fold with the fhears on the fallows intended for turnips, and the lambs are put to fresh grass reserved for that purpose; all the sheep on turnips and cole having hay, they consume about twenty-five tons. The general winter provision is 80 acres of turnips, 20 of cole, and 30 of rye, for the spring. Mr. Bevan ploughs in his rye-tilth-holes before the flocks are carried to turn in the scattered feed, harrowing in half a peck of cole-feed for sheep-feed in the spring, and finds it of very great service. The latter, after feeding, stands for a crop. He values his turnips on the average at 30l. per acre, and cole at 25l. After turnip-fowing, the

Vol. XXXII.
flock is folded on old layers for rye, till the end of August, when the ewes intended for breeding are put to good pasturage till the tups are let in. But in 1802, the tups now put to the ewes about a week later, and the lambs not weaned till the latter end of June. Provision this year, 100 acres of turnips, 30 cole, 30 rye, for 25 score breeding ewes, 15 score hoggets, 20 tups, 10 score fatting flock; 51 score in all.

Turnips, as a holding-out winter food for sheep, are unquestionably excellent, particularly when not given in too large quantities, and with some sort of dry food with them, as faifoin hay in this season, common hay, cut pea, bean, or wheat-straw. There is also said to be an advantage in having them drawn one or two days before they are used, in some districts, and even in having them flacked. But potatoes are thought a much better food than turnips in other parts where sheep are a great object, as being more fully and regularly to be depended on, and as preventing the diseases to which the animals are liable in a more effectual manner. The Swedish turnip come into use the latest, as in the early spring.

It is stated in the Corrected Agricultural Report of the County of Suffolk, that general Murray fed 5000 sheep with potatoes and hay, 1651 of his breeding ewes ate 51 bushels every day, giving a quart to each; and which, for 120 days, is 6120 bushels: while the Norfolk flock-farmer provides for 720 sheep, 80 acres of turnips, 16 tons of hay, 20 acres of rye. The following is the comparison of the value, &c. of the provision.

It is said, that if 720 sheep require 80 acres of turnips, 2240, the upland flock at general Murray's, will require 248 acres of turnips; but they have only 50. That if 720 sheep require 16 tons of hay, or 10 acres, 2240 should require 40; instead of which they have 120, which is 71 surplus, or, at one load and an half the acre, 48 acres. And that, if 720 sheep require 20 acres of rye, 2240 should require 62, instead of which they have none at all.

Which is, it is said, a difference of 63 per cent. This vast difference is to be attributed, it is supposed, in a great measure, to the distinction between the breeds of the flocks, as one being the Norfolk, and the other the South Down, as all the circumstances are in favour of it; but it may be partly owing to potatoes being a cheaper food than turnips. As to the feeding of sheep with potatoes, however, it is, though accounted on the above farm on a very large scale, a more disputed and doubtful circumstance; and for this reason, they are allowed, hinted, or hinted in their consumption, which is not the case with turnips: these, on the Norfolk farm, are fed off on the land, and, of course, in the greatest plenty. The other accidents and objections to which they are constantly liable, are also not to be overlooked: while potatoes are a regular certain crop, and subject to few accidents or inconveniences. When these circumstances are therefore well considered, in the pinch of a severe season, it will be readily agreed that the introduction of this root, and the proof of its advantage by the above extensive trial, as a winter and spring provision for sheep-flock, is really important.

The quantity of a quart every day of this root for each sheep is probably, however, much too small, as in fattening them with it in suitable yards for the purpose, a far greater quantity has been found necessary. But lean sheep certainly do not require the same proportion for keeping them as is requisite in the fattening fylem, as may be seen below, in speaking of that part of management.

Cabbages, as a food for sheep, are of great importance and utility in many situations, particularly in those where the land is suitable for raising them, though it may not be of the very rich quality. They are of vast service in carrying on improvements in sheep husbandry, and as the means of keeping a greatly inerced flock, where good management is followed.

The artificial grazes, such as ray-grasfs and red clover, are of much consequence as spring food for sheep; the first is early, and comes in after common turnips, when much wanted. It may be cultivated to advantage when the latter will not succeed. The clover comes into use in this way at a later period, and on stronger descriptions of land. Many other grazes of this sort, as well as some of the natural grazes kind, might be very beneficially grown in this intention, as the cock's-foot in some cafes, faifoin, &c. on foils of the calcareous kind, and some of the peas and alopecurces, in other circumstances; by which means earliness, quantity, and quality of keep might be secured.
SHEEP.

Tares, rye, and cole, are in great request as spring food for sheep-flock, the first being raised on the stronger sorts of land, the second on such as are of a lighter quality, and the last on many kinds, even the billy calcareous sort. They are all sufficiently early for being fed in April, or the following month, when turnips are done. Spring tares are likewise often put in to be fed off at the close of the autumns. These practices answer very well; but mixed crops of tares and rye never do well for the purpose of sheep-feed; as they do not by any means come well together, of course there is much loss. These and other mixed crops are, however, frequently had recourse to in this sort of management, with evident benefit.

The flrubble turnip system of food is very good in this sort of husbandry, for late succor or other feed; where crops of such kinds take well in succession to those of other sorts.

The plan of preferring after-grafs for the purpose of sheep-feed is certainly very useful, especially for the support of ewes and lambs in the early spring. It provides well for the time of scarcity.

The practice of converting young wheat crops to spring sheep-food is seldom good. It is mostly the bafe of necessity and want of forecast in the sheep manager. On light and dry lands it may occasionally be useful, but it often does much harm.

Winter barley, and some other sorts of crops, have also been tried as sheep-food, but hitherto only by particular individuals on a small scale.

Whatever the nature of the food which is raised with this design may be, it should always be provided in ample abundance to the quantity of sheep-flock which is to be kept, as no sort of pinching ever answers any purpose in this management. Good water should likewise be constantly attended to in this practice.

By thus cultivating proper quantities of proper sheep-food in connection with the keeping and managing of flocks of this sort, many important benefits and advantages would necessarily result, a far greater quantity of sheep would be kept on the same extent of ground, they would be preferred in a much better state of condition, and they would be in a much more profitable situation for the purposes of breeding or being fattened, and consequently in every way greatly more profitable to the sheep-farmer; while the growth of such sorts of food would prepare admirably for grain crops, by which little expense would be incurred. Besides these, it would contribute in several other less important ways to the benefit of the flock-farmer, in many cases and situations.

And it is observed that, by the means which have been fluted above, the sheep and lambs are capable of being continued in good healthy condition, a matter of great consequence to the flock, until the period of turning on the pastures, when they should be separated, where the lands are inclosed, into proper divisions, in proportion to the quantity each pasture can support, care being taken not to over-flock the fields, though hard flocking in some cases may be beneficial. With some farmers they are put upon the richest pasture of the farm, while with others it is the custom to let them have those of the inferior kinds. This must depend much upon circumstances; but whatever mode is adopted, the punt of having the flock preferred in good condition is never to be lost sight of. It is advised, that in keeping sheep on inclosed pastures, particularly where the lands are much occupied with wood, constant care is necessary, in order to guard against the mischief of the fly, as its effects are often irremediable in the course of a very short time in such situations, if not attended to, in hot seasons. With the view of fully guarding against this infest, a very frequent and particular examination must be made by the shepherd.

Further, on this subject it may be noticed, that the next circumstance in the management of these animals is that of weaning the lambs, which is a business that shou'd be effected when they are three or four months old, as about July, but it is done more early in some districts than in others. And to effect it in the best and most beneficial manner, a proper retire of some fresh pasture graze, where there may be a good bite for the lambs to feed upon, should be had recourse to, as it is of much consequence that an ample provision of this sort be had, in order that the growth of this young flock may not suffer any check on being taken from the mother. Where they have been continued so long as to graze with the dams, little check will be sustained in their separation, if turned upon such good feed. Some advise clover in blossom as the most forcing food of the season in this intention, and with others fainbon rosen is highly valued for the same purpose. When good feed is not provided, of some of these kinds, the lambs soon decline in flesh, or in the technical language of the shepherd, the flock are said to pitch; and when once this happens, they never afterwards thrive so well, however good the management may be. With regard to the ewes, they should be removed to such distant pastures or other places, as that they may not be heard by the lambs, which would cause them to be disturbed in their feeding. And where the ewes sustain any inconvenience from their milk, as by their udders swelling, it should be drawn once or twice, as by this means bad conceptions may be prevented. And as soon as the lambs have been removed, the ewes are returned upon the pastures defined for their summer support. There is, however, one caution to be attended to in first turning the lambs upon rich keep, which is that of letting them be in some degree satisfied with food previously, that they may not be starved by too quick and full feeding, and be made the more valuable by the means and benefit, as it is termed; keeping them gently moving about the field has also been advised in this intention. In some places where the lands are of the most poor kind, it is a custom to send the lambs to the more rich vale or marsh districts, to be brought forward in condition, or fattened. In these cases, where the lambs of the male kind are reared on the home lands, as wethers, they are usually restored to the flock in the latter end of the year, but which is not by any means a good practice, as they often suffer for want of proper keep in the winter, and lose what they had previously gained in growth and condition.

And in the usual management of sheep-flocks, it is the common practice to remove a certain number of the old ewes or crones every year, replacing them by the best lambs, in order that they may be kept up in the greatest perfection; it is, of course, a matter of considerable importance to have this done in a proper manner. And in almost all the sheep districts in the southern part of the island, this selection, or setting of the lamb-flock, is performed about August, at which period the fairs for the sale of lambs mostly take place. And as at this time the whole are collected together for drawing into different lots, it is a very suitable period for selecting or choosing those that are to supply such deficiencies in the breeding flocks. In his Calendar of Husbandry, Mr. Young has well remarked, that in making this selection, the farmer or his shepherd usually (whatever the breed may be) rejects all that manifest any departure from certain signs of the true breed; thus, in a Norfolk flock, a white leg, and a face not of a hue sufficiently dark, would be excluded, however,
however well-formed; in the same manner a white face on the South Downs; in Wiltshire, a black face would be an exclusion, or a horn that does not fall back; in Dorsetshire, a horn that does not project, &c. &c. And where the produce is annually fold lean, there is, he maintains, reason in all this; for customers who have been used to and prefer certain breeds, as having paid them well, are apt to be faddish when they purchase. Some farmers in this section look chiefly at size, always keeping the largest frame; but this is probably erroneous, unless they keep very high. It connects with a question by no means ascertained, whether sheep do or do not eat a quantity of food proportioned to their weight? In general it is a safer rule to choose a well-formed lamb, or that indicates the probability of making a well-formed ewe, rather than to select for fize. The attention that is to be paid to wool in the breeds that produce the carding fort, will depend on the price to be received: if the farmer lives in a district where the price of the year is given equally to all flocks, there is little encouragement to lessen quantity for the sake of quality; retaining, however, the idea, that both are attainable, that it is very common to feed coarse bred sheep with light flkes, and those of a fine quality heavy in weight. The Spanish flkes, which are finer than any other, are heavier than those of our finest woolled sheep. With combing wool the importance of the flkee depends still more on price; we have seen it at 8s. a tod; and it has lately been 36s. Quality is of very little consequence indeed, compared with quantity; and when wool sells high, no prudent breeder will fet his flock without being governed considerably by this object. And it is added by the lame writer, that the high prices at which new Leiceter and new South Down rams let and fell, has opened a field of speculation in flkee-breeding. It is sufficient to remark, that this spirit of breeding, whether it shall prove durable or not, whether much money shall or shall not be made in it, is not what any prudent man beginning business will adventure in, but with great caution: men of such immense fortune are now taking a lead in it, and are in many respects doing it on such liberal principles, that the wiseft conduct of such farmers as he may be supposed to address, is to take proper opportunities of converting their experiments to their own (the farmer's) profit. Leave the expense to them; but, when you can, convert the profit to your own advantage. In letting a flock of lambs, therefore, you may mark a fcore of the best, for a future ram to be picked upon, when opportunity offers it. Better still, to lend to the top of some ram-letter that takes them in at a reasonable price per head. By every year selecting five or six per cent. and by every year covering that number by a ram better than your own, the flock must be on the improving hand; and this may be done at a very small expense. Altogether this period, besides filling up the deficiencies in the ewe flock, the increasing or diminishing the quantity of flock usually kept, by rearing a larger or smaller number than that of the old sheep which are disposed of, is also a point that demands particular notice. Mr. Young has given the following useful directions on this subject, in his Calendar of Husbandry.

On a farm, says he, with a given stationary sheep-walk, it is probably regulated by circumstances that rarely change; but on inclosed farms, where the sheep are supported by fields alternately in grass and tillage, variations may easily be supposed, and the question of hard or light flkeering, that is of close feeding or a head of grass, then comes in to decide the number kept. If the produce or profit per head is looked to, the conduct to be pursued is evidently to flke lightly; but if the return is looked for in corn from fields laid down for refreshment by rest, then close feeding is a very material point, and the number kept will depend on it. With all grazes, &c. that do not decline from age, the more sheep you keep the more you may keep, and the more corn you will reap when such are ploughed; a circumstance too important to be forgotten. But the young farmer will remember, that upon this system he must not have a brow flock, or let the variety of a farm have the least influence with him: if in this way he will have a something to talk of, a score or two of pampered favourites, the fewer the better, for they may cost him more than they are worth.

And as soon as this has been properly executed, the ewe and wether lambs that are left are mostly sent to the neighbouring lamb-fairs to be fold off. But where the fairs for this purpose happen later than the above period, as in the beginning or latter end of September, as is the case in some situations, it has been advised by the writer first mentioned, that great care be taken to keep them in forcing food, as in spring fairs, early fawn fome, good grazes of the right degree of bite, &c. &c. in order to promote their growth and increase their value; but to sell in August is more beneficial.

It cannot but be obvious, that in the management of breeding flocks, the lambs come to be disposed of at different periods; irksome that have been fputed or fattened in the house, in which the time of fattening, much attention is required to have them early, to their being well, regularly, and very cleanly kept and fucted, as well as to the ewes being of the right fort, and the bell milkers that can be provided, and to their being fully supplied with food of the most nourishing and fuculent kinds. Their tails and udders should have the wool well clipped away from them in order that they may be preferred in a perfectly clean state. The lambs also require, especially towards the clofe of their fattening, to have regular supplies of barley, wheat, and peas, meal ground together in combination with fine green rouen hay, &c. See Lamb Sucking.

And as soon as these have been fold off, the lambs which have been fattened on the belt grazes-land will be ready to succeed them at the markets, in the spring and summer months, and there will be followed by the sale of the fore- lambs at the different antumnal fairs, or more properly the winter fairs.

Further, there are different local practices also adopted in different counties, to suit the particular methods in which their sheep husbandry is conducted, as well as the particular objects of it. The following is given as a hint from Sir Joseph Banks, by the writer of the Lincolnshire Agricultural Survey, on the sheep system of that extensive district: that as tups are there always hired by the breeders, the lambs may be paid to be purchased before they are born a year's credit, however, is given on this occasion, they are not paid for till the actual value can be fairly estimated; if, therefore, any one who has hired a tup at a considerable price, finds the lambs he has got not sufficiently above the ordinary fort to pay him the difference, with interest; he complains to the tup-man, who generally views the lambs with him, and makes a fair abatement, which is generally settled in the price of the hire of the next year's tup; this regulates the price of letting, and makes the tup-men a most useful set of people. The great mafs of breeders in Lincolnshire sell their breeder lambs about old Michaelmas time, or a little after: a succession of fairs for that purpose are held in the village called Partney. These lambs are refold in the spring at Lincoln fair, under the name of hogs; at Midsummer their owners clip, and then winter them; the succeeding spring they are carried to Bolton, where, in a long succession of markets, they are sold to the graziers, with their wool
wool, under the name of shearlings, and immediately turned into the marsh to fatten; the graziers take their fheep, and having wintered them, get the kindleff to Smithfield in the course of the succeeding spring; those that do not fat fo early, yield the grazer a fleece at Midsummer, and are got off the ground in the course of the next autumn. Here you see a combined fystem of fheep agriculture, for as the animals are eternally either changing hands or yielding fleeces, they make a return of some kind or other to their owners, nearly half-yearly from the time of their birth, to that of their final pollution at Smithfield.

See RAM.

In the fheep fystem of management which is practised on the large rich tracts of the Romney, Walland, and Denge marhes in the county of Kent, there is also a local peculiarity and difference which is worthy of notice. The usual practice with the lambs in these marhes, is that of feeding them about the beginning of September to be kept by the neighbouring upland or hill farmers during the winter. They go in separate lots, being received at certain appointed places by the farmers, and driven to the houses, or taken to the farms by their ervants. They are then commonly put upon the stubbles or grartons, as they are called; but in some places they have also to run upon, though too little attention is, in general, paid to the changing of them, by which they suffer much, and are often greatly injured, especially such as are weakly and delicate. Much advantage would probably be gained by having them put in separate lots, in different fields, and by giving them in wet feasons, once a day, some fort of dry food, such as hay, or thofe of better kinds in particular cases. It is not improbable, indeed, that lambs might be safely kept in these marhes through the winter, by the use of fuch food and proper care. It is found that there is a prodigious benefit in keeping the lambs in winter, in fuch situations, in having the grounds dry and warm, instead of being of a cold, wet, clayey nature. Lambs should by no means be flocket along with the ewes, as the old fheep will continually take the feed, and fleece the land, by which the lambs may be greatly hurt. They should always be flocket separately, and the pastures be frequently changed, circumstances which are little regarded here. Some think that lambs do not thrive well on being put to grafs, after having been fed on luxuriant food, such as turnips, old tares, rye-grafs, &c.

The price of the keeping of lambs in these cafes is very different; some paying only 4s. 6d. the lamb, while others pay 5s.; and where no neat flock are kept, they charge as high as from 6s. to 6s. 6d. the head, for the space of about six months. This is but a late advance; however, it makes the price of keep a serious object. The lots of lambs in this fystem of winter management, is occasionally consider- able, but depends much on the nature of the feafon, as to mildness or severity, amounting in some cafes to four or more in a hundred.

The tegs, or one-year-old lambs, in this fystem are brought from the uplands, where they have been wintered too often in a low state of condition, for the supply of the fheep graziers, which enables them to keep more ewes and fattening-fheep on the marsh lands. This is done about the beginning of April, when the upland farmers are indulged with a feast or treat at the expense of the graziers, as a recompence for their care and attention to the lambs, in which liberality has a great effect. As the flocks reach the marsh, they are put upon the poorest pastures, at the rate of five to the acre, their old fheep being just fold to make room for them. There are commonly the left conditioned tegs, in which there may sometimes be lots from the sudden transition from poor to too good keep, though they are not, in general, fo subject to some forts of disease as the old ones, on such changes being made in their food.

The fheep graziers have lately been much in the practice of prevailing on the farmers to keep fuch flocks a fortnight, or even double that time, on turnips, which has the advantage of enabling them to double the flock on the fame pastures during the summer; while on the other hand, it is evident, that when they are fo hard flocket early in the spring, they can neither have fo luxuriant a growth, nor be fo full of grafs. The pastures are likewise falted gradually, as the fat ewes or wethers are taken off, and their places supplied by the wether-tegs, while the ewe-tegs are suffered to remain on their original pastures, until they are fected, or let for going to the farms.

In the ewe management of the fheep fystem, which is by no means well regulated, the ewe-tegs, one-lamb, two-lamb, and three-lamb ewes, are all mixed together, fo that they cannot be diftinguifhed by the grazer, as they are not marked until turned off for fattening. A better and more convenient way would, however, probably be to keep the different kinds separate as much as pofible; as many advan- tages would refult from it. In winter the land is flocket in proportion of from two to three ewes on the acre, as it may be of a more or lefs good quality, and in summer with from three to four and their lambs. In cafe of twin lambs, with not ever more than three to the acre upon the bell pastures. The fummer flocket with ewes is here fuppoled to have too much uniformity in it, though it may perhaps be proper in the winter, yet when that feafon is mild more might certainly be kept than under the contrary circumstances, for which no fort of allowance is made. It is conceived, that it would be good policy, when there is the probability of plenty of keep, to increase the number of ewes on the breeding pa- tures, though there fhould be a neceffity, on that account, to provide an additional pafture field or two; however, fo prejudiced are many fheep-farmers in favour of the common practice, that they do not even make the neceffary additions of flock to keep the grafs properly under, by which means it is apt to become benty, the pafture injured, and con- siderable wafte sustained. The old fheep, or thofe which have had the third fheep, are commonly cut off for fatt- ening, and the others marked for fores, and weaned from their lambs, by putting them into one of the pafture fields for some days, which not only improves the field, but prevents the ewes from receiving injury by the flow of milk. This is a practice which in the fheep management is termed bleating the ewes. Some reject this mode, and put the ewes immediately on the fattening ground, from the conviction that more injury is likely to ensue by keeping them in a furred condition, for even a short time, than by throwing them at once into fresh keep. Whatever of this is, the moft eligible practice is not attempted to be decided, but the moft general one is that of bleating aged fheep are not fo liable to be struck with disease as young ones in such cafes, or the feafon of the year or favourable.

The fystem of the marf for the management of the wethers, and the time of drawing them for the market, is this: the wether-tegs are in the general practice put upon the fattening land for the winter about Michaelmas, in the proportion of from two to three upon the acre, as may fuit the defigns of the grazer. Thofe who intend to keep them for a whole year, commonly put three on each acre of the bell pastures for the winter flock; but thofe whole intention is to make a fecond or third return, are satisfied with two on the fame extent; in which cafe, however, it is neceffary that they be put more early upon the land, in order that they
may get properly fat before winter, and go off sufficiently early, which would otherwise not be the case. The latter method is thought unquestionably to be the most profitable; but those who have not a sufficient supply of fummer pastures, conceive that it will pay them better to keep three to the acre, in barely a thriving state, and fatten them in the following spring and fummer. However, though they may continue to increase in fize, it is most likely they will not be of more value at Michaelmas than they were in the spring; so that there is a clear loss of the whole summer keep; as mutton may often fall for 6s. or 7s. the stone in the spring, and not bring more than from 4s. to 5s. at that period in the autumn. It has long been a question, whether other fheep or old barrens fatten the moit quickly, on which it may be noticed, that any increafe in the food of full-grown fheep must have a tendency to the formation of fat, whereas in wethers or other young fheep, it must be partly expended in the evolution and development of their frames, and, of course, lefs fat be produced. Much, however, will depend upon the fize and disposition of the fheep.

There is great difference in the practice of different graziers, in regard to the time and manner of drawing the fheep for the market, some beginning much earlier than others, though the fheep were all put into the fattening pastures at the fame time. Some draw the worl of the fheep firft, conceiving that the prime fheep pay the belt for keeping; while others fend them to market as they get fat, by which means, time is given for the advancement of the more common ones. Which of these methods is the moft to be preferred, it is not at all attempted to determine; but the fending of inferior mutton to market, it may be remarked, is only giving it away, while, on the contrary, the retaining of fuch fheep as are deficient in disposition to fatten, is a complete loss of the keep of them. Towards the end of the summer, keep, however, is of but little value, and of course, their remaining a little longer is not of any material conquence. It is therefore thought, perhaps, the belt not to part with them until the approach of autumn, when inferior mutton often falls well in the vicinity of the march, or to difpofe of them to lamb butchers at a somewhat reduced price. This inconvenience would, however, be much removed by a better and more proper felection of the fheep than that which at preftent is the cafe.

In fending the fheep to market, care should be taken to have them as nearly as possible of the fame fize and condition, as a few inferior ones are apt to lower the value with the butchers. In this intention they are by fome divided into two or three lots, while others fend them in one only; the former, however, in general obtain the highest price. By more attention to the regulation of fize and keep, a greater equality would be met with in the vether fheep on the fattening pastures of the district than that which at preftent prevails.

In the fystem of these marches, the ewes which are designed for breeding ram-lambs from, are selected and drawn before the riding time, as directly upon the weaning season, or a few weeks previous to giving them the ram; there being great differences in the forms and fizes which are thought the belt calculated for this purpofe, in the notions of different graziers; fome preferring large, others middling fizes, while many fteem molt, fuch as have long legs and bodies. There is here, however, much too little principle in the management of this buifiness. Such ewe lambs as come from ram-lamb ewes, fhoould be fo marked as to diftinguifh them, and be constantly preferred for breeding ram-lambs from. The ram-lamb ewes are mostly lambed by themselves, and have superior keep. Thofe which do not fuit the intention of the grazer are caflrated; while fuch as are to be faved have a small part of the tip end of the ferum cut off, and two marks fixed upon them, one on the shoulder and the other on the hip; being continually indulged with the belt fattening keep, as it is the common opinion that they cannot be too large. They are fend to particular situations on the neighbouring hills during the winter feafon, where they are tended with the utmoft care and circumpection, having hay and turnips occasionally given them. On being brought back to the marches in the spring, they have the run of the bell pastures, being flocked focompactly upon them, as to be in every way disadvantageous to the grazing farmer.

Another felection sometimes takes place from them during the fummer, in which, thofe which do not fuit are either fend to market, or nettled, while thofe which are approved are employed in the enfuing riding time. Thofe young rams should only have a few ewes, as thirty or forty; as more greatly injures their growth, &c. They are usually fold or hired out, by which much money is often made.

It is the practice here to keep too many rams together in the fame pasture, as much fols is fometimes fublimed by it. The ufual time of putting the rams to the ewes here is about the middle of November, though fome prefer a month, and others a week or a fortnight sooner, as their notions may be in regard to the conveniences of lambing and other matters. A week or two before the riding time the ewes are prepared by being put into the larger fields; only one ram being admitted in each, unless it be fo large as to fland in need of two, when with the old ram a young one is admitted. This management prevents fighting and all inconveniences of that kind. The rams commonly remain with the ewes a month, care being taken that they perform their buifinesfs properly; fome change the rams occasionally, as after the firft fortnight, and at other times according to circumstances. Sixty ewes are ufually allowed to an old ram, and thirty to a teq ram in this march fystem. See Stocking Land.

It may be observed that there is fome difference in the method of managing heath, down, and mountain flocks of fheep, from thofe which are purfued on the inclofed pasture lands, though in the felection of the rams and breeding flock, the fame practices are followed by the bell fheep-mafters. The principal difference consists in the manner of keeping them, by putting them as early as possible in the spring month, as in the beginning of April, upon the downs, heaths, and commons, and keeping them upon the march until the approach of the autumn, as the beginning of October; the fine loft sweet herbage in these cafes preferring them in a flate of tolerably good condition. And where it begins to grow scanty and decline in goodnefs, other sorts of feed which have been previously provided are had recourse to, fuch as turpines, coke, &c. on which they are fedded during the autunm and winter till confumed, when hay which has been facked for the purpofe in fuch fitions, is employed until the grazes has again advanced to a proper fize. In cafes the fystem of feeding is generally recurved to during the whole year, in the fummer and autumn chiefly on the ground in a flate of preparation for the wheat crops, but in the winter feedion often on the flabbles, though more extenfively upon the downs and pastures; while in the spring feedion the lands under preparation for the barley crops receive them. This fystem is considered as very beneficial by the farmers in thofe districts where it is in ufe. And in the more hilly and elevated fitions in the northern parts of the kingdom, other methods of management with this fort of stock are employed. In Argyll being the principal circumftances attended to by the moft intelligent fheep-farmers are thofe: to flock lightly, which will mend the fize of the fheep, with
SHEEP.

with the quantity and quality of the wool; and also render
them less subject to diseases. In all these respects, it is al-
lowed by good judges, that 500 kept well, will return more
profit than 600 kept indifferently. To feed the bell lambs,
and such as have the finest, clofled, and whitest wool, the
fants and breeding ewes, and to cut and play the word. To
get a change of rams frequently, and of breeding ewes occa-
sonally.

To put the bell-tups to the bell ewes, which is con-
sidered as necessary for bringing any breed to perfection.
Not to tup their year-old ewes; which, if allowed to fatten
especially, would render the lambs produced by them of little
value, as the ewes would not have a suficiently of milk;
and would also tend to lessen the size of the flock. To
keep no rams above three, or at most four years old, nor any
breeding ewes above five or fix. To separate the rams from
the 10th of October, for a month, or fix weeks, to prevent
the lambs from coming too early in spring. To separate
the lambs between the 15th and 25th of June; to have good
grafts prepared for them; and, if they can, to keep them
separate, and on good grafts, all winter; that they may be
better attended to, and have the better chance of avoiding
diseases. A few wood calves will enable them to do it;
keep not only their lambs or hogs, but also their wedders,
ewe, &c. in separate herds; by which every shepherd, hav-
ing his own charge, can attend it to better than if all were
in common; and each kind had the pasture that suit it.

But in Linten, the following management, according
to the survey of that district, is observed: in summer the
flock is divided into three herds. In the first are all the
hogs and yield sheep; in the second, the milk ewes; in the
third, the lambs. In winter they are kept only in two herds.
In the one are the hogs, in the other the ewes and yield
sheep. The lambs are weaned about the end of June, the
ewes milked from the 1st of July to the middle of August,
and the milk made into cheese. The sheep are clipped
from the end of June to the end of July, according to the weather
and condition of the flock. The rams are let to the ewes
from the 15th to the end of November, according to the
situation of the ground, and the nature of the grafts. From
40 to 50 ewes are allowed to one tup. The breeding flock
is changed every five years, by selling off the superannu-
ated ewes. Some ewes, however, are kept longer than five years,
and some shorter, according to their condition; for they do
not all decline equally soon. In East Lothian, sheep are in
much esteem, and kept in considerable numbers every where,
especially on the coast lands. Permanent flocks, however,
and regular sheep management, may be said to be almost
confined still to the higher parts of the country. In the
low country they are kept chiefly to eat the turnips, and
sometimes fawn grafts, which is permitted to be a year or
Two for pasture. Flying flocks therefore are generally kept,
and as soon as they are fattened for the market, which is
usually within the year, they are sold off. A considerable
number of lambs likewise are reared, only so far how-
ever as to render them fit for the butcher, or to be sold fat.

But as the great object, in the lower districts, is feeding,
little attention is paid to particular kinds; every farmer
keeps those which he thinks are likely to pay well for the
food which they consume. The black-faced, or Tweeddale
breed, are most generally preferred for feeding on turnips,
because they are most esteemed in the market; but many
of the Cheviot breed are likewise kept, and even some of
the Improved Leicesters.

It may be noticed, that it is, however, only in the Lam-
mer-muir district that sheep husbandry can be said to be
regularly practised, the management of which is this, ac-

...
when the bleak tracts on which they live are deeply covered with snow. According to the writer of the Perthshire Agricultural Report, in their cases the sheep have their chief dependence for subsistence on their own habits, which lead them to remove the snow by their feet with great facility, till they reach the heath or withered herbages. But when the snow is falling, or blown by a storm, the shepherds drive their flocks, without internal flocks, round the top of a hill in a circle, in order to keep them from lowering, and being drifted up or smothered. It has been the practice, in some districts, to erect a fort of circular fads on the tops of low hills, for the same purpose; and when the heath is all covered, they sometimes rake or harrow the snow, in order to bring up the heath, with a fort of long-toothed rake or small harrow. With some sheep-farmers it is the mode to have recourse to feeding with hay, or unthreshed oats, which is deposited in handfuls upon the snow.

Mr. Marshall has suggested', that cultivating plots of furze, broom, juniper, &c. by sod-burning, and rapping the surface, or by other more eligible means, could not fail of proving beneficial upon the wintering grounds of a sheep-farm. By means of these, as a resource in the deeps, snow, when the herbage of the eaves was buried too deep and too evenly to be uncovered by the raking of the sheep, by keeping the most exposed part of the eaves full herbage for legs general coverings of snow, and by reverence of care for the season of lambing, even ewe-flocks might be supported through the winter with some degree of certainty, without dry fodder, and without being left to the uncertainty of the seasons, and the mercy of the winds and weather, as they are at present.

The practice of birfeling, where no more lambs are kept than what is necessary for drawing the flock, is now much objectified to by fome, though it may be beneficial in rearing wether hoggs; as they are found not only to do much better, when at large with the ewes, but there is much less destruction of grass by trampling, and the pastures are fed down more properly, and with less injury to, and loss of, the sheep. Besides, the sheep thrive better, and are kept in far better condition, while much less herding is required, by which there is a considerable saving of expense.

There are several different modes of rearing the lamb hogs in these situations; as by laying them, when lambs, upon a certain part of the ground, and keeping them separate from the old sheep, through the whole winter and spring, until they are clipped; and then blending them again with the old sheep, putting more lambs upon the same ground, &c.; by allowing the hog lambs, when gimmers, to remain upon the same land on which they were bred, and breeding the hogs on a different part of it, and continuing them on that also till they are gimmers or diminutos, and then introducing them among the old sheep, the lambs being every year laid on the land, where such gimmers or diminutos had been the previous year; by keeping the hogs and diminutos or gimmers together, and putting the gimmers or diminutos only among the old sheep, and the lambs among the hogs, in the same place, &c.; and by breeding the hogs among the old sheep. The three last of these modes of management are supposed the most useful, but the last the most powerful in preventing disease; though the first and second probably afford the most equal flock of this description, in such exposed situations.

Profits of Sheep-Management.—It is evident that there is a variety of circumstances in the practice of sheep husbandry, that must affect any statement that can be made, in respect to the profit that may be derived from it: the nature of the system of management pursued, and that of the breed of

sheep employed, must operate so much in this way, as to leave the profits of no two sheep-farmers scarcely the same. But our limits will not allow us to introduce any particular statements on the subject.

In all sorts of sheep-grazing, it should be the constant aim of this kind of farmer to have his pasture or other land so focked and provided, as to derive the greatest possible profit from it; as where this is not the case, he not only injures himself, but the whole community. Where systems and practices of this nature are followed, which are not sufficiently profitable, they should be given up, and changed for such as are more fully beneficial. The same plan cannot, however, be always equally productive of advantage, as the fluctuation in the value of flock in different places, and from the case or difficulty of providing it, at different times, as well as the nature of the season, must be the causes of much diversity in it, which are invariably to be well attended to by the sheep-grazer, and turned as much as possible to his own account. See Grazing, and Stocking Land.

The practices and profits of different sheep-grazing farmers are often very different in the same situations, as scarcely any two farms of this kind are conducted exactly in the same manner for the whole of the same year, or probably the same farms for two succeeding years together; as farmers of this fort must be directed and regulated in their management by times, circumstances, and seasons, so as to have their lands focked according to the growth, or the probability of the growth, of grasps on them; taking care to have them always provided during the early summer months. Particular local circumstances, and the difference in the conduct and management of individuals, as well as capital, may also have great influence on the profit. On these grounds, the ordinary profit may amount, in favourable cases, to one pound the acre, and from that to two or three, as they are less or more favourable. The difference of practice which is had recourse to, as it relates to the forts of sheep-flock, may likewise further increase it.

The employing sheep-flock wholly is probably the most profitable plan of all others, where such flock can be readily and reasonably procured, at all times, in the least flate; but which is not always the case. And where the grazing farmer, as in the Romney-Marsh practice, can either fend them readily to the uplands for the winter, or feed them on turnips, and have their lambs well fed, and fend out a sufficient number, as well of them as of the tegs or two-years old sheep, or render these lall fat, as is sometimes the case, a greater profit, it is said, will be produced than in other ways. The value of the wool is likewise to be taken into consideration in this sort of flock, as it tends to profit.

The profits of the breeding system, in the above marsh, with sheep, depends much upon the qualities and properties of the lands for the purpose, as some will carry and keep a far greater number of them than others; as two to the acre, two and a half, and three on the same extent of ground. It is unquestionable, that by lightly flocking such lands in the winter season, the growth of the summer grasps would be greatly benefited; but 100 acres of such breeding pasture land, which keep only 200 sheep, producing 220 lambs, will not pay so well, it is thought, as if 300 ewes were kept, producing 340 lambs. Two returns, therefore, are not capable of being made in the breeding system, as many ewes are, of course, under the necessity of being kept in the winter time as such lands will support. It is, however, suggested, that by the use of hay and artificial food, much increase of profit might not only be produced, but
such pastures be improved; which should be the constant aim of the sheep-grazing farmer, whenever the expences will allow of it. Further, the expences of labour and keeping such pasture-lands in proper order, losses of flock, &c. must take greatly away from the profits of this kind of farming. It is, on the whole, thought, that though the profits of the breeding system may fluctuate considerably, it will not be so great as in some other modes of sheep-grazing. The breeding sheep-farmer may, it is said, "have a large or a small crop of lambs; he may lose a great many, or only a few ewes. There may be an increase or decrease in the value of the lambs, old sheep, or wool; there may be a prolific or scanty crop, an increase or decrease of rent; which circumstances cannot fail to alter the profits of a breeding grazer." But that lately, for many years, the great demand for lean sheep and wool has contributed greatly to the profits of farmers of this kind. The profits and advantages of the fattening system of sheep management, which is more varying, will be afterwards particularly considered, and in some measure compared with the breeding practice.

The original differences in the value of lean sheep, for the purposes of the breeding sheep-farmer, and as they may happen to be in a better or more reduced condition, must have a further effect on the profit of this system of management, as often amounting to not less than from three or four to eight or nine shillings the head.

Fattening Management of Sheep.—In the business of fattening store sheep, there are many circumstances that should be carefully attended to, as well as that of managing the breeding and other flocks. The kind of sheep that are most advantageous under the different sorts of keep, situations and kinds of land, must be well considered; the differences in the forage of food, in regard to the improvement of the sheep; and the most beneficial methods of employing it in different cafes; and lastly, the markets. And as the sheep under this treatment should never be suffered to have any fort of want of fresh food, they should never be kept too long upon any inclosure or grufs-piece, or any other sort of keep, so as to be compelled to feed upon the fullled or trampled food, as it always greatly retards the fattening of the animals, or what is termed proof, which is constantly the most promoted by the allowance of only the prime fresh food.

There are many different sorts of food made use of in this business, such as the different sorts of turnips, which are very extensively applied in this system, and some use them alone, but it is probably a better practice to give some sort of dry food with them, especially where the common turnip is employed, as it is more watery and less nutrient than that of the Swedifh kind. Cut hay, chaff, bran, corn, oil-cake, all answer well in this intention; and of the first two or three sorts they should have a pretty full supply; but the latter, from their expence, should be more sparingly given; several pounds of oats will however be required for each sheep per day, according to the kind and size. It is stated in the Norfolk Agricultural Survey, lately published, that captain Beacher having 700 fatting sheep, and turnips running short, put 200 of them to oats (not ground); he found that the practice would not answer if oats were more than 6s. per coomb, and then not for longer than six weeks: they were fed on a pature, and the improvement of it very great. He thinks grey pea or beans would have answered much better.

With oil-cake, some give half a cake a day to each sheep, but the quantity must depend in some measure upon the other keep which they have. All food of this sort should be given in moveable troughs, divided in the middle, so that the sheep may feed on each side, with a floping roof over them, so as to cover the sheep's heads and necks while feeding, as wet is not only prejudicial to the sheep, but spoils the cake. A rack for hay, fixed over the trough, might probably be made to answer in this intention, while it would be very convenient for holding that material, and preventing waste. The whole should be fixed on wheels, and be made to stand ready, and a sufficient number for the quantity of sheep be always in readiness.

Steamed or baked potatoes, cheap convenient contrivances for the preparation of which have been lately invented, have been suppolled by some to be preferable to turnips as a food in this intention. And they have been employed raw in the proportion of eight or ten pounds per sheep in the course of the day or night; but they are certainly a much better food in their prepared state. The quantity of common turnips consumed by each sheep in the same length of time, is usually about eighteen or twenty pounds. Where this last sort of crop is good, an acre is supposed to support about five score sheep in the field, six or seven weeks in the winter feason: an acre of good grazs supporting at the rate of one hundred couples from five days to a week.

In the fattening of wedders, the use of barley meal, with grazs or some other fort of green food, has likewise been found highly beneficial, and when it can be procured at a reasable rate, should not be neglected, as it is quick in rendering them fat, and the mutton is excellent.

Different other articles are occasionally made use of as the fattening food of sheep, such as peas and beans, or pea and bean meal in the winter feason, and some sustances of other kinds. It is not known that any fort of pure saccharine matter has ever yet been tried in this intention in sheep, but it is probable that it could not fail having the effect in a very experimentitious manner, if the expence of it would allow of its application in such a way; and it might be conveniently given, in small quantities at a time, in mixture with chaff, cut hay, bran, or any other similar fort of material, in covered troughs or bins for the purpose, suitable other sorts of food being had recourse to at the same time.

On the most usual sort of food for this use, that of turnips, sheep are very apt to go backward, unless fattened out before the winter feason sets in. Indeed the loss from keeping fat sheep through the winter is often so considerable, that it is advisable to have them ready to fall at the close of summer, to prevent the winter keep from being thrown away. The most beneficial application of this sort of food in fattening sheep, has, however, probably not yet been fully hewn, as some kinds of sheep are said to pay well in winter fattening.

In fattening sheep in yards with potatoes, some take them in towards the latter end of the year, and keep them until they are ready for sale about the beginning of March. They have the potatoes fixed, and put into covered sheep-troughs, a gallon being sufficient for a sheep in the day. They mostly prove well on this sort of food, so that if a fair trial be made, the potato system will probably be found the most expeditious of any in fattening these animals. When compared with different sorts of grain, oil-cake, &c. by means of accurate trials with sheep in every way the same, it has been proved to be the most ready in effecting the business. A little hay is mostly given with the potatoes, morning and evening. A salt mixt of excellent manure is likewise raised by this practice, where due care is bestowed in the preparation of the yard. Many other sustances tried in the same way, may possibly be equally beneficial in this intention, though they have not yet been made use of by sheep-farmers.

In regard to the profits of the fattening practice of sheep management...
management on the more rich lands of the marsh kind, they
must vary much according to the nature of the methods
which are pursued by different sheep-grazing and fattening
farmers, as some will make their land carry nearly one-third
more flock than others, though the quality of it may be
the same, while such flock will do equally well, if not bet-
ter. Such commonly make the largest profits as have con-
tantly the best supply of additional sheep-flock to succeed
such as are taken away, and who regard the number more
than the quality of them. The fattening practice may like-
wise be carried further than is proper and beneficial, by which
the profits of the individuals will be lessened, and a less sup-
tained by the nation at large. The nature of the breeds of
this fort of flock will have some influence, as they make a
more or less quick return, and as they may come to a more
cheap or dear market. The belt way in general, is to sell
the fat flock of this fort when ready, without waiting, but
which is not always the case. Where more returns than one
are made in the year, there is commonly the most profit made
by the sheep-farmer; and the practical management which is
had recourse to in such cases, will have a great effect on the
profits, as different rich sheep-fattening districts have many
different practices, which are more or less profitable, as that
of flocking the land with sheep, at the rate of three to the
acre, from the beginning of one autumn to that of another,
and having recourse to mixed flock of other forts during
the summer for producing the profits: that of flocking
with barren ewes which have left lambs, at the same time,
but only at the rate of two to the acre, so that the keep
may render them in a great measure fat by the beginning
of the new year, and they may be sold off in March or the
following month, in their wool, so as that the advance in their
price may more than compensate for having it, by keeping
them on until May. And after these are gone, by again
flocking the same land with sheep brought in from the mar-
kets, fairs, hills, or neighbouring high grounds, or the two-
years old wethers that have been kept out, or, which is per-
haps the best flock in these cases, with such teats as have been
well kept through the winter, and which are equal in weight
with furred or inturled two-yearlings. This is a most pro-
fitable sheep-fattening system, where it can be carried into
practice, that of putting, what are denominated make bar-
rens, or such ewes as have miffed going to lamb, upon the
fattening land; but as these will not form the necessary
supply of flock, other sheep or mixed flock must be pro-
vided to produce sufficient profit. It is never a good prac-
tice to turn poor lean sheep directly upon the rich fat-
tening lands, but to keep them some time on the inferior
pastures, as they are in danger of becoming diseased by the
former method. But half-fat sheep may be put immediately
upon them without danger, and be fed out, often in the
course of a few months or less, by which the sheep-grazing
farmer is enabled to have another return, which may con-
tribute greatly to his profits.
In the sheep-fattening system, it is often of advantage to
have a portion of land, of a superior rich quality, for the
purpose of finishing them out upon; as by such means not
only more sheep can be fed out and returned, than if the re-
gular quantity of flock was kept upon the different fields,
but the less rich pastures be flock'd in a more clofe manner,
and as the more quick feeding sheep advance, be taken into
the rich finishing portion.
There are several other circumstances which have much ef-
eft in this system of sheep management; but the profits
will materially depend on the proportion, the richfness, and
the quality of the farmer's fattening to his other lands, on
the judgment which he pofticles in the buying in lean flock,
not to be prevented from doing. The taibe is much more
than lost in mutton. And Mr. Reeve, of Wighton, never
folds; folding from layers, upon fallow, is only robbing one
field to enrich another. He is clear in this point; and also
in the fact, that if sheep (whatever the breed) are driven
by foul weather to a hedge, there is the proper place for them,
and not by penning left to abide the beating of the storm.
Mr. H. Blythe, of Burnham, sometimes folds, but never from
choice, but solely by reason of the openness of his farm;
nor does he approve the practice. And he explained a point
in his manuring for wheat, which, the writer says, comes
to the question: he never sows tempered land with
wheat, without either oil-cake, or muck, except on pieces
from which the sheep were not folded while feeding the
layers. And Mr. Durigate remarks, that folded sheep
certainly demand more food than those which are not folded;
and a quarter of a ton of rape-cake is equal to the fold; and the
flock, without any doubt, suffers more than that value by
folding. In short, folding is to gain one shilling in manure,
by the loss of two in flesh. Some, however, fold with large
flocks. But Mr. Becker, of Riving, does not fold; and he
is very certain that if he did fold, he could not keep any
thing like the number of his present flock. It is added,
that as the writer rode across a layer of forty or fifty acres,
on Mr. Overman's farm, he observed a great difference in
the verdure, to a line across it, the appearance of one side of
that line being so much superior to the other; and on his
remarking it, he was informed, that it was an accidental ex-
periment, which was well worth attention: there was no other
difference in the management, to make one part of that
layer better than another, except the sheep that fed it being
from one part of it folded on another arable field during the
sumner; but from the other part they were not folded at all,
but left in the layer night and day. The difference was
very considerable, and might have been discerned half a mile
off. This experiment made that farmer give up folding,
except when his flock was in a saltmarsh; and Mr. Tuttle,
his neighbour, averted, he would never fold at all had he no
marlflies. Nor does Mr. Etheridge, of Stanhow, fold. These
casts should, the writer says, be combined with an-
other, that of heaths and sheep-walks that have been fed
with sheep for centuries; but these sheep continually folded on
other lands, are so far from improving them, that they are to
all appearance as poor as they could have been at any former
period. It is further stated, that Mr. Styleman, at Snct-
tifham, turned his flock loose, and without folding, in twenty
acres of allotment every night, for the same period that
would have folded it in the common manner. The sheep did
much better than they would have done had they been folded;
the face of the herbage materially improved during the period,
and upon ploughing it up for wheat the crop was equal to
what it would have been with folding, and chewed by a
regular verdure, that they had distributed the manure equally
in every part. He concedes that hams fell 2s. a-head lower
on account of folding, than they would do without it; but
this is only his opinion. He thinks also that the ewe is much
injured.
But Mr. Pitts, of Thorpe Abbots, finds that no mucking,
on his burning gravels, will do so much good as the fold,
and especially on a white clover and trefoil layer for bar-
ley. And in the clay district of the county of Hertford,
Mr. Byde remarks that sheep have been too much leaffed.
Of all the common manures, he considers the fold as the
best; and he has observed in many farms the general appear-
ance of the crops decline, as the number of the sheep kept
has leaffed. That at the Hadhams, every man folds the
sheep which he keeps; a little farmer will even let four
hurdles, if he has not sheep for more. But that good as the
manure of the fold is, Mr. Chapman has found by trial in
the same field, for turnips, that yard-dung was much better
than both fold and malt-dung together. However, Mr. Ro-
borts, of King's Walden, thinks nothing is equal to the
fold; he never reckoned it worth less than 40s. per acre,
corn being cheap; but of late much more; he folds two
poles of ground with twenty sheep. And Mr. Sedgwick,
of Rickmanworth, is clearly in favour of folding on all farms.
See Folding of Sheep.
It has been observed by Mr. Ellman, in the Annals of
Agriculture, that just twenty South Down sheep (if a large
forty, a less number will do) will fold one rood per night: three
thousand two hundred will fold one English acre per night.
We value the manure at from 35s. to 50s. per acre, the goodnees
of which depends much on the manner in which the sheep are
kept; if kept on artificial food, such as tares, rape, clover,
turnips, &c. they will drop more foel than if fed on grasss only.
Suppose we estimate the folding at 40s. per acre, it will
amount per year to 42l. 62d. per sheep; 22l. 16s. 3d. per
hundred; or 223l. 28s. 6d. per thousand, supposing the sheep
folded throughout the year. If it be a breeding flock, it
might be well to omit folding for five or six weeks imme-
diately after lambing, as the young lambs might suffer from
being trampled upon, and from driving to and from fold,
would often lose their dams, and suffer in that way more
than if they remained quiet. There is, however, another
method of folding, by which all the advantages may be
attained during winter on all soils, without the inconveni-
cences of the former plan. This is flated to be by confining
them at night in a sheep-yard, well and regularly littered
with straw, flable, or fern; by which means you keep your
flock warm and healthy in bad weasons, and, at the same time,
obtain a surprizing quantity of dung, so great a quantity, if
you have plenty of litter, that the profit will be better than
folding on the land. A great improvement in this method
would be giving the sheep all their food (except their paf-
ture) in such yard, viz. hay and turnips, for which purpose
they may be brought up, not only at night but also at noon,
to be baited; but if their pasture be a distance, they should
then, instead of baiting at noon, come to the yard earlier in
the evening, and go out later in the morning. This is a
practice which cannot be too much recommended; for so
warm a lodging is a great matter to young lambs, and will
tend much to forward their growth; the sheep will also be
kept in good health, and, what is a point of confection to
all farms, the quantity of dung raised will be very great.
If this method is pursd through the months of December,
January, February, March, and April, with plenty of litter,
a hundred sheep will make a dunghill of, at least, fifty loads
of excelellent fluff, which will amply manure two acres of land,
whereas one hundred sheep folded (supposing the grass dry
enough) will not in that time equally manure one acre.
And in Norfolk, Mr. Bevan finds a yard well fenced in
for standing fold for littering and for folding in bad wea-
ther convenient; and is fully convinced of the great ad-
vantage of it. He intends in future to have his flock in it
for yeaning, whether the season be good or bad. And in
Hertfordshire, the earl of Clarendon has a fold which con-
tains good room for three hundred sheep, the number kept
in it: an open shed surrounds it, except on one side, where
a barn is the fence; the outside of the shed is formed of
wattled hurdle-work, without straw or other materials, for
coolnefs, left a greater clofenefs should make the yard too
hot: it is all kept well littered with fltable, and yields, from
three hundred sheep, eighty large cart-loads of manure.
This systlem agrees perfectly well with the shee and keeps
Sheep.
SHEEP.

them more healthy than when they were left in the fields in the common manner. His lordship has another yard for lambing, which has also a level. These sorts of yards, from their beneficial tendency in different views, should be more generally made use of by sheep-farmers in all situations. See Sheep-House.

This practice is had recourse to on arable land for raising different sorts of crops of the corn and green kind, as well as on grass-lands. It is superseded by some, that a flock of about five hundred sheep will be sufficient to pen twenty-eight square perches of land each night, which will amount to about fifty acres in the year, where the practice is discontinued two months in the course of that time. The value of this is different in different districts, as from above thirty to more than forty shillings the acre, which, for five hundred sheep, would be from 87l. to 100l. for fifty acres, which, taking the average at 94l. for that amount of stock, the annual advantage of the fold may be set at 32. 9d. a-head, or rather more; taking it at 100l. it would be 42. 3½d., or rather more. This shows the great utility of it in some places. All sorts of sheep, except the fattening ones, and those disposed to that plate, are mostly folded. It forms a sort of moving dung-hill, which enriches the land but little expense, and which may probably be rendered further useful by a greater division of the flocks. It is also beneficial in preventing the waste of food on grass-lands, as well as in confining particular sorts of crops. See Sheep-Fold.

Hurdling-Management of Sheep.—It may be noticed, that the great utility of hurdlings off different kinds of green crops, in confining them by sheep, has been long known and practiced; and equal advantage may be derived in many cases, by having recourse to the same method on rich grass-lands in large enclosures, so as to let the animals have a fresh space or bite every day. The sheep are found to thrive better, and the same extent of land to support considerably more in number, while the land is at the same time much improved. And it is not improbable, but that other sorts of flocks may be managed in the same way with similar advantage. In these cases the hurdlings must be let according to the nature of the grain; where it is bare and thin, larger pieces should be folded, than in the contrary circumstances. See Hurdles.

Washing-Management of Sheep.—From the flocks of sheep becoming much loaded and filled with dust and dirt of various kinds, in the hot summer season, by way of preparation for shearing, it is necessary to have recourse to the operation of washing. It was formerly the method of performing this business to have the washers standing up to the breast in the water; but from the inconvenience and danger of it, the men requiring a large supply of spirituous liquors, and being liable to be attacked with colds, rheumatism, and other diseases, as well as being apt to dispart the work with too much expedition, so as to leave the wool insufficiently clean; it has been proposed by Mr. Young, in his Calendar, to raise off a portion of the water (in a stream or pond) for the sheep to walk into by a sloping mouth at one end, with a depth sufficient at one part for them to swim; and to pave the whole; the breadth need not be more than six or seven feet; at one end to let in on each side of this passage, where the depth is just sufficient for the water to flow over the sheep's back, a cask either fixed or led, for a man to stand in dry; the sheep being in the water between them, they are washed in perfection, and pulling them on, they swim through the deep part, and walk out at the other mouth, where a clean pen, or a very clean dry pasture, is to receive them; of course there is a bridge rail-way to the tubs, and a pen at the first mouth of the water, whence the sheep are turned into it, where they may be soaking a few minutes before being driven to the washers. But other more cheap contrivances may be provided where there is clean water at hand for the purpose. And sheep should on no account be driven on dry or dusty roads after this operation.

But in all cases before this work commences, the lambs should be separated from the ewes and other sheep, and each be put in separate pens. With these it is seldom necessary to do much more than just will them through the water, without their being touched by the washers. As soon as they have been washed, the sheep should have a clean hard pail time for a few days, until they are perfectly dry, and in a proper condition to be shorn. The lambs are generally shorn, especially in the northern districts, a few weeks after the old sheep, and the operation is termed shearing. The lambs that are sold in Smithfield market are, we believe, seldom or ever shorn. See Sheep-Shearing, and Shearing of Lambs.

The practice of washing the sheep before they are shorn is a custom that prevails over most part of the kingdom, especially with the long-wooled breeds, and pretty generally with those of the short-wooled kinds also, but which is performed with more difficulty in them from the closer-matted nature of the fleece. It is said, however, to have been the custom in Devonshire, for a great length of time, never to wash the short-wooled sheep, but to shear them dry, as is constantly the case in Spain.

The practice of washing the sheep before shearing now, however, begins to prevail in some parts of it, according to the writer of the Agricultural Report of the county. This has at length been enforced, it is suppos'd, by the difference in the price which the wool-buyers make between wool in the yolk and washed wool, which is no less than 50 per cent. in the Dorset fort of wool; and though it is not so much, it is greatly more than proportionate in the coarser fleeces, besides the over-weight of 5 per cent. The wool of the Dorset fat wether sheep, which is about five pounds each when washed in the yolk, rarely sells for more than 1s. the pound, but when washed, it is considered of 1s. 6d. The weight of a fleece in the yolk, is to the same fleece when washed, it is said, as six and three quarters to five, and the consequent value is as 6s. 9d. to 7s. 6d. the fleece. This has, at length, been made evident to the sheep-farmers of this district, who now willingly agree, that it is advantageous to wash short-wooled sheep before shearing, but to fell the long and coarse fleeced flocks in the yolk.

Good clean washing is a matter of great consequence to the wool; and it is of much advantage to it as well as the sheep to have the weather fair and fine at the time it is performed, as they are much less liable to have colds.

Shearing-Time.—In respect to the proper period of clipping or shearing sheep, it must be directed by the state of the weather, and the climate in the particular district; and by this means the danger of injury by cold, from depriving the sheep of their coats at too early a season, and from heat, by permitting them to continue on them too long, may be avoided in the best manner. But another circumstance, that should likewise be attended to in this business, is that of the wool being fully grown, or at the state of maturity; as where the clipping precedes that period, it is said, in the Annals of Agriculture, to be weak, and scarcely capable of being spun; and if protracted later, it is yellow, felted, and of an imperfect nature. It has been stated, that for the more warm sheltered situations in the southern parts of the kingdom, the beginning or middle of June, when the weather is fine, may be in general the most proper; but in the more exposed districts, in the northern parts
parts of the island, the middle or latter end of the same month may be more suitable, provided the season be favourable. But with the fattening sheep in the inclosures, it will mostly be necessary to perform the work at an earlier period, in every situation; as the great increase of heat, from the setting in of the summer weather, added to the warmth of the fleece, becomes very oppressive and injurious to them, in their feeding and other properties.

It is an excellent practice with many good sheep-farmers, to clip off all the coarse wool about the thighs and docks, some weeks before the usual time of walking and clipping the sheep; as by this means the sheep are kept clean and cool, when the season is hot, and with ewes the udders are prevented from becoming sore. This practice is common with some South Down sheep-masters, as well as in Yorkshire. In the former situation, Mr. Elliman sells his, as locks, at 3½d. per pound, having about four ounces from each sheep.

By some it has been proposed to shear sheep two or three times in the course of the year, with the view of having finer, as well as a larger quantity of wool; but it is probable that such a practice cannot be of any general advantage, though the trials that have been made in Northumberland in this way seem to have shown that advantages may be derived in both these intentions; but the disadvantages in respect to the sheep do not seem to have been sufficiently attended to. And with the same view, the clothing of the fleece has been had recourse to. In experiments made in this way in Scotland, the advantage in respect to wool is stated to have been very considerable, and the expence not more than 7d. per sheep. By having recourse to this practice with that of the above, it has been suggested that combing wool may be rendered fit for the purpose of clothing, and at the same time the mutton rendered more valuable. The trials in these ways have, however, hitherto been but few, and do not seem to extend.

It may also be noticed, that in the general management of sheep, it is usual, after the shearing has been performed, to mark the sheep with reddle, ochre, or some similar substance; and some also cut the ear in different ways. The marking with tar has been said to be prejudicial; but where a small quantity is only employed, little injury can be sustained. And in almost all the sheep districts of the kingdom, except in Dorsetshire, the tails of sheep are shortened, which seems to be an useful practice in keeping the animals more clean behind, and of course less liable to be stricken with the fly. It has, however, been suggested in the ninth volume of Annals of Agriculture, that by this custom the sheep may be rendered less able to drive away the flies. The general prevalence of the practice would, however, seem to prove its being of advantage. There is much difference in the manner of performing the shears in different districts, in respect to the length; but four or five inches being left, are quite sufficient. It is usually done while the animals are young. In all sheep-pastures the hedges should be well cleared from briars, as their roots are often injured by being torn by them; and all sorts of pernicious reptiles should be as much as possible destroyed, and removed from such land.

Further, in respect to the shears of cutting or giving the lambs, it may be performed any time from the age of a fortnight or three weeks to that of a month or six weeks; and in some districts it is deferred to a considerably later period. It is, however, the safest method to have it executed early, as there is less danger of too much inflammation taking place. But in all cases, the lambs should be in a healthy state, when it is done; as under other circumstances, they are liable to be destroyed by it. The operation is usually performed by the shepherd, by opening the ferotum or cod, and drawing out the teaticles, with the periment cord. This he often does with his teeth, in the young state of the animal. But where the operation is performed at a later period, it is usual to have recourse to the knife; the arteries being taken up, and secured by means of ligatures or the fearing-iron. The shears, if possible, should be done in fine weather, when not too warm; and the gilded lambs be kept in a dry, sheltered, quiet situation, for a few days, until the inflammation is gone off. If it should happen to be wet at the time, it may be advisable to have them under some sort of shelter, where they can have room to move freely about.

It is now well known that the mode of ascertaining the age of these animals is chiefly by their teeth; but they are likewise sometimes named from the number of coats or fleeces that have been thorn from them, as one-flee, two-flee, &c. The sheep of one-flee having two broad teeth before; that of two-flee, four; that of three, six; and that of four, eight, which is full-mouthed. See Age of Sheep.

And they have also different names in different districts. After being weaned, the ram or wedder-lamb is sometimes termed hog, hoggit, tag, or tag; during the whole of the first year; and the female lamb, an ewe or gimmer-lamb, and ewe-tag. The second year, the wedder has the title of fheer-hog, or a two-toothed tag or tag; and the ewe is called a tharoe, tharoe, or two-toothed ewe. In the third year, a fheer-hog, or four-toothed wedder; and a four-toothed ewe, or tharoe. The fourth year, a six-toothed wedder, or ewe. And in some places, from the time of lambing till that of salting, the males are called tup-lambs; and from that period till the time of shearing, tup-hogs; and ever afterwards, tops; the females in the same order being termed ewe-lambs, ewe-hogs, gimmers, young ewes, old ewes. The gilded male lambs, caffated wedder-lambs, wedder-hogs, dammonds, or dinmons, wedders. Crones also signify old ewes; and there are several other provincial names, which are explained in their proper places, under their different heads. See Sheep, Names of.

In the management of this fort of stock, it must be sufficiently evident that a great deal of the profit and advantage must depend upon having a careful attentive shepherd, who perfectly understands his business, and is at all times willing to perform it. See Shepherd.

Sheep are subject to a variety of diseases, which should be carefully attended to by those who have the care of such fort of stock, as soon as they occur themselves; as a very short time often renders them irrecoverable. The nature of them, and the means of removal, are described under the proper heads to which they belong.

The above accounts, observations, and details, may serve to afford the inquirer a general knowledge of the nature of sheep husbandry, and of the usual methods of management which are required with that fort of live-stock, as well as the benefits and advantages which may be derived from it in many different ways.

Sheep, and their Varieties, Chiefly in Connection with the Woollen Manufacture. History of. Of all the animals that have been domesticated by man, none have rendered him more essential service than the sheep. A large part of the food and clothing of the civilized world is furnished by this useful animal. The culture, improvement, and manufacture of its fleece, have constantly accompanied and marked the progress of civilization, both in ancient and modern times.

In
SHEEP.

In the early ages of society, sheep appear to have been principally domesticated for the sake of the skin, or the fleece: we shall, therefore, first take a short view of their cultivation and improvement in different countries, as wool-bearing animals; whether as producing fine or coarse wool, or as long or short-woolléd sheep; the produce of the two latter differing from each other in the mode of manufacture, and the use to which it is applied, more than silk and cotton, considered as articles of manufacture.

It is not a little remarkable, that the domesticated sheep depends for its subfemile almost entirely on the care of man, and is never found at any great distance from his habitation. "Left to itself, it becomes the subject of disease, and the prey of ferocious animals; or if these should spare it, its own fleece becomes the abode of insects, which continually nourish themselves with its blood, and destroy its constitution. Its enemies are indeed so numerous, and constantly at hand, that it has no chance of escaping them."

Naturalists are not fully agreed from what animal the different varieties of domestic sheep originally sprang. The Siberian argali, as described by Pallas, was most probably the parent of all the cultivated flocks in Asia, from whence they have spread to other parts of the world. This animal, the argali, which in the Siberian language means wild sheep, is called by the Russians kamats baran, or sheep of the rocks, from its ordinary place of abode. According to Pallas, it is the same with the mouffon of Pliny, and the opinion of the Greeks. It is found, in all its native wildness, vigour, and activity, inhabiting the vail chain of mountains which run through the centre of Asia to the Eastern sea, and the various branches of this chain, extending through Great Tartary, China, the north of Hindoostan, and Persia. The argali delights to bask in the sun on the bare rocks, but avoids the woods and shade; it feeds on alpine plants and shrubs; it prefers a temperate climate, but is found also amongst the rocks of Asiatic Siberia. This animal loves a flat of solitude, and flees the haunts of men. According to professor Pallas, nothing but the surrounding sea can account for the argali being found on an inhabited island, as is sometimes the case.

The ewe of the argali brings forth before the melting of the snow: the lamb resembles a young kid, except that it has a flat protuberance in place of horns, and is covered with dark grey hair, frizzled and woolly.

There are few animals more difficult to overtake than the argali. When pursued, it turns and doubles like a hare, scrambling over the rocks with wonderful agility. Though the adult animal is untameable, the lamb is easily domesticated, when taken young, and fed on milk, and afterwards on fodder, which is proved by numerous experiments made in the Russian settlements.

The argali is about the size of the fallow deer, but its make is more robust, being less elegant than the deer, and its neck and legs are shorter. Its head resembles that of a ram, with long fraggling hairs about the mouth, but no beard like the goat. The horns, according to the drawing given by Pallas, bear a similiarity to those of the Merino rams; their weight is about sixteen pounds; the tail is short. The summer covering of the argali is a short fleecy hair, resembling that of the deer; the winter coat consists of wool, like down, generally of a white colour, and intermixed with longer hair. See ARGALI.

From the facility with which the young of the argali is domesticated, and from the character of this animal, as well as its situation, we may with much probability infer that it was the parent of the Asiatic flocks. According to other travellers, the coat of the argali is of a grey or nut-brown colour; probably it may be of different colours in the different districts it inhabits. In early ages the fleeces of domestic sheep appear to have been all of a dark colour. Such was the flock of Laban, in Mesopotamia; and the narrative of the manner in which the change was effected, may serve to shew that, previously to that time, the common colour of the fleece was black or dark-brown. The improvement in the quality, as well as the colour of the fleece, has always been closely connected with the progress of the arts; for we uniformly find in countries, where there have flourished, a race of sheep which yield wool of a superior quality to those around them. In Persia and Syria, the influence of ancient manufactures is full visible in the superiority of their sheep, as fine-woolléd animals. From Asia Minor these animals were transported into Greece, and from thence into Italy and Sicily. They were diffused by the Romans over various parts of Europe; and the Tarentine sheep, formerly celebrated for their fine soft wool, were introduced into Spain, where they have flourished for sixteen centuries; the present Merino race being their immediate descendants, but rendered more hardy by an intermixture with the original native sheep of Spain.

From the writings of Columella, and the incidental circumstances mentioned by ancient historians, we may infer that the fine fleeces of Greece and Italy were of the short-woolléd kind, producing clothing wool, which was manufactured into woollen cloth, similar to what is at present worn; but probably more flexible, from not undergoing to completely the milling or felting process. (See WOOL.) Indeed, from the remains of the Tarentine fleeces at present in Italy, we can be at no loss to determine the nature of the former Tarentine fleece. Thirteen centuries of neglected cultivation, and intermixture with other breeds, have not been sufficient to obliterate the labours of former times. From what we have seen of the finer Italian wools, we have no hesitation in allerting, that by judicious and careful selection, it would be practicable to restore the Tarentine race once more to its original purity, in the course of a few years; were it found to possess any superior merit, compared with the fine-woolléd sheep of Spain. The circumstances respecting the management of the Tarentine fleeces, recorded by ancient writers, when compared with the present treatment of the Merino fleeces in Spain, leave no doubt respecting the origin of the latter.

The term Merino, in the Spanish language, is an adjective, derived from the corrupt Latin merinus, or majorinus: when united with ovijas, it signifies the royal judge, or superintendent of the sheep-walk. At the period when the traphumantes, or travelling flocks in Spain, were established, they became the objects of police, and were placed under the exclusive jurisdiction of mayors, with public walks and large districts allotted for their subsistence, and were termed Merinos ovijas, or the sheep under the care of the merino or mayor. The names peculiar to the establishment of these flocks, such as mejillas, savanas, &c. are derived, not from the Moriscos, but from the provincial Latin that prevailed in Spain before and after it was subdued by the Goths. (See MESTA.) The management of the flocks is peculiarly Roman; the merino, or mayor, corresponds exactly with the magister pecorum of Varro and Columella, and was superior to the opiniones and pastores. The practice of dividing half the sheep at their birth, and of suckling each of the survivors on two ewes; of shearing the sheep before they were born, to increase the softness of the fleece; and of conducting them from their winter to their summer stations, by long journeys through public sheep-walks, has been derived from Roman institutions, with this difference, that in Italy their migrations were
were confined to the coarse-woolled sheep, while the molles oves, or fine-woolled flocks of antiquity, were always housed.

The experiment of Columella's uncle sets the stage for the introduction of fine-woolled sheep into Spain. Having procured some wild African rams at Cadiz of a coarse fleece, but of an admirable colour, he gave them to some fine-woolled ewes, and the male progeny being again given to Tarentine ewes, the offspring, with their descendants, united the paternal colour with the peculiar softness of the maternal fleece. Columella's uncle resided in Bocica, which comprised the modern Eltramadura; and as Columella flourished under the emperor Claudius, the Tarentine breed must have been introduced into that province at the commencement of the Christian era. Whatever was the peculiar colour which the elder Columella introduced by means of African rams into his Tarentine flock, we may conclude that the same successful experiment was employed by other agriculturalists of Bocica, to convert these coarse into fine-woolled breeds, and to communicate the pure white to the black or parti-coloured native flocks, which, according to Pliny, were common in Spain. The original intermixture of distinct breeds of native Spanish sheep with the Tarentine in different parts of Spain, may be inferred from other circumstances: each cavea, or flock, forms a distinct breed; and the Nigrette no more resembles the Palaee, than the Merino South Down resembles the Merino Cheviot. The genuine unmixed descendants of the Tarentine breed would have preferred one uniform character; but the native flocks crossed with Tarentine rams would retain their distinctive varieties, and transmit them to each cavea.

That the Merino is a mixed race, seems to be further indicated by the more tender constitutions of the fine-woolled flocks of antiquity. Of these, the Tarentine were most celebrated in Italy, and the Milefian in Asia Minor. They were termed pellite and teftex oves, from the coverings of skin with which they were clothed to deferve the fleece. They were denominated alfo molles oves, not only from the softness of the fleece, but from the delicacy of the constitution. They were always fed in the house; and though fattened with brambles, or the coarser food, they are described as a most voracious breed: a diminution of their allowance from the fraud of servants, or the parsimony of the owner, was attended with certain destruction to the flock. (Plin. lib. viii. cap. 47.) As there was no sale for the lambs, nor any profit from the milk of a Tarentine flock, half the lambs were destroyed at the birth. The ram-lambs were chiefly reared, and were killed at two years, when their pelts sold to the merchant at an advanced price, on account of the beauty of the pile. This breed demanded constant care, when in the fields, to preserve their coverings from being torn, and the fleeces destroyed. At home they required even greater care than abroad, as they were not daily conducted to their pastures. They were frequently uncovered and exposed to refreshment. The staples of the fleece were opened and disparted, and were frequently molested with wine and oil. The whole flock was walked three times a-year, when the weather was warm. The staples were frequently swept, cleaned, and fumigated: for these different offices two shepherds were constantly required for every hundred sheep.

The excessive care bestowed on these flocks by the nations of antiquity, shews in what estimation their fleeces were held; and though such attention is remote from modern practice, we are fully convinced that, by selecting the very finest and softest Merino flocks, and covering the wool, and frequently anointing and washing, it would give to the pile that degree of softness which is so much wanted in the manufacture of shawls, and other costly articles of luxury, but which we seek for in vain in the finest fleeces of modern Europe. However expensive such attention might prove, we have no doubt that, on a limited scale, it would well repay the labour of the judicious experimentalist, as the wool would be worth more than 30s. per pound, could it be made to equal that of India in softness. It would appear that the Tarentine breed were selected with much care for breeding, and every expedient adopted, which was proved by experience to attenuate and soften the pile. The transition of these delicate animals into the Merinos of Spain, which are a hardy race, can only be explained by supposing that other agriculturalists had imitated Columella, and obtained a fine-woolled race, by crossing their native breeds with the more delicate animals from Italy. The beginning of this improvement is indeed described by Strabo in the reign of Tiberius: he informs us that the inhabitants of Truditia had formerly imported many garments, but that their wool in his time surprised that of the Coraxi, and exceeded it in beauty so much, that a talent, equal to two hundred guineas, was the lowest price of a ram to breed from; and that they excelled also in the fabrics which the Sal-tiatae manufactured. Truditia, according to Strabo, comprehended the province of Bocica, from the Guadana to the confines of Lusitania, and southward to Gibraltar, and eastward to Toledo. The wool of the Coraxi, with which Strabo compares that of this part of Spain, we are informed, in his account of Pontus, was from the soft-woolled Milefian sheep. Such high prices as a talent must have been produced by a very general demand for rams, not for the use of the Tarentine flocks, which could occasion no such competition, but for the purpose of culling the indigenous breeds of the province, which, from the earliest period, appears to have abounded in sheep.

The travelling flocks were not at that time introduced, as the mountainous regions had been till then infested by native as well as Lusitanian robbers, whom the Romans dislodged from their villages, and dispersed into cantons. (Diodorus Siculus, lib. v. cap. 32.) The Moorish looms of Andaluflia and Catalonia, and those of the Christians at Segovia, in the 15th century, must have been supplied by the fine-woolled flocks introduced by the Romans. The vacant mountains, when cleared of banditti, offered a vast range of pasture from Eltramadura, northward, towards Galicia, and the Avaria. A similar opportunity occurred to establish or renew the institution of travelling flocks when the Christians defended, in the middle of the 13th century, to occupy the conquered provinces of Andaluflia and Murcia.

After that time the travelling flocks became so well established, that the montargo, or tolls, on their passage through the mountains, from province to province, the servicio, or tax to the crown, and the laws of the mesta, were imposed or ratified by government, in the middle of the 15th century, before the Moorish kingdom of Granada had been finally reduced.

We are thus enabled from history to trace the introduction and establishment of the Merino race of sheep in Spain, from which, or from their descendants, nearly all the manufactories of fine cloth in Europe are at present supplied with wool. See Wool.

The native breeds of Bocica were originally and gradually converted into fine-woolled animals, by repeated crossings with the Tarentine flocks, and thus an immense number of hardy sheep, producing a moft valuable pile, were spread over the country, and survived the successive conquests of the Goths and Vandals, and the protracted war-
In the early ages of society, sheep appear to have been principally domesticated for the sake of the skin, or the fleece: we shall, therefore, first take a short view of their cultivation and improvement in different countries, as wool-bearing animals; whether as producing fine or coarse wool, or as long or short-wooled sheep; the produce of the two latter differing from each other in the mode of manufacture, and the uses to which it is applied, more than silk and cotton, considered as articles of manufacture.

It is not a little remarkable, that the domesticated sheep depends for its subsistence almost entirely on the care of man, and is never found at any great distance from his habitation. "Left to itself, it becomes the subject of disease, and the prey of ferocious animals; or if these should spare it, its own fleece becomes the abode of insects, which continually nourish themselves with its blood, and destroy its constitution. Its enemies are indeed so numerous, and constantly at hand, that it has no chance of escaping them."

Naturalists are not fully agreed from what animal the different varieties of domestic sheep originally sprung. The Siberian argali, as described by Pallas, was most probably the parent of all the cultivated flocks in Asia, from whence they have spread to other parts of the world. This animal, the argali, which in the Siberian language means wild sheep, is called by the Russians kamjnoi baran, or sheep of the rocks, from its ordinary place of abode. According to Pallas, it is the same with the mufon of Pliny, and the ophion of the Greeks. It is found, in all its native wildness, vigour, and activity, inhabiting the vall chain of mountains which run through the centre of Asia to the Eastern sea, and the various branches of this chain, extending through Great Tartary, China, the north of Hindoosfan, and Peru. The argali delights to bask in the sun on the bare rocks, but avoids the woods and shade; it feeds on alpine plants and shrubs; it prefers a temperate climate, but is found also amongst the rocks of Asiatic Siberia. This animal loves a flat of solitude, and flees the haunts of men. According to professor Pallas, nothing but the surrounding sea can account for the argali being found on an inhabited island, as is sometimes the case.

The ewe of the argali brings forth before the melting of the snow: the lamb resembles a young kid, except that it has a flat protuberance in place of horns, and is covered with dark grey hair, frizzled and woolly.

There are few animals more difficult to overtake than the argali. When pursued, it turns and doubles like a hare, fernambuline over the rocks with wonderful agility. Though the adult animal is untameable, the lamb is easily domesticated, when taken young, and fed on milk, and afterwards on fodder, which is proved by numerous experiments made in the Russian settlements.

The argali is about the size of the fallow deer, but its make is more robust, being less elegant than the deer, and its neck and legs are shorter. Its head resembles that of a ram, with long drooping hairs about the mouth, but no beard like the goat. The horns, according to the drawing given by Pallas, bear a similarity to those of the Merino rams; their weight is about fourteen pounds; the tail is short. The summer covering of the argali is a short fleecy hair, resembling that of the deer; the winter coat consists of wool, like down, generally of a white colour, and intermixed with longer hair. See Argali.

From the facility with which the young of the argali is domesticated, and from the character of this animal, as well as its situation, we may with much probability infer that it was the parent of the Asiatic flocks. According to other travellers, the coat of the argali is of a grey or nut-brown colour; probably it may be of different colours in the different districts it inhabits. In early ages the flocks of domestic sheep appear to have been all of a dark colour: such was the flock of Laban, in Mesopotamia; and the narrative of the manner in which the change was effected, may serve to shew that, previously to that time, the common colour of the sheep was black or dark-brown. The improvement in the quality, as well as the colour of the fleece, has always been closely connected with the progress of the arts; for we uniformly find in countries, where these have flourished, a race of sheep which yield wool of a superior quality to those around them. In Persia and Syria, the influence of ancient manufactures is still visible in the superiority of their sheep, as fine-wooled animals. From Asia Minor these animals were transported into Greece, and from hence into Italy and Sicily. They were diffused by the Romans over various parts of Europe; and the Tarentine sheep, formerly celebrated for their fine soft wool, were introduced into Spain, where they have flourished for sixteen centuries; the present Merino race being their immediate descendants, but rendered more hardy by an intermixture with the original native sheep of Spain.

From the writings of Columella, and the incidental circumstances mentioned by ancient historians, we may infer that the fine flocks of Greece and Italy were of the short-wooled kind, producing clothing wool, which was manufactured into woollen cloth, similar to what is at present worn; but probably more flexible, from not undergoing to completely the milling or felting process. (See Wool.) Indeed, from the remains of the Tarentine flocks at present in Italy, we can be at no loss to determine the nature of the former Tarentine fleece. Thirteen centuries of neglected cultivation, and intermixture with other breeds, have not been sufficient to obliterate the labours of former times. From what we have seen of the finer Italian wools, we have no hesitation in asserting, that by judicious and careful selection, it would be practicable to restore the Tarentine race once more to its original purity, in the course of a few years; were it found possible any superior merit, compared with the fine-wooled sheep of Spain. The circumstances respecting the management of the Tarentine flocks, recorded by ancient writers, when compared with the present treatment of the Merino flocks in Spain, leave no doubt respecting the origin of the latter.

The term Merino, in the Spanish language, is an adjective, derived from the corrupt Latin merinum, or majorinus: when united with ovijas, it signifies the royal judge, or superintendent of the sheep-walk. At the period when the trujbnantes, or travelling flocks in Spain, were established, they became the objects of police, and were placed under the exclusive jurisdiction of mayors, with public walks and large districts allotted for their sustenance, and were termed Merinos ovijas, or the sheep under the care of the merino or mayor. The names peculiar to the establishment of these flocks, such as mesta, cavana, &c. are derived, not from the Moriscos, but from the provincial Latin that prevailed in Spain before and after it was subjugated by the Goths. (See Mesta.) The management of the flocks is peculiarly Roman; the merino, or mayor, corresponds exactly with the magister pecoros of Varro and Columella, and was superior to the opiliones and palfiores. The practice of destroying half the sheep at their birth, and of furloughing each of the survivors on two ewes; of swathing the sheep before they were born, to increase the softness of the fleece; and of conducting them from their winter to their summer pastures, by long journeys through public sheep-walks, has been derived from Roman institutions, with this difference, that in Italy their migrations
were confined to the coarse-woolled sheep, while the molle
over, or fine-woolled flocks of antiquity, were always housed.

The experiment of Columella's uncle ascertains the early
introduction of fine-woolled sheep into Spain. Having
procured some wild African rams at Cadiz of a coarse
fleece, but of an admirable colour, he gave them to some
fine-woolled ewes, and the male progeny being again given
to Tarentine ewes, the offspring, with their descendants,
united the paternal colour with the peculiar softness of the
maternal fleece. Columella's uncle resided in Batica,
which comprehended the modern Extremadura; and as
Columella Bournido under the emperor Claudius, the
Tarentine breed must have been introduced into that prov-
ince at the commencement of the Christian era. Whatever
was the peculiar colour which the elder Columella intro-
duced by means of African rams into his Tarentine flock,
we may conclude that the same successful expedient was
employed by other agriculturists of Batica, to convert
thee coarse into fine-woolled breeds, and to communi-
cate the purest white to the black or parti-coloured
native flocks, which, according to Pliny, were common in
Spain. The original intermixture of distinct breeds of
native Spanish sheep with the Tarentine in different parts
of Spain, may be inferred from other circumstances: each
cavano, or flock, forms a distinct breed; and the Nigrette
no more resembles the Panalac, than the Merino South Down
resembles the Merino Cheviot. The genuine unmixed
defendants of the Tarentine breed would have preferred
one uniform character; but the native flocks crossed with
Tarentine rams would retain the distinctive varieties, and
transmit them to each cavano.

That the Merino is a mixed race, seems to be further
indicated by the more tender constitutions of the fine-
woolled flocks of antiquity. Of these, the Tarentine were
most celebrated in Italy, and the Milehsian in Alba Minor.
They were termed pelita and tezca oves, from the cover-
ings of skin with which they were clothed to defend
the fleece. They were denominated also molle oves, not
only from the softness of the fleece, but from the delicacy
of the constitution. They were always fed in the house;
and though satiated with blemishes, or the coarsest food,
they are described as a most voracious breed: a diminu-
tion of their allowance from the fraud of servants, or the
parimony of the owner, was attended with certain destruc-
tion to the flock. (Plin. lib. viii. cap. 47.) As there was no
sale for the lambs, nor any profit from the milk of a
Tarentine flock, half the lambs were destroyed at the birth.
The ram-lambs were chiefly reared, and were killed at two
years, when their pelts sold to the merchant at an advanced
price, on account of the beauty of the pike. This breed
demanded constant care, when in the fields, to preserve their
coverings from being torn, and the fleshes destroyed.
At home they required even greater care than abroad, as they
were not daily conducted to their pastures. They were
frequently uncovered and cooled for refreshment. The
flepas of the fleece were opened and dispartoed, and were
frequently moistened with wine and oil. The whole flock
was washed three times a-year, when the weather was warm.
The flepas were frequently swept, cleaned, and fumigated:
for these different offices two shepherds were constantly re-
duced for every hundred sheep.

The excessive care bestowed on these flocks by the nations
of antiquity, shews in what estimation their fleces were
held; and though such attention is remote from modern
practice, we are fully convinced that, by selecting the very
finest and softest Merino flocks, and covering the wool, and
frequently anointing and washing, it would give to the
pale that degree of softness which is so much wanted in the
manufacture of shawls, and other costly articles of luxury,
but which we seek for in vain in the finest fleees of modern
Europe. However expensive such attention might prove,
we have no doubt that, on a limited scale, it would well
repay the labour of the judicious experimentalists, as the
wool would be worth more than 30s. per pound, could it be
made to equal that of India in softness. It would appear
that the Tarentine breed were selected with much care for
breeding; and every expedient adopted, which was proved by
experience to attenuate and soften the pike. The transition
of these delicate animals into the Merinos of Spain, which are
a hardy race, can only be explained by supposing that other
agriculturalists had imitated Columella, and obtained a fine-
woolled race, by crossing their native breeds with the more
delicate animals from Italy. The beginning of this im-
provement is indeed described by Strabo in the reign of
Tiberius: he informs us that the inhabitants of Truditia
had formerly imported many garments, but that their wool
in his time surpassed that of the Coraxi, and excelled it in
beauty so much, that a talent, equal to two hundred guineas,
was the stated price of a ram to breed from; and
that they excelled also in the fabrics which the Salt-
turke manufactured. Truditia, according to Strabo,
comprehended the province of Batica, from the Guadiana
to the confines of Lusitania, and southward to Gibraltar,
and caftward to Toledo. The wool of the Coraxi, with
which Strabo compares that of this part of Spain, we are
informed, in his account of Pontus, was from the soft-
woolled Milehsian sheep. Such high prices as a talent must
have been produced by a very general demand for rams,
not for the use of the Tarentine flocks, which could occasion
no such competition, but for the purpose of crossing the
indigenous breeds of the province, which, from the earliest
period, appears to have abounded in sheep.

The travelling flocks were not at that time introduced, as
the mountainous regions had been till then infested by native
as well as Lusitanian robbers, whom the Romans dislodged
from their villages, and dispersed into cantons. (Diodorus
Siculus, lib. v. cap. 32.) The Moorish looms of Anda-
lusa and Catalonia, and those of the Chriltians at Segovia, in
the 13th century, must have been supplied by the fine-
woolled flocks introduced by the Romans. The vacant
mountains, when cleared of banditti, offered a vast range
of pasture from Extremadura northward, toward: Galicia
and the Alburis. A similar opportunity occurred to es-
ablish or renew the institution of travelling flocks when the
Chriltians defended, in the middle of the 13th century, to
occupy the conquered provinces of Andalusa and Murcia.
After that time the travelling flocks became so well es-
tablished, that the mentapo, or tolls, on their paige
through the mountains, from province to province, the
servicio, or tax to the crown, and the laws of the mella,
were imposed or ratified by government, in the middle of
the 15th century, before the Moorish dominion of Grenada
had been finally reduced.

We are thus enabled from history to trace the introduc-
tion and establishment of the Merino race of sheep in Spain,
from which, or from their descendants, nearly all the manu-
factories of fine cloth in Europe are at present supplied with
wool. See Wool.

The native breeds of Batica were originally and gra-
dually converted into fine-woolled animals, by repeated
crosses with the Tarentine flocks, and thus an immense num-
ber of hardy sheep, producing a most valuable pike, were
spread over the country, and survived the succesive con-
quests of the Goths and Vandals, and the protracted war-
fare
fare of many centuries. The pure Tarentine breed in Greece and Italy being more delicate, is said to have become extinct with the destruction of the Roman empire; but the mixture of this race with the original flocks of Italy may still be distinctly traced, particularly in the middle and southern parts. The Italian wool was finer than that of any other country in Europe, except Spain, prior to the improvements which have recently taken place by the introduction of the Merinos. It is not improbable that the fine-wooled flocks of England, though generally inferior to the Merinos in the quality of the wool, were also originally descended from croftes with the Tarentine breed introduced by the Romans, when they established a manufacture of woollen cloth at Winchester.

The deterioration or deterioration of the improved flocks in the ages of barbarism which succeeded the fall of the Roman empire, was the natural consequence of the decay of the manufactures, and of a total inattention to prevent the intermixture with coarser breeds. In Spain alone, the improved race had taken such complete possession of the mountainous districts, that it remained unmixed and unimpaired till the revival of commerce and the arts, when that country supplied the neighbouring nations with fine wool, and was supposed to possess some peculiar advantages of soil and climate, which it would be vain to seek for elsewhere. The opinion that the superior fineness of the Spanish fleeces was derived entirely from some peculiarity of the soil and climate, had obtained so generally, and was so firmly believed, even twenty-five years since, in this country, that he who advanced the contrary, was regarded by agriculturalists and clothiers as a speculative theorist, only deferving their pity.

It is not a little remarkable, that this prejudice continued undiminished nearly a century after the Merino sheep had been introduced into Sweden and Saxony, and had continued to produce wool in those countries, equally fine with that of their parent flocks in the Spanish peninsula.

It might have been previously supposed that the climate of Sweden, being much colder than that of Great Britain, and more remote from the annual mean temperature of Spain, would render that country peculiarly unfriendly to the Merino race and to the production of fine wool. This prejudice respecting the influence of climate would have been removed by considering that almost all the finest furs are the production of cold climates, and that the growth of fine wool and fur is a provision of nature, to defend animals against the severe cold of the districts near the poles.

Mr. Allstroemer, who had previously endeavoured to ameliorate the breed of sheep in Sweden, by importations from England and Germany, obtained a flock of Merinos, which he introduced into that country in the year 1723. In the year 1739, the Swedish government, for the promotion of this race, instituted a school of shepherds, under the direction of Mr. Allstroemer, and public funds were appointed for granting premiums to those who fold rams of the Spanish breed; and from the same period, to 1780, a premium of twenty-five per cent. was also granted on the sale of fine wool of a good quality. These premiums were afterwards reduced, and finally discontinued in 1792, being no longer necessary. From exact accounts, it appears that the fine wool fold from 1751 to the year 1790, amounted to 3,402,961 francs.

The quantity of fine wool actually produced was much greater than what had been fold to receive the premium, a considerable part having been consumed in domestic manufactures by the growers and others; and the distance of the public magazines, where the wools were sent to receive the premium, prevented the public returns from including the real quantity of fine wool grown. In the year 1764, there were in Sweden 65,369 sheep of the pure Merino race, and 32,384 of a mixed breed, producing fine wool. The Swedish Merinos prefer their primitive form; their fleece is very close, and the wool has not deteriorated in fineness, length, or elasticity; and the sheep produce as great a weight of fleece as in Spain, wherever they are supplied with a sufficient quantity of food. This race, now naturalized in Sweden, are larger and stronger than the Spanish sheep. M. Laytfer examined the flock of M. Schulzenheim, at Gronfoe, in the province of Upland, which had been introduced from Spain 55 years. On comparing the wool with that of other Spanish sheep recently imported, he did not find it inferior either in beauty or fineness. M. Schulzenheim preferred the descendants of sheep which he imported from Spain to the fifth generation, and the comparison of their fleeces proved that they had not in the least degenerated. These facts prove decidedly that the Spanish sheep do not lose the good qualities of their wool by a removal to cold countries. At the same time it must be observed, that the sheep degenerated which had been neglected, or treated in the same wretched manner as the native flocks, by confining them in damp, infested, and dirty stables during a part of the year, and omitting the requisite quantity of food; or paining them in summer in forests and marshes, or in low moit situations, where they could neither find the proper kind nor due quantity of herbage.

The introduction of the Merinos into Saxony took place in 1751, and again in the year 1778. The first flock consisted of one hundred rams and two hundred ewes, chosen for the electors of Saxony from the best flocks in Spain; they were placed under the care of a Spanish major, or mayor, at Stolpen, fix leagues from Dresden, on the frontiers of Bohemia.

After ten years' experience, it was found that they had preferred all the original good qualities of the fleece, and the wool from the mixed breed had also acquired a degree of fineness which did not yield to that from Spain. As soon as it was ascertained, by experience, that it was easy to naturalize the Spanish sheep in Saxony, and that the croftes from this race with the native flocks were so greatly ameliorated, the attention of the agriculturalists was directed to the general improvement of the flocks, and such has been the success, that their produce is at present one of the greatest fources of profit to the cultivator. During the last fifteen years, a very considerable quantity of fine wool has been imported from Saxony into England, and the price of the best sort is greater than that of the finest Spanish wool, a sufficient proof of the estimation in which it is held by the manufacturers. It is better suited for the finest kerseymeres, and the more delicate articles of the woollen trade, as it can be spun to a greater length than any other kind of carded wool grown in Europe; it is also superior in fineness, but owing to the scarcity of winter food, it is generally less found than the best Spanish, and not so well suited for stout cloths. See Wool.

The Merino race has since been introduced into Denmark, the Prussian states, Austria, France, Holland, Italy, the Cape of Good Hope, and the United States of America. Of its introduction into England, we shall afterwards speak.

As Saxony is the only country which has yet cultivated the Merinos so extensively, as to come in competition with Spain in the exportation of fine wool, it may be proper to state the modes of treatment adopted in that country. It is generally believed in Saxony, and in other parts of Germany and Holland, that the practice of breeding from the same race
race, or what the English graziers technically denominate "breeding in and in," occasions a deterioration of the flock; owing to this prejudice, the Swedish farmers frequently change the rams of the Spanish race for others of the same race from neighbouring flocks, and some proprietors bind their farmers to renew a certain quantity of rams every year. But this practice is useless, where the rams upon an estate are already of a good quality; if the contrary were the case, there could not exist a perfect Merino sheep in Spain, as the sheep have continued to breed from the same flock, without any attention to confanuginity, for many centuries. The good quality of a race of sheep may be preferred, either by selecting the most perfect from the same flock to breed from, or by constantly taking out those which are most defective.

The common food of sheep in Saxony, during winter, is hay, which is distributed three times a day, in a greater or less quantity, according to the flock of the farmer: those who have not sufficient hay, substitute oil-cakes, crushed seeds, and lentils. They take care to mow the crops before maturing, that they may be more nutritive, and to prevent the falling of the leaves before mowing. Some farmers supply the deficiency of hay with powdered oil-cakes, crushed seeds, and meal; they put the cake or meal into troughs with water, which they give the sheep to drink, and afterwards they give them the solid residue, which sinks to the bottom of the trough. This treatment serves to keep them in a healthy state, at a feaon when they cannot have fresh food. Eight pounds of cake or meal diffused in water are given to every hundred sheep. When the snow remains long on the ground, they sometimes give them straw which has not been threshed, and even corn; but as this is expensive, they generally substitute roots of different kinds, such as beets, turnips, and carrots, but particularly potatoes.

The Saxon farmers collect with great care the horse-chef-nuts in autumn, which they give their sheep as a remedy against the rot. The nuts are cut small, to prevent them getting into the throat, and choking the animal.

They feed out their sheep in winter, when the weather permits, and the snow is not too deep, to the woods or dry situations sheltered with underwood. Proprietors who have no winter pastures, leave their sheep in the sheep-houses from the beginning of November to April, but they take care to turn them out each day in the fresh air, for three or four hours, and they keep open the doors, to cause a continual ventilation. Some proprietors keep their sheep confined the whole year, and where the sheep-houses are kept clean, and the sheep are supplied with proper food, this practice is not found to injure either the wool or the animal.

During fine weather in summer, they are allowed to range in the pastures. They leave the sheep-house after the dew is entirely diffused, and they repose in the shade during the heat of the day. This practice of providing shade during the hot weather cannot be too strongly recommended to the cultivators of fine wool in England, both with respect to the health of the animal and the improvement of the wool. Nor is another practice less deserving of attention, which is, to shelter them during heavy rains, hailstorms, and thick fogs. In many sheep-houses, water is conducted in troughs, from which the sheep may drink at pleasure. Saxon farmers consider falt not only as necessary to the health of sheep, but as contributing to the finenes of the fleece; it is sprinkled in their forage, and is diffused in their drink; it is given principally in summer, when the weather is dry. They cease to give it to the ewes five or six weeks before lambing, because they think that the excess of water which it occasions them to drink, is injurious to them at that time, and that it also prevents them from licking their lambs.

The rams and ewes are not put together before the age of two or three years: they allow one ram to twenty-five ewes, and leave them together day and night during the season. The lambs are kept in the sheep-houses, but some proprietors allow them to go out with the ewes after eight days.

Before shearing, the sheep are washed in the English manner, but with greater care. First they make them swim through a river or dam; the following day they are again driven through, and plunged in separately, and the fleece piled with the hands, beginning from the head, and passing on to the extremities of the body; they are again driven through the water in the afternoon. The fleece is suffered to dry during two days, and torn on the third. Saxon wool, thus washed, is much cleaner than the English, which generally undergoes but one washing. It lofes by a further scouring by the manufacturer, about 12 per cent. more than Spanish wool already scourcd. English wool loses about 25 per cent. in the hands of the manufacturer.

The general treatment of the Saxon Merino sheep we consider as judicious, but we have frequently noticed that the wool had been somewhat injured by want of sufficient nourishment in winter, which renders it tender. The hay being given in racks, feeds and straw falls into the fleece when the animal is eating, which the English manufacturer finds great difficulty in eradicating; this might be prevented, in a considerable degree, by lowering the racks, so that the food might be level with the head, or somewhat below.

As France is perhaps the most formidable rival which our manufacturers of fine cloths will meet in foreign markets, the progress made in the amelioration of her native flocks becomes an object of interest to the Englih agriculturalist and clothier. The celebrated minister Colbert first formed the design of improving the breeds of French sheep, by importations from England and Spain. But his intentions were at that time opposed. It was not till the year 1776 that the Spanish breed was introduced into France by M. M. Trudaine, intendant of finances, under the direction of the celebrated naturalist d'Aubenton. The experiments which he made on these sheep, and numerous crosses from them, with four distinct breeds, which he had on his estate in Auxes, demonstrated to the government that it was easy to introduce and prefer a race of sheep in France, producing superfine wool; and in the year 1786, a selecion of 375 rams and ewes, from the finest flocks in Spain, was conducted, under the care of a mayor, to the farm of Rambouillet. They consisted of individuals of extraordinary beauty, superior to any previously introduced into France, but having been chosen from a number of distant flocks, they presented great varieties of shape and size, which have since disappeared by intermixture; and a new race has been formed, differing from any of the primitive flock, but which equals the best of them in form and constitution, and in the fineness, length, softness, elasticity, and quantity of wool.

It is to be observed, that the wool-dealers and manufacturers in France were at first disposed to depreciate the value of the wool; but numerous accurate experiments having proved that the cloths manufactured from it were in every respect equal to those made from the best Spanish wool, these prejudices disappeared, and the republican government, as well as that of the emperor Napoleon, interested themselves in the further introduction of Spanish sheep into France. In the year 1802 it was calculated that there were one million sheep in France, either of pure Merinos, or of an ameliorated variety.
tionated mixed breed. Since that time many large flocks have been imported from Spain, the temporary command which the French obtained of that country having afforded them facilities for their introduction. In the course of a few years France will, in all probability, produce a sufficient supply of superfine wool for her extensive woollen manufactories.

The experiments which have been made by the introduction of the Merino sheep into the United States of America, the Cape of Good Hope, and New Holland, prove that fine wool may be grown wherever there are intelligent cultivators, and that it is not the gift of a peculiar soil or climate. We are, however, fully convinced, that very elevated temperatures will require greater care to prevent deterioration. The specimens of wool which we have seen from New Holland, appear to have been affected by an arid sandy soil, and by the great heat of the sun, which has in some degree injured the softness of the fleece. Between the tropics, elevated mountains and shade would be essentially requisite to preserve a race of fine-woolled sheep from degenerating.

The advantages which the Merino sheep possess as wool-bearing animals, over the native breeds of English fine-woolled sheep, confift in three important peculiarities: 1ft, the wool is much finer; 2dly, it is more regularly fine over the body; and 3dly, it is grown in a larger quantity from the same surface of skin. That the Merino wool is finer than the bell English, is proved from this circumstance: the bell forted Spanish wool, or the R wool, as it is called, from the finest flocks, sells at nearly double the price of the bell English forted wool, or what the wool-staplers call the prime and picked lock. Those English fleeces which yield a portion of the bell fort, generally contain a larger portion of inferior fots; sometimes eight forts will be found in one fleece, and the fleece will not constitute one-eighth of the whole. On the contrary, the fleeces of the Merino sheep are so regularly fine over the whole body, as generally to yield from two-thirds to three-fourths of the superfine or R wool. The second fort, called the F wool, is also fine; and with the T wool, or third fort, bears a higher price than the bell English wool. The quantity of wool on a Merino sheep is considerably greater than on an English sheep of the same fize: this is not owing to the greater length of the wool, but to the animal being more fully clothed over the body and legs; and the wool is also grown closer than on English sheep; that is, there are more filaments on the same surface. A moderate sized well-clothed Merino sheep will yield a fleece which, when brought to the same flaté of purity as the English wool, will weigh 3lbs. A Ryeland, Norfolk, or South Down sheep, of the same fize, will produce a fleece only weighing about 2lbs. The value will be nearly as five to two in favour of the Merino fleece. In this flaté, however, the Merino fleece is not clean, as the wools imported from Spain, which are scoured after they are shorn, and before they are forted, by which means it is much cleaner than it can be made by washing on the back of the animal. The Merino rams are horned, which is not generally the case with the ewes. The average weight of a fat ram per quarter, is about 17lbs. of a cwe, about 11lbs. per quarter.

The shape of these animals by no means corresponds with the symmetry of form which an English grazier confiders as the criterion of excellence. The legs are rather long, the neck curved, and from the throat there hangs a pendulous skin, or dewlap, which is very offensive to those who are only accustomed to view the improved breeds of English sheep. This appendage is valued in Spain, as indicating a tendency to produce wool. The colour of the skin beneath the wool, on the back and sides, is of a rote red colour: this is also confidered by the Spaniards as a sign of a robust constitution, and an abundant fleece. The only English sheep which have the same coloured skin with the pendulous dewlap, are the Ryeland, which produce also the finest English wool. In these circumstances, with the ancient practice of houing the sheep, continued in Herefordshire, where it is called cotting, confirm the opinion before advanced, that the Ryeland sheep were descended from the Tarentine race introduced by the Romans into this country.

It is not to be wondered at, that the Merino sheep, which are cultivated in Spain almost exclusively for their wool, and not for their flesh, should present that deformity of shape which at first was particularly offensive to the eye of the English farmer, accustomed to the new Leicester and South Down sheep. There cannot, however, be a doubt that the Merino breed is as susceptible of improvement as the English. Indeed there is a very great diversity of form in the flocks in different parts of Spain; and were the same attention paid to selecting the most perfect type from, as has been given in England to the South Down sheep, there is every reason to believe that a new race would be formed, polishing all the good qualities which both the grazier and the manufacturer might require. The South Down sheep, which have been greatly improved, and rendered almost perfect in form, have preserved all the good qualities of the fleece. This alone is sufficient to prove, that there is no necessary connection between deformity of shape, and the finesness of the wool.

The Spanish breed of sheep were first introduced into Great Britain in the year 1787. Some individuals of the black and spotted sheep had indeed been procured, and kept in the parks of noblemen previously, but without any regard to the wool; nor was much interest excited by the flock introduced in 1787. The sheep, however, lived, though treated in the English manner, and the wool had not deteriorated. These facts having proved that the Merino race might be naturalized in England, his majesty George III. obtained from the marquis of Campo Alajize five rams and thirty-five ewes of the Nigrette race. They were imported in the year 1792, and were for some time at Oatlands, the seat of his royal highness the duke of York. On their arrival they were extremely low in flesh, but they soon began to improve; and the diseases with which they had been afflicted, were removed by a plentiful supply of food. They left Oatlands greatly advanced in bulk, and with renovated constitutions; and the quantity and quality of the wool were greatly admired.

The prejudices of the manufacturers were not so speedily to be surmounted, as the difficulties attending the naturalization of the Merino sheep. Though the wool was admitted to be equally fine with the best imported wool from Spain, they would not offer a proportionate price, fearing that it might not prove equally good, when manufactured. It ought, however, to be stated, that the condition in which the English Merino wool was offered for sale, either very imperfectly washed, or entirely in the grease, prevented the manufacturer from forming a just comparison with the wools from Spain, which came to this country clean scoured, and regularly forted; nor could they appreciate the losi it would sustain in scouring, which is not less than from 60 to 70 per cent. We are well persuaded that this uncertainty respecting the losi in scouring, has, more than any other circumstance, retarded the sale of the English Merino wool, from the year 1792 to the present time. Nor will
our manufacturers ever greatly encourage the growth of this wool, until it be brought to market, either furred and scoured like the wools from Spain, or in the same state of purity in the fleece as the fine English or Saxon wool. Many manufacturers, who have purchased it, have been greatly disappointed, not in the quality, which was excellent, but in the small quantity which remained after scouring. In consequence of the manufacturers declining to purchase his majesty's wool, it became necessary to have it manufactured on his majesty's account, to demonstrate its fitness for superfine cloths. This was done till the year 1796, when it was resolved to sell the wool at the price which was offered, that the manufacturers might have a fair trial. The clip was sold that year for 2s. per pound, and the following year for 2s. 2d. In the years 1797 and 1798 the wool was forced in the Spanish manner, and scoured, after having been previously washed on the sheep's back. The following is an account of the produce.

</table>

The prices have, since that time, progressively increased with the price of Spanish wool, and have been nearly equal to that of the best piles from Spain. In the year 1801, the right honourable lord Somerville took a voyage to the peninsula, for the purpose of selecting such sheep as were in the greatest degree the excellence of the fleece with a good carcasse. His efforts were in a considerable degree successful, and, as far as related to the fleece, completely so. Since that time, particular political events have increased the facility of procuring Merino sheep from the various Spanish flocks; and the flock of these sheep in England at present is sufficiently great to change, in a few years, the whole race of fine-wooled sheep in Great Britain, which was such a change desirable. Many of the native flocks of fine-wooled sheep in England have been considerably diminished in the last forty years, owing to the numerous enclosures of fowls and common; that were formerly only suited to fatten a race of small light sheep; but which, in consequence of improvement, are now capable of maintaining a heavier race of animals; the former requiring a light dry soil, and an extensive range; and the latter, a rich and more confined pasture. The Ryeland sheep in Herefordshire afford the finest wool in England, of any of our native breeds; but the pure race is nearly extinct. The fleece weighs less than two pounds, but if generally cleared from the Shank-locks and skirts before it is wound, in this state it bears the highest price of any English fleeces. It is not a little remarkable, that the practice of cotting or housing the sheep is peculiar to Herefordshire; and it is not improbable but it may have been originally introduced by the Romans, with the race of sheep from which the Ryelands originally sprung. A mixture of the Ryeland sheep is spread over some of the counties adjoining to Herefordshire, but the number is not very considerable. The light sandy soil of Norfolk is pattered by another breed of fine-wooled sheep, which supply a considerable quantity of fine English wool for the Yorkshire market, and it is not only free from the property of Sufle, when manufactured, which is wanting in many of our English wools. The original Norfolk breed have black faces and spiral horns, small, long, thin carcasses, with long black or grey legs. The fleece weighs from one pound and a half to two pounds. The form of the animal is not such as to recommend it to the grazer, but it has been greatly improved by an intermixure with the South Down breed. Mr. Coke of Holkham, the celebrated agriculturist of Norfolk, has disposed of his native flocks of that county, from a conviction, founded on long experience, that they are an unprofitable breed. The principal recommendation of this breed was the excellence of their wool; and they might be well suited to the former uncultivated state of the sandy tracks in that district.

Of all the native fine-wooled breeds of England, the South Downs appear to polles, in the most eminent degree, the combined advantage of excellence of form, with a superior quality of the fleece. The average weight of the two-year old wethers is 18 pounds per quarter; the mutton is fine-grained, and of an excellent flavour. The weight of the fleece of the finest kind is about two pounds on the average. Some of the coarse fleeces exceed three pounds. The South Down breed takes its name from the district on which these sheep were originally cultivated. It is a long range of rather elevated chalk hills, extending from the south-western side of the counties of Kent and Surrey, through Sufle, into Hampshire, confining of open downs, well suited for sheep-walks.

The animal has no horns; its face and legs are grey; the bones fine, and the form compact. It has indeed greatly improved of late years, by the particular care of intelligent growers. The lambs are generally dropped from the middle of March to the end of April. If the ewes have been well kept, one-third will be twins. The wethers are fit for the butcher in two years; many graziers fatten them at 18 months. From the South Downs these sheep have been sent to different parts of the kingdom; and in all dry and rather elevated situations they will preserve the excellent qualities of their wool. Indeed, in all situations where the soil is covered by a good clove herbage, and the sub-soil is not calcareous, the wool will be of a superior quality to that of the same animal would produce on the chalky downs of Sufle. Of this we have had decisive proofs. The South Downs, though in many respects well suited to sheep, yet in those parts where the chalk is exposed, or near the surface, the calcareous particles get intermixed with the yolk or natural grease of the fleece, and produce a degree of hardflees in the wool, which is very perceptible, when it is manufactured into cloth: it also injures the felt-
ing quality of the wool. This is so well known to
Yorkshire manufacturers, that they always avoid the cloths
grown on chalk foils, when they want a soft thick pile to
the cloth. The fine wool from the South Down fleeces is
chiefly used for light goods, such as kerseymeres and pelleth
cloths, which require very little milling or felting. When
the South Down sheep are removed from chalk lands, the
wool may be grown remarkably soft, and possess all the
good qualities of the best native English wool.

The action of the foil on the fleece was long known to
manufacturers, viz. that wool grown on argillaceous foils
were softer, and proved better in the process of manufac-
ture, than those on calcareous foils. The cause of this was
involved in much obscurity, and generally supposed to be
owing to the quality of the herbage on different soils. Mr.
Bakewell, of Wakefield, in Yorkshire, in a little tract "On
the Influence of Soil and Climate on Wool," proved that
the influence of the foil on the fleece arose from the action
of the minute particles on the surface of the fibre or flake.
"Not only can this action affect the quality, but impart
indefibly the colour of the foil to the wool. In part of
Gloucestershire the fleece acquires a deep orange colour
from the foil. In Hertfordshire, and part of Warwickshire,
and in every country having a red soil, the wool is inclined
to brownish-red. Wool on chalky soils are distinguished
by their whiteness; and in every district in England the
action of the foil is evinced, by communicating its own
colour to the fleece. The colour thus acquired is as inde-
libly fixed in the wool as the colouring matter of an arti-
ficial dye, nor can its whiteness be perfectly restored by any
artificial process hitherto known.

"That the same cause can change the hardness or softness
of wool, is proved from the different effects which argil-
laceous, silicious, and calcareous soils are invariably found
to have on these qualities. This is perhaps no where more
clearly shown than in the northern part of Derbyshire,
where the flax are so abruptly broken, that two adjoining
farms, separated by a small brook, will not unfrequently be
found, the one upon lime-foile, the other on a silicious
grit or sand-foile. The difference of the wool on these
two farms, from the same breed of sheep, was so distinctly
marked, that the grower always obtained a higher price
when grown upon the latter foil. 'My wool is grit-foile,
and I expect a better price than my neighbours,' was the
language in common use, and the meaning was well under-
flood by the buyer. In the process of separating wool
from the skin by the fell-monger, the pelts are steeped
some days in lime and water. The softest wool, when thus
exposed to the action of lime, loses its distinguishing ex-
cellence, and acquire all the hardness of wools grown on lime-
foile foils.'

To remedy this injurious effect of calcareous foils, Mr.
Bakewell recommends the practice of the farmers in North-
umberland, and in North Britain, of anointing the skin of
the animal with butter, in which a small quantity of tar is
melted to give it confidence. In Northumberland this is
practised with the fine-woolled sheep on the Cheviots;
and the wool from these sheep bears a higher price in Yorksire,
in proportion to its relative fineness, than any other English
wool, on account of the superior softness of the cloth made
from it. The ointment is also used to defend the animal
against flies and sheep-ticks, and to be a prejudicive against
the severity of the weather. The only inconvenience is,
that the whiteness of the wool is in some degree affected by it;
and it is not suited for white flaved cloth, or for any delicate
colours. Could any good and cheap substitute for tar be devised,
there cannot be a doubt that the practice would be of great
benefit to the South Down fleeces on their native chalky
foils. It is, in fact, similar to what the Romans adopted
with the Tarentine breed, which were frequently washed,
and the skins anointed with the dregs of olive-oil, mixed
with other ingredients. A similar treatment of all English
sheep, after being shorn, would be found a most effective
remedy against flies and insects when the skin is exposed:
and it is also proved by experience to be a preferrible against
the feb.

The South Down breed, so far as relates to the fleece,
will admit of considerable improvement in the following par-
ticulars. First, it might attain a degree of fineness more nearly
approaching that of the Merino fleece; secondly, the fleece
might be grown more uniformly fine over the body; and
thirdly, almost all the South Down fleeces have a few
grey or black hairs intermixed, which is a great defect,
where the goods made from it are intended to be flaved
white. At present, the finest part of the South Down
fleeces, called by the wool-tapler the prime, does not bear
half the price of the prime Spanish, or R. wool, from the
best Merino flocks. In the South Down fleeces very rarely
more than one-fourth part is of the best quality; but in the
Merino breed full two-thirds of each fleece will be of one
uniform quality, and that the prime or R. wool. In the
South Down fleeces, those parts from the bellies, and
shanks will also be as coarse as the coarsest wool from heavy
sheep. These defects in the South Down fleeces are common
to almost all our native fine-woolled sheep, except the
Ryeland; but we conceive they admit of a remedy
without any injury to the form of the animal, or the weight
of the fleece. If the opinion of an intelligent wool-tapler
were first taken on the qualities of the different fleeces of
those ewes from which it were proposed to raise a stock,
and selecting for them some of the best formed rams bred
from South Downs and Merinos, called Anglo-merinos;
from this progeny the most perfect forms might be again
chozen: and if these were still too strongly marked with
the character of the Merino form, another cross with per-
fect South Down ewes would produce a progeny from
which a race might be selected possessing whatever was
desirable in the carcase, with a considerable amelioration of
the fleece, both in the fineness of the wool and the regularity
of the quality, over the greater part of the skin. The
weight of the fleece would also be increased, for the wool
is grown closer and thicker on the Merinos than on any of the
English breeds; and this property continues in the croffes
from that breed. The advantage of employing an intel-
ligent wool-tapler to judge of the quality of the fleeces
will be admitted, when we consider that a fibre of the finest
wool is perhaps little more than the two-thousandth part
of an inch in diameter; and that a variation from this,
which is too small to be visible by the unpractifed eye,
may occasion a difference in price not less than 40 per cent.
Indeed, it is truly astonishing that the eye can detect
this microscopic difference unaided by instruments. Nothing
but long and constant practice can secure the facility of
determining the fineness of wool; and the most experienced
dealer in English fine wool, were he to discontinue entirely
the examination of wool for three months, would not be able,
at first sight, to ascertain its quality and value to 15 or 20
per cent., supposing no change to have taken place in the
markets. Can it then be supposéd that a grazer, who
has never acquired this fine sense of vision, and to whom wool
is only an object of particular attention at one season of
the year, we say, can it be possible for such a person to be an
accurate judge of the quality of wool, and the comparative
fineness of fibres ranging between the fifteen-hundredth and

9
the two-thousandth part of an inch? Yet many of our English wool-growers will decide, with the utmost confidence, whether their wool be finer or coarser than it was in the former year; or rather, they will decide that their wool is always growing finer. To this great confidence of the wool-growers, and to their real ignorance on this subject, more than to any other cause, may be ascribed the little improvement in the culture of English fine wools prior to the introduction of the Merino breed into Britain.

The South Down breed, in its improved state, is likely to supplant most of the English fine-woolled breeds, except perhaps the Cheviots in Northumberland, which are become habituated to the severity of the climate, on the elevated hills in the northern parts of that county bordering on Scotland. This race we think much better suited to supplant the coarse-woolled sheep in the Highlands of Scotland, than another of our English breeds. The Cheviot sheep are described by Mr. Culley, an intelligent farmer in Northumberland, as hornless; the faces and legs are, in general, white; the left kinds have a fine open countenance, with lively prominent eyes; the body long, fore-quarter wanting depth in the breast, and breadth both there and on thechine; fine, clean, small-boned legs; thin pelts; weight of carcass, when fat, from 12lbs. to 18lbs. per quarter; fleeces from 2lbs. to 3lbs. The qualities of the Cheviot fleeces are various; some of them contain a small portion of fine wool, which, as we have before remarked, is more soft than any of our native English wools. The price at Lord Somerville’s annual show in 1813, for the finest cloth from English wool, was given to Mr. J. F. Smith, for a piece of cloth manufactured from the prime part of the Cheviot fleeces.

In general, the quality of these fleeces might be much improved by a judicious selection. The great defect is, that in the finest fleeces only, a small part is of the best quality. Some of the Cheviot sheep are speckled on the face and legs; but these are probably a mixed breed, from crossing at different times with Heath sheep, to whom they have long been neighbours; for leaving the heights of Annandale to the eastward, we infenstly lose the Heath sheep and mixed breeds; after which all the extensive fine green hills on the Scotch and English borders from the sides of the Cheviots to the barren heaths of Lammermuir are covered with the Cheviot breed. The best kind of the Cheviot sheep is certainly a valuable mountain-sheep, where the pasture is mostly green sward, or contains a large portion of that kind of herbage, which is the caese with all the hills around the Cheviots, where these sheep are bred; and the fine herbage which the border hills give every where produce, supports them well in summer, as to enable them to stand the severities of the winter.

The shape of this breed of sheep has been greatly improved of late years, but will still admit of much improvement. “We cannot (says Mr. Culley) expect the perfection of this breed of sheep can be obtained at once, it must proceed by slow gradation, as every other improvement hath done.

That breed of sheep which brings the moli profit to the farmer will always be preferred, but this object is not to be obtained in this district by fine wool alone. Perfect mountain sheep should be hardy, well-formed, and quick feeders. These qualities will always recommend them to the grazier; but if to these qualities, so essential to the use of a mountain farmer’s flock, can be added a fleece of fine wool, a breed of sheep might then be obtained, the properest for a hilly district of any we have yet seen. There is little doubt but this may be accomplished by proper selection, and probably the best kind of Cheviot sheep, from their hardiness, and producing a portion of fine wool, are the properest flock for laying the foundation of so desirable a change.”

With these sentiments of Mr. Culley we entirely agree, and particularly in the propriety of selecting from the finest breeds, from the Cheviots to lay the foundation of a valuable flock of mountain sheep, which might supplant the coarse-woolled Heath sheep in North Britain. Every situation may be said to have its peculiar advantages for particular breeds of sheep; and the rage for improvement, and desire of change, have in some instances been carried too far. There can be no doubt, that the rich pastures on the eastern side of England are better suited for heavy long-woolled sheep than for South Downs or Merinos, whilst it would be folly to attempt to stock the mountainous parts of Britain with the Difley or Lincolnshire breeds. But many of the flocks in the uplands are susceptible of much improvement by selection, without any admixture, and in very exposed situations it might not be desirable to attempt improvement by introducing a less hardy race. In dry and moderately elevated situations there are none of the fine-wooled native or Anglo-merino breeds, that might not be cultivated with advantage; but we are well persuaded, that with the present demand for, and price of animal food, the breed which will tend to the market the largest quantity of good meat in the shortest time, will have the preference over any superior quality of the wool alone. On which account the improvement of the South Down breed, which combines both advantages, is perhaps an object the deferring attention, in all situations suited for fine-wooled sheep, that are not too much exposed to the inclemency of the climate.

A particular race of sheep exist in the Shetland islands, which produce a fleece more like that from the sheep on the mountains of Tibet, than any of the European sheep with which we are acquainted. From the report of Mr. Thomas Johnson, addressed to the British Wool Society, it appears that there are two varieties of Shetland sheep.

One of these varieties carry coarse wool above and soft wool below, and have three different successions of wool yearly, two of which resemble long hairs more than wool, and are termed by the common people in Scotland isles and feuudas. When the wool begins to loosen at the roots, which generally happens about the month of February, the hairs or feuuda spiring up; and when the wool is carefully pulled off, the tough hairs continue fall until the new wool grows up about a quarter of an inch in length, then they gradually wear off; and when the new fleece has acquired about two months’ growth, the rough hairs termed forspire up, and keep root until the proper season for pulling it arrives, when it is plucked off along with the wool, and is separated from it at dreeling the fleece, by an operation called forfing. The feuuda remains upon the skin of the animal, as if it were a thick coat or fence against the inclemency of the seasons, which provident nature has furnished for supplying the want of the fleece. See the preceding article Sheep.

The native or kindly breed, which bear the soft cottony fleeces (as they are called), are rather of a delicate nature; their wool is short and open, and delilute of a covering of long hairs. These soft-woolled fleeces are very often loof or rubbed off, during the winter or early in the spring, which it supposeth might be prevented by clipping or shearing the sheep, in place of pulling off the wool, a barbarous practice, tending to weaken the sheep and hurt the length of the flake.

The Shetland sheep are of various colours; the silver-grey wool is thought to be the finest and softest, but the black, the white, the mornat, or brown, is very little inferior; it
SHEEP.

is all of the softest texture, fit for the finest manufactory, and in some instances has been found to rival Spanish wool itself; but the pure white is generally the most valuable for all the finer purposes for which combing wool can be used. For softfens and for lustre, no wool equals it; and the skin, with the fleece on, can be converted into a fur of very great value, some specimens of which have already been sent to the China market.

They are in general very hardy. In the winter season, when the ground is covered with snow, they eat the sea-weed very greedily, and often during long and severe snows they have little else to live upon. Nature seem to have imparted to them a perfect knowledge of the time at which this food may be procured; for immediately upon the tide beginning to fall, the sheep in one body run directly down to the sea-flakes, although feeding on the hills hundreds miles distant from the sea, where they remain until the tide returns and obliges them to seek their usual haunts.

It is to be regretted, that we know so little of this peculiar race of sheep, or of the time when they were introduced, and the country from whence they came. The wool, though intermixed with coarse hairs, polishes a most extraordinary degree of softness, approaching, if not equaling, that from the sheep of Tibet, and might, if proper attention were paid to it, be applied with advantage to the manufacture of shawls and other articles now imported from the East. None of the European wools which we have seen, polishes this quality in any degree to be compared with that from the Shetland sheep. The circumference of the fine wool growing as down under a pile of coarse wool or hair, is not peculiar to these sheep. We believe that unmixed fine wool is rather a product of cultivation than natural to the animal in a wild state. In the argali, as well as in numerous animals, the inhabitants of cold countries, the skin is covered with a short fine down, and this is protected by a covering of longer coarse hair growing through the former. By regular keeping and warmth, the coarse hairs fall off in many animals, and this has probably been the cause originally with all our fine-woolly sheep, many of which, if neglected, few indications of their original condition, growing coarse hair intermixed with the finer parts of the fleece. Even in the coarser-woolly sheep of cold countries, such as the Heath sheep in the Highlands of Scotland, we have often seen a small portion of fine wool growing under the coarse fleeces with which these animals are covered. It appears to be a benificent provision of the Author of nature, to accommodate animals to different climates. European sheep removed between the tropics, languish and become sickly from excessive heat, and lose their fleeces in the course of the ensuing year. They are afterwards covered with a thin crop of coarse short hair. We have seen a finely-shaped ram, of the European breed, brought from Louisiana, which was entirely covered with white hair, as coarse and short as that on a dog. We have no doubt, however, that in hot climates, when sheep have the advantage of a mountain pasture, that with care and proper shelter these fleeces might be preserved, but they would certainly be a useless incumbrance. Fine fleeces seem to be more particularly the produce of cool or temperate climates; for it is observed, in most of our English sheep, that the part of the wool or flâpe which is grown during winter, is finer than that part which is grown in summer. Extreme heat and cold appear to have both an effect upon the skins of sheep, to cover them with coarse hair; but in cold climates there is also a tendency in the animal to produce a fine down underneath. It is not improbable that the Shetland sheep may have been originally descended from the Tarentine breed, the "molles ovae," which the Romans had introduced into Britain; their infallible situation protecting them, in a considerable degree, from intermixture. For, according to Dr. Anderson, though the coarse-woolly Heath sheep are introduced into these isles, the native active sheep frequenting the more defolate wilds at the greatest distance from man, withdraw themselves from the others, and thus the breed is only partially debased by accidental fraggles. The whole system of management, respecting these sheep, is directly the reverse of what it should be, and it is truly alarming that they have preferred to long the peculiar softness of the wool. Could these sheep be introduced into more favourable situations, and proper attention paid to them, we have no doubt that their wool might be grown free from the coarse hairs with which it is at present intermixed; it would then be of far greater value than the finest Merino fleeces, as it might be applied to the fabrication of shawls, approaching in softness to those of Cashmere.

We have now to describe the long-woolly breed of sheep, which may be considered as almost peculiar to Great Britain and Ireland; for though sheep of this breed are found in Flanders, and some other parts of Europe, their number is inconsiderable; and they have no exift with the fame perfection of form, and producing the same quantity or quality of wool as in the united kingdoms. Their fleece is the envy of the other manufacturing countries of Europe, and can only be grown upon rich pastures. Long combing wool, and the varieties, will be described under the article Wool; but it may be necessary here to state that the longer kind varies from six to about nine or more inches in the length of the flâpe, or filaments. In the manufacture of this wool by the comb, the fibres are laid parallel; whereas in short-clothing wool, they are broken in all directions by the cards.

Long wool is manufactured into shalloons, camblets, morrens, bombazesens, and various other articles; and a large quantity is also manufactured into what is called hose millinery, confisting of girts, fringes, and other articles of use or ornament in equipges. The coarser kind makes the warps for carpets.

Short combing wool is manufactured into hosiery.

The Lincolnshire sheep may be considered as the original of our heavy sheep in England. These, with the new Leiceter or Didley breed, have nearly supplanted the other varieties of long-woolly sheep. The Lincolnshire breed has also been generally somewhat changed of late, by an intermixture with the Leiceter breed. The original Lincolnshire sheep have no horns, and long carcases; the ewes weighing from 14 lbs. to 20 lbs. per quarter; the three-year old wethers from 20 lbs. to 30 lbs. The average weight of the fleece is about 90 lbs., or three fleeces to the tod of 28 lbs. Some of the heavier fleeces weigh 14 lbs. The richer parts of Lincolnshire will support five of these sheep on the acre; and when we take into account the price of the wool, which in 1814 was 24, per pound, it will be seen that the sheep of this description are the most profitable for the lands to which they are suited. The improvement made in their form, by the mixture with the Leiceter breed, reduced the weight of the fleece, but the extraordinary demand for heavy combing wool is inducing some of the farmers to return to their heavy breed. It is probable that this kind of wool will soon fall under 13. 6d. per pound; and the production of a fleece, which weighs 10 or 12 lbs., must be an object of attention to the grower, not less than that of the carcase. For though the wool from the Leiceter breed is somewhat finer, the weight seldom exceeds 7 lbs., and the difference of price is not more than about 24.
per tod of 28 lbs. The advantage of the latter breed consists in being made fit for the butcher in less time; in this it excels all the other breeds before known. At the time when Mr. Robert Bakewell of Ditby, in Leicestershire, directed his attention to the improvement of sheep, the price of long wool was less than 4d. per pound; the fleece was hence of little value to the grower, and Mr. Bakewell was exclusively employed in improving the carcasse of sheep, and all other domestic quadrupeds. Previously to about the middle of the last century, little attention was paid to the improvement of live-flock, except horses. Nothing could be more repugnant to common sense than the general practice of farmers; they selected for daughter that part of their flock which was most disposed to fatten, as offering them an early profit; the remainder were left to breed from promiscuously. A considerable part of England was then unimproved, and the flocks of different proprietors being unavoidably intermixed, prevented a due regard to the improvement of the breed. Mr. Bakewell commenced his improvements subsequent to the year 1760, and succeeded in exciting the attention of the public to the amelioration of live-flock, by shewing the most effectual method of accomplishing this important object. The principal object which Mr. Bakewell had in view, in his improvement of different animals, except horses, was to produce the greatest weight and value of flesh, with the smallest expense of food.

Vailing himself of the observations which he had made on different animals, that certain peculiarities of form were always attended by a disposition to grow fat, and that animals inherited this disposition from their ancestors; and if they were kept free from intermixtures with other breeds, in the course of a few generations the peculiar properties will be perpetuated, and form a distinct species; the laws of animal life being in this respect regular and permanent. He, therefore, selected from his own flock, and from the flocks of others, those sheep to breed from, which possessed in the greatest degree that perfection of form he was desirous to attain and perpetuate. By judiciously crossing them, and selecting the most perfect of their progeny, he at length succeeded in forming the breed, which has been distinguished by the name of the new Leicestershire breed; and having attained his object, he carefully guarded against any future intermixtures with other breeds. This breed excels all others in its propensity to fatten; and by crossing with rams from this breed, a very considerable portion of the long-wooled sheep in England have been greatly improved in this respect.

The peculiar characters of these sheep have been well described by Mr. Cudley, an eminent grazier in Northumberland, who introduced the breed into that part of England.

"The Ditby breed are particularly distinguished from other long-wooled breeds, by their fine lively eyes, clean heads, square, broad, flat backs, round (barrel-like) bodies, very fine small bones, thin pelts, and inclination to fat at an early age. The latter property is probably owing to the before-specified qualities, which, from observation and experience, there is reason to believe extends generally through every species of domestic quadrupeds. The Ditby breed is not only peculiar for its mutton being fat, but also for the finenesse of the grain: the flavour is superior to the mutton of most other long-wooled breeds. The weight of the carcasse may be stated in general: ewes, three or four years old, from 18 lbs. to 26 lbs. per quarter; wethers, two years old, from 20 lbs. to 30 lbs." The fleece is flated by Mr. Cudley at 38 lbs.; but in Leicestershire, we believe, the average weight is not more than 6 or 7 lbs., about four and five to the tod. The wool is finer and shorter than the Lincolnshire, and a portion of it is better suited for the hosiery trade than for thin goods, such as stockings, &c.; but considering the difference of weight, the fleece is not so profitable to the grower as that from the Lincolnshire sheep.

There are two reasons for killing the wethers of the Ditby breed at two years old: first, they leave the most profit; and, secondly, if kept longer, they grow too fat for gentry tables. It is very common for two-years old wethers to cut four inches thick of fat on the ribs, and from two to three inches all down the back. Even ewes of this kind, which have bred andangkan lambs till July, when killed about the Christmas following, will frequently measure four or five inches thick of fat on the sides, and two or three inches down the back, all the way from the head to the tail; and though sheep of this breed are not eminent for much tallow, yet ewes, under such circumstances, generally produce from 18 lbs. to 24 lbs. of tallow each. This mutton is not so inviting as the leaner kinds, but it finds a ready market among the manufacturing and laborious part of the community.

The graziers in different parts of England, who had been too negligent respecting the improvement of flocks, no longer became sensible of the possibility of forming a race of sheep, that would produce a large weight of meat in a much shorter time than before known, that they became desirous of introducing the breed; and the table for growing fat mutton became generally adopted, and in many instances without proper regard to other considerations. In some instances, fine-wooled flocks were crossed with this breed, and it was widely expected that they should preserve the quality of the wool, and increase the carcasse at the same time. In other instances, the Leicestershire breed were introduced on land only suited for a lighter race of sheep; and even where the pastures were suitable, the propensity to fat was encouraged, until it became a disease, and the animal was scarcely able to move under its own weight. Whatever the advocates of this breed may advance in its support, it cannot be contended that the mutton is equal in favour to that of the smaller sheep.

The object of Mr. Bakewell was in these instances mistaken; it was not to produce meat for the tables of the rich, but to supply substantial nourishment for the working classes. We have heard him say, "a small quantity of this fat meat, cooked over a large dish of potatoes, is a good dinner for a poor man's family; and this is what I proposed in the selection of this breed."

The increased demand for animal food could not have been supplied had not some improvement taken place, and the working classes will ever prefer the fatted meat. In this respect they resemble the North American Indians and the back settlers, who regard fat as the only nutritious part of meat, and accordingly Volney describes the lean by a name which signifies meat bread. The rage for excessively fat meat has in some degree subsided, and the new Leicestershires are likely to be confined to those districts which are peculiarly suited for their growth, and the object of the grazier will be directed to producing a large quantity of meat for the consumption of the working classes. Instead of attempting to improve the fine-wooled breeds by crosses with a heavy race, it would be more judicious to pursue the same plan of improvement with those breeds which Mr. Bakewell attempted with such success in the heavy sheep.

The improvement of the carcasse may, we are convinced, be effected without injuring the quality or diminishing the quantity of the wool. Of this Mr. Bakewell was well aware,
SHEEP.

aware, but the price of wool in England at the time of the American war (the period of his celebrity) was so low, that he used to say, it would be defirable to grow sheep without wool, and confine the attention to the carcase exclusively.

In selecting the most profitable breed of sheep for a farm, it can never answer to flock hilly districts with a heavy race of sheep, and in such districts the improvement of the wool is an object more particularly devoting attention, because we believe it would be possible to grow an equal weight of wool of a much finer quality than what is produced by many of our coarse-wooled breeds of sheep, and particularly by the Heath sheep, which pasture the mountainous parts of North Britain.

In rich pastures, weight of carcase must in a considerable degree supercede the improvement of the wool, at least so far as relates to its finer flees; for the real interest of the grower of long wool is to produce a heavier fleece. At the present price of wool, a Lincolnshire fleece of twelve pounds being more valuable than any other native English fleeces. To combine, therefore, the perfection of form in the Difhley breed with the heavy fleece of Lincoln, is what will best reward the owners of long-wooled fleeces.

There are, besides long and short-wooled sheep, numerous fleeces which produce wool suited for the comb, but of a finer and shorter kind than the heavy combing wool. The worsted yarn made from this wool is spun soft, and manufactured into hosiery. A very considerable quantity of wool, suited for hosiery, is grown in the county of Kent; but the breed of sheep which produce it, has not any distinctive name, and appears to have originated from an intermixture of the short-wooled sheep of the southern counties with heavy long-wooled sheep. We believe there is no country in Europe, which at present produces combing wool of this kind equal in quality to that grown in England. See WOOL and WORSTED.

SHEEP, Stealing of, is now made felony without benefit of clergy. See CATTLE.

By an ancient statute, no person shall keep, at one time, above two thousand sheep; but lambs are not to be accounted sheep till they are a year old. (25 Hen. VIII. c. 13.) Persons exporting sheep shall forfeit them, and 20s. for every sheep, &c. (12 Car. II. c. 32.) And persons in the counties of Kent and Suffolk, within ten miles of the sea, are to give an account, in writing, after sheep-shearing, of the number of fleeces, to the next officer of the customs, &c. (9 & 10 W. III. c. 40.)

SHEEP, Cladding of, in Agriculture, a term given to the busines of preparing the ewes of them for lambing in some places, which commonly takes place about a week before the lambing season commences. In such cases the ewes are usually driven into a pound, when the clatter, looker, or shepherd, draws them out singly and separately, turning them upon their backs, and removes with the shears the locks of wool from the underfides of their tails, from about their udders, and from the insides of their thighs. This becomes necessary, in consequence of the dirt and filth which often adheres to the wool about these parts, especially in moist growing spring seasons, when the ewes are affected with much purging. The wool being removed in this manner, not only renders the parts more neat, but enables the lamber, or person who has the care and direction of the busines of lambing, to dilinguish when the ewes have lambed, by the mark or flain which is generally left on the back parts of the udders; as, if such marks were not to occur, he would sometimes be at a loss, as the young ewes not unfrequently defert their lambs, and endeavour to escape along with the other ewes, pafuring as unconcernedly as if nothing had happened to them.

Some think, that it would also be a good method at this time to have the different ewes marked in a different way about the face, in the order of their lambing, and to have those of different forwardness put together into separate suitable pastures, to be taken care of in the most proper ways.

The barren ewes, or those not with lamb, are likewise now distinguished by the clatter, looker, &c. by their not having any enlargement of their udders or their bellies, as well as by their jumping and skipping about in a nimble manner; such being usually turned off directly upon the fattening grounds.

SHEEP, Lambing of, the busineses of managing the lambing of the ewe flocks, which is very essential and important, though but little known or attended to in many places, even where sheep are at once the whole flock of the farmer. However, in consequence of this, and the employing of unskilled persons, much loss is not unfrequently sustained, to the great injury and inconvenience of the sheep-grazing farmer. In some situations, as those of the enclosed, dry, and warm kind, and the more poor mountainous ones, as well as the upland pastures and downs, such a very minute attention to this busines need not, perhaps, be bestowed, as accidents less frequently occur, than on rich pastures or marshes, where the lambs are much exposed to danger and destruction from many causes, unless very carefully attended to at this time. The nature of the principles and practices which are necessary in the busineses of lambing, are, in short, yet much too confined and too little known to sheep-farmers in general to be of any great advantage. The first thing which is requisite in preparing for this busines, is the making choice of proper dry warm fields and pastures for the purpose, and having them made as safe and secure as possible from the danger of all sorts of accidents and inconveniences to the lambs. Where they have large wet open exposed ditches, or any other sort of inconvenient fences on their fides or other parts, they should be well guarded and secured by means of suitable low dead or other hedges being raised on the fides of them, by the use of small light hurdles, about two feet in height, with two rails, fixed down around them or in the most dangerous parts; by placing brush-faggots of a proper size round the fides of their banks, and faking them well down to prevent their being disturbed by the winds and storms: by hanging old sea-nets along their banks or borders: or by some other kind of cheap low defence, which the local nature of the situation may suggest. The nature of the pastures for this use should constantly be such as are fine and short in their grasf, and neither of too poor nor too rich a quality, as inconveniences are liable to take place from each of these fates.

It was formerly the practice to have the lambing of the ewe flocks performed on a great breadth of pasture-land, as two or three to the acre, or in a very thin manner, which was extremely troublesome; but it is now found that much benefit attends its being done in a clofer or thicker way, as ten or twelve more to the acre, in some cafes; as it is not only more convenient and successful, but far more profitable. By thus doing it in a narrow compass, according to the state of the grasf, the work is more safely gone on with, is more under the direction of the manager, and more convenient in case of difficulties arising in it, while there is much less danger of lobs among the ewes in consequence of the nature of the keep, which is very material, as it is often
often by no means inconsiderable, especially in certain circumstances and situations towards the close of the lambing season.

In some places it is not unusual, before the lambing takes place, to provide a better fort of pature-field for the reception of such ewes as may chance to have twin-lambs, as more food is required for them. This is best when in or near the middle part of the lambing pature, as the ewes and lambs, in that case, can be the most readily and conveniently removed, whereas in other circumstances there is often much trouble and difficulty caused with the young lambs, which should always be marked and removed as soon as they are enabled to walk.

The next preparatory business, in some situations, is that of clathing the ewes, which commonly takes place a little before the lambing begins; but in many places this is wholly neglected and thought quite useless. See Sheep, Clathing of.

The lambing season takes place at different periods in different places, according to the nature of the situation and other circumstances, and often a week or ten days sooner or later in the same situation, as the season may be more or less favourable, and the flocking of the land has been more light or more hard. But about the beginning of April is probably the best and most general time. Early lambing is mortally advantageous, where the circumstances of the land will admit of it. The season of lambing mortally continues about a month, and in some places, where lambers are employed without any lookers, two guineas and the lamb-laws are paid for that time.

In the actual business of lambing, much care and attention are necessary in the person who has the direction and management of it. In all natural cases of this sort the law that is done, perhaps, in general, the better, as nature will for the most part effect the business in the safest and most proper manner. The chief difficulty, it has been said, consists in knowing when the ewes should be affiled, as young persons employed in this management are much too apt to interfere, from which much mischief and loss unfortunately proceed. The nature of the particular case, and the workings of the ewes, should constantly be the principal directors in this matter. Some conceive, that when ewes have been at work some length of time, they should be affiled; others, that when the lambs' tongues are protruded from the mouths, they should have affilation; but neither of these rules is always to be depended upon.

There are still others who think, that when the ewes rise and walk off on being approached without any thing being the matter, they require no interference; but that when they will not rise, but appear a good deal spent, they should have immediate affilation. Some also suppose, that considerable force may be exerted in such cases without danger. But though there may be some truth in the remark, it is always necessary that much caution should be taken where force is employed on these occasions. Besides these, something may probably depend upon the state of the ewes in this business, as affilation will be left necessary in such as are cold, than when they are warm. The ewes should, in fact, never be meddled with in their lambing, in their cases, until there is an absolute necessity.

In all unnatural cases of this kind, which vary very much in different instances, according to the nature of the unnatural part of the lamb which may present itself, and which require the affilation of proper persons; those who have had the fullest experience, and are the most cool and cautious, will be the most proper for performing the business, as where this is not the case, there will often be great loss of lambs, as well as of ewes. In every case of this nature, where much force, or any other means are necessary to be employed, very great care and circumspection should cautiously be used to have it exerted and done in the most gentle, deliberate, and safe manner possible, as otherwise much danger and inconvenience may arise, that might have been avoided.

In some instances, where the lambs are apparently dead when they are lambed, they may be recovered and restored by forcing air into their lungs in an easy manner. This should however always be done with caution afterwards, otherwise it seldom succeeds.

As soon as the lambs are brought forth, they have commonly some milk from their mothers given them, or are allowed to suck them for some little time, which are supposed to increase the affection of the ewes for them; the lambs being at first left as close by the noes of the ewes as possible, which should be done quickly, that they may not go away without noticing them. The lambs are always greatly strengthened and improved by the ewes licking them, which they constantly do, where they have a proper affection for them.

When lambs droop and hang their heads immediately after they are lambed, they are bad and unfavourable signs, as showing them to be in a weak and dangerous state. The practice often made use of in some places, of putting the tail of the lambs, which is just lambed, into the ewe's mouth, in order to promote her affection for it, is very silly, and of no avail.

In the catching of all ewes in the lambing state, every fort of exertion, trouble, and fatigue, is to be injured them, should be avoided as much as possible; in order that they may lamb, or be affiled to lamb, in a cool suitable state.

During the time of lambing, the looker, or other person who has the management, should be very careful and attentive early in the mornings, and at other times, in looking over the ewes and lambs, so that they are not injured or hurt by neglect in any way.

In cases where this business is carried on upon a large scale, when every thing has been properly prepared and got in readiness, the lambher, or other person employed in the management, begins his labours and difficult undertaking, by entering and going over the lambing pature at the time of day-break, with his lamb-hook in his hand, that he may notice and examine the ewes, raise up such as have lain down, and determine whether such lambs as are dropped be capable of sucking, which is commonly readily decided by the length of the belly. In cases where this last is not able to be done, the ewes are either caught, and the lambs struck, or the lambher is provided with some ewe's milk in a bottle for the purpose, a precaution which is usually proper on many occasions, as when the weather is severe, wet, and stormy, in which circumstances the lambs quickly perish, if not supplied with such food. This attention often strengthens the lambs in a wonderful manner, and prevents much trouble in removing them and the ewes to the pounds. The continuance of the affection of the ewes is proved by the callings and noises they make. The twin lambs are now usually marked, to prevent confusion, as the ewes frequently leave one of them, after which they are not meddled or interfered with for some little time, as a few hours, or a day; as their strength may be; but as soon as they can walk, they are mostly removed with the mothers into better keep. The ewes which have single lambs commonly remain in the pasture-fields where they have lambed, unless the number be great, in which case, the lambs with the ewes are occasionally removed into the pasture-fields, where they are intended to be kept during
the summer. It is supposed, that by the above practice the lambing pastures are sometimes less discommoded, than is the case where too great a number of ewes and lambs are crowded together. Sometimes, when an ewe has lost her lamb by any accident, and yet is deemed capable of bringing one up, a twin lamb is given her. When a weakly lamb, however, is put to an old ewe, the milk is often too strong for it, and will speedily cause its destruction, by scouring or in other ways; such lambs are likewise incapable of keeping the udders of the ewes properly drawn, by which means much injury is frequently done to them. These ewes are therefore often better turned off for fattening, than being employed in this way. Various methods are practised with the ewes which have dead lambs, by using such lambs so as that their affections may be increased, and the ewes be drawn into the pounds, and have other lambs put to them. All such measures, however, often fail. The custom of running the ewes down to get them into the pounds is always very bad, as frequently causing their destruction. The ears of ewes being flapped down, and the ewes not looking back, are in every case bad signs of affection, but the contrary good ones. Lambing pounds are mostly supplied with suitable pens or coops for the convenience ofucking the strange lambs in. And the coats of the natural lambs are sometimes employed on the others. Whatever is done in this way, must, however, be done by deception, and not force, as the ewes are very refractory. Many other modes are had recourse to in different cafes for taming the refractory ewes, and causing them to fuckle the lambs in a proper manner.

It will now be necessary for the lammer to be particularly careful of the twin and other lambs, to see that they are regularly kept, and properly fuccked in all cafes, especially those which are in a weakly state. For this purpose some milk of the cow or other kinds is often carried and made use of by him, which prevents trouble afterwards. In these intentions, it is proper to go over the fields twice or oftener during the day; and to be particularly attentive in cold stormy weather. All forts of accidents and dangers are at these times to be looked to, and guarded against in the most cautious manner.

About the end of the first week of the lambing season, one-half of the ewes will mostly have lambed, and more than two-thirds of them probably at the termination of the second, when the ewes may be brought into a fea compas, and the lambing-field or pasture be cleared of all the twins and molt of the single lambs, and they which are necessary may be had ready to cut, which in suitable circumstances is often done at this early period, by which the manager will be freed from much of his future labour and trouble.

By this fort of cautious attention and management in the lambing of the ewe flocks, and the use of proper forts of shelter, a vast saving of lambs and ewes may in all cafes be made, and the interefts and profits of the sheep-breeding farmer be greatly aided and promoted. See Sheep.

Sheep, Names of, the several names which are given, applied, or appropriated to them, at different ages, in different parts and places where they are much kept. These are very numerous, and of a very local nature; but the following are the greatest part of them.

These arbitrary names, which are given to sheep at different periods of their existence, in different parts of the country, serve to guide the breeding and grazing sheep-farmers of such places in their management with these animals.

Sheep, Smearing of, the practice of salving or laying them over with some sort of substance of the unctuous kind, for the purpose of improving the wool, and preferring the animals from disease. It is only had recourse to in some districts, and those mostly in the northern parts of the kingdom. See Salving of Sheep.

Raw unboiled tar, not mixed with butter, is sometimes very dangerous and hurtful to sheep, especially rams, when laid on in large, or even moderate quantities. There are, indeed, some forts of tar which are very acrid, and blister sheep, causing the wool to fall off, and the death of the animals. When it is thin, and appears black on ftringer, with an offensive smell, and caustic acrid taste, it should never be used for sheep, especially without boiling, to destroy such properties. The persons engaged in the work of salving often find proofs of the danger of this sort of tar, in the burning effects which it has on their fingers. Good salving tar, it is said, on being firmed, has a thick, brown, ropy
ropiness, and a more pleasant smell, with a less acid taste than the other kind. Tar should probably always be well mixed with butter in performing this sort of work.

**Sheep, Teeth of**, the parts of the mouth of these animals by which their ages are often, in some measure, ascertained. When full-mouthed, they have usually eight teeth of the inferior kind in the lower jaw. They throw up two such each year until this takes place, by which means their walking teeth are displaced or lost. See Age of Sheep, and Teeth.

**Sheep-Shearing**, in Rural Economy, the business of clipping or cutting off the coats or fleeces of sheep, by means of shears constructed for the purpose, which are termed wool-shears. It also sometimes signifies the feaçon in which this sort of work is usually performed, which was formerly, and is even in some cafes at present, a sort of festival. The operation is performed in different ways by different persons, but the best mode is that of the circular, or round the sheep, instead of the longitudinal, which is at present most in use. It is usually performed about June or July, according to situation and season, but should not be done either too early or too late, proportionately, as injury and inconvenience may attend either extreme. A good clipper is capable of clipping from seven to fourteen or fifteen, and up to twenty or twenty-five in the day; and more are frequently done by very expert persons.

Good care should be taken not to cut or prick the animals; but where this accident happens in the northern parts of the kingdom, they touch the part with a little tar, or sheep-salve; and in Sweden it is often done with train-oil and resin melted together. In addition to what has been already observed on this subject, it may be stated, that much improvement has taken place in this art, especially in the more southern districts of the kingdom, in making use of the mode of clipping round the sheep, which has gradually extended itself from the northern districts of the island; by which means wool is left by being left upon the sheep, and the busines is performed in a more expeditious, neat, and convenient manner. It was much the practice formerly to clip lengthways of the sheep, and in some cafes in many different directions, according to the convenience of the person who executed the work, by which means it was often ill done. And in Ireland it has been stated, that they clip in short strokes, catching a bit of wool first in one place and then in another; and that if they are not looked narrowly after, they will leave many parts, such as the heads, tails, and interfides of the thighs, untouched.

We have, in speaking of sheep, noticed the most proper periods of performing this very important operation; and the following remarks, by Mr. Price, an excellent sheep-farmer in the county of Kent, with the comments of Mr. Culley, as stated in the Annals of Agriculture, will shew the proper mode of managing the sheep in the time of shearing, as well as the manner of executing the busines with these sheep-masters. It is stated by the former, that the sheep-shearing in Romney-Marsh commences about Midsummer, and finishes about the middle of July. Those who shear first, think they escape the effects of the fly, and those that shear late, apprehend they gain half a pound weight in every fleece, by the increased perspiration of the sheep. In early shearing the wool has not the condition which it afterwards acquires, but the hot weather occasions a good deal of trouble in detecting the fly. In order to begin, a large pen is filled with sheep ready for the coming of the shearers, in number from four to twelve, in proportion to the extent of the flock. The time employed is from two to four days. The sheep are led into a small pen, thirty or forty at a time, and when taken out to be sheared, all except three, more are put in, because one or two only left would be apt to jump out. A boy keeps the gate, and the account of the number sheared, with small laden tellers. These shearers by profession differ much as to quantity and method of performance; never begin early, but are satisfied with eight or ten hours shearing; a good shearer will shear ten an hour, a bad one seven. Their emulation tends only to dispatch and profit, not excellence of performance, and the sheep are too often pulled about in a rude and barbarous manner, and even wounded by the shears with cuts of the length of three or four inches, and the wool left unevenly thinned; tar, or some ointment, is then applied carefully by the boy, in order to keep off the flies. The master's office is usually to give the pitch-mark, and when one field is finished, the sheep are returned, and others are in readiness to take their place.

The common mode of catching the sheep is by the hinder leg, drawing the animal backward to the adjacent shearing-place, the hand holding the leg to be kept low; when at the place it is turned on its back. Or they are moved bodily, or one hand placed on the neck, and another behind, and in that manner walked along; the right, or common mode, he thinks the most safe. The parts of sheep fed on rich patures, and flethy, if handled hard, and bruised, are liable to fatal mortifications; an accident which often happens, on which account the pens upon some lands are obliged to be lined with woolen, or many would die from bruises. The price of shearing is 18d. or 2s. a score, with a dinner, and 2s. 6d. or 1l. a sheep without victuals, but with drink. They vary much in different places. A good wind will wind 400 fleeces a day, at the same price per hundred as the shearer has per score.

The method of shearing—the left side of the sheep to the shearer's left leg, his left foot at the root of the sheep's tail, and his left knee at the sheep's left shoulder. The process commences with the shears at the crown of the sheep's head, with a straight cut along to the loins, returning to the shoulder, and making a circular sheared round the off-side to the middle of the belly; the off hinder leg next; the left hand holding the tail, a circular sheared of the rump to the near back of the sheep's hind leg; the two forefeet are taken next in the left hand, the sheep raised, and the shears set in at the breast, when the remaining part of the belly is sheared round to the near rife; lastly, the operator kneeling down on his right knee, and the sheep's neck being laid over his left thigh, he shears along the remaining side.

However, on these statements Mr. Culley has made the following practical comments; namely, that Mr. Price's observation is just, with regard to the benefit arising to wool from being late clipped, and that it is consonant with the opinion of the Lincolnshire graziers and breeders, who have paid more attention to the subject, and understand it better than any other of the profession in this island; but very great attention is required from the shepherd to keep the sheep, under the circumstances of late clipping, free from the fly and maggots, also from the danger of being beaten by small flies, which, if fallen upon those parts where the points of the shears have made the smallest scratch. But that, in regard to shearing seven or ten sheep in an hour, nothing can be more absurd and improper than such attempts, since it is impossible for the best shearer to clip the lowest number within the time, and perform it well, as it ought to be done. Forty years ago, the same absurd practice prevailed in Durham, and particular men would clip sixty or seventy of that large breed in a day; but the consequence of such improvident haste was, that besides imperfect shearing, large pieces of skin were cut, particularly from the bellies of the sheep, which,
when, being constantly pestered and tortured in those parts by the flies throughout the summer, suffered much injury in their health and condition, some of them never recovering. Several sheep have died immediately after shearing, owing, perhaps, to having their legs tied, which, with hurrying and toffing them about, brought on a colic or cramp, putting a period to their existence in a moment. At that time, in a flock of two hundred sheep, we seldom escaped without the loss of one or two in a season; since, in the clipping of three thousand and upwards annually, we have not lost one these seven years. But, says he, instead of tying their legs, and trying who could clip the most per hour, or day, we have wisely begun to try who could clip the best, and from that change of system, instead of clipping fifty sheep per day, we think it a fair day's work to clip twenty-five upon an average. Where sheep are clipped by the great, and the men paid for number done, thirty or upwards may be sheared in the day; but ours are done by the day, without hurry, and fearlessly winding a sheep in the day. Each shearer makes his peculiar mark on the sheep, red or blue, that bad shearing may be detected; an useful stimulus to exertion. And he thinks that the sheep may be caught by the hinder leg, above the hough, but not by any means drawn backwards; on the contrary, as soon as the catcher has caught the sheep by the hough, he should draw it backwards, until he can, with his left hand, reach the throat, then, with the right hand behind its tail, he conveys it along with ease and safety. He thus continues: thirty years ago, it was the general practice in this county (Northumberland), and some old-fashioned bigoted people adhere to it still, to shear the sheep thus; the clipper first opened the belly, and then, after tying all the four legs, fat down upon a jack filled with straw, the sheep lying between his legs; when, in the most awkward manner, he flushed and tore the fleece off, beginning at the neck, and going down the left side first, finishing at the right. Instead of clipping around the sheep, as at present, they then clipped them molly lengthways. The present method is to begin at the back part of the head, in order to give room for the shears to make their way down the right side of the neck, to the open of the breast. The man then fits down upon his right knee, laying the head of the sheep over his left knee bent, and beginning at the breast, clips the underside of the throat upwards to the left cheek; then takes off the back of the neck, and all the way down below the left shoulder. He then changes to the contrary side, and makes his way down to the open of the right flank. This done, he returns to the breast, and takes off the belly, after which it matters not which side he clips, because being able to clip with either hand, he meets his shears-points exactly at the middle of the back, all the way, until he arrive at the thighs or legs. He then places the sheep on its left side, and putting his right foot over the neck, and the other foot upward to the undermost hind leg, clears the right side; then turning the sheep over, finishes the whole.

Our price for clipping used to be one shilling per dozen, and a half of a shilling about ten o'clock, and another at four in the afternoon. He supposes a man will have one shilling and sixpence per dozen now; but we clip all with our own men, mostly the shepherds, many of whom now do it most admirably: and we have in general prevailed upon them to clip with either hand; which is not only the easiest for the clipper, but enables him to do his work in the neatest and most complete manner.

These remarks deserve the regard of the sheep-farmers in other districts, as well as the following hint by Mr. Price. It is, says he, astonishing to see a good shearer handle a sheep; he studies its cafe, and the sheep seems delighted in its situation. This should always be the cafe with these animals, which are often much injured by coarse management, and the most sober men be constantly employed.

The fat sheep should always be thorn earlier than those which are lean. In the South Down sheep district, a good sheep-shearer is paid to be able to sheaf fifty sheep daily, for which he has 2s. 6d. or 3s. the score, and board. Great care should at all times be taken not to injure the sheep in shearing, as the least cut is sometimes dangerous, though at others not. In cases of cuts, wax ointment or well boiled tar must be used, and the sheep have an open airy pasture.

The very same method is taken in shearing the lambs as in that of the old sheep, which, in many districts, takes place nearly at the same time, or about the last end of June and the beginning of the following month; some shearing them immediately on their being weaned, but others some little time before, for the sake of allowing the old ewes to become fat. See Sherling of Lambs.

The writer of the "General Treatise on Cattle," states, that the royal flocks of fine-woollen sheep in Spain are sheared in the beginning of May. There are shearing-houses, each of which will contain twenty thousand sheep, and cost in building above five thousand pounds sterling. To shear a flock of sixteen thousand sheep requires one hundred and twenty-five men, a man shearing twelve ewes, or eight rams, in a day. The sheep are sweating previously to being sheared, in a long, narrow, low, calf, called the sweating-place, where they remain a night, crowded as close together as the shepherd can keep them. The thorn sheep are permitted to go to pasture if the weather be fine, returning home in the evening, to pass the night within shelter of the walls, or in the house, if cold or cloudy; by which means they are brought by degrees to endure the open air.

And it is a point of great consequence in this business to have a person well conversant with the winding of the wool, in order that it may be well performed, and look in a proper manner to the buyer. In some places the wool is laid in a heap on being wound, and conveyed in the evening of the same day to the wool-lofts, or other depositories. Some bore their wool constantly in upper chambers, as the moisture which is produced by it on ground floors, when it is continued there for any length of time, is supposed to be very injurious to it. See Wool.

Sheep-fold, in Agriculture, a space of arable or other land huddled in for the purpose of being manured, or a fort of yard or other contrivance for the purpose of confining and keeping sheep in during the nights or in bad weather, in order to afford them protection and shelter. They are sometimes fixed, being constructed of any convenient fort of light materials, so as to incline a space in proportion to the number of sheep in the form of a kind of yard or fold, which is kept constantly well littered with some sort of dry substance, such as flufhe, refuse straw, dry land, etc., during the whole of the time the sheep are folded and foddered in them, in order that such mansure may be raised as possible. In some cafes also, for the more perfect protection of the sheep, they have heds all round them, under which the sheep may be without injury from rain, snow, or any sort of moisture. These are usually termed flandering folds, and are either formed about the hom-falls, or in some dry, rather elevated situations, on the farms, having the bottoms well laid with some sort of material that is capable of keeping the sheep dry and clean. And in the covered fold, or what is termed covering, which is in use in Herefordshire, there are sometimes formed into different divisions, so as to contain a certain number or kinds of sheep.

They are, however, in other cafes formed so as to be movable,
SHEEP.

moveable, either by means of wheels or other contrivances, being drawn to different situations according as they may be wanted. See Sheep-House.

There is likewise another sort of more imperfect sheepfold, which is formed by the planting of trees in different methods, so as to afford the animals a sort of protection from the severity of the winter season, as well as from the excessive heats of the summer. These are termed tree-folds, and sometimes plantation folds, from the manner in which they are formed. See Tree-Fold.

In the construction of the second sort of sheep-folds, which were mostly formed in some distant parts of the farm, in which cases they were often denominated standing-out folds, a cheap and simple method was had recourse to by an excellent sheep-farmer in Suffolk (Mr. Macro). He inflicted a double fold with thirteen dozen of old hurdles seven feet long each, formed of wands, and raised a baulk fence around them, composed of upwards of sixty loads of when rubble, in the works being littered with about thirty loads more: in this the flock were to be lodged where the fold was unsafe, or could not be removed from place to place, on account of frost, snow, or flood; and it is stated, that he made during the same winter season, 493 loads of manure, improving at the same time the condition of his flock. The land, it is observed, lay at too great a distance to be manured from the home-fall. He likewise adds, that before he thought of this plan, his sheep were always obliged to lie in bad weather, upon a certain sheltered part of the heath, where the fold manure was not only lost to his farm, but the wires on which the dung was heaped in large quantity became a cause and four, that nothing would eat it: and that, exclusive of this injury, he used to lose by mortality, in a wet or severe season, during yeaming time, a much greater number of both sheep and lambs, for want of the dry, warm lodging of a sheltered fold, the advantage of which he estimated at thirty or forty pounds a-year at least. He saved not less by his improved plan than thirty lambs in a year, besides sheep amounting to a greater number of lambs than he usually reared in one year during the period of his farming business.

And by the forming of these folds in any other cheap convenient manner, similar benefits may be derived by the sheep-farmer.

In all these cases the sheep should be littered down as above as often as necessary, and be well fed, twice in the day at least, with such food as has been provided, being let out during the middle of the day, except when the season is very stormy and severe. It is stated in the Annals of Agriculture, that one hundred and thirty-four sheep confined in this way for the period of six weeks, and littered with five loads of forty trusses each of oat-flour, forty pounds to the truss, made twenty-eight large loads of manure, consuming two acres of turnips within the time.

The great superiority of this sort of fold over that of the naked moveable kind, is therefore sufficiently obvious, and may probably be had recourse to at all lessons with some advantage. See Sheep, and FOLDING of Sheep. Also SHEEP-FOLD.

A sheep-fold has been lately invented by Mr. Plowman of Broome, Norfolk, upon an improved and very simple principle, combining many advantages over the old and expensive method of folding by hurdles; and as the whole fold can be removed with ease at all times, it will be found peculiarly useful in feeding off turnips on the land in frothy weather, when hurdles cannot be used. It is stated that the expense, in the first instance, will exceed that of hurdles, for the same given quantity of feed; but having had one in use nearly three years, he is satisfied the saving will be very considerable: for, before he adopted this method of folding, he lost from thirty to forty nights folding in the year, owing to the land being hard in dry seasons; which renders folding almost impracticable, as they never can be kept without great labour and destruction of hurdles. He is also clearly of opinion, that the flock of sheep will be greatly increased when this method of folding becomes more known; and that it will enable many small farmers to keep from 50 to 100 sheep, who are now deterred from it on account of the small quantity of feed they have not answering to keep a man for that purpose only; but by this plan, they may keep a boy at 32. or 33. 2d. per week, who can attend on 100 or 200 sheep, and move the fold himself without any assistance. In heavy gales of wind it frequently happens that the hurdles are blown down, and the sheep of course being at liberty to range over the crops do irreparable mischief, which cannot happen with this fold. And in some counties in England, where hogs are folded, great difficulties are experienced for want of hayage, for them to feed off winter tares, &c. &c. as they root up every flake or hurdle; and having tried the experiment, he is certain this fold will keep them in, and defy their attempts to displace it. And an astonishing quantity of time is saved, as a man can remove a fold to contain 500 sheep in five minutes, which by the old method frequently takes some hours to accomplish. Many are now using folds from his model; and he received for the invention the gold medal of the Society for the Encouragement of Arts, &c.

It is further remarked, that where the fold is wanted to be used on very hilly ground, it must be begun at the top and worked downward to the bottom for the sake of removing it, and then drawn up again with a horse. This, however, he has never had occasion to do, for his land is ploughed in a contrary direction, and he works the fold in the same course as the ridges. By this means the inconvenience is avoided of crossing the furrows; and they are also a guide to keep the fold in a straight direction. With respect to the sheep getting under, he does not recollect that circumstance to have ever happened, nor does he conceive that any land, which is cultivated, can be so uneven as to admit of it.

This sheep-fold is twenty-one feet in length and three feet eleven inches in height, being composed of a top-rail, and bars below panelled through uprights; the whole moving on low cast-iron wheels, and made strong, but in a light manner.

Sheep-House, a sort of flight wooden building, constructed for the purpose of containing and protecting sheep in bad weather, &c. Houset of this kind are usually made low, for the sake of warmth in the winter, being mostly a third part longer than they have breadth; they should also be sufficiently large for the quantity of sheep they are to contain. The sides should be lined with boards, and the bottom be laid in an even manner with stone or some other material, that the litter may be well impregnated with the urine of the sheep. And it has been advised to have the sides exposed to the sun, wet with lined moveable hurdles, that when it thaws the whole may be had open, to afford due refreshment, and give the sheep an opportunity of feeding upon the pasture wherein they stand. They should be well and securely covered with some sort of proper material upon the tops. They are sometimes fixed in particular situations, but in other cases, which is the more improved method, to constructed as to be capable of being removed as they may be wanted. One of the latter kind, employed on the farm of the Hon. George Villers, in Hertfordshire, which is very complete, is described, with a plate, in the Corrected Agricultural Survey.
SHEEP.

The survey of that district, lately published by the Board of Agriculture,

In this sheep-house the wheels are fixed to the sides, being sixteen inches in diameter, and having an axletree to harness the horse to, with weather-boarded flaps hung with hinges, to turn up and button against the sides when it is removed. It has also folding doors to open when the sheep are let in or out, and fixed weather-boarding, with cover-boarded windows to open on hinges sideways, in order to put fodder into the racks. Likewise a canvas roof, with open railing for air.

It is observed, that the length of the building is from twenty feet to any length; the width to be such as to enable the building to pass through the field-gates; the weather-boarding and flaps to be made as thin as possible, and covered with pitch.

But how far the advantages of houses of this fort may compensate the expenses of constructing and keeping them in repair, has not been fully shewn; nor has perhaps a sufficient number of trials been made to shew the benefit of confining sheep in covered houses or folds, or whether the economy of the animals is well suited to such a system. Some circumstances of advantage attending the practice of housing sheep have certainly been stated, but no satisfactory comparative experiments have, so far as we know, been made. And from the plan being little or not at all adopted in many extensive sheep districts, and in others where it once prevailed being either wholly in disuse or much on the decline, as is well known to be the case in Gloucestershire and the county of Hereford, there seems reason at least to presume that it is not so necessary or so well suited to the habits of the animal, nor even so beneficial as has been supposed by some writers on the subject. See Sheep, and Folding of Sheep.

Houses of this nature, for the purpose of sheltering sheep and lambs in bad weather, are formed in a very cheap and simple manner in Romney-Marsh, as may be seen in Price's account of the sheep-husbandry of that district.

Sheep-Hurdles, the flake or fort of fence-gates which are set up so as to confine sheep at the time of folding them on arable land, or while they are feeding down, or upon any particular fort of food. They are of several different kinds, and either close or open; but the former are in general to be preferred, as affording the most shelter. It is obvious that the number required to inclose a certain space must depend upon the length. See Hurdle.

Sheep-Husbandry or Farming, that fort of farm management which relates to or has sheep for its principal object. There are various modifications of this fort of farming, depending upon the differences in the circumstances of the lands, their nature and situations, as well as other local matters. See Sheep.

It is not improbable that in this fort of husbandry and farming, the most benefit and advantage may often be derived where there is a judicious intermixture and conjunction of other sorts of management, as those of cultivation, cattle, planting, and some others, sheep being constantly the great object. By such means advantages are afforded and brought forth in a great variety of different ways to the individuals themselves as well as the community at large.

In this fort of farming management it is of much consequence to have recourse to the fixing upon such plans and methods as are the most and most suited to the climate and nature of the farms and markets for the fates of the animals. In cases where the farms are high, and of a cold exposed nature, the weather may often enter largely into the plan which is to be adopted. Where they are of the more mixed nature, and of high, as well as low lands, they may sometimes be most suitably stocked, in a partial manner, with ewes and lambs, and with wethers. In those of the more common fort, the breeding or rearing fyllens, according to circumstances, may frequently be the most profitable modes. And in rich grazds land and mixed farms, which are provided with parks and paturages, as well as arable lands, the sheep-farmer may not unfrequently be tempted to fatten the saleable part of his sheep-rock, particularly where the markets are convenient for him in respect to distance.

In all these forts of farms in this kind of husbandry, the breeds or kinds of sheep should always be selected and provided with a perfect consideration of their nature, and the management of the sheep be carefully directed with the same intention. The means of feeding of them should also be well regarded. Many other circumstances likewise require attention in this fort of husbandry and management. The inquirer may find much useful information on the subject of Highland sheep-farms and sheep-farming, in the third volume of the "Transactions of the Highland Society.

Sheep-Marks, and Markings, the marks and means of performing those which are put upon sheep in different ways and manners; as by means of tar, ochre, redde, wad, and other similar substances, and by cutting the ears of the animals in different forms and methods. These are useful and necessary to the sheep-farmer on many occasions and accounts; they serve to distinguish his particular sheep and flocks from those of others, to discriminate the several different kinds, and to point out the various forts of management which are necessary with different kinds of sheep and lambs, as well as to answer different purposes in the sale of them, &c. In the marking with tar, a tool or contrivance having letters fixed to the end of it, is mostly made ufe of, the initials of the name of the farmer being most commonly employed. With the other matters different methods are taken; such as wetting and rubbing them on flates, statues, or other matters, and then marking the sheep with them in the ways that may be thought necessary. Sheep and lambs are marked by these means in many different parts, as in the face, on the fides, the hips, and in several other places; the work being mostly done according to the fancy of the person engaged in it, or of the owner of the flock, often in different curious modes and forms, as straight lines, curves, circles, and a variety of other more out-of-the-way methods.

The marking of the sheep in the caers is performed by cutting them with a sharp knife in different forms and manners, as in that of a fork, an under and upper flint, an under and upper square, an under and upper notch, a flake, an under and upper flint, a straight flint, a crop, a crop and flint, a hole, a hole and flint, &c. All these several modes may be well represented in Price's System of Romney-Marsh Sheep-grazing.

Marking sheep in the caers, in these or other methods, forms excellent and correct means of distinction, for knowing them by, in a variety of cafes and circumstances in sheep-farming.

Dr. Lewis recommends the following composition for marking of sheep; viz. melted tallow, with so much charcoal, in fine powder, heated into it, as is sufficient to make it of a full black colour, and of a thick consistence. This mixture, being applied warm, with a marking-iron, on pieces of flannel, quickly fixed or hardened, before moderate rubbing, refulted the sun and rain, and yet could be washed out freely with soap, or ley, or flake urine. In order to render it full more durable, and prevent its being rubbed off, with the tallow may be melted an eighth, a sixth, or fourth of its weight.
weight of tar, which will readily wash out along with it from the wool. Lewis's Com. Phil. Techn. p. 361.

Sheep-Pens, the divisions made by the small movable gates or hurdles, which are set up to keep sheep in some particular situation. They are usually formed on a dry place, about the corners where different inclosures of the pasture kinds meet, so as to be convenient for the whole. They are useful in examining and selecting the sheep, being divided so as to contain about three dozen each, as by this means they are always at the command of the shepherd for any purposes he may have in view. The bottoms should be firm and dry, so that the sheep may not be foiled.

Pens or coops are likewise made and used in the pounds where the ewes are lambed or put, in some sheep districts. These are usually about two feet seven or eight inches in the square, into each of which one ewe and the lamb are put, and buckled, where there is a disinclination in the ewes to let their own lambs suck, as occasionally happens, and where strange lambs are put to them. Two of the side-boards of these pens are capable of being lifted up and let down so as just to admit the ewes; in which they move with difficulty, consequently are not able to reach the lambs to beat them away; by which means they thus find an opportunity of sucking against the wills of the ewes. These pens are therefore often very convenient in these cases, two of which are mostly kept in each lambing-ground or yard. See Sheep-Pound.

Sheep-Pound, any fort of narrow inclosure for the confining of sheep. Pounds of this kind are of many different sorts, and useful for several different purposes in the management of sheep-flocks, as those of lambing, catching, pasturing, and droving them in different ways, &c. They sometimes occupy pretty large spaces of ground, but at other times are only of very small extent.

Sheep Rubbing-Polls, the small polls and pieces of wood which are fixed up in sheep-paddles for them to rub themselves against. They are sometimes simple upright polls, but at others they have crofs pieces put through them. They are very necessary and useful to the animals. See Rubbing-Polls.

Sheep-Shares, the shears used in clipping or shearing of sheep. They are frequently termed wool-shears. They are made with a spring bow in the handle part, which causes them to open readily in working with them. The handle part is molly about six inches in length, and that of the blade about five; but shears of this kind very much in size in different places.

Sheep-Skin, or Pelt, the common covering by which the sheep is surrounded and defended. The skins of these animals differ much in thickness, size, and other properties, according to the nature of the different breeds. Sheep pelt, or skin, sometimes form an article of great utility and profit to sheep-farmers, being sold to the fell-mongers, or other persons in their neighbourhood, under constant contracts by the year, at different prices, as from the time of shearing to Michaelmas, at from 1s. to 1s. 6d. from that until Shrove tide, at from 2s. to 2s. 6d. and from Shrove tide to shearing-time again, at from 3s. to 3s. 6d. Something of this method is pursued by the South Down sheep-farmers in the sale of their sheep-skins, as well as by those of several other great sheep districts, by which great advantage often arises.

Sheep Washing-Hooks, the long-handled hooks which are made use of in washing sheep in some places. The hooks are in these cases fixed at the small ends of the long handles, in several different forms, as in that of somewhat the manner of an S; that of two small forts of half circles, with a little straight portion in the middle, to which the handle is joined, and, in short, quite straight portions. They are very useful, in some inclusions, in guiding and directing the sheep in this business.

Sheep-Yard, any fort of inclosed yard or place in which sheep are confined and kept, either for the purpose of bringing forth their young, feeding, or fattening. These forts of yards are now becoming pretty general in many sheep districts, as well as some other places. They are made in several different ways, according to the nature of the situation and other circumstances; and are often capable of being formed in easy, cheap, and convenient methods. See Sheep-Fold, and Sheep-House.

It is stated in the Agricultural Report of the County of Oxford, that at Clifton, Mrs. Latham has one of the most complete sheep-yards in it; a shed surrounds three sides of it, in which are racks and troughs for the sheep to take their food from; it is thirty-one yards in length and sixteen in breadth; the sheds being five yards broad. This sheep-yard does very well for two hundred ewes. The ewes are usually brought into the yard from four to six weeks before the lambing-time, and continued in it until that is over, going out however in the day-time. This is said to be considered as a very excellent method, but attention must be paid in it, that the dung does not accumulate, as by its fermentation the sheep are liable to be injured. It should, of course, be carted out in a repeated manner. When not removed so often as to prevent its taking on heat, it has also been found, in Essex, to prove dangerous to lambing ewes, as well as ewes and lambs.

The sheds may be raised on the sides of these yards so as to serve as fences also. Stubble, blue, and other similar matters, may likewise be made to form warm walls as the outside fences of them.

All yards of this sort should be kept constantly well littered with suitable substances of that kind, upon foundations laid with good earth, sand, or some other proper material.

In some large sheep districts, as the South Down, in Suffolk, the farmers have sometimes two or three of these yards, which are well sheltered for the sheep to lie down in at night, in very rainy and stormy weather. In some inclusions a yard of this nature, including the sheds, comprehends a space of not less than three hundred and fifty-five square yards; the sheds around which are about four yards wide. The whole are kept, for the mott part, thoroughly well littered down. They are commonly extremely warm, and found to preserve many lambs in bad weather. The whole of the circumference around them, in some cases, has a rack for containing hay.

In the Dorchester district of the frill of the above counties, natural grasses being extremely scarce, light is given in large quantities to sheep, as soon as ever the frosty mornings come on; barley-light is laid recourse to in these yards, or in lambing pens; and afterwards bean and pea-light, which are very good of; they pick off the pods and tops, and do very well with these sustenance. These forts of light are occasionally carted to the field for their use; and what they do not consume, brought back to the yards; a practice which is pursued to the saving a great many tons of hay. Such dung as is made in this way is found to be very good.

Pens may likewise be applied in these yards, or other ways, in fattening lambs, the mothers of which are at turnips. They are given in troughs, six or eight weeks after the lambs have been dropped. By the lambs having the liberty of running through the openings in the hurdles, where the field mode is followed, it is often some time before they will take to this fort
SHEEP.

fort of food, but they mostly come on gradually, until a foree will eat a peck a day. Peas are sometimes given in this manner, till they reach fix shillings a bufler, and found to answer. A great many forts of food of these and other kinds may be used with superior advantage for sheep in these yards, and a vast supply of good manure be provided at the same time.

Sheep-Clutter, in Rural Economy, a term applied in some sheep districts to the person who has the care of clotting the ewes just before the lambing-time begins.

Sheep-Lamb, a name given to the person who has the care and management of the ewe-flocks, which are under the slate of lambing, in some sheep districts. It is of very great advantage to a sheep-farmer to have a careful, steady, active lamb, unless he attends to the business himself, which is always the best way where it can be done; as few will be found who are sufficiently attentive and diligent at this period, and, of course, much loss may be sustained. Where persons are hired for this purpose, they should, it is supposed, be rather elderly than young, as being more experienced and left apt to be hasty, as the business is intricate, tedious, and often subject to much trouble, confusion, and disorder, which stand in need of a great deal of patience to have them properly attended to and rectified. If they are, or had been lookers, it is so much the better, but this is far from being always the case, even in the principal stations where sheep are kept. In the great sheep district of Romney-Marsh, it is the custom for the lambers to have the fleas of the dead lambs as a perquisite, which are usually sold at about $2. the dozen. This is certainly a bad practice, as it tends to the making of rogues. The interest of the sheep-matter and his servant, which ought to be the same, are separated, as what is the loss of the one is the gain of the other, and much injury and disappointment result from it.

In the above great district for sheep, it is usual for the lamber to go his regular rounds at four o’clock in the morning, and to continue with the ewes until about seven or eight, returning to the fields until dinner-time; then going off again at one, and returning about five; setting off on his last round at six o’clock, when he does not return until dark. There is indeed sometimes too much to do, that he cannot come home above once or twice a day; the lambling should on no account be ever left until the lamber has every thing in a fair way, especially at the time of night.

Sheep-Looker, the name of the person who has the over-looking and management of the sheep-flocks, in some districts. Persons of this kind should always be of careful, steady, active dispositions; with sufficient experience, and a full knowledge of the different modes of sheep management. See SHEEP.

SHEEP LAMING-Hooks and MARKS, the instruments of the hook and mark kind, which are made use of in laying hold of the lambs, and in marking them, in particular cafes and circumstances. In the former the handle is about seven feet in length, the head, or circular open part, three inches in width; the neck, or opening part to it, two inches and one-eighth wide; and the guide, or bill, six inches and a half in length. The latter has the handles about seven inches and a half long, with straight and curved or circular marks at the ends, one inch and three-eighths in length, and one inch and two-thirds in width, inside the circle. These instruments are very useful on many occasions.

SHEEP Hay-Rack, that fort of rack which is provided for the use of sheep in their consumption of hay and other forts of fodder of the same nature. They are made in many different ways, as open or covered on the tops, and boarded or barred up a little height at the bottom part, as well as railed on low wheels, or wholly without them.

They are usually from about fix to nine feet in length, and about two feet and a half in height; the space for the hay at the top about one foot ten inches, but which sometimes contracted at the bottom for the two sides to come nearly together, standing out in the manner of common horse racks. The openings for the sheep to feed through from three, four, or five inches to seven or eight. The smaller they are the less loss there will be, provided they are sufficient for the sheep getting at the fodder. The bars and boards put at bottom in some forts of these racks prevent the animals getting into them. When formed with covers and fences for keeping the hay or other food, and the sheep, while feeding, from being wet; they are the most complete, especially if, at the same time, they be provided with low wheels, so as to be capable of being moved from place to place. In small racks, where wheels are put at one end, they can be readily moved about.

These racks are of very great use and convenience on all farms where sheep are kept in any quantity. See RACK.

SHEEP Coro-Bin, any fort of trough or bin formed for the purpose of containing the corn, or any other similar kind of food for sheep, either in fattening, or in other modes of managing them. Bins or troughs of this nature are usually contrived in a light manner, so as to be movable on low wheels; having covers at some height over them, supported from below by the ends and upright pieces in somewhat the roof-form, so that the wet may be prevented from getting to such provisions, and the sheep enabled to feed dry. They are generally made very narrow, but of consider able length, the box or trough for the food having only the depth of a few inches.

Sheep-bins of this fort are very necessary and useful in many kinds of sheep management.

SHEEP-Dung, the manure afforded by sheep, which, by means of proper folding in yards properly littered with straw, bubble, &c. may, in many cafes, be increased to a consider able extent, so as to render it an object with the farmer. See DUNG, FOLDING OF SHEEP, and MANURE.

SHEEP-Drains, a name sometimes given to those small drains which are frequently formed upon the more soft and damp sheep-walks and pathways in different parts of the kingdom, in order to render them in a state of greater dryness. They are often made not more than two feet in width at the surface, and one spit and the flowing in depth. They are most suited to that fort of wetness where the bottom is of a clayey or silty nature. Such fort of work can, in some places, often be done at three-halfpence the rod of Scotch eels. These drains should constantly have a gentle slope or declination across the declivities of the grounds on which they are made.

SHEEP-Farm, that fort of farm which is principally conducted under some system of sheep management. Many situations are suited to some branch of this husbandry, which cannot be converted to the purposes of raising grain or fattening cattle, &c. See SHEEP, and FARM.

The more dry the lands are, and the more fine and short the grass is which is upon them, the better and more proper and suitable they are, in general, for the purposes of sheep-farms. Where the substructure is of a lime-stone quality, this is mostly the case, in the most favourable degree. But in many instances now, arable farms are likewise sheep-farms, to a very considerable extent; artificial food being grown and raised for the sheep-flock in sufficiently suitable proportions. There is probably much advantage in this combination in all cafes in which it can be properly admitted. Sheep-
farms should constantly be formed with great attention to
the nature of the grass, the exposure, and the shelter for the
animals. They should also be kept dry and in good order
on the surface, with every fort of proper convenience for
the management of sheep. See SHEEP-Husbandry, and
FARMING.

SHEEP-LEAF, a term applied to pasture-land appro-
riated to the feeding or supporting of sheep; or any fort
of pasture-land on which this kind of animal or live-rock
is kept.

SHEEP-POULTRY, that kind of dry, firm pasture land which
is suitable for the purposes of grazing, feeding, and fattening
sheep. Many forts of moit land are not at all proper for,
or adapted to this use, though well suited for some
other forts of farm management.

SHEEP'S-TROTTERS, a refuse material procured from fell-
mongers, which is made use of in some places as a manure to
be turned into the land. They are bought at about 6d. the
bushel, loosely heaped, in some places, and coal about 2d.
more in carriage, being used in the proportion of from twenty
to forty bushels the acre, being afterwards pricked in to
prevent their being eaten by dogs, crows, &c. They answer
belt on such lands as are rather dry, and where the sea-
on is rather moit. They contain a large proportion of
lime, and are often adulterated by being mixed with sand, as
well as oak sawdust; which half is said not to injure them.
Furriers' cuttings are nearly the same, and made use of in a
similar manner.

SHEEP'S COVE, in Geography, a bay on the E. coast of
Newfoundland, between Bay Robert and Port Grave.

SHEEP ISLAND, a small island near the coast of South
Wales, E. of the entrance into Milford Haven. N. lat.
51° 38'. W. long. 5° 0'.—Also, a small island on the
northern coast of the county of Antrim, Ireland, oppo-
to the extreme point of the head-land, between Ballintoy
and Ballycally, not far from the remarkable rock, called
Carrick-a-Rede. N. lat. 55° 15'. W. long. 6° 11'.

SHEEP-FISEE GROAS, in Agriculture, a sort of grass which,
while it has been much praised by some as useful in pastures,
having been condemned by others as of little importance from
its smallness, and being liable to be burnt up in dry seasons.
It is said to succed well with leas soillier than most other
forts of grass. As forming a close-matted turf, where no
great produce is required, it may be found a beneficial
plant. See FESTUC A OVA ANA, and GRASS.

SHEEP-Nose-Worms, in Natural History, a species of fly-
worm, found in the noes of sheeps, goats, and rams, and
produced there from the egg of a large two-winged fly.
The frontal sinuses above the nose in sheeps, and other
animals, are the places where these worms live, and attain
their full growth. These sinuses are always full of a soft
white matter, which furnishes these worms with a proper
nourishment, and are sufficiently large for their habitation;
and when they have here acquired their defined growth,
in which they are fit to undergo their changes for the fly-
state, they leave their old habitation, and, falling to the
earth, bury themselves there; and when these are hatched
into flies, the female, when she has been impregnated by
the male, knows that the nose of a sheep, or other animal, is
the only place for her to deposit her eggs, in order to their
coming to maturity. Mr. Valintier, to whom the world
owes so many discoveries in the infest clafs, is the first who
has given any true account of the origin of these worms.
But though their true history had been, till that time, un-
known, the creatures themselves were very early discovered,
and many ages since were esteemed great medicines in
epilepsies.

Vol. XXXII.

The fly, produced from this worm, has all the time of
its life a very lazy disposition, and does not like to make
any use of either of its legs or wings. Its head and corneal
Together are about as long as its body, which is com-posed
of five rings, streaked on the back; a pale yellow and
brown are there dispersed in irregular spots; the belly is of
the same colours, but they are there more regularly dis-
pofed, for the brown here makes three lines, one in the
middle, and one on each side, and all the intermediate
spaces are yellow; the wings are nearly of the same length
with the body, and are a little inclined in their position,
so as to lie upon the body; they do not, however, cover it, but a naked space is left between them; the
aikrons, or petty wings, which are found under each of
the wings, are of a whitish colour, and perfectly cover the
balancers, so that they are not to be seen without lifting
up theve.

The fly will live two months after it is first produced,
but will take no nourishment of any kind; and possibly it
may be of the same nature with the butterflies, which never
take any food during the whole time of their living in that

SHEEP-SCABIOUS, in Botany. See JASION.

SHEEP-SHANK, in Sea Language, is a sort of knot, or
hitch, cast on a rope, to shorten it as occasion requires;
particularly, to increase the sweep or length of a tackle,
by contracting its runner. By this contrivance the body,
to which the tackle is applied, may be hoisted much higher,
or removed much farther, in a shorter time. Falconer.

Thus, if any weighty body is to be hoisted into a ship, &c.
and it be found that the blocks of the tackle meet, or
block and block, before the object can reach the top of
the side, it will be necessary to lower it again, or hang it by
some other method, till the runner of the tackle be sheep-
shanked, by which the blocks will again be separated to
a competent distance. See RIGGING, Plate 1, fig. 16.

SHEEPCADE, in Agriculture, a name provincially ap-
plied to the large sheep-loaue.

SHEEPENT, or SHEEPSCOT, in Geography, a river of
America, in the district of Maine, which runs into the sea.
N. lat. 43° 43'. W. long. 69° 38'.

SHEEPHAVEN, a harbour on the northern coast of
the county of Donegal, Ireland, situated west of the Mul-
roy, and separated from it by a long, and, in some parts,
very narrow peninsula. The surrounding country is moun-
tainous, and thinly inhabited; nor is there any town of
consequence in the neighbourhood. Dunfanagh, near
Hornhead, is no more than a village, though ruins near
it seem to indicate that it was formerly much larger. The
fertile sand found in this district is of excellent quality for
making glafs, and it is carried to Belfast for that purpose.
Under the article HORNHEAD, a promontory which forms
the western boundary of the harbour, we noticed, on the author-
ity of the late Dr. William Hamilton, in the Trance-
factions of the Royal Irish Academy, the effect of drifting sands in
overwhelming the vestiges of cultivation; and the change
thus produced in the appearance of a country. A similar
effect took place on the eastern side, which is thus described
by the same writer. "About a century ago, an elegant
defile, according to the tale of that age, was built on the
peninsula, between the harbours of Sheephaven and Mulroy,
which at present stands like Tadmor of the East; the soli-
tary wonder of a surrounding desert." The gardens are
totally denuded of trees and shrubs by the fury of the
western winds; their walls, unable to sustain the masts of
overbearing ships, have bent before the accumulated pre-
sumption; and, overthrown in numberless places, have given rise
pallage
pallage to this reflets enemy of all fertility. The courts, the flights of steps, the terraces, are all involved in equal ruin; and their limits only discoverable by tops of embattled walls, visible amid hills of ruin. The mansion itself, yielding to the unconquerable fury of the temple, approaches fall to destruction: the frightful whirlwind howling through every avenue and crevice, bears ineffectually along its drifted burden, which has already filled the lower apartments of the building, and begins now to rise above the once elevated thresholds. Fields, fences, villages, involved in common defoliation, are reduced to one undistinguishable scene of sterile uniformity, and twelve hundred acres of land are said thus to have been buried, within a short period, in irrecoverable ruin." N. lat. 55° 12'. W. long. 7° 45'. Transactions of the Irish Academy, vol. vi.

SHEEPSCUT, a river of the United States, which joins the Kennebeck E. of its mouth, and is navigable 20 or 30 miles. On the W. side of this river is the excellent port of Wiccalet.

SHEEPHEAD, a cape on the S. coast of Ireland, between Bantry bay and Dunkinmous bay. N. lat. 51° 29'. W. long. 9° 45'.

SHEER, a town of Candahar; 40 miles W. of Ghiziniz.

Sheer, in Agriculture, a term used to signify pure, clean, unmixed, as in the case of grain-feeds, and many kinds of substrances.

Sheer, in Ship-building, the fore and aft curve or hang of a ship's sides or deck.

Sheer-Draft, the plan of elevation of a ship, on which is described the out-board: works, as the sheer-rails, wales, ports, drifts, head, quarter, poll, and stern, &c. The hang or sheer of each deck inside, the height of the water-lines, &c. See Ship-building, Plate I.

Sheer-Hooks, are large iron hooks used when a ship desires to board another.

Sheer-Hulk, is an old ship of war of 74 guns, cut down to the lower deck, or nearly so, and fitted in the following manner, to fix or take out the lower masts of ships in the royal navy, as occasion requires. It has a mast fixed in midships, about 33 inches in diameter, and 108 feet high, supported by stays, the upper shore 87, and the lower shore 81 feet long, and each 19 inches in diameter, their heels reeling against the inside, abreast the heels of the sheers, which are three in number, each composed of two pieces, 22 inches diameter, bedded together in the middle, to make 116 feet in height. The heels rest upon the outside, abreast the mate, the heads unite, and are firmly moored together, and incline outwards, to hang to the vessel whole masts are to be fixed or taken out. The sheers are likewise supported by a derrick, which is 100 feet long, and 22 inches in diameter. The mast is further secured by shrouds and stays, and the sheers by stays and large tackles, from the masts to each sheer. From the head of the sheers depend two large tackles, by which the largest masts are raised or lowered: the effort of these tackles is produced by two capstans, fixed on the hulk's deck for this purpose. There is also a luff-flanged tackle for halting small vessels. See Hulk.

Sheer-Rails. See Rail.

Sheer-Strake, the upper strake or strakes on the topside in midships. It forms the chief strength of the topside, and is therefore thicker, and continued the whole length parallel to the top timber-line and farchs at the buttts between the drifts.

Sheer-Weather, those strakes of thick stuff in the topside of three-decked ships, which are wrought between the middle and lower deck ports. Sometimes they are called middle-waides.

Sheer-Bucks, in Geography, a town of Peru, in Khorallan; 30 miles S. E. of Herat.

Sheer-Gotty, a town of Hindoostan, in Bahar; 68 miles S. S. W. of Patna. N. lat. 24° 30'. E. long. 84° 56'.

Sheer-Gur, a town of Hindoostan, in Malwa; 30 miles N. W. of Ragagur. N. lat. 24° 49'. E. long. 77°. — Also, a town of Hindoostan, in the cercar of Gohad; 5 miles E. of Narwa.

Sheering, or Shearing, in the Woollen Manufactures, the cloth-worker or sheerman's craft, or office; or the cutting off, with large sheers, the too long and superfluous knap, or flaps, found on the surface of woollen stuffs, fulkins, cottons, &c. in order to make them more smooth and even.

Stuffs are shown more or fewer times, according to their quality and fineness.

Some use the phrase sheering of hats, for the passing of hats made of wool over the flame of a clear fire made of straw, or sprue, to take off the long hairs; others call this flaming, and others singeing. Other hats, as calsars, femecallors, &c. are turned, by rubbing them over with pumice-stone. See Hat.

Sheering, or Shearing, in Sea Language, a term used for the motion of a ship, when the deviates from the line of the course, either to the right or left, so as to form a crooked and irregular path through the water, either by reason that she is not cleared steadily, or on account of the drift running of the tide, &c. in which case she is said to shear, or go a shearing. Hence, to shear off, is to remove to a greater distance.

When she lies at anchor, near port, &c. by reason of the drift running of the tide-gate, &c. she is often said to be in danger of sheering from her anchor, or sheering offshore. See Chest-Rope.

Sheer Mohammed Pett, in Geography, a town of Hindoostan, in the cercar of Condopilly, on the borders of Goleondia; 21 miles W. N. W. of Condopilly.

Sheerness, a sea-port and market-town in the Isle of Sheepy, and county of Kent, England, is seated at the mouth of the river Medway, and has derived its origin and importance from this circumstance. In the reign of King Charles II. it was deemed advisable to form a fort here, to protect the entrance to the river; and in 1667 that monarch, with an engineer and other officers, surveyed this spot, and strengthened the works. The Dutch, however, sent a fleet to this point, destroyed the fortifications, and failed up the Medway as far as Upnor castle. After returning again from this enterprise, the government directed some strong works to be formed here, because the spot was deemed of great importance. A regular fort was soon constructed, and mounted with a line of large and heavy cannon; and at the same time several smaller forts were built at different stations on the banks of the river. Since that time Sheerness has progressively been augmented and strengthened by new works, and now constitutes a regular garrison. It is commanded by a governor, lieutenant-governor, a fort-major, and inferior officers; and the ordnance establishment is under the control of a store-keeper, a clerk of the cheque, and a clerk of the survey. Adjoining the fort is the king's yard or dock, which has been made subquent to the former. This yard is chiefly used for the repair of ships that have been slightly damaged, and for building frigates and smaller vessels. A resident commissio-
SHE
SHE

ioner, with two clerks, a master-shipwright, and other officers, with labourers, are stationed here.

A modern chapel has been erected at the expense of government; but in ecclesiastical rites and privileges this is subordinate to the parish church of Minster. According to the population reports of 1811, Sheerness was returned to contain 134 inhabited houses, and 96 uninhabited; and the inhabitants, including the convicts in the hulks, and independent of the garrison, were estimated at 1685. The hulks of the ships, called break-water, are occupied by about seventy or eighty families, and altogether present a very singular appearance, the chimneys being raised of brick from the lower gun-decks. The market-day at Sheerness is Saturday, weekly.

For a long period, the garrison and inhabitants of Sheerness experienced a scarcity of fresh water, the chief supply being brought in vessels from Chatham; but it was determined by the Board of Ordnance, that an attempt should be made to sink a well within the fort; and the execution of this was entrusted to Sir Thomas Hyde Page, an able engineer, whose skill and perseverance were found fully equal to the task that had been reposed in him. The preparation of the materials, and the boring, to ascertain the different strata, were begun in April, 1781; and the sinking of the well was commenced in June following. The land-springs, &c. which greatly interrupted the progress of the work during the first 100 or 150 feet, were excluded by regularly steaming in the inside of the well; till, at length, the workmen came to an immense stratam of chalk, which prevented the further necessity of steaming, and enabled them to proceed with less inconvenience. They went on, however, with great caution; and having dug to the vast depth of 328 feet, the auger with which they were trying the strata dropped down, and the water rushed up with such velocity, that the workmen could hardly be drawn out with sufficient haste to escape drowning. In fix hours it rode 189 feet, and in a few days was within eight feet of the top; and has ever since produced a never-failing supply; for, though constantly drawn from it, has never been lowered more than 200 feet. The quality of the water is fine and cold, and its temperature is somewhat warmer than commonly happens in other wells. From this well, conjointly with that of Queenborough, not only the garrison and inhabitants are supplied, but also the shipping which lies at anchor at the entrance of the Medway. (See QUEENBOROUGH.) Hallid's History, &c. of the County of Kent, fol. 1. 8vo. edit. Canterbury, 1798. Beauties of England and Wales, vol. vii. by E. W. Brayley, 8vo. 1806.

SHEEPOR, a town of Hindooistan, in Bahar; 43 miles S.S.W. of Patna. N. lat. 24° 55'. E. long. 85° 10'.

—ALO, a town of Hindooistan; 30 miles E. of Delhi.—Allo, a town of Hindooistan, in Mewat; 25 miles N.E. of Dig.

SHEERS, in Ship-Building, are two masts or spars, set across at the upper end of each other, and there lathed together with tackles depending from the intersection; and they are kept upright by guys extending each way from the heads. The heels are spread and lathed, or clefted, to prevent their flapping. By this contrivance very heavy bodies are raised, such as the stem, stern-frame, and the frame-timbers of ships; likewise ships are mated by sheers, or have their masts taken out where there is no sheer-hulk.

SHEET, in the Manege. See CARTAPANX.

SHEET, in Sea Language, a rope fastened to one or both the lower corners of a sail, to extend and retain it in a particular direction. When a ship falls with a lateral wind, the lower corner of the main and fore-sail are fattened by a tack and a sheet; the former being to windward, and the latter to leeward; the tack, however, is entirely suffused with a light wind, whereas the sail is never spread without the assistance of one or both of the sheets. The stay-falls and flapping-sails have only one tack, and one sheet each; the stay-falls are always felled fore and aft, and the sheet drawn aft; but the luffing-fall-tack draws the under edge of the sail to the extremity of the voile, whereas the sheet is employed to extend the mainsail. Falconer. See SHEETS.

SHEET, To hole home the. See HOME.

SHEET-Anchor. See ANCHOR.

SHEET-Nails. See NAIL.

SHEET-Stopper. See STOPPER.

SHEETING, a term signifying the flooring of jointed planks, under the lock-gates of a canal, and at the tail of every lock and sluice, &c.

SHEFFIELD, John, in Biography, duke of Buckinghamshire, son of the earl of Mulgrave, was born in the year 1649. At the death of his father he succeeded to his title; this was in the year 1658. At an early age he dismissed his governor, but supplying the want by his own industry, he acquired a considerable proficiency in literature. His patriotic ardour broke out at the age of seventeen, when he engaged in the first Dutch war as a volunteer. The indications which he gave of the love of pleasure, united with literary talents, which had a peculiar value in the reign of Charles II. rendered him a favourite at court, and he materially assisted in the obtaining for Dryden the appointment to the post of laureat. At the commencement of the second Dutch war, he was a volunteer in the fleet commanded by the duke of York, and was present at the battle of Solebay, in which he behaved with so much gallantry, that on his return he was made captain of a second-rate ship of war. In the following year he was appointed colonel of a regiment of foot under general Schomberg. In 1674 he was decorated with the order of the Garter. He was, in 1679, appointed lord-lieutenant of Yorkshire, and governor of Hull, in which year he wrote a piece, entitled "The Character of a Tory, in answer to that of a Trimmer." In this we have an avowal of his political principles, which were those of the party in whose name he wrote, and to which he adhered during life. In 1680 he went out with a force to the relief of Tangier, then invested by the Moors. In this expedition he completely succeeded, and with it ended the military services of lord Mulgrave. On the accession of James II. he was chosen of the privy-council, and made lord-chamberlain of the household. He returned these favours by a zealous attachment to his master, which led him to take a seat in the ecclesiastical commission; but in this he opposed those measures of the priets which brought on the speedy ruin of that exalted prince. Though inimical to the revolution, yet he voted for the conjunction of sovereignty of king William with Mary. In 1694 he was made marquis of Normanby; notwithstanding this, and his admission into the cabinet, with a pension, yet he still had a great dislike to the king. On the accession, however, of queen Anne, his former attachment to the court was revived, and he experienced her favour by an appointment to the privy-seal, and by other honours, which were terminated in 1703, by a nomination to the dukedom of Buckinghamshire. Jealous of the influence of the duke of Marlborough, he resigned the office of privy-seal, and remained out of office several years, during which he built the house in St. James's park, which has, during this reign, been the principal residence of the queen. At the great change of the ministry in 1710, he was again introduced, first as steward of the

houte-
household, and then as president of the council. After the
death of queen Anne he was an opponent of the court, and
employed his time chiefly in literary pursuits, till his death,
in 1721.

The duke had been thrice married, and each time to a
widow: his last wife was a natural daughter of James II.,
by whom he had a son that survived him. Following the
example of the court of Charles II., he freely indulged in
licentious amours; nevertheless, it has been said that he
had occasionally ferious thoughts of religion, though pro-
bably not restricted to any particular party. The following
is the epitaph which he composed for himself: "Dubius
fed non improbus vivit: incertus morior, fed interbus:
Humanum est necire et errare. Chirillum avdencer: Deco
confido omnipotenti, benevolentissimo: Ens certum miære mei."
This was inscribed on his magnificent monument in
Wellsminster Abbey, with the exception of the clause respect-
ing Chirill, which bishop Atterbury rejected, thinking simple
veneration a derogatory application to the second
person in the Trinity.

In the capacity of poet, the duke of Buckinghamshire
does not rank very high; his compositions are on a variety
of topics, of which, however, the chief is "An Elia on
Poetry," which, according to Dr. Johnson, contains judici-
ous precepts, which are sometimes new, and often happily
expressed, but with many weak lines, and some strange
instances of negligence. In his "Elia on Satire," he is
supposed to have been a pen name of Dryden, who, for some
peculiarities in it, had the misfortune to be taken as the
real author.

The duke of Buckinghamshire composed two tragedies,
entitled "Julius Cæsar," and the "Death of Brutus;"
for the latter of which, at his request, Pope wrote two
chorus; of these, Warburton says, that they have the usual
effect of ill-placed ornaments, they make the meanness of
the piece more conspicuous. In the collection of the duke's
works are likewise historical memoirs, speeches, effays, &c.

Sheffield, or Sheaffd, in Geography, a large and
populous market and manufacturing town in the South
division of the wapentake of Stratford and Tichill,
liberty of Hallamshire, Well Riding of Yorkshire, England,
is situated at the distance of 36 miles S. from Leeds, and
162 N.N.W. from London. The origin and remote history
of this town are totally unknown. In the 13th cen-
tury it was noted as a staple for articles of iron manufacture.
Chaucer, who wrote in the reign of Edward III., men-
tions the "Sheffield Whittle" in one of his poems. At that
period it was likewise distinguished by a strong caille, which
stood at the north-ea of the town, and is said to have been
designed during the sovereignty of Henry III. This caille
defended from the Lovelots to the Nevils, lords Furnival,
and padded from them to the Talbots, sons of Shrewsbury,
and subsequently to the Howards, dukes of Norfolk, in
whose family the lordship of the manor is still vested.
During the civil wars between Charles I. and his parliament,
Sheffield caille suffered a long siege in the cause of royalty,
but eventually surrendered upon honourable terms, on the
tenth of August, 1644, and was soon afterwards ordered to be
demolished, which seems to have been done most effectually,
as fiercely a veiltige of it can now be discovered.

Though Sheffield, as already said, was considered as a
staple for iron manufactures at a very early period, its trade,
for several centuries, was comparatively confined and pre-
carious, and consisted almost entirely in the making of sheath-
knives, scissors, sickles, and fcythes. About the commence-
ment of the 17th century, an ordinary kind of tobacco-box
of iron, and Jews' harps, began to be manufactured here;
and in 1625 the master manufacturers were first incor-
porated by the style of "The Company of Cutlers of
Hallamshire." This corporation is governed by a master,
elected annually, six searchers, and twenty-four assistants,
and is the only body corporate yet existing in Sheffield.
It was not, however, till after the year 1750, that this
town assumed the rank it now holds in manufacturing
opulence. Previously to that period, none of the manu-
facturers had extended their trade beyond the limits of
Great Britain; but in the same year Mr. Joseph Broadbent
opened a direct trade with the continent; and in 1751,
the river Don having been rendered navigable to within three
miles of the town, that facility was given to exportation,
which has since proved so beneficial to its manufacturing
interests. Soon afterwards Mr. Thomas Bollower began
to plate brases and copper buttons with silver; and in 1758
the silver plated manufacture was commenced on an exten-
sive scale by Mr. Joseph Hancock, and has subsequently
been prosecuted with great advantage by a numerous claf
of individuals. The opulence and population of the town
increased from that time with great rapidity, and soon
gave rise to numerous conveniences and improvements,
both useful and ornamental. In 1760, the first stage-coach
started from Sheffield for London; and in 1762, the
theatre and assembly-room were built by subscription.
In 1770, the first bank in Sheffield was opened by Mr. Roe-
buck; and in 1786, the new market-place was formed,
about the same time that Meffrs. Proctors erected the first
steam-engine grinding-wheel. In 1795, hackney coaches
were introduced; and in the same year also was laid the
foundation of the General Infirmary. These circumstances
are mentioned, because they are calculated to display the
progressive benefits resulting from successful industry
and ingenuity, the contemplation of which can scarcely fail
to excite pleasurably emotions in every breast.

To notice particularly the various articles manufactured
at Sheffield of late years, would occupy too considerable
a space to admit of the attempt. The two great divi-
sions of them are into cutlery and plated goods, each of
which branch out into numerous ramifications. The
manufacture of the latter is almost entirely confined to the
town, and comprehends a great diversity of articles: such
to as tea-urns, coffee-pots, tankards, cups, candlesticks,
and other pieces of table furniture. The cutlery division
embraces the making of edge-tools, combs, cafes, buttons,
fenders, files, anvils, joiners' tools, lances, forks, hafts,
ink-stands, nails, knives of every description, scissors,
cythes, sickles, awl-blades, bellows, &c. to which we shall
only further add the refining of steel. Many of these
manufactures are carried on in the country, as well as in
the town, especially in the villages and hamlets of Alte-
cliff, Bentgreen, Brightside, Butterwith, Carysbrook,
Darnel, Dyon-Holmes, Dungworth, Ecclesfield, Green-
side, Grimeshorpe, Hallam, Milno-rous, Newfield-Gre-
over, Pottsmoor, Stanington, Sheffeild, Upper-
Wheeley, Wadley, Woodfleets, &c.; all of which are
situated within four miles of Sheffield. Besides the above
manufactures, there are in the town and its vicinity several
extensive foundries for iron, brass, and white metal.

Sheffield occupies a fine eminence at the confluence of two
rivers, the Sheaf, whence the name of the town is
derived, and the Don. In former times the houses
were entirely built of stone; but for the last century they
have been chiefly composed of brick. There are very few
towns which surpass it in the regularity of its streets, many
of them running in a direct line, and displaying a series of
uniform and respectable edifices. Sheffield extends about
a mile
a mile in length, from north to south, and nearly as much in breadth, from east to west. According to the population census of 1811, it contains 7927 houses, and 35,840 inhabitants, being an increase of 4526 persons since 1801; the date of the preceding report, notwithstanding the retardation its manufacturing prosperity has sustained during that eventful period. According to Goffling’s plan of the town, made in 1732, there were 32 streets in Sheffield at that time: in 1771 these were increased by 25 new streets; and in 1792, seventeen additional streets had been made. Sheffield is not particularly distinguished by the superiority of its public buildings, which are rather calculated for purposes of utility than for show. The principal of them are the Town-hall, built in 1700, Cutlers’-hall, the General Infirmary, the assembly-room, and theatre, and four churches belonging to the establishment. Neither the Town-hall nor Cutlers’-hall deserve attention as architectural productions; but the infirmary and theatre are handsome structures. The former, commenced in 1703, stands on the west side of the town; and in respect of situation, plan, medical aid, and comfortable treatment, may vie with almost any similar institution in Great Britain. The latter, which occupies the same building with the assembly-room, stands in Norfolk-street. The four churches are Trinity church, St. Paul’s, St. James’s, and a chapel belonging to the duke of Norfolk’s hospital. Trinity church, anciently called St. Peter’s, is the parish church of Sheffield, and appears to have been erected as early as the reign of Henry I. On the south side of the chancel is the Shrewsbury chapel, which contains four monuments to the memory of the earls of Shrewsbury of the family of Talbot; and on the north side is a monument commemorating judge Jelfop of Broom-hall, and his lady. At the entrance to the same division of the church are deposited the remains of William Walker, of Darvel, in this parish, who is said to have been the executioner of Charles I. Besides the above churches, Sheffield contains seven meeting-houses for Protestant dissenters, one for Unitarians, two for Methodists, one for Quakers, and a Roman Catholic chapel.

The duke of Norfolk’s hospital, mentioned above, stands on the eastern bank of the Sheaf. It was founded and endowed in 1670, by Henry, earl of Norwich, and received a considerable accession of property by Edward, duke of Norfolk, in 1770. The building consists of two quadrangles, each containing eighteen dwellings, for the accommodation of eighteen men, and the same number of women, all of whom receive five shillings a-week, with clothing and coals. Here is also an hospital founded by Mr. Thomas Hollis, a merchant of London, in 1703, for poor cutlers’ widows; likewise a free grammar-school, and two charity-schools, one for boys, and another for girls.

The other objects of a public kind which remain to be noticed are, the military barracks, situated at the north-eastern extremity of the town; and the bridges thrown over the Sheaf and the Don. That upon the latter river is called Lady’s bridge, from a religious house, which formerly stood near it, and was dedicated to the Virgin Mary. It was built in 1485, but undergone great alterations and improvements in 1762.

Sheffield has two market days, weekly, Tuesday and Saturday; the first for corn, &c. and the second for butchers’ meat. There are also fish-markets on Monday and Thursday, and two annual fairs, one on the first Tuesday after Whitsun week, and another on the 28th of November. A new market-place, with extensive and commodious flanes and other conveniences, was formed and finished here Aug. 31, 1786. Sheffield supports a weekly newspaper, called the "Iris," which is edited by Mr. James Montgomery, the author of "The World before the Flood," and other interesting poems.

The scenery in the vicinity of this town may be characterized as romantic. It is surrounded by lofty hills, commanding fine views over a populous and varied country. At the distance of about a mile and a half to the eastward, and the ruins of Sheffield manor-house, the ancient seat of the earls of Shrewsbury, where cardinal Wolsey was feigned with the disease which terminated his life about a week afterwards, at the abbey of Leicestershire. Wharncliffe park, the seat of the honourable James Archibald Stuart Wortley, situated on the river Don, six miles to the north-west of Sheffield, is equally remarkable for the elegance of its mansion, and the beauty of the surrounding grounds. In the neighbourhood of Sheffield are some alum mines; and at Wickerley, near the town, is a quarry, which supplies the manufacturers with grind-stones for the finer articles of cutlery. Aikin’s Description of the Country round Manchester, 4to. 1795. Magna Britannia, 4to. 1793. Camden’s Britannia, fol. edit. 1789. Beauties of England and Wales, vol. xvi. by John Bigland, 8vo. 1812. Gentleman’s Magazine, April and September, 1764.

Sheffield, a town of America, in the state of Vermont, and county of Caledonia, containing 455 inhabitants.—Also, a town of the state of Massachusetts, in the county of Berkshire; incorporated in 1733, and containing 2459 inhabitants. It is traversed by Hoquastonic river, which supplies water for several mills and river-works. South mountain extends along the whole length of the town, on the E. side of the river.

Sheffieldia, in Botany, Forl. Gen. t. 9, was so called by Forster in honour of the Rev. Mr. Sheffield, whom he designates as the chief botanist at Oxford. This gentleman was, we believe, one of the companions of the illustrious Banks, in the early part of his studies, and retained to the last a love of the science, though without having materially contributed to its advancement. He was living as a fellow of a college, at rather an advanced age, in 1788. The genus in question is now sunk in Samoaus; see that article.

Sheffield, in Geography, a market-town in the parish of Compton, hundred of Chifton, and county of Bedford, England, is situated at the distance of 10 miles S.E. from Bedford, and 41 miles N.N.W. from London. It was formerly a place of much more importance than at present, and had a large weekly market on Friday, which has now become almost nominal. Still, however, it possesses the advantages arising from four annual fairs, held on the 23rd of January, Easter Monday, the 19th of May, and the 10th of October. The two first usually afford a large supply of sheep and cows; the third is less important; and the fourth is now only a holiday fair. Sheffield is a chapelry, having distinct officers of its own, and maintaining its own poor. Here is a Roman Catholic chapel, endowed with an annual rental left in trust for that purpose. According to the parliamentary returns of 1811, this town contained 123 houses and 536 inhabitants.

In the parish of Flinton, and at the distance of about four miles from Sheffield, is Wreel Park, the seat of baronets Lucas, as representative of the family of the Greys, earls and dukes of Kent. In its present state the house retains little appearance of antiquity, having been at various times altered and modernized. It contains a large collection of portraits, forming nearly a complete series of all the members of the noble family just mentioned, from Henry, earl of Kent, one of the peers who sat on the trial of Mary, queen
queen of Scots, down to the present time. Here are likewise several portraits of the Crew family, and others; among which are Sir Randolph Crew, lord chief justice of the court of king’s bench; a fine picture of Thomas Lord Crew, by Sir Peter Lely; Nathaniel lord Crew, bishop of Durham; and the late lord chancellor Hardwicke.

The garden attached to this mansion exhibits a specimen of the old style of arrangement and ornament, modified and improved by the celebrated Brown, who formed the terraqueous canal, which nearly surrounds the garden, and is supplied by a spring rising near the house. At the spring-head is a cold bath, over which is a building, designed by Sir William Chambers, in imitation of a Roman temple. The late duke of Kent, who was very partial to this residence, adorned the gardens with obelisks, and other buildings, particularly a magnificent banqueting house, which terminates a spacious avenue in front of the house. Lyford’s Magna Britannia, Bedfordshire, 4to. 1806. Beauties of England and Wales, vol. i. by John Britton and E. W. Brayley, 8vo. 1803.

SHENAL. See Shappal.

SHEHERON, a town of Peru, in the province of Irak; 15 miles E. of Kermanshaw.

SHEHERVERD, a town of Peru, in the province of Irak; 30 miles S.W. of Sultania.

SHEHOUN, a town of Syria, under the jurisdiction of an independent aga, called “Capparares,” 18 miles N. of Hamah.

SHEHHRAN, or Shereban, a town of the Arabian Irak, on the Diala; 50 miles N. of Bagdad. N. lat. 34° 8’. E. long. 44° 5’.

SHEHrichter, a town of Peru, in the province of Irak; 33 miles W.S.W. of Kom.

SHEHRISTAN, a town of Peru, in Khorasan; 210 miles W. of Herat. N. lat. 35° 10’. E. long. 56° 20’.—Allo, a town of Peru, in the province of Chufidan, or Kuzifian; 50 miles N.W. of Schiras.

SHEIB, a lake of Egypt; 48 miles E.N.E. of Cairo.

SHEIKE, a mountain of Switzerland, in the S.E. part of the canton of Berne; 10 miles S.E. of Interlaken.

SHEIK, or Sheik, in the Oriental Caglams, the person who has the care of the mosques in Egypt; his duty is the same as that of the imans at Constantinople. There are more or fewer of these to every mosque, according to its size or revenues. One of these is head over the rest, and answers to a parish-priest with us, and has under him, in large mosques, the readers and people who cry out to go to prayers; but in small mosques the sheik is obliged to do all this himself. In such it is their business to open the mosque, to cry to prayers, and to begin their short devotions at the head of the congregation, who stand rank and file in great order, and make all their motions together. Every Friday the sheik makes an harangue to his congregation. Pococke’s Egypt, p. 171.

Sheik-Bellek, the name of an officer in the Oriental nations.

In Egypt the sheik bellek is the head of a city, and is appointed by the pacha. The business of this officer is to take care that no innovation be made, which may be prejudicial to the Porte, and that they send no orders which may hurt the liberties of the people. But all his authority depends on his credit and interest, not his office: for the government of Egypt is of such a kind, that often the people of the leal power by their poth have the greatest influence; and a cala of the janizaries, or Arabs, and sometimes one of their meanest officers, an oda-balha, finds means, by his parts and abilities, to govern all things. Pococke’s Egypt, p. 161.

SHELKAUT, in Geography, a town of Bengal; 8 miles N. of Hulamabad.

SHEIKH-UL-JEBAL, Dominions of, or lord of the mountains (commonly called the old man of the mountain) compris’d the whole of that elevated tract in the province of Azerbijan in the Persian empire, which runs parallel with the course of the Kizilkes and the greater part of Golan. When destroyed by Holak, the Houtiens, or Afshins, polleled upwards of 100 strong holds; but the residence of the prince was generally confined to the caftles Roodbar and Allah Ahmaud both of which are situated in the Kohr Caucasus, near Kazawen.

SHEIKPOUR, a town of Hindoostan, in Bahar; 28 miles E. of Bahar. N. lat. 25° 9’. E. long. 80° 9’.

SHEIMERS, a town of New Jersey; 34 miles N.W. of Morristown.

SHEK ABAD, a town of Egypt, anciently called Antinöe; 8 miles N. of Abu Girge.

SHEK ABDELLA, a village of Syria, in the pachalic of Aleppo, where are some springs of water; 20 miles S.E. of Aleppo.

SHEK Abu Enaur, a town of Egypt; 7 miles S. of Benfifuef.

SHEK Amur, a town of Egypt, situated on the Nile; 17 miles N. of Syene.

SHEK Embadhe, a town of Egypt, on the right bank of the Nile; 16 miles S.S.E. of Girge.

SHEK ERED, or Haradhe, a town of Egypt, on the E. side of the Nile. Here is the tomb of a Turkish laint, who after his death is said to have been metamorphosed into a serpent, which never dies, and is consulted as a physician; 8 miles N.N.E. of Ashrawn.

SHEK il Eitman, a town of Egypt, on the Nile; 7 miles S.S.W. of Cairo.

SHEK Fadhe, a town of Egypt, on the right bank of the Nile; 10 miles S. of Abu Girge.

SHEK Zaimeddin, a town of Egypt, on the left bank of the Nile; 3 miles N. of Tabtha.

SHEKEL, Shekhe, Shekles, Siclus, an ancient Hebrew silver coin, which was originally a drachm, but, after the Maccabees, about the value of the Greek tetradrachm, or four Attic drachmas, or four Roman denarii, allowing the drachma and denarius to be of the same value, and, according to Mr. Raper’s valuation of the drachma at 9d. 286, equal to £2. 14s. 3d. See Denarius and Drachm.

In the Bible, the shekel is sometimes also rendered solidus, and sometimes stater.

The Jewish doctors are in great doubt about the weight of the shekel; and it is only by conjecture, and by the weight of the modern shekel, that the ancient one is judged equal to four Attic drachms.

Father Socquet has described several of these shekels in his Dissertation on the Hebrew Medals. By the way he observes, that the third and fourth parts of a shekel, described by Waeferus, de Ant. Numb. Heb. are counterfeits of that author.

The Hebrew shekel, according to F. Merfenne, weighs 268 grains, and is composed of 20 oboli, each obolus weighing 16 grains of wheat. This, he says, is the just weight, as he found by weighing one in the French king’s cabinet. He adds, that such as come short of this weight have been filed or clipped. Bishop Cumberland tells us, he has weighed several, and always found them near the weight of a Roman semuncia, or half ounce. Mr. Raper infers from various considerations (see Drachm), that the mean
mean didrachm, of 133 troy grains, must be very near its just weight, and its half, or 66_\frac{1}{2} grains, that of the Attic drachm. The weight of the shilling would therefore be 66_\frac{1}{2} \times 4 = 266 troy grains.

Some are of opinion, that the Hebrews had two kinds of shekels, the common, or profane shekel, called didrachm; and the shekel of the sanctuary; which last they will have to be double the former. By this expedient they think we may get clear of some difficulties occurring in Scripture, where things are mentioned as of incredible weight; particularly that passage where it is said, that every time Aba-lom cut off his hair, the weight of which we used to incommod e him, he cut off the weight of two hundred shekels.

But Villalpando will not hear of such a distinction; nor do bishop Cumberland, M. Morin, Greaves, &c. take the opinion to have any foundation. The profane shekel, or shekel of four drachmas, they agree, was the same with the faceel shekel; and it was only called by this last name, because the standard of it was kept in the sanctuary by the priests.

Greaves apprehends, that the τρίγωνα σηχείας, or 30 pieces of silver, which were given to Judas, as the reward of his treason, were 30 shekels. Some modern writers, he says, imagine they were 30 denarii, and others, that they were triginta librae, or triginta talenta. Greaves's Works, vol. i. p. 257, note n.

It is maintained by several, that the Jews had also a gold shekel, Thiên aureus, of the same weight with the silver one; and valued at 16. 6s. 6d. Berling.

The shekel is supposed to have been first struck in the Defart, on the footing of 100 to the Attic mina, weighing 160 grains of wheat, and current for 10 geratis, or obols; but that afterwards they were struck of double that weight. Some will have the shekel to be the oldest piece of money in the world, as being in use in Abraham's time; but this was not coined, or minted, nor had any other value besides its intrinsic worth.

Xenophon mentions shekels as current in Arabia; and Du-Cange speaks of others struck and current in England.

Pinkerton, in his Essay on Medals, (vol. i. p. 291.) fig- ures, that the Hebrew shekel, and also the brals coins, with Samaritan characters, were not most of them later than the Christi an era, and generally the fabrications of the Jews. At any rate, the same impression of a sprig on one side, and a vafe upon the other, runs through all the coins of that barbarous nation; and the admixture of but one of them is rightly esteemed to be almost a disgrace to a cabinet.

SHEKIDJEK, in Geography, a town of Grand Bu- charia; 60 miles N.W. of Sagana.

SHEKOABAD, a town of Hindoostan, in Doob; 60 miles W. of Canage. N. lat. 27° 9'. E. long. 79° 2'.

SHELAH, a town of Afiatic Turkey, in Nautola, near the Black sea; 12 miles N. of llm.

SHELAN, a town of Persia, in the province of Far- fallan, near the Persian gulf; 75 miles S.S.W. of Jamor.

SHELURN, a town of America, in the province of Ve- rmont, and county of Chittenden, on the E. side of Lake Champlain, containing 987 inhabitants.

SHELURN Bay, a bay on the N. coast of New Hol- land, between Oxfordnse and Cape Grenville.

SHELURNE, sometimes called Port Refway, a fea- port town of Nova Scotia, at the head of a bay, in the S.W. part of the province. At the conclusion of the American war, this place was made the seat of royalty, and it was designed to erect many buildings here, and in 1783 it contained above 600 families: but being neglected and unable to defend themselves, many of them afterwards left the town; 90 miles W. of Halifax. N. lat. 43° 50'. W. long. 63° 15'.

SHELURN, a town of America, in the province of Massachussetts and county of Hampshire, containing 661 inhabitants; 98 miles W. of Boflon.—Also, a town of New Hampshire, in the county of Coxs, incorporated in 1769, and containing 1756 inhabitants.

SHELBY. See SHEBBY.

SHELDAFLE, a name used in several parts of the kingdom for the chaffinch.

SHELTON, Gilbert, in Biography, archbishop of Canterbury, was born in 1598, at Stanton, in Staffordshire. His father was a memial servant of Gilbert, earl of Shrew- bury, though defended from an ancient family in Stafford- shire. The subject of this article took his name from the earl, who was his god-father. Having laid the foundation of a good education, he was entered of Trinity college, Oxford, in 1613, and after taking the usual degrees was elected fellow of All Souls' college, in 1622. When he had taken orders he became chaplain to lord keeper Coventry, who made use of his services on various important occasions. As a reward for these services he presented him with a presbend of Glo- celter, and recommended him to his majesty, as one extremely well versed in political affairs. When he had taken his doctor's degree, in 1634, he was elected warden of All Souls' college. He was also chaplain in ordinary to the king, and clerk of the college, and was in the road to further promotion when the civil wars broke out, and checked his career. He was a zealous adherent to the royal cause, attended the king on various occasions, and rendered himself obnoxious to the parliament: on which account he was ejected from his wardenship, and imprisoned for six months. On his liberation, he retired to his friends in the country, and from his own purse, and the contributions of others, he sent frequent supplies to Charles II. during his exile. On the restoration he received ample rewards for his sufferings and steady loyalty, being restored to his offices, and promoted to the see of London.

The conference between the episcopal and presbyterian divines in 1661, was held at the Savoy, in bishop Sheldon's lodgings. On this occasion he is accused by the opposite party of want of fairness, and he rejected the proposal of an amicable disputation, and inflamed that the Presbyterians should first bring in writing all their objections against the liturgy, and all the additions which they proposed. He did not appear often at the conference, and never entered into disputation, yet he was known to have had the principal share in the determination. To conclude was not his object; he was resolved to carry his point by power: when it was debated in council in Augllt 1662, whether the act of Uniformity should be punctually executed that month, or be suspended for a time, bishop Sheldon pleaded against the suspension, and carried the council with him. "If," says his biographer, "in these and other instances he appears too much the political churchman, in public spirit and mani- fersence he fulfilled, after an exemplary manner, the char- acter of a great prelate. He expended large sums upon the episcopal houses of the see of London, and being in 1665 translated to that of Canterbury, he rebuilt the library at Lambeth, and made many additions to its contents."

On the removal of lord Clarendon from the chancellor- ship of the university of Oxford, he was chosen to succeed him in December 1667, and he immortalized his name in that university by the erection, at his sole expense, of the celebrated theatre at Oxford. Of this act bishop Lowth says, "Munus dignum auctore—quod cum intuor et circum- specto videor mili in ipfa Roma, vel in medii Athenis, antquis
tiquis illis, et cum maxime floribustibus versari." This edifice was opened in July 1679, and almost immediately after the archbishop resigned the chancellorship, and retired from all public business: during the latter part of his life he chiefly resided at Croydon. He died at Lambeth, on the 9th of November, 1677, in the 86th year of his age.

This prelate appears to have been more attached to the duties of morality, than to the profession of any particular doctrines of religion; to young men of rank his advice was always this: "Let it be your principal aim to become honest men, and afterwards be as devout and religious as you will. No piety will be of advantage to yourselves or others, unless you are honest and moral men." Burnet says that "he seemed not to have a deep fenfe of religion, if any at all, and spoke of it commonly as an engine of government, and a matter of policy;" but he allows that he was a very generous and charitable man. From his own books it appears, that from the time of his becoming bishop of London till his death, he expended for public and charitable uses 66,000L. He published a sermon at the thanksgiving for the king's restoration. He was intimate with Chillingworth, and found means to overcome his scruples respecting subscription to the articles of the church of England.

SHELDON, formerly Hungerford, in Geography, a poft-town of America, in the state of Vermont, and county of Franklin, containing 883 inhabitants; 14 miles E. of lake Champlain.

SHELE, a river of England, in the county of Northumberland, which runs into the Tyne, near its head.

SHELF, a term used by the miners in many parts of England, to express a distinction of the inner structure of the earth, so little known to philosphers, that they have no word to express it by. These workmen sometimes also express it by the term soil ground, or soil country. What they mean by this is, that part of the earth, which they find lying even, and in an orderly manner, and evidently having attained its primitive form and situation, unmoved by the waters of the general deluge, while the circumjacent, and upper strata, have plainly been removed, and toled about.

It is evident to reason, that there must have been a very violent concussion of the superficial part of the earth, in the time of its being covered by the waters of the deluge; and experience as much evinces this as reason. Before this concussion it appears probable, that the uppermost surface of mineral veins, or loads, did in most places lie even with the then surface of the earth. The remains of this surface, found at different depths in digging, the miners express by the word shelf.

In this concussion of the waters covering the whole earth, its natural surface, together with the uppermost surface of those mineral veins, were then in many places loosened, and torn off; and the earth, and with it the mineral nodules, called loadstones, were carried down with the descending waters from hills into the adjacent valleys, and sometimes into the streams of rivers, by which they were washed to yet greater distances from their original place. On this depends the method of training mines. Phil. Trans. N° 69. See Training.

SHELFY, or SLaty Soil, in Agriculture, that sort which is chiefly formed of a kind of thin laminated, brittle, flaty material, or which it has much mixed and incorporated with other earthy parts. It is a prevailong sort of land in some districts; this sort of roten flaty matter being largely intermixed with the light loamy mould that constitutes the earthy parts of it.

Where the subfoil or sublimate is a scyllitus, or soft

flate, as is al the cafe in some places in Cornwall, there is great difference, in point of fertility, in the land, according as the disposition of the lamine is more flat, or the contrary; as when flat, the surface is more retentive of the manure which is employed; but when on the edge, what is called a greedy or hungry fort of land is formed, that permits the manure to be washed down through it in too ready a manner, and be lost. See Soil.

SHELL, TESTA, in Natural history, a hard calcareous crust, serving to cover and inclose a kind of animal, hence called testaceous. See Conchology and Testaceology.

SHELLS, Collecting and cleaning of. See Conchology.

SHELLS, Figures and Colours, &c. of. It is observed, that river-shells have not so agreeable or diversified a colour as the land and sea-shells; but the variety in the figure, colours, and other characters of sea-shells, is almost infinite. The number of distinct species we find in the cabinets of the curious is very great; and doubtless the deep bottoms of the sea, and the yet unsearched shores, contain multitude more, yet unknown to us. Even the same species differ in some degree in almost every individual, so that it is rare to find any two shells which are alike in all respects.

Bonani observes, that the most beautiful shells we are acquainted with come from the East Indies, and from the Red Sea. This is in some degree countenanced by what is found to this day; from the general observations of the curious, it seems that the fun, by the great heat that it gives to the countries near the line, exalts the colours of the shells produced there, and gives them a luftre and brilliancy, that those of colder climates always want; and it may be, that the waters of those vast seas, which are not subject to be weakened by fresh rivers, give a nourishment to the fish, that may add to the brilliancy of their shells.

The shores of Asia furnish us with the pearl oysters and scallops in great perfection. About Ambonya are found the most beautiful specimens of the cabbage-shell, the arborfair, the ducal mantle, and the coral oysters, or echinated oysters. Here also are found a great variety of extremely beautiful mussels, tellins, and volution; some fine buccinums, and the shell called the Ethiopian crown, in its greatest perfection.

The dolia, the murices, and the cassinodes, are also found on these coasts in great beauty. Many elegant snails and screw-shells are also brought from thence; and finally the ferapion and spider-shells. Hist. Nat. Eclairc. p. 168.

The Maldive, and Philippine islands, B-negal, and the coast of Malabar, abound with the most elegant of all the species of snails, and furnish many other kinds of shells in great abundance and perfection.

China abounds in the finest species of porcelain shells, and has also a great variety of beautiful snails.

Japan furnishes us with all the thicker and larger bivalves; and the shell of Cyprus is famous above all other parts of the world, for the beauty and variety of the patellas, or limpet, found there.

America affords many very elegant shells, but neither in so great abundance nor beauty as the shores of Asia.

Panama is famous for the cylinders or rhombi, and we have beside, from the same place, some good porcelains, and a very fine species of dolium, or concha globosa, called from this place the Panama purple shell. One of the most beautiful of the cylinders is also known among our naturalists under the name of the Panama shell. About
SHELLS.

About Brazil, and in the gulfs of Mexico, there are found murexes and dolia of extreme beauty, and also a great variety of porcelains, purpure, pectens, nerites, baccardize, or heart-shells, and elegant limpets.

The isle of Cayenne affords one of the most beautiful of the buccinum kind, and the Midas ear is found principally about this place.

Jamaica, and the island of Barbadoes, have their shores covered with porcelains, chame, and baccina; and at St. Domingo there are found almost all the same species of shells that we have from the East Indies, though they are less beautiful, and the colours more pale and dead. The pearl oyster is found also on this coast, but smaller than in the Perian gulf. At Martinico there are found in general the same shells as at St. Domingo, but yet less beautiful.

About Canada are found the violet chame, and the lakes of that country abound with mussels of very elegant pale blue and pale red colours; some species of these are remarkably light and thin; others are very thick and heavy.

The Great Bank of Newfoundland is very barren in shells: the principal kinds found there are mussels of several species, some of which are of considerable beauty.

About Carthagena there are many mother-of-pearl shells, but they are not of so brilliant colours as those of the Perian gulf.

The isle of Magellan, at the southern point of America, furnishes us with a very remarkable species of muffle, called by its name; and several very elegant species of limpets are found there, particularly the pyramidal.

In Africa, on the coast of Guinea, there is a prodigious quantity of that small species of porcelain, which is used there as money; and there is another species of porcelain on the same coast, which is all over white: the women make bracelets of these, and the people of the Levant adorn their hair with them.

The coast of Zanguebar is very rich in shells: we find there a vast variety of the large porcelains, many of them of great beauty; and the *nux maris*, or sea-nut, is very frequent there. Befide these, and many other shells, there are found on this coast all the species of nautil, many of which are very beautiful.

The Canary Isles are found to abound with a vast variety of the murexes, and some other good shells; and we have from Madeira great variety of the echini, or sea-eggs, different from those of the European seas. Several species of mussels are also common there, and the aures marina is no where more abundant.

The Red sea is beyond all other parts of the world abundant in shells, so that scarcely any kind is wanting there; but those we principally have from thence are the purpure, porcelains, and echini marini.

The Mediterranean and Northern ocean contain a great variety of shells, and many of very remarkable elegance and beauty: they are upon the whole, however, greatly inferior to those of the East Indies. The Mediterranean abounds much more in shells than the ocean.

The gulf of Tarentum affords a great variety of purpure, of porcelains, nautil, and elegant oysters; the coasts of Naples and Sardinia afford also the same, and with them a vast number of the molusks of all the known species.

The island of Sicily is famous for a very elegant kind of oyster, which is white all over; *pinna marina* and porcelains are also found in great plenty there, with tellina and *chaema* of many species, and a great variety of other beautiful shells.

Corfica is famous beyond all other places for vall qua-
We have a small species of buccinum common in our fresh waters, which is very elegant, and always has its operculum in the manner of the larger buccina; a small kind of mere is also very common, which is so extremely thin and tender, that it can hardly be handled without breaking to pieces.

The large fresh-water mere, commonly called in England the horse mere, is too well known to need a description, and the fize of this gives it a difference from all other fresh-water shells.

Shells Polishing of. (See Conchology.) This is an art of no long standing in the world, in its present perfection; and as the love of fee-shells is become so common among us, it may not be disagreeable to the reader to find some instructions in executing it pleasing a method of adding to their natural beauty, the rules for which are at present fo little known, though the effect of them is so much esteemed.

Among the immense variety of shells which we are acquainted with, some are taken out of the sea, or found on its shores in all their perfection and beauty; their colours being all spread by nature upon the surface, and their natural polish superior to any thing that art could give. Where nature is in herself thus perfect, it were madness to attempt to add any thing to her charms; but in others, where the beauties are latent and covered with a coarser outer skin, art is to be called in, and the outer veig taken off, all the internal beauties appear.

Among the shells which are found naturally polished are the porcelains, or cowries, the callenders, the dolla, or conchae globosi or tuns, some buccina, the volutes, and the cylinders, or olives, or, as they are generally thought improperly called, the rhombi; excepting only two or three, as the tiara, the plume, and the butter-tub rhombus; where there is an unpromising film on the surface, hiding a very great share of beauty within. Though the generality of the shells of these genera are taken out of the sea in all their beauty, and in their utmost natural polish, there are several other genera, in which all, or most of the species, are taken up naturally rough and foul, and covered with an epidermis, or coarse outer skin, which is in many rough and downy, or hairy. The telingas, the mucus, the coccles, and many others, are of this kind. The more nice collectors, as naturalists, insift upon having all their shells in their native and genuine appearance, as they are found when living at sea; but the Ladies who make collections hate the disagreeable outsides, and will have all such polished. It would be very adviseable, however, for both kinds of collectors to have the fame shells in different specimens, both rough and polished; the naturalist would, by this means, besides knowing the out side of the shell, be better acquainted with its internal characters than he otherwise could be; and the lady would have a pleasure in comparing the beauties of the shell, in its unpolished state, to its coarse appearance as nature gives it.

How many elegancies in this part of the creation must be wholly lost to us, if it were not for the affilience of an art of this kind! Many shells in their native state are like rough diamonds, and we can form no just idea of their beauties till they have been polished and wrought into form.

Though the art of polishing shells is a very valuable one, yet it is very dangerous to the shells; for without the utmost care, the means used to polish and beautify a shell often wholly destroy it. When a shell is to be polished, the first thing to be examined is whether it has naturally a smooth surface, or be covered with tubercles or prominences. A shell which has a smooth surface, and a natural dull polish, need only be rubbed with the hand, or with a piece of chamoy leather, with some tripoli, or fine rotten stone, and will become of a perfectly bright and fine polish.

The operation requires the hand of an experienced person, that knows how superficial the work must be, and where he is to stop; for in many of these shells the lines are only on the surface, and the wearing away ever so little of the shell defaces them. A shell that is rough, foul, and cruddy, or covered with a tartarose coat, must be left a whole day steeping in hot water; when it has imbibed a large quantity of this, it is to be rubbed with rough emery on a flitch, or with the blade of a knife, in order to get off the coat. After this it may be dipped in diluted aqua fortis, spirit of salt, or any other acid; and after remaining a few moments in it, be again plunged into common water. This will greatly add to the speed of the work. After this it is to be well rubbed with linen cloths impregnated with common soap; and when by these several means it is made perfectly clean, the polishing is to be finished with fine emery and a hair-brush. If after this the shell appears not to have good a polish as was desired, it must be rubbed over with a solution of gum arabic; and this will add greatly to its gloss, without doing it any sort of injury. The gum water must not be too thick, and then it gives no sensible coat, only heightening the colours. The white of an egg answers this purpose alfo very well; but it is subject to turn yellow. If the shell has an epidermis, which will by no means admit the polishing of it, it is to be dipped several times in diluted aqua fortis, that this may be eaten off; and then the shell is to be polished in the usual way with putty, fine emery, or tripoli, on the hair of a fine brush. When it is only a pellicle that hides the colours, the shells must be steeped in hot water, and after that the skin worked off by degrees with an old file. This is the case with several of the cylinders, which have not the natural polish of the reef.

When a shell is covered with a thick and fatty epidermis, as is the case with several of the mucus and telline; in this case aqua fortis will do no service, as it will not touch the skin; then a rough brush and coarse emery are to be used; and if this does not succeed, a telline skin, or, as the workmen call it, silk skin and pumice stone, are to be employed.

When a shell has a thick crust, which will not give way to any of these means, the only way left is to plunge it several times into strong aqua fortis, till the thick crust is wholly eroded. The limpets, auris marina, the helmet-shells, and several other species of this kind, must have this sort of management; but as the design is to swell the hidden beauties under the crust, and not to destroy the natural beauty and polish of the inside of the shell, the method of using the aqua fortis must be this; a long piece of was must be provided, and one end of it made perfectly to cover the whole mouth of the shell; the other end will then serve as a handle, and the mouth being stopped by the wax, the liquor cannot get in to the inside to spoil it; then there must be placed on a table a vessel full of aqua fortis, and another full of common water.

The shell is to be plunged into the aqua fortis; and after remaining a few minutes in it, is to be taken out, and plunged into the common water. The progress the aqua fortis makes in eroding the surface is thus to be carefully observed every time it is taken out; the point of the shell, and any other tender parts, are to be covered with wax, to prevent the aqua fortis from eating them away; and if there be any worm-holes, they also must be stopped up with wax; other-
wife the aqua fortis would soon eat through in those places. When the repeated dippings into the aqua fortis showed that the coat is sufficiently eaten away, then the shell is to be wrought carefully with fine emery and a brush; and when it is polished as high as can be by this means, it must be wiped clean, and rubbed over with gum-water, or the white of an egg. In this sort of work the operator must always have the caution to wear gloves, otherwise the least touch of the aqua fortis will burn the fingers, and turn them yellow; and often, if it be not regarded, will eat off the skin and the nails.

These are the methods to be used with shells, which require but a moderate quantity of the surface to be taken off; but there are others which require to have a larger quantity taken off, and to be uncovered deeper; this is called entirely scaling a shell. This is done by means of an horizontal wheel of lead or tin, impregnated with rough emery; and the shell is wrought down in the same manner in which stones are wrought by the lapidary. Nothing is more difficult; however, than the performing this work with nicety; very often shells are cut down too far by it, and wholly spoiled; and to avoid this, a coarse vein must be often left running in some place, and taken down afterwards with the file, when the cutting it down at the wheel would have spoiled the adjacent parts.

After the shell is thus cut down to a proper degree, it is to be polished with fine emery, tripoli, or rotten stone, with a wooden wheel turned by the same machine as the leaden one, or by the common method of working with the hand with the same ingredients, when a shell is full of tubercles, or protuberances, which must be preferred. It is then impossible to use the wheel; and if the common way of dipping into aqua fortis be attempted, the tubercles, being harder than the rest of the shell, will be eat through before the rest is sufficiently scaled, and the shell will be spoiled; in this case industry and patience are the only means of effecting a polish.

A camel's-hair pencil must be dipped in aqua fortis, and with this the intermediate parts of the shell must be wetted, leaving the protuberances dry; this is to be often repeated, and after a few moments the shell is always to be plunged into water to stop the erosion of the acid, which would otherwise eat too deep, and destroy the beauty of the shell. When this has sufficiently taken off the fouslens of the shell, it is to be polished with emery of the finest kind, or with tripoli, by means of a small block, or the common polishing stone of the goldsmiths may be used.

This is a very tedious and troublesome thing, especially when the ecchinate oysters and murices, and some other such shells, are to be wrought; and what is worse of all, that when all this labour has been employed, the business is not well done; for there still remain several places which could not be reached by any instrument; so that the shell must necessarily be rubbed over with gum-water, or the white of an egg afterwards, in order to bring out the colours, and give a gloss: in some cases it is even necessary to give a coat of varnish.

These are the means used by artists to brighten the colours, and add to the beauty of shells; and the changes produced by polishing in this manner are so great, that the shell is often not to be known afterwards for the same it was; and hence we hear of new shells in the cabinets of collectors, which have no real existence as separate species, but are the polished appearance of others well known. To caution the reader against errors of this kind, it may be proper to add the most remarkable species thus usually altered.

The onyx-shell, or volute, called by us the purple or violet-tip, which in its natural state is of a simple pale brown, when it is wrought slightly, or polished with just the superficialities taken off, is of a fine bright yellow; and when it is eaten away deeper, it appears of a fine milk-white, with the lower part blue; it is in this state that it is called the onyx-shell; and it is preferred in many cabinets in its rough state, and in its yellow appearance as different species of shells.

The violet-shell, so common among the curious, is a species of porcelain, or common cowry, which does not appear in that elegance till it has been polished; and the common auris marina flews itself in two or three different forms, as it is more or less deeply wrought. In its rough state it is dull and coarse, of a pale brown on the outside, and pearly within; when it is eaten down a little way below the surface, it flews variegations of black and green; and when full further eroded, it appears of a fine pearly hue within and without.

The nautilus, when it is polished down, appears all over of a fine pearly colour; but when it is eaten away but to a small depth, it appears of a fine yellowish colour, with dusty hairs. The burghen, when entirely cleared of its coat, is of the most beautiful pearl-colour; but when only slightly eroded, it appears of a variegated mixture of green and red; whence it has been called the parquet-shell.

The common helmet-shell, when wrought, is of the colour of the finest agate; and the muscles, in general, though very plain shells, in their common appearance, become very beautiful when polished, and show large veins of the most elegant colours. The Persian shell, in its natural state, is all over white, and covered with tubercles; but when it has been ground down on a wheel, and polished, it appears of a grey colour, with spots and veins of a very bright and highly polished white. The limpets, in general, become very different when polished, most of them showing very elegant colours; among these the tortoise-shell limpet is the principal; it does not appear at all of that colour or transparency, till it has been wrought.

That elegant species of shell called the junquil-chama, which has deceived so many judges of these things into an opinion of its being a new species, is only a white chama, with a reticulated surface; but when this is polished, it loses at once its reticular work and its colour, and becomes perfectly smooth, and of a fine bright yellow; and the violet-coloured chama of New England, when worked down and polished, is of a fine milk-white, with a great number of blue veins, disposed like the variegations in agates.

The sifles car-shell, when polished, after working it down with the file, becomes extremely glossy, and obtains a fine-rose-colour all about the mouth. These are some of the most frequent among an endless variety of changes wrought on shells by polishing; and we find there are many of the very greatest beauties of this part of the creation which must have been lost, but for this method of searching deep in the substance of the shell for them.

The Dutch are very fond of shells, and are very nice in their manner of working them: they are under no restraint, however, in their works, but use the most violent methods, so as often to destroy all the beauty of the shell. They file them down on all sides, and often take them to the wheel, when it muff destroy the very characters of the species. Nor do they stop at this, but, determined to have beauty at any rate, they are for improving upon nature, and frequently add some lines and colours with a pencil, afterwards covering them with a fine coat of varnish; so that they seem the natural lines of the shell. The Dutch cabinets are by
SHELLS.

This means made very beautiful, but they are by no means to be regarded as instructors in natural history. There are some artificers of this nation who have a way of covering shells all over with a different tinge from that which nature gives them; and the curious are often deceived by these tricks into the purchasing of them as new species.

There is another kind of work belted on certain species of shells, particularly the nautilus; this is the engraving on it lines and circles, and figures of stars, and other things: this is too obvious a work of art to suffer any one to suppose it natural. Bonani has figured several of these wrought shells at the end of his work; but it is miserably throwing away labour to do them: the shells are spoiled as objects of natural history by it, and the engraving is seldom worth any thing. They are principally done in the East Indies.

Shells are subject to several imperfections: some of these are natural, and others accidental: the natural ones are the effect of age, or sickness in the shell. The greatest mischief happens to shells by the fih dying in them. The curious in these things pretend to be always able to distinguish a shell taken up with the fih alive, from one found on the shores: they call the fih a living, the second a dead shell, and say that the colours are always much the faintest in the dead shells. When the shells have lain long dead on the shores, they are subject to many injuries, of which the being eaten by fea-worms is not the least: age renders the finest shells livid or dead in their colours.

The finest shells are those which are fished up at sea, not found on the shores. The other natural defects of shells are their having morbid cavities, or protuberances, in parts where there should be none. When the shell is valuable, these faults may be hid, and much added to the beauty of the specimen, without at all injuring it as an object of natural history, which should always be the great end of collecting these things. The cavities may be filled up with marble, dissolved in spirit of wine, or with tinfoil: these subfiances must be either coloured to the tinge of the shell, or else a pencil dipped in water-colours must fill them up to the reclamation of the reef, and then the whole shell being rubbed over with gum-water, or with the white of an egg, scarcely any eye can perceive the artifice; the fame subfiances may be used to repair the battered edge of a shell, provided the pieces chipped off be not too large. And when the excreances of a shell are faulty, they are to be taken down with a fine file. If the lip of a shell be fo battered, that it will not admit of repairing by any cement, the whole must be filled down to an eveness, or ground on the wheel.

Shells, Fossil. See Conchology and Petrifications.

Shells are frequently found under ground, in places far remote from the sea, in mines, and even on the tops of mountains; but how they should come thither is a thing that naturalists are greatly divided about. The most usual and eafy opinion is, that those parts have been formerly sea, or, at leaft, have been overflown thereby; and many even go back as far as the grand deluge for this. Others take thefe to be the natural places of their birth or formation, some of them being found little other than crude clay, others of the fame texture with the rock to which they grow, though others seem of as absolute a shellfy subfiance as any in the sea. In effect, they fay, there may be only fo many different gradations of nature, which can as well produce shells in mines as in the sea, there being no want of fahine or earty particles for the purpofe; nor is there any great difference between fome forts of fars and fahills.

Dr. Litter judges, that the shells found in ftony quarries were never any part of an animal, and gives this reason for it, that quarries of different fone yield quite different fpecies of shells; different not only from one anothers, but from any thing in nature besides, which either sea or land does yield. This opinion has been fince proved erroneous, and all these bodies to have been really once parts of living animals. See Fossil, Adventitious, Marine Remains, and Formed Stones.

Of these shells, some are found remaining almost entirely in their native state, but others are variously altered, by being impregnated with particles of ftony, and of other fossils; in the place of others there is found mere ftony or spar, or other native mineral body, exprefling all their linesments in the greatest nicety, as having been formed wholly from them, the fhell having been firft deposited in some folid matrix, and thence diffolved by very flow degrees, and this matter left in its place, on the cavities of ftony and other folid subfiances, out of which shells had been diffolved and washed away, being afterwards filled up fhes flowly with these different subfances, whether fpar or whatever else; these subfances, in filling the cavities, can apparently be of no other form than that of the fhell, to the absence of which the cavity was owing, though all the nicer linesments may not be fo exactly expreffed. Before thofe, we have alfo in many places masses of ftony formed within various shells; and thofe having been received into the cavities of the ftons, while they were perfectly fluid, and having therefore nicely filled all their cavities, must retain the perfect figures of the internal part of the fshell, when the shell itself should be worn away, or perifhed from their outside. The various species we find of thofe are in many genera as numerous as the known recent ones; and as we have in our own ifland not only the shells of our own fhores, but thofe of many other very diftant ones, fo we have also many species, and thofe in great numbers, which are in their recent flate, the inhabitants of other yet unknown or unfeard fons and fhores.

The cockles, mufcles, oysters, and the other common bivalves of our own fons, are very abundant; but we have also an amazing number of the nautilus kind, particularly of the nautilus gracerom, which though a fhell not found living in our own, or any neighbouring fons, yet is found buried in all our clay-pits about London and elsewhere; and the moft frequent of all fossil shells in fome of our counties, are the conchæ anomies, which yet we know not of in any part of the world in their recent flate. Of this fort alfo are the conus ammonis and the gyphites, with ferveral of the echinæ and others.

The eztact fimilitude of the known shells, recent and fossil, in their ferveral kinds, will by no means fuffer us to believe, that thofe, though not yet known to us in their living fate, are, as fome have idly thought, a fort of fulus nature.

It is certain, that of the many known fones, very few, not even thofe of our own ifland, have been yet carefully searched for the shell-fih that inhabit them; and as we fee in the nautilus gracerom an infance of shells being brought from very diftant parts of the world to be buried there, we cannot wonder, that yet unknown fones, or the unknown bottoms of deep fons, should have furnished us with many unknown shell-fish, which may have been brought with the fels; whether that were at the time of the general deluge, or the effect of any other catastrophe of a like kind, or by whatever other means to be left in the yet unhardened matter of our ftons and clayey ftrata. Hill's Hift. of Foss. p. 616.

Fossil shells are found to be of great ufe in manuring land. See Manuring.
They are much used in France for this purpose; and Mr. Reaumur treats of their effects in fertilizing the earth very fully, concluding his useful account of these substances by observing, that it is much more easy to account for the manner of their acting upon land, than for the manner of their coming where they are found. It has been the favourite system of our Dr. Woodward, that all these shells were the remains of the universal deluge, which having overflowed the whole earth, might easily leave them in all places; but Mr. Reaumur has much more rationally accounted for their coming to those parts of France, where they are found at this time in such vast abundance, by carefully tracing the course of the beds of them, so far as known there, and easily proving that all that extent of country, under which they are found, may have been once overflowed by the sea without a deluge; it being very plain that a large body of waters, let in at one part of the kingdom, must have taken, in order to getting out at another. Mem. de l'Acad. Par. 1720.

**Shell, Arabian**, a name given by some to a species of porcelain shell, not because it is found on the coast of Arabia, but because its lines and variegations are supposed to represent the figures of Arabick characters.

**Shell, Aurora**, a very remarkable species of shell-fish, found in cabinets of the curious. It is of the figure of a bird, having a head, wings, and tail, and is of a flame-colour; it owes much of its beauty, however, to art and accident; the shell is an oyster of a peculiar variation of figure from the common one; the head of the bird is the cardo or hinge; the wings are the body of the shells; and the tail is a peculiar process, like that of the marten, only fingle.

It is naturally of a dusky brown on the outside, and pearly within, but when its rough coat is taken off, it appears of this beautiful flame-colour.

**Shell, Caterpillar.** See Turbo.

**Shell, Centre**, a name given to the balanus marinus, a kind of sea-shell of the multivalve kind, with an open mouth, frequently found fixed to the bottoms of ships, and other things covered with sea-water. See Balanus and Conchology.

**Shell, Chiaries, or Cup-shell**, a species of the balanus. See Balanus.

**Shell, Gnaws-letter**, a name given by many to that species of chama, usually called by authors the chama Arabica. It is of a pale brownish ground, and is variegated with a great number of black lines, which are as slender as the strokes of a pen, and are of such odd figures, that they represent some of the Arabic, or, as others fancy, Chinese characters. See Chama.

**Shell, Crown Imperial**, a species of the voluta.

**Shell, Dog-tooth**, a species of dentalis.

**Shell, Ear**, See Auris.

**Shell, Guinea**, the English name for a very beautiful variegated species of voluta, called by the French la speculation.

**Shell, Heart.** See Cardium, under Conchology.

**Shell, Helmet**, the name of a kind of murex, of which there are several species. They all approach somewhat towards a triangular figure, and are free from any long spines.

**Shell, Leopard**, the English name of the pardus, a kind of voluta, so called from its spots resembling those of a leopard. There are three kinds of this, one spotted with black, another with yellow, and another with red.

**Shell, Leveret**, a name given by many to a species of porcelain-shell, resembling a young hare in colour.

**Shell, Lightning**, a name given by some authors to a species of murex, with variegations on its body, resembling the pictures we commonly see of flashes of lightning.

**Shell, Map**, the name given by some to a peculiar species of porcelain-shell, the figures on which represent the lines on a map.

**Shell, Needle.** See Centoria and Needle.

**Shell, Noah's Ark.** See Noah.

**Shell, Oyster.** See Oyster.

**Shell, Old Wife**, the name given by some to that species of chama, which the French also have called vielle ridee.

**Shell, Onion**, a species of oyster.

**Shell, Pipe.** See Entalium.

**Shell, Saddle**, the name of a species of oyster, which in some degree represents a saddle in its shape.

**Shell, St. James's**, a name given by writers on shells to a very beautiful species of variegated pecken.

**Shell, St. Michael's**, a name given by authors to a species of pecken, or scallop-shell. It is of a bright yellow colour.

**Shell, Scorpion**, the name of a species of murex, very much approaching to the nature of the spider-shell. This is a common shell in cabinets; it is of a yellow colour, and very deeply ridged, and full of tubercles; there arise from the lip of the shell five large spines, or, as they are usually called, fingers, and two others, which are very much bent, the one from the head, the other from the tail; these are very elegantly radiated with white, and a fine violet colour on the lips.

**Shell, Screw.** See Turbo.

**Shell, Small-pox**, a name given to a remarkable kind of concha venerea, or porcelain-shell, the protuberances on the surface of which are supposed to represent the pustules of the small-pox. There are two species of this shell, the one white, with flatish protuberances, the other greenish, with more elevated ones.

**Shell, Snake**, the name given by many to that beautiful species of porcelain-shell, the spots of which represent those of a snake's skin.

**Shell, Spider.** See Aranea.

**Shell, Strawberry**, a name given by collectors of shells to a very beautiful species of cordiforms, spotted with small round red spots.

**Shell, Swallow**, a name given by authors to a species of oyster, which in some degree represents the figure of a small bird flying.

**Shell, Tiger**, the name of a species of porcelain, or concha venerea, supposed to represent the spots on a tiger's skin.

**Shell, Tor.** See Pollicipes.

**Shell, Tortoise.** See Tortoise.

**Shell, Trumpet.** See Trumpet.

**Shell, Turban.** See Turban.

**Shell, Turnip.** This is a species of sea-shell, by others called the radialis shell; it is exactly of the shape of a turnip, and is of the dolium, or concha globosa kind. Those who have called it the radialis shell, allude to the great black round-rooted radialis, not to our common radialis.

**Shell, Turtle**, the name of two species of shells. See Murex and Voluta.

**Shell, in Agriculture**, a term applied to a hard, and as it were flinty covering, with which certain substances and animals are defended, and thence in the latter cafe called shell-fish. It is observed that the salt beds of flinty shells found at great depths in the earth, as well as those lying
Lying on the sea-shore, make an excellent manure for cold clayey lands. See Sand and Clay.

It is likewise a term applied to the light calcined pieces of calcareous flints, which have been converted into lime; and also to the kind of turpines scooped by sheep, which are mostly applied to the purpose of feeding the store-sheep. See Lime and Turpines.

Shell-Apple, in Ornithology, an English name for the loxia or crosbill, given from his manner of splitting an apple, and feeding on the kernels, leaving the shell of the pulp untouched.

Shell-Drake, a common English name for the tadorne.

Shell-Fish, a collective name for fishes naturally inclosed in shells. These animals are in general oviparous, very few instances having been found of such as are viviparous. Among the oviparous kinds, anatomists have found that some species are of different sexes in the different individuals of the same species, but others are hermaphrodites, every one being in itself both male and female: in both cases their incurve is very numerous, and scarcely inferior to that of plants, or of the most fruitful of the infect clads. The eggs are very small, and are hung together in a fort of clutters by means of a glutinous humour, which is always placed about them, and is of the nature of the jelly of frogs' spawn; by means of this they are not only kept together in the parcel, but the whole clutter is fastened to the rocks, shells, or other solid substances, and thus they are preferred from being driven on shore by the waves, and left where they cannot succeed.

Shell-Gall-Infest, an infect of the gall-infest clads, somewhat resembling those which are called the boat-fashioned ones, but differing in this, that the two ends of that species are not very different in form. In this kind one of the ends is sharp and pointed in comparison with the other.

It has its name of shell-infect from the resemblance it bears to a muscle-shell; as it is, in its whole form, not unlike one of the two shells in which the common sea-muscle is inclosed, but the pointed end of this infect is much more extended in length than the smaller end of this shell.

This species is extremely small, and may be easily mistaken for the minute case out of which some small infect has escaped; or in another flate, for the nelt in which some small infect had deposited its eggs; but if the assiduity of the microscope be called in, they will easily be discovered to be true gall-infests, even as soon as they are hatched from the eggs. This species, at its full growth, is so small, that it requires good eyes to discover it: it is brown, very smooth, and polished on the surface, and much of the colour of the bark of some trees; it has usually an edge of a cottony matter, visible where its sides touch the tree, and its eggs are always deposited on a fine cottony bed; the young ones are white, flat, and have two small horns, and fix legs; in this state they are known to be of the gall-infest clads, not by their likenes to their parent, but to the young gall-infests of other species. They march about very briskly for some time after they are hatched, and after that fix themselves, and then begin to grow, and by degrees alter their form, until they are length of the same shape with those parent. Reaumur, Hist. Inf. tom. iv. p. 69, 70.

Shell-Marls, in Agriculture, a subfrance of the marly kind, which is of a flaky or shelly nature. Though Mr. Marshall has not seen this material made ufe of in any of the southern parts of this country, he supposes it highly probable, that in the more northern counties it may be found in considerable quantity; and that in different parts of Scotland, it is in common ufe as a manure. And he considers it as usually found in low moit situations, under what is termed bog-meadow, a fort of half-reclaimed moras; namely, tough, coarse fward, formed upon a depth of black moory earth, which rests on the marle; this being, in some instances, several feet in depth. In respect to appearance, the colour is nearly white. Its confidence, in the pit, is that of soft curd, roughly broken; with the perceptible remains of small shells interpersed among it; and generally with some part of earthy particles. It was found by analysis, that one hundred grains of a specimen taken in 1793, from the extraordinary pits on the elate of Aucbertyre, belonging to the late Sir William Murray, on the southern skirls of the highlands of Perthshire, yielded eighty-two grains of calcareous earth: the refuse being brown earthy matter, mostly, it is probable, animal mould, with a flight intersmixture of vegetable fibres. One hundred grains, taken from a pit in Strath Tay, within the central highlands, yielded seventy-four grains of chalk; the refuse being similar to the above. The search for this species of marle is so obvious and eafy, that nothing but unpardonable negleét can caifer a quantity of it to remain within an elate (situated in a country where it is known to abound) unknown to its manager. Wherever, in valleys and dips of surface, level water-formed lands (whether they are already fwarded over, or yet remain in a state of moras) are found, there exist the borer: not in one place only, but in various parts of it, that no hollow receptacle of marle may be missed by the farmer.

And with marles of the foilie kind it is remarked, that where, by analysis, the proportion of chalk is found to be small, as not more than one-third of the whole; if the earthy matter with which it is combined appears to be of a rich fertilizing nature, such marle becomes, he thinks, a proper subject of trial in the field. And a good method for making this fort of trial, is to spread the marle, at a leisure time, as in winter; or the early part of summer, upon grass-land; and catching a favourable opportunity, when the foil is in a mellow friable state, between wet and dry, to break down and spread the lumps, with the roller and harrow, to give freedom to the grafs, and an opportunity of gathering off the flores and rubbish, which may have been carried on with the marle; and in order that summer showers may wash the finer parts of it down into the soil, while it is open to receive them; repeating the operation as often as it may be required. And he knows no better method than this, by which to apply marles, on a large scale, in practice.

Shell-Sand, a name given by the farmers, in some parts of England, to the fragments of shells found on the sea-shores, and ground to a fort of powder, so that they rememble sand. See Manuring.

There is also another kind, ufed as this, in some parts of Cornwall, and composed of fragments of a fort of tender white coral. This is found principally about Falmouth, and is called by the fame name of Shell-Sand, though very improperly. All the kinds are of great ufe in agriculture, but they are differently esteemed by the farmers, as they are more or less rich, which they know by their colours: the reddish kind is esteemed most of all; next to this the blue is judged the best, and after this the white. Such as is dredged up from under the water, is always found better than such as is found dry on the shores; and such as is entirely composed of shells is to be chosen, rather than such as has fragments of stone among it, which is a very common cafe. See Sand, and Shelly Sand.

Shell-Toothed, in the Manges, an appellation given to a horse that from four years old to old age, naturally, and without
without any artifice, bears mark in all his fore-teeth, and there still keeps that hollow place with the black mark, which is called in French germe de feve, i.e. the eye of a bean, innumerable, that at twelve or fifteen he appears with the mark of a horse that is not yet fix'd; for in the nippers of other horses, the hollow place is filled, and the mark disappears towards the sixtith year, by reason of the wearing of the tooth. About the same age it is half worn out in the middle teeth, and towards the eighth year it disappears in the corner teeth; but after a shall-toothed horse has marked, he marks still equally in the nippers, the middle, and the corner teeth; which proceeds from this, that having harder teeth than other horses, his teeth do not wear, and so he does not lose the black spot.

Among the Polits, Hungarian, and Croatian horses, we find a great many of them hollow-toothed, and generally the mares are more apt to be so than the horses.

**SHELL**, in *Mechanics*. See *BOMBS* and *MORTARS*.

**SHELLS**, *Muzzles*, are hollow-shells, within which are included a letter, or other papers; the fuze-hole is stopped up with wood or cork, and the shells are fired into a garrison or camp.

**SHELL of a Block**, in *Mechanics*, is the outer frame or cafe, in which the heave or wheel is contained, and traverses about its axis.

**SHELL-ROOM**, in *Ship-Building*, a compartment in a bomb-vellet, fitted up with strong shelves, excavated so as to receive the bomb-shells when charged; it is therefore built as secure as possible, to prevent accident from fire.

**SHELLS**, *Littoral*. See *LITTORAL*.

**SHELL-Gold*. See *GOLD*.

**SHELL-Silver*. See *SILVER*.

**SHELL, Island*, in *Geography*, a small island near the coast of Carolina, in Pamlico Sound. N. lat. 34° 50'. W. long. 76° 30'.

**SHELL Key**, a small island, or rather rock, in the gulf of Mexico. N. lat. 29° 48'. W. long. 89° 15'.

**SELLA**, a walled town of Morocco, on the eastern side of Rabat, in N. lat. 34° 3'. This is faced ground, and contains many Moorish tombs, that are held in great veneration; and the town is a faced asylum, entered only by Mahometans. Sella was probably the Carthaginian metropolis on the coast of the ocean. Various Roman and ancient African coins were formerly dug up here, but their high price induced the Jews to imitate them, and thus to deceive amateurs, and hence has arisen a suspicion even of the antiques themselves. The place is now in a state of decay; 4 miles E. of Salee.

**SHELLACK POINT**, a cape of the Isle of Man, forming the N. part of Ramfay bay.

**SHELL DRAKE RIVER**, a river of Canada, which runs into the river St. Lawrence. N. lat. 50° 20'. W. long. 64° 50'.

**SHELLBENGEN**, a mountain of Bavaria, occupied by the Swedes, and strongly fortified in the 30 years' war; 3 miles N.E. of Donawert.

**SHELLF*, the Celestial of antiquity, a river of Africa, and the most considerable in the kingdom of Algiers, which rises in the northern side of the Atlas, and runs into the Mediterranean, N. lat. 30° 12'. E. long. 0° 24'.

**SHELLFESS**, a cape at the E. end of the island of Shepey. N. lat. 51° 2'. E. long. 0° 50'.

**SHELLuhs**, a tribe of the inhabitants in the dominions of the emperor of Morocco; they occupy the Atlas mountains, and the various branches of them S. of Morocco; living generally in towns, and, for the most part, occupied in husbandry like the Berchebers, though differing from them in their language, dress, and manners. They fufbitt almost wholly on Aouia (barley meal made into gruel), and barley roasted or granulated, which they mix with cold water when traveling, and they call it "Zimata." They occasionally indulge in the use of "Cufcufoc," a nutritive farinaceous food, made of granulated flour, and afterwards boiled by steam, and mixed with butter, mutton, fowls, and vegetables. Many families among them are said to be descended from the Portuguese, who formerly poftessed all the ports on the coast, but who, after the discovery of America, gradually withdrew thither. East of Morocco, near Dimenen, on the Atlas mountains, there is still remaining a church, having inscriptions in Latin over the entrance, supposed to have been built by them, which, being superflitously reported to be haunted, has escaped destruction. Their language is called Amazirk.

**SHELOPGUR**, a town of Hindoostan, in the Carnatic; 18 miles N.W. of Tricolore.

**SHELTER**, in *Agriculture*, a term applied to the means of affording warmth, and procuring protection for lands and live-stock in situations which are too much exposed to storms, and inclement weather. This is mostly accomplished by the use of trees, which should be chosen of the most proper shapes and kinds for effecting the purpose, as those which are the most branchy from the ground, and the most permanent and close in their foliage. The fir tribe, the holly, and the beech, are probably the most suited to this intention, though there are great numbers that may be made use of in this way.

Proper shelter has the effect of producing much improvement in land, trees, plants, and live-stock. See *SHELTERING PLANTATIONS*.

**SHELTER Island*, in *Geography*, a small island at the E. end of Long Island, in Suffolk county, New York, about five miles from E. to W., and seven from N. to S. It is fertile, and contains about 8000 acres; it was incorporated in 1783; and is said to contain 201 inhabitants. It furnishes cattle, sheep, and poultry.

**SHELTERING PLANTATIONS*, in *Agriculture*, the means of guarding and protecting them, so as to promote the growth and advancement of the young trees. This is frequently necessary, and of very great utility. In some very exposed situations, trees cannot indeed be reared to any advantage without it. The business is performed in different manners, according to their nature and circumstances. See *PLANTATION*.

**SHELTERS*, Horizontal. See *Horizontal*.

**SHELTEE*, the name of a small, but strong kind of horse, found in the island of Zetland, commonly called Shetland. In the country, the price of one of these horses was formerly about a guinea.

**SHELVES*, in *Sea Language*, a general name given to any dangerous shallows, sand banks, or rocks; lying immediately under the surface of the water, so as to intercept any ship in her passage, and endanger her destruction.

**SHELVING-ROADS*, in *Rural Economy*, are such as are formed in a fomented shelving manner, either on both sides from the middle part, or in the whole from side to side. It is a mode that forms a great improvement in making roads in different situations; as a greater travelable breadth is gained without ruts being formed. And it is particularly applicable in making the side long roads on the declivities of hills, &c. See *Road*.

**SHELVINGS*, in *Agriculture*, a name applied to the moveable side rails of a waggon or cart, which are occasionally put on for top loads.

**SHEMEN**,
SHE

SHEMEN, in Geography, a town of Curdiolan; 44 miles N.W. of Kerku.

SHEMIUM, a town of Persia, in the province of Khorasan; 10 miles N.W. of Herat.

SHENANDOAH, a county of Virginia, bounded N. by Frederick, and S. by Rockingham. It contains 13,045 inhabitants, of whom 1293 are slaves. Its chief town is Woodstock.

Shenandoah, or Shenandoa, a river of Virginia, which rises in Augusta county, and after running a N.E. course of about 200 miles, joins the Patowmack in about N. lat. 39° 4', just before the latter burts through Blue Ridge. This river is composed of four branches, S. river, Middle river, N. river, and Shenandoah, which, though the smallest branch, gives name to the united streams. It is navigable about 100 miles, and might be rendered so through its whole course, at a small expense. When this is done, it will convey the produce of the richest part of the State to Washington.

Shenandoah Valley, a valley which extends from Winchester in Virginia, to Carlisle and the Susqueannah in Pennsylvania, chiefly inhabited by Germans and Dutch.

SHENANGO, a town of Pennsylvania, in Crawford county, containing 727 inhabitants.

Shenaw, a town of Austria; 4 miles S. of Kirch Schlague.

Shencotty, a town of Hindooftan; 45 miles N.E. of Travancore.

SHENECTADY. See Shenectady.

Shenegan, a town of Hindooftan, in the Carnatic; 25 miles S.S.W. of Madura.

Shenkfeld, a town of Austria; 5 miles W. of Freyland.

Shen-see. See Chen Shih.

Shensen, in Rural Economy, a term applied, in some districts, as Devonshire, to dried cow and horse-dung, which is laid up and used as fuel for the winter season.

Shenshil, in Geography, a town of Egypt, on the right bank of the Nile; 2 miles N. of Achmim.

Shenstone, William, in Biography, a poet of celebrity, was born at Hales Owen, in Shropshire, in the year 1714. His father was an uneducated gentleman farmer, who cultivated an estate of his own called the Leafowes, which the son afterwards rendered celebrated. William received the elements of instruction from a village dame, whom he has finely described in one of his poems. After this he was sent to the grammar-school at Hales Owen, whence he was removed to that of a clergyman at Solihull, from whom he not only acquired solid learning in classical knowledge, but a cultivated taste. In 1732 he was entered of Pembroke college, Oxford, where, he did not make a large acquaintance, but he was one of a few who met at each other's rooms to read and examine the belles lettres in English literature. Here it was that he discovered his poetical genius, and produced some compositions of considerable merit, and he had thoughts of taking his degrees, and proceeding to study for a profession, but coming, by the death of his father, into the full possession of his paternal property, he gave himself up to literary cafe, and rural retirement, abandoning at once all intentions of active pursuits; hence his biographer judicious remarks, "that nothing is more unfavourable to the exertion of those energies which lead to a useful and honourable station in society, than the early possession of a fortune sufficient to gratify present wishes, and preclude the necessity of immediate entrance into any vigorous course of action." An acquaintance which Shenstone formed with Mr. Graves of Mickleton, in Gloucestershire, inspired him with an affection for that gentleman's sister; but the passion of love, which, in some minds, operates as a stimulus to enterprise, seems to him to have wasted its force on plaintive elegies, and other effusions of sentimental poetry. To one species of employment, indeed, he was probably animated by his visit to Mr. Graves,—that of rural embellishment,—which he afterwards befell to his favourite place of the Leafowes, with that taste that conferred more to his celebrity than his comfort.

In 1737 he printed, but without his name, a small volume of juvenile poems, which obtained scarcely any notice. In 1740 he came to London, and was introduced to Doddley, who printed his poem of "The Judgment of Hercules," dedicated to lord Littleton. This was followed by "The School-mistrefs," of which the heroine was the village dame already referred to. This is thought, by some very respectable critics, to stand at the head of Shenstone's compositions.

Shenstone, from this time, devoted himself to improving the picturesque beauties of the Leafowes, and sometimes exercising his pen in effusions of verse and prose. The celebrity of this place led him into excursions which his fortune was unequal to, and he was perpetually under the pressure of poverty; which, with the deficiency of regular employment, and the perpetual desire of doing more, and appearing better off, than his means admitted, preyed on his spirits, and rendered him the miserable inhabitant of the Eden which his taste and genius had created. Grey has described him in the following sentence, which may in some respects be rather a caricature likenet. "Poor man! he was always wishing for money, for fame, and for other distinctions; and his whole philosophy consisted in living against his will in retirement, and in a place which his taste had adorned, but which he only enjoyed when people of note came to see and commend it." It has been thought a matter of surprize, considering his connections, that nothing was done to place him in easier circumstances. Application was said to have been made to lord Bute to procure him a pension from the privy purse, but before the wishes of his friends could be realized he died. This event took place in February 1763, when he was in the 50th year of his age; he was interred in the church-yard of Hales Owen.

Of his poetical compositions many were inserted in Doddley's collection of original pieces; and after his death, his "Works in Verse and Prose" were published in two vols, 8vo. in 1764, and a third volume, consisting of "Letters," was published in 1769. "Of his poetry," says the critic, "the general opinion was almost uniform; it is regarded as commonly elegant, melodious, tender, and correct in sentiment, and often pleasing and natural in description, but verging to the languid and feeble, and never exhibiting either the powers of the imagination, or the energy and splendid of diction, that characterize compositions of the higher order. His prose writings display good sense and a cultivated taste, and contain just and sometimes new and acute observations on mankind."

Shenuzan, in Geography, a town of Candaor; 42 miles E. of Ghizini.

Shepey, Ile of, an island within the liberty of the fame, lathe of Sway, and county of Kent, England, is situated near the mouth of the river Thames, and is separated from the mainland by a narrow arm of the sea, called the Swale, which bounds it on the south, while the estuary of the Medway, and the German ocean, bound it on the west, north, and east. It is uncertain by what name this island was known to the Romans; for though Tolemy, in his Geography, mentions two islands in this part of Britain by the
SHE

the appellations Toliapis and Coums, he does not describe either of them so precisely as to identify it with Shepey. Hence this subject is a matter of dispute among our most eminent antiquaries; Camden and Batteley contending for Toliapis; and Lambard, Leland, and others, for Coums. In Saxon times it was called Sacapige, or the island of sheep, from the great numbers of that animal which were then pastured upon it, whence originated, by corruption, the name by which it is now distinguished. Baxter, in his Glossary, under the word Malata, remarks, "Verumquam Patria, or the Isle of Sheep, now named Shepey." This is corruptly called by the book of Ravennas, Malaca, by the Britons Verpes? but these observations are rather conjectural than well authenticated.

The Isle of Shepey, including the small adjoining islands of Elmley and Hartly, which lie at the south-east side of it, measure about 32 miles in circumference, being about 11 miles long and 5 broad. On the southern side the lands are flat and marshy, but the interior is diversified by hills, and the northern shore presents a range of cliffs, extending six miles in direct length. These cliffs are chiefly composed of a flame friable marle, abounding in pyrites, and in some places rising perpendicularly to the height of 90 feet. They belong principally to the three manors of Minster, Shurland, and Warden, the owners of which let them to the copperas makers, who employ the poor inhabitants to collect the pyrites, or copperas stones, which are continually washed out of the cliffs by the force of the waves, and are of various forms, as globular, oblong, &c. Their external covering is a ferruginous coat; and within they are of a friated texture, commonly radiated from a centre. The ludi Helmontii also abound in these cliffs. They are in general of a compressed form, from twelve inches to two feet and a half long, and covered with a thick crust of indurated clay. Where the clay is most tenacious, ceilings are found of several varieties. Large nodules of petrified wood, retaining the appearance and grain of oak, are likewise met with in these cliffs and on the shores; also a vast number of fruits; but as these are always saturated with pyritical matter, they soon fall to pieces. Animal remains have likewise been found here of many different kinds: as the thigh-bones, tufks, and grinders of elephants; two species of tortoises; the heads, tails, and palates of fish; the teeth and vertebrae of sharks, crabs, lobsters, shells, &c.

The greatest part of this island is of an exceeding flinty clay soil, and consists chiefly of upland pastures and marsh lands. Towards the north side, however, in the parishes of Minster and Ealchurch, it is very fertile in corn, the inclosures of which are small, and surrounded with thick hedge-rows of elm. The roads throughout the island are very good during the whole year, owing to the great plenty of fine gravel found in the beach-pits, and the prospects from them are very pleasing and extensive on every side. Fresh water is very scarce, and the greatest part of it brackish, though between Ealchurch and Minster there are a few springs, which, notwithstanding they rise near the sea, the waters of them are perfectly good and fresh. The air is generally thick, and much subject to noxious vapours, arising from the large quantity of marshes in and near it. Hence, and from the badness of the water, few people of substance live in it, the inhabitants consisting in general of lookers, bailiffs, farmers, and servants. The garrison and dock of Sheerness and its environs, the reader will however of course except from this observation, where there are many gentlemen employed in the government service constantly resident. See Sheerness.

The water which flows between this island and the main land is called the Swale, and the two extremities of it the East and West Swale. It reaches about twelve miles in length, and is navigable for ships of two hundred tons burthen. This water seems formerly to have been accounted a part of the river Thames, and to have been the usual, as being the safest, passage for the shipping between London and the North Foreland. Accordingly Sandwich is frequently visited by our ancient historians Landumus, or the Thames mouth, being the name given to it by the Saxons, and the town of Milton is said by them to stand on the south bank of the Thames. Leland in particular says, in his Itinerary, "that towse stands on an arm of the Tamye," and he speaks of the point against "Quinboro-rough entering into the mayne Tamye."

The usual passage to this island is by a ferry, called King's Ferry, for carriages, horses, cattle, and passengers. The ferry-boat is moved forward by a long cable, of about one hundred and forty fathoms, or more, which being fastened at each end across the Swale, serves to move it forward by hand. On the side opposite to the island there is a small house of stone, in the room of one formerly erected by one George Fox, who having lived a long while in the cold waiting for the boat, and being much affected by it, built it to shelter others from the like inconvenience.

The very convenient situation of the Isle of Shepey for the excelling purfuits of the Danes, occasioned it to be made their accustomed rendezvous; and they sometimes wintered here during the course of the ninth century. The inhabitants were then but few, and chiefly congregated in the neighbourhood of Minster, where Saxon, widow of Ercemont, king of Kent, had founded a nunnery, which, after being several times plundered by the invaders, was at length, in a great measure, destroyed, and the nuns dispersed. The large tumuli in the lower or southern part of the isle, and which are termed coterets by the country people, are supposed to cover the remains of different Danilh chiefs, who were in battle during their piratical incursions. The years which have been particularly recorded as those wherein these marauders were most active here, are 832, 849, 851, and 854; in the year 1016, king Canute is said to have collected the scattered remains of his army in this isle, after his defeat in the vicinity of Otford, by Edmund Ironside. India's History and Antiquities of Kent, 8vo. 1798. Beauties of England and Wales, vol. iii. by E. W. Brayley and John Britton, 8vo. 1806.

SHEPERD, in Agriculture, a labourer or other person who has the care and management of a flock of sheep. It is a business that requires much care, attention, and knowledge of the various methods of treating animals of this kind. Mr. Bannister thinks, that it is necessary for this employment a person who is well skilled in the nature and management of sheep, and hath been brought up in that employment from his infancy; who is sober, diligent, and good-natured; qualities essentially necessary in a shepherd, who, although he may seem to live a life of indolence, when contrasted with the more laborious servants of the farm, need rarely to have a minute's time hung heavily on his hands, if he will be attentive to his business, which will furnish him with sufficient employment throughout the day, particularly in the lambing season, or where there are two folds at work; or will he want opportunity for the exercise of his patience and good temper in his attendance on the sheep, which are by nature animals of great obstinacy and perseverence, and which have often paid the forfeit of their lives to these innate qualities, where the shepherd was a man of morose and furious disposition. It is said that on the continent they have schools wherein young shepherds are instructed in the necessary
cellary knowledge of their business, as well as the anatomy
and physiology of sheep, the food and treatment proper
for them in different seasons, and the nature of their diseases,
and the common operations respecting them, especially re-
garding the parturition of the ewes, &c. And in the Ge-
neral Treatise on Cattle, it is remarked, that the method
of encouragement, adopted in some districts, of allowing the
shepherd to possess a small flock, or as many ewes as his
means will allow, is probably one of the most powerful. It
gives him that freedom appertaining to property, and is
an additional and strong incentive to the attainment of
knowledge in his business. A shepherd should be naturally
active, both in body and mind, clear-headed and clear-
fighted; such an one, for instance, as can distinguish
the individual countenances of a numerous flock, and running
over them with his bodily and mental eye, infallibly give
the exact number and condition; or perceive at a glance, a
bird's nest in the tidiest quickset. Fond of animals and
attractive to them, the latter quality of which is well known
to inhore in some persons; poecilising a musical voice and
shrill whistle; hardy, patient, watchful; fatished with little
sheep, and temperate in drink. It is conceived that he ought
never to be sufferer, if he profests, to practice physic, nor
any but the most easy and common operations, a farce that
too often ends in a tragedy; for if of two evils we ought
to choose the least, the office of medical practice had better
devolve on the matter. And for his comfort in the fevere
weather, in some situations, the movable wooden houle on
wheels may be of use. Allo that he ought to be clad dur-
ing winter, with subintiial woollen next his skin, from his
feet upwards, as the bell defense against those rheumatic
ail to which he must be necessarily subject; and he should
always go provided with the instruments proper to his pro-
fession, ready for immediate occasions, namely, whips, knife,
flcet, fleam, false-box, &c. And in folding, as the shep-
heard will have the flock perpetually under his eye, the first
writer thinks, he will be capable of judging with certainty
and precision respecting the state of every individual, so that
the earliest remedy may be applied to every disorder, and such
sheep may be turned out of the fold which are found not to
be able to go through their work without manifest injury to
their health; and if a sheep or lamb be seized with a dan-
grous and incurable malady, to kill and dres it immediately;
for it is one part of the business of a shepherd to be
so far skilled in the butcher's trade, as to be able to slaughter,
fc, and dres a sheep on occasion. Further, that a good
shepherd will be careful that his flock be driven late to
fold of an evening, and released early in the morning from
their confinement, in order that they may enjoy the coolest
parts of the day on the food. He will be cautious that they
are allowed a sufficient time to graze in the uplands pre-
vious to their being driven into the fold, that they may retire
to reit with full bellies, by which the quantity of the dung
and urine will be considerably augmented. He will like-
wise be careful in reviewing the hurdles, and providing that
there be fixed in the ground, left by any accident they
should be thrown down during the night, and the flock by
there means get into mischief, or intermix with other sheep;
he will count his sheep regularly every evening when he drives
them to the fold, and take a fresh tall in the morning, when
he turns them on their feed; he will, previous to diunififying
them from the fold, worry them gently round the same, in
order to caufe them to dung and itale plentifully, that the
manure may be left in the field, otherwise the greatest part
of the trundles will be drop on the road, or carried on to
the march, where lying thin, this dresing can do but little
service, and where in truth it is not wanted; he will bellow
a particular attention on every individual in his flock, and for
those which fhew any appearance of being flung by the fly,
he will be prepared with a pair of sheers to clip away the
wool from the part, and having taken out the maggots, will
anoint the place with a mixture of train-oil and brahamine;
but if slightly attacked, he will destroy the maggots by
frowning on them powder of white lead; and if any of the
flock should haply break with the fcab, a disorder to which
folding sheep are continually subject, and which seldom falls
to hver itself in the spring and fall, he will be provided with
a proper remedy to keep it under, and prevent the contagion
from spreading. See SCAB.

It is likewise thought, that one shepherd will be able to
look after three hundred sheep.

In repect to the neceflity of a dog, as an assistant to the
shepherd, Mr. Lawrence thinks, that it has of late very
rationally become a question among the most intelligent
sheep-masters: it may probably be thus settled,—there can be
no occasion for such aid, nor any neceflity for incurring
the danger of it, amidst convenient inclosures, or where
quiet breeds of sheep are kept, and where it is made an ob-
ject to render them tame and docile: and if upon extensive
wadies and mountain districts, the service of dogs cannot
well be dispensed with, it ought to be made a main point,
that they be trained early to a kindness for the sheep, and to
view them rather as their companions, than their prey; a
thing which he knows by experience to be most easy; and
he also knows that such dogs are infinitely of the greater use,
as the sheep, far from dreading or flanning, will run to
them, in case of need, for protection; and he has often witniffed
the carffes and gambols of thefe and the lambs, with a deligt which he never experienced in the combats of
animals.

Shepherds of Egypt, Shepherd kings, or royal Shepherds,
in Ancient History, the denomination of a class of inhab-
inants of a part of Egypt, concerning whose origin, place
of abode, and migration, ancient and modern writers have
entertained different opinions. Some sketches of their his-
tory will be found under the articles AURIITRE, CUSH, DI-
ERSION OF MANKIND, AND EGYPT. The learned Bryant
has published, besides several notices that occur in his
"Analysis of Ancient Mythology," an elaborate "Dif-
taration" on this subject. Differing from others concerning
the situation of the land of Goshen, (see GOSHEN,) he con-
ceives it to have been the Nome called the Arabian, from
the Arabian shepherds who had formerly settled in those
parts, and held them for many years, and denominated by
the LXX, Περιγοή της Αίγυπτος. The province of Arabia, fays
this author, was one of the three most remarkable nomes,
the other two being those of Bubalitus and Helopolis.
These three nomes were contiguous to each other, and
towards the summit of Lower Egypt. The nome of Helio-
polis, according to his statement, was a Mediterranean
district; and consequently the two provinces, or that of
Phacusa (i.e. the Arabian nome), and that of Bubalitus,
that are always mentioned with the former, were so likewise.
Phacusa, mentioned by Strabo only as a village, was the
province at whose summit the Nile was first divided, where
stood the city of Cerecora. It was called the Arabian
nome for the reafon above-mentioned, and had for its metrop-
olis Phacusa, and the places situated upon its borders were
Babyon, Helopolis, and Heroum. From Synecillus we
learn, that Egypt had been in subjection to a three-fold race
of kings, who are termed the Aurite, the Menetræ, and the
Egyptian. The Aurite were the Arabian shepherds
and their kings, who reigned here a considerable time,
maintaining themselves by force; till, after many struggles,
they
they were finally expelled by the natives. According to Manetho, the whole body of these people bore the appellation of Hukfos, that is, royal shepherds; the first syllable, in the sacred dialect, signifying a king, and the latter, in the popular language, signifying a shepherd; and by a composition of these two was formed the word Hukfos. These people are said to have been Arabians. Josephus further informs us from Manetho, that the shepherds maintained themselves in Egypt 511 years. At that period the people of Upper Egypt rose in opposition to them, and after some time expelled them the country. However, on their departure, they were afraid of going towards Ailpyria, and therefore returned to the country called afterwards Judea, and built Jerusalem. We learn also, from the same authority, that another class of people, sojourned in Egypt in the reign of Amenophis; and that they were treated as slaves by the prince of the country, because they were infected with the leprosy. As their number very much increased, they employed them in the stone quarries that lay on the east side of the Nile, in company with some of the Egyptians. Upon a remonstrance afterwards made to him, he granted them for a retreat the city of Abaris, where the former shepherds had resided, that now lay desolate. The people belonging to each of the two classes now mentioned were esteemed shepherds; the first shepherds were lords and conquerors; the others were servants, to whom was assigned the city which the former had evacuated. The latter were Israelites, as appears from the name of their leader and lawgiver, Moses; and the former were Arabians, who are said to have come from the East; and they are, without doubt, the Aurite, who founded the city Auris or Abaris, which is no other than the city ΤΥόν, or Auran, signifying light and fire, of which element the Aurites must have been worshipers, as all the Arabians were. Their chief god was Auros (Διος), the god of fire. Accordingly the shepherds were called Aureus from the chief object of their worship, and their kings were styled priests of Aureus, or, according to the Greeks, priests of Vulcan. Hence it has been inferred that they came from Babylon, a country that lay due south from Egypt, which country was the original seat of the genuine Arabians, and the true source whence their religion flowed. The two principal cities of that country were Ur or Aur, and Babylon: in memory of which they built two of the same name in Egypt. Wherever they resided, they introduced the Tzeba Schanaz, or Zabian worship, together with the worship of fire. Hence we are informed by Herodotus, that Vulcan was particularly honoured at Helionpolis and Memphis, which places they are said to have built. The true name of these people, says Bryant, who were called by the Greeks and Romans Arabians, was Cuahan or Cufcans, the fame that they gave to the province where they settled. (See Cusin.) These strangers, therefore, who settled in Egypt, were no other than the Cufcans; and they have been styled Arabian shepherds, because all the primitive Arabians were Nomades, or shepherds. These people becoming lords of the country, undoubtedly chose that part which was the most eligible, and their profession would lead them to the belt land for pasture; in respect of which Gothen had not its equal. For it was part of the πέδων Αιγύπτου, the rich champaign of Egypt; so that this circumstance among others would induce one to think that they settled here. This is confirmed by the worship which they settled in these parts; the cities they built; and the names which they bequeathed to the province. According to the Mosaic account, the land of Gothen is repeatedly said to be in the land of Egypt, "in the belt of the land;" and yet the LXX call it

The text continues with detailed historical and geographical information about the migration of shepherds, their impact on the land, and their influence on the early settlements. It references sources like Manetho and Bryant's Observations and Inquiries to substantiate the claims made. The text is rich with historical context, providing insights into the early development of the region, influenced by the sacred and secular practices of the time.
in the materia medica, or for the acid inflammatory power which some (probably misled by its botanic affinity with mustard, and some other acid vegetables) have ascribed to it. Lewis's Mat. Med.

SHEPHERD'S STAFF, or SHEPHERD'S ROD. See Teazle.

SHEPHERDSTOWN, in Geography, a poll-town of America, in the state of Virginia, and county of Jefferson, on the S. side of Patowmack river. Its situation is agreeable and healthy, and the neighbouring country fertile and well cultivated. It is said to contain 1033 inhabitants, chiefly of German extraction.

SHEPHERDVILLE, a poll-town in Bullet county, Kentucky; 640 miles from Washington.

SHEPECK, in Agriculture, the provincial name of a prong or fort of hay-fork, employed in some places.

SHEPPEY, in Geography. See Sheppey.

SHEPREV, John, in Biography, an English poet, was born in Berkshire, and educated at Corpus Christi college, Oxford, where he took his degrees in arts, and became Hebrew professor about the year 1538. He had a most surprizing memory, and was one of the most learned men in his time. He died in the year 1542. His works are "Summa et Synopsis Novi Test." &c.; "Hippolytus Ovidianae Phaedræ respondens," &c. Wood.

SHEPTONMALLEY, in Geography, a market-town in the hundred of Whitelocke and county of Somerset, England, is situated about five miles E. from the city of Wells, and 115 W. by S. from London. This town has been long celebrated for its manufacture of woollen cloths and knit stockings, which affords employment to upwards of 2000 persons resident in the town or its vicinity. Edward II. granted a charter for a market to be held here on Monday, weekly; but it is now kept on Friday; besides which there is an annual fair, called Silver-fleet fair, which takes place on the 8th of August. The market-place is remarkable for a very curious stone cross, which appears, from an inscription upon it, to have been erected in the year 1500, by "Walter Buckland and Agnes his wyff." It consists of five arches, supported by pentagonal pillars, with an hexagonal column in the centre. From the roof, which is perfectly flat, rises a lofty pyramidal spire, adorned with Gothic niches, and crowned with an oblong entablature, on which are represented figures of our Saviour on the cross between the two malefactors; also those of several saints. Lintel of considerable value are appropriated for the repair of this frangible structure. The church here is a large and handsome edifice in the pointed style of architecture, and composed of a nave, chancel, north and south aisle, and transept, with a tower at the west end, ornamented with effigies in niches of the Virgin Mary, St. Peter, and St. Paul. The pulpit and font are each cut out of one solid stone, and from the rudeness of their workmanship would seem to be of very great antiquity. In two of the windows are some remains of painted glass, displaying the mutilated effigies of knights Templars, said to represent the two Williams Mallet, who had commands in an expedition to the Holy Land during the reign of King Henry II. The monuments in this church are numerous, but none of them are particularly remarkable, either for their style of execution, or for the character of the persons they commemorate.

Shepton Mallet, in ancient times, formed part of the manor of Pilton, which King Ina gave to the abbey of Glastonbury, A.D. 705. At the time of the Conquest it was held from the abbot by Roger de Curcelle; but soon afterwards passed into the possession of the barons Mallet, from whom it derived the latter part of its name. After a variety of changes, this manor was divided into two moieties, one of which came to the crown, and was annexed to the duchy of Cornwall, to which it still belongs. The other moiety became the property of the family of Shepton. Shepton Mallet is noted as the birth-place of three men of distinguished talents and learning; viz. Hugh Inge, D.D. archbishop of Dublin, and chancellor of Ireland, who died in 1528: Dr. Walter Charleton, an eminent physician, and author of Chorea Gigantum, or an account of Stonehenge, who died in 1707; and Simon Browne, a learned diligent minister, celebrated for his controversial writings against Woolston and Tindal, who died in 1732. The parish of Shepton Mallet is of small extent, but populous, containing, according to the parliamentary returns of 1811, 1129 houses, and 4638 inhabitants. Within its bounds are situated the county Bridewell, and a large parish workhouse. The History and Antiquities of the County of Somerset; by the Rev. J. Collinson, F.S.A. 4to. vol. ii. Bath, 1791.

SHERARD, William, in Biography, a very learned and munificent botanist, on whom the titles of prince and Mecenas of botany have been, more juicly than usual, bestowed, was the son of George Sherwood, (for so it seems the name was written by the father,) of Bishby, in Leicestershire. He was born in 1645; educated first at Merchant Taylors' school, and then at St. John's college, Oxford, where he entered in 1667. He subsequently became a fellow of this college, and took the degree of Bachelor of Law, December 16, 1683. Being appointed travelling tutor, successively, to Charles, afterwards the second viscount Townshend, and to Wriothesley lord Howland, son of the murdered lord Ruffell, who in 1700 became the second duke of Bedford, Sherard made two succecssive tours through Holland, France, Italy, &c. returning from the last, as we presume, not much before the year 1700, when his last-mentioned pupil was twenty years old. Dr. Fulleney supposes him to have come back in 1693, led perhaps by the date of Ray's Sylva Sylvis Europarum, printed in 1694, to which Sherard communicated a catalogue of plants gathered on mount Jura, Saleve, and the neighbourhood of Geneva. These were probably collected in his first journey; for it should seem by Collins's Peerage, that the lord Howland, so created on account of his union with the heiress of the Howland family, was married to her in May 1655, when he was little more than fourteen years of age. He was made a peer June 15, 1655; "after which," says Collins, "he travelled into France and Italy." Such youthful bridegrooms were, doubtless, in the hands of his tutor, in a distant country from his, still more youthful, spouse. The subject of our memoir is said to have fulfilled his trust to the satisfaction of both the noble families who confided in him. His friend, his friend for Arthur Rawdon, of Moira, Ireland, was apparently made in the interval of these two foreign journeys. Long before either of them, he had travelled over various parts of England, and proceeded to Jersey, for the purpose of botanical investigation; and the fruits of his discoveries enriched the publications of the illustrious Ray; see that article.

Botany was ever the prominent pursuit of Sherard in all his journeys. He cultivated the friendship and correspondence of the most able men on the continent, such as Boerhave, Hermann, Tournefort, Vaillant, Micheli, &c. He is universally believed to have been the author of a 12mo. volume, entitled Schola Botanica, published at Amsterdam in 1689, and reprinted in 1691 and 1699. This is a systematic catalogue of the Paris garden. Its preface, dated London, Nov. 1688, is signed S.W.A., which the French
French writers have interpreted Samuel Wharton, Anglius, under which name the book occurs in Haller's Bibliotheca Botanica, v. 1, 643. But as no one ever heard of such a botanist as Wharton, and the preface in question displays the objects and acquisitions of one of the first rank, who could certainly not long remain in obscurity, the above initials are presumed to mean William Sherard, to whom alone indeed, with or without a signature, that preface could belong. Its writer is described as having attended three courses of Tournefort's botanical lectures, in 1686, 87, and 88, all which years, he says, he spent at Paris. In the summer of 1688 he describes himself as having passed some time in Holland, collecting specimens of plants from the rich gardens of that country and getting them named by professor Hermann himself, who allowed him to peruse the manuscript rudiments of his Paradisus Batavus, to examine his herbarium, and to compose a Predominus of that work, which subjoined to the little volume now under our consideration. All this can apply to Sherard only, who became the editor of Hermann's book itself, and who in its preface, dated from Geneva in 1697, appears under his own name, and speaks of himself as having long enjoyed the friendship and the communications of that eminent man, whose judgment and talents he justly commemorates, and of whose various literary performances, as well as of his botanical principles, he gives an account. Dr. Pulteney conceives this preface to have been written during a third tour of its author to the continent; but we presume it to have then been with the young lord Howland, and consequent on his second tour only.

Sherard communicated to the Royal Society, in 1705, a paper relative to the making of Chine or Japan ferns, which is printed in the Philosophical Transactions, v. 22. The information which it contains was sent by the Jesuits to the grand duke of Tuscany, and probably obtained by our author at Florence.

He now entered on a more public walk of life, becoming one of the commissioners for sick and wounded seamen at Portsmouth, and about the year 1702, or soon after, was sent out as British consul to Smyrna. Here his botanical taste met with fresh gratification; nor was he neglectful of other curiosities of science or literature. He visited the seven churches of Asia, copied several ancient inscriptions, and communicated to the Royal Society an account of the new volcanic island, near Santorini, which rose out of the sea May 12, 1707.

Botany, however, continued to be his leading object. He had a villa at Sedekio, near Smyrna, where he could with the more ease reign himself to the contemplation of plants, and where he began that great herbarium of which we shall speak hereafter. Haffelquill visited this spot, with the devotion of a pilgrim, in the spring of 1750. He saw the house, with a small garden laid out by Sherard, but not enriched at any great expense, nor stored with extensive collections of exotics. Many of the latter indeed might, in the course of thirty-two years, have disappeared. Whatever specimens Sherard could obtain from Greece, and the neighbouring countries, he here carefully preferred; and being well aware of the insufficiency of Bauhin's Pinax, as a clue to the botanical knowledge then in the world, he is said to have here formed the project of continuing it, and even to have made some progres in that arduous undertaking, before he returned to his native country in 1718. Soon after his return he received at Oxford the degree of L.I.D.

In 1721 Dr. Sherard revisited the continent. Vaillant was now in a declining state of health, and died in May 1722. Previous to his decease he concluded, through the mediation of Sherard, the sale of his manuscripts and drawings of Paradisus Batavus, to Boerhaave, who published in 1727 the splendid Botanisca Parthenia. This work, though not free from imperfections in the distribution of its materials, would doubtless have been far less correct, but for the superintendence of Sherard, who published a preface with Boerhaave in revising the manuscript. Our great botanist had already rendered a more important service to his favourite science by bringing with him from Germany, in August 1721, the celebrated Dillenius (see that article). By a comparison of dates, it appears that Sherard made several visits to the continent. He went from Paris to Holland in 1721, and thence with Dillenius, the same year, to England. He stayed some time with Boerhaave again in 1724, or perhaps 1725. We know not precisely when or where it happened that he was, like Linnaeus in Norway, in danger of being shot for a wolf, or a thief, by some half-humiliated rustic, akin to the thief-takers and Oxfordshire justices, who feized upon another illustrious botanist, of our time, as a highwayman.

What principally attached Sherard to Dillenius, was the similarity of their talents respecting those intricate tribes of vegetables, now termed cryptogramic. To the former attention of both had been long directed, and hence originated the cultivation, which this line of botanical study has received, from that period, in England and Germany. This talent, however, was not exclusive; for these friends and fellow-labourers left no department of botany unimproved. James Sherard, seven years younger than his brother, who had acquired opulence by medical practice, first as an apothecary, and then as a physician, in London, had a great fondness for the same pursuit, and reared at his country seat at Eelham, a number of exotic plants, from every climate. Hither the more learned subject of our present article frequently repaired. He had acquired influence by his public appointments, but his style of living was simple and private. Devoted to the cultivation of knowledge in himself, and to the diffusion of that of others, he lent his aid to all who required it, without coming forward conspicuously as an author. He affiliated Catesby with information and with money, to bring out his Natural History of Carolina, though neither that work, nor the Hortus Eysteameus of Dillenius, appeared till some time after his decease, which happened on the 12th of August, 1728, when he was 69 years of age. Of the place of his interment we find no mention. His brother died Feb. 12, 1737, aged 72, and is buried in Evington church, near Leiceste, with his wife, whose maiden name was Lockwood, by whom he had no children.

The most obvious and splendid service to botany, though it for a long time yielded but little fruit, was rendered by the will of Dr. William Sherard, who left 5000l. to found and support a botanical professorship at Oxford, of which we have spoken under the biographical article Dillenius. He bequeathed to this establishment his choice botanical library, his ample herbarium, and the manuscript of his Pinax, the completion of which he intended should be one of the objects and duties of the new professor. We have already expressed our doubts whether the failure of the latter, in this point, were any great loss to science. Nevertheless, the manuscript, as Sherard left it, would probably have been a great acquisition to the world, and might still be worthy of publication. Dillenius accomplished more appropriate, and perhaps more difficult designs; but every scientitc object slept with his successor for forty years. Sherard has sometimes been blamed for excluding clergymen from
from his professorship, and it is usual to hear a complaint at Oxford, that this order of men has no interest therein. If by interest is meant the acquisition of a very moderate stipend, which only one can enjoy, the complaint is just: but surely the more important interest of a whole university consists in having this, or any other, science taught in the best manner. Sherard therefore would have done much more wisely, instead of limiting the appointment at all, to have left it open, like the Cambridge professorship and garden, to all the world, and to have placed the choice in the hands of those who would perceive their own advantage, and probably feel some sense of duty, in not making any professorship a sinecure or a job.

The herbarium of Sherard is perhaps, except that of Linnaeus, the most ample, authentic, and valuable botanical record in the world. In it may be seen original specimens from Tournefort, and all the writers of that day, named by themselves, accompanied by remarks, or by queries scarcely left instructive. He collected also copies of original drawings, from botanists whose specimens were not to be had, such as Plummer. The most rare, and even unique, books are to be found in his library, as the first volume of Rudbeck's *Campi Lyfiisi*. (See Rudbeck.) All these precious collections are still in good preservation, although the noble stone building, originally constructed to receive them, was sacrificed a few years since to public convenience, that the adjoining street might be widened.

The name of Sherard has been commemorated by Vailant, in some plants referred by Linnaeus to *Veratum*. Dillenius established a *Sherardia*, which has remained; see the next article. Pulteney's Sketches of Botany, Hailer's Letters, and Bibl. Bot. Aikin's Gen. Biog. S.

Eff. Ch. Corolla of one petal, funnel-shaped, superior. Seeds two, naked, each crowned with three teeth.

1. *S. aveneas*. Blue Sherardia, or Little Field Madder. Linn. Sp. Pl. 149. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 891. Curt. Lond. f. ac. 5. t. 13. Fl. Dan. t. 439. (Apertula flore carneo, acuto folio; Barbel. 4. t. 541.)—All the leaves whorled. Flowers terminal. Native of cultivated or fallow fields, throughout Europe, from Sweden to Greece, flowering all summer long. The root is annual, fibrous, small. Herb generally hairy. Stems several, branched, leafy, angular, spreading in every direction, from three to five inches long; most slender at the base. Leaves spreading, mostly fix in each whorl, elliptical or obovate, pointed, entire, rough at the edges and keel. Flowers from four to fix or eight, in a little terminal umbel, enclosed in the uppermost whorl, which consists of more leaves than the rest. Calyx of two or three-crested acute leaves, afterwards enlarged, and forming a crest, or crown, to each leaf. Corolla purplish-blue, with a slender tube, much exceeding the calyx.

2. *S. murale*. Wall Sherardia. Linn. Sp. Pl. 149. Willd. n. 2. Sm. Fl. Gr. Sibth. v. 2. t. 13. (Galium murale; Allion. Pedem. v. 1. t. 77. f. 1. G. minimum, feminum oblongis; Buxb. Cent. f. 31. t. 50. f. 2.)—Stems diffuse. Leaves four in a whorl, or in pairs, spreading. Whorls two-flowered. Stalks of the fruit reflexed.—Native of old walls, and rocks, in Italy and the Levant. Found in Crete by Dr. Sibthorp. Annual, about the size of the former, decumbent, and rough, but the leaves are smaller, sometimes fix, sometimes two, usually four, in a whorl. Flowers axillar, opposite, minute, shorter than the leaves, stalked. Corolla yellow, with a short tube. Fruit reflexed, of two bipid, oblong seeds, starting from each other in the middle, meeting at top and bottom, their crown, or calyx, hardly discoverable.

3. *S. erecta*. Upright Sherardia. Sm. Fl. Gr. Sibth. v. 2. t. 14. g. 1. (Apertula muralis verticillata minima; Column. Elysi. t. 50. t. 500. A. verticillata Iuteola; Bauh. Pin. 334.)—Stems erect. Leaves four in a whorl, or in pairs, deflexed. Whorls many-flowered. Fruit nearly erect. Native of rocks and walls, in Italy and the Archipelago. Annual, erect, and more slender than the last, a slender high. The shorter deflexed leaves, numerous flowers, and erect fruit, distinguish this species clearly, though Linnaeus confounded its synonyms with *murale*. The crown of the flowers is equally obscure in both, and the habit of the plants answers better to that of the genuine *Valeriana*, though the fruitification differs. They but ill agree with *Sherardia*; yet their fruit will not allow them to be referred to *Galium*.

4. *S. fruticosa*. Shrubby Sherardia. Linn. Sp. Pl. 149. Willd. n. 3. Swartz, Ob. 46.—Leaves four in a whorl, linear-lanceolate, revolute. Stem shrubby.—Gathered by Olbeek in the island of Ascension. The stem is woody, branched, leafy, fragranging or prostrate, and the whole plant has the aspect of *Ernoda montana* (see *Ernoda*); but is distinct. Leaves an inch long, rather downy. Calyx of four only teeth. Corolla white, as long as the stem. Swartz strictly observes, that this species but ill accords with *Sherardia*, being intermediate, as it were, between *Diodia* and *Spermacoce*.

**Sherardia** is also a name given by Pontederia to the genus of plants, called by Linnaeus *gallenica*. **SHERARIB**, in Geography, a town of Africa, in Bergoo; 116 miles S.W. of Wara.

**SHERAVEND**, a town of Persia, in the province of Ghilan, on the Caspian sea; 20 miles S. of *Aftara*.

**SHERBET**, or *Sherritt*, a compound drink, first brought into England from Turkey and Persia, consisting of fair water, lemon-juice, sugar, amber, and other ingredients.

Another kind of it is made of violets, honey, juice of raisins, &c.

The word *fiorlet*, in the Persian language, signifies pleasant liquor.

**SHERBORNE**, or *Sherborne*, anciently called *Sarceburn*, in Geography, a market-town and parish in the hundred of that name, county of Dorset, England, is situated in the vale of Blakemore, near the borders of Somersetshire, at the distance of 16 miles W. from Sheffordbury, 18 N. by W. from Dorchester, and 117 W.S.W. from
from London. It is a town of very high antiquity, but its origin is not precisely ascertained. Baxter contends that it was the Arianus, or Aratus of Ravenna, deriving its name from "Arian Uife, Argenteus Fluxus Aquae," or "Fons Clarus." This opinion, however, is rendered extremely doubtful, by the total absence of all those appearances which almost invariably characterize the cities of British or Roman towns. It seems, therefore, more probable that it had its commencement in Saxon times, and germinated from a religious house, founded here soon after the conversion of the Saxons to Christianity. This monastery was richly endowed by several of the kings of Wessex, particularly by Cenwalch, and the great Alfred. After the Conquest, it was raised to the rank of an abbey, and the monks were exalted spiritual barons, and in consequence were frequently summoned to assist in the parliament or great council of the nation. At the dissolution, its revenues were rated, according to Speed and Dugdale, at 612l. 14s. 7d. per annum.

Sherborne was further distinguished, in ancient times, as the seat of an episcopal see, having been constituted such by king Ina, on the division of the bishopric of Winchester, A.D. 704. The first bishop of this diocese was Aldhelm, nephew to Ina, who is reported to have been a man of extraordinary talents, and a great benefactor to the see. His successors have been differently named by different writers, so that much uncertainty prevails respecting them. The most probable view of the subject, however, is, that they were twenty-live in number, and conjointly preified a period of 366 years. The most celebrated among them was Aelfred Menevenlos, who wrote the life of Alfred the Great, and assisted him in his literary pursuits. In his time the see of Sherborne comprehended the counties of Dorset, Buck's, Wilts, Somerset, Devon, and Cornwall; but in 904, shortly after his death, the three latter counties were separated from it, and united to other bishoprics, by a bull of pope Sergius III. Herman, the 26th bishop, attempted to remove the seat of the bishopric to Malmesbury, but his intentions were thwarted by Godwin, earl of Kent, and the monks of that abbey. He succeeded, however, in effecting its removal some years afterwards, viz. in 1075, to Old Sarum, in consequence of the edict of the council at London, which directed that all bishops' fees should be transferred from obscure places to the more important town in each diocese.

See SALISBURY.

From the great eagers of Herman to quit Sherborne, it might reasonably be inferred that it was become a town of much less extent and importance than it was under his predecessors. Accordingly such is the fact, and the circumstance is easily accounted for; it being flated by historians, that it was laid in ashes by the Danes, under king Sweyn, during one of his vindictive excursions through this part of the kingdom. Besides, both Matthew of Well- minder and William of Malmesbury describe it "as a small street, in which was nothing agreeable in number of inhabitants, or pleasantness of situation; and that it was matter of reproach and wonder that an episcopal seat had continued there so long." In this situation it appears to have remained for several centuries; but in the time of Edward it had recovered itself very considerably, as we find Sherborne mentioned in his Itinerary as the most frequented town in the county, and that in which the woollen trade was turned to the best account. After his time, however, this branch of business was much decreased; and the manufacture of buttons, haberdashery wares, and bone-lace, introduced in its stead. These trades have also decreased, and now the silk and linen manufactures constitute the principal employment of the inhabitants.

Sherborne, though neither a borough by charter nor prefrerention, on one occasion sent members to parliament, in the reign of Edward III. At that time the alizies were regularly held here; but since the reign of his successor, that practice has only been occasional, as in cases of epidemic disorders, or otherwise. The general quarter sessions for the peace, however, are still held here once a year, on Tuesday after the close of Easter. The market-day here is Saturday, weekly; and there are fairs annually on Wednesday before Holy Thursday, 16th and 18th July, and the first Monday after 10th October.

The church of Sherborne, which is the only public building within the town of any importance, is a large and magnificent structure. It is built in the form of a cross, and entirely of free-stone. The original edifice was the work of bishop Aldhelm. But no part of that building probably now remains, as it has undergone frequent alterations, and in the time of king Henry VI. was almost wholly rebuilt. Hence, though displaying various styles of architecture, the greater part of it is in the pointed style of that age. The most material exceptions to this remark are the pillars supporting the tower, the south porch, and the chancel of our Lady, all of which are of early Norman origin, and the large lancet window at the eastern end of the chancel north of the chancel, which, with some smaller fragments in other parts, seem to be of the same date with Salisbury cathedral, viz. about the year 1220. All the later parts of the church are richly ornamented with tracerie work, vine leaves, and flowers. The piers between the windows on each side are supported by light flying buttresses stretching over the side aisles. The roof is of stone, and supported by numerous groins springing from the side aisles; and between the tracerie work is a number of shields bearing different arms, with rosettes, palmettes, and cut devices. This church was made parochial after the dissolution of the abbey, to which it previously belonged. It contains the ashes of many persons of distinction, and among others those of Ethelbold, king of Wessex, and his brother Ethelbert. The only modern monuments of note are those of John, earl of Bristol, who died in 1698, and of a son and daughter of William, lord Digby. On the latter are inscribed the following beautiful lines by Pope.

"Go, fair example of untainted youth, Of modest reason, and pacific trust; Composed in suffering, and in joy sedate, Good without noise, without pretension great. Go, just of word, in every thought sincere, Who knew no wish but what the world might hear. Of gentle manners, unaffected mind; Lover of peace, and friend of human-kind. Go, live, for heaven's eternal year is thine; Go, and exalt thy mortal to divine. And thou, too close attendant on his doom, Heiress maid, hast hastened to the silent tomb, Steer'd the fame course to the fame quiet shore; Not parted long, and now to part no more: Go, then, where only bliss sincere is known, Go, where to love and to enjoy is one. Yet take these tears, mortality's rebel, And, till we share your joys, forgive our grief. These little rites, a shame and veris, receive; 'Tis all a father, all a friend can give."
SHE

Besides the established church, there were formerly in Sherborne two meeting-houses for dissenters; but at present there is only one, situated in Long-street. The other public structures here are the market-house, the work-house, an almshouse, and a free grammar-school. The almshouse was formerly a religious hospital dedicated to St. Augustine, and has a chapel attached to it, which appears to have been erected in the fifteenth century, and contains a very curious ancient painting upon oak in high preservation. This picture consists of three pieces, representing three of our Saviour's most remarkable miracles, and is characterized by Mr. Hutchins, in his History of Dorsetshire, as "very beautiful, and evidently executed by a masterly hand." The free grammar-school was founded and endowed by king Edward VI., and the government of it vested, by charter, in twenty principal inhabitants of Sherborne. At present, there are two masters attached to this school, who must be clergymen, and graduates of one or other of the universities. The buildings occupy the site of part of the ancient abbey, some considerable portions of which are still standing. The plan of education adopted here is similar to that of Eton. There are likewise in Sherborne two charity-schools on a contracted scale, three benefit societies, two for men, and one for women; and an institution of rather an uncommon kind, called the Green Girls' Society, which, from its excellent tendency, deserves to be more generally adopted. It was established in 1711. The members pay into it a small sum weekly, and wear, till they arrive at a certain age, green gowns and straw hats.

When a girl attains the age of eighteen, she is at liberty to leave it, and if married before she is twenty-five, is entitled to 1l. on her wedding-day; and 1l. on the birth of her first child. If unmarried till twenty-five, she is then entitled to the first sum, provided she has lived a sober and virtuous life, otherwise her claims are forfeited to the society. The founder of this institution was the late Mr. John Toogood.

The parish of Sherborne extends about three miles and a half in length, and two miles and a half in breadth, and contains, according to the population census of 1811, 597 houses, and 3370 inhabitants, of whom above 2000 reside in the town. The late eminent Dr. Joseph Towers is generally stated to have been born at Sherborne, but we know from authority that he was not even a native of the county.

In a hamlet, or suburb called Cattleton, about half a mile eastward from the town, stood the ancient castle of Sherborne. This fortress was built by Roger, third bishop of Salisbury, and occupied a rocky eminence on the north bank of the river Irk. The area contained within the deep fosse, which inclosed the whole works, measured about four acres in extent. Few castles surpassed this in strength and magnificence of structure. It was one of the three, erected by the same bishop, which William of Malmesbury mentions among the wonders of the world. It was of an octagonal form, and had seven courts, with strong battlements surrounding it, and was built after the plan of a spider's web. It had also a tower at each angle, there being fifteen in all without the citadel, and appears to have been in every respect admirably calculated for security and defence; for if any one of the courts were scaled or taken, the soldiers in the gallery above would so annoy the assailants with their arrows and other missile weapons, as to render it impossible for them to retain possession of it. But notwithstanding the strength and importance of this castle, it does not appear to have been the scene of any events of interest in the history of the kingdom, till the reign of Charles I., when it was one of the first besieged by the parliament, and one of the last which abandoned the cause of the king. Since that time it has been gradually falling into ruin, so that only a few fragments of it now remain.

The manor of Sherborne was very early granted to the See, and continued attached to it, during its successive removals, till the reign of King Henry VIII., when compelled bishop Piers to alienate it to the crown. Queen Elizabeth granted it to Sir Walter Raleigh, on whose unjust execution by King James I. it was feized and given to the favourite Carr, notwithstanding the interference of various distinguished individuals to obtain it for the family of its great, though unfortunate possessor. It afterwards became the property of Sir John Digby, whose descendants still continue to enjoy it. The History and Antiquities of the County of Dorset, by John Hutchins, M.A., 2d edition, corrected and improved by Richard Gough, esq. and John Bowyer Nichols, esq. vol. iv. fol. 1815.

SHERBURN, a market-town in a parish of the name, partly within the liberty of St. Peter of York, and partly in the upper division of the wapentake of Barkston Ash, West Riding of Yorkshire, England, is situated at the distance of 14 miles S.W. from the city of York, and 181 miles W. by N. from London. The market is held on Monday weekly, but is little frequented, and there is only one annual fair, on the 24th of September. This place was formerly, however, much more important, and was distinguished by a palace belonging to the archbishops of York, of which not a vestige now remains. It is only at present, therefore, remarkable for a particular species of plant called the Wine-few, which grows in the vicinity. Sherburn township, according to the parliamentary returns of 1811, contains 188 houses, and 958 inhabitants. Beauties of England and Wales, vol. xvi. by John Bigland, 1812.

SHERBURN, Edward, in Biography, an ingenious writer, was born in London in 1618, and educated under Farnaby; after which he went abroad, but returned in 1641, and succeeded, on the death of his father, to the office of clerk of the ordnance. He was imprisoned for some time by the parliament, and, on recovering his liberty, joined the king, whom he served with fidelity and great bravery, by which he suffered considerably in his estate. After the battle of Edgehill he went to Oxford, where he was created master of arts. At the restoration he recovered his situation under government, was knighted, and made commissary-general of the artillery. He died in 1702. He translated Seneca's tragedies, the Sphere of Marcus Manilius, and other works, into the English language, and was author of a volume of poems.

SHERBURN, in Geography, a post-town of America, in Chenango county, New York; containing 1282 inhabitants. — Also, a town in the state of Massachusetts, and island of Nantucket. The island contains 6897 inhabitants. (See NANTUCKET.) — Also, a town in Middlesex county, Massachusetts, containing 770 inhabitants; 18 miles S.W. of Boston. — Also, a town in Herkimer county, New York; containing, by the census in 1790, 483 inhabitants. — Also, a town of Rutland county, Vermont; containing 116 inhabitants.

SHEREBATOF, Prince, in Biography, a learned Ruffian nobleman, who published several works in his own language, the chief of which is "The History of Ruffia from the earliest Times," which is said to be well arranged, and faithfully drawn up. Mr. Coxe, in speaking of this writer, says, several persons have published collections of the papers and other documents, but the honour of composing a complete history of Ruffia is probably reserved for prince Sherebatof; who, if we except Mr. Muller, has contributed
contributed more than any other person towards illustrating the Ruffian annals. This learned nobleman is editor of "A Journal of Peter the Great," in 2 vols. 4to., which he found in the archives, and published by order of the empress; of "The Ruffian History, by an ancient Annalist, from the Beginning of the Reign of Vladimir Monomak in 1114 to 1472?" "The Life of Peter the Great," in the Ruffian language, first published at Venice, which the prince reprinted in 1774, and, according to his usual custom, enriched with many historical observations. Of his History, already referred to, our author says, "I have read the German translation of this performance, which appears to me a most valuable addition to the history of the North. The author has had access to the imperial archives; he draws his information from the most ancient and unquestionable sources, is particularly exact in quoting his authorities, and ranges the events in a chronological series with great perspicuity." Coxe's Travels, vol. iii.

SHERÉT, in Geography, a town of Asiatic Turkey, in the government of Trebifond; 30 miles S.W. of Trebifond.

SHEREDUR, or SHERZOUR, or SHEREZUR, a town of Curdistan, the capital of a government, and residence of a Turkish pasha; 150 miles N. of Bagdad. N. lat. 35° 46'. E. long. 44° 25'.

SHERIBON. See SHERZOUR.

SHERIDAN, or SHERIDAN, in Biography, was born probably about the year 1684, in the county of Cavan, where his parent lived in such a state of indigence, as not to be able to afford him the advantages of a liberal education; but being observed to give early indications of genius, he attracted the notice of a friend to his family, who sent him to the college of Dublin, and contributed towards his support, while he remained there. Afterwards he proceeded to a doctor's degree, and took orders, and set up a school in Dublin, which long maintained a very high degree of reputation, as well for the attention bestowed on the morals of the scholars, as for their proficiency in literature. He does not appear to have had any considerable preferment; but his intimacy with Swift procured for him, in 1725, a living in the south of Ireland, worth about 150l. per annum, which he went to take possession of; and, by an act of inadverence, it is said, destroyed all his future expectations of rising in the church: for being at Cork on the 1st of August, the anniversary of the king's birthday, he preached from the text "Sufficient for the day is the evil thereof." The report of the fact was spread abroad: he was hurled out of the list of chaplains to the lord-lieutenant, and forbidden the castle. He afterwards changed his living for that of Dunboyne, which by the knavery of the farmers, and power of the gentlemen in the neighbourhood, fell in value to 80l. per annum. He willingly resigned it for the free-school of Cavan, where he might have lived well; but the air being moyal, and as he thought unhealthy, and being disgraced with some of his parishioners, he sold the school for about 400l.; and having spent the money, he fell into ill health, and died September 10th, 1758, in the 55th year of his age. He is thus characterized by lord Corke: "Dr. Sheridan was a schoolmaster, and in many instances perfectly adapted to that station. He was deeply versed in the Greek and Roman languages, and in their customs and antiquities. He had that kind of good nature, which absence of mind, indolence of body, and carelessness of fortune, produce; and though not over-strict in his own conduct, yet he took care of the morals of his scholars, whom he sent to the university remarkably well grounded in all kinds of classical learning, and not ill instructed in the local duties of life. He was eloquent, indigent, and cheerful.

SHE

He knew books much better than men, but he knew the value of money least of all. In this situation, and with this disposition, Swift fastened upon him as upon a prey, with which he intended to regale himself, whenever his appetite should prompt him." Dr. Sheridan published a prose translation of Petrus, to which he added the best notes of former editors, together with some very judicious ones of his own. He also translated the Philoctetes of Sophocles.

SHERIDAN, THOMAS, son of the preceding, was born at Quíæ, in the county of Cavan, in Ireland; and he had for his godfather Dean Swift. The early part of his education he received from his father, who afterwards sent him to Westminster school, and at a time when he could very ill afford it. Here, upon examination, he attracted notice; and although a mere stranger, he was elected a king's scholar, on account of his merit. But their maintenance sometimes running short, the doctor was so poor that he could not add fourteen pounds, to enable his son to finish the year; which if he had been able to have done, he would have been removed to a higher class, and in another year would have been sent off to a fellowship at college. Being thus recalled to Dublin, he was sent to the university, where he obtained an exhibition, and in 1733 took his degree of M.A. Having no interell in the church, nor the means of preparing himself for one of the liberal professions, he resolved to seek a support on the stage. He was received with great applause, and in a short time became manager of the Dublin theatre; in which capacity he successfully undertook the curbing of that licentiousness, which had long reigned with an almost unlimited empire behind the scenes, and the putting a stop to the liberties daily taken by the young men with the female actresses. During eight years Mr. Sheridan polished this important office of manager of the Dublin theatre with all the success, both with respect to fame and fortune, that could well be expected, when an unfortunate circumstance led him to oppose the wishes of the public, which obliged him to withdraw from the management of the theatre, and even to quit the country. He continued in England till the year 1756, when he returned to Dublin, and was again received on the stage with the highest applause; but he did not continue long in that situation, being opposed and ruined by rival actors.

In 1757 he published a plan, in which he proposed to the Irish the establishment of an academy, for the accomplishment of youth in every qualification necessary for a gentleman. In the formation of this design he included oratory, as one of the essentials; and in order to give a stronger idea of the utility of that art, he opened his plan to the public in some orations, which were so well written, and so admirably delivered, as to give the highest proofs of the ability of the proposer, and his fitness for the office of superintendent of such an institution, for which poll he had offered himself. Nevertheless, though the plan was, in a measure, carried into execution, Mr. Sheridan was excluded from any share in the conduct of it. He now came again to England, and delivered lectures on elocution and oratory in the theatres of Oxford and Cambridge, to very numerous audiences, and with the highest reputation. From thence he again came to London, where he was engaged as an actor and a lecturer. In 1778 he published "A Pronouncing Dictionary of the English Language;" and after this he became a manager of the Drury-lane theatre, under his son, the present Mr. Sheridan, who was then one of the patentees. He died in Auguü, 1788. His works are as follow: 1. "A Dictionary of the English Language." 2. "Lectures on the Art of Reading." 3. "British Education, or the Source of the Disorders of Great Britain." 4. "A Disquisition on the Causes of the Difficulties which
which occur in learning the English Tongue." 5. "A Course of Lectures on Eloquence." 6. "The Life of Swift," prefixed to an edition of his works, edited by Mr. Sheridan. 7. "Elements of English," his wife Frances, whose maiden name was Chamberlaine, was a very in-
genious woman, and was author of a novel, entitled "Sidney Biddulph," a moral romance, entitled "Nour-
jahad"; "The Diary," a comedy; and another, en-
titled "The Dupe." She died at Blois, in 1767.

Sheridan, the late Mrs., was daughter of the excellent
musician, Mr. Linley, so well known at Bath, by his pro-
fessional merit as a matter, by the beauty and talents of his
family, and by his vocal composition, particularly his
Elegies. If this were a place to celebrate the beauty and
felicating manner of Mrs. Sheridan, we could dwell upon
them as long as on her voice and musical talents; but to
these we must confine ourselves. There was a brilliancy,
a spirit, and a mollifious sweetness in the tone of her
voice, which infinitely penetrated the hearts of her hearers,
as much as her angelic looks delighted their eyes. Her
shakes were perfect, her intonation truth itself, and the agility of her
throst equal to any difficulty and rapidity that was pleasing.

But in Handel’s pathetic song, in Purcell’s “Mad Days,”
in the upper part of serious glees, or whatever vocal music
had impressed words to express, she was sure to make
them felt by every hearer possessed of intelligence and
femibility.

She knew music so well, that she was sure to do justice to
every kind of Italian composition, as much as a foreigner
ever did to a language not her own; though the energy and
accent given by the natives of Italy, particularly in recita-
tive, is ever comparatively deficient in the best fingers of all
other countries; as nothing but a long residence, early in
life, in a foreign country, can acquire the correct pronuncia-
tion of its music, any more than of its language. It was
observed by Sacchini, who heard Miss Linley sing at Ox-
ford for the last time, that if she had happened to have been
born in Italy, she would have been as much superior to
all Italian fingers, as she was then to those of her own
country.

Sheriff, in the Egyptian Orders, the relations of Ma-
homet, the same tribe of persons called emir by the
Turks.

The word is Persian, and signifies great or noble; and
these persons have the privilege of being exempt from ap-
pearing before any judge but their own head; and if any of
the military orders are obliged to punish them for any mis-
demeanor, they shall take off their green turban, in respect
to their character; and the same is done even when they are
punished by their own magistrates.

The shérif, shériff, or sherif of Mecca, is the title of
the descendants of Mahomet by Hafian ibn Ali. Al-
though this branch of the potterity of Mahomet has never
attained to the dignities of caliph or imam, it appears to
have always enjoyed the sovereignty over most of the cities
in the Arabian province of Hadsjas. The family of Ali-
Bunemi, being one branch of the descendants of Hafian ibn
Ali, and consisting of about 500 individuals, enjoys the sole
right to the throne of Mecca. This family is likewise sub-
divided into two subordinate branches, of which sometimes
the one, sometimes the other, has given sovereigns to Mecca
and Medina; when these were separate states; but the
Turkish sultan is indifferent about the order of succession
in the family, rather wishing to favour the strongest, that he
may weaken them all. As the order of succession is not
absolutely fixed, and the sheriffs may all aspire alike to
the sovereign power, this uncertainty of right, aided by the
intrigues of the Turkish officers, occasion frequent revolu-
tions. The grand shérif is seldom able to maintain him-
self on the throne; and it still seldom happens, that his
reign is not disputed by the revolt of his nearest relations.
The dominions of the shérif comprehend the cities of
Mecca, Medina, Jambo, Taif, Sadi, Ghunfded, Hal, and
and thirteen other less considerable, all situated in Hadsjas.
As these dominions are neither extensive nor opulent, the
revenue of their sovereign cannot be considerable. He finds
a rich resourse, however, in the imposts levied on pilgrims,
and in the gratuities offered him by Musulman monarchs.
Every pilgrim pays a tax of from 10 to 100 crowns, in pro-
portion to his ability. The Grand Mogul remits annually
the imposts to the shérifs, by an alligament on the go-
vernment of Surat; but since the English have made them-
sefles masters of this city, and the territory belonging to it,
the nabob of Surat has no longer been able to pay the sum.
The power of the shérifs extends not to spiritual matters:
these are entirely managed by the heads of the clergy of
different sects, who are resident at Mecca. Rigid Musul-
man, such as the Turks, are not very favourable in their
sentiments of the shérifs, but suspect their orthodoxy,
and look upon them as tacitly attached to the tolerant sect of
the Zeidi. See Sheriff.

Sheriff, or Sheriff, an officer in each county of
England, of very great antiquity; his name being derived
from the two Saxon words fætis, province or shire; or rather
from færen, to divide, and greafa, grave, rose, or presf; the
shériff being denominated from the first division of the king-
dom into counties.

He is called in Latin vice-comes, as being the deputy of
the earl or comte, to whom the custody of the shire is said
to have been committed at the first division of this kingdom
into counties: but the earls being afterwards unable, by
reason of their high employments, and attendance on the
king’s person, to transact the business of the county, the
labour was committed to the shériff; who now performs all
the king’s business in the county; and though he be still
called vice-comes, yet he is entirely independent of, and
not subject to, the earl: the king, by his letters patent, commit-
ing custodiem comitatus to the shériff.

Sheriffs were formerly chosen by the inhabitants of the
several counties; in confirmation of which, it was ordained
by 28 Edw. I. c. 8, that the people should have election of
sheriffs in every shire, where the sheriffsalty is not of inher-
ance; for anciently in some counties the sheriffs were here-
ditary, as judge Blackstone apprehends they were in Scot-
land, till the statute 20 Geo. II. c. 43, and still continue in
the county of Wellmoreland to this day: the city of London
having also the inheritance of the sheriffsalty of Middlesex
vested in their body by charter. This election, says the
same author, was, in all probability, not absolutely vested
in the commoners, but required the royal approbation. For
in the Gothic constitution, the judges of their county-
courts (which office is executed by our shériff) were elected
by the people, but confirmed by the king; and the form of
their election was thus managed: the people, or incola ter-
rorii, chose twelve electors, and they nominated three per-
sons, ex quibus rex unum confirmabit. But with us in Eng-
land, these popular elections growing tumultuous, were
put an end to by the statute 9 Edw. II. fl. 2, which enact-
ed, that the sheriffs should from thenceforth be appointed
by the chancellor, treasurer, and the judges, as being persons
in whom the same trust might with confidence be repose.
By statutes 14 Edw. III. c. 7, 23 Hen. VI. c. 8, and
21 Hen. VIII. c. 20, the chancellor, treasurer, president of
the king’s council, chief justices, and chief baron, are to make
this election on the morrow of All-Souls in the exchequer:
and the king’s letters patent, appointing the new sheriffs,
used commonly to bear date the sixth day of November.

12 Edw. IV. c. 1.

And the custom now is, which has obtained since the time of Henry VI. that all the judges, together with the other great officers, meet in the exchequer chamber on the morrow of All-Souls yearly (which day is now altered to the morrow of St. Martin, by the last act for abbreviating Michaelmas term), and then and there propose three persons to the king, who afterwards appoints one of them to be sheriff.

This custom of the twelve judges proposing three persons, seems borrowed from the Gothic constitution before-mentioned; with this difference, that among the Goths the twelve nominees were first elected by the people themselves: which usage of ours was probably founded upon some statute, though not now to be found among our printed laws. But notwithstanding an unanimous resolution of all the judges of England to this purpose, entered in the council-book of 3 March, 34 Hen. VI. and the statute 34 & 35 Hen. VIII. cap. 26. sect. 61. which expressly recognizes this to be the law of the land; some of our writers have affirmed, that the king, by his prerogative, may name whom he pleases to be sheriff, whether chosen by the judges or not. This is grounded on a very particular case in the fifth year of Queen Elizabeth, when, by reason of the plague, there was no Michaelmas term kept at Welshminton, so that the judges could not meet there in regalino animarum, to nominate the sheriffs; upon which the queen named them herself, without such previous assembly, appointing for the most part one of the two remaining in the last year’s list. And this case, so circumstances, is the only authority in our books for making these extraordinary sheriffs.

However, it must be acknowledged, that the practice of occasionally naming what are called pocket-sheriffs, by the sole authority of the crown, hath uniformly continued to the reign of his present majesty, George III. in which, says Blackstone, few, if any, instances have occurred.

By four several statutes it is enacted, that no one shall be sheriff, except he have sufficient land within the shire to answer the king and the people in any manner of complaint. 9 Edw. II. fl. 2. 4 Edw. III. c. 9. 5 Edw. III. c. 4. 13 & 14 Car. II. c. 21.

It has been judged, that an attorney is exempted from the office of sheriff, by reason of his attendance on the courts of Welshminton.

By 2 Geo. III. c. 20. no person, during the time he is acting as a militia-officer, shall be obliged to serve the office of sheriff.

Protestant dissenters, who are exempted by the Toleration act from the obligation of complying with the requisition of the Corporation act, and who can plead their non-compliance as a reasonable and sufficient excuse, are not compellable to serve this office, nor of course to pay any fine for refusal. See Furner's Notes to Blackstone, ed. 2, and particularly the Appendix, containing lord Mansfield's speech in the house of lords 1767, on the cause between the city of London and the dissenters, when the house affirmed the unanimous judgment of the commissioners' delegates, who hearing counsel several days.

By a by-law of the city of London, passed in a common council June 11th, 1799, amending an act of April the 7th, 1748, no freeman chosen sheriff, &c. shall be excused, unless he voluntarily swears he is not worth 20,000l. &c. which oath shall be attested by the oaths of six other freemen; and if he refuses to take the office, he incurs a forfeiture of 400l. and twenty marks towards the maintenance of the ministers of the several prisons within the city, together with the usual fines. If, however, he shall afterwards take upon him the office of an alderman of the city, he shall be eligible to the said office of sheriffalty, notwithstanding the fore-mentioned payment.

The sheriff, before he exercises any part of his office, and before his patent is made out, is to give security in the king's remembrancer's office in the exchequer, under penalty of 100l., for the payment of his provisors, and all other profits of the sheriffwiek; he must also take the oaths of allegiance and abjuration, and all, except the sheriffs of Wales and Chester, an oath appointed by 3 Geo. I. cap. 15. sect. 18. for the due execution of their office. This oath may be administered in pursuance of a writ of dedimus potestatem.

Sheriffs, by virtue of several old statutes, are to continue in their office no longer than one year; and yet it hath been said, that a sheriff may be appointed durante bene placito, or during the king's pleasure, and so is the form of the royal writ; therefore, till a new sheriff be named, his office cannot be determined, unless by his own death, or the demise of the king.

And by 1 Ann. fl. 1. c. 8. all officers appointed by the preceding king may hold their offices for six months after the king’s demise, unless sooner displaced by the successor.

We may farther observe, that by 1 Rich. II. c. 11. no man, that has served the office of sheriff for one year, can be compelled to serve the same within three years after.

The power and duty of a sheriff are those that belong to him as a judge, as a keeper of the king's peace, as a ministerial officer of the superior courts of justice, or as the king's bailiff.

In his judicial capacity he is to hear and determine all causes of forty shillings value and under, in his county-court; and he has also a judicial power in divers other civil causes. He is likewise to decide the elections of knights of the shire (subject to the control of the house of commons), of coroners, and of verderors; to judge of the qualification of voters; and to return such as he shall determine to be duly elected, but incapable of being elected himself for the county, &c. of which he is returning officer.

As the keeper of the king's peace, both by common law and special commission, he is the first man in the county, and in rank to any nobleman therein, during his office. He may apprehend and commit to prison all persons who break the peace, or attempt to break it; and may bind any one in a recognizance to keep the peace. He may, and is bound, ex officio, to pursue and take all traitors, murderers, felons, and other misdemeanors, and commit them to gaol for safe custody. He is also to defend his county against any of the king's enemies when they come into the land; and, for this purpose, as well as for keeping the peace and purifying felons, he may raise the posse comitatus.

However, by the express directions of the great charter, the sheriff, together with the constable, coroner, and certain other officers of the king, are forbidden to hold any pleas of the crown, or, in other words, to try any criminal offence; for it would be highly unbecoming, that the executioners of justice should be also the judges; should impo

But neither may he act as an ordinary justice of the peace during the time of his office, for this would be equally inconsistent, he being in many respects the servant of the justices.

In his ministerial capacity, the sheriff is bound to execute all processes issuing from the king's courts of justice. In the commencement of civil causes, he is to serve the writ, to arrest, and to take bail; when the cause comes to trial, he

3 R 2
SHE

mult summon, and return the jury; when it is determined, he must see the judgment of the court carried into execution. In criminal matters, he also arrests and imprisons; he returns the jury; he has the custody of the delinquent; and he executes the sentence of the court, though it extend to death itself.

As the king's bailiff, it is the sheriff's business to preserve the rights of the king within his bailiwick; for to his county is frequently called in the writs. He must seize, to the king's use, all lands devoted to the crown by attainder or escheat; must levy all fines and forfeitures; must seize and keep all waifs, wrecks, esrattes, and the like, unless they be granted to some subject; and must also collect the king's rents within his bailiwick, if commanded by process from the exchequer.

To execute these various offices, the sheriff has under him many inferior officers, an under-sheriff, bailiffs, and gaolers, who must neither buy, sell, nor farm their offices, on forfeiture of 50l. 3 Geo. I. c. 15.

The under-sheriff usually performs all the duties of office, few excepted, with regard to which the personal presence of the high sheriff is necessary. But no under-sheriff shall abide in his office above one year by 42 Edw. III. c. 9. and if he does, by 23 Hen. VI. c. 8. he forfeits 200l.; and no under-sheriff, or sheriff's officer, shall practise as an attorney during the time he continues in such office, by 1 Hen. V. c. 4.

But these regulations are evaded, by practise in the names of attorneys, and putting in them deputies by way of nominal under-sheriffs.

The under-sheriff, before he enters upon his office, is to be sworn, by 27 Eliz. c. 12. and by 3 Geo. I. c. 15. sect. 19, it is enacted, that all under-sheriffs of any counties in South Britain, except the counties in Wales, and the county palatine of Chester, shall take an oath for the due execution of their office. SHERLING, or SHIRLING Lambs, in Rural Economy, the practice of cutting or fleecing the short woolly coats or coverings of these young animals in the summer season, about the time at which the old sheep are clipped. Both the term and the custom are common in the northern districts, though they are scarcely known in the more southern parts of the island. Probably the greatest part of the lambs which are brought to Smithfield market, as well as of those which are bought by the butchers of the metropolis, are never sherd or freed from their coats, by which a very great individual as well as national loss is sustained. Perhaps the lambs are more saleable when kept in their full coats. The practice is, however, worthy of being more attended to in all situations.

The clipping or shirling of the lambs in some districts has, however, been considered as injurious, by the operation's hurting the growth of them; though no such effect has been discovered to take place in the South Down sheep tract of the county of Surle, or those of many other parts of the north. The profit in the above district is, however, thought to be trifling, or such as only to repay the expenses, and a little more; but it has a tendency to improve the wool, and cause it to throw out a more luxuriant fleec. See Wool.

SHERLOCK, William, in Biography, an eminent divine in the English church, was born in London in 1641. He was educated at Eton, and thence he went to Peter-House, Cambridge, where he applied himself with much application to his studies, obtained a good reputation, took orders, and officiated as a curate till the year 1669, when he was presented to the rectory of St. George's, Botolph Lane, London. He stood high in character among the London clergy, when he published "A Discourse concerning the Knowledge of Christ, and our Communion with Him," being intended as a controversy of the Antinomian doctrine, which brought upon him several antagonists, against whom he vindicated himself with judgment and zeal. In 1680 he took the degree of D.D. and in the following year he obtained a prebend in the cathedral of St. Paul's. The discovery of what was called the Rye-house plot, having called forth the spirit of loyalty, Dr. Sherlock appeared as an adherent of the doctrine of non-refusal, in a work entitled "The Case of Refusal to the supreme Powers flated and resolved according to the Doctrines of the Holy Scriptures." In this piece he maintained that the authority of the sovereign was in his person, and not in the law:—that he does not receive his authority from the laws, but that the laws receive their power from him;—and that it does not become a man who can reason at all to talk of the authority of the laws in derogation to the authority of the sovereign power. From these novel principles he did not in the least waver, even after the accession of James II. had still more endangered the public liberties and religion of the country. His notion of passive obedience did not, however, prevent him from opposing Popery, for he was among the first who, in those times, engaged in controversy with the Papists, in which he wrote a great number of tracts.

After the revolution, Dr. Sherlock for some time remained firm in his high monarchical principles; and refusing to take the oaths to the new government, was suspended from all his preferments, among which was the mastership of the Temple. It was during this suspension from his labours as a preacher, that he published the treatise on "Death," to which he is chiefly indebted for celebrity as an author. It was entitled "A Practical Discourse concerning Death," and few works have been more popular among all classes. It went through thirty editions in a short space of time, has been printed in all sizes and forms, and has been applauded by the most able critics.

Not long after the publication of this work, Dr. Sherlock's scruples with regard to government gave way; he took the oaths, and was reinstated in all his preferments. This step of course exposed him to the censure of the party with whom he had long acted, and to vindicate himself he published a piece, entitled "The Case of the Allegiance due to sovereign Powers ratified and resolved." In 1692 he published his "Vindication of the Doctrine of the Holy and Ever-blessed Trinity." In this he maintained that there were three eternal minds, which exposed him to the charge of tritheism; it did not, however, prevent his promotion to the deanship of St. Paul's, on the recommendation of Dr. Tilloton, who was raised to the archbishopric of Canterbury.

This rise in the church exasperated still more those who were already indignant against him for his denial of his former principles, and Dr. South published in 1693, "Animadversions upon Dr. Sherlock's Book," &c. An eager controversy followed, in which the university of Oxford took part, by enforcing in a public decree the hypothesis of Dr. Sherlock, as maintained by a preacher at that place. The controversy being carried on with great acrimony, the king, at the
In 1704 Dr. Sherlock published "A Discourse on the Immortality of the Soul," in which he made an attack on Locke's opinion concerning innate ideas. He died in 1707, in the 67th year of his age. After his decease, his sermons, which had been printed during his life, were collected, and with others printed in two volumes, 8vo.

SHERLOCK, Thomas, a distinguished prelate, and one of the preceding, was born in London in 1678. He received his classical education at Eton, and from thence he removed to Catharine-hall, Cambridge, about the year 1693. In process of time he became a fellow of that society, entered into holy orders, and upon the resignation of his father in 1704, he succeeded to the office of master of the Temple. In the duties of this office he exerted himself with so much success, that few English divines have acquired so high a reputation for pulpit oratory, in the qualities of strength and solidity of reasoning, and forcible and manly eloquence.

He commenced doctor of divinity in 1707, and in 1714 was elected master of Catharine-hall. Being promoted to the deanship of Chichester in 1726, he soon after made his first appearance in print, as a champion of the establishment, in "A Vindication of the Corporation and Temporal Acts, in answer to the Bishop of Bangor's Reasons for the Repeal of them." This was replied to by the worthy prelate, and supported in a rejoinder by the dean.

Dr. Sherlock's next work was entitled "The Use and Intent of Prophecy in the several Ages of the World," which was the substance of some sermons preached in the Temple church, occasioned by the controversy between Collins and several divines on the subject of prophecy. In 1728 he was promoted to the see of Bangor, in which he succeeded his antagonist Howley, as he did, in 1738, in that of Salisbury. As a member of the upper house, he took an active part in its debates, and was always a supporter of the interests of the crown and the church. He was considered, in parliament, as a great authority in ecclesiastical law, and frequently led the judgment of the house; and such at length was the reputation which he had in the episcopal character, that upon the death of archbishop Potter, in 1747, he was offered to succeed him in the see of Canterbury, which he declined on account of ill health, but afterwards recovering, he accepted the see of London in 1749.

In 1753 he resigned the mastership of the Temple, and was very soon after incapacitated for any very active service: he nearly lost the use of his limbs and speech; but still retained the vigour of his understanding, and was capable of revising and correcting a volume of sermons; this was followed by four others, which are in high estimation. The bishop died in 1761, in the 84th year of his age.

SHERMII, or CHERAM, in Geography, a province of the kingdom of Morocco, which lies between the province of Hea and that of Morocco, and has been demifemerged from that of Hea. See SHIRMA.

SHERMAN, a town of America, in the state of Connecticut and county of Fairfield, containing 659 inhabitants; 6 miles SSW. of New London.

SHERON, a town of Egypt, on the right bank of the Nile; 8 miles N. of Abu Girghe.

SHERINGHAM, in Geography, a composer of songs in parts during the reign of Henry VIII. which have been preferred with those of other contemporary composers in the Fairfax MS., the most ancient book of the kind that we have ever been able to discover. See FAIRFAX.

SHERSHOLL, in Geography, a town of Africa, in the kingdom of Algiers, generally supposed to be the city called Jol, and by the younger Juba named Caesarea, in compliment to Augustus. This town, when Dr. Shaw saw it, in the year 1730, was in great reputation for making felts, earthen vessels, and such iron tools as are wanted in the neighbourhood: but a few years afterwards (1738) it was entirely destroyed by an earthquake. The ruins upon which this town was situated, are not inferior in extent to those of Carthage; and we may likewise conceive no small opinion of its former magnificence, from the fine pillars, capitals, spacious cellars, and beautiful Mosaic pavements, that are every where remaining. They have a tradition, that the ancient city was destroyed, as the new one was lately, by an earthquake; and that the port, formerly very large and commodious, was destroyed by the arsenal and other adjacent buildings being thrown into it by the shock. The citadel, or artificial harbour, that had a communication with the western part of the port, is the best proof of this tradition: for when the sea is calm, and the water low, (as frequently happens after strong south or east winds,) all over the area of it to many miles pillars and pieces of great walls may be seen, that it cannot well be conceived how they should come there without such a concussion. The port is nearly of a circular form, of 200 yards in diameter; but the secured part of it, which, till of late was towards the citadel, is now filled up with a bank of sand, that daily increases.

However, there still lies in the mouth of it a small rocky island, which at present is the main shelter and defence against the northern tempest. N. lat. 36° 35'. E. long. 2° 30'.

SHERVEND, a town of Persia, in the province of Irak; 32 miles N. of Confar.

SHERWOOD FOREST. See SHREWWOOD Forest.

SHERZOUR. See SHERZUR.

SHESEBOUN, a post-town of America, in Luzerne county, Pennsylvania; 80 miles N.N.W. of Philadelpia.

SHESHMO-BAND, a town of Persia, in the province of Segeltan; 60 miles W.S.W. of Ferah.

SHESMISHA, a town of Persia, in the province of Khorasan; 95 miles W. of Tabas-Kileki.

SHETABA, a town of Hindooestan, in the Carnatic; 40 miles N. of Tanjore.

SHETERU, a town of Hindooestan, in Coimbatore; 5 miles N.W. of Erood.

SHETLAND ISLANDS. See ZETLAND ISLANDS.

SHETLAND SHEEP, in Agriculture, a breed of fine-wooled sheep peculiar to the Shetland islands. See SHEEP.

SHETUCKET, in Geography, a river of America, in Connecticut, formed by the junction of Willimantic and Mount Hope rivers, which after running E. a few miles pursues a southern course, and uniting with Quinabang river discharges itself into the Thames in the southern part of the township of Norwich.

SHEVADY, a town of Hindooestan; 8 miles W.N.W. of Pulunnare.

SHEVAGUNA, a town of Hindooestan, in Mysoon; 25 miles N.W. of Bangalore. N. lat. 13° 6'. E. long. 77° 13'.

SHEVAGURY, a town of Hindooestan, in Madura; 15 miles N.W. of Colpetta.

SHEVALORE, a town of Hindooestan, in Marawar; 8 miles N.W. of Trumian.

SHEVALPETTORE, a town of Hindooestan, in Marawar; 22 miles N.N.W. of Ramannadurum.—Also, a town of Hindooestan, in the province of Madura; 35 miles S.S.W. of Madura.

SHEVA-
SHEVAPORUM, a town of Hindooftan, in the country of the Nayrs; 15 miles E. of Tellicherry.
SHEVGUNGA, a town of Hindooftan, in Maravar; 20 miles S. of Tripattore.
SHEVITOON INDIANS, Indians of North America. N. lat. 47° 30'. W. long. 104° 45'.
SHEW-Box for Prints. See Camera.
SHEWAGE. See Scavage.
SHEW-BREAD, in the Jewish Economy. The Hebrew (Exod. xxi. 30.) גְּדַלֶּה, xiphos, xiphos, signifies literally "bread of faces, or of the faces." This denomination was given to the loaves of bread, which the priests of the week placed every Sabbath-day on the golden table in the sanctuary, before the Lord. These loaves were of a square form, with four faces, as the rabbins say, and were twice in number, reprenting the twelve tribes of Israel. They supplied the place of those which had been exposed the whole week, and none could lawfully eat them but the priests. This offering was accompanied with frankincense and salt. Of the first fruits and tenths presented by the Israelites to the priests, the latter took that which was necessary for making the shee-bread, and for supplying the service of the temple with any thing else which it was their duty to furnish.
SHEWIN, or Sewin, in Ichthyology. See Grey.
SHIGATCHEE, in Geography. See Sigatchee.
SHIB, a town of Arabia, in the province of Hadjas; 84 miles S.E. of Calaaf al Molaih.
SHIANDAMAGLY, a town of Hindooftan, in the province of Timewelly; 10 miles S. of Tutacorin.
SHIANSHIA, a town of Egypt; 25 miles S. of Manfora.
SHIANT ISLANDS. See Shiant.
SHIBBOLETH, or Sibboleth, a Hebrew word which signified epica, or an ear of corn. It was used by way of distinguishing the Ephraimites from the men of Gilgal. For the latter having killed a great number of the former, set guards at all the paffes of Jordan; and when an Ephraimite, who had escaped, came to the water-side, and desired to pass over, they asked him if he was not an Ephraimite? If he said no, then they bade him pronounce Shibboleth. But he pronouncing it Sibboleth, according to the manner of the Ephraimites, and thus not enunciating the first letter, was killed on the spot: on this occasion, 42,000 Ephraimites were killed. By thus not distinguishing between the ש and the ס, the schin and the sin, they exposed themselves to this mischief: hence the terms have been used to denote the trivial grounds on which contending parties, particularly in theological disputes, often differ, and are likely to contribute to ill of, and actually to perpetuate, one another.
SHIBBAK, in Geography, an extensive salt-plain of Algiers, overflown in winter, but dry in summer; 10 miles S. of Oran.
SHICARAN, a town of Asiatic Turkey, in the province of Diarbekir; 18 miles W.S.W. of Hazou.
SHIDES. See Shingles.
SHIEL, Loch, in Geography, a lake in the parish of Ardnamurchan, and county of Inverness, Scotland; extending ten miles in length, and two in breadth. Near its centre rises an islet, called Island Fiaun, which contains the ruins of a chapel dedicated to the saint of that name. This lake discharges its waters into the Western ocean at Caille Tioram, by the river Shiel. Statistical Account of Scotland, by Sir John Sinclair, vol. ii. 1792.
SHIELD, an ancient weapon of defence, in form of a light buckler, borne on the arm to fend off lances, darts, &c.

The form of the shield is represented by the escutcheon in coats of arms.
The shield was that part of the ancient armour on which thad the pertons of distinction in the field of battle always had their arms painted; and most of the words used at this time to express the space that holds the arms of families, are de-
A fort of shields was worn by the Scots at the battle of Mungallborough, in the first year of Edward VI. Shields or bucklers seem to have been used in affrays and private quarrels, by persons in the civil line, as late as the reigns of Elizabeth and King James I. The common appellation for a quarrelstone or fighting fellow about that period was a wathbuckler, that is, a breaker or clasher of bucklers. Maurice, prince of Orange, was a great advocate for the shield, and even attempted to revive the use of it. His company of Dutch guards was armed with targets and roundels, and he formed a regular plan of exercise for them. The target and broad sword were the favourite arms of the Scotch Highlanders as late as the year 1746, and even after. Swords and bucklers were anciently borne before great military officers, as insignia of their dignity: those carried before King Edward III. in France, are shewn in Wiltminter Abbey. The shield borne before the commandant of the forces on board the Spanish Armada, is preserved in the Tower, and a sword was borne before the bishop of Norwich, as commander of the troops with which he intended to serve king Richard II. Most of the ornamented metal shields, and many of the very large swords, were designed for this use.

The Spaniards and Portuguese have the like general form of shields, but they are round at the bottom, without the point; and the Germans, beside the Samnite shield, have two others pretty much in use: these are, 1. The bulging shield, distinguished by its swelling or bulging out at the flanks; and, 2. The indented shield, or shield chanteree, which has a number of notches and indentings all round its sides. The use of the ancient shield of this form was, that the notches served to retie the lance up, so that it might be firm while it gave the thrust; but this form being least proper for the receiving armorial figures, the two former have been much more used in the heraldry of that nation.

Another form of shield derived its name roundel, or rondache, from its circular figure; it was made of boards, boards of light wood, fines or ropes, covered with leather, plates of metal, or thick full of nails, in concentric circles, or other figures. The shields and roundels of metal, particularly those richly embroidered or embossed, seem rather to have been of dignity, anciently borne before generals or great officers, than calculated for war; most of them being either too heavy for convenient use, or too flight to refit the violence of a stroke either from a sword or battle-axe. Although most roundels are convex, we meet with many that are concave; but these have commonly an umbo. The handles are placed as in the shield and target. The roundel seems, in many instances, to resemble the Roman para. For another form of shield, see Pavais.

Besides this different form of the shield in heraldry, we find them also often distinguished by their different positions, some of them flanging erect, and others flanging various ways, and in different degrees; this the heralds express by the word pendant, hanging, they seeming to be hung up, not by the centre, but by the right or left corner. The French call these ces pendents, and the common antique triangular ones en ancien. The Italians call this i gl' antichi; and the reason given for exhibiting the shield in these figures in heraldry is, that in the ancient tilts and tournaments, they who were to joust at these military exercises, were obliged to hang up their shields, with their armories or coats of arms on them, out at the windows and balconies of the houses near the place; or upon trees, pavilions, or the barriers of the ground, if the exercise was to be performed in the field. Those who were to fight on foot, according to Columbier, had their shields hung up by the right corner, and those who were to fight on horse-back, had theirs hung up by the left.

This position of the shields in heraldry is called couche by some writers, though by the generality pendant.

It was very frequent in all parts of Europe, in arms given between the eleventh and fourteenth centuries; but it is to be observed, that the hanging by the left corner, as it was the token of the owner's being to fight on horse-back, so it was esteemed the most honourable and noble situation; and all the pendant shields of the lords of the royal family of Scotland and England, and of our nobility, at that time, are thus hanging from the left corner. The hanging from this corner was a token of the owner's being of noble birth, and having fought in the tournaments before; but no sovereign ever had a shield pendant any way, but always erect, as they never formally entered the lists of the tournament.

The Italians generally have their shields of arms of an oval form; this seems to be done in imitation of those of the popes, and other dignified clergy; but their herald, Petru Sancto, seems to regret the use of this figure of the shield, as an innovation brought in by the painters and engravers, as most convenient for holding the figures, but derogatory to the honour of the polello, as not representing either antiquity, or honours won in war, but rather the honours of some citizen, or person of learning. Some have carried it so far, as to say that these, who either have no ancient title to nobility, or have fulfilled it by any unworthy action, cannot any longer wear their arms in shields properly figured, but were obliged to have them painted in an oval or round shield.

In Flanders, where this author lived, the round and oval shields are in the disrepute he speaks of; but in Italy, besides the popes and dignified prelates, many of the first families of the laity have them.

The peculiar princes, in many other countries, also retain this form of the shield, as the most ancient, and truly expressive of the Roman cypcebs. Nifbet's Heraldry, p. 12. Componille, Herald.

Shield, in Heraldry, denotes the escutcheon, or field, whereon the bearings of the armoury are placed. See Escutcheon.

ShieldRake. See Tadorna.

Shields, William, in Biography. Though this musical professor, for the happiness of his acquaintance, filled ranks with the living, and we can tell our contemporaries nothing concerning his worth and talents which is not already well known, yet as his name has penetrated into Germany, and has furnished an article in Gerber's Continuation of Walther's Musical Lexicon, we cannot refrain from confirming the account given of his compositions in that work.

Shields, North, in Geography, a market-town and ferry-port in Carlisle ward, county of Northumberland, England, is situated near the entrance of the river Tyne, on its northern bank, at the distance of half a mile W.S.W. from the town of Tynemouth, and 179 miles N. by W. from London. This town is indebted for its origin to the monks of Tynemouth priory, who erected a number of houses here, and encouraged the settlement of ship-owners and trade-men, early in the reign of Edward I. They at the same time formed a harbour here for lading and unlading of ships, and established a weekly market and fairs; but the exercise of these privileges having been disputed by the corporation of Newcastle, they were inhibited by a decree of the itinerant judges. From that period it continued to be a mere fishing village till the middle of the seventeenth century, when new efforts were made to render it an important ferry-port, for which purpose its situation is admirably adapted. Cromwell, who then held the reins of government, with the consent of
parliament passed an act, in which it was ordered, "that sufficient and well-fenced battal.-flores, quays, and fleets, be built at Shields," and "that North Shields be made a market-town two days in the week, for the relief of the country and garrison of Tynemouth, and for all the great confluence of people and fleets of ships."

In consequence of this act, North Shields would soon have become a place of great commercial importance; but on the restoration, the rights claimed by the corporation of Newcastle were reëstablished; and North Shields was deprived of its markets and fair. From that time every mean which a narrow and illiberal policy could devise, was employed to retard the growing prosperity of this port; but towards the conclusion of last century, many of the unjust restrictions which formerly subsisted were removed, and the different trades permitted to be followed without molestation. It was only, however, in the year 1804, that North Shields obtained the privilege of holding a weekly market and fairs, by petition of the inhabitants to the duke of Northumberland, as lord of the manor of Tynemouth, in which the feite of North Shields is included. The day of the first opening of the market was ushered in with great rejoicings, and at noon a salute of cannon announced the completion of the long wished-for event. The market-day is Friday, and the fairs are held on the last Friday in April, and the first Friday in November.

North Shields, from these circumstances, and the patriotic exertions of the duke of Northumberland, is become, in the course of a few years, a large and populous town. It contains many handsome streets, and two elegant squares, besides the market-place, lately formed, which may rival any provincial market-place in the kingdom. On one side is a spacious quay, with a crane for the delivery of goods, where ships of 300 tons burthen may discharge or take in cargoes with perfect safety. Another side is adorned with a noble rice building, which is now used as an inn, and is surmounted with the Percy arms. North Shields, forming part of the parish of Tynemouth, has no parish church, but it posses several chapels of ease, and meeting-houses for almost every class of dissenters. The other public structures and establishments here are a theatre, a gymnasium, and a large school-house, erected by subscription, in commemoration of the royal jubilee, where a great number of boys and girls are educated on the Lancastrian plan. Here are likewise many well-conducted and flourishing benefit societies, an asylum for sick and friendless seamen, and a lying-in hospital. A subscription library has also been opened in North Shields, and is said to contain an extensive collection of valuable books.

The harbour of North Shields is calculated to accommodate 2500 sail of ships; and in spring tides, vessels of 500 tons burthen can pass the bar without danger. The vessels belonging to this port, exclusive of small coasters, are stated in the "Historical View of Northumberland," to amount to 1000; but this number, we premise, includes the shipping of Newcastle and South Shields also, of which North Shields may justly claim one half. One great inconvenience complained of by the commercial interest here and at South Shields, is the want of an independent custom-house; which obliges the captains of all vessels falling from this port to clear their ships at Newcastle, a distance of ten miles up the river.

The principal trade of North Shields, as of the river Tyne generally, consists in the exportation of coals to London, and other parts of the eastern coast of England; but some vessels are likewise employed in the Baltic and American trade; and during the late wars, a great number was hired to government for the transport service. The manufactures established here are chiefly such as depend upon the shipping interest, as ship and boat-building, rope and sailcloth making, brewing, baking, &c.; but there are likewise in North Shields a foundry for cast iron, an extensive tannery, one skinner, a tobacco manufactory, a glove manufactory, and five hat manufactories.

The feamen of this port are frequently very riotous and turbulent, when they want a rife of wages, or are in any way disatisfied with the conduct of the ship-owners. In these instances they have generally acted upon a regular plan; forcing every tailor to remain on shore, and preventing any vessel from proceeding to sea until their demands were complied with. An alarming combination of this kind was formed in the months of September and October last, (1815,) and threatened such ferious consequences, as to render government interference necessary, when order was happily restored without bloodshed.

North Shields, according to the parliamentary returns of 1811, contains 804 houses, and a population of 7699 persons.

For some further account of this port and the adjoining country, see the articles Newcastle, Tyne, Tynemouth, and South Shields. A Historical and Descriptive View of the County of Northumberland, &c. two vols. 8vo. Newcastle, 1812.

Shields, South, a market-town and sea-port in the parish of Jarrow, civil division of Chelmer ward, and county palatine of Durham, situated directly opposite to North Shields, at the distance of 21 miles N.N.E. from the city of Durham, and 275 N.N.E. from London. Like North Shields, it owes its importance chiefly to the coal trade and shipping interest, but the proportion of manufactures carried on here is greater than at the former town. About fifty years ago this place possessed upwards of two hundred faltipans, but that branch of business has greatly declined, and others of higher importance are substituted in its stead, as ship-building, and the manufacture of glafs, soap, &c. South Shields was constituted a market-town by bishop Trevor, in the year 1770. The market-day is Wednesday, and there are two annual fairs, on the 24th of June and the 4th of September. The vessels belonging to this port amount to about 300 in number. The church, which is a chapel of ease under Jarrow, is evidently a structure of great antiquity; the style of its architecture being that of the Anglo-Norman era. Some antiquaries are of opinion that there was a Roman station at the point of land near South Shields, which forms the southern entrance into the Tyne; and the conjecture is certainly probable, though by no means authenticated as a fact.

South Shields, like North Shields, has, of late years, greatly increased in population and extent; but it is destitute of many of the advantages possessed by the other. Here are, besides the established church, several dissenting meeting-houses; also several benevolent societies and charity-schools. The petty fettlements for the civil division of Chelmer ward are held in the town-house here, which is a respectable building, situated in the centre of the market-place. Most of the streets of this town, however, are narrow, and the houses very indifferently built. According to the parliamentary returns of 1811, it contains 525 houses, and a population of 9501 persons.

About two miles to the westward of South Shields is the village of Jarrow, celebrated for its monastery, which was originally founded about the year 685; but has since been frequently rebuilt. This religious house was dedicated to St. Paul, and appropriated to the reception of Benedictine monks.

monks. Its remains, together with the church of Jarrow, occupy the summit of an elevated ridge, but display little worthy of notice. The History and Antiquities of the County Palatine of Durham, by W. Hutchinson, 4to. 1778. Beauties of England and Wales, vol. vi. by E. W. Brakley, and John Britton.

SHIFFMAL, a market-town in the parish of Shiffnal, hundred of Brimley, and county of Salop, England, is situated at the distance of 10 miles E. by S. from Shrewsbury, and 143 miles N.W. from London. The market-day is Monday weekly, and there are fairs on the 5th of August and the 22d of November. The petty fairs for Shiffnal division of the hundred are held here; but in other respects this town is a trifling place, the whole parish, which is extensive, and includes four townships, containing, according to the parliamentary returns of 1811, only 828 houses, and 4061 inhabitants.

SHIFT, a term in Music, used for conducting the hand on the finger-board of the violin, and instruments with a neck.

By moving the left hand a little towards the bridge, and placing the first finger where the second was, on the second string of the violin, in the natural position of the hand, it will produce C instead of B, and the little finger will then produce C on the first string; and this is called the half shift. The first, or whole shift, is placing the first finger where the third was, in the natural position of the hand, which will produce D on the second string, and the little finger its octave on the first. The next movement of the hand towards the bridge is the placing of the first finger on E of the second string, when the little finger will give its octave on the first string, and this is termed the double shift; each shiftcommanding all the intermediate notes of an octave to the first finger. By this means a half, a whole note, or any number of notes, may be gained upwards upon each string, to the end of the finger-board. A ready guide at these shifts, on short notice, in all keys, and in true intonation, is said to be knowing the finger-board well. At present (1809) high solo parts for the violoncello are written in the treble clef.

SHIFT, in Ship-Building, a term applied to disposing the butts of the planks, &c. so that they may over-lieach each other, without reducing the length, and so as to gain the most strength. The planks of the bottom, in British-built ships of war, have a fix-feet shift, with three planks between each butt, so that the planks run twenty-four feet long. In the bottoms of merchant-ships, they have a fix-feet shift, with only two planks between each butt, making but eighteen-feet planks in length. The shift of the timbers is from three feet to ten feet six inches in length, according to the size of the ship.

SHIFTED, in Sea Language, denotes the state of a ship's ballast or cargo, when it is shaken from one side to the other, either by the violence of her rolling in a tumultuous sea, or by an extraordinary inclination to one side, when under a great pressure of wind. This circumstance rarely happens, unless to those cargoes which are stowed in bulk, as corn, salt, and such materials.

SHIFT, as expressed of the wind, implies altered.

SHIFTER, a person appointed to shift the ship's cook, particularly in washing, fleecing, and shifting the sail provisions.

SHIFTING, in Ship-Building, the act of setting off the length of the planks, &c. of a ship, so that the butts may over-lieach each other, as to produce a good shift. (See Shift.) Replacing old stuff with new is also called shifting.

Vol. XXXII.

SHIFTING a Tackle, in Sea Language, the act of removing the blocks of a tackle to a greater distance from each other, on the object to which they are applied, in order to give a greater scope or extent to their purchase. This operation is otherwise called fleeting.

SHIFTING the Helm, is altering its position from one side to the other, or from one side to midships.

SHIFTING the Voyer, or Maffinger, changing its position on the capstern, so as to heave in the cable from the starboard or larboard side.

SHIFTING of Plants, in Gardening, the busines of removing plants in pots, from smaller into larger ones, &c. to give them fresh earth or mould. It is necessary occasionally, in all plants in pots, to affitl them with larger ones, according as the advanced growth of the particular sorts renders it proper; and at the same time to supply an additional proportion of fresh earth about the root-fibres of the plants, to promote their growth; and sometimes, for the application of fresh compost, either in part or wholly, from the plants having remained long unremoved, and the old earth in the pots being much decayed, or on account of some defect of growth in the particular plants.

In regard to the necessity of shifting, it is, in some degree, according to the advancing growth of the different sorts of plants: some sorts of a strong free growth require shifting once every year or two; others, more moderate growers, or of more fettled growths, once in two or three years; and some large growing kinds, which are advanced to a considerable size, having been occasionally shifted, in their increasing growth, from smaller into larger pots of different proportions, and some from large pots into tubs of still larger dimensions, as large plants of the American aloe, orange, and lemon-tree kinds, &c. in that advanced state, sometimes only need occasional shifting once in three or several years, especially when the pots or tubs are capacious, containing a large supply of earth, and are occasionally refreshed with some new compost at top, and a little way down, round the sides about the extreme roots. And in some small slow-growing plants, as in many of the succulent tribe, shifting them in one to two or three years may be sufficient; other sorts want shifting annually into larger pots, according as they advance in a free growth, as the hardy and tender kinds of herbaceous and shrubby plants, &c. And some of the tender annual flower-plants, cultivated in pots, and forwarded in hot-beds, being planted first in small pots, want shifting, in their increasing growth, into larger sizes, once or twice the same season, as from April to the beginning of June, when being shifted finally into the requisite full-sized pots, they remain during their excellence. But though large-grown plants, either of the shrub or tree kind, as well as other plants of large growths, after being finally stationed in the full-sized large pots and tubs, succeed several years without shifting, they should in the interval have the top earth loosened, and down round the sides to some little depth, removing the loosened old soil, and filling up the pots, tubs, &c. with fresh earth, setting it close by a moderate watering.

The usual leason for occasional shifting such plants as require it, is principally the spring and autumn, as from March to May for the spring shifting; and from August to the end of September for the autumn; though in plants that can be removed with the full ball of earth about the roots, it may be occasionally performed almost at any time; however, for any general shifting the spring and autumn are the most successful seasons, as the plants then lose their fresh root; and many sorts preferably in the spring, by having the benefit of the same growing season, and that of sum-
mer. In performing the business, it is most proper to remove the plants from the smaller to the larger pots, with the balls of earth about the roots, either wholly, or some of the outward old earth, the dry or matted radical fibres only being carefully trimmed away, so as not to disturb the principal roots in the bodies of them, as by this means the plants receive but little check in their growth by the removal. Sometimes, when any particular plants, shrubs, or trees, 
&c. in their pots, discover by their tops that they are in a declining state, as probably the defect may be either in the root, or the old balls of earth, it may be proper to shake all the earth entirely away, in order to examine the roots, and to trim and dress them as the case may require, replanting them in entire fresh compost or mould.

And in preparing for this fort of work, where necessary to give larger pots, &c. it is proper to provide them of suitable size, in some regular gradation larger than the old ones, according to the nature and growth of the plants, the whole being placed ready, with a proper quantity of fresh compost earth, in proportion to the number and size of the plants intended to be shifted: then let those plants intended to be removed with balls, be taken out of their old pots separately, with the whole balls or clumps of earth about the roots as entire as possible; and when large, or tolerably full, with a knife trim off some of the outward loofed earth, and the extreme fibres of the roots; but when small, and adhering together compactly, the whole may be preserved entire; and in either case, where there are very matted, dry, or decayed fibres surrounding the balls, they should be trimmed as it may seem necessary: in those of a fresh lively growth, the loose fraggling parts only should be cut away. The requisite pruning, trimming, or dressing in the heads or tops, should also be given where it may seem proper, according to the state of growth, and the natural habit of the different plants; but many forts require little or none of this fort of attention.

Then having prepared the intended pots for the reception of the plants, by placing some pieces of tile or oyster-shell, 
&c. loosely over the holes at bottom, and laid in a little fresh earth, two, three, or four inches deep, or more, according to the size of the pot, the plant should be set in with its ball of earth, as above, filling up around it with more fresh mould, raising it an inch or two over the top of the ball; and giving directly a moderate watering, to settle the earth close about the ball and roots, particularly in every part, in a proper manner. In those cases where the ball is particular, plants appears very compactly hard and binding, it may be proper to loosen it a little, by thrusting a sharp-pointed stick down into the earth in different parts, giving it a gentle wrench, to open the earth moderately; or sometimes it may also be proper to trim away some of the earth on the top and sides, then planting it as above, and filling up round and over the ball with fresh earth, and watering it afterwards.

Also, in shifting hardy or tender, thuggish, succulent, or herbaceous plants, when any appear of a sickly, weak, or unhealthy growth, it may be advisable to clear off a considerable part of the outward old earth from the balls about the roots; or, in some cases, to shake it wholly away, that the defects in the growths, occasioned either by faults in the roots or in the earth, may be removed by pruning out any decayed or bad parts of the roots, and replanting them wholly in fresh earth.

And sometimes particular sorts of plants in pots require shifting, more for the advantage of having fresh earth, than for want of new, or larger pots; and as in this case some of the same pots may be still of an eligible size to report them in, these pots should be well cleaned from all the adhering parts of the old earth, and be replenished with entire new, at the time of repotting the plants; which being removed out of their pots, either with the entire balls about the roots, and part of the old mould cleared off all round, to admit of a larger portion of fresh earth in the pot at replanting; or in some, appearing of an infirm or declining habit, the whole balls of old earth displaced clean to the roots; then having furnished the pots with fresh earth, the plants should be replaced in them, filling up the pots regularly with a sufficiency of the same fresh mould, and finishing with a moderate watering to settle the whole clothe about their roots.

Likewise after shifting, when the plants are not watered at the time, a moderate watering, both to the earth in the pots to settle it close about the roots, and in most forts highly over the tops or heads of the plants, should be given, in order to wash off any foreign; then the pots of plants should be set in their respective plantations in the garden, &c.: the hardy kinds, if warm funny weather, may be placed in a shady border for two or three weeks, till they have struck fresh root in the new earth: the tender sorts should be disposed in their places among the green-house and flower-plants, or to have the benefit of shade in the middle of hot sunny days, till fresh struck, or probably some of the more tender particular sorts may require to be plunged in a hot-bed or bark-bed, especially some of the flower kinds: some principal sorts of the more curious or tender green-house plants, in order to expedite their fresh-rooting more effectually; and sometimes tender annuals in hot-beds, potted in their early young growth, may require to be replugged in the hot-bed to fresh strike, and forward them till June; but generally all the full ground or open air plants only require a little occasional shade in hot dry weather the first two or three weeks, and some shifted with full balls about the roots, only need occasional watering; afterwards, on the whole, both the hardy and tender kinds should have repeated moderate waterings given them, according to their kinds.

SHIFTS, such parts of a farm as are allotted for the reception of either flock or crops. It is also a term applied to the rotations of cropping lands: thus we have three, four, five, and six course shifts. See Course of Croppers.

SHIJASCHKOTAN, in Geography. See SYASKUTAN.

SHIITES, in the History of Mahometanism, were the opponents of the Kharjites; see that article. This name properly signifies sectaries or heretics, a general term, but is particularly used to denote those of Ali Ebn Ali Taleb; who maintain him to be lawful caliph and imam, and that the supreme authority, both in spirituals and temporals, of right belongs to his descendents, notwithstanding they may be deprived of it by the injustice of others, or their own fear. They also teach, that the office of imam is not a common thing, depending on the will of the vulgar, fo that they may let up whom they please; but a fundamental affair of religion, and an article which the prophet could not have neglected, or left to the fancy of the common people; nay more, thence called Imamians, go fo far as to assert, that religion confuts solely in the knowledge of the true imam. The principal facts of the Shiites are five, which are subdivided into an almost incredible number; so that some understand Mohammed's prophecy of the seventy odd facts, of the Shiites only. Their general opinions are, 1. That the peculiar designation of the imam, and the testimonies of the Koran and Mohammed concerning him, are necessary points. 2. That the imams ought necessarily to keep themselves free from light sins as well as more grievous. 3. That every one ought publicly to declare who it is that he ad-
here to, and from whom he separates himself, by word, deed, and engagement, and that herein there should be no dillematation. But in this last point some of the Zeydians, a sect so named from Zeyd, the son of Ali, surnamed Zeyn al Abedin, and great grandson of Ali, differed from the rest of the Shiites. As to other articles, wherein they agreed not, some of them came pretty near to the notions of the Mortzaizites, others to those of the Mohabbehites, and others to those of the Sonnites. Among the latter of these, Mahomed al Baker, another son of Zeyn al Abedin's, seems to claim a place: for his opinion as to the will of God was, that God willed something in us, and something from us; and that he willed from us he hath revealed to us; for which reason he thought it preposterous that we should employ our thoughts about those things which God willed in us, and neglect those which he willed from us: and as to God's decree, he held that the way lay in the middle, and that there was neither compulsion nor free liberty. A tenet of the Khattabians, or disciples of one Abul Khattab, is too peculiar to be omitted. These maintained paradise to be no other than the pleasures of this world, and hell-fire to be the pains thereof, and that the world will never decay: which proposition being first laid down, it is no wonder they went farther, and declared it lawful to indulge themselves in drinking wine and whoring, and to do other things forbidden by the law, and also to omit doing the things commanded by the law.

Many of the Shiites carried their veneration for Ali and his descendants so far, that they transgressed all bounds of reason and decency; though some of them were less extravagant than others. The Gholaites, who had their name from their exclusive zeal for their imams, were so highly transported therewith, that they raised them above the degree of created beings, and attributed divine properties to them; transgressing on either hand, by defying of mortal men, and by making God corporeal: for one while they liken one of their imams to God, and another while they liken God to a creature. The sects of these are various, and have various appellations in different countries. Abdallâh Ebn Saba, (who had been a Jew, and had adhered to the true faith of Josua the son of Nun,) was the ring-leader of one of them. This man gave the following salutation to Ali: viz. Thou art Thou, i.e. thou art God: and hereupon the Gholaites became divided into several species: some maintaining the same thing, or something like it, of Ali, and others of some one of his descendants: affirming that he was not dead, but would return again in the clouds, and fill the earth with justice. But howsoever they differaged in other things, they unanimously held a medemphecy in, and what they call al Hadil, or the defect of God on his creatures; meaning thereby that God is present in every place, and speaks with every tongue, and appears in some individual persons; and hence some of them affirmed their imams to be prophets, and at length gods. The Nofai-rians and the Ithkaniins taught that spiritual substanstes appear in groffer bodies; and that the angels and the devil have appeared in this manner. They also assert that God hath appeared in the form of certain men; and since, after Mohammed, there hath been no man more excellent than Ali, and, after him, his sons have excelled all other men, that God hath appeared in their form, spoken with their tongue, and made use of their hands, for which reason, say they, we attribute divinity to them. And to support these blasphemies, they tell several miraculous things of Ali, as his moving the gates of Khabar, which they urge as a plain proof that he was endued with a particle of divinity; and with sovereign power, and that he was the person in whose

form God appeared, with whose hands he created all things, and with whose tongue he published his commands; and therefore they say he was in being before the creation of heaven and earth. In so impious a manner do they seem to wrest those things which are said in scripture of Christ, by applying them to Ali. These extravagant fancies of the Shiites, however, in making their imams partakers of the divine nature, and the impiety of some of those imams in laying claim thereto, are so far from being peculiar to this sect, that most of the other Mohammedan sects are tainted with the same madness; there being many found among them, and among the Sahifs especially, who pretend to be nearly related to heaven, and who boast of strange revelations before the credulous people. To this account of the Shiites of the first ages we shall subjoin a brief mention of the great fechim at this day subfiding between the Sonnites and the Shiites, or partisans of Ali, and maintained on either side with implacable hatred and furious zeal. Though the difference arose at first on a political occasion, it has, notwithstanding, been so well improved by additional circumstances, and the spirit of contradiction, that each party detests and anathematizes the other as abominable heretics, and farther from the truth than either the Chrristians or the Jews. The chief points wherein they differ are, 1. That the Shiites reject Abu Beer, Omar, and Othman, the three first caliphs as usurpers and intruders; whereas the Sonnites acknowledge and respect them as rightfull imams. 2. The Shiites prefer Ali to Mohammed, or, at least, esteem them both equal; but the Sonnites admit neither Ali, nor any of the prophet's, to be equal to Mohammed. 3. The Sonnites charge the Shiites with corrupting the Koran, and neglecting its precepts; and the Shiites return the same charge on the Sonnites. 4. The Sonnites receive the Sonna, or book of traditions of their prophet, as of canonical authority; whereas the Shiites reject it as apocryphal and unworthy of credit. And to these disputes, and some others of lesser moment, is principally owing the antipathy which has long reigned between the Turks, who are Sonnites, and the Perisians, who are of the sect of Ali. Sale's Koran, Introd.

SHILLACON, in Geography, a town of Egypt, on the E. side of the Nile; 8 miles N. of Cairo.

SHILL, in Agriculture, principally to separate the rind, pulp, or skin, as of oats, or other crops. It also signifies the turning a small portion of milk into curd.

SHILLAY, in Geography, a small island near the W. coast of the island of Lewis; 5 miles W.S.W. of To Head. N. lat. 54° 48'. W. long. 7° 14'.

SHILLELEAH, a town of Algiers, anciently Tarsaphilum; 10 miles S.W. of Burg Hamza.

SHILLER-STONE, or SHILLER-SPAR, in Mineralogy, the diallage metalloide of Hauy, a mineral nearly allied to serpentine. (See SERPENTINE.) It is considered by some mineralogists as a crystalline variety of that rock; in which it generally occurs, either in beds or disseminated. Its colour is commonly olive-green, with a shining lustre, which is sometimes semi-metallic. The structure is lamellar, with joints in one direction; it yields to the knife. In the vicinity of New Radnor, in Wales, there is a rock of this mineral intermixed with felsite.

SHILLING, an English silver coin, equal to twelve pence, or the twentieth part of a pound.

Frohicus derives the Saxon football, whence our football, from a corruption of folqua; proving the derivation by several texts of law, and among others, by the twenty-sixth law, De annuis legatis. Skinner deduces it from the Saxon folc, field, by reason of the excussion of arms upon it.

Bilhop Hooper derives it from the Arabic sahi, signifying
SHILLING.

flying a weight; but others, with greater probability, deduce it from the Latin *siliacus*, which signified in that language, a quarter of an ounce, or the forty-eighth part of a Roman pound. In confirmation of this etymology, it is alleged, that the shilling kept its original signification, and bore the same proportion to the Saxon pound, as siliacus did to the Roman and the Greek, being exactly the forty-eighth part of the Saxon pound; a difference which we owe to Mr. Lambard. *Explication Rerum et Verborum in Legg. Sax. voc. Libra.*

Others say, that the shilling was at first a German appellation, *safeling*; coins of which name had been struck at Hamburg in 1407.

However, the Saxon laws reckon the pound in the round number at fifty shillings, but they really coined out of it only forty-eight; the value of the shilling was five-pence; but it was reduced to four-pence above a century before the Conquest; for several of the Saxon laws made in Athelstan's reign, oblige us to take this estimate. Thus it continued to the Norman times, as one of the Conqueror's laws (Legg. Sax. p. 221.) sufficiently aforesays; and it seems to have been the common coin by which the English payments were adjusted. After the Conquest, the French solidus of twelve-pence, which was in use among the Normans, was called by the English name of shilling; and the Saxon shilling of four-pence took a Norman name, and was called the great, or great coin, because it was the largest English coin then known in England.

The groat, from the French *grose*, a large piece, was introduced by Edward III. in 1354, and continues, though not in common circulation, to this day. The half-groat, or two-pence, is of the same date and continuance. In Scotland, about the year 1553, were first coined teftoons, or shillings, bearing the bust of the queen, and the arms of France and Scotland on the reverse: they being of the same intrinsic value as those of England, were then worth four shillings, and the half-teftoon two, Scotch money.

It has been the opinion of bishops Fleetwood and Gibson, and of the antiquaries in general, that though the method of reckoning by pounds, marks, and shillings, as well as by pence and farthings, had been in constant use even from the Saxon times, long before the Norman conquest, there never was such a coin in England as either a pound or a mark, nor any shilling or teftoon, till the years 1503, 1504, or 1505; but in the twentieth year of king Henry VII. (A.D. 1505, 1506,) a few silver shillings, or twopence, were coined, being about one-half the size of the modern shillings, or forty out of a pound weight of silver, which were fair and broad pieces. These, however, it is said, have long since been solely confined to the cabinets of collectors.

Mr. Clarke contests this opinion, alleging, that some coins mentioned by Mr. Folkes, under Edward I. were probably Saxon shillings newly minted, and that archbishop Aelfric (Gram. Sax. p. 52., at the end of Somner's Saxon Diction.) expressly says, that the Saxons had three names for their money, viz. mancuses, shillings, and pences. He also urges the different value of the Saxon shilling at different times, and its uniform proportion to the pound, as an argument, that their shilling was a coin; and the testimony of the Saxon groats, in which the word we have translated *pieces of silver,* is rendered shillings, which, he says, they would hardly have done, if there had been no such coin as a shilling then in use. Accordingly, the Saxons expressed their shilling in Latin by *fivelius* and *argentius.*

He farther adds, that the Saxon shilling was never ex-

preffed by *solidus,* till after the Norman settlements in England; and howsoever it altered during the long period that elapsed from the Conquest to the time of Henry VII. it was the most constant denomination of money in all payments, though it was then only a species of account, or the twentieth part of the pound farthing; and when it was again revived as a coin, it flattened gradually as the pound farthing lefened, from the twenty-eighth of Edward III. to the forty-third of Elizabeth. Clarke on Coins, &c. p. 120, 152, 155, 200, 376.

Silver farthings ceased with Edward VI., but the silver half-pence continued the soe coins till Charles II. The silver penny was much used to the end of the regim of George I., and so far from being no where to be found, as Hume affirms (Hist. vol. i.), is superabundant of every reign since that period, not excepting even the present reign of George III.

In the year 1506, there was a peculiar fort of shilling struck in Ireland, of the value of nine-pence English, which palled in Ireland for twelve-pence. The motto on the revers of thefe, is, *Pohu Dcm Adjutorem Meum.*

Eighty-two of these shillings, according to Malynes, went to the pound, they therefore weighed twenty grains one-fourth each, which is somewhat heavier in proportion than the English shilling of that time, sixty-two of which went to the pound, each weighing ninety-two grains seven-eighths; and the Irish shilling being valued at the Tower at nine-pence English, that is, one-fourth part less than the English shilling, it should, therefore, proportionably weigh one-fourth part less, and its full weight be somewhat more than sixty-two grains; but some of them found at this time, though much worn, weighed sixty-nine grains.

In the year 1508, five different pieces of money of this kind were struck in England for the service of the kingdom of Ireland.

These were shillings to be current in Ireland at twelve-pence each; half shillings to be current at fix-pence; and quarter shillings at three-pence.

Pennies and half-pennies were also struck of the same kind, and lent over for the payment of the army in Ireland. The money thus coined was of a very bale mixture of copper and silver, and two years after there were more pieces of the same kinds struck for the same service, which were still worse; the former being three ounces of silver to nine ounces of copper; and these latter only two ounces eighteen pennyweights, to nine ounces two pennyweights of the alloy. Simon's Irish Coins.

The Dutch, Flemish, and Germans, have likewise their shilling, called *fabinet,* *felling,* *sothlin,* &c.; but these, not being of the same weight or fineness with the English shilling, are not current at the same value. See Shilling and Skilling.

The pound Flemish in accounts is divided into twenty shillings, and subdivided into twelve gros or pence Flemish. The coins in Holland are good shillings, or ecaulis, and half ditto, at fix and three farthings; ushuaped or bafe shillings reckoned at five and a half farthings, and called selhalls.

At Hamburg, accounts are kept in shillings, sixteen of which are equal to a mark, and each containing twelve pfennings; and sometimes in pounds, shillings and pence Flemish; the pound being equal to twenty shillings, and the shilling equal to twelve-pence or greater.

The English shilling is worth about twenty-three French sols; thofe of Holland and Germany about eleven sols and a half; thofe of Flanders about nine. The Dutch shillings are also called *fols de gros,* because equal to twelve gros.
The Danes have copper shillings, worth about one-fourth of a farthing sterling. See CORN.

SHILLUK, in Geography, a town of Africa, in the kingdom of Sennar, on the E. side of the river Balut-el-Abiad, and not far removed from it. This town is built of clay, and its inhabitants are idolaters. They have no other clothing than bands of long graits, which they pass round the waist and between the thighs. They are all black, and those of both sexes have their heads. The people of Shilluk have the dominion of the river, and take toll of all passengers, in such articles of traffic as pass among them. These people, who allot importance from their command of the river, are represented as hospitable to those who come among them in a peaceable manner, and as never betraying those to whom they have once avowed friendship; 50 miles W. of Sennar.

SHILOH, in Scripture Criticism, a term that occurs in Jacob's celebrated prophecy concerning the Messiah (Gen. xlix. 10); concerning the etymology and application of which, biblical commentators have differed in opinion. "The sceptre shall not depart from Judah, and a law-giver from between his feet; till Shiloh come; and to him shall the gathering of the people be." The word Shiloh, says one writer (Mr. Mann), is a modern reading; unknown in any other part of the scripture, or any of the old commentaries; coined by the Jewish correctors of the bible into שִׁלֹהֵי, a word of no signification; whereas the LXX read שִׁלֹהָה, that is, שִׁלֹהָה, he, to whom it is; he, to whom it. viz. the sceptre, belongs; שִׁלֹהָ, he for whom it is reserved, as it is in the original belt edition of the LXX version, as Justin Martyr long ago affirmed, (Dial. cum Tryph.,) and as it now stands in the Alexandrian MS. And if this be the true meaning, it plainly refers to the king of the Jews; for whom the sceptre was reserved, and to whom the people were to be gathered. Mr. Ainsworth and others render Shiloh the prosperer or safe-maker; others the peace-maker, from שלוח, all which agree to the same person. But the most probable interpretation, as the author of Mordecai's Letters, (Mr. Taylor,) apprehends, is given us by the very learned and judicious Dr. Hunt, professor of Arabic at Oxford. He understands the true etymology of the word Shiloh to remain in the Arabic שלוח, שִׁלֹּחַ, liberavit, subdixit ab anguilia et exitio. According to this etymology, Shiloh will be the deliverer from distress and destruction: a title, which justly belongs to Jesus Christ, the Lord of life; and Saviour of the world. If it should be objected to this etymology, that the rod (י) is wanting between the rod and the hamed, he observes, that in the Samaritan copy of Genesis, xlix. 10, the word is written without the rod, as it is likewise in one of the most ancient Hebrew MSS. which Dr. Kennicott has consulted on this text. Some moderns have pretended, in order to evade the prophetic force of this text, that the sceptre departed from Judah before the advent of Christ, by its falling into the hands of foreigners, which objection is sufficiently answered by Cuneus (De Repub. Legisl. lib. 5, p. 280, c. 10.) and others; who have shown, that the text only regards the continuance of the Jewish state; and that Judah, as separated from Israel, should remain a kingdom till the coming of the Messiah. On the other hand, Abravanel and others suppose, that the sceptre is not yet departed from Israel; and Menahem ben Hradetz alleges, that it is still in the hands of the tribe of Judah. The ancients undeniably understood this text of the Messiah. The Chaldean Paraphrast says, "He that hath dominion shall not be taken away from Judah, nor a scrip from his children's children, until the time when Christ shall come, whose the dominion is; and he shall the people (or nations) obey." And the Jerusalem Targum says, "Kings shall not cease from the house of Judah, nor doctors that teach the law from his children's children, until the time that Christ do come, whole kingdom is; and all the kings of the earth shall be subject unto him;" so that both the Targums confine the sense to this; that the peoples (i.e. both Jews and Gentiles) should gather unto and obey Christ; or, in other words, that the person here spoken of should be the prince that should reign over all; יִפְתַּחְתָּה נֵצֶר, as the LXX lay in this place; and that this should happen before Judah should cease to be a kingdom: which is verified by fact. Ben Mordecai's Letters, Letter iv.

SHILON, or Silo, in Ancient Geography, a famous city of Ephraim (Josh. xviii. xix. xx.), 12 miles distant from Shechem or Sichem, according to Eusebius, or 10 miles according to Jerome, and situated, according to both, in Acrabatene. In Jerome's time this city was ruined, nothing remaining but the foundation of the altar of burnt offerings, which had been erected when the tabernacle was there. At Shiloh, Joshua assembled the people to make the second distribution of the land of promise. (Josh. xviii. 1, 2, 3.) Here the tabernacle of the Lord was set up, when the people were settled in the country. (Josh. xix. 51.) The ark and the tabernacle of the Lord continued at Shiloh, from A.M. 2560, when it was set up by Joshua, to A.M. 2888, B.C. 1116, when it was taken by the Philistines, under the administration of the high-priest Eli. At Shiloh Samuel began to prophesy. (1 Sam. iv. 4.) Here the prophet Abijah dwelt. (1 Kings, xiv. 2.) Jeremiah foretold that the temple of Jerusalem should be reduced to the same condition as Shiloh was. (Jer. vii. 12, 14, xxvi. 6, 9.) After the return of the ark out of the country of the Philistines, instead of returning it to Shiloh, it was taken to Kirjath-jearim. (1 Sam. vi. 21.) Mr. Roland conjectures, that from the name Shiloh, Paulanias (l. vi. c. 24.) took occasion to say, that Silenus, the companion of Bacchus, was buried in Palellene. Benjamin of Tudela affirms, that the tomb of Samuel was to be seen here.

SHIM, in Agriculture, a tool of the tillage kind, used in breaking down and reducing the more stiff and heavy fields of land, as well as cutting up and clearing them from weeds. They are made in different forms and constructions, to suit different purposes. In the Hertford Agricultural Survey by the Board of Agriculture, the writer remarks, that a tool of this kind is in use by Mr. Calvert, of Albury, which differs from those usually employed, in which the cutting-iron or plate, which for the work it is adapted for, as that of cutting up weeds on two-bow or four-furrow Ellix ridges, or of cleaning land without ploughing or burying the soil, is a small segment of a large circle. It dispatches a ridge at a time, and is an implement that performs its business well, and which deserves the notice of the tillage-farmer in other places. It is readily altered for flat work, and is said to be well recomposed by other farmers with success in the same district. And an useful tool of this fort has also been recommended by Mr. Young, in his Annals, the hint of which he took from the Berkshire one, and to which the beam and block is capable of being applied. In a wide interval, the three shares may be worked on a level. Between the rows of cabbages, after earthing up, the two external shares may be set to cut the weeds that are apt to rise on the sides of the ridges, without disturbing too much earth, and the centre share sunk to scrape the bottom of the furrow. The centre one may also be worked alone, between narrow rows. In forging the shares of all kinds, he has well observed, that the
the blacksmith should be careful to give them tendency enough into the ground, by bending them downwards: for want of this caution, he has found many of them to work badly. The wheel in the beam counteracts this tendency sufficiently when at work.

These tools should be upon all tillage farms, in all their different and best constructions.

**SHIN, Potatoes**, a tool of the shin kind, used for cleaning potato crops.

**SHIN, Loch**, in Geography, an extensive lake in the county of Sutherland, Scotland. This lake extends above 20 miles in length, but no where exceeds two miles in breadth, and seldom above a mile and a half. The banks are finely covered with natural wood, particularly the southern bank. It is connected with the Northern ocean, at Dornoch Firth, by the river Shin, which abounds with salmon, and forms several falls in the short course of eight miles. Sinclair's Statistical Account of Scotland, vol. xi. 1794.

**SHINAAS**, a small town of Persia, in the province of Larifian. This and bothana lie between Lings and Cape Boftana; but though they are small towns, they afford some refreshment. Lings, the chief town of the piratical tribe of Joamnis on the Persian shore, is situated close to the sea, in N. lat. 26° 33', about eight leagues from Khish. It has a securc road, where ships may ride out a north-west gale in five fathoms water. Cape Boftana forms to the eastward the roadstead of the town of Moggo, which is one of the most secure in the gulf; and this roadstead has to the westward the point improperly called Cortes. This roadstead is capable of holding the largest fleets.

**SHINDAN, a mountain of Persia**, between the provinces of Adirbeizen or Azerbijan and Ghilan.

**SHINGARIN**, a town of Africa, in the country of Sahara, where falt is found; 9 miles N. of Walet.

**SHINGEAT**, a town of Africa, in the country of Bergoo; 90 miles W. of Wara.

**SHINGLE, in Agriculture**, a term sometimes applied to the thinnings of fir and other timber trees, in the northern districts, and which are of much use for various purposes in farming, as the making of fences, &c.

**Shingle**, a sub stance found and collected on the sea-beach, or shore, which is used for several purpooses, as ballasting of ships, filling surface hollow drains, protecting the foundations of embankments, and other similar uses. See **Surface Drain**, and **Surface Draining**.

It is said to be a very valuable substance for the use of filling drains, as being particularly durable in its nature. In the county of Sussex, as well as in Essex, much of it is made use of in this way; in the former, under the denomination of sea-beach, or beach.

**Shingle Shoal**, in Geography, a shoal in the English Channel, near the coast of Hampshire. N. lat. 50° 38'. W. long. 1° 26'.

**SHINGLES. See Shambles.**

**Shingles, or Shingles**, in Building, small pieces of wood, or quartered oaken boards, fawed to a certain scantling, or more usually cleft to about an inch thick at one end, and made like wedges, four or five inches broad, and eight or nine inches long. They are used in covering, especially for churches and steeple's, instead of tiles or slates.

This covering is dear; yet where tiles, &c. are very scarce, and a light cover is required, it is preferable to thatch. If made of good oak, and cleft, not fawed, and well seafoned, shingles make a sure, light, and durable covering.

The building is first to be covered all over with boards, and the shingles then nailed thereon.

**SHINGLES, in Medicine**, the popular appellation of a vesicular eruption, which appears on the trunk of the body, extending generally half round, like a belt: whence probably the term is a corruption of the Latin word singular, or singularum, signifying a belt. It is the herpes zoster of medical writers, the Greek word, ἱτωρς, having the same signification. It is sometimes called simply zona, or zoster. For the description and treatment of this curious and harmful, though sometimes painful, affection, see Herpes Zoster. See also Bateman's Practical Synopsis of Cutaneous Diseases, p. 226.

**SHINGLING, in the Iron-Works**, in many parts of England, is the operation of hammering the bow, or cast iron, into blooms. The tongs, used for holding the iron in this operation, are called shingling-tongs, and the iron to be thus wrought is called a loop.

**SHINING MOUNTAINS, in Geography**, mountains that bound Louiziana on the west, which, though little known, are supposed to terminate in N. lat. 45° or 48°; whence spring a number of rivers, that discharge themselves into the North Pacific ocean, Hudson's bay, the waters which lie between them, or the Atlantic ocean. They are also called the "mountains of bright fomes," on account of the immense number of large crystals floating from the rocks, and sparkling in the rays of the sun, so as to be seen at a great distance.

**SHIOBERT el Yemeni, a town of Egypt, in the right bank of the Nile; 8 miles S.E. of Meshulet Kebir.**

**SHIONKAN, a town of Pegu; 8 miles N. of Sirian.**

**SHIP, a general name for all large vessels navigated with sails. Among people unacquainted with marine dis- tinctions, this term has a very vague and indiscriminate acceptation. In the sea-language, however, it is more particularly applied to a vessel furnished with three masts, each of which is composed of a lower mast, top mast, and top gallant mast, with the usual rigging and appendages thereto belonging.**

The heur Aubin defines a ship, a timber building, consisting of various parts and pieces, nailed and pinned together with iron and wood, in such form, as to be fit to float, and to be conducted by wind and sails from sea to sea.

The invention of ships is very ancient, and, at the same time, very uncertain. Mythologists attribute it to Da- dus, and pretend that the wings he invented to save himself withal from the labyrinth of Crete, were nothing but sails, which he first gave to vessels, and with which he eluded the vigilance and pursuit of Minos. Others give the honour to Janus, on the credit of some ancient Greek and Latin coins, on one side of which is represented his double face, and on the reverse a ship. Lastly, others look on Noah to have been the first ship-builder.

The most celebrated ships of antiquity are, that of Pto- lemy Philopator, which is said to have been two hundred and eighty cubits (i.e. four hundred and twenty feet) long, thirty-eight broad, and forty-eight high: it carried four thousand rows, four thousand sailors, and three thousand soldiers. That which the same prince made to sail on the Nile, we are told, was three hundred and twelve feet long, forty-five feet broad, with a mast one hundred and twenty feet high. Yet these were nothing in comparison with Hiero's ship, built under the direction of Archimedes, on the structure of which Mochion, as we are told by Snellius, wrote a whole volume. There was wood enough employed in it to make fifty galleys. It had all the variety of apart-
SHIP.

ments of a palace: banqueting-rooms, galleries, gardens, fish-ponds, stables, mills, baths, a temple of Venus, &c. It was surrounded with an iron rampart, and eight towers, with walls and bulwarks, furnished with machines of war, particularly one, which threw a stone of three hundred pounds, or a dart twelve cubits long, the space of half a mile; with many other particulars related by Athenaeus. Deipnosophil. lib. v. p. 204, &c. ed. Caufab. Lugd. 1657.

A ship is undoubtedly the noblest machine that ever was invented, and consists of so many various parts, that to form some idea of its importance and qualities will require the attention of the gentleman and the artif.

All ships at first were of the same form, whatever uses they were destined to; but the various ends of navigation, some of which were better answered by one form, some by another, soon gave occasion to build and fit out ships, not only different in size, but also in their construction and rigging; as also gave occasion to the fitting out large fleets of different kinds of merchant-ships, so ships of war became necessary to preserve them to their just owners.

The gradually improving state of shipping, in the last century, has kept pace with the regular advancement of every other branch of mechanical science. For, prior to that period, even our first-rate ships, now equal in perfection to those of any other rate, were then extremely defective, as their want of stability made their magnitude highly objectionable. These disadvantages have been gradually obviated, since the usual causes of instability have been discovered, the dimension enlarged, and the practical management familiarized; and they are now, in general, especially those that have most stability, admirable ships in every respect; as they sail well, and combine almost every good quality. Large as they are, they are perfectly manageable; and their evolutions are generally made with wonderful facility.

Second-rate ships, or those about ninety guns, have too generally those defects in their construction, which contribute to instability, arising from want of that capacity which most of the first-rates possess. The French, on this account, have discontinued this class of shipping.

Third-rate ships, or those of eighty and seventy-four guns upon two decks, are altogether the most useful and valuable ships in the navy; and possessing, in an eminent degree, all the properties of capacity, stability, and swiftness; the particulars of which last property will be found hereafter under Ship-building, and this ship may be considered as the first of its class, from its great length and superior capacity.

The above are particularly distinguished as line-of-battle ships, and are found in general to suit the most powerful exigencies of the naval services. About ten years ago an additional lieutenant was appointed to the line-of-battle ships. See RATE.

Fourth-rate ships are those of fifty guns. They may be employed, if necessary, in the line-of-battle, but most suitable to be stationed amongst the foreign colonies, or on expeditions of great distance; since these vessels are usually excellent for keeping and fulfilling the sea.

Fifth-rate ships are frigates of from forty-four guns to thirty-two guns upon one deck, and even to fifty guns in America, (being restricted formerly to vessels of war with one deck); and though too weak to suffer the shock of a line-of-battle, they are very useful to accompany fleets, to lead the convoys of merchant-ships, to protect colonial commerce, to cruise in different stations, or to be sent with necessary intelligence and orders.

The forty-four gun frigate being the most powerful, and most valuable of this class, has induced us to give a plate of one, so constructed as to have all the qualities which can possibly be united in one ship; for having but one deck, her breadth and height are so proportionable to her length, that she may be brought down in the water to that depth which is allowed to be the belit falling trim for ships in general. Ships of fifty and thirty-eight guns have four lieutenants. See RATE.

The sixth-rate includes all the smaller class of vessels in the navy, except the yacht, fire-ship, and bomb-vessel; they are classed as fifth-rates, to increase the pay; the former by way of distinction, the latter on account of the dangers to which they are exposed. Frigates of twenty-eight, twenty-four, and twenty guns, are included in this class; but those with the thirty-two gun ship, in the former class, are so inferior to the forty-four and thirty-six gun frigate, as not to deserve notice nor continuance by a great maritime power. Ships of twenty guns, and all vessels upon the establishment of the five of war, have two lieutenants. See RATE.

The large sloops of war and brig are very serviceable vessels to cruise against privateers, contraband trade, and for small convoys. Some of the latter have lately been built in this country, and are admirably adapted for good sea-boats, as well as good fakers; their upper works being light, all unnecessary top-hamper avoided, having a flat stern, and apparently every good quality that can be expected in a vessel of this description.

One of these vessels, the Raven, upon being fitted for sea at Woolwich, under the directions of her very ingenious and active commander, captain William Layman, had, agreeably to his recommendation and wishes, among other alterations, the two foremost ports closed up, and the guns taken away; in lieu of which was fitted in midship, immediately before the fore-mall, a sixty-eight pounder carronade upon a fixed traverse carriage, so as to fire in almost every direction clear of the gunwale; and, in lieu of the two flern-chasers, a carronade of the same power, upon an inclined plane abaft. The wonderful accession of force derived from these alterations, and the great advantages to be derived from them in chace, in clearing an enemy's coasts, &c. are too obvious to need comment.

Ships in the royal navy are commanded by captain or to 22 guns; sloops by master and commander.

The following Table furnishes a correct full of the dimensions of ships of different rates. See RATE, under which article a less perfect table is inserted.

**Yacht** as a vessel of state, is usually employed to convey princes, ambassadors, or other great personages, from one kingdom to another, or even kings, to take pleasure in; of which our present gracious majesty was very fond. The Royal Sovereign yacht was launched for the particular service of his majesty at Deptford, in the year 1804; a ship whose exterior and interior are of incomparable beauty, but whose ornaments, splendid as they are, will scarcely be confided by the artist as more than adequate to the beauty of her form; and her qualities as an excellent faster and good sea-boat, from experiment, stand unrivalled. We have, therefore, given a plate of this excellent vessel, by a quarter of an inch scale.

Yachts, as may be expected from the purposes for which they are designed, are the most beautiful of all vessels which navigate the ocean; nor are their superb embellishments and stately apartments their highest excellencies. They are models, in which may be seen a combination of the best principles of the art.

The **fire-ship** differs but little in its outer construction from a sloop of war. She may be built light and very clean for fast sailing; but the inner part is very differently fitted, in the manner described under the article **Firing Ship**.

The **bomb-boat** is particularly constructed for throwing shells from a mortar. They are built very strong, and firmly ridden; are usually fitted with two bomb-beds, which are platforms or strong frames of thick fluff and timber, laid transversely over large beams, and are rabbeded and solidly bolted all together. The mortar-bed, or carriage which carries the mortar, travels on a large iron pivot, in the centre of the bomb-bed, in a circular excavation. The sides of the bomb-bed, round the mortar, are fitted with strong cheeks of oak, of an octagonal form; in every square of which are driven two pin-bolts, for traversing the mortar in any direction. The bomb-bed underneath, to support the shock in throwing the shell, has three ranges of large pillars, fixed in a range, tenoned at the head and heel into large carlings fore and aft the bed, along the middle and sides, which are scored on the riders below, and into the beams above the pillars, flanging double in the middle of the bed athwart-flaps.

A strong compartment, called the **shell-room**, is built round the outside of the pillars. See **Shell Room**. See also **Bomb-Boats** and **Ketch**.

**Ship, Armed.** See **Arms**.

**Ship, Guard,** is a vessel of war appointed to superintend the marine affairs in a harbour or river, and to see that the ships which are not commissioned have their proper watch kept dully, by sending her guard-boats around them every night; she is also to receive seamen who are impressed in time of war.

**Ship, Hospital,** a vessel fitted up to attend on a fleet of men of war, and receive their sick or wounded; for which purpose
purpoze her decks should be high, and her ports sufficiently large; her cables ought also to run upon the upper deck, to the end that the beds or cradles may be more commodiously placed between decks, and admit a free passage of the air, to disperse that which is offensive or corrupted.

SHIP, Lee-ward. See Lee-ward Ship.

SHIP, Merchant, a vessel employed in commerce, to carry commodities of various sorts from one port to another.

Merchant shipping, in general, being scarcely definable into distinct classes, we cannot speak with that degree of precision of them as of those of the royal navy; because their respective forms and dimensions are dependent, almost entirely, on the local practice or ideas of their respective owners or constructors, and fluctuate accordingly. Those belonging to the East India Company are by far the largest, and are very fine ships, and of course rank in the first class of merchant ships. Well India ships are little inferior to the former, but in size; and some of the largest have been employed occasionally either to the East or West Indies.

The East India ship (Plate XII.) has been actually built, and found upon trial to answer every purpose expected from her.

Some ships of a very fine model, being less burthensome than Well India ships, are employed in the Straits' trade; and others used in the East country trade, for carrying of timber, exceed either of the latter for size, the largest of them being no less than 700 tons.

SHIP OF WAR, Private. See Privaters.

SHIP, Store, a vessel employed to carry artillery or naval stores, for the use of a fleet, fortress, or garrison.

SHIP, Transport. See Transport Ship.

SHIP, Troop. See Troop Ship.

We shall here observe in general, that it is highly necessary to the health of seamen, that ships should be cleared of foul air; for it has been found by frequent experience, that air shut up, and confined in a close place, without a fresh and frequent supply of it, becomes unhealthy, and unfit for the use of life. This is more sensibly so, if any irritating water be pent up with it. But it grows still worse, if such an air as this is made use of in respiration; that is, becomes moister, and hotter, and phlogificated, by panting and repulsing through the lungs.

These bad effects, in different degrees, according to the different manner in which air is inclosed, are observed in many cafes, particularly in deep wells and caverns of the earth, in prisons or cloistered houses, where people are shut up with heat and stiftness; but most of all in large ships, in which, with the fench of water in the hold, many men being crowded up in those quarters, all the mentioned circumstances concur in producing greater mischief than would follow from any of them singly. For an account of Mr. Sutton's contrivance for clearing the holds of ships of the bad air contained in them, we refer to the article Anti-Pipes.

The mixture used sometimes for covering the bottom and sides of ships is made of one part of tallow, of one part of brimstone, and of three parts nearly of rosin. The tallow and rosin are melted together, and the brimstone is stirred into them; one hundred and forty pounds of brimstone will serve for a vessel of one hundred and forty tons. See PAIL.

To prevent ships, whose bottoms are worm-eaten, from leaking, this method has been proposed. Caulk well the inside planks or timbers, then fill the vacant spaces between the timber; and the out and inside planks, with boiling pitch or rosin, to high as the main gun-deck. The pitch being put in very hot, will run into the smallest cranny, and make the ship as tight as a bottle. There will be no room left for vermin, as rats, &c.; and the pitch will serve for other uses when taken out, therefore the expence will be but small. Phil. Trans. No. 476. p. 372.

For the laws relating to ships, &c. see Atlas of English Navigation. See also FREIGHT, MARINERS, and NAVY.

SHIP, bulk, burden, captain, clerk, company, corporal, flag, grounding, master, mine, regally, rigging, run, sailing, squadron, stays, weather, in reference to a ship, see the respective articles.

For further particulars respecting ships, the reader is referred to the article SHIP-BUILDING.

SHIP, To, in Sea Language, is used either actively, as to embark any person, or put any thing aboard ship; or passively, to receive any thing into a ship; as we shipped a heavy sea, &c.

To ship also implies to fix any thing in its place, as to ship the oars; to ship the swivel guns, i.e. to fix them in their sockets, &c.

SHIP OF PLEASURE, among the Ancients. See Thalassus.

SHIP, in the Salt Works, is a large cistern, out of which the salt-pan* are supplied for boiling.

This cistern is built close to the salters, and is made either of wood, brick, or clay; and it ought always to be covered with a shed, that the sea-water, contained in it, may be kept clean from foot, and other impurities, and not mixed with fresh water in rains; and it must be always placed so high, that the water may easily run out of it into the pans, to supply them for boiling.

SHIP GUN. See CANNON.

SHIP CLOY, in Geography, a cove of Queen Charlotte's Sound, in the southern island of New Zealand. This harbour, according to captain Cook, is not inferior to any found, either for convenience or safety. It lies on the west side of the island, and is the innermost of three coves, that are situated within the island of Motuara, which bears south of it. Ship Cove may be entered either between Motuara and a long island called by the natives Hamoto, or between Motuara and the western shore. In the fall of these two channels are ledges of rocks, three fathoms under water, which may be easily known by the sea-weed that grows upon them. S. lat. 41° 10'. E. long. 175° 6'.

SHIP ISLAND, a small island in the gulf of Mexico, near the coast of West Florida, nine miles long and two broad. It produces pine-trees and graps, and has a tolerable well of salt water. N. lat. 30° 5'; W. long. 88° 49'.—Also, a small island of Upper Canada, in Lake Erie.

SHIP PONT, a cape on the coast of North Carolina. N. lat. 35° 59'. W. long. 76° 30'.

SHIP-BUILDING, or Naval Architecture, is the art of constructing and rigging, or building that noble fabric called a ship.

This science, or whatever relates to navigation, is, without doubt, one of the most important and most useful employments of the human mind; especially in a country whose marine is its bulwark, and its commerce the admiration, and we may add, the envy of the world.

Nevertheless, the scientific part of ship-building has been too much neglected; and although some few years have elapsed since mathematicians (particularly in France) have laboured with some success, yet their discoveries are so much enveloped in profound calculations, that ship-builders, in general, have scarcely been able to derive any advantage from them.

It must be allowed, that an exact knowledge of the
true principles upon which the construction of ships, so as to answer the particular purposes of war or commerce, is founded, must conduct to remedy all the present defects, to render the theory more perfect, and enable the English architects to become as eminently skilful in the scientific, as they now confessedly are in the practical branches of ship-building.

In order to smooth the way in a science thought so incomprehensible, our readers must be made familiar with the several draughts and plans requisite to construct and raise so noble a body of architecture; for the proportional size of every part must be laid down, from whence the form and dimensions of the several timbers, and every particular part that enters into the construction, are to be obtained. Therefore, as a ship has length, breadth, and depth, three different plans at least are necessary to represent the form of the several parts of her; as in the sheer-draught, Plate I. of Ship-building, which comprehends the sheer-plan, the body-plan, and the half-breadth plan.

The sheer-plan, or as it is called in civil architecture, the plan of elevation, is a vertical section, passing through the vessel in its whole length, or fore and aft. Upon this plan the length and depth of the keel are represented, also the height and rake of the stem and stern-post; the situation and height of the midship and other frames; the waterlines; heights of the decks, gun-ports, and wales; the centres of the main; the situation of the channels; length and depth of the head and rails, quarter-galleries, rudder, &c. &c.

The body-plan, or plan of projection, to the left of the sheer-plan, is a transverse section of the ship at the midship-frame, or broadside place perpendicular to the keel. The several breadths, and the particular form of every frame-timber, are described on this plan. Now as the two sides of the ship are, or should be, exactly similar to each other, it is therefore unnecessary to represent both; hence the frames contained in the fore-body, between the midship-frame and the stem, are described on the right-hand side of the middle line, and the aftermost frames on the left of the said middle line.

The half-breadth or floor-plan, under the sheer-plan, and parallel thereto, or as it is frequently called, the horizontal plan, contains the several half-breadths at every frame-timber, at the different heights of the water-lines, main-breadth, top-side, ribband-lines, &c.

The consideration of these three principal plans is so much the more important, as it comprehends a sufficient knowledge of the figures of all vessels. For although these three plans do not really determine the figure of the vessel, and may belong to an infinity of different kinds, yet all these differences cannot exceed certain limits sufficiently confined; so that whatever idea we might form of the figure of the vessel, it cannot deviate considerably from the truth.

In order to explain this better, we will proceed to construct the sheer-draught, Plate I.; and here the nature, and all the properties of the vessel, according to her design for war or commerce, must be taken into consideration, upon which the whole theory of the art depends: such are, capacity, flability, velocity, and ease in the sea or at anchor. These properties are not to be adopted merely from speculative theory, but from those that have actually been demonstrated by repeated experiments. That our readers may have the clearest conception of the various parts of a ship, represented by the plates of the 74-gun ship, we will endeavour to describe them in as familiar a manner as possible, introducing also all that is necessary to be known as we proceed. The 74-gun ship is preferred as the medium between the first-rate and the frigate, and is esteemed the most useful of all others.

Therefore, the first thing to be determined is the length on the gun-deck; and here sufficient distance must be allowed for the ports, which are fifteen in number, three feet five inches wide, or fore and aft, each, so as to have a sufficient distance between each port for working the guns, which is about seven feet eight inches; likewise room forward, between the foremost-port and the stem, for the manger; and also abaft the after-port, to the transom; these considered make the length on the gun-deck 180 feet.

Draw therefore, as in sheer-plan, Plate I., a straight line, which represents the upper edge of the keel, and in naval ships the upper edge of the rabat (East India ships and merchant-ships in general have the rabat in the middle of the keel), leaving under this line sufficient space for the main and false keels, scale, and half-breadth plan. Upon this line square up a perpendicular towards the right hand, leaving a sufficient space to represent the head, and call it the foremost-perpendicular; then, at 22½ inches abaft it, square up the after-perpendicular, which is 180 feet, by one-eighth of an inch to a foot, or the length on the gun-deck, from the aft-side of the rabat of the stem to the fore-side of the rabat at the stern-post. Below the upper edge of the keel, and parallel thereto, set down two feet for the main and false keel, and under it draw the scale of equal parts, one-eighth of an inch to a foot, and from this scale set off all the following dimensions. Observe, draughts in general are drawn from a scale of one quarter of an inch to a foot, but this, for convenience, to one-eighth.

The length between the foremost and aftermost perpendiculars, in merchant-ships, is given from the aft-side of the stern-post, at the height of the wing-transea, to the fore-side of the stem, at the same height.

The stem, or fore-boundary of the ship, may now be drawn, and a segment of a circle for its lower part has long been considered as the best form for dividing the fluid; therefore, fix its centre so that the aft-side of the rabat (which is in the middle of the stem, towards the upper part) may intersect the foremost-perpendicular at the height of the gun-deck: thus, let a ft from the foremost-perpendicular, as in Plate I., upon an horizontal line, 24 feet above the upper edge of the keel, 2 ft. 3 in.; and from thence, as the centre, draw an arc of a circle from the upper edge of the keel-line, and another arc 18 inches before it, from the same centre; then will the moulding, or fore and after-sides of the stem, be represented: sweep likewise the rabat, as in Plate I.; then let up 36 feet for the height of the head of the stem, and at that height let forward 15 inches from the foremost-perpendicular; from thence draw a faint curve, to intersect with the foremost segment, and the fore-part of the stem will be shown: continue upwards another parallel thereto, and the aft-side or whole stem is completed, except the lower end or boxing, which will be determined hereafter.

The stern-post, or after-boundary under water, may be next drawn; thus, let up from the upper edge of the keel-line 26 ft. 10 in., which is the upper side of the wing-transea at the after-perpendicular, and upon that line let ft from the perpendicular 1 ft. 10 in., and upon the upper edge of the keel, 6½ inches before the after-perpendicular; then a line drawn through these points will represent the aft-side of the stern-post; another line, drawn at fourteen inches before the aft-side of the stern-post, at the wing-transea, and at two feet one inch on the upper edge of the keel, will be the
the aft-side of the rabbet; and another line parallel four inches before it (or at the thicknes of the bottom plank) is the fore-side of the rabbet, which will interfere the after-perpendicular at the gun-deck. Thus far the stern-post at present.

Having fixed on the length of the gun-deck, the next principal dimension to be considered is the main-breadth, and this, in ships of war in general, is about three-elevens of the said length for their moulded breadth, and in merchant-ships about three-twelfths of their length; excepting cutters and smaller vessels. The moulded breadth given in Plate 1. of the 74-gun ship, is 48 feet.

Before we proceed, it will be necessary here to remark, that much has been said in regard to the breadth to be given to a vessel in respect to her length, and in what part of that length it is best to place it; as being the section of the greatest area of the whole vessel, its true situation becomes an object of importance.

Those who would diminish the breadth have alleged, and truly, that a narrow vessel meets with less resistence in passing through the water, and by increasing in length, the vessel will drive less to leeward, and the water-lines consequently be more delicately formed to divide the fluid; that a long narrow ship will require less sail to gain velocity, consequently the sails will be lower, the rigging lighter, and the vessel navigated by fewer hands. On the contrary, a ship's being broader at the line of flotation will admit of being narrower on the floor, particularly at the fore and after parts; that by being broader it can carry more sail, and more readily rise upon the waves than a narrow one. The breadth, and its situation, when determined on, require much skill in narrowing therefrom, as we approach the keel, particularly forward and aft, to give that form to the body under water that shall best answer in dividing the fluid, enable her to carry the lower tier of guns sufficiently out of the water, prevent her pitching, and give a free passage to the rudder, that she may readily answer her helm.

Now to prevent the vessel pitching, the fore-body must be so shaped, that its bearings should catch the vessel in its defcent, that is, the harpin should increase in breadth upwards, and the bow be so formed, as rather to throw off the sea than pitch or bury in it: a long floor, with little rising afore and abaft, the displacement of the fore-body to be duly proportioned to the after-body, and hollow water-lines, or inflected curves at the fore-part, are to be carefully avoided. Taking into consideration the weight of the anchors on the bows, we may easily conceive, that with the pressure of the wind upon the falls, without sufficient bearing in the fore-body, the bow would be pressed down into the hollow of every sea; and if the greatest area or midship-bend were placed too far aft, the support would only be in the after-body, and this would tend to plunge her bows still deeper, and retard her velocity, and the free passage of the water to the rudder.

In order that the ship should steer well, and quickly answer her helm, the wing-trIanfom must not be placed too low, nor the fahan-figures too full below the load-water line; and the narrowing of the floor, or half-breadth of the rising, not continued too full towards aft, but that the water-lines, as they approach the stern-post, may taper handomely into the same, so that every succeeding water-line, as they approach nearer the keel, may have their curvature more delicate, as may be seen by referring to the half breadth plan in Plate 1. It is also evident, that the prompt effect of the rudder must depend in a great measure on the clearance of the ship's run, so that the fluid shall have an unimpeded passage to it, whereby its inclination shall have the greatest effent from the water.

That a ship may carry her guns well above the water, a long floor timber will be neccesary, and not much rising; the midship-frame should be very full, upper futtocks nearly straight, upper works very light, and kept as low as possible, and the wing-trianfom not placed too high.

To make a ship carry her guns well above water, carry much flail, be a fast failer, and likewise ficer well, are four such rare qualities, as are hardly to be united in the fame vessel, because it would require a very full bottom and great breadth to gain the two former qualities, and less breadth and a sharp or clean bottom to gain the latter; but if we confider that a full ship will carry more fail than a sharp one, we may perceive the pliability of fo constructing the body, as to poifefs these qualities, and they may be fo united, that each of them may be diftinguished in some degree of eminence, for it is not poifible that all of them can be united in one body to a degree of perfection; we muft, therefore, while we retain a portion of each, give the superiority to that which is moft convenient with the purposes for which the vessel is peculiarly designed.

Hence it is plain, that judiciously placing the midship-bend is of the utmost conquence in the construction of ships' bodies; and its being placed nearer forward, will, consequently, make the fore-body more full, and will beft answer every purpose, especially that of velocity; and although it is plain, that by so doing the entrance of the ship will be more full, and prefent apparently more absolute force against the refifling medium, than when the midship-bend is placed nearer to the middle of the ship's length, yet by placing it more forward, the body will decline horizontally so much the quicker, and part of the effect of that refifance, caused by the lateral preffure of the water, will be lefled, which muft certainly be of more fervice to the velocity, than what is loft by making the fore-part of the ship somewhat fuller, and this seems to promote the connection of capacity with velocity, the two great objects to be pursued in the formation of ships' bodies under water. In addition to this, by carrying the midship-bend forward, a ship will fcer better, and the rudder have the more command to bear up the ship in a gale of wind; for when a ship is under a press of fail, the water is forced up at the bow above the horizontal, and the bow likewise prefled down, which amounts to nearly the fame, with refpect to her helm, as if the ship was trimmed by the head; again, ships that carry their helm amidships in light winds, require it more a-weather when the wind blows.

After all that has been written concerning the placing of the midship-bend, all agree to place it before the middle of the length, or about five-twelfths of the length abait the foremost-perpendicular; but in Plate 1. which ship has flood the test of experiment, it was placed at 60 feet abait the foremost-perpendicular, consequently this is the broadefl part of the ship, called the midships, or dead-flat, known by this character ☞, and where all the heights in midships are fet up. From ☞ the flations of all the timbers may be fet off; but it will only be neccesary to figure up a perpendicular at the joint of every frame-timber, their distance being double that of the room and fpace, which in Plate 1. is two feet nine inches.

The dead-flat in Plate 1. is a fingle timber, and the perpendicular, marked ☞, the middle of it: therefore, for the joints of the annexed frames set off before ☞, two feet nine inches for the joint of (A), and two feet nine inches abait ☞ for the joint of (1), figure up perpendiculars from the upper edge of the keel; then from (A) continue setting off five feet six inches for the joints of frame B, C, D, to X, in the fore-body, and the fame distance abait (1) for the joints of frame.
frame (3), 2, 4, 6, to 30 in the after-body, as shewn in Plate I. Now @, (A), (1), (2), and (3), are called flats, as they are the timbers which are placed in the flat part of the ship amidships, have no bevelings, and consequently do not partake of the rising.

The lower height of breadth is an imaginary line, not only to afford in the construction of the body, but a line defining the greatest breadth in the ship, all fore and aft, and should next be determined upon. Its height at @ is 21 feet 3 inches above the upper edge of the keel; and that the said height of breadth should be higher afore and abaft is only reasonable as a reserve, to be a support to the vessel when heeling by the preasure of the wind upon the sails; for when a ship is close-hauled by the wind, and lies much over, the weather-side would lose much of the breadth, whereas, on the contrary, the lee-side would then gain considerably, and meeting with a greater resistance, be enabled to carry the greater fail; therefore forward at the rabett of the stem its height is 29 feet, and abaft at the counter-timber 29 feet 6 inches; and all the heights between should form a fair curve, like the ticked line in the sheer-draught, Plate I.

It may be remarked, that flat-floored ships do not require their height of breadth to be raised so high forward and aft, for by their construction they are fuller under fail, and carry their weight of cargo low down.

The body below the lower height of breadth may now be formed, as the frames or bosses, when put together, and the joint placed to the fore-mentioned perpendiculars, the sides of every port will be formed so as to cut none of the principal timbers, and are so disposed as to weaken the ship as little as possible. Now as capacity, velocity, &c. depend upon the figure of the imdered part of the body, and because the properties which every ship ought to possess are, in a manner, subversive of, or in opposition to, each other, as before observed, the great art certainly is so to form the body, that none of the desired qualities shall be omitted, giving, at the same time, preference to that which is most required. In ships of war, capacity, flatness, velocity, and strength, are essentially necessary; the first and second we shall endeavour to prove by calculations hereafter; the third may be affirmed, as the vessel was actually built, and answered that purpose; and the last is now so well established in the British navy as to need little addition.

The half-breadth plan must be next drawn; thus, draw a straight line below the sheer-plan, as in Plate I., the whole length of the ship, and parallel to the upper edge of the keel, which line will represent the middle line of the ship, at any height palling fore and aft, or lengthwise; observing to keep the said middle line sufficiently below the scale, so as to admit of the main half-breadth line coming clear of it.

Then figure down from the sheer-plan all the perpendiculars or joints of the frame-timbers, to the middle line of the half-breadth plan, and likewise the forefoot and after-perpendicular. The main half-breadth line may now be drawn, by setting-off from the middle line in the plan the following half-breadths at each respective timber; thus, at @, 24 feet; at F, 23 feet 11½ inches; at H, 23 feet 11 inches; at K, 23 feet 10 inches; at M, 23 feet 5½ inches; at Q, 23 feet; at S, 22 feet 2 inches; at E, 20 feet 4 inches; at J, 17 feet 6 inches; at X, 12 feet 6 inches; and to end this line at the fore part, let the height of the breadth-line in the sheer-plan, where it intersects the aft-side of the rabbet at the item, be squared down to the middle line in the half-breadth plan, and likewise the fore part of the item; upon the lines last squared down, set off the half-siding of the item from the middle line and parallel thereunto, which is ten inches; then, with compasses, take the thickness of the bottom plank, which is four inches, and describe the rabbet of the item by the triangle shown in the half-breadth plan; from thence a fair curve line drawn through the half-breadths for off, forms the half-breadth line to @. In the same manner set off the half-breadths abaft @, and draw in the remainder of the half-breadth line, as the ending of it abaft will be described hereafter.

Observe, the various curves represented on the several plans used in ship-building, except where they are segments of circles, such as the fore part of the main half-breadth, &c. are drawn by small pliable battens confined thereto by weights, or by thin moulds made of pear tree veneers, whole edges are made to geometrical curves of all kinds.

Now the main half-breadth line being drawn, we have a half section of the ship lengthwise at the broadest place, that is at the height, and in the direction of the lower height of breadth line in the sheer-plan, Plate I.

The imdered part, or body of the ship under water, must be next formed, and the capacity of the vessel ascertained, before the upper works; and, that above the water, need come under consideration, it is therefore necessary to describe in what manner the several forms of ships' bodies are to be constructed. In the royal navy, the midship parts of the body of ships are formed by segments of circles called sweeps; such are the lower and upper breadth-sweeps, floor-sweep, and reconciling-sweep, their several centres being given by lines, except the reconciling-sweep, whose centre is without the limits of the draught. The lower and floor-sweeps are joined by the reconciling-sweep, and make a fair curve from the lower height of breadth to the rising-line, by which the floor-sweep is governed; then, by drawing a straight or curving line from the upper edge of the rabett of the keel to touch the back of the floor-sweep, the form of the midship part of the body below the lower height of breadth will be complete.

Observe, the floor-sweep forms the body at the floor-heads, particularly along the midship part of the body, and is limited by an horizontal line above the keel in the body-plan, and its distance above the keel at the midship-timber is called the dead-rising. The rising of the floor in the sheer-plan is a curve line intersecting the dead-rising at the midships; and in flat-floored, or burthen-some ships, it continues nearly parallel with the keel for some distance afore and abaft the midship-timber; and all the timbers, where the rising is parallel with the keel, are called flats, as before observed. The rising-line, which governs the floor-sweeps, is not the least interesting of the series, because it exhibits, on many points, general deductions, and tends to establish theories which may serve to direct future observations; and the method of constructing the midship-floors of ships, where velocity is preferred, by lengthening the radius of the floor-sweep forward and aft, is preferable to the rising-line, as used in constructing merchant-ships for burden, where the radius of the floor-sweeps all fore and aft are of the same length as at the midship-timber; because by the former method, every floor-timber from the dead-flat is graduated by a larger circle. By the latter method, not only the construction, but the laying-off of the ship is facilitated, because in any ship constructed by the same length of radius, we may venture, so far as the rising-line is continued, not only to form all the lower part of the ship on the draught, but also on the mould-loft-floor, without running any ribband or horizontal lines till that part is finished. Again, this method affords a greater affilience, as by it the floors may be constructed all fore and aft; but the floors near the midships only can be constructed,
SHIP-BUILDING.

Neither the rising-line in the sheer-plan, nor the half-breadth of the rising, would continue to be the curves as first constructed, if the form of the body first designed were to be altered in that part. It is evident, then, that the rising-line may be drawn according to the judgment of the artist in the construction of any draught, observing to make it a fair elliptical curve, (for much depends on the construction of the lower part of the body,) by judiciously narrowing the floor-sweeps, or half-breadth of the rising; for the move parallel it is kept with the middle line, the lefs will be the velocity of the ship. Again, the quicker this curve is, the less bearing will the ship have; and though it may be supposed, when the rising-line is formed in the sheer-plan, and likewise its half-breadth, it is reasonable to expect a fair body; yet we cannot be certain of its producing that form of body which is really intended agreeable to the use which the ship is designed for, unless by frequently designing of bodies we can form an exact idea before we proceed. Therefore the young artist should improve himself by drawing bodies constructed by the rising-line of ships of different properties, till he forms in his own judgment a perfect idea of this mode of construction. For instance, if it be required to make the ship cleaner, lift the rising-line in the sheer-plan, and narrow its half-breadth; and where it may be required to make the ship fuller, lower the rising-line in the sheer-plan, and increase its half-breadth; which sufficiently proves that the rising-line is as variable as the different forms of ships' bodies may require. See for fulness of the plate of the East India ship, the plate of the 74-gun ship, which is sharper, and also the frigate of 40 guns, which is sharper still; and we shall then find it a very complete method of constructing the lower parts of such ships fair, particularly those that require some provision of fulness of body to assist them in taking the ground. The further forward and aft the body is allifted by the rising-line, the more merit there will be in the construction, and the greater certainty of producing a fair body: notwithstanding all this, some bodies are constructed without any floor-sweeps, which must be the case in very sharp bodies, such as cutters, &c.

It may be further observed, that the rising-line cannot, from its nature, be formed by any regular proportional method, from which there can be no variation without impropriety; nor can it be constructed to any fixed proportion, unless ships of different classes were built exactly similar to each other, because the rising-line in ships of war, and those which are constructed for velocity, though suitable to the construction of the lower part of each ship, and likely to answer the purpose for which they are designed, cannot be equally proper for ships of the same length and breadth, if required chiefly for burden; as in the last case not only the form of the midship-bend, but every part of the bottom must be differently formed, which will be clearly seen by examining the plates of the 74 and 42-gun ships, and the plate of the East India ship, which was found to answer admirably well.

Whole-moulding was formerly a method of constructing the immersed part of ships' bodies, by the mould being made to the form of the midship-bend, which, with the addition of the floor-hollow, would mould all the timbers below the main-breadth in the square body. But since the art of ship-building has arrived to its present perfection, the method of whole-moulding, for the following reasons, has been justly laid aside. For by whole-moulding, no more is narrowed at the floor than at the main-breadth, that is to say, the curves of each are kept parallel; nor must the rising-line in the sheer-plan lift any more than the lower height of breadth; which, according to the form of some midship-bends, would make a very ill-contructed body; for by continuing that nearly forward and aft, the ship would not only be incapable of rising in a heavy sea, but be deprived in a great measure of the more advantageous use of her rudder. Nevertheless, this method is still continued in the formation of boats.

Proceed now to draw the plan of projection, or body-plan, thus: continue the line at the upper edge of the keel beyond the after-end of the sheer-plan, as in Plate I., and square up a perpendicular for the side-line of the fore-body, observing to keep it clear of the form; from that perpendicular set off 48 feet, the ship's main breadth at dead-flat, and square up another perpendicular for the side-line of the after-body, and equally between both square up another perpendicular, which is the middle line to both bodies respectively; then the line prolonged from the upper edge of the keel is the base line of the body-plan. Draw in the horizontal lines, as may be seen in the body-plan, Plate I., at the lower heights of breadth, by transferring their heights from the sheer-plan at the several frame-timbers: those before the dead-flat, set up in the body-plan to the right of the middle line, which are to represent the fore-body, and those heights abaft dead-flat, to the left hand for the after-body. Then from the half-breadth plan take the main half-breadth of each frame, and set it off from the middle line in the body-plan, upon its corresponding height of breadth; and from thence set off towards the middle line the length of their respective lower-breadth sweeps; thus to describe the midship-timber, or dead-flat, extend the compasses to 18 feet 6 inches, the radii of lower-breadth sweeps at dead-flat, and draw part of a circle downwards, intersecting its main breadth at its horizontal height.

Then the centre heights of the floor-sweeps in the body-plan must be taken from the curve-line representing their heights in the sheer-plan, which at dead-flat will be found to intersect the upper edge of the keel; but in the body-plan, its height at dead-flat is 11 feet 6 inches, and there an horizontal line is drawn to the distance of the centre, or its half-breadth from the middle line, and all the heights of centres are respectively set upwards above this line, on parallels squared upwards at the half-breadth of the centre of each floor-sweep of its corresponding frame or timber, as taken from the half-breadth plan; and the reason for not keeping the said curve-line or heights in the sheer-plan as in the body-plan, is because it would interfere with the curve-lines above. Now by inspecting Plate I. it will be readily seen, that by raising the heights of those centres in the sheer-plan, consequently in the body-plan, and by narrowing their half-breadths in the half-breadth plan, their centres would be brought nearer the middle line in the body-plan, the floor-rising would become quicker, and the ship have less bearing, and vice versa, more firm and burthensome: thus must the rising and narrowing of the centres be adjusted till the body of the vessel has the capacity required for whatever service it may be designed.

But as in this mode of construction the centres only, and not the length of the floor-sweeps, are given, a diagonal ribband must be drawn in the half-breadth plan, as in Plate I., by setting off from the middle line at 43, 16 feet; at H, 15 feet 9 inches; at D, 15 feet 5 inches; at F, 15 feet 1 inch; at N, 15 feet 7 inches; at K, 14 feet; at M, 13 feet 3 inches; at O, 11 feet 11 inches; at Q, 10 feet 4 inches; at R, 8 feet 6 inches; at U, 6 feet 1 inch; and at X, 2 feet 5 inches. Then in the after-body let off at B, 15 feet 11 inches; at 4, 15 feet 10½ inches; at 6, 15 feet 9 inches; at 8, 15 feet 6 inches; at 10, 15 feet 4 inches; at 12, 15 feet 1 inch; at 14, 14 feet.
SHIP-BUILDING.

14 feet 11 inches; at 16, 14 feet 5 inches; at 18, 14 feet; at 20, 13 feet 3 inches; at 22, 12 feet 5 inches; at 24, 11 feet 7 inches; at 26, 10 feet 5 inches; at 28, 9 feet 1 inch; at 30, 6 feet 7 inches; at 32, 5 feet 10 inches; at 34, 4 feet; and at 36, 2 feet.

Now to end this diagonal, it must be drawn in the body-plan thus; set up the middle line from the base 12 feet 2 inches, and on the base, from each side of the middle line, 11 feet 9 inches, and draw the diagonal point lines, as shown in Plate I. In draughts, diagonal lines are distinguished by red ink. Then in the body-plan draw the half-fiding of the stem in the fore-body, and the half-fiding of the stern-post in the after-body; for the latter set up 26 feet above the base, and at that height set off from the middle line 10 inches in the half-fiding of the post at the head, and 9 inches in the fore-body, the half-fiding of the stem at that height; and on the base line 7½ inches from each side the middle line, the half-fiding of post and stem at the heel; then draw straight lines to each spot set off, and the half-fiding of the stern-post and stem will be represented in the body-plan. Now to complete this diagonal line on the half-breadth plan, its height or intersection at the post and stem must be taken in the body-plan, and transferred respectively to the fore-side of the rabbet of the stem, and aft-side of the rabbet of the post in the sheer-plan, and from thence let them be squared down to the middle line of the half-breadth plan; then take with compasses the half thickness of the post and stem in the body-plan, in the direction of the said diagonal line, and set them off respectively from the middle line in the half-breadth plan, on the lines laid squared down; and from the intersection as a centre, sweep an arc towards the midship, with compasses opened to the thicknesses of the rabbet taken diagonally; then a fair curve drawn through all the spots; as above set off, touching the back of the arcs, will form the diagonal line at the floor-heads, as shown in the half-breadth plan, Plate I.

Now may the timbers, as far as the floor-sweeps are useful, be completed in the body-plan below the lower height of breadth, beginning at dead-flat; thus, take the half-breadth of the floor diagonal at 0 in the half-breadth plan, and set it down the diagonal from the middle line in the body-plan; then take the half-breadth of the floor-sweeps in like manner, and set it off from the middle line in the body-plan on the horizontal line before drawn at its height, and from the intersection extend the compasses to the half-breadth of the floor diagonal, and sweep an arc upwards from the dead-flat, which is six inches at 0; then with the reconciling-sweep, which is of a long radius compared with the others, unite the lower-breadth sweep and floor-sweep together; for the more the midship-frames deviate from the segment of a circle, the less will be the rolling motion of the ship; unite the floor-sweep with the upper edge of the rabbet of the keel with a curve or straight line, and the middle-timber will be formed below the lower breadth. In the same manner may be formed the frame-timbers B, D, F, H, and K, in the fore-body, and 2, 4, 6, 8, 10, to 24 in the after-body, by setting off the half-breadth of each frame’s diagonal as at 0, their corresponding heights of breadths, main half-breadths, and centres of each sweep, as before directed, and by reconciling the lower-breadth sweeps and floor-sweeps together, and ending them into the rabbet at the keel; thus the midship part of the body will be formed from K forward to 24 abaft.

Hence it may be readily conceived, that bodies full or sharp, either for burthen or velocity, may be constructed by altering the radii of the different sweeps; and unclefs bodies of ships could be constructed from some geometrical figure, a more certain method than the above cannot be given.

The body being thus far formed, that is from K forward to 24 abaft, proceed to prove it by horizontal lines, and finish the remaining part forward and aft. These lines are generally called water-lines, as the ship’s bottom at the surface of the water, supposing the keel kept parallel there-to, would be of the same figure as those lines represented in the half-breadth plan, with the addition of the thickness of the bottom planks in that direction. The upper one is called the load-water-line, or line of floatation, when the vessel is supposed at for sea, which will be treated of more particularly hereafter; the other water-lines may be equally divided between the upper or load-water-line, and upper edge of the keel or rabbet. Although a ship may draw more water abaft than forward for her ball falling trim, yet to keep the several water-lines horizontal, or parallel with the upper edge of the keel, is the most useful in construction; and the water-lines, as represented in the half-breadth plan, form curves, limiting the various half-breadths of the ship at the heights of their corresponding lines in the body-plan. They are generally drawn with green ink, but in Plate I., with corresponding dotted lines, and are represented by straight lines in the sheer-plan; and if parallel with the keel they will be horizontal lines in the body-plan, but if the vessel is to be constructed to draw much more water athwart forward, the water-lines will not of course be parallel with the upper edge of the keel; then, owing to their various heights at each timber in the sheer-plan, they will form curves at those heights in the body-plan, and the more they vary from an horizontal line, the less accurate will be the limits of their half-breadths be described in the half-breadth plan.

In Plate I. the upper horizontal water-line is 20 feet above the lower edge of the keel; and between that and the upper edge of the rabbet of the keel, are equally divided four more water-lines, as in the sheer-plan. The water-lines may now be drawn in the half-breadth plan from the body-plan, as far as the timbers are thereof formed; thus, continue the water-lines aft from the sheer-plan across the body-plan, then take off with compasses, or a flip of paper and pencil, their various half-breadths from the middle line, to the places where the several timbers intersect each water-line, and let them off on their corresponding timbers from the middle line in the half-breadth plan; then to each water-line square down where they intersect the fore-part of the rabbet at the stem, and aft-part of the rabbet at the stern-post in the sheer-plan to the middle line of the half-breadth-plan; then take the half-fiding of the stem and stern-post at each water-line from the middle line in the body-plan, and set them respectively on the lines laid squared down from the middle line in the half-breadth plan; from thence, as the centre, with compasses opened to the thicknesses of the bottom planks, make a sweep, the back of which is the ending of the line. Then complete the fore and after ends of each water-line with curves, as in the half-breadth plan, avoiding all inflected curves or hollow water-lines at the fore part, as they may be drawn by arcs of circles, although their centres may be without the limits of the plates of ship-building.

Now the whole of the body may be completed under the lower height of breadth, observing to sweep each timber below its height of breadth, as before directed; then by taking off the half-breadth of each timber, where they intersect the water-lines from the middle line in the half-breadth plan, and setting them off on their corresponding water-lines from the middle line in the body-plan, curves passing through those spots will shape the timber; but to end them into the rabbet, or complete the leeling, the keel
SHIP-BUILDING.

must be drawn in the body-plan; thus, set off nine inches on the base line from each side of the middle line, being the half-sideling of the keel, and also 18 inches below the base line, which squared will represent the thwartership fection of the keel in midship: then, with compasses opened to the thickneses of the bottom plank, fix one leg where the keel intersects the base line, which is the upper side of the rabbit, and sweep an arc within the keel to intercept the side, and from that intersection sweep another arc upwards; then a triangle drawn within these arcs, represents the rabbit of the keel in midship, and all the timbers along the midship, until the rabbit opens, end where the rabbit intersects the base line; but when the rabbit opens by the timbers rising forward and aft, they will end over the back of the sweep to the inner edge of the rabbit. The timbers near the after-end of the keel must be ended agreeably to the tapering of the keel, which tapers in the sideing from frame 24 to 15 inches at the after-end: this must be set off from the middle line in the half-breadth plan, and the half-sideling of the keel taken at each timber, and set off on the upper edge of the keel from the middle line in the body-plan; then, set within the half-sideling of the keel the thickneses of the bottom plank, and that ends the timber. But as the frames in the fore-body before the heel upon the item, their heights must be taken in the sheer-plan, where they intercept the lower part of the rabbit, and those heights set up in the body-plan upon the half-thickneses of the item; then with compasses opened to the thickneses of the bottom plank, fix one leg in the heights laid set off, and sweep a circle within the sideing, and the heel passes over the back of the circle, and the rabbit completed by a square applied to the line of the timber, so as to intercept the height set up, as shewn in the plan for the fore-body, Plate 1.

Now, as a further proof of the correctnes of the after-body, draw four or five perpendicular sections, or, as they are commonly called, buttock-lines; but first, prove the heels of the after-timbers by the beam-ing line, thus; represent the half-thickneses of the dead or rising wood in the body-plan, by drawing a perpendicular from the base line to the head of the stern-post. Then from the base line take the heights where the after-timbers cross the half-thickneses of the dead wood, and set them up from the upper edge of the rabbit on their corresponding timbers in the sheer-plan; then draw a curve through those heights, to break in fair with the fore-side of the rabbit on the stern-post, and this curve will represent the beam-ing line in the sheer-plan, and limits the heels of the after-timbers, as far as they cut off or stay against the dead-wood.

The heels of the timbers being found to agree with the beam-ing line, from the fairness of its curve (observe, the term fair, so often used in the delineation of the several plans of a ship, signifies that the variety of curved lines therein used have no inequalities in them, but are even as a circle struck from its centre, as most of the lines in the formation of ships' bodies are curves, but many of their centres are too distant for application; and the fairness required is, that where every different curve unites no angle may be discoverable), proceed to prove the after-timbers by the buttock-lines; thus, square up from the base line in the after-body plan five perpendiculars, equally divided between the outside of the wing-transom, and the half-thickneses of the dead-wood; that is, the outer buttock-line at 15 feet 10 inches, and the intermediate four at 3 feet 2 inches afother.

Then take the heights at the first buttock-line, or that next the poll, at the intersecion of each timber from the base line in the after-body, and set them up from the upper edge of the rabbit on the corresponding timbers in the sheer-plan; and to end the buttock-lines, the upper side of the wing-transom and margin-line must be drawn in the several plans; thus, set up 26 feet 10 inches for the height of the upper side of the wing-transom in the sheer and body-plans, drawing a horizontal line at the stern-post and across the body-plan; then from the middle line set off 16 feet 6 inches, the half-breadth of the wing-transom, and at that place set down, below the upper side of the wing-transom, six inches, and sweep the arc, whole centre will be in the middle line; and the round-up of the upper side of the wing-transom will be represented as in the body-plan, Plate I; from the same centre sweep another arc six inches below the upper side of the wing-transom, which is called the margin-line. Then, in the half-breadth plan, sweep in the round aft or aft-side of the wing-transom; thus, square down from the sheer-plan the fore-side of the rabbit of the stern-post, where it cuts the upper side of the wing-transom, to the half-breadth plan, and upon the line so squared down, set off the half-breadth of the wing-transom from the middle line, and at that place set forward seven inches, and sweep the arc representing the round aft of the wing-transom, the centre of which is in the middle line.

Draw an horizontal line at six inches below the upper side of the wing-transom in the sheer-plan, and upon it square up the round forward of the wing-transom from the half-breadth plan; and from thence draw a line to the upper side of the wing-transom at the rabbit of the poll, and the upper side of the wing-transom will be shewn, both to its round down and forward in the sheer-plan. Transfer the height of the margin-line from the body to the sheer-plan, and there draw a line parallel to the upper side of the wing-transom half drawn, and unite them at the fore part of the wing-transom by a line parallel to the rabbit of the poll. The margin-line must next be shewn in the half-breadth plan, by squaring it down from the sheer-plan, and making it a parallel curve to the aft-side of the wing-transom; the distance, however small, being equal to the rake of the rabbit of the poll, in the depth of the margin at the aft-side of the wing-transom. The margin-line being drawn in every plan of Plate I, proceed to end the buttock-lines in the sheer-plan; thus, take the distance of the buttock-lines square from the middle line of the body-plan, and set them off from the same from the middle line in the half-breadth plan, drawing lines parallel thereto from the aft-side of the wing-transom to the after square timber, which will represent the buttock-lines in the half-breadth plan; then, where those lines intersect the margin-line in the half-breadth plan, square up spots to the margin-line in the sheer-plan, which spots will give the true ending of the buttock-lines, also square up the intersecion of the buttock-lines with the water-lines from the half-breadth to the sheer-plan; then transfer all the heights of the buttock-lines, where the timbers cross them in the body-plan, to the sheer-plan, as before directed, and draw fair curves through all the spots set off to the endings, and the after part of the ship will be represented in the sheer-plan, as cut by those perpendicular sections, as in Plate I.

Now if the buttock-lines make fair curves, the after-timbers will be proved correct, and likewise the water-lines abaft in the half-breadth plan; but if the buttock-lines to be made fair curves deviate from the spots as set off, then must the timbers be altered accordingly, and consequently the water-lines. But as a further proof as to the correctnes of the buttock, or that part of the body close abait, square up one or two imaginary or proof-timbers, equally between the after frame-timber 37 and the wing-transom at the side, as represented by the ticked lines in the sheer-plan, Plate 1. Then take the heights on a perpendicular from the upper edge of the keel in the sheer-plan, where the proof-
proof-timbers intersect the buttock-lines and bearding-line, and transfer them to the body-plan above the base line upon each corresponding buttock-line, and half-thickness of the dead-wood; take also the half-breadth of the proof-timbers where they intersect the water-lines in the half-breadth plan, and transfer them to their respective water-lines in the body-plan; but though the proof-timbers cross the stern-post, their heels may be set off, as before directed for the after-timbers; then if the Ipots do set off produce fair curves, as the tacked timber shown in the body-plan, *Plate I.* we may conclude that the after-body is sufficiently proved and its fairness accurate. The fore-body may be proved by vertical sections, in a similar manner as described above, only their ending will be determined by squaring up their interjections with the main-breadth line, from the half-breadth plan to the sheer-plan.

Having completed the form of the body thus far, it will be necessary to ascertain the capacity and stability of the part immersed, as in all ships of war there is a fixed height for the lower fill of the midship port above the load-water-line, allowing for six months' stores, provisions, &c. to be on board; and the capacity should be sufficiently adequate for this purpose: for the nearer this is approached unto, the more merit is due to the constructor: it should not be more, to avoid superfluous expense in the building, and the additional men required to navigate her; nor should it be less, from an obvious general insufficiency to answer the required purposes: the bias should rather lead to increase than diminish in capacity. In ships for commerce, an exact estimation of their capacity is more frequently required to regulate the port duties, and the contracts between merchant owners and builders, than to insure their stability, a fixed line of flotation, and falt failing, as the charge may be regulated by their ability to support it, and their load-water-line may be considerably varied, without any hurtful interference with other essential qualities.

Let us at present suppose the 74-gun ship, *Plate I.* as floating upon the water in equilibrium, and the upper water-line upon a level with the surface of the water, by which the ship is divided into two parts, the one above and the other under the water, which we call the immersed part of the body. In order to judge of this state of equilibrium, in which we suppose the vessel to be, it is necessary to take into consideration all the forces which act upon the vessel: and first the weight of the whole vessel presents itself, by which it is pressed down vertically in a line passing through the centre of gravity of the vessel. This force must therefore be counterbalanced by all the efforts which the water exerts upon the surface of the immersed part, and consequently it will be necessary to determine the pressure that each particle of the immersed surface sustains from the water, which requires researches very embarrassing, and a long series of calculations; but the following considerations will easily lead us to the defined end.

As the vessel occupies in the water, by its immersed part, the cavity formed by the body under the upper water-line, let us compare this case with another, the above cavity being filled with water: it is at first evident, that this mass of water will be in a perfect equilibrium with the water that surrounds it; and it is also plain, that this mass sustains from the part of the surrounding water, the same efforts which the vessel suffers from it. From thence we see, that these efforts of the water balance the weight of the mass of water which we have just sublated in the place of the vessel. Therefore, since these same efforts sustain also the weight of the whole vessel, it follows that this weight is precisely equal to the weight of the mass of water which fills the same cavity as formed by the body of the vessel under the upper water-line; or rather, whose volume is equal to the volume of the immersed part of the vessel.

Here, therefore, is the first great principle upon which is founded the theory of the floating of bodies that swim upon the water. It is, that the immersed part must always be equal in volume to a mass of water, which would have the same weight as that of the vessel; and it is from this principle that we determine the true weight of a vessel, by measuring the volume of its immersed part in the water; for then, by reckoning 64,375 lbs. avoirdupois for each cubic foot, we shall find the weight of the vessel expressed in pounds.

However, this principle, only, is not sufficient to determine the state of the equilibrium of the vessel; another must be still joined to it, and which we shall find with the same facility. We have only to consider in *Plate I.* the centre of gravity of the mass of water under the upper water-line; then we shall easily conceive that all the efforts of the surrounding water are in equilibrium with a force equal to the weight of the mass of water displaced by the bottom under the upper water-line, which should act in a perpendicular direction through the centre of gravity of the said mass of water downwards: therefore, in order that the vessel may be in equilibrium with the same efforts, it is necessary that the centre of gravity of the vessel be in the same vertical line in which the centre of gravity of the immersed part is found. For that purpose we have only to mark within the vessel the very point where the centre of gravity of the immersed part would be, if it was composed of an homogeneous matter, and this point we shall term the centre of gravity.

Now the state of the equilibrium of any vessel will be determined from these two principles: first, that the immersed part must be equal in volume to a mass of water, whose weight would be equal to that of the vessel; and secondly, that the centre of gravity of the vessel, and the centre of gravity of the water, fall in the same vertical line, which is the vertical axis of the vessel. With respect to the centre of gravity, it is evident that it must always fall below the load-water-line; and if the immersed part should prefer, in defecding, every where the same surface, or that it had either a prismatic or cylindrical figure, then the centre of gravity would fall in the middle of the vertical axis between the load-water-line and the keel. But if the extent diminished uniformly from the load-water-line to the keel, and it at last terminated in a right line drawn through the keel, equal and parallel to the load-water-line, then the elevation of the centre of gravity would be two-thirds of the immersed part above the keel; and if the same immersed part should terminate in a point at the keel as a pyramid reversed, then the centre of gravity would be three-fourths of the immersed part above the keel; but with respect to the centre of gravity of the vessel, it may fall either above or below the load-water-line, according as the fadling should be distributed throughout the body of the vessel. Thus in *Plate I.* of ships of war in general, where the gun constitutes a considerable part of the weight, since they are placed above the water, the centre of gravity will be situated above its surface.

The bottoms, or immersed parts of vessels in general not strictly agreeing with any of the above-mentioned geometrical forms, it will be necessary to guage the form of the immersed part of the vessel's bottom, or, which is the same thing, the quantity of water displaced by the bottom; the weight of which, as before observed, is equal to the weight of the ship, its rigging, provisions, and every thing on board. If, therefore, the exact weight of the ship when ready for sea be calculated, and also the number of cubic feet of water displaced by the ship's bottom below the load-water-line, it will then be known if the load-water-line is properly placed
SHIP-BUILDING.

placed on the draught. However operative and difficult the calculations necessary to ascertain the capacity, stability, &c. of ships may be, it must be allowed that it will require the utmost care in the execution, to find the exact dimensions of the several sections of the ship from the draught, (especially as every dimension in the ship is forty-eight times bigger than their similar ones on the draught, supposing it to be drawn by a quarter of an inch scale to a foot,) as an error of a quarter of an inch in the draught, which is only the forty-eighth part of a real inch in the ship, will occasion an error of 110,592 cubic quarters of an inch in the ship, provided the error be in all the three dimensions, viz. length, breadth, and depth. Great precision, indeed, must be used to measure to a quarter of an inch in Plate I., seeing it is only drawn, for convenience, to an eighth of an inch scale. But as these calculations cannot be made with too great an exactness, the body had better be expanded on the mould- loft floor to the full size, and then the various dimensions may be taken very accurately.

The estimated weight of a 74-gun ship, as fitted for sea, with six months' provisions on board, is given in the following table.

An Estimate of the Weight of the 74-Gun Ship, Plate I., as fitted for Sea, with Six Months' Provisions, Guns, &c.

Vol. XXXII.
By the preceding estimate, we find the 74-gun ship, Pl. I. weighs, when brought down to her load-water-line, 2810 tons 745 pounds, that is to say, when fitted for sea, with six months' provisions on board. It may now be known, with some degree of certainty, if the upper water-line on the sheer-draught, Plate I., be properly placed, only by reducing the immered part of the bottom into cubic feet; for, if the 74-gun ship, when brought down to the load-water-line, weighs 2810 tons 745 pounds, the quantity of water displaced must also be 2810 tons 745 pounds, or 6,295,145 pounds. Now a cubic foot of salt-water being supposed to weigh 64,375 pounds, we shall therefore find, that if we divide 6,295,145 by 64,375, the quotient will be 97,788 solid feet, which is the contents of that volume of water which the ship displace corresponding to her weight.

**Displacement or Capacity.**

The solid contents of a ship's bottom, were it any regular figure, might be easily calculated geometrically; but as its curves are so various, the following rule, by approximation, may be near enough for practice.

Take the half-breath of every other frame, and double them, from 26 to O, in the half-breath plan upon the upper water-line; then find the sum of these, together with half the foremost frame O, and aftermost frame 26. Now, the frames being equidistant, multiply that sum by 11 feet, the distance between every other frame, and the product is the area of the water-line contained between the frames 26 and O; then find the area of that part of the water-line afore O, and abaft 26, by taking the half-breath of every timber, and proceed as before, and multiply by 2 feet 9 inches; find also the area of the stem, knee, and gripe, before the foremast-timber, also the area of the stem-pole and rudder abaft the after-timber; then these areas being added to the first found, will be the area of the surface of the whole water-line. Note, the thickness of the bottom plank, as taken in that direction, must be added.

The areas of the other water-lines may be found in the same manner: then the sum of all these areas, except the uppermost and lowermost, of which only one-half of each must be taken, being multiplied by 3.6 feet, the distance between the water-lines (the lines in the sheer-plan being also equidistant from each other), and the product will be the solid content of the space contained between the lower and upper water-lines.

Add the area of the lower water-line to the area of the upper side of the keel; multiply half that sum by the distance between them, the product will be the solid content of that part between the lower water-line and upper edge of the keel.

The solid contents of the keel must be next found, by multiplying the area by its depth; then the sum of these solid contents will be the number of cubic feet contained in the immered part of the bottoms below the upper water-line.

The reason of the above rule will be obvious, by referring to the article STEREOLOGY; for there, to find the solid contents of any irregular body, the area of the surfaces must be taken by ordinates (and such are the joints of the frames of a ship), and those surfaces multiplied by the depth or depths (and such are the water-lines), which give the solid contents required.

The application of this rule, in finding the cubic feet contained in the bottom of the 74-gun ship, below the upper water-line in Plate I.

**SHIP-BUILDING.**

| $x$ by pounds in a cubic foot of salt-water | 64.375 |

$6086151$ lbs.

Method of finding the Centre of Displacement or Support.

The centre of gravity of a ship, supposed homogeneous, and in a state of equilibrium, is in a perpendicular section, passing through the keel, and dividing the ship into two equal and similar parts, at a certain distance from the stern and altitude above the keel.

To ascertain the centre of displacement, or centre of gravity, of the immersed part of a ship's bottom, in a state of equilibrium, begin by determining the centre of gravity of the upper horizontal section, or water-line; and as the two sides are equal and similar, the middle line may be considered as the axis of the equilibrium, in which the centre of gravity of that surface is to be found; and as the surface of the upper water-line, and so of the others, has been already divided into equal parts, and the breadths taken at several timbers or ordinates to find the displacement, we have only to observe that the spaces between those timbers are here considered as so many parallelograms, the centres of gravity of which parallelograms will form a system distributed on the middle line.

Then to find the centre of gravity of the system, in respect to the aft-side of the rudder, which is assumed for the first term of the momenta, we need not find the centre of gravity of each parallelogram, but divide the whole surface into three sections, and multiply their sums, as before, by the distance between the ordinates, and the product will be the area of each section.

Then to obtain the sum of the momenta of all the elementary parts of the surface, multiply the breadth of each ordinate into its distance from the axis of the momenta, or first ordinate; then take the sum of all these products, and, by multiplying this sum by the distance between the ordinates, we shall have the sum of all the momenta of the elementary parts of the surface; which, divided by the sum of the ordinates, will quote the distance of the centre of gravity of the whole surface from the axis of the momenta.

Lastly, the areas of the several planes or surfaces, and their momenta, being found, divide one by the other, and the quotient will be the distance of the centre of gravity of the whole section from the aft-side of the rudder.
To find the centre of gravity of the plane abaft 26, from 37, its first ordinate.

Now 377065 ft. 10 3/8 in. divided by 3764 ft. 8 1/8 in. gives 100 ft. 1 1/2 in., the distance of the centre of gravity of the whole section of the first or lower horizontal water-line from the vessel of the rudder.
SHIP-BUILDING.

Operation for the Plane of the Keel, &c.

To find the centre of gravity for the plane of the keel, &c.

The length on the upper side or plane of the keel, from the aft-side of the rudder, is 177 2
Multiplied by its thickness 1 6
Area of the plane 265 9
Distance of its centre of gravity from the aft-side of the rudder, being equal to half its length 88 7
Now 265 feet 9 inches, multiplied by 88 feet 7 inches, is equal to the momentum 23540 feet 1 6 inch.
The centres of gravity of the six planes having been found, the distance of the centre of gravity of the whole bottom of the ship, from the aft-side of the rudder, is obtained as follows:

From the principles already explained, the distance of the centre of gravity of the bottom, from the aft-side of the rudder, is equal to the sum of the moments of an infinite number of horizontal planes, divided by the sum of these planes; or, which is the same, by the solidity of the bottom. As, however, we have no more than six planes, we must conceive their momenta as the ordinates of a curve, whose distances may be the same as that of the horizontal planes.

Now the sum of these ordinates, or planes, except the first and last, of which take but half, being multiplied by their distance, gives the surface of the curve; of which any ordinate whatever represents the momentum of the horizontal plane at the same height as these ordinates; and the whole surface will represent the sum of the momenta of all the horizontal planes.

Area of the Planes.

<td>11770 0 2</td>
</tr>
<tr>
<td>Sum</td>
<td>26114 0 5</td>
<td>2553337 4 4</td>
</tr>
</tbody>
</table>

Now 2553337 feet 4 1 inches, divided by 26114 feet 2 3 of an inch, gives 97 feet 9 2 inches, the distance of the centre of gravity of the bottom of the ship from the aft-side of the rudder.
The height of the centre of gravity of the bottom may be thus found.

To half of the plane of the keel and half of the upper horizontal plane, add all the intermediate planes, and multiply them progressively as before, taking the upper side of the keel for the axis of the momenta; then that sum being multiplied by the distance between the planes, and divided by the sum of the planes, taking half of the first and last, gives the height of the centre of gravity of the bottom above the keel.

<td>26114 0 5</td>
</tr>
</tbody>
</table>

Now 26114 feet 0 5 inches, divided by 8860 feet 0 1 6 of an inch, gives 3 feet 2 3 of an inch; which, multiplied by 3.6 feet, the distance between the horizontal sections, gives 11 feet 4 6 of an inch, the height of the centre of gravity of the bottom of the ship above the under side of the keel.
The height of the centre of gravity of the bottom of the ship, and its distance from the aft-side of the rudder, being found, the ship being supposed in an upright position, the centre of gravity will necessarily be in the perpendicular longitudinal section, supposed to divide the ship in two equal and similar parts at 97 feet 9 3 inches, the distance of the centre of gravity of the bottom of the ship before the aft-side of the rudder, which comes between the frame 6 and 2 in the afterbody. It may now be ascertained whether the ship will be in her natural position when floating at the upper horizontal line, or constructed to fail on an even keel. Thus, separate the displacement of that part of the bottom before the centre of gravity or support, and see how it agrees with that part of the bottom abaft it, as we may then examine the difference, if any, as in the following examples.
SHIP-BUILDING.

Find the Displacement or Solidity of the Bottom before the Centre of Gravity or Support, which is 5 ft. 3\(\frac{1}{2}\) in. abait Frame 2.

SHIP-BUILDING.

By the result of the above calculation it appears, that the after-part of the bottom has a minus of 983.324 feet, its contents being 983.324 less than the fore-part; and was the ship to be constructed to fail on an even keel, it would be necessary to fill the after-part half the difference, or 491.6612 feet, and reduce the fore-part until it had lost the same quantity; but to alter the after-part of the ship from its present construction, or to make it fuller, would retard her velocity, and prevent the water collapsing at the rudder; for the run of a ship should be neither too fine nor too full, but so constructed that the column of water should exactly meet upon the stern-post, then the rudder will have its full power. The quarter above the load-water-line should be very full, to support the ship when rising forward to a sea, and also to enable her to scud.

In regard to the failing trim of a vessel, it is the decided opinion of most scientific men, that ships or vessels of the larger classes should always be so constructed as to fail on, or nearly on an even keel, that is, so that the ship, when trimmed for failing, should have her keel parallel to the surface of the water; therefore, by as much as the effort of the wind on the sails and masts in forcing the ship through the water has a conflagrant tendency to deprefs the bow, so must ship be trimmed by the stern, as that will be found most advantageous both to their failing and creering.

Many think it inconsistent to construct a ship to fail on an even keel, and yet to place the midship-bend or greatest breadth very forward. A ship so intended to fail, ought, as they conceive, when launched, to have an equal bearing fore and aft, in order that, before the ballast is lowered, the may be on an even keel; and they think that the ballast, if not placed equally fore and aft, must inevitably lrain the crew of the ship. Nevertheless, experience convinces us it is not materially detrimental; for many ships, when launched, will swim four feet by the stern, more or less, and yet when trimmed for failing, they are found to go faster on an even keel, and receive little or no damage if carefully rowed.

Some ships are too clean abaat, and require to fail by the stern; because they have no bearing for fifteen or twenty feet from aft, till the buttock is brought well into the water; and even then, for want of being fuller lower down, when the sea leaves the buttock, the over-hanging of the stern will strain the ship, and occasion her to tumeble, till the next sea, with redoubled force, strike the buttock as the stern is falling, and to shake the ship; in which case it will be well, if some part of the masts be not carried away by the shock: however, this kind of motion may retard the velocity. This accident, though rare, is dangerous, and should be prevented in the construction of the ship.

With respect to ships that ought to fail some feet by the stern, on account of their insufficiency abaat, it is the opinion of many, that if a line were drawn to be well with the lower side of the keel, in the middle of the ship's length, and half the difference set up at the aft-part of the stern-post from the lower side of the keel, and that part of the keel and dead-wood were taken off, and placed under the fore-part of the keel, with the after-end that was before to be forward, so as to make the lower part of the keel straight, as before, the ship would then fail somewhat faster, and be the better: for when a ship is brought so much down by the stern, the keel, not being parallel to the surface of the water, (to which the ship generally fails parallel,) must occasion a pressure at the under side of the keel, equal to the weight of water displaced by the breadth of the keel, and to the angle which the keel makes with the surface of the water in its own length. This may shew why so many ships, differently constructed, are found to fail best on an even keel, although many of them were designed by the constructor to fail by the stern. Ending the result rather in favour of an even keel, the 74, Plate 1., was so constructed, as most likely to answer every purpose.

By that means the water-lines were drawn parallel to the keel, and were thereby more useful as well as more properly placed to form the body; for when the square timbers, and the water-lines, being square to the timber, properly agree with each other, and are fair curves, the ribband-lines, or any other fection, will likewise be fair, or as fair as they should be, allowing the preference to the water-lines and square timbers.

When water-lines are not designed to be parallel to the keel, the draught is generally formed by ribband-lines, because the water-lines differing in height at every timber, require the square timbers to be formed before their height can be set off; and when the water-lines are run, if not approved of, much of the work must be done over again, the water-lines being more regarded than the ribband-lines; for many ships are contrived by ribband-lines only, which seem to produce fair curves, yet forward, and aft especially, they make a very unfair body, which is detrimental to velocity.

Small vessels, as cutters, &c. drawn much more water aft than forward, and their bows are more full in proportion to the after-part; nor would it answer fo well were their line of floatation nearly parallel with the keel, but spreading as it does aloof, especially towards their bow, the bow meets the fluid in a more planing direction, and experiences far less resistance; and the depression of the stern, with the impulfe of the after-mast fails, causes a proper counter-balance, and propels the vessel through the water with greater velocity than if otherwise constructed; for the after-part of these vessels is generally very clean or tapering, which necessarily contributes to make the vessel weatherly, and caufes it, under judicious management, to turn as it were on a pivot.

A ship may be built to a precise draught of water, by which the construction will be founded upon true principles; but when a ship is not built to one precise draught more than another, it will be a very difficult, and one of the most complex questions in ship-building to determine this point. It may be imagined that no more is necessary than to make the ship swim in the water, so as to be capable of carrying the greatest fail; but when a ship is very deep in the water, it will greatly increase the resistence, and consequently retard her failing; hence a long ship will draw less water than a short one, which is a good property, and the resistance at the stern being less, she will therefore fail faster. The resistence, however, must be calculated, not absolutely, but relatively, and in proportion to the fail she spreads.

In ships of war, the load-water-line must be governed by the height of the lower ports above the water in midships; and this we find in line-of-battle ships should invariably be from five to six feet, in frigates from six to seven feet, and in sloops, cutters, &c. from four to five feet.

Ships for commerce are generally constructed to carry a certain cargo, and their principal dimensions are determined according to the trade for which they are particularly designed; therefore the line of floatation, or load-water-line, is not confined in them so exactly to a certain height.

Ships of the line, from long practice, have been found to fail best when inclined one foot, or rather more, by the stern. Thus, the 74-gun ship in Plate 1. load-water-line, when fitted for sea, was 20 feet forward and 21 feet abaft; therefore it only remains to be certain whether the whole displacement of the bottom under the load-water-line agrees with the ellimated weight of the ship, &c. when fit for sea, by multiplying the mean area of the load and upper horizontal water-lines by six inches, the mean depth, and adding it to the displacement already found: as in the folowing operation.
SHIP-BUILDING.

Area of the Load-Water-Line.

</table>

We now find that the 74-gun ship, Plate I., load-water-line, is not only properly placed with regard to her belt falling trim, but the displacement also agrees with the ellipsoid weight of the whole ship when fit for sea, which was 2810 tons 745 lbs., or exceeds it by 18 tons 430 lbs., which is better; as the bias should rather lead to increase than diminish in capacity, and favours any little inaccuracies in the admeneuments; though surely there is little room for error in either extreme, if proper attention be paid to the subject. In like manner may, therefore, the weight of any other ship be found; and, by reducing the displacement of the bottom into cubic feet, we may always ascertain if the load-water-line in the draught be properly placed.

Stability, or Stiffness.

The stability or stiffness of a ship comes next under consideration, being a quality so essential to the safety of navigation as to cause that which a ship is totally disqualified for the purposes of war, being unable to use her guns with effect, or carry a press of sail in case of emergency. Before we proceed further, the following particulars, as they relate to vessels at rest, or in motion, should be defined.

The centre of gravity, or displacement, already mentioned, is the centre of gravity of the volume of water displaced by the immerged part of the ship's bottom; and is also the centre of all the vertical force that the water exerts to support the vessel; for as heavy bodies by their gravity endeavour to approach the centre of the earth in a vertical line, passing through their centre of gravity, tending directly towards the centre of the earth; so the pressure of fluids endeavours to carry bodies in a vertical line tending from the centre of the earth towards their surface, and passing through the centre of gravity of the immerged part, which forces them towards the surface; so also in any immerged body at rest these two opposite forces coincide in the same vertical line, acting in a quite contrary direction to one another. Thus, every floating body is necessarily supported, or presses upwards, by the fluid with a force equal to its weight, or presses downwards, otherwise no body could remain at rest on a fluid, but would ascend or descend as the prevailing force determined; and the moments of all the forces with which a floating body presses on a fluid, and the moments of the forces of the fluid which supports the floating body, are equal and contrary, and are resolved into the same right line, perpendicular to the plane of the fluid. But as this centre depends upon the shape of the body immerged, it of course varies with every inclination of a ship; and whilst the centre of gravity goes farther, and further over to the ship's side in her motions, so as to keep without the perpendicular of the centre of gravity, the ship will be supported; and the water will act upon the centre of gravity.
cavity in the immersed body with more or less power, in proportion to its distance without the centre of gravity, to bring the ship upright, where the acting force or power ceases which occasioned the vessel to heel.

The line of support is the vertical or perpendicular line supposing the vessel to pass through the centre of gravity, and intersecting a line perpendicular to the keel of the vessel through the point, called the meta-centre. For if a floating body is inclined by any power which does not change the position of its centre of gravity, the line of support must necessarily pass between that power and the centre of gravity; and the force or moment of that power is equal to the weight of the floating body, multiplied into the distance of its centre of gravity from the line of support. As the line of support must pass between the centre of gravity and the power applied to heel the vessel, the moment of that power, or its force, multiplied into its distance above the meta-centre, is equal to the moment of its gravity, or the weight of the floating body multiplied into the distance of the centre of gravity below the meta-centre.

Suppose the vessel inclined, or heeling by the power of the wind on the sails, if the line of support passes on the windward-side the vessel would upset, as the power and gravity are at the same side operating to incline it; but if it passes to the lee-side of that power, the vessel will be refretted, as the power and weight operate to that effect; and if the moments of the power and gravity be not equal, the body will not remain at rest, but will incline more or less, as the power or the weight prevail.

Hence it is plain, that the distance from the centre of gravity to the line of support, multiplied into the weight of the vessel, is the measure of the stability of the vessel, or its effort to redress itself when inclined, and that its stability is as that distance.

The meta-centre usually signifies a point to which, if the centre of gravity of a floating body be raised, the smallest lateral effort will make it incline. It is plain, that in an homogeneous cylinder, or sphere, the meta-centre, and centre of gravity, being always in the same point or centre of the sphere, however these bodies are inclined, there is no stability. The centre of gravity must, by no means, be placed above the meta-centre, because if it were the vessel would overtop. This centre, which has likewise been called the shifting centre, depends upon the position of the centre of gravity, for it is that point where a vertical line drawn from the centre of gravity intersects a line passing through the centre of gravity, and being perpendicular to the keel.

The centre of gravity of a ship, is that point by which it may be suspended, and the parts remain in perfect equilibrium. It is also the centre of all the forces, or moments, which press it vertically, or directly downwards towards the centre of the earth.

The lower the centre of gravity is placed, the farther it is from the line of support, and consequently the greater stability.

In ships of war, the centre of gravity can never be far removed from the load-water-line; for if the centre of gravity could be placed nearer the keel, it is not to be desired, as the farther it is removed from the load-water-line, the rolling of the ship becomes more uneasy.

The centre of motion is that point upon which a vessel oscillates or rolls when put in motion. This centre is always in a line with the water's edge, when the centre of gravity is even with, or below the surface of the water; but whenever the centre of gravity is above the water's surface, the centre of gravity is then the centre of motion.

The longitudinal axis of a ship is an imaginary line, which passes horizontally from head to stern through the centre of gravity.

The transverse axis is an imaginary horizontal line, passing athwartships through the centre of gravity.

The vertical axis is an imaginary perpendicular line, drawn through the centre of gravity when the vessel is in equilibrium.

It is about these axes that every ship or vessel in motion may be supposed to turn. In rolling, the ship may be supposed to oscillate on the longitudinal axis; in pitching, on the transverse axis; and in working, &c., to turn on her vertical axis.

From constantly observing that the performance of ships at sea depends materially on their stability, both naval architects and navigators must, at all times, be deligous of discovering in what particular circumstances of construction this property conflicts, and according to what laws the stability is affected by any varieties that may be given to their forms, dimensions, and disposition of contents; which are determined, partly according to the skill and judgment of the constructor, and partly, in some vessels, as we shall show, by adjustments after the vessel is afloat.

The form of the immersed body, and the weight of the ship, are the chief terms in the composition of stability, and they are only to be attained, in the requisite degree, by full dimensions near the load-water-line, with sufficient capacity.

At first sight, it is certain that all the weight above the load-water-line helps to make the ship crank, and, of consequence, the lighter the upper works the stiffer the ship.

Contractors may vary the form of a ship chiefly in three dimensions, that is, in the length, breadth, or depth: let us examine how far enlarging of ships, in any of these particulars, will contribute toward making them more stable or, in other words, gain stability; for although the wind may, in one sense, be laid to constitute the power by which ships are moved forward in the sea, yet if it acts on a vessel deficient of stability, the effect will be to heel the ship rather than to propel it forward; stability is, therefore, not less necessary, than the impulses of the wind are to the progressive motion of vessels.

If the length only, without altering the other dimensions, were enlarged, the centre of gravity and the meta-centre will continue the same height, and her stability in respect of inclination to one side will increase in proportion to the weight of the ship; and as the weight generally increases or diminishes in proportion to the length, we may say that in ships that differ only in length, their stability will be in proportion to their length.

Yet although an increase of length would enable a ship to carry the most sail, consequentlily sail faster, it must not be carried to an extreme; because if so constructed, a ship would neither tack nor veer to quickly; neither would the launch in a sea like one shorter; she would strain more, and be very liable to have the sea break over her. The influence of the rudder may be weakened, and may even be totally lost. The greatest judgment is therefore required in proportioning the length, which may be proportionally greater in those ships that generally navigate in the smoother seas, or are not intended to be deeply laden.

By altering the breadth, the stability is materially affected; for by enlarging it we gain, and by diminishing the breadth we lose a great deal of the stability. M. Bouguer has proved, that the stability increases in proportion to the cubes of the breadth; for, supposing the bottom homogeneous, then, if the increase of weight, and of consequent stability, will be double the increase of the breadth, and atly, the additional weight will act with so much the greater force, as the length of the lever is increased, or as the meta-centre is raised, and the height of that point is augmented in proportion to the square of the breadth; hence the stability will
will be increased in proportion to the cube of the breadth; for example, without altering the other dimensions, let the breadths be doubled, we thereby double the weight, which, by acting upon the arm of a lever, double the length will be quadrupled, so the ship will acquire eight times the stability.

Thus we see an increase of breadth will produce an increase of stability; for a ship that is broad and shallow has much more fitness than one that is narrow and deep; but the failing of the ship may be much retarded, as the certainly would be leewardly under little fail, which ought to be particularly guarded against, especially in constructing large ships of war. The expense in the building would also be materially increased, according to the usual mode of computing the tonnage, as may be readily seen in the next section.

If the depth only is increased, without enlarging either the length or breadth, all the stability that can be gained will be in the stowage. To increase the depth or draught of water would lower the centre of gravity, and increase the weight; this would operate against velocity, because the resistance is as the quantity of water to be removed; or nearly as the area of the thwartship section of the immeasurable part of the body at the midship-bend. It would at the same time render the immeasurable body of a figure less proper to separate the line of support from the centre of gravity, so that the effect on one side would be in some measure destroyed on the other; and, by lowering the centre of gravity too much, the ship would labour excessively, and endanger the masts, too large a draught of water being both dangerous and inexpedient.

Ships having a sufficient degree of stability arising from their construction, will certainly fall faster than others, which, in order to carry the fame quantity of fail, require to be ballasted with a much greater weight; for the latter, so ballasted, will be much more liable to roll than the former.

The following circumstance will prove, that instability in the construction cannot be rectified to any considerable degree by the stowage, although, on the contrary, that the stability of many ships, however perfect in construction, may be materially injured by improper trim, or an injudicious mode of stowage.

And, first, as there is nothing of more importance to the well-being of a ship than its stability, it will not be improper to mention an opinion which prevails with seamen in general, that the stability depends chiefly on the stowage of the hold; and at the same time, in order to shew that a very great change in that respect will produce a very trifling difference in the stability, we shall quote a professional author of great merit, M. de Romme, in his book L'Art de la Marine, page 105.

"As to the position of the centre of gravity, no doubt it may vary, but the limits to which it is confined are very straitly, especially in ships of war. An example in the Scipio, of 74 guns, armed for the first time in 1779, was hardly in the road before she was suspected of instability. It was important in time of war to clear up those doubts, and to make the necessary experiments to prove this dangerous defect, if it existed. First, the lower-deck guns were run out on one side, while hove on the other, which heeled the ship thirteen inches; the ship's company were then ordered to their quarters at the side the guns were out, which increased the inclination to twenty-four inches. After these eflays the fails were let, and in fine weather the ship was found to crank, as to render the use of the lower-deck guns difficult and dangerous; thus, her instability being proved, she was ordered to port to be remedied.

"Opinions were divided as to the cause of the defect; some imagining it to proceed from the form of the hull; others from the ill arrangement of the charge. The first engineer was ordered to attend at Rochfort, and direct the choice of measures to give the Scipio, as well as two other ships, the Pluto and Hercules, built from the same plan, the stability they wanted. He judged that new stowage would remedy the defect, and his opinion was adopted by the marine council. The Scipio was unloaded, and charged anew, under the direction of the chief engineer. In the first charge she had 84 tons of iron, and 100 tons of stone ballast, and was re-loaded with 198 tons of iron, and 122 tons of stone ballast; and as her draught of water, or displacement, could not be altered, it was necessary to diminish 130 tons of water to preserve the same line of flotation; by this means 132 tons were placed, in the second loading, eight feet lower than in the first; yet when the ship was completed with the new distribution of her charge, she was found precisely as deficient as before, inclining twenty-four inches, with the men at quarters, and the guns out. She was afterwards doubled with light wood, a foot thick at the extreme breadth, and ten feet under water, decrasing to four inches length and depthways."

M. de Romme very judiciously observes, that the defect of instability was not so much owing to a want of extreme breadth, as several other 74-gun ships had had the fame, or even less, but in diminishing the breadth at the plane of flotation too quickly forward and aft, which at once lessened the capacity and position of the line of support.

A French 36-pounder weight, with carriage, &c. 4½ French tons, and their increased length caușes their centres of gravity, when run out, to be removed 4½ feet; so that the moment produced by running out the lower-deck guns of a French 74, the opposite side housed, is more than doubled the moment for an English 74, in the same circumstances.

It is certain this change of place in the centre of gravity, which lowered it nearly five inches, must have contributed to increase the stability, and have occasioned nearly a difference of three inches in the greatest inclination; but as the experiment where the men are stationed at quarters is liable to such irregularity, an error of this magnitude is to be accounted for from the men running to the side, to mark more strongly the defect of a bad ship.

Secondly, the stability of many ships, however perfect in the construction, may be materially injured by an improper trim, or an injudicious mode of stowage; for was the centre of gravity raised too high by the weightier part of the cargo being placed uppermost, the ship would not only be rendered incapable of carrying a sufficient quantity of fail, but in danger of being overfet; and was the cargo lead, or any other such weighty body, and placed too low in the hold, the centre of gravity would consequently be so lowered as to endanger the ship's rolling away her masts. When a ship is so loaded, as that her centre of gravity is carried too far forward, the ship will pitch and labour heavily; and when too far off, the will occasionally be exposed to the dangerous circumstances of a pooping sea, &c.

As it is of the utmost importance to the well-being of a ship to ascertain its stability, the greatest attention must be given, in the construction, to the finding of the exact distance, between the meta-centre and centre of gravity, that every ship requires, according to her form; the maximum of which is, that the ship shall not, by the length of lever, either become too stiff, or be subject to sudden motion or rolling; nor, on the contrary, from the lever's being too short, the vessel is unable to carry fail. Therefore, in the construction, to ascertain the height of the meta-centre above the centre of gravity of the immeasurable part of the bottom, the half section of the load-water-line must be taken as was divided to find the displacement. Then the sum of the cubes of the half sections, or ordinates, is to be multiplied by the distance between them, and by the product
SHIP-BUILDING.

product are to be divided by the immered part of the bottom of the ship. It is hence evident, that while the section at the water-line is the same, and the volume of the immered part of the bottom remains also the same, the altitude of the meta-centre will remain the same, whatever may be the form of the bottom.

Sum of the products $2189296.94$

Cubic feet of salt-water displaced by the bottom $98436.07$ $145931.29$ ($14$ ft. $9\frac{1}{2}$ in.)

The above operation gives $14$ feet $9\frac{1}{2}$ inches, the height of the meta-centre above the centre of gravity of the immered part of the bottom of the $74$-gun ship, Plate 11.

Now let us see how the above calculations in determining the height of the meta-centre above the centre of gravity agrees with actual experiment; for theory (particularly in the constructing of ships) that agrees with experiment is only to be regarded. We are in this particular indebted to the late admiral Leveson Gower, who directed several experiments to be made to try the relative stability of the following ships of war, by heeling them with their lower-deck guns out on one side, and housed on the other; and afterwards with their men at quarters, the guns remaining as above.

| Formidable, | Barfleur, | Brunswick, | Bedford, | Bombay Cattle, |
| 99 guns. | 98 guns. | 74 guns. | 74 guns. | 74 guns. |
| Fr. | Fr. | Fr. | Fr. | Fr. | Fr. |
| 22 | 23 | 20 | 21 | 21 | 21 |
| 3 | 3 | 4 | 3 | 0 | 0 |

| 0 | 3 | 0 | 3 | Not mentioned | 0 |
| 2 | 12 | 1 | 10 | 11 | 1 |
As the inclinations of the Brunswick and Bedford are omitted in the first experiment, we shall only compare the relative liability of the other three ships, which are quite sufficient to explain every thing necessary to be remarked on the subject. It is to be regretted that the first inclination of the Brunswick was omitted, as it comes the nearest to Plate 1.

The estimated weight or displacement of Formidable 3150 Tons.

or Barfleur 3360 Tons.

the Bombay Castle 2700 Tons.

The difference of the draught of water of the Formidable and Barfleur, 14 1/2 inches, gives at least 210 tons difference in the weight. Both ships have similar dimensions nearly, and are supported on an even keel.

These three ships have the fame number and weight of guns on the lower gun-deck; therefore the moment of the guns, whether quite exact or not, does not signify, as any error will not have a partial influence. We suppose each gun and carriage together to weigh three tons, and allow three feet removal when the gun is run out; and as there are 14 guns run out in each ship, the equal moments for them are 3 x 14, or 126 tons at three feet; the weight on one side the balance is 42 tons, at three feet distance from the support, and on the other, in the Formidable, 3150 tons, at 48 hundredths of an inch (less than half an inch), which will be found to balance 42 tons at three feet:—for the Barfleur 3360 tons, at 45 hundredths of an inch, which will balance 42 tons at three feet; for the Bombay Castle 2700 tons, at 56 hundredths of an inch, which will balance 42 tons at three feet.

Having found the distance each centre of gravity is separated from the line of support, which is in these small inclinations the fame as the line of the angle; the colline, or distance of the centre of gravity from the meta-centre, is easily known, and will be found to be, for the

Formidable’s centre of gravity Barfleur’s Bombay Castle’s
below the meta-centre 3 5½ 3 9½ 4 5½

When the Formidable and Barfleur were farther inclined by the men at quarters, the Barfleur continued to have one-seventh more liability than the Formidable; which proves that the Formidable’s centre of gravity was above the line of floatation; for otherwise, if her imbedded body was better calculated to separate the line of support from the centre of gravity than the Barfleur’s, she would have inclined less proportionably, if the centre of gravity had not acted against her liability: 100 tons of iron ballast at the keelson would have only increased her draught of water six inches, and have given her more liability than the Barfleur, leaving her the advantage of six inches more height for her ports, and nearly 34 feet square less resitance at her mid-ship-bend. Thus it is demonstrable, that those ships should have no more shingle ballast than is necessary for the ground tier, and should have above 200 tons of iron; nor would there be any danger of their being labourfome, as their centre of gravity would be at the line of floatation or load-water-line. The same regulation should prevail with the first-rates.

The Bombay Castle is certainly stiff enough, yet no doubt her lower deck might have been placed six inches higher without any detriment whatever to the ship, and her ports would of consequence have been at a reasonable height from the water.

In Plate 1, we find, by the preceding calculations, that the centre of gravity of the imbedded part of the bottom was above the under side of

Centre of gravity below the meta-centre 5 0

Which we find exceeds the Bombay Castle’s; and the ports in Plate 1 are five feet eight inches above the water.

By the above experiment we observe, that the guns being run out on one side and hauled on the other, inclined the ship to a certain point, and at the same time there was an exact equilibrium between the momentum of the guns, and the whole weight of the ship on each side the line of support, in the direction of the vertical effort of the water. The centre of gravity of the ship is in the same vertical line with the meta-centre when the ship is in an horizontal position; and the more the ship inclines, the more will the centre of gravity of the ship be removed from the vertical line of the meta-centre, or line of support. Hence it is plain, that the distance of the centre of gravity from the line of support is always in proportion to the line of the inclination; at least when the inclination is but small, as before observed. Now, if that distance, and likewise the whole weight of the ship, be known, we have also its momentum, or the relative force with which that weight acts in endeavouring to right the ship, and bring her again into an horizontal position, and which is the measure of her liability; but since both the situation, and likewise the weight that produces the inclination, are known, we may thence know if the momentum of one be equal to that of the other, and thereby easily discover if the centre of gravity be in that very point we propose.

The success of the above experiment (which might be rendered very useful if more frequently tried) depends on the nicety to be observed in taking the exact quantity of the angle of inclination: to attain this, a level line for the fensible horizon of the sea may be used, or, what is much better, a plumb-line fastened to the head of the mast, taking its distance from the heel of the mast, both when the ship is upright, and likewise when the heels. The plumb-line seems to be the most convenient, because we have thereby immediately the proportion in which the centre of gravity recedes from the vertical line of the meta-centre, which will always be in proportion to the distance of the plumb-line from the heel of the mast. During the whole time of the operation, it is necessary to be very careful to render all the circumstances absolutely the same, so as to be well assured the inclination is produced only by the momentum of the guns, &c.

We may in this manner prove the centre of gravity of the 74-gun ship, Plate 1., knowing the height of the meta-centre; for, having the quantity of the weight producing the inclination (which is the same as the above,) and examining the distance of the centre of gravity from the line of support in which the effort of the water exerts itself, we have also its momentum, or its relative force, which is equal to the whole ship, since these two exactly balance one another; so that it is only dividing this momentum by the whole weight of the ship, and the quotient will give us the distance of the centre of gravity of the ship from the line of support, or vertical line of the meta-centre.

For the Bombay Castle of 74 guns and 2700 tons, in estimating
estimating the weight or displacement, it was found, that 56
hundredths of an inch balanced 42 tons at three feet; and
it will be found by the following operation, that 53.445
hundredths of an inch in Plate I. will balance 42 tons at
three feet, Plate I., displacement 2829.4 tons 175 lbs. =
2829.078 x 53.445 = 1512000 ÷ 1200 = 126.

We now find that the distance of the centre of gravity is
removed from the line of support 53.445 hundredths of an
inch. After this, it will be easy to discover how far the
centre of gravity is from the meta-centre, since there will
be the same proportion betwixt the distance of the plumb-
line from the heel of the mast, and the height of the mast,
that there is betwixt the distance of the centre of gravity
from the line of support. Thus, the length of the mast is
113 feet which multiplied by 53.445 = 5985.8 ÷ 1200 =
4 ft. 113 in., the distance of the centre of gravity below the
meta-centre nearly agrees with the calculation above given.

Tonnage or Burthen.

By the tonnage of a ship, is meant to convey the idea of
the weight of the cargo she is intended to carry from her light
to her load water-line, or feast in the water, when best
equipped for sea. It may also be called the ship's real bur-
then. Therefore, to ascertain the true burthen or tonnage
by calculation, is a question of equal importance and diffi-
culty, as preceding displacement, &c.

It is of importance, because it is by this that the mer-
chant or freighter judges of the fitness of the ship for his
purpose; and although customary rules are given for com-
puting the tonnages of ships, the bare inspection of them
will prove how futile they are. It would be very difficult
to fix upon any general rule which shall be very exact,
because it depends not only on the cubical dimensions of the
ship's bottom, but also on the scantling of her whole frame;
and, in short, on the weight of every article to complete the
fain ship ready to receive on board her cargo. The weight of
timber is variable; the scantling of the frame being no
less so.

The following rules for computing the tonnage of a ship are
commonly adopted and made use of between the contractor
and the builder, at a certain rate per ton for the building,
and will be found to be quite unconnected with the above
definition of a ship's tonnage; for as the depth is out of
the question, the contractor finds a paying in less breadth
and great depth, which make against stability, and conse-
quentially injure the velocity; on the contrary, great breadth
and less depth will be found more advantageous to the
builder; thus are the interests of the two parties oppositely
concerned in the result, and both, when carried to the ex-
reme, are exceedingly injurious to the construction of
vessels.

The General Rules observed for measuring the Tonnage of Ships
in the Royal Navy and the Merchants' Service.

Let fall a perpendicular from the fore-side of the item,
at the height of the upper deck, or middle deck, in three-
deck ships, and another perpendicular from the aft-side of
the main-poil, at the height of the wing-tranfmom. In mer-
chant-ships, the foremost perpendicular is let fall from the
fore-side of the item, at the height of the wing-tranfmom.
From the length between these perpendiculars, deduct three-
thirds of the extreme breadth, (that is the thickness of the
bottom plank on each side added to the moulded-breadth),
and likewise as many 2½ inches as the wing-tranfmom is above
the upper edge of the keel, and the remainder is reckoned
the length of the keel for tonnage.

Then multiply the length of the keel for tonnage by
the extreme breadth, and that product by half the extreme
breadth; then dividing by 94, the quotient will be the
burthen, in what may be denominated builder's tonnage.

Calculation of the burthen in tons of the 74-gun ship.

| mon rule |       |
| Difference | 617 1585 |

By the above it may be readily seen, that the 74-gun
ship (Plate I.) will not carry the number of tons the is
rated for, by 617 tons 1585 lbs.; and hence the im-
propriety of such a rule being made general, as it will always
be found greatly to increase the tonnage of sharp-built
vessels; while those that are full-built, as ships in the East
India Company's service, will carry a great deal more.
We shall, therefore, calculate the tonnage of the East India
ship (Plate XII.) both ways as above, in order to prove the
great inaccuracy of the rules with respect to those vessels,
as well as to ships of war.

Calculation
Calculation of the burthen in tons of the East India ship, *
(Plate XII.) according to the common rule.

We now find that the East India ship will carry 218 tons
747 lbs. more than she is rated for by the common rule;
which, it plainly appears, is in confequence of her body
being formed to full; and the greater the contrail between
full and sharp bodies, the greater will be the error in the
tonnage call by this rule; which fhews the imprefriority of
the erroneous method perfcribed for calning a ship's
tonnage.

Hence it is obvious, that no dependence can be placed
on the common rules for acertaining the true ton-
nage of veffels. Indeed we neither have, nor expect to
have, any rule that shall be quite exact; because the ton-
nage depends not only upon the cubical dimensions of the
ship's bottom, but also on the weight and leaunting of her
whole frame. For instance, a ship built at Archangel of
fir, will carry considerably more than another of the fame
plan in every repect, built at the Havannah of live oak;
nor is there a greater difference in some fhips, when
the weight of every thing which properly makes a part of
the ship, as to the falling; &c. &c. is considered. We must,
therefore, be contented with the rule that approximates nearer
to the truth; and this is the following, propounded by the
late Mr. Parkyns, of Chatham-yard.

Rule 1. For sharp fhips, particularly those of the royal
navy.

1st. Take the length on the gun-deck, from the rabbet
of the stem to the rabbet of the flern-poll, or between the
perpendiculars. Then take 4/5ths of this length, and call
it the keel for tonnage.

2dly. To the extreme breadth add the length of the
gun-deck, or length between the perpendiculars. Then take
2/3d of this sum, and call it the depth for tonnage.

3dly. Set up this depth from the limber-flake; and, at that
height, take a breadth also from out to out fide of the plank
at dead-flat; and another breadth between that and the
limber-flake; and together the extreme breadth and the
two breadths. Take one-third of the sum, and call it the
breadth for tonnage.

Lastly. Multiply the length for tonnage by the depth for
tonnage, and the produc of the breadth for tonnage, and
divide by 49. The quotient will be the burthen in tons
nearly.

The following trials have been made, to prove the accu-
rcy of this rule.

Rule 2. For fhips of burthen, or commercial fhips in
general.

1st. Take the length of the lower deck, from the rabbet
of the stem to the rabbet of the flern-poll. Then take 4/5ths
of this length, and call it the keel for tonnage.

2dly. To the extreme breadth add the length of the
lower deck. Then take 2/3d of this sum, and call it the
depth for tonnage.

3dly. Set up this depth from the limber-flake; and, at
that height, take a breadth also from out to out fide of the
plank at dead-flat; take another at two-thirds of this height,
and another at one-third of the height; add the extreme
breadth and these three breadths together, and take one-
fourth of the sum for the breadth for tonnage.

Lastly. Multiply the length for tonnage by the depth
for tonnage, and the produc of the breadth for tonnage,
and divide by 36.6666 or 36; and the quotient will be the
burthen in tons.

The following trials, among many others, fhew that this
rule does not deviate much from the truth.

Granby,
SHIP-BUILDING.

The general rule for calculating the loading of colliers is as follows:

From the length of the keel subtract 6 or 7 feet for the dead flowage fore and aft; multiply the remainder by the breadth at the midship-figm, and that product by the depth of water the ship draws when loaded; divide this by 96, and you will have the number of London chaldrons the ship will carry.

A method of constructing a scale of solidity, by which may be ascertained the quantity of water displaced at any given draught, and the weight required to bring the ship down to any draught of water propelid.

In order to construct this scale for any ship, it is requisite, in the first instance, to calculate the quantity of water displaced by the bottom, below each water-line, and by the keel, in the same manner that we have already done for the 74-gun ship (Plate I.); for which ship, as the areas of the several water-lines are already calculated, a scale of solidity may be readily constructed as follows:

Construct a scale of equal parts, to represent tons, as the scale so marked in Plate XIV.; and another to represent feet and inches, as that below it. The larger thefe scales, the more exact will be the performance.

<table>

</tbody>
</table>

Now let off the tonnages from the above table upon the corresponding water-lines, &c. in Plate XIV. fig. 1, thus: upon C, representing the upper side of the keel, let off, from the perpendicular A H, 15 tons 615 lbs., taken from the scale of tons, equal to C C. Upon the line D, or lower water-line, let off 223 tons, 1728 lbs. equal to D d. Upon the line E, or second water-line, let off 683 tons 823 lbs. equal to E e. In like manner, let off the other tonnages upon their correpsonding water-lines: then through the points C c, D d, E e, F f, G g, H h, draw the curve A S, which will represent the solidity of displacement at any given height.

For example, the 74 (Plate I.) draught of water, when launched, was 13 feet forward and 17 feet abaft; which gives 14 feet 3 inches at dead-flat, or midships, the ship's chief support in this light flake. Take, therefore, 14 feet 3 inches from the scale of feet, and set it up parallel from the line A B, or lower side of the keel, to intersect the curve of displacement, as at I i. Take the nearest distance from the intersection of the curve to the perpendicular A H, and apply it on the scale of tons, and it gives 1550 tons 1120 lbs. But by the estimate, the weight of the ship, at her launching draught of water, was 1377 tons 2108 lbs., which exceeds the above by 172 tons 1162 lbs.; but that
SHIP-BUILDING.

may be easily accounted for, by the weight of anchors, cables, men, ballast, &c. as additional weight in the ship at that time. Take 1577 tons 2198 lbs., the weight of the hull exclusively, from the scale of tons, and set it off from the perpendicular line A H, along the line A B, or base; whence square up the perpendicular K L, to intersect the curve of displacement. That depth we find by the scale of feet to be 13 feet 4 inches, 2 difference of 11 inches, accounted for as above.

Now to prove the real burthen of the ship by this scale of displacement, we have found, by the estimate, that the ship, with her furniture, &c. displaces 1582 tons 998 lbs. at her light water-mark. Take 1582 tons 998 lbs. from the scale of tons, set it off as before, and raise the perpendicular L L to intersect the curve of displacement; and another perpendicular at 2829 tons 175 lbs., taken from the scale of tons, which is the weight of the ship at her load water-line, as L L. Then take the distance between the two perpendiculars last drawn, and apply it on the tonnage scale, and we have 1247 tons nearly, the real burthen, as before thrown by calculation.

Again, take the height where the perpendicular L L intersects the curve of displacement, and apply it on the scale of feet, and we have 20 feet 6 inches, the medium height of the load draught of water, which was 20 feet forward, and 21 feet abaft.

Now the perpendicular L being the utmost limit of the quantity of water, expressed in tons, displaced by the bottom of the ship, when she is brought down to her load water-line, it is evident, from what has been already said, that if the number of cubic feet of water which the ship displaces, when light, or, which is the fame, the number of cubic feet below the light water-line, be subtracted from the number of cubic feet contained in the bottom, below the load water-line, the quotient will be the real burthen or tonnage.

Any other case to which this scale may be applied is obvious, particularly to merchant-ships. Let it be required to find the number of cubic feet displaced, when the draught of water is 17 feet 7 inches, and the additional number of tons required to bring the ship down to her load water-line.

Take 17 feet 7 inches from the scale of feet, and set it up upon the perpendiculars A N and L L, above the base line A B, and draw an horizontal line through those spots, intersecting the curve of displacement at 63, from thence drop the perpendicular O a. Take the distance a, in the horizontal line, to the perpendicular A N, and apply it on the tonnage scale, it will measure 2205 tons 1706 lbs., the displacement answerable to that draught of water; and the measurement from a, taken to the perpendicular L L, applied on the tonnage scale, will give 623 tons 708 lbs., the additional weight necessary to bring the ship down to her load water-line. Again, 623 tons 708 lbs. added to 1582 tons 998 lbs., give 2205 tons 1706 lbs., as above, and thus it is proved that the perpendicular O a is equally distant from the perpendiculars M m and L L.

The measurement of the tonnage might be facilitated, by drawing the tonnage scale reversed on the base line A B, and at the load water-line, as in the plate.

Now if the draught of water be required, corresponding to any weight intended to be put on board, it may be readily known as follows.

Find the given number of tons, suppose 928, in the scale on the line m l, through which drop a perpendicular to intersect the curve of displacement, as at P P; and at P draw an horizontal line. Now the perpendicular distance between the base line A B, and intersection of P, being applied on the scale of feet, will give 19 feet, the draught of water required.

Many useful discoveries may be made by blocks or models of ships, and with as great certainty as by the nicest calculations; for it must be allowed, as before observed, that in calculating from a draught drawn from a quarter of an inch scale, it will be liable to some inaccuracies, which cannot be obviated in practice, by reason of various little alterations which may be made in laying off the ship in the mould-loft; consequently the draught and the ship will, in those points, disagree. And likewise, upon strict examination, we shall be enabled to find, that there are not many ships that have both their sides exactly equal in every respect.

Let the block, or model, be constructed to a scale of one-quarter of an inch to a foot of the corresponding parts on the ship; and care should be taken to provide the wood as light and dry as possible.

The model being accurately constructed, it may be also proved by suspending it by a line, fastened to a hook in any part of a straight line, drawn from the middle line of the item to that of the stern-pole. This hook may be moved forward and aft to different places in the middle line, and a weight may be suspended from the upper part of the middle line, on the pole. If the two sides be exactly of equal dimensions, and homogenee, they will then be of equal weight. A plane passing through these three lines, whatever part of the middle line the hook be in, will likewise pass through the middle line of the keel, stem, and pole; therefore, if the model stands this proof, it will be as true to work from as the nicest calculations.

The model, having flood this test, may be suspended by the same line, or filk, in different positions, until it points out the centre of gravity; which will be found, when the block hangs in a state of equilibrium. This practice is, doubtless, very simple; but it will be found very convenient. Further, the model being suspended by the hook, the lines hanging at the item and pole corresponding to their middle lines, and to that which suspends the block, we may hold a batten out of winding with the line that suspends it, and, with a pencil, draw a line upon it. A plane passing through this pencil line, at right angles to the keel, and passing likewise through the line that suspends the block, will likewise pass through the centre of gravity, which, therefore, must be somewhere in this plane. Again, move the hook to some other part of the middle line, and let the block be suspended from that point; draw also another pencil line, out of winding with this left line of suspension, and the intersection of the two lines will give the height of the centre of gravity above the keel, and likewise its distance from the pole and item; and if the hook be moved to any other part of the middle line, and a pencil line be drawn as before, it will likewise intersect in the same point; or, let there be ever so many points assumed in the middle line, and the block suspended by each, and pencil lines drawn, they will all intersect in the same point, and as the centre of gravity will always be in that plane which passes through the middle line of the keel, item, and pole, it may with certainty be marked on the draught.

This will certainly require the greatest nicety; but, if well executed, it will agree with that found by calculation, provided the dimensions be taken very exactly, and likewise from a true scale of equal parts.

By the same model may be found the true tonnage of a ship, thus: Let the light and load water-lines be marked on it; then put the model in water, and load it until the surface
SHIP-BUILDING.

face of the water is exactly at the light water-line; and let it be suspended until the water drains off, and then weighed. Now, since the weights of similar bodies are in a triplicate ratio, or as the cubes of their homologous dimensions, the weight of the ship, when light, is, therefore, equal to the product of the cube of the number of times the ship exceeds its model by the weight of the model, which is to be reduced to tons. Hence, if the model is constructed to a quarter of an inch scale, multiply the weight of the model by the cube of 48, (one-fourth of an inch being equal to 36 inches,) or 110592, which will give the weight of the ship. If the multiplier be ounces, the product will be ounces; if pounds, it will be pounds: and it is to be reduced to tons accordingly.

Example.—Suppose the weight of a model of the 74 (Plate I.) to be 32 lbs. 13 drachms, when brought down to the light water-line.

The cube of 48 = 110592
Multiplied by 32 lbs. 13 drachms

Produces 3341560 lbs. = 1582 tons 880 lbs.

The weight of the ship at her light water-mark, within 118 lbs.

Again, let the model be loaded, until the surface of the water is exactly at the load-water-line. Now the model being weighed, the weight of the ship is to be found by the preceding rule; then the difference between the weights of the ship, when light and loaded, is the tonnage required.

Upon the Efforts of the Water to bend the Vessel.

Here we can do no better than quote Wattom's translation of Euler upon the Théorie, &c. des Vaillieux; to which book we refer our readers for a further illustration of the foregoing particulars, and to Atwood on the Stability of Vessels.

When we say, that the pressure of the water upon the immerged part of a vessel counterbalances its weight, we suppose that the different parts of a vessel are so closely connected together, that the forces which act upon its surface are not capable of producing any change; for we easily conceive, if the connection of the parts was not sufficiently strong, the vessel would run the risk either of being broken in pieces, or of sufficing some alteration in its figure.

The vessel is in a situation similar to that of a rod A B (Plate XIV. fig. 2.), which, being acted upon by the forces A a, C c, D d, B b, may be maintained in equilibrium, provided it has a sufficient degree of stiffness; but as soon as it begins to give way, we see that it must bend in a convex manner, since it's middle will obey the forces C c and D d, whilst its extremities will be actually drawn downwards by the forces A a and B b.

The vessel is generally found in such a situation; and since similar efforts continually act, whilst the vessel is immerger in the water, it happens but too often that the knee experiences the bad effect of a strain. It is, therefore, very important to inquire into the true cause of the accident.

For this purpose, let us conceive the vessel divided into two parts, by a transverse section through the vertical axis of the vessel, in which both the centre of gravity, G, of the whole vessel, and that of the immerged part, Q, are situated; so that one of them will represent the head part, and the other that of the stern; each of which we shall consider separately. Let g be, therefore, the centre of gravity of the entire weight of the first, and o that of the immerged part corresponding. In the same manner, let y be the centre of gravity of the whole stern part, and w that of its immediate portion.

Now it is plain that the head will be acted upon by the two forces g m and o n, of which the first will press it down, and the latter push it up. In the same manner, the stern will be pressed down by the force y u, and pushed up by the force w y v; but these four forces will maintain themselves in equilibrium, as well as the total forces reunited in the points G and O, which are equivalent to them; but whilst neither the forces before nor those abait fall in the same direction, the vessel will evidently fulfill efforts tending to bend the keel upwards (called hogging) if the two points o, w, are nearer the middle than the two other forces g m and y u. A contrary effect would happen if the points o and w were more distant from the middle than from the points g and y v, called sagging.

But the first of these two cases usually takes place in almost all vessels; since their hollow has a greater breadth towards the middle, and becomes more and more narrow towards the extremities; whilst the weight of the vessel is, in proportion, much more considerable towards the extremities than at the middle. From thence we fee, that the greater this difference becomes, the more also will the vessel be subject to the forces which tend to bend its keel upwards: it is, therefore, from thence that we must judge how much strength it is necessary to give to this part of the vessel, in order to avoid such a consequence.

If other circumstances would permit, either to load the vessel more in the middle, or to give to the part immerger a greater hollow towards the head and stern, such an effect would no longer be feared; but the declination of most vessels is entirely opposite to such an arrangement; by which means we are obliged to strengthen the keel as much as may be necessary, in order to avoid such a disalter.

Having now investigated the centre of gravity of the displacement, meta-centre, and centre of gravity of the whole ship, with other particulars, and laid down all that is requisite to be attended to, in that respect, for the construction of a ship's body under water, we shall, in the next section, proceed to complete the remainder of the sheerc-draught.

To complete the Construction of the Sheerc-draught, Plate I.

Having found that the displacement of the ship at the load-water-line gives the ship sufficient stability to keep the lower ports 5 feet 10 inches above the water, we may proceed to draw all the decks in the sheerc-plan, beginning with the lower, or gun-deck. The height of the lower fills of the gun-deck ports should be 2 feet 4 inches above the gun-deck plank, which is four inches thick; consequently the upper side of the beam along the side must be 2 feet 8 inches below the fills; add six inches to that for the round-up of the beam; and the under side of the gun-deck at the middle line in midships will be 22 feet 2 inches above the upper edge of the keel; at the foremoast-perpendicular set up 24 feet, and at the after-perpendicular 24 feet 8 inches; then a segment of a circle drawn through these three heights will represent the under side of the gun-deck at the middle line. (These kinds of seeps are drawn by thin veneers of pear-tree wood, called sweep-woods, drawn from a long radius on purpose, or by a drawing-bow.) Now set up four inches, the thickness of the gun-deck plank, above the line last drawn, and let another line be drawn parallel thereto, and the gun-deck will be described at the middle line in the sheerc-plan.

Next proceed to draw the upper deck; set up 7 feet 2 inches, being the height from the upper side of the gun-deck plank to the under side of the upper deck, along the
SHIP-BUILDING.

the middle line, through which heights draw a curve parallel to the gun-deck, and another curve three inches parallel above it, and the upper deck will be represented at the middle line of the sheer-plan.

The stern-timbers should be next drawn, to shew the boundaries of the sheer-plan above the wing-transom. Set up above an horizontal line drawn at the upper side of the wing-transom at the middle line four feet, upon a perpendicular 6 feet 10 inches abaft the aft-side of the wing-transom, which will be the height and knuckle of the upper counter at the middle line; from thence draw a curve, about six inches hollow, to the upper side of the wing-transom, where the fore part of the rabbit of the stern-post intersects it; and that curve will represent the lower counter at the middle line.

In the same manner, set up the height of the upper counter 7 feet 5 inches, upon a perpendicular nine feet abaft the aft-side of the wing-transom, which will be the height and knuckle of the upper counter at the middle line; then drawing a curve about one inch hollow from thence to the knuckle of the lower counter, the upper counter will likewise be described at the middle line.

Having the upper and lower counters drawn at the middle line, the upper part of the stern-timber is straight above the upper counter, and must be drawn as follows:

Set up 23 feet 8 inches, upon a perpendicular 14 feet abaft the aft-side of the wing-transom, as before, and then drawing a straight line from the knuckle of the upper counter, to pass through the said point, the upper part of the stern-timber will be shewn at the middle line, by which the rake of the stern will be described.

As the stern rounds two ways, both up and aft, (or forward from the timber already drawn,) the stern-timber at the side must alter so much from that at the middle line, and therefore remains to be represented. Set down from the knuckle of the upper counter on its perpendicular 9 inches, and draw an horizontal line before it at that place, and set off thereon 15 inches from the said perpendicular, which will be the knuckle of the upper counter at the side the 9 inches is the round-up, and the 16 inches the round- aft at the upper counter. Then proceed in like manner for the lower counter, by setting down 9 inches, and forward 15 inches, and the knuckle for the lower counter at the side will be produced; then, by drawing a curve from the knuckles at the side (similar to the curve or hollow at the middle line), observing the lower counter at the side is drawn to intersect the touch of the wing-transom at the side, the side stern-timber only wants the upper part to complete it. But as the straight line, which remains to be drawn for the upper part of the side-timber, should not be parallel to that at the middle line, the following method will determine the exact rake thereof.

Draw a straight line at pleasure, as the tacked line under the body-plan, on which set off the breadth of the stern at the upper counter, or 13 feet 4 inches, equally on each side of the middle line; and there figure up a perpendicular on each side: set up from the straight line 16 inches, the round-aft of the upper counter on each perpendicular, and draw a segment of a circle that shall intersect those spots and the straight line at the middle, and the round-aft of the stern will be described at any part of the breadth above the upper counter; thus, take the breadth of the item at the top timber-line, which is 24 feet 8 inches above the wing-transom, which is 24 feet, and set it off equally on each side the middle, to where it shall intersect the round-aft under the body-plan; thence draw a line parallel to that first drawn, and the distance between the two lines, 13 inches, is the
distance that the side-timber will be from the middle-timber: on an horizontal line, at the height of the top timber-line, draw a straight line through the last spot set off to intersect the knuckle of the upper counter at the side, and that will be the rake of the side counter-timber, as shewn by the ticked lines in the sheer-plan, Plate I.

The rake of the stern-timbers being determined, proceed to finish the decks. Set up from the upper side of the upper deck 6 feet 10 inches at the middle stern-timber, and 6 feet 8 inches fore part at frame 8, and above that 3 inches, drawing curves as before, and the quarter-deck at the middle line will be represented.

Proceed in the same manner with the round-house abaft. Set up from the upper side of the quarter-deck 6 feet 8 inches at the middle stern-timber, and 6 feet 6 inches at fore part or frame 2, and above that 2 1/2 inches. The forecastle forward is represented in the same way, by drawing curves, one parallel to the upper side of the upper deck 6 feet 7 inches above it, and another at 3 inches from the beak-head to frame D.

All the decks having been drawn, representing their heights at the middle line, their heights at the sides differ from the former, agreeable to the round of the beam in the breadth of the ship: to do which correctly, take the round-up of the beam of its respective deck, say the gun-deck, 6 inches, and set it up in the middle of any straight line, to that the half-breadth in midships at the height of the gun-deck may be set off on each side of the line. Then raise the segment of a circle that shall intersect the round-up at the middle, with the spots at the breadth, and the round-up of the deck will be described at any part of its breadth. Thus, take the half-breadth at the height of the deck at any timber in the body-plan, and set it off equally from the middle of the round-up till it intersects the curve; whence draw a line parallel to that first drawn, and the distance between the last line to the round-up in the middle is what the beam rounds at that place: thus may the round-up be taken at as many timbers as may be found necessary, and set below the side of the deck, at its respective timber in the sheer-plan; then a curved line passing through those spots, will represent the deck at the side but observe, that the decks are to have a sufficient round about, to correspond with the round-up of the stern above the lights, and that the additional round wanted to be set down at the side line.

The sheer or top timber-line may be next drawn, by letting up its height in the sheer-plan above in midships, and abaft: thus, at timber X forwards, 37 feet 8 inches; at midships, 35 feet 4 inches; and at the stern-timber abaft, 41 feet 6 inches; then, by drawing a curve through those spots, as in Plate I. the sheer of the ship, or top-timber line, will be represented.

The ports may now be drawn in the sheer-plan, thus: draw two curves in pencil parallel to the deck at the side, fore and aft, adding the thickness of the deck to that already drawn, as that represents the under side of the deck, or upper side of the beam. The gun-deck ports are to be 2 feet 4 inches from the upper side of the gun-deck plank to the upper side of the lower fills, 2 feet 8 inches deep, and 3 feet 5 inches fore and aft, or from the fore to the after fills, which may now be squared up between the lines last drawn; placing the fore-side of the foremost port 1 foot 5 inches abaft timber X, and 3 feet 1 inch only off athwartship line; the aft-side of the after-port to be 14 inches abaft timber 32, and the fore-side 3 feet 5 inches fore it, or in the clear; and the remaining 13 to be 7 feet 7 inches slunder. In the same manner draw in the upper deck ports, which
SHIP-BUILDING.

which are from the planks to the port-half 1 foot 11 inches, 2 feet 8 inches deep, and fore and aft 3 feet; and are to be placed equally between and over the gun-deck ports, as circumstances will admit, as shewn in the fore-forecastle, Plate 1. The ports on the quarter-deck, round-housetop, and forecastle, must be placed hereafter where there is a vacancy between the dead-eyes to admit of them, observing to place them as nearly as possible at equal distances.

To know the heights, round-up, &c. &c. of the other decks, take them with compasses, in like manner as the gun-deck was set off from the given dimensions; and by applying them to the scale of feet, much repetition will be avoided.

The round-housetop being drawn, draw a line parallel to the top timber-line, and another line three inches above it, which is the thickness of the planks upper; corresponding with the fore part of the round-housetop, so as to make both planks water and set the same, so will the extreme height of the top-sides be obtained abaft: the plank-shelf, which completes the height of the side to the fore part of the quarter-deck, is four feet four inches to the under side above the top timber-line, and parallel thereto. The fore part abreast the main-mast hances down eleven inches for seven feet abaft the ganway or fore part of the quarter-deck.

The drift-rail may now be drawn, the side of which is two feet ten inches above the top timber-line, and parallel thereto from the hinge of the plank-shelf at the main-mast to the quarter-galleria. The drift-rail is four and a half inches deep, and drawn parallel to the under side last drawn, and hances as the plank-shelf abreast the main-mast, and stops with a scroll upon the foresheet at the ganway. The sheet-rail may next be drawn: it is six inches deep, and parallel to the top timber-line from the cat-head to the quarter-galleria. The plank-shelf and sheet-rail at the fore part of the ship delineate the height of the top-side there below: the under side of the plank-shelf is two feet nine inches above the top timber-line, and the under side of the drift-rail one foot eight inches, and turns off with scrolls at the after part of the forecastle, but in other respects the same as those at the quarter-deck.

It is the practice in the navy of late years, to have square drifts instead of scrolls or hances of any kind.

The upper part of the ship being thus far complete, we have at one view the utmost extent of the sheer, as seen on a plane.

It now remains to be drawn in the finishing parts, as the wales, flem, head, rails, &c.

Proceed to represent the main wales by setting up their lower edge, at the rabbit of the flem or fore part, above the upper edge of the keel 22 feet 6 inches, in midship or dead-flat 18 feet 8 inches, and at timber 34, 23 feet, and draw the curve as in sheet-rail, Plate 1. Above that, and parallel thereto, draw another curve at 4 feet 4 inches, the breadth of the main wales.

Next draw in the channel wales, let up as before, at the rabbit of the flem 30 feet 2 inches, in midship 27 feet 3 inches, and at timber 34, 31 feet 6 inches. Set up their breadth 3 feet, and draw curves as in sheet-rail, Plate 1.

The wait-rail may now be drawn: its distance below the top timber-line is one foot ten inches, the upper side and its depth six inches, and it is drawn parallel to the top timber-line from fore and aft.

Now, before the channels and dead-eyes can be drawn, the centres and raking of the masts must be determined; their centres on the gun-deck being fixed upon in proportion to the length of the gun-deck, thus: the centre of the main-mast 21 feet 4 inches abaft the aft-side of the flem, or half its diameter before the one-third of the length on the gun-deck: the centre of the main-mast 101 feet 4 inches abaft the aft-side of the flem, or half its diameter before the five-ninths of the length of the gun-deck; and the centre of the mizen-mast 27 feet before the rabbit of the flem-mast, or half its diameter before the one-seventh of the length of the gun-deck. The centre being fixed, the fore-mast rakes 49 or inclines from a perpendicular with the keel one-eighth of an inch in every yard of its length; the main-mast rakes 49 one inch in every yard in the length; and the mizen-mast one inch and a half in every yard of its length, as drawn in the fore-forecastle, Plate 1.

Now draw the channels, placing their upper edges next the side in a line with the upper edge of the sheet-rail; or, which is much better, since the rails on the side are discontinued, rather lower down, clear of the beam. The fore channel to be 36 feet long, and so placed as to take the anchor-lining and bill-board for flowing the anchor at its end, thus: get the length of the anchor to the bill, or extent of the arm, and allow for the cat-block; then with that distance sweep upwards from the channel to the channel, from the outer end of the cat-head nearly, and the curve that the bill of the anchor is supposed to make, will give the middle of the line: the aft-side from the channel may be perpendicular, and the fore part follow the curve made by the anchor. The bill-board may then be carried upwards from the upper side of the channel to the top of the side. The anchor-lining commences at the upper side of the boltler, which rests on the channel-wale, and is long enough at the fore part for a man to land upon.

The main channel is 29 feet 6 inches long, placed in the same range as the fore channel, and its fore-end before the centre of the main about six inches.

The mizen channel is 16 feet 4 inches long, placed like the former, but is more convenient when placed, as it now is, above the quarter-deck ports.

The dead-eyes may now be drawn, observing to place them in such a manner that the chains may be sufficiently clear of the ports. All the preventer-plates must be so placed on the channel-wales, and of such a length, that the centre of the chain-bolt may come about six inches below the upper edge, and the preventer-bolt about four inches above the lower edge of the channel-wales. The dead-eyes in the main and fore channels are sixteen inches in diameter, and eleven in number in the fore and twelve in the main, though lately another is added in each. In the mizen are seven, of eleven inches diameter; the centre of the foremost dead-eye is placed at or just abaft the centre of the mast, and the centres of the others are spaced so as to clear each other about three inches, which will admit of four dead-eyes between each port. It must also be observed to give each of the chain and preventer-plates a proper rake; that is, to let them range in the direction of the shrouds, which may be done in the following manner: draw a pencil line upwards at the centre of each mast, upon which set off its length to the lower part of the head; then, by drawing straight lines from that height, through the centre of each dead-eye, the direction of each chain will be obtained by the direction of its corresponding line. The dead-eyes for the backstays are to be similar to the former, that it need only be observed, that for the raking of them, the height of the top-mast to its head must be added to the lower half, and that they are fixed at the after-end of the channel, or on foot, if need be, above the channels, as in sheet-rail, Plate 1.

The quarter-deck and forecastle ports can now be determined, as they must be placed clear of the shrouds, and equally alined, or nearly so, as circumstances will admit: thus, there are three on each side on the forecastle, made by
SHIP-BUILDING.

by the timber-heads there shewn, having also a timber-head between. But the practice now is to have a rail upon the heads of the timbers, and the sides birthed up on each side to the under side of the rail between the ports, and only three or four timber-heads run up, one in particular before the bill-board for the thonce-painter. On the quarter-deck are seven ports of a side, and four on the round-houle, placed as clear as possible of the shrouds, as shewn in sheer-plan, Plate I.

The cheek-tree for hauling home the main-tack must be placed near the after-end of the fore channel, or half the length of the main-yard before the centre of the main-malt, and drawn from the top of the side down to the upper edge of the channel-wale.

The leps on the side may next be drawn: they must be placed at the fore part of the main drift or gangway, about three feet in length, six inches aluder in the clear, and five inches deep; the upper lep to be eleven inches from the top of the side, continuing the others to the upper edge of the wale.

To complete the sheer-plan, the head and item only remain to be drawn, which are as useful as ornamental. Therefore we will proceed with the head, thus: draw the beak-head or its boundary aft, by raising a perpendicular fix feet abaft the aft-side of the item, at one foot eleven inches above the deck at the side, or draw an horizontal line at the same height as the upper deck port-fills; the horizontal is the flat of the beak-head, and the perpendicular continued up to the rail above the forecaftle, represents the fore part of the beak-head, and will likewise determine the foremost end of the forecaftle. Since Plate I. has been engraved, the beak-head in the navy seems to be done away, and the bow continued to the top of the side, as in the East India ship, Plate XII. It may be stronger thus, but the beakhead was very useful. Let 15 feet 6 inches, the length of the head, be set off from the fore part of the item, and there draw a perpendicular which will determine the fore part of the block or figure; draw another perpendicular at 5 feet 10 inches abaft the former, which is the moulded breadth of the figure, and boundary of the hair-bracket at the upper part. Before the height of the figure can be ascertained, the bowprit must be drawn, thus: set off 4 feet 6 inches at the side of the item, above the upper deck, for its middle line, and five or forty that line 5 inches or 5½ inches above an horizontal in every foot forward; then set off 1 foot ½ inches above and below this middle line, and draw lines parallel thereto, and the bowprit will be represented in the sheer-plan, Plate I. Now the upper part of the block for the figure can be determined, as that should be at least six inches clear of the under side of the bowprit, which should pass the under side of the foremost upper beam, and lep in the partners on the gun-deck a convenient height for the after part of the manger, as in the inboard works, Plate IV. of Ship-building.

The checks are next to be drawn: set up the height of the lower cheek, which is 25 feet at its under side, above the rabbet of the keel, and draw the after-end to the heeak, and the fore part with a handiome flight, so as to break in with the perpendicular at the fore part of the figure; then set up from the under side of the lower cheek, 3 feet 5 inches at the item for the under side of the upper cheek; draw the after-end rather more than the heeak, and the fore part with more flight than the lower cheek, so as to make a handiome curve line with the fore part of the hair-bracket. From the under side of the lower cheek, set up at the fore part of the item 7 feet 11 inches, which is the upper side of the upper rail, and draw the bag of it, or the part immediately before the item, nearly horizontal, or to the sheek of the flat of the beak-head, it agreeing to that height. The fore-end should curve upwards, so as to appear parallel with the upper cheek, or nearly so; and to form the after-end, draw a curve from the bag to break in fair with the beak-head line.

Now the moulding of the upper rail and siding of the cheeks may be drawn, and as they taper all their length regularly, set off 1 foot above the lower side at the after-end of the cheeks, which is 5 feet abaft the fore-side of the item on the sheek, and 7 inches at the fore-end, or about 8 feet 6 inches before the item. Then the moulding of the upper head-rail, which is 1 foot, must be set off abaft the beakhead line, or fore-side of the rail, and drawn parallel thereto from about 5 feet below its head, (which must range with the under side of the rail above the forecaftle, or fix inches higher than the range of the other timber-heads,) and from thence to taper to fix inches at the fore-end, which comes to the hair-bracket, which is a continuation of the upper cheek, and runs in a handiome serpentine line up the back of the figure, as high as where the shoulder of the figure is supposed to come; at which place it terminates with a scroll. The upper part of the figure or block of the figure to the top of the hair-bracket, observing to keep the upper part fix inches clear of the under side of the bowprit, as before observed.

The head-timbers may now be drawn, placing the item-timber its thickness, which is 7 inches, before the item, and to hand perpendicular from the upper side of the lower cheek to the under side of the upper rail. The foremost timber to be 8 feet before the item, and to hand parallel to the item-timber, or rake half its thickness at leaft, which is 2½ inches, which will produce a lighter appearance in the head; the middle timber is placed equally between the two former, and is fix inches thick. Another timber is sometimes placed abaft the item-timber, at the same distance as the one before it, the heel of it Reeping on the upper edge of the lower rail. The length of the block for the figure sometimes terminates by a perpendicular line at the heel of the foremost head-timber; the lower cheek ends there or is continued higher up the figure, and finishes with a scroll. The hair-bracket also continues down to the heel of the figure.

The head-timbers being drawn, the middle and lower rails may be drawn by dividing the space between the upper side of the upper cheek and under side of the upper rail equally at every head-timber; then drawing curves to pass through the moulding depth of each rail, equally fet off from the above spaces, which moulding depth is ½ inches at the item, and 4½ inches at the hair-bracket. The after-end of the lower rail may terminate where it touches the side. Before the rail above it can be finished, the cat-head must be drawn, letting it project from the aft-side of the upper part of the main or upper rail to rake forward, so as to stand square with the bow, or nearly so, and to rise upwards 5½ inches in every foot of its length, which is 8 feet 6 inches without the bow; observing that the under side is to say on the plank of the forecaftle at the side; the upper side may be drawn parallel to the under side at 1 foot ½ inches, its depth: the knee or supportor under the cat-head forms a fair curve to the after-end of the upper middle rail, as in sheer-draught, Plate I. The knee or supportor under the cat-head lately hangs perpendicularly, or nearly so, and the rail ends against the side.

The knee of the head may now be drawn; it is to project from the breast of the figure about four inches; thence draw
SHIP-BUILDING.

draw the fore part of the knee, with an agreeable serpen-
tine line to its breadth from the item, which should not ex-
tend two feet on a square at the load-water-line; then, by
continuing the same line downwards, narrowing more and
more till it approaches the grips, and drawing it more dif-
tant from the item, to about four feet in the broadest place,
let the lower part break in fair with the under side of
the falle keel, where it terminates with the fore foot or fore
part of the keel, which will be next described. The gam-
moning-holes come between the head-timbers, and the bob-
stay-holes at the fore part of the knee, and the hawse-holes
between the cheeks are to be 2 feet 6 inches up from the
deck, and 1 foot 3 inches in diameter, as shewn in the sheer-plan, Plate I. See Hawse-holes, hereafter described.

From the line representing the upper edge of the keel,
slet down 1 foot 6 inches, its depth, and draw a line parallel
to its upper edge the whole length, which is 1 foot 2 inches
before timber S, to the aft-side of the stern-poll, and the
lower edge of the keel will be repreffented; but to com-
plete the fore foot, which must be of a sufficient depth to
receive the lower part of the item, called the boxing, square
up the fore end of the keel from the under side to the fore-
side of the item, and from thence square it to the aft-side
of the item from its curve. The boxing, or lower part of the
item, may now be drawn: set aft from the line last squared
6 feet 6 inches, and draw a perpendicular to half the depth
of the keel, and from thence continue a line forward, parallel
to the lower edge of the keel, one-third the length of the
scarc, which will meet the fore-side of the item and
complete it.

The falle keel, which is six inches deep, may be drawn by
a line parallel to the under edge of the main-keel; the fore
end of it may continue about three inches before the main-
keel, or run through to the fore part of the gripe.

The sheer-draught being thus far completed forward, the
stern and quarters may be finished; and first draw a line
which shall represent the aft-side of the quarter-piece, agree-
able to the round-forward of the stern, which is 13 inches
before the fide stern-timber, on a square, and nearly parallel
thereto, continuing this line from the plank-flr to the lower
gallery rim, the upper side of which is, at the line last
drawn, 6 feet 5 inches above an horizontal line, at the upper
side of the wing-ram on the middle. (Observe, all the
heights of the stern will be set up above this line, for the
manner of obtaining which, with particular relative to
the stern, the reader is referred to the section Laying-
off the Stern, and Plate X.) At the height last set off,
draw the upper side of the rim forward parallel to the sheer
or top timber-line to 16 feet 6 inches, its length; then draw
another line parallel under it at 10 feet, its depth. The
height of the upper side of the rail at the middle floor is 11 feet
9 inches at the quarter-piece, which must also be drawn for-
ward parallel to the sheer to 16 feet 8 inches, its length; its
depth, which is 9'2 inches, drawn in as the middle rim. The
fore part of the quarter-piece may next be drawn, as the
heal of it steps on the after end of the middle floor, by
drawing a line parallel to the aft-side of 14 inches, its rinding.
Draw the middle rim-rail, as before directed, at 15 feet
3 inches, the height of the upper side at the fore-side of the
quarter-piece, to 12 feet 2 inches, its length. In the same
manner draw the upper floor-rail, its upper side being 19 feet
5 inches up at the quarter-piece, and its length forward
12 feet 8 inches. Above this rail is the upper finishing, the
upper rail of which ranges with the height of the plank-
flr, with another rail below it at 9 inches in the clear; the
upper rail may be about 3½ inches, and the other 4 inches.

The upper rail of the finishing is 2 feet 8 inches short of
the upper floor-rail, and finishes at the fore part, as in the
sheer-draught, Plate I. The boundary, or fore part of the
upper gallery, is 11 feet 7 inches on the run of the middle
rim; from thence a line is drawn upwards, parallel to the
quarter-piece. Between the middle floor-rail and the rim
above it, the fore part is completed by a curve. The length
or boundary of the lower gallery is 15 feet 6 inches on the
lower rim; from thence a line is drawn upwards, parallel to
the rake of the side stern-timber. Now the lights and
munions, which are three in each gallery, may be equally
paced; the lights in the lower gallery to be 2 feet 9 inches
in the clear on a square, and the munions about 11 inches
each; the lights in the upper gallery 2 feet 4 inches in the
clear on a square, and the munions about 9½ inches each;
observing to keep their lower sides up from the rail, about
5 inches the lower ones and 4 inches the upper ones for
the water-table, and their upper sides about 4 inches clear
of the under sides of the floor-rails above. Draw the
lower floor-rail along the quarter, which is a continuation
of the lower counter-rail, as the middle rim is of the upper
counter-rail, at the side of the quarter-piece, from whence
they are to be continued their length parallel to the sheer,
and that will be the height of thofe rails, as viewed on a
level. The height of the lower counter-rail, at the side
above, is 3 feet 4 inches, and from thence continued parallel
to the rim-rail above: to its length, which is 13 feet, set
down 10½ inches, its depth, and draw it parallel to the
upper side.

The lower finishing is 2 feet 3 inches deep below the
lower floor, and its boundary formed by curves, so as to
have a light airy appearance, with a floor nearly in the
middle of its depth.

The foot-space rail may be 9½ inches deep, and rabblets
on the ends of the flat of the quarter-deck. The breadth
rail is 9½ inches deep, and its upper side is 2 feet 2 inches
above and parallel to the other, both projecting 2 feet
6 inches on a square to the aft-side at the middle line from
the midship stern-timber. But to complete the balcony,
quarter-piece, and taffrail, as shown in the sheer-plan, the
reader is again referred to laying-off the stern, and Plate X.

The birthing of the lower counter may be represented by
drawing a curve 4 inches parallel abait the side of the
counter-timbers, from the keel to the tuck-rail, which
covers the margin on the wing-ram, and projects its
thickness 9½ inches. Draw likewise the birthing of the
upper counter, which is 23 inches thick, and parallel to
the stern-timbers. Above the upper counter-rail draw in the
thickness of the middle munion, which is 5 inches, and par-
allel to the middle stern-timber, and continued upwards to
the arch-board over the lights, which is about 4½ inches
deep.

The rudder may now be represented in the sheer-plan, ob-
serving, that the head is continued above the upper deck,
high enough to receive a tiller about four inches above the
deck; then allow for two hoops above the hole, making
the upper part of the head 2 feet 6 inches above the deck.
Continue upwards the side of the stern-poll, which repre-
sents the fore-side of the rudder, from whence its breadth
or side is set off; and as this should not be more nor less
than sufficient to direct the course of the ship, the com-
mon practice is to make the breadth at the heel, or lower
deck, one-eighth of the main breadth, which will be six feet
for ships having a clean run above, but for merchant-ships,
these constructed chiefly for burthen, it may be one-
eighth. The height of the lower lance may be fixed at
the load-water-line, or about six inches above it, and its
breadth there should be five-sevenths of the breadth at the
heel.
helel, back included; set forward from thence 10 inches, or reduce the breadth to 3 feet 5 inches. The upper hance may be at one-third the height of the lower hance, and the breadth of the rudder should be five-sevenths of the breadth at the lower hance, or 3 feet 1 inch; there reduce the breadth 5 inches, which makes it 2 feet 8 inches, from whence a straight line may be continued to the head, which is 2 feet 4 inches fore and aft, or larger, if the piece will admit of it: each hance should be reduced with mouldings, as in heer-draught, Plate I., and 3½ inches drawn parallel to the after-side, to represent the thickness of the back. The heel of the rudder, at the fore part, should be 9 inches short of the under side of the fallen keel, and 11 inches at the after-part, the foil included, which is 6 inches deep.

The pintoles and braces may be now represented, placing the upper brace about four inches above the wing-tranom, that the straps may clap round the standard on the gun-deck. The second brace should be placed so as to fasten on the middle of the gun-deck tranom. The lower brace may be placed 15 inches above the upper side of the keel, and the intermediate ones, four in number, to be equally placed between the two latter, making seven in all. The length of the braces may be governed by a straight line drawn from the third brace, which should be 4 feet 6 inches from the rabbet of the post to the lower one, which is to be fix feet.

The length of all the straps of the pintoles, which come up on the rudder immediately above the braces (except the thickness of the bar or fancies), may extend within four inches of the after-side; the pintoles are 3½ inches in diameter, and all 14 inches long, except the lower one, which is 2 inches longer. The straps of the braces and pintoles are five inches broad.

The length and breadth of the rudder being represented in the sheer-plan, Plate I., it is evident the breaks or hances are merely to reduce the breadth as it rises towards the head, the greatest breadth being only required below the water, where it feels the motion of the ship.

The fluid, in passing to the rudder, exactly follows the outlines of the bottom; and supposing the rudder to make an angle of 45 degrees with the keel, it may be readily seen, by the water-lines abaft in the half-breadth plan, that the immediate shock it receives from the water increases as it approaches to the load-water-line, where they become nearly at right angles with the side of the rudder in that position, and this holds good, whatever angle the rudder makes with the keel; hence some are of opinion, that the rudder should be made broader near the line of flotation, and narrower towards the keel; but the present method of making the rudder with increasing breadth downwards, is only in proportion to the obliquity of impulse the water acts against it near the keel. It must be observed, that the above force strikes the rudder obliquely, and only strikes it with that part of its motion which, according to the line of incidence, forces it in a contrary direction, with a momentum which not only depends on the velocity of the ship’s course, by which this current of water is produced, but also upon the extent of the line of incidence. This force is by conseqence composed of the square of the velocity with which the ship advances, and the square of the line of incidence, which will necessarily be greater or smaller according to circumstances; so that if the vessel increases her velocity three or four times faster, the absolute shock of the water upon the rudder will be nine or sixteen times stronger, under the same incidence; and if the incidence is increased, it will yet be augmented in a greater proportion, because the square of the line of incidence is more enlarged.

Amongst the several angles that the rudder makes with the keel, there is always one position more favourable than any of the others, as it more readily produces the desired effect of turning the ship, in order to change her course.

If the angle of the rudder with the keel is greater than 45 degrees, the action of the water upon the rudder will increase, and at the same time oppose the course of the ship in a greater degree; because the angle of incidence will be more open, so as to present a greater surface to the shock of the water, and by consequence will only receive a feeble effort. Thus it appears, that between the effects which result from the water’s absolute force, there is one which always opposes the ship’s course, and contributes less to her motion of turning, whilst the other produces only this movement of rotation, without operating to retard her velocity. Hence we may conclude, that when the water either strikes the rudder too directly, or too obliquely, it loses a great deal of the effect it ought to produce. Between the two extremes there is, therefore, a mean position, which is the most favourable to its operation, viz. the angle 45°, or between that and 42 degrees. See Watson’s Euler, p. 130. See also RUDDER.

It is evident, that the fore part of the rudder, as high up as the head of the post, mull be trimmed on each side, to the middle of its thickness, (which is the same thickness as the after-side of the stern-poll, or rather less, as it not need project the poll when the helm is hard over,) to the greatest angle the rudder is proposed to make with the keel; however, the common method is to set off two-fifths the thickness of the rudder from the fore part on each side, and from thence trim it straight through to the middle of its thickness, or, what is better, to leave the middle to the convexity of the pintoles, rather than a sharp edge. By this method the rudder may be put over to the angle of 50 degrees, which is more than is necessary, and it is very seldom that the rudder, owing to its length, can be put over so far to the side as to allow of the rudder making an angle of more than 45 degrees, which angle is quite sufficient.

When the above angle, or what is technically called the boarding, is wholly taken from the fore part of the rudder, the main piece is very much wounded by letting on the upper pintoles; but this of late years has been greatly remedied, by taking half the boarding from the after-side of the stern-poll at the head, and from one to two inches on the heel; of course the rudder is bearded to much the less. This, also, will greatly affist the conversion of the stern-poll.

The boarding on the rudder is represented by the shading on the fore part of the rudder, and the boarding on the poll by the ticked line in sheer-plan, Plate I.

The rudder, which is represented in the sheer-draught, Plate I., and is as at present used in the navy, having its axis of rotation in the centre of its pintoles, which are parallel to the after-side of the stern-poll, causes a space, considerably greater than its transverse section, to be cut in the counter for the rudder to revolve in, which would be impervious to the waves, were it not defended by a coating of tarred canvas, nailed in such a manner to the rudder and counter, as to cover the whole space required. But the ill effects of having so large a space fo ill guarded, have proved very dangerous.

It was to remedy this defect that round-headed rudders of late years have been adopted in many merchant-ships, particularly
particularly those in the service of the East India Company.

The round-headed rudder is represented in the sheer-plan of the East India ship, Plate XII, which consists in making the upper part of the rudder above, and four inches below the hole in the counter, cylindrical, and giving that part, at the same time, a cast forward above the upper brace, so that the axis of rotation may by that means be the line passing, as usual, from the heel of the rudder to the upper brace, or that next below the counter, and from thence upwards through the axis of the cylindrical part, or head, in order that the transverse section at the counter may be a circle revolving upon its centre; in which case the space of half an inch is more than sufficient between the rudder and the counter, and consequently the necessity of a rudder-coat entirely done away. But as it was foreseen, that if the rudder was by any accident unhitched, this alteration might endanger the tearing away of the counter, the hole is made from two to four inches larger all round, according to the size of the ship, than the transverse section of the cylindrical part of the rudder, but that space is easily covered over with a wooden rim, about two inches thick, and of sufficient breadth to nail to the counter clear of the hole; this rim is fitted nearly close to the rudder, and is capable of withstanding the shock of the sea, but easily carried away with the rudder, leaving the counter, under such circumstances, in as safe a state as it would be, agreeable to the present form of making rudders in the navy.

It is easy to conceive that the braces cannot be carried up so high on the stern-post with a round-headed rudder, as in Plate I. But then the head is better formed, as it has a large bolt driven down through the centre, that traverses in a thick brass plate confined in a strong oak frame, fixed over the head.

It may also be readily seen, that to bring the axis of rotation through the centre of the rudder-head, it must cast so much forward, as was before observed, which requires a sudden bend between the upper brace and the counter; but to avoid this bend cutting away the main post too much at the head, a false post, sufficiently thick, is tabled or caulked to the aft-fide of the main post, as in Plate XII.

The body and half-breadth plans may now be completed, as it remains to add the supematent part, or top-fide.

Transfer the heights of the top timber-line from the sheer-plan, Plate I, to the body-plan, and draw an horizontal, at each height, across each respective body. Now the breadth of the ship at this height determines the tumbling-home of the top-fide, which should not be too much, as formerly, as it creates an unnecessary consumption of crooked or compas-timber, or an extravagant waste of large timber, which must be much weakened by being cut across the grain. Again, great advantages would be derived from having little or no tumbling-home to the fides, as it gives more room upon deck, a greater spread to the throuds, additional security to the masts, makes the ship lighter, a much better sea-boat, and in every respect safer, stronger, and better. On the contrary, it may be argued, that by the top-fide tumbling-home, particularly in ships of war, all the weight of guns, &c. lying above the load-water-line, may thereby be brought nearer to the middle line, when of course the ship he less strained by the working of her guns also; but others have endeavoured to prove, that by the weights being equal on both sides, they counterpoise each other, and do not strain the ship, whatever distance they may be removed from the middle line. Again, the top-fide narrowing or tumbling-home, as it approaches the top of the fide, particularly in ships having two or three gun-decks, the smoke of the lower guns in action less annoys those on the decks above.

In Plate I. the top-timber breadth in midship is four feet less than the main breadth, consequently the top-fide tumbles home two feet on each fide, and may be so continued in the half-breadth plan parallel to the main breadth, from frame 22 abaft to H forward; then from the middle line at K to the fide 2 feet 11 inches; at M, 21 feet 8 inches; at O, 21 feet 6 inches; at Q, 21 feet; at S, 20 feet 4 inches; at U, 19 feet; and at the beak-head, 17 feet: at 24, in the after body, 20 feet 7 inches; at 26, 20 feet; at 28, 19 feet 6 inches; at 30, 18 feet 9 inches; at 32, 18 feet; at 34, 17 feet 2 inches; at 36, 16 feet; then to end it abaft, square down to the half-breadth plan the intersection of the top timber-line at the fide counter-timber in the sheer-plan, and set up, as before, 12 feet. Then a fair curve-line drawn through these spots, represents the top-timber half-breadth.

Transfer the top-timber half-breadths from the halfbreadth plan to their corresponding horizontal lines at the top-timber-line from the middle line in the body-plan. Now the timbers may be formed above the lower height of breadth in the body-plan, thus; transfer the upper height of breadth-line from the sheer-plan to the body-plan, drawing thereat horizontal lines; then square up the timbers already drawn to intersect the upper height of breadth respectively; open the compasses to 15 feet, the length of the upper-breadth sweeps, and fix one foot on each line lat drawn; then from the lines, as squared up, describe an arc of a circle upwards at each timber; then draw at the curve to the hollow of the top fide, touching the back of the upperbreadth sweep, and the breadth at the top timber-line, thus; the timber at the top-fide is formed in midships, to which let a mould be made from the upper height of breadth upwards, continuing the same hollow of topfide one feet above the top-timber-line at which, by mould all the timbers of the top-fide, except two or three quite aft and forward, may be drawn, and both bodies completed to the top of the fide, by moving the mould at each timber gradually upwards, so as to make a fair line with the upper breadth sweep, touching the breadth at the top timber-line.

The foremost frames, as X, U, and S, towards the top of the fide, curve outwards, or the contrary way to those abaft them; because the breadth at the top timber-line projects the main breadth below, by which the anchor is hove up clear of the bow. From their breadth at the top timber-line, square up a perpendicular line to the top of the fide, which produces a sudden angle or knuckle at the top timber-line, from whence they are called knuckle-timbers.

From the sheer-plan transfer the heights of the top fide to their respective timbers in the body-plan, and draw a curve line through those heights, and the top of the fide will be represented in the body-plan. Then, to prove that the heads of the timbers make a fair longitudinal curve, transfer their half-breadths at the height of the top fide in the body-plan to their respective timbers in the half-breadth plan; that is, from frame D forward, and from 10 abaft; if they produce fair curves, the top of the fide is correct.

Now the side stern-timber may be drawn in the body-plan, thus: transfer the height of the wing-tranfom, lower counter, upper counter-knuckle, top timber-line, and top fide, from the side stern-timber in the sheer-plan to the after body-plan, and draw an horizontal line at each height; draw likewise two horizontal lines, equally spaced, between the wing-tranfom and lower counter-knuckle, and one equally between the upper counter-knuckle and the top timber-line. Transfer the half-breadths of the fix after-frames, where they are intersected by the above horizontal lines, to their corre-
corresponding timbers in the half-breadth plan, and draw curves through the above half-breaths, some distance abaat the after-frame; then square down where the several heights intersect the side stern-timber in the sheer-plan, to the half-breadth plan on the corresponding lines, and from thence transfer the several half-breaths to their corresponding heights on the body-plan; then, by drawing curves through those half-breaths, the side stern-timber will be represented.

The main half-breadth and top-timber half-breath lines may now be ended abaft in the half-breadth plan: thus, square down from the sheer-plan, where they intersect the side stern-timber, to their corresponding lines in the half-breadth plan; also, where they intersect the middle stern-timber in the sheer-plan, square them down to the middle line in the half-breadth plan; then, with a radius in the said middle line, sweep an arc of a circle to intersect the spots last squared down, which will represent the round-ast of the stern at the main half-breadth and top timber-lines in that direction.

In a similar manner may be drawn the round-up of the stern at the knuckles of the lower and upper counter in the body-plan, by transferring the heights of the lower and upper knuckles, at the middle stern-timber in the sheer-plan, to the middle line in the body-plan; their height at the side being let up before; then, with a radius from the middle line in the body-plan, sweep a segment of a circle to pass through each height, and the round-up of the stern, at each counter, will be represented as in the body-plan, Plate I.

**Apron, or Inner Stem, &c.**

The apron may now be drawn in the sheer-plan, by continuing a line parallel to the aflate of the stern, at twelve inches, its moulding from the head of the stern, to about seven feet abaft the boxing, by which it will give shift to the fcarfs of the stern as represented by the ticked line in the sheer-plan, Plate I.

The cutting-down, or height of the upper side of the floors in the main fore and aft, is represented by the ticked line at the following heights: viz., at 14; and from frame D to 8, 1 foot 10 inches; at F, 1 foot 10½ inches; at H, 2 feet 1½ inches; at K, 2 feet 2 inches; at M, 2 feet 5½ inches; at O, 2 feet 1½ inches; at S, 4 feet 6 inches; at U, 6 feet 6 inches; at 10, 1 foot 5 inches; at 12, 1 foot 11 inches; at 14, 2 feet; at 16, 2 feet 1 inch; at 18, 2 feet 2 inches; at 20, 2 feet 6 inches; at 22, 2 feet 10 inches; at 24, 3 feet 2 inches; at 26, 3 feet 10 inches; at 28, 4 feet 7 inches; at 30, 4 feet 11 inches; at 32, 7 feet 7 inches; at 34, 10 feet 1¼ inches, above the upper side of the keel: then a curve line drawn through those heights, will shew the cutting-down.

The depth of the keelson is also represented by a line eighteen inches above, and parallel to the cutting-down, into which forward is scarfed the stem, which is continued upwards to the under side of the gun-deck hook, and nearly parallel to the apron, it being ten inches moulded at the head. The after-end of the keelson is completed by the sternon-knee, which scars into the keelson, and runs up the fore side of the transom to the under side of the carving under the gun-deck beams, as shewn in the sheer-plan, Plate I. Sometimes a knee is introduced in the dead-wood, as shewn in the sheer-plan, which fays against the inner post, which is fifteen inches moulded at the heel, and one foot at the head at the under side of the gun-deck transom.

**Nature and Use of the Timbers, when canted.**

Hitherto we have considered the timbers as having their planes athwartships, or at right angles, square to the keel, and have consequently called them square-timbers. The cant-timbers have their planes inclined forward from the keel in the fore-body, and the contrary way, or ast, in the after-body, or canted, as shipwrights term it.

That the reader may clearly understand the nature of the cant-timbers, observe in the half-breadth plan, Plate I., where the joint of cant-timber U intersects the middle line; at which place suppose it hung on a hinge, moving fore and aft; and also imagine the line drawn for the cant-timbers on the half-breadth plan to represent the upper edge of a surface, of a sufficient breadth to form the shape of the said cant-timber from the middle line in the body-plan; supposing the horizontal view of that surface to be represented by that one line. It immediately follows, that the surface will find an perpendicular to the upper edge of the keel, similar to a door swinging on its hinges; and, if we draw the moulding of the cant-timber, according to what is laid off in Plate VII., fig. 3., upon this surface, from the keel to the top of the line (not moving its position), and then cut it out, we shall have the true position of the cant-timber, as in its place on the ship, which will find an perpendicular direction; we may also, supposing it to be hung, fixing it or cant it either forward or ast, and it will still maintain its perpendicularity with respect to the keel.

The canting of the timbers is of great utility, as it affords the conversion of the timber, and likewise greatly contributes to the strength of the ship in the fore and after parts. For in the first place, were all the timbers of the bow and buttock to be continued square, as those of the square body, though the scantlings of the square timbers on a square should be equal to the scantlings of the timbers, if canted, yet the camber of the bow and buttock-timbers would be so great, that the consumption, in some places, in order to get the timbers clear of faire, would be greater by one half than that in the timbers when canted. And, exceedingly, by canting the timbers gradually from athwartship line, we thereby bring each timber nearer to a square with the planks of the bottom, which is not only the best position to receive the fastenings of the planks, &c., but the timbers are also better able to bear those fastenings.

We may now proceed to cants to the timbers of the forebody, so that they may lind as square to the curvature of the bow as possible; which will not only lessen the bevelling, but will very much straighten the moulding of the timbers; by which means they will be much stronger, not so liable to be grain-cut, and leaving less compass, the conversion will be greatly simplified.

Therefore determine on the cant of the forenoon timber, which is y, by letting four forward two feet one inch on the norh of the main half-breadth line before the perpendicular of X, and its heel nine inches abaft the perpendicular of U on the flepping-line, which is three inches nearer the middle line than the bearding, or half-thickness of the dead-wood, and draw the ticked line marked cy in the half-breadth plan, Plate I. The after cant-timber of the forebody may be before the forenoon square timber O two feet nine inches on the main half-breadth line, and the heel on the flepping-line two feet five inches before O, on the ticked line marked cp, drawn as before; then may the intermediate canttimbers cg, go, e, c, e, e, c, c, c, e, c, e, be drawn, with their joints to intersect their respective perpendiculars as far as U, at the main-breadth line: then ec and eg equally between ec and cy; draw the ticked lines representing each cant-timber from thence to their heels, which are all equally spaced on the flepping-line, between cp and cy.

The **Hawse-pieces can now be determined on and drawn in the**
SHIP-BUILDING.

the half-breadth plan, the sides of which may stand parallel with the middle line, or canted square with the bow, which will lessen their heels and bevelings, and affilt their conversion, as before observed, by the cant-timbers; their number may be four, besides the knight-head, which comes next the item, unless the apron is fized more than the item, which cannot be the case when the rabbit is in the middle; as that has now become general, a filling about fix inches fized is fayed next the item, which makes it unnecessary to call the knight-head again the item to receive the bow-spirit. In the half-breadth plan, Plate 1., the knight-head is drawn next the item, therefore let off from the item one foot four inches, its fiding at the top-timber line or head; before cant 3, is introduced a short timber, which shortens the heel of the knight-head and hawse-pieces, not that the heels are expected to be gotten fo low down as to fay against it, for if the knight-head runs down low enough to take a bolt through the gun-deck hook, it is reckoned fufficient, the remainder being made good with a chock. From the item, at the timber or timbers before cant 3, let up the fiding of the heel, which is thirteen inches. In the fame manner let off the fiding of the hawse-pieces, four in number, from each other, as they岙afee together, in wake of the hawse-holes; that is, 18 inches at the head for the firft hawse-piece, 17 inches for the head of the fecound and third, and 18 inches for the fourth; and the fiding at the heels to be all alike 13 inches, as in the half-breadth plan, Plate 1.

The hawse-holes may now be drawn, which fhou’d be fo fized as to wound the hawse-pieces as little as poftible; they may therefore be placed fo that the middle or centre of the midship-hole may come in the joint of the firft and second hawse-pieces, and that of the outer hole in the joint of the third and fourth hawse-pieces. The holes to be in diameter, after the holes are let out, 17 inches, and in dilance from each other on a fquare 18 inches, to which lines may be drawn in the half-breadth plan to extend from the thick-ness of the outufide to the infide plank, and in a fore and aft direction, fo as to crofs the middle line of the gun-deck at the main-mall. Sometimes, to avoid wounding the hawse-pieces too much, middle pieces are introduced in wake of the holes fided, about fix inches lefs than the diameter of the holes; then, by cutting three inches on the fides of the hawse-pieces between the holes, those hawse-pieces become confequently more fided, and are wounded proportionally, but little.

The hawse-holes may now be reprefented in the feer-plan, thus; let up their height above the gun-deck, which is two feet eight inches, to their under fides, then their diameter above that, which will be clear of the clamps above; then, with a proper flive outwards, we fhall find them about fix inches above the upper fide of the lower check, which will leave a fufficient fubftance of bulter under the hole for the wear of the cable. Square up, from the half-breadth plan, where the holes interfet the infide and outufide plank at the main half-breadth line, that being very near their height; then by drawing lines to their five parallel to their depth, they will be reprefented as the dotted lines in the feer-plan, Plate 1.; but fo continue them to the outufide of the bulter, as the fided holes in the feer-plan are, square up from the half-breadth plan, where they interfet the fore paf part of the check.

The cant-timbers in the after-body may now be drawn, and every part depending on them; in order to which we must firft determine on the cant of the fashion-piece; therefore, having the round-af of the wing-tranfom reprefented in the half-breadth plan, and likewise an horizontal line at the height of the wing-tranfom, let off fifteen inches, its moulded breadth, at the fide on the horizontal line, which is the fization of the aft-line of the fashion-piece; then, to determine on the cant of it, the shape of the body must be considered, for the more it is canted the ftraighter will be the timber, and square with the plank of the buttock, confequently stronger and much eafier obtained.

Therefore, let the heel of the fashion-piece at the aft-line be nine inches on the flepping-line in the half-breadth plan before perpendicular 34, and drawing a ftraight line from thence to the fore-line of the wing-tranfom, as above, the cant of the fashion-piece will be defcribed, and will be found situated in the bell manner poftible to afwer the before-mentioned purprofes.

The cant of the fashion-piece being reprefented, the cant of the timbers before it may be easily determined; let 29 be the foremoft cant-timber in the after-body, which, on the main half-breadth line, may be equally fpaced between the after square-timber 28, and the perpendicular 30, and its heel on the flepping-line be one foot nine inches abaf 28, drawing a ftraight line, as before; the other cant-timbers between 29 and the fashion-piece, which are e 30, e 31, e 32, e 33, e 34, e 35, and e 36, may be equally fpaced on the flepping-line at the heels, likewise on the main half-breadth line, drawing ftraight lines as before, which will infi- fect their perpendiculars as far aft as 34, on the main half-breadth line; thus the cant-timbers in the after-body will be reprefented as in the half-breadth plan, Plate 1.

The line drawn for the cant of the fashion-piece repre- fents the aft-line of it, as before observed, which lets on to the ends of the tranfoms; but, in order to affilt the conversion with regard to the lower tranfoms, there may be two more fashion-pieces abaf the former; therefore the foremoft fashion-piece, or that which is already drawn in the half- breadth plan, only takes the ends of the three upper tranfoms, which are the wing, filling, and leg tranfoms; the middle fashion-piece takes the three next, and the after fashion-piece the three lower ones; therefore let off in the half-breadth the fiding of the middle and after fashion-pieces, which is 12 inches each; then draw lines parallel to the foremoft fashion-piece at the fiders, and the middle and after fashion- pieces will be reprefented in the half-breadth plan.

The fashion-pieces and tranfoms may now be reprefented in the feer-plan, as the thwartship appearance of the fashion-pieces limits the length of the tranfoms as they ap- pear therein; square up from the half-breadth plan, where the fashion-pieces there interfet the flepping, the horizontal or water-lines to their repective water or horizontal lines, and flepping-line, in the feer-plan; but as the foremoft fashion-piece runs up three or more feet, if to be gotten above the wing-tranfom, an horizontal line at the head, and three more between that and the load-water-line, should be drawn from the body to the half-breadth plan, in pencil, as they may be rubbed out afterwards, and the interfetion of the fashion- pieces squared up as before; then curves drawn through the spots as squared up will reprefent the thwartship appear- ance of the fashion-pieces in the feer-plan, as in Plate 1.

The height and fiding of all the tranfoms may now be drawn in the feer-plan, thus; let down 13 inches below the horizontal line representing the upper fide of the wing- tranfom already drawn, and draw a line parallel thereto, which will fhew the fiding or under fide of the wing-tranfom as far forward as the fashion-piece.

The filling-tranfom is the next, which nearly fills up the vacancy between the under fide of the wing-tranfom and upper fide of the gun-deck plank, and may be reprefented by drawing two parallel lines under the wing-tranfom to its fiding, which may be ten inches, if it will allow two inches between
between its upper side and the lower side of the wing-transom, and
four inches from its lower side and the gun-deck plank.
The deck-transom must be governed by the gun-deck, let-
ing the under side of the gun-deck plank represent the up-
per side of it; draw another line at fourteen inches, its fiding
parallel to the upper side, which will complete the gun-deck
transom. The transoms below the gun-deck, which are fix
in number, are all eleven inches fided, and are represented by
drawing horizontal lines from the fore-side of the rabbit of
the stern-post; the three upper ones to the middle fashion-
piece, and the lower three to the after fashion-piece, keeping
each of them about three inches afther for a free circulation
of air. Every means should be taken to preserve them, as
they are more difficult to shift than any timbers in the ship.
The stern-post may now be completed, by drawing the
fore-side thus; set forward upon the upper side of the keel
three feet from the line, representing its aft-side, and likewise
twenty inches at the head, which may be three feet above
the wing-transom, which will admit of the tiller to be three
inches clear of the helm-port transom, and two inches from
the under side of the beams above; then a straight line drawn
from the heel to the head to the dimensions set off, will
represent the fore-side, observing not to draw the fore-side
of the post through the transoms.

The inner post may be drawn by setting off before the
main post sixteen inches, its size at the upper edge of the
keel, and thirteen inches at the head, which comes no higher
than the under side of the gun-deck transom; then, by draw-
ing a line, as before, for the fore-side of the main post, the
inner post will be represented as in the hear-plan, Plate I.

To Define the Perpendicular View of the Stern.

In designing the perpendicular view of the stern, there will
be an opportunity of seeing whether the knuckles of the
counters are disposed, that the lower and second counters
are in proportion to the rail of the stern; at the same time,
whether the heights of the decks, which, in the present
draught, Plate I. are sprung shaft sufficiently to give depth
to the lights, as well as for other conveniences to make a
well-proportioned stern.

Draw an horizontal line at the upper side of the wing-
transom at the middle line, in the hear-plan, body-plan, and
likewise for the stern underneath the body-plan, as the basis
of the stern, from which all the heights will be set up or
transferred. Continue down thereon the middle line of the
stern from the body-plan, and drop perpendiculars from the
knuckles of the side counter-timer in the body-plan, to the
base line in the plan of the stern, and then draw the side
counter-timer on each side of the middle line, the same as in
the body-plan above, and the round-up of the upper and lower
counter at the knuckles of each timber. Having the form
of the side counter-timers in the plan of the stern, set
within them the scantling of the timber, and draw their
infillides.
The lower and upper counter-rails being drawn in hear-
plan, try if the under sides at the midship-timer project
enough to bury their respective counter-planks, thus; square
aft a line from each counter at the knuckle, and on those
lines set aft from the knuckle the thickness of the counter-
plank, say three inches at the lower counter, and one quarter
more, that the moulding may not come to a sharp edge.
The lower counter-plank may be increased to four inches,
it general thickness. Proceed in the same manner with the
upper counter, its birthing being two and half inches thick.
This will shew how much the fight-part of the rails will be
on a level view below the knuckles of the timbers. Then
transfer their height to the plan of the stern at the middle,
and keep them parallel to the knuckles to the outside, suffi-
cient for the projection of the quarter-galleries, as in plan
of the stern, Plate I.

Take the height of the under side of the quarter-deck at
the aft part of the middle stern-timber in the hear-plan, and
set it up in the plan of the stern at the middle line; then
round the quarter-deck in the stern, agreeable to the upper
counter-rail, in the following manner; take the height from
the upper counter-rail, in the plan of the stern, to the quar-
ter-deck at the middle line, and set it off in the direction of
the side-timber at the inside. This makes the quarter-deck
round more than the upper counter-rail, and adds life to the
stern; for the upper part of the lights in the stern should be
parallel to the transom. As, if they were to round by the
fame mould as the upper counter-rail, the bars in the fashes
next the side would be longer than those in the middle line,
and would appear as if the top of the lights rounded less
than the upper counter-rail. Draw in the upper part of the
lights about an inch and half below the under side of the
quarter-deck transom, and their lower part about six inches
above, and parallel to the upper counter-rail, which will
allow sufficient depth for the water-table. Set off within-
side the stern-timbers, in the plan of the stern, the thickness
of the clamps, and the projection of the cornice in the cabin,
and let that be the side of the lights.

Then determine on the breadth of the murons, allowing
sufficient for the weights and pulley-pieces, and divide the
fashes, fix is number, equally.

Now, as well-proportioned lights are great ornaments in
sterns, having the breadth of the lower part of the lights in
the clear, let their depth be at least one-third more than the
fated breadth; set off upon the rake of the stern-timbers, in
the hear-plan, and transfer that to the plan of the stern,
which makes a good proportioned light. Set off likewise
the mock-light in the aft part of the quarter-gallery the
fame size as the ruff.

Then to rake the fashes regularly from the middle to the
fides, continue upwards the middle line and the outside of
the side ftern-timbers in the plan of the stern, till they interflect
at the said middle line; then from their spacings at the lower
part, the fides of the lights may be drawn to their heads, or
upper part, with a straight batten fixed at the intersection of
the middle line. In the same manner may all the interme-
diate stern-timbers be drawn to their fiding in the middle of
each muron from the wing-transom to the under side of the
quarter-deck, likewise the shorter ones that make the side of
the counter-ports, and those under the middle of the lights
to the upper counter-rail. At about half the breadth of the
murons from the mock-light, place the inside of the quarter-
piece; then set off at the heel sixteen inches, its moulded
breadth, and continue upwards the outside of the quarter-
piece, as before, for the lights. In the middle of the quarter-
piece, or nearly so, place the outside of the gallery, which
determines the projection of the gallery from the side.

Draw in the plan of the stern the foot-space rail, its under
side to be about an inch and a half below the aft part of the
quarter-deck, and parallel thereto to the outside of the
quarter-piece; likewise draw the brest-rail, transferring its
height from the hear-plan at the after-part, and set it up at
the middle line as in the plan of the stern, and rounding it, as
defscribed for the quarter-deck, to the inside of the quarter-
piece. Then let the round-house deck be drawn in the plan
of the stern as directed for the quarter-deck, when will de-
terline the lower part of the taffrail, as the necking-moulding
should be kept an inch and a quarter below the round-house
transom. Then may the boundary, or upper part of the
taffrail and quarter-pieces, be finished as in the plan of the
stern.
In the starboard quarter-piece is designed the aft part of the gallery, which is at the middle of the quarter-piece in the sheer-plan; therefore it will be proper to draw the form of the middle of the quarter-piece, and the fore-side of the taffrail, upon the sheer-plan. Thus, take the heights from the level line at the upper side of the wing-remainder in the plan of the stern, to the lower part of the quarter-piece, or upper side of the upper counter-rail, and likewise in as many places as may be found necessary, to get the exact form, and set them up in the sheer-plan, drawing level lines. Square up the spots on the quarter-piece and taffrail to the round-oft of the stern on a level; then take what the round gives at each spot squared up, and set it off from the midship stern-timber on their corresponding level lines in the sheer-plan. This produces the ticked line that was drawn in pencil in the sheer-plan, shewing the middle of the quarter-piece and fore-side of the taffrail. Take the side of the taffrail, and draw the aft-side of the taffrail and quarter-piece parallel to the middle line of the quarter-piece, and fore-side of the taffrail, and draw likewise the fore-side of the quarter-piece parallel to the middle. By the same method, prove the thwartship view in the sheer-plan of the lower side of the taffrail, and inside of the quarter-piece.

Take the height in the plan of the stern of the upper counter-rail at the outer part, and set it up in the sheer-plan, drawing a level line. But to find how much the after-end of the rail will be before the knob of the upper counter at the side-timber, the round-oft of the upper counter-rail must be laid down on a level, as in the half-breadth plan; transfer the outer end of the said rail square from the middle line in the plan of the stern, on to the round-oft from the middle line in the half-breadth plan; then square it up to the sheer-plan, on the level line last drawn. Design the lower gallery rim, with the lights and mummies, as in the half-breadth plan, which is a continuation of the upper counter-rail, and this will determine the length of the gallery in the sheer-plan. Take the height in the plan of the stern to the foot-space rail, at the outside of the quarter-piece, and transfer it to the aft-side of the quarter-piece in the sheer-plan. Take likewise the upper and lower part of the lights in the plan of the stern, at the birthing of the outside of the gallery, and set them up in the sheer-plan, at the ticked line, for the middle of the quarter-piece. Design the lower finishing as in the plan of the stern, and transfer the height and round-oft of the lower counter-rail, as before described, at its outer end, and then draw all the rails and lights, as set up in the sheer-plan, from thence forward, agreeable to the sheer of the ship, to their boundary, or fore part of the quarter-gallery.

Lastly, the upper finishing being designed in the sheer-plan, transfer their heights, and complete the quarter-gallery, as drawn in the starboard quarter-piece in the plan of the stern, Plate I.: the aft-side of the rudder, counter-ports, and helm-port taffrail, may also be drawn.

To Design the Plan of the Head.

Continue forward the middle line of the half-breadth plan. Upon it square down the fore-side and aft-side of the figure from the sheer-plan, and upon those lines set off the half-finding of the figure.

Then draw the main rail to its half-breadth appearance, thus: set off the finding of the after-end of the main rail from the outside of the plank at the top-timber half-breadth, to the fore-side of the beak-head in the half-breadth plan; and also the finding of the fore-end from the outside of the figure, the fore-end being square down from the fore-part of the hair-bracket in the sheer-plan; observing, however, to add to the finding the thickness of the lining: then, by drawing straight lines to those spots, the half-breadth plan of the main rail will be represented as in Plate I.

Square down from the sheer-plan the head-timbers, where they interfect the under side of the main-rail, to the middle line of the half-breadth plan: likewise square down the fore and after-sides of the knight-head, and draw the half-breadth line at the upper side of the beak-head-flat, and the thickness of the outside plank.

Square up from the middle line in the half-breadth plan the head-beam, so as to let ait about two inches upon the stern; and square up likewise the cross-piece close to the aft-side of the foremost head-timber, to which and the head-beam the main rail is secured by knees on the aft-side.

Draw the moulding fize of the upper cheek as you see the ticked line in the half-breadth plan, then the half diameter of the bowfprit parallel to the middle line; and also the fore and aft carling as much without the bowfprit as the gammoning may lead down clear of the bowfprit, and outside of the upper cheek.

The feet of each, no less than two double ones, should be placed the most conveniently, as shown in the plan. The remaining space of the flat of the head may be composed of ledges; and, lastly, may be drawn the boomkins, which spread the fore-tack, thus: square down from the centre of the fore-mail from the sheer-plan to the middle line of the half-breadth plan, and from that intersection draw a line forward, to form an angle of thirty-fix degrees with the said middle line; and upon it set off half the length of the fore-yard; then draw in the boomkin parallel to the line representing the fore-yard braced up sharp, and it will come nearly over the middle head-timber on the main rail, its heel rolling against the knight-head; the length may be ascertained by a line drawn from the fore yard-arm at the outer end.

The round-hooves, or seats of each for the officers, are clearly shown in the plans of the upper deck and forecastle; which plans and draught of the inboard works will be designed hereafter, the sheer-draught plate being completed.

To Design the Disposition of the Frame. Plate II.

The utility of a plan of this description requires little explanation; as it is evident, upon inspection, that it exhibits the disposition and shift of every timber, and consequently affords the means of difposing of every piece to the greatest advantage, both with respect to the strength of the ship, and to the conversion of the timber; and, moreover, of preparing every piece for its proper situation, before the ship comes on the flocks, with the greatest facility.

The frame-timbers are formed into bends, as before observed, by the union of first futtocks, second or middle futtocks, third and fourth futtocks, with top-timbers, which are severally carved together and bolted. Sometimes the frames are fayed close together, or separated, for air; those that are separated have dry pieces of oak fayed between them in wake of the bolts; these should all be fplit out before the planking is brought on, that a free pafage may be given for the circulation of air.

By the disposition of the frames in their several flations, they fland respectively one on each side of every gun-deck port, by which the sides of every middle and upper deck port are likewise provided for. Thus, one fourth futtock and one long top-timber will form the side of every gun-deck port in two-decked ships, and the side of every upper deck port in three-decked ships. A long top-timber and a
fourth futtock will, in like manner, make the sides of the middle deck ports in three-decked ships, and the sides of the upper deck ports in those of two decks.

With respect to the frame-timbers, it is, in the first instance, of the greatest consequence to the strength of a ship, that they should be cut as little as possible by the ports on each deck, scuttles, scuppers, &c.; and, secondly, that all the timbers designed to make the sides of ports, are, or should be, continued, if possible, without scarring, up to the top of the side. Those timbers, however, in the sudden turn of the body, having so much compacts in their length, and others which run up to receive the rough-tree rail having too great a length to be otherwise obtained, must be admitted to scarfs, as shown in the disposition, Plate II.

Those timbers that run up to make the sides of quarter-deck ports, forecastle ports, or to the rough-tree rail, should, if possible, be made of timbers standing up on the upper deck fills, over the upper deck ports. The side along the wall, between the ports, may be filled in with fir timber, laid fore and aft, and dove-tailed into the frames.

All timbers in the range of the fore and main channels should run up to the top of the side; and the filling-timbers between each frame are all to be equally spaced between the frames; and all the openings between the range of the chain and preventer-bolts are to be filled in foldily with dry oak fillings, as are also those over every gun-deck and middle deck port, that there may be held boring in wake of the port-rope-pipes, and mumble-lashing eye-bolts; also behind iron knees and standards. But as fillings of this kind interrupt the free passage of the air, let a hole, one inch and upwards, be bored throughout their length. All fillings should be charred, or burnt.

All ships should be as light as possible in their upper works, consistently with the services for which they are intended; and, as the frame should not be incumbered with more short timbers than are absolutely necessary, two timbers over each point are sufficient. The frame will be adequately full, and every purpose answered, when timbers are provided to form the gallery doors, and to fill in the quarters from the after-frame to the fide timbers; and forward, from the foremost frame to the hawepieces.

Having considered the several subjects above-mentioned, transfer from the sheer-draught, Plate I., the keel, likewise the stem and stern-post, with the transoms, and flapping-line for the heels of the cant-timbers, the under side of the decks at the side, also the ports, the plank-sheers, rough-tree rails, and beak-head; then the side fide timber.

Square up from the half-breadth plan, Plate I., the joints and fillings of the cant-timbers, where they intersect the water-lines, main and top-breadths, and plank-sheer, to their respective lines in the sheer-plan, as Plate II. at 9, 8, in the fore-body, and at 1, 32 in the after-body. Thus may their thwartship appearance be transferred to the disposition, Plate II. In the same manner may be squared up the thwartship appearance of the knight-head and hawepieces, which may likewise be transferred as the rest, and also the hawef-holes.

The height of the heads of all the timbers may now be taken above the base line in the body-plan, Plate I., and transferred to their respective timbers above the upper edge of the keel, in Plate II. Curves being drawn through those heights, will show the head of each timber on a perpendicular view in the disposition.

Now square up in the disposition the fillings of all the timbers between the cant-bodies; and as the upper deck ports are left fore and aft than those of the gun-deck, the upper part of the frame-timbers must be opened for much from the joint. The frame-timbers may now be marked with their respective names, likewise the single timber dead-flat, where the body turns to shift the floors, as they are always under-bevelled.

The fore-fide, or moulding of the side stern-timbers, may be drawn, and the gallery doors from the sheer-plan, Plate I. Then the fills, and all the timbers necessary to frame the quarters afloat frame 36.

The parts being drawn, their fills may all be represented; making the upper fills in wake of the chain-bolts much deeper. Then the blocks through the side should be drawn, that the long timbers may not be provided, and afterwards cut afunder by these blocks; namely, the main tack-block between D and B, the fore sheet-block between 4 and 6, and the main sheet-block between 24 and 26.

The fourth futtock being the longest timbers in the ship, and from their shape, very difficult to be gotten of the whole length, especially for ships which have much tumbler-home, or even long enough to run up fo as to make the side of the upper deck ports, particularly forward and aft, the sides of such ports should have their fourth futtocks scarfed together with a hook and butt, as at fourth futtock 26 in the disposition, Plate II., giving shift to the port and each other; or, if preferred, the scarf sides, as represented at fourth futtock O.

The third futtock that come under the gun-deck ports, are to be continued upwards to the under side of the fill, as at D. But when the third futtocks, owing to their great compacts, cannot be gotten fo long, they may be scarfed, as at 4, observing always to get them longer than the regular shift.

The design of Plate II. is to have at one view every timber on one side the ship, that the utmost care may be taken to reduce every timber to the shortest length admirably as, in a disposition of this kind there is every opportunity of so doing; and likewise of pointing out and converting to the best advantage the most scarce and valuable timber.

The Design of Expanding the Bottom and Top-side. Plate III. The design of expanding the bottom and top-side, is to have the lengths and breadths of all the planks at one view, that the planking may be shifted agreeable to the lengths to be obtained, so as to run no hazard of beginning with a shift of planking that could not afterwards be continued. For the planking of a ship is a branch fo very material, that, unless it be judiciously performed, it will unavoidably be very injurious to, or subversive of, those good qualities that might be expected from the superior construction of the ship. The planking ought, therefore, to be particularly well performed: as, in the proper shifting, fastening, and caulking, the goodness of every part of the materials for that purpose should, consequently, be very carefully inspected.

The length of plank is a very great object to be considered; and, in the shifting, it is principally to be observed. For English plank it is allowed, and hath generally been found to answer, that if three whole planks be wrought between every two butts on the same timber, and all the planks to have a fix-feet shift, or be in distance from each other fix feet, the planks will only be twenty-four feet long: this shift is generally followed, excepting for the wales, &c. for ships of every clats in the royal navy. But as English oak-plank, having sufficient breadth at the tops in that length, has become exceedingly scarce, merchant-ships have the planks
SHIP-BUILDING.

Planks shifted of various lengths, according to their thickness; as two and a half and three-inch plank to have a fix-feet shift, and two planks between; and four-inch plank and upwards, to have a five-feet shift, and three planks between every two butts on the same timber. It is possible, however, to have a very bad shift, and yet have three strakes between every two butts on the same timber: that is, when the butts rise one above another in a regular manner, like steps; for, as the upper butts, or those in the top-side, are the most likely to give way, all below would be inclined to follow; as, if the ship begins to break her after amidship, it is most probable that the butts are of the same length; therefore, let one of the butts between have a double shift, or extend twelve feet; then will the stepping of the butts before mentioned be prevented, and the planks be twenty-four feet long.

The wales must be wrought of such length, and the butts shifted, so as to give the strongest shift to the ports and each other. To do this, some of the planks in midships should have a three-port shift; that is, should over-launch three ports; being careful, in large ships, to make one butt answer for the pump-dale scupper. To affit the conversion, the planks may be wrought top and butt. When the wales consist of four strakes, they have a fair feam in the middle; but if wrought in three strakes, let the two lower strakes be worked top and butt, and the upper strake of a parallel breadth.

The thick-fluid, or diminishing strakes, from the lower edge of the wale to the thickness of the bottom plank, being of English oak, is wrought top and butt, and should be shifted from the butts of the wales to the regular lengths of the bottom plank as soon as possible.

The plank of the bottom is English oak-plank; as low as the light water-mark, and below that, may be Eastcountry plank of the best quality. The English plank is worked top and butt, to twenty-four-feet lengths at least. Now, to break the shift, fo as to work East country plank to advantage, requires care; for, as just observed, the general shift of English plank is twenty-four feet, whereas East country plank is from thirty to fifty feet; consequently, the best way is to work a double shift at first, or one of forty-eight feet in length. It rarely happens that the shift is broken from English plank to East country plank, without introducing two planks between two butts on the same timber in some places; and it may be admitted, owing to the superior length. Be careful, in shifting the East country plank, to keep the shift as nearly equal as possible, not being confined to butt on one timber, but to make an advantage of drawing the butts having no less than a fix-feet shift.

East country plank is wrought of a parallel breadth from ten to eleven inches, excepting forward and aft; for the fore and after-hoods that come into the rabbet should be English oak-plank. Four or five strakes nearest the keel may be of elm or beech, observing to shift the butts clear of the scarp of the keel; and, likewise, that no butt is placed under the pumps, and to work them very hard at the poll. The edges and butts of the fix or eight strakes next the keel in East India ships, are rabbetted close; and fine flannel, dipt in tar, is put between, and thick kerly, also dipt in tar, is spread between those planks and the timbers.

In planking the fore part of the bottom, the breadth of the strakes must be considered, and also the shape of the bow, that every strake of plank may be brought into the rabbet; and every plank should be kept from inyng as much as possible. But, in full-bowed ships, it would be impossible to bring every strake to the item without too much try. It is, therefore, customary to work in the bow of such ships a drop-strake next under the water, or more, if necessary, and a cleat at about four strakes under it; by which means all the strakes that come in the rabbet will be of sufficient breadth. In order to take out the try, bring the cleat well forward. In most ships, a drop-strake abaft, close up under the water, affits the planks very much; and to produce a fair edge, be careful not to work too broad on the fusilion-piece.

The plank of the top-side is generally wrought in parallel breadths, therefore it had better not be more than nine inches broad. The top-side, being cut by the ports, drifts, &c., requires the greatest strength to be given to it in shifting the plank; as no butt should be placed immediately over or under a port, unless there are two planks between. The planks in wake of the main-mast should have a three-port shift: the others, afore and abaft, may have a two-port shift. As it is stronger to butt between the ports, it may be allowed sufficient to have a shift of five feet six inches, where a plank comes between; or five feet, where two come between. But there should not be less than a fix-feet shift where no plank comes between. The channel and sheer-wales, in large ships, should work down to the lops of the ports in midships; and, where the sheer lifts forward and aft, should work down to as many ports as may leave sufficient lop, and afford wood to receive the port-hooks, letting the wood so worked down be continued six inches each way beyond the lops of the ports; thence to hance one foot to the regular breadth: but, by all means, let planks run through, if they hold but five inches after the lops are cut, so that the port-hooks will clear the seam; for planks, however broad, working down to the ports, make that part no stronger than any other.

Forward in wake of the hawse-holes, the planks should be so wrought as to have the seam to cut the plank as little as possible by the holes; and care must be taken that no seams come behind the cheeks.

The sheer-strakes, as they are the greatest strengtheners of the upper part of the top-side, should have their butts disposed with the utmost care, in order to produce the greatest strength between the drifts, and give the strongest shift to each other. They are wrought of parallel breadths, with hook and butt sars about four feet long between the drifts. The butts afore and abaft may be square, especially behind the channels, which should be of English oak. The others, owing to their great lengths, must be of Eastcountry plank.

Observe; if the channel or sheer-wales are in three strakes, two of them may be wrought top and butt, to affit the conversion.

In planking the inside, attention must be paid that the butts of the clamps, spikings, and fringes in the oilt, should give shift to the butts outlise.

Clamps, when wrought of a single strake, should have hook and butt sars about four feet long.

Gun-deck clamps and spikings should have a three-port shift in midships, as should likewise those of the middle and upper deck. Clamps and spikings, when wrought in two strakes, may work top and butt, and one butt of the latter is to come in wake of the pump-dale scupper.

The clamps of the lower deck cannot be wrought towards the after part of the ship, agreeably to the hang of the deck, fo as to admit of the after-beam's coming home to the timbers, as it would wound them too much, or produce too great a try; therefore the clamps may lift aft to produce an easy edge, and some of the after-beams, of course, must face on the clamps.
SHIP-BUILDING.

However desirable a three-port shift may be with regard to strength, planks of that length are hard to be gotten; therefore, to add security to a two-port shift, let the plank below or above the butt be douelled into each timber next the butt, and likewise edgeways, keeping the douls clear of each other.

To design on a plan the body of the ship, shewing the lengths and breadths of all the planks as near as is required for practice, will be found by experience to be necessar y; for when the ship is planking, without a plan of this fort to affit, it is requisite to girt the body in several places, to know the number of strakes the bottom will require, in order to work the planks of each quality of an equal breadth, and likewise to know the diminishing of the breadths of the planks forward and aft. To do this satisfactorily, without a plan, is attended with much inconvenience and trouble. It also affords an opportunity of not only shifting the work before it be immediately wanted, but by having the whole shift of the bottom and top-side before you at one view, you have a better opportunity of seeing whether the butts are sufficiently clear of each other, which is better than seeing them on the ship's side. And when the ship is planking, if there should be any lengths which may prove difficult, you may, by referring to the plan, see if the butt can conveniently be altered, without prejudicing the shift that is not wrought; some part of which it is likely may be altered to conform thereto.

The bottom may be expanded by the horizontal or water-lines, also by the ribband-lines; therefore, from the sheer-plan, Plate I., may be taken the flation of all the timbers, and the lower edge of the rabbit of the keel, from the attic of the rabbet of the stern-post, to as far forward as the rabbet of the keel continues straight, that is to timber M; likewise the scarfs of the keel; all of which are to be set off on the plan of expansion, as in Plate III. Then to expand the square body, transfer the heights of the upper and lower edge of the main-wale, channel-wale, sheer-frakes, upper and lower sides of all the ports, the height of the decks at the side, and under side of the plank-flare, from the sheer-plan, Plate I., to the body-plan. Transfer from the body-plan the half breadth of the timbers at the upper and lower edge of the main-wale, channel-wale, sheer-frake, and under side of the plank-flare, to the half-breadth plan, and draw in the lines to their half breadth; which being done, apply to those lines, and also to the horizontal or water-lines, narrow slips of paper, confining them thereto by needles or small pins, from dead-flat forward to square timber O, and from thence abaft to 28; marking upon each slip of paper the station of every timber, and its respective water-line, &c., as girted.

In the same manner, girt the timber dead-flat in the body-plan, Plate I., from the inside of the rabbet of the keel to the under side of the plan-flare or gun-wale; then mark upon it the heads of the timbers, water-lines, upper and lower edges of the wales, and ports; likewise the decks at the side and under side of the plank-flare. Then square up the station of dead-flat, as shown on Plate III.; and upon that line set up the middle of the rabbet, to which spot fix, with a needle, the spot corresponding thereto on the slip of paper that girted dead-flat; then upon the line mark off from the said slip the water-lines, heads of the timbers, upper and lower edges of the wales, ports, &c. In the same manner proceed to girt every square timber in the body-plan, Plate I., marking thereon the name of its respective timber. Then fix the spot marked for the middle of the rabbet of each girt, to the middle of the rabbet of its respective timber in Plate III.

Now fix the girt of each water-line, &c. as taken from the half-breadth plan, to its corresponding height, as marked on dead-flat, Plate III.; then stretch each girt, observing it does not pucker, in such a manner that the stations of the timbers, as marked on the girts of the water-lines, &c. and their corresponding heights, as marked on the girt of each timber, may intersect each other; then with needles confine them in that situation, and make dots at every intersection, which will represent the expanded heights and lengths of all the water-lines, main-wales, &c. in the square bodies. Fair curves may then be drawn through these dots, which will shew the square bodies expanded from 28 aft to O forward.

Then, to expand the cant-bodies afore and abaft, proceed to draw in pencil the joints of the cant-timbers in the body-plan, Plate I., thus, lay a slip of paper in the direction of each cant-timber in the half-breadth plan, and mark on it their intersection at each water-line, main-wale, channel-wale, ports, sheer-frake, and plank-flare; also the middle of the rabbet of the keel and flim, and middle line. Then transfer each timber to marked to the body-plan, Plate I.; and mark on each corresponding line their half-breadths from the middle line; then curves drawn through those spots will represent the joint of each cant-timber from the keel to the top of the side. In the same manner draw the sides of the short timber before cant y.

The thwarts of the joints of all the cant-timbers being represented in the sheer-plan, Plate I., square up from the half-breadth plan the fore-side of cant y and the timber before it, and likewise the sides of the hawse-pieces, where they intersect the water-lines, main-wale, &c. to their corresponding lines in the sheer-plan. Then drawing lines in pencil through the spots so squared up, the thwartship view of the hawse-pieces, and the cant-timber before y, will be also represented in the sheer-plan.

Now draw in pencil the fore and aft view of the hawse-pieces in the body-plan, Plate I., by setting off their fiding at the heads and heels from the side of the flim, and draw straight lines to intersect the fore-side of cant y and the timber before it; then transfer the height of the flims from the sheer-plan, where they cut off against the foremost timbers, to the same timbers in the body-plan, as in Plate VIII. Lay ing-off By figs. 1 and 2.

Transfer the heights of the main-wale, &c. where they intersect the joint of the cant-timbers in the sheer-plan, Plate I., to their corresponding timbers in the body-plan. Then with slips of paper girt the cant-timbers, as before, for the square ones, marking all the heights let off, and the heels where they cut the flim forward and those abaft on the keel.

Likewise girt each water-line, main-wale, &c. from square timber O, in the half-breadth plan, round to the flim, marking thereon the joints of all the cant-timbers, the sides of the hawse-pieces, and flim; then girt the flim in the sheer-plan from M, marking O, the heels of all the cant-timbers, and the heights of the water-lines, wales, &c.

Then place the girt of the flim on Plate III., confining it at M; and likewise fix all the girts of the cant-timbers in the fore-body, confining their heels respectively to their stations on the flim; also the girts of each water-line, wales, &c. confining them respectively at square timber O; then move the whole till they all agree, that is, the ends of the water-lines, &c. are to agree with their respective heights on the girt of the flim, confining them with pins till the whole of the fore-cant-body agree, and as much as possible let them lie smooth, without puckering. Then may be marked on the plan the proper edges of the slips of paper, which
SHIP-BUILDING.

which will represent the moulding edges of the cant-timbers, the water-lines, wales, &c. Likewise mark the heads of the timbers, as taken from the body-plan, as the slips now lie, which heads may be drawn when the slips of paper are taken up.

The fixings of all the timbers may then be drawn from their moulding edges, and the openings shown where required for air, or to make the sides of ports, observing to taper the heels of the cant-timbers on the leaping-line.

The operation of expanding the after cant-body is so similar to the above as not to need repetition; therefore, supposing the after cant-body to be expanded as far aft as the fashion-pieces and Itern-timber, there only remains to be explained the expanding of the transoms.

The buttock-lines being drawn in the several plans of Plate I., proceed to draw in pencil the moulding edges of the transoms in the half-breadth plan, thus: lay a slip of paper in the direction of the upper edge of each transom in the fleer-plan, and mark thereon where they cut each buttock-line fore-side of the rabbot of the Itern-poilt, and the after perpendicular.

Square down the after perpendicular to the half-breadth plan, and thence from off each transom on its corresponding buttock-line, and the rabbot on the half-thickness of the port. Then draw curves through those spots, till they intersect the aft-side of the fashion-pieces, and the moulding edges of the transoms will be represented in the half-breadth plan.

Now draw in pencil the transoms and buttock-lines, where they cross the aft-sides of the fashion-pieces in the body-plan, by transferring their heights from the fleer-plan, where they intersect the thwartship view of the fashion-pieces on the aft-side.

Provide narrow slips of paper, as before, and extend one round the aft-side of each fashion-piece in the body-plan, Plate I.; and mark thereon where the upper sides of the transoms and buttock-lines cross them. Then place other slips round the moulding edges of the transoms, below the wing-transom in the half-breadth plan, marking the aft-sides of the fashion-pieces against which the transoms cut off, and the several buttock-lines, as also the side of the Itern-poilt, or infide of the rabbot, which is the extreme length of the planks when worked. Then extend other slips of paper round the several buttock-lines in the fleer-plan, Plate I., and mark on them the aft-sides of the fashion-pieces, and the moulding or upper edges of all the transoms below the wing, and likewise the margin-line of the wing-transom, which is the end of the buttock-lines and planks also.

Then place the slips of paper as on Plate III., those for the heights of the transoms and buttock-lines to the aft-sides of the fashion-pieces, respectively marking their heights, to which fix those for the buttock-lines and moulding edges of the transoms to correspond; then move both the latter, till their corresponding spots agree together, and so confine them with pins; then mark the proper edges of the slips of paper, which will give the expanded form of the moulding edges of the transoms, and likewise the buttock-lines as they properly intersect the transoms. The farthest spots on the papers of the transoms give the boundary of the Itern-frame at the infide of the rabbot, and the farthest spots on the papers of the buttock-lines and the margin, of the wing-transom.

In the same manner may be taken off the lower edges of all the transoms, and draw the upper part of the wing-transom, which makes the Itern-frame complete.

Take a slip of paper, and place it up the rabbot of the Itern-poilt, in the fleer-plan, Plate I., and mark on the paper the lower edge of the rabbot of the keel, the three lower water-lines, and the lower edge of the lower transom; then place the slip of paper as in Plate III., keeping the spot for the lower edge of the rabbot well with its corresponding spot on the keel; and move the slip of paper, till the marks for the water-lines and lower edge of the transom agree with their extremities; then, by marking the edge, the poilt will be deferred, and the boundary of the planks below the transom.

The operation may be performed by the ribband-lines, as well as by the water-lines, as before observed; but in that case, the cant-timbers must have been drawn in the body-plan, Plate I., on the square as well as on the cant, to level through their proper heights, which was omitted, to prevent confusion: nevertheless the lower ribband is represented in Plate III.

The whole side being now expanded, the planks of the bottom and wales may all be represented, agreeable to the foregoing directions. Likewise, on the top-side we have an opportunity of seeing the distance of every beam from the port-hulls, whereby you may judge whether it is better to cut down upon the strakes for the ports, or to work the strakes somewhat broader, to correspond with the steps of the ports. This should be carefully examined, otherwise you will be under the necessity of making a bad shift in the top-side; or be forced to cut too low down upon the lower strake, that the bolts, which are driven through the lower fills, will be of little use; and also to cut up too much for the upper part of the ports, that there will not be left sufficient wood for the port-hooks to bear the weight of the ports; inconveniences which ought to be well considered, before it be too late to alter them.

The strength of the ship, with respect to keeping her from breaking her thier, chiefly depends on the thrust of the planks from the water to the gun-wale, of which the greatest care should be taken to make the best possible, agreeable to the usual lengths of the planks; and likewise that the infide plank, especially the strake above and below the ports, should be shifted as clear as possible of the outside strakes.

The longer the planks in the top-side are wrought, the stronger must be the work; but then it would be imprudent to work longer than the usual length of the planks, because when the ship is in repair work, you would be forced to cut plank on purpose, and thereby work green plank instead of seasoned. The breadth of the planks should be consulted, before you determine on the number of strakes in the top-side, as before observed; for if the planks are rather narrow, the top-side will look the neater, and be equally as strong, if not bored too much.

To design the Profile, or inboard Works of the 74-Gun Ship, with Observations on the inboard Works of Ships in general. Plate IV.

Sometimes the inboard works are drawn in the fleer-plan of Plate I.; but when so drawn, they appear so confused, that the best and readiest method is to appropriate a draught for that purpose, as Plate IV., in which every particular will be more clear and conspicuous.

To construct this draught, it will be necessary to take from the fleer-plan of Plate I. the scale, keel and fflag, flern, Itern-poilt, rudder, counter-timbers, fashion-pieces, transoms, cutting-down lines, keelson, apron, flemson, all the decks, and centres of the masts; also the drifts, plank-flere, and line of the frame-timbers, and their ports.

The situations of the beams are next to be considered, and should be so disposed as to come one under, and one between, each port, or as nearly so as possible, to answer the other
other works of the ship, as the hatchways, ladder-ways, 
maft-rooms, &c.; but where a beam cannot possibly be 
placed under a port, or too wide apart, then a beam-arm, 
or half-beam, should be introduced to make good the de-
cency.

To difpoze of the beams, as in the profile, Plate IV., 
draw a fine pencil line under the deck-line at the side, and 
parallel thereto, to the moulding of the beams, which is for 
the gun-deck, 16 inches; upper-deck, 12 inches; quarter-
deck and forecastle, 8½ inches; and round-house, 6 inches.
Then place the first beam of the gun-deck under the middle 
of the first port, or nearly fo; the second between that and 
the third, which takes the heels of the bow-sprit-steel; the aft-
side of the latter to be 3 feet 10 inches before the centre of 
the fore-mast; the fore-side of the fourth to be 2 feet 6 inches 
abate it; the aft-side of the fifth to be 10 feet 9 inches abate 
the centre of the fore-mast, against which are the fore riding-
bitts; the aft-side of the seventh to be 21 feet 10 inches 
abate the yard centre, which takes the after riding-bitts; 
the sixth comes equally between; the aft-side of the tenth 
beam plumbs the after-part of the forecastle, or nearly so, 
and makes the fore-side of the fore-hatchway, which is 4 
feet 10 inches fore and aft, and is made by the eleventh 
beam; the ladder-way between the ninth and tenth beam is 
3 feet 2 inches in the clear; the aft-side of the twelfth beam 
is 5 feet 8 inches abate the fore-hatchway; and the fore-side 
of the thirteenth 11 feet; between these two beams are let 
down the fore-jeer capitan-steel. The fore-side of the 
seventeenth beam is 5 feet 8 inches before the centre of the 
main-mast, and makes the aft-side of the main-hatchway, 
which is 8 feet fore and aft, and is made by the sixteenth 
beam; the eighteenth beam is 9 feet 9 inches in the clear 
abate the seventeenth; and the nineteenth 4 feet 10 inches 
in the clear, which makes the after-hatch; the aft-side of 
the twenty-first beam is 12 feet abate the after-hatch; and 
the twenty-second 5 feet 6 inches in the clear abate it, which 
takes the step of the main-jeer-capitan; from the twenty-
third to the thirtieth are about 4 feet in the clear abinder. 
Between the twenty-third and twenty-fifth is the ladder-way 
to the cock-pit, and hatch to spirit-room; and the twenty-
third beam should be placed exactly under the centre of 
the main-mast, all the beams having any thing attached to 
them being particularized. The intermediate ones may 
be equally spaced between them; and their firdings, which are 
16 inches, may now be set off, and each beam be drawn. 

As beams are seldom made of less than two pieces, the 
lips, which are four inches, had better be added to the firding.

On the upper deck the first beam is placed under the 
beak-head, to receive the tenons of the beak-head fantages; 
the second beam must be so fixed, as not to be too much 
wounded by the bow-sprit; the third and fourth about 2 feet 
6 inches in the clear on each side the centre of the fore-
mast; the others, particularly those that have pillars under 
them, should be stationed over the gun-deck; from the 
fifth beam to the tenth is let up in the middle 2 inches of 
the fore-hearth carling, which is 12 inches square; between 
the tenth and the eleventh beam is the fore-hatch over 
the gun-deck, abat a which is a ladder-way, and next abat it 
the capitan; the seventeenth beam takes the top-fall-sheet-
bitts on the aft-side; and the next beam before makes the 
fore-side of the main-hatchway, before which is a ladder-
way about 4 feet 6 inches in the clear. The eighteenth 
beam on the fore-side takes the main-jeer-bitts, and the next 
abat makes the after-hatchway; between the twenty-first 
and twenty-second is the capitan-room, which should be at 
least 5 feet 8 inches in the clear, to admit the capitan. From 
the twenty-second to the twenty-fifth are gratings, and a 
ladder-way to the gun-room, &c. The transom abatis 
fores in to the fore-timbers.

The quarter-deck beams having no framing of carlings and 
ledges as the others below, require nearly twice the number 
in the same length, and a greater round-up, otherwise 
they would be apt to bend with their own weight.

The length of the quarter-deck is determined by having 
the aft-side of the foremost beam about four feet before 
the centre of the main-mast, and in general receives the tenon 
at the heads of the main-topfall-sheet-bitts; the second beam 
is about 4 feet 6 inches abat the centre of the main-mast, 
and receives the tenon at the heads of the main-jeer-bitts; of 
late these bits are clear of the beams above the riding-bitts; 
the other beams, in general as far as the mizen-mast are 
kept about 2 feet 8 inches in the clear abinder. Between 
the third and fourth beams is a fluttle on each side for the 
top-tackle; from the seventh to the eleventh are gratings; 
and between the eleventh and twelfth a ladder-way for the 
officers. Fourteen and fifteen are placed about 1 foot 
10 inches on each side the centre of the mizen-mast; and 
the twentieth 3 feet 6 inches before fourteen, so as to receive 
the tenons of the steering-wheel flutations in the middle; 
the twenty-fourth beam is placed so as to receive the tenons 
of the munion of the steer-bulk-head, and sometimes 
rounds aft for the bulk-head to follow the round-aft of the 
tern, or nearly so. Against the fore-side of the foart-
timbers, and scored aft into them, is a transom like the 
deck below, but having a balcony: the deals run aft 
to form the same.

The forecastle beams should be four more in number than 
there are in the upper deck, in the length of the forecastle; 
and where a wide opening occurs, such as the milt-room, a 
half-beam should be introduced, to make good the deficiency.

The cat-beam is so placed that the flutations of the beak-
head-bulk-head may face on the fore-side ½ inch; and when 
the cat's-tail comes in upon the forecastle, and is secured 
thereon, it must be three-feet sided, as it requires a rabbit 
of five inches on the aft-side to receive the ends of the deals; 
but of late years the cat's-tail comes in under the beams, which 
greatly alld the conversion of the cat-heads, and makes 
more room on the forecastle, and consequently the beam 
need be no larger than the others, whereby a great weight 
is taken off this part of the ship. Between the first and 
second beam is a ladder-way about two feet in the clear. 
The third beam is two feet before the centre of the fore-mast; the 
fore-topfall-sheet-bitts come on the fore-side, and the heels 
upon the upper deck. The fore-side of the fourth beam 
is three feet abat the centre of the fore-mast, which allows for 
the fore-jeer bitts to come on the fore-side of the beam; and 
their heels should cast outwards sufficient to lead the fore-
tack ait clear of the galley. From the fifth to the eighth 
bears are the gratings over the galley; on the fore-side of 
the ninth beam is the fluttle for the fire-bearth funnel; etween that and the tenth, the stem-gratting over the boiler; 
and on the after-beams was a cupola, or belfry for the bell, 
but that of late has been removed to the fore-part of the 
quarter-deck, between the main-topfall-sheet-bitts, in 
the royal navy.

The round-house beams are smaller than those of the 
quarter-deck; therefore, let the number of beams on the round-
houe be two, or more, in number than in the fame length 
of the quarter-deck. The round-house should always have 
a great round-up, both for strength and convenience.

With regard to placing the round-house beams, we have 
only to attend to the foremost flutation of the steering-wheel, 
so as to receive the tenon at the head; the mizen-mast 
must also have a beam about 20 inches on each side the 
centre,
SHIP-BUILDING.

The beams of the several decks, as taken from the sheer-plan, Plate I., being described, those of the orlop only remain: therefore, let down from the upper side of the gun-deck beams 7 feet 1 inch, for the upper side of the orlop beams; but as the platforms forward and abaft are laid with three-inch deal or plank, they may be kept to much below the range of the other beams, that is, from forward to beam number fix, and from the twentieth to the after-beam, which is immediately under the twenty-seventh beam of the gun-deck.

The beams of the orlop round-up 2½ or 3 inches in midships, and should be placed directly under those of the gun-deck, except the second beam from forward, which may be equally spaced between the first and third. Between the tenth and the eleventh beams is the capitan-steel, &c. for lowering the fore-jeer capitan down on the orlop occasionally; but this has been left off in the navy some years. The fifteenth and sixteenth beams take the well-bulk-heads; and till of late years the well was inclosed by a looper-board bulk-head from the orlop to the gun-deck, but is now only laid over with grating. Between the twentieth and twenty-first is a hatch to the spirit-room; and between the twenty-second and twenty-third, a hatch to the coal-hole.

Below the orlop are the works in the hold: such are the breast-hooks from number one to fix; the flaps of the fore-mall being made by the fifth and sixth hooks, and framed by carlings. These hooks stand square with the body, but the hooks under the gun-deck and upper deck lay with the shear of the deck; there is likewise a hook under the hawse-holes. The magazine and light-room extend from the aft-side of the first beam of the orlop to the aft-side of the sixth, which takes the heels of the after-riding-bitts. Next abaft the magazine-bulk-head are the floor-rooms to the aft-side of the eighth beam; and under those a shot-locker. Close abaft the main-hatchway is the pump-well, inclosed with a bulkhead of three-inch plank, about ten feet fore and aft, and eight feet athwartships in the clear. In the well is the step for the main-mall, and the pumps on each side; and adjoining the well, on the fore and after-floors, are shot-lockers about two feet in the clear. On the fore-side of the twentieth beam is the bulk-head of the spirit-room, which extends to the aft-side of the twenty-second beam; and on the fore-side of the twenty-third beam is the after-bulk-head of the coal-hole, and fore-part of the powder-room, which extends to the after-side of the twenty-fourth or after-beam. The orlop cannot extend further aft, or sufficient space would not be left for the bread-room. On the fore-side of the after-beam of the gun-deck is a bulk-head, which terminates the bread-room; and the space abaft it to the transoms is called lady's-hole. Close before the powder-room-bulk-head is a crutch; and two more crutches are spaced abaft the powder-room.

In the profile, Plate IV., is represented the method of connecting the fides and beams together by knees and riders, as used when that plate was engraved; but owing to the great scarcity of knee-timber since that time, other methods of connecting the fides and beams together have been adopted, which will be more noticed hereafter, under the head of improvements and projected improvements in the building of ships. See Substitute.

Hanging and lodging-knees of wood of a kindly growth is certainly the best mode of connecting the fides and beams together. The addition of breadth and top-riders, particularly in wake of the masts, and three or four in the waist, where they rake much, and so cross several of the timbers, must certainly diffuse the fide; but this may be more necessary in repairs than in new ships, if the hanging-knees are of a good growth, as before observed: but by no means to dispense with a hanging-knee to introduce a rider, but only when they can clear each other, as the gun-deck beam fifteen and upper deck beam fourteen, then it may be allowed to be very strong. Observe, whenever a rider comes in the throat of a lodging-knee, it can only be made of iron.

In the hold it is customary to place four floor-riders, one under the beam at the aft-side of the fore-hatchway, and the other under the beam abaft the main-mall; the next under the beam before the main-mall, and the other midway between that and the fore-hatchway. The floor-riders extend about twelve feet on each side beyond the keelson, and about one foot four inches square.

Lower futtock-riders are from five to fix in number, one on the side of each floor-riper, and one or two abaft the after floor-riper. Their length is from the side of the keelson, to give about eight-feet shift to the

Second futtock-riders, which extend from the floor-riper head up to the under side of the orlop-beam, and are about one foot two inches square.

Third futtock-riders are in length from the head of the lower futtock-riper to the under side of the gun-deck beam, and score on the side of the orlop-beam 1½ inches wide with a dove-tail, and are in size the same as the second futtock-riders. Observe, in shifting the riders, that they come clear of the pumps and of each other, otherwise they must call side ways, as at the nineteenth beam of the orlop.

A long carling 14 inches deep and 12 inches broad, is scored two inches on the under side of the fix after gun-deck beams, or to the beam before the mizen-mall, and connected to the sternpost-knee by an iron plate on each side at the after-end, the bolts being driven through and clenched on each plate alternately.

The inboard works being described in profile on the several decks, it is necessary also to represent them on the plan of each deck.

Instructions for designing the Plans of the Decks. Plates V. and VI.

Transfer from the sheer-plan, Plate I., the heights of each deck at the side, at every timber, to its corresponding timber in the body-plan; then upon each plan draw a middle line, and therefrom square up the flations of all the timbers, as taken from the sheer-plan. Next transfer from the body-plan the half-breadth of each timber at the height of the deck intended to be drawn, and let them off on each side the middle line, at its corresponding timber and plan; but in Plates VI. and VI*: half the deck only is represented; then transfer from the sheer-plan, where the deck intersects the aft-side of the stern and stern-post at the rabbet, as in Plate VI., and on those lines set off half the thickness of the stern and stern-post. A curve drawn through the half-breadths as cut off, ending in the rabbet above and abaft, will represent the outside of the timbers; then within that line set off the moulding of the timbers, and drawing another curve thereto, gives the boundary of the deck at the side, and determines the length of the beams.
SHIP-BUILDING.

Upon each plan square down the sides of the ports and beams, and centres of the masts and capstans, from the profile, Plate IV.

Thus far the plans of the decks are general; but as each deck is very differently fitted, it is necessary to have a half-plan of all at least, and what little difference there may be on the opposite side, let the explanation suffice.

In the plan of gun-deck, Plate V., is shown not only the upper sides of all the beams, and the method of tabling them together in two or more pieces, as then customary, but now douelled instead of tabbed; those in midships, being the longer, are made of three pieces; and those where they are shorter, as at the twenty-sixth beam, are in two pieces: those in three pieces have the middle piece leared to each arm. The method of connecting the sides by hanging and lodging-knees is likewise shewn in this plan, with the iron lodging-knee behind the rider, (engraved hanging by mistake,) as at the fifteen and sixteenth beams. The beam-arms at the main-hatchway and main-rooms are represented as tabbed into their adjoining beams, the seventeenth and eighteenth. The framing of the deck to receive the flat having three tier of carlings, nearly all fore and aft, with a sufficient number of ledges let into them parallel with the sides of the beams, is also represented here. The framings in the middle are the main-partners; those for the fore-masts to be formed by the standard against the fore-side of the fore-riding-bitts, the infide of which must be kept half the diameter of the mast, and five inches more for the wedging, and extend from the bitts to the flcpe of the bow-sprit: the cross-chocks, which frame the main-hole athwartships, are to be eight inches thick, and kept at the frame distance on each side the centre of the mast, and rabbot into the partners: the main-hole is made eight square, but now circular, by corner-pieces rabbetted to half their thickness into the partners and cross-chocks: on the fore-side of the fifth beam is a cap-choclet, about two feet square, and another abaat the fifth beam for handing up carldges, &c. from the magazine. The fore riding-bitts are 1 foot 8 inches square, and placed four feet aunder, or two feet on each side the middle line; the after riding-bitts are of the same size, and placed 4 feet 6 inches aunder, and the standard against their fore-sides extends to the fore riding-bitts: the cross-pieces abaat the riding-bitts are 1 foot 6 inches fore and aft, and two inches lefs deep, and the face-pieces on their aft-sides are of elm six inches thick. The framing of the fore-hatchway and ladder-way consists of coamings 1 foot 6 inches above the beam, that is, the lower piece to be 9 inches deep and 10 inches thick, and the upper piece 9 inches deep and 7 inches thick, dovetailed together, and spread in the clear 4 feet 8 inches; and the head-ledges to be 7 inches thick, scored and tailed into the coamings, and to round-up above the latter, at the rate of 2 inches in six feet of length. The capstan-partners are here framed as on the upper deck; but by this method of lowering the fore-jeer capstan is discontinued, let it be framed as the main-jeer capstan. The main-mast partners are framed similar to the fore partners, the carling being 1 foot 5 inches broad, and 1 foot 6 inches deep. The chain-pumps are represented on the plan as fitting the pump-cases through the mast-partners, and the back-cases without; the fprocket-wheel and fpindle-work in brass rhodings or gudgeons, let into the top-fail-sheet and jeer-bitts, and the winches also in the pump-pillars. The main-hatchway is 6 feet 4 inches athwartships, and fitted with coamings and head-edges as the fore-hatchway. The after-hatchway is the same as the fore-hatchway. The flap for the main-jeer capstan is 1 foot 10 inches broad, and 1 foot 6 inches deep, to be scord down between beams 21 and 22, and lap thereon 8 inches above the beam, with broad carlings on each side to receive the bolts of the pall-rim; in the middle of the flap is an iron cap to receive the fpindle. The hatch to the spirit-room, and ladder-way to the cock-pit, are framed as the fore-hatchway. The main flap to be 1 foot 8 inches broad, and 1 foot 4 inches deep, and scored down between beams 25, 26, and 27, two inches. The bread-room flap is doubled, which is 2 feet 4 inches square, is on the larboard-side, and is framed with coamings and head-edges, with a cap or top as high above the deck as at the hatchways: on the starboard-flap this is a flap cut about two feet square over lady's-hole, and another 1 feet square over the fpindle to the magazine. On the gun-deck, in the middle of the three or four after-beams, is a standard, sided 12 inches, the upper end to stay against the transoms, as high as the helm-port tranform.

A fpindle without the coamings at the main-hatch is represented, the binding-flaps all fore and aft, which are to strengthen the decks, as they are weakened by the hatchways, therefore the butts should be shifted clear of them; in the inner flap are driven the stopper-bolts. Forward is shewn the moulded size of the deck-hook and eaking, also the plan of the hawle-holes and manger, with the flations.

On the same plate is drawn the plan of the orlop, with its several conveniences. On the fore-platform, which extends from the fore-peak to the fore-hatchway, is the boatwain's cabin on the larboard-side, with such another for the carpenter directly opposite; and before each is a floof-room, to hold their respective flores; before the boatwain's floof-room is a flail-room: between the fore-riding-bitts are two doors, one leading to the light-room passage on the larboard-side, and that on the starboard-side to the magazine and gunner's floof-room. Cloke before the heel of the larboard fore-foorl riding-bitts is a cap-choclet, inclosed, to hand up filled carlings; and on the opposite side a flat fpindle to the magazine, likewise inclosed; at the end of the light-room passage is a fpindle to the light-room: abaft the riding-bitts are fpindle to the boatwain's, gunner's, and carpenter's floof-rooms under the orlop. The fore-fpindle is of the same size, and immediately under that on the gun-deck, but has only a flat framing round it, to take the hatsches that cover it. The beams of the orlop are rabbetted on each edge to receive the flat, which is only oak boards 1/2 inch thick as far as the after-platform. The midship flail-room now extends from the main-hatchway to the fore-hatchway, and is framed round with pillars upon a carling ten inches deep; and as the captain-room is not used, the gunner's cabin is made at the fore-part. The main-hatchway is of the same size as that over it, and is framed round as the fore-hatchway. The well is not inclosed, as shewn on the plan, but at present is laid over with gratings. The after-hatchway is of the same size as the hatch over it, and framed like the others. Between the beams 21 and 22 is a double hatch to the spirit-room, and one next abaft it to the coal-hole. On the fore-side of beam 23 is the bulk-head of the cock-pit, and abaft it inclosed are two spindles, one to the powder-room the other to the light-room.

On the larboard-side abaft is the fleward's room, abaft which is the bread-room; and the interval between the fleward's room and light-room bulk-head is the fleward's bed-place and racks for flowing cheeche: next before the fleward's room is the purfer's cabin, before that the flop-room, and next to that a compartment for the mariners' clothing. From the fleward's room, to nearly forward on each side, are the wings, or an open space about 4 feet 6 inches from the side, sufficient to swing a mall, if necessary, to plug up shot-holes in the time of action. From the fleward's room to the mariners' clothing
is birthed up with a bulk-head of 1 3/4-inch deal, and the fame
from the boat-swain's cabin forward, and between those
flations and whole deck battens or lattice-work. On
the starboard-side, opposite to the steward's room, &c. is the
captain's flore-room, doctor's cabin, and firit lieutenant's
flore-room; and between the captain's flore-room and paffage
to powder-room, is fitted a dippermary for the doorf.
On this plan it is cumfory with a different coloured ink to
draw the plan of the works in the hold; and to diftinguifh them on the plate, they are reprefented by fine ticked
lines.
Under beam 1 is a bulk-head for the boundary of the light-
room, together with its plan, and also the magazine-lights,
jams, and flap-boards, (to throw the rays of light more
into the magazine). The magazine is surrounded by a frong
bulk-head of three-inch plank, the edges rabbeted together,
the inside of which is doubly lined with felt flat, fo as to
cover each joint, and on the outside with flat deal, and a thick
coat of mortar under it. The flat of the magazine is firt
laid with three-inch plank, caulked on beams underneath,
upon which are not flain, with copperldumps, the palling beams,
framed together at right angles, about three feet
alunher: the upper edges are rabbeted to receive the flat,
which is 1 3/4-inch deal, lined on the underfide. The bulk
head at the fide, which forms the wing, is conftrued with pannels,
and rabbeted flations to receive the pallings: in the fore-
part of the magazine in midfhips is the filling-room, which
is lower than the surface of the flat about twelve inches:
this is lined with lead, as it is the place where the cartridges
are filled, (hence its name,) for greater security: as it is fide
abof the lights, glafs falls from the sides, guarded with a
copper-wire net-work: in the fides of the filling-room are
racks for filled cartridges, and a compartment behind them
for faves of empty barrels. The powder barrels are flowed
upon dunnage battens, over the palling flat, which is
parted off from the filling by an open bulk-head of flations
and battens. Magazines are now only fitted up to receive
barrels with cartridges already filled.
Abaft the magazine are a flore-room for the boat-swain; on the
larboard-side, in midfhips, a flore-room for the gunner,
and under that a fhot-locker; and on the starboard-side a
flore-room for the carpenter.
Next abaft the main-hatchway is the plan of the well,
and fhot-locker afore and abaft it. Under the fore-fide of
the 20th beam is the bulk-head of the fpirit-room, and under
the aft-fide of the 22d beam the bulk-head of the coal-hole:
its after bulk-head is under the fore-fide of the 23d beam,
which also makes the fore bulk-head of the powder-room,
which is inclofed round with a bulk-head similar to that of
the magazine forward; likewise the light-room, and paffage
to the powder-room, which is inclofed up with racks for
flowing filled cartridges, as reprefented in the plan: all
of the powder-room bulk-head is occupied for the broad-
room, to the bulk-head for lady's-hole.
On Plate VI. is reprefented the half-plan of the quarter-
dock, wait, and forfeilace, likewise the half-plan of the
upper deck.
On the plan of the upper deck is fhewn the bead-head flations,
whole fides are rabbeted to receive the bulk-head: the
midft flations to be about 2 feet 6 inches on each fide
the middle line, and 12 inches square as high as the flat of the
beak-head; they tenon at the heel into the foemt
beam of the upper deck, and receive into their outflades
the tenon of the collar-calling, which is of the fame fize as the
flations, having its upper fide well with the flat of the
beak-head, which is of the fame height as the lower fides of the
ports. The midft flations to be 6 3/4 inches square above the
Vol. XXXII.
collar-calling: the other flations, which are four in number
on each fide, are all 6 3/4 inches square, and face aft 3/8ths of an
inch into the cat-beam: the two outer flations are placed
afunder to the spread of the round-houfes, and fhould be
kept far enough out that the funnel may come clear of the
fide: the third flation from the middle line must be fpaced
fo as to make the bow-fhape port: the next flation within
makes the head-door: on the midft-side of the head-door is
a fcuttle, with a flap hung over it to lead in the fore-tack.
The heels of all thefe flations tenon into the collar-calling
with a double-flop.
The framing of the fore-maft partners are fhewn, as before
directed, for the main partners on the gun-deck, on the out-
fide of which are the heels of the fore-sheet and jeeb-bitts;
the heel of the former to spread sufficiently from the middle
line to lead the fore-tack clear of the gallery, having a fheeve
fitted into it for that purpofe. Aft ahaft the fore-maft partners
are the cans for the galley, which is inclofed abaft by two
doors.
The fore-hatch and ladder-way to be framed, as directed
on the gun-deck, with coamings ten inches broad, and nine
inches above the deck, and head-ledges fix inches thick:
next abaft are the fore-jeeb-capitain partners, to be seven
inches thick, their ends let down into a framing similar to the
hatchway (or to have their ends fquare, and flipt in with the
deck), and bolted through the beams and callings, and their
edges to be rabbeted to flop the caulkings. The ladder-way,
main hatchway, main-maft partners, after-hatch, main-jeeb
capitan partners, gratings, and ladder-ways, are all framed
as before defcribed.
On this plan the flat of the deck is reprefented, and the
several butts shifted: close to the fide are the water-ways,
five inches thick, and the firft frapke of oak which is cut
off between the riders; the next four frapakes are all English
oak in the wear of the guns, flipt in fhort lengths, and
anchor-fock, or top and butt, to affift the converfion.
The felf of the deck is three-inch Puffis deal, except the binding-
frakes, which are the second and third, without the main
hatch-coamings, and under the forefeilace: the deals muft
be fo flipt as to work their whole lengths, and great waite
will occur, that is, 30, 36, and 40-feet lengths. The mizen
partners are framed with a cauling on each fide, and corner-
pieces as high as the beams, and the flat round them is oak,
five inches thick.
Clove up under the beams is reprefented the tiller, as fitted
with the horn-loop over the end, for keeping up the tiller-
rope in the fweep, and a hoop abaft it, with eyes in it,
through which the rope is reeled, to be fet up taught by
tackles hooked to the eye-bolts: further aft, at the after-
ed, are iron rods, which are hoove taught by a frew-nut, to
keep the tiller aft. At the fore-end, on the upper fide, is
an iron goofeneck, which traveries on the fweep, and keeps
up the fore-end; the rope traveries round the fweep in a
groove, and is led up to the wheel on the deck above by
fheaves fitted at the end of the fweep, and the blocks afiore
the maft reprefented by the ticked line.
Sometimes abaft, where the fide is to round to have
riders, iron f tandards are fitted, as on beams 26 and 27.
On the beam, before the mizen-maft, is the bulk-head of
the ward-room, fitted with double doors on each fide.
The knee under the cat-beam prevents the hanging of
a door at the aft-fide of the round-houfes forward: they are
therefore inclofed with a bulk-head, and a door on the att-
fide.
On the plan of the forefeilace is fhewn (as was the prac-
tice when the plate was engraved), the conftruction of the
fife-rail, as let over the heads of the bead-head flations,
with the chafe-port and upper part of the round-houses; also the plan of the cat-head, cat's-tail, and the knee abaft the cat-head. Between the cat's-tail and the fore-mall is framed in midhips a ladder-way, and round the fore-mall are the fore-top-fall-fleet and jeer-bitts, with their cross-pieces; on the fides of the bitts the check-blacks, or they must be provided very large, to receive all the sheaves necessary for sheets, braces, &c. A bitt of the fore-mall, on each side, is a fairritt for the top-tackles to lead through to a hook to an eye-bolt on the upper deck. Over the gallery, in midhips, are framed the deck-gratings; and between them coamings for the chimney-chim. At the aft-part of the forecastle are represented the belfry bitts, with the knees to support them; and over the breast-beam are flown the foot-rail and stantions, as then used, but now discontinued.

Along the walk into the side, instead of gang-boards, as formerly, the deck is continued from forward to aft seven feet three inches from the side; likewise the flat is continued along the midhips, five feet three inches on each side the middle line, except an opening over the main-hatchway.

Upon the plan of the quarter-deck is shown the plan of the breast and foot-rail over the breast-beam, with their stantions, now rendered unnecessary by continuing to much of the deck along. On each side of the main-mall is a flat fairritt for the pumps to be paddled through; and on the aft-side of the beam abaft the mall are the brace-bitts. A bitt of the breast-bitts, on each side, is a flat fairritt, for leading through the main top-tackles to an eye-bolt driven in the upper deck. From the lefthand beam to the twentieth the space is framed for gratings, and a ladder-way, as before directed, five feet four inches in the clear. Between the fourteenth and fifteenth beams are fixed the steering-wheel and its stantions; in the next opening is the mizen-mall: the partners are formed with thick-plug, as at the upper deck. On the beam abaft the mall is the bulk-head of the lobby and bed-place, and on the twenty-sixth beam the bulk-head of the captain's cabin: between these bulk-heads are a fore and aft bulk-head that part the lobby and bed-place; and on the twenty-fourth beam is the selden-bulk-head. The latter is unnecessary, when there is no walk or balcony abaft.

A plan of the round-house is not wanted, as, besides its beams and ports, there are only the mizen-top-fall-fleet-bitts on the fore-side of the beam before the mall, and stantions are abaft: when an open stantion, illuminators instead of a companion are let into the deck.

Explanation of the Methods of Laying-off all the Parts of a Ship on the Mould-loft Floor, preparatory to the actual Building of the Ship.

The sheer-draught, Plate I., being completely drawn upon paper, mostly to a scale of a quarter of an inch to a foot, as before observed, or forty-eight times less than the real size of the ship, it remains to expand it to its fize on the mould-loft-floor; but the latter is seldom long enough to admit the laying-off of any large vessel in one length; in small mould-lofts they must of course lay-off in three or four lengths. Indeed, to lay-off in one length would cause unnecessary waste of time; for many of the joints of the timbers, or perpendiculars of the fore-body, answer alike for the after-body.

Laying-off. Plate VII.

Plate A may be laid to represent the mould-loft-floor in miniature, by the same scale as Plate I.; but here, to prevent confusion, the different plans are shown separate, but on the floor in the grove: the several plans are laid off one over the other, as to the practisioner, is perfectly clear.

The mould-loft-floor being cleared, begin by striking a straight line from one end to the other, as A A in the above plate, in distance from the side of the loft as much as the keel is deep. This line will represent the upper edge of the rabbit of the keel in the sheer-plan, fig. 1., above which all the heights are to be set up, and it will represent also the middle line of the half breadth plan, fig. 2.

Proceed now to lay-off the fore-body, by transferring from the sheer-plan, Plate I., and erecting from the line A A to the right-hand, the several perpendiculars or joints of the frames B, D, E, H, K, M, O, Q, S, U, X, and the foremold-perpendiculars, and likewise frames 2 and 4 abaft. This must be accurately done, so as not to exceed the room and space.

Now describe the stantion, as in Plate VII., fig. 1., supposing it of the full size, by setting up from the line A A the height of the centre from Plate I., and the near side distance thereon from the adjoining perpendicular, as at Q, Q; by which radius the fore and after sides are swept, likewise the rabbit in the middle, from the keel upwards to S. Then set up the height of the head, or upper part, and its distance forward from the nearest perpendicular; then, by pinning a batten to the tops last let off, and to the curves already swept, the stantion will be formed likewise.

Transfer from the sheer-plan, Plate I., the heights of the lower and upper height of breadth-lines from the line A A, as in Plate VII., from the perpendicular 4 to the stantion; then, by pinning a batten to those heights, produce the fair curves E and F.

Let the outlines of the fore-body plan, Plate VII., fig. 3., be represented, that is to say, the middle line by the line A A; the base line, or upper edge of the keel, by one of the perpendiculars; then will the outside line, R.L., be parallel to the line A A; at the moulded breadth at dead-flat (as few mould-lofts are broad enough to admit the height of the timbers as in the plate,) strike the middle-siding of the stantion S from the middle line.

The main half-breadth line may now be laid off, by transferring it from the half-breath-plan, Plate I., to its corresponding timbers on the floor, from the line A A; and to end this line at the stantion, take the height in the sheer-plan, fig. 1., where the lower height of breadth-line intersects the aft-side of the rabbit of the stantion, and transfer it to the middle line of the body-plan, fig. 3.; and from thence take the half-thickness of the stantion, and set it up from the middle line of the half-breadth plan upon a line squared down from the aft-side of the rabbit of the stantion, at the lower height of breadth in the sheer-plan. Then, by pinning a batten to the several half-breath lines, fast off, and to its ending at the stantion, we form the fair curve D, as in Plate VII., fig. 2., or main half-breadth line.

Observe, when the batten is pinned, to look along it strictly, and see that its edge produces a fair line; this must be always understood, and therefore need not be repeated.

Transfer from the sheer-plan, Plate I., the heights of the centres for the radius of the floor-sweeps of the fore-body on to the floor, and by pinning a batten thereto, produce the line B, in fig. 1.

Transfer from the half-breath plan, Plate I., the rising half-breath, or narrowing of the floor-sweeps of the fore-body, and by pinning a batten thereto, produce the line B, in fig. 2.

Transfer from the sheer-plan, Plate I., the heights of the top timber-line to the floor; and should the floor not be broad enough to admit the whole heights, set them up their
their respective timbers from some straight line, as AA, allowing the addition of twenty feet; then, by pinning a batten to these heights set up, produce the curve, Plate VII. fig. 1.

Transfer from the half-breadth-plan, Plate I., the top-timber half-breadth on to the floor, and by pinning a batten to the several half-breadths set off, the curve C, in Plate VII. fig. 2, will also be represented.

Then, having marked the several lines laid off with their respective names, proceed to lay-off the fore-body, fixing on some convenient part of the floor, making the line AA, Plate VII. fig. 1, serve for the middle line M, Plate VII. fig. 3, and one of the perpendiculars for the base line, or upper edge of the keel, as before observed. The diagonal lines in the body-plan are not only used in laying-off the body on the floor, and taking the bevelling of the several timbers, but are of very principal use in the actual building; for at their stations the ribbands and harpins, which keep the whole frame of the ship together until the planking is brought on, their situation with regard to the heads of the timbers must be determined; it consequently follows, that a particular explanation of them is necessary.

The floor-head diagonal marked C in Plate VII. figs. 3 and 5, terminates the length of the floors, hence its name. The placing of this diagonal is of the utmost consequence to the strength of the ship, being so near the bilge, or that part which takes the ground, that it consequently is always liable to the greatest strain. It should, therefore, be placed as much above the bearing of the body in midships as can be conveniently allowed by conversion of the timber; but, afore and abaft, it is not of so much consequence. Bevellings are taken at this diagonal to as far forward and aft as the floor extends.

The diagonal marked B in Plate VII. figs. 3 and 5, is placed in midships from eighteen inches to two feet, according to the size of the ship, below the floor-head C; it is the station where the floor-ribband is placed in midships, and likewise the floor-harpin forward. Bevellings are also taken at this diagonal, all fore and aft, from which it is termed the floor-ribband.

The lower diagonal, marked A in Plate VII. figs. 3 and 5, is situated generally in the middle between the keel and floor-ribband; at which place the lowest bevelling of the timbers are taken.

The diagonal marked D in Plate VII. figs. 3 and 5, is situated in the middle, between the floor-head and first futtock-head, at which place a ribband and harpin are necessary for the security of the first or lower futtocks, and hence called the first futtock-ribband. There are also bevellings taken at this diagonal, all fore and aft; which, being the part of the body where the timbers most vary, occasion them to be the greatest bevellings in the whole body.

The diagonal marked E in Plate VII. figs. 3 and 5, terminates the heads of the first futtocks, and is therefore called the first futtock-head: it should be spaced about seven feet above the floor-head, in order to give sufficient scarf or shift to the lower part of the second futtocks. Bevellings are likewise taken at this diagonal, all fore and aft.

The diagonal marked F in Plate VII. figs. 3 and 5, is situated in the middle, between the first futtock-head and the second futtock-head, at which place a ribband and harpin are necessary for the security of the second futtocks, and hence called the second futtock-ribband. Bevellings are also taken at this diagonal, all fore and aft.

The diagonal marked G in Plate VII. figs. 3 and 5, terminates the heads of the second futtocks, also the heads of the double futtocks afore and abaft the floors, and is therefore called the second futtock-head; it should be spaced about seven feet above the first or lower futtock-head, in order to give sufficient scarf or shift to the lower part of the third futtocks. Bevellings are also taken at this diagonal, all fore and aft.

The diagonal marked H in Plate VII. figs. 3 and 5, is situated in midships in the middle, between the second futtock-head and the third futtock-head, at which place a ribband and harpin are necessary for the security of the third futtocks, and hence called the third futtock-ribband. Observe, the harpin is placed low enough at the item that the wales may be worked before it is taken down, or it may fly up like the others, and not come home to the item. Bevellings are also taken at this diagonal, all fore and aft.

The diagonal marked I in Plate VII. figs. 3 and 5, terminates the heads of the third futtocks, and is therefore called the third futtock-head, and should be spaced about seven feet above the second futtock-head, so as to give the same shift to the fourth futtocks as the other futtocks have. Observe, such third futtocks as come under the gun-deck ports, must be continued upwards to the under part of the ports, if possible to be gotten. Bevellings are also taken at this diagonal, fore and aft.

It must be observed, that the diagonals for the ribbands, as above described, must all be drawn in pencil on the body-plan, Plate I.

A ribband and harpin are also placed all fore and aft below the gun-deck and upper deck ports, and one likewise at the top timber-line, as at M, N, and O, Plate VII. figs. 3 and 5, which, with the ribbands and harpins before mentioned, keep the whole framing of the ship together to its true model.

Having described the diagonals, and struck them across the fore-body on the floor, as in Plate VII. fig. 3, the several timbers may be completed, by firing transferring the lower height of breadth-line E from the sheer-plan, Plate VII. fig. 1, from H to X, to the fore body-plan, fig. 3, and striking horizontal lines at each of these heights across the body-plan, as at K; then transfer the main half-breadth of each timber from the half-breadth plan, fig. 2, upon their corresponding heights from the middle line of the body-plan, fig. 3. Then by taking the radius or length of the lower breadth sweep from the fore body-plan, Plate I., of timber dead-flat, set it off upon its lower height of breadth line, and it will sweep it downwards nearly as low as the second futtock-head; in the same manner proceed with all the timbers to Y.

Take off the half-breadths of each timber in the fore body-plan, Plate I., from the middle line on the diagonal floor-ribband, as far forward as X, and set them up from the middle line of the half-breadth plan, fig. 2, upon their respective timbers; then, to end it at the item, transfer the height where it intersects the half-thickness of the item in the body-plan, fig. 3, to the fore part of the rabbet of the item in the sheer-plan, fig. 1; from thence square it down to the middle line of the half-breadth plan, fig. 2. Take the half-thickness of the item in the body-plan, fig. 3, on the diagonal, and set it up from the middle line of the half-breadth plan, fig. 2, upon the line half squared down; and from thence sweep an arc the thickness of the bottom plank taken on the diagonal, the after part of which are is the ending of the fore part of the floor-ribbands. Then, by pinning a batten to the several half-breadths, and to the back of the are or ending, the floor-ribband will be laid off.

In the same manner proceed with the ribbands or diagonals
D, F, and H, fig. 3, as you find ticked from @ to the item in the half-breadth plan, fig. 2, to their respective diagonals in the body-plan, fig. 3.

Set up 11 feet from the base line in the body-plan, fig. 3 and 5, and strike a line parallel thereto, which is the height of the centre of the floor-sweep at dead-flat. Then take the heights in the sheer-plan, fig. 1, for the centre of the floor-sweeps B, from B to K, and set them up in the body-plan, fig. 3, above the centre at dead-flat, and at each height strike level lines. Then take the half-breadths in the half-breadth plan, fig. 2, of the centres of the floor-sweeps B, and let them off on their corresponding heights from the middle line in the fore body-plan, fig. 3. Then, with a radius at the centre in the body-plan, to its corresponding half-breadth on the diagonal floor-ribband, sweep the curves of the several timbers at the floor-head, from @ to K.

Having swept in the various curves below the lower height of breadth, and at the floor-heads, pin a batten to the half-breadths, as set off on the diagonals for dead-flat, and the back of the above sweeps; continue it with a small curve or hollow from the sweep at the floor-head to the rabbet of the keel, which completes that timber from the lower height of breadth to the keel. The same process will complete all the timbers. With regard to the heeling of the timbers exactly, set off the half-thickness of the keel from the middle line in the body-plan, fig. 3, on the base line, and parallel thereof to its depth; then with compasses, opened to the thickness of the bottom plank, sweep two arcs, so as to form the triangle at the outfire on the upper edge, and it will be readily seen that the timbers along the midships will end at the outside of the rabbet; but as they approach forward, they will end on the inside of the rabbet; and as the keel tapers at the fore-end, they must be heeled sufficiently within the keel to admit the thickness of the plank; then to keep the timbers that rise on the item, transfer their heights where they cut the outside of the rabbet of the item in the sheer-plan, fig. 1, to the half-thicknesses of the item in the body-plan, fig. 3; from thence, with compasses opened to the thickness of the bottom plank, sweep an arc inwards, the back of which is the ending of the timber, and a line squared from the timber to the height set off on the outside of the item represents the rabbet in that direction.

The fore-body being completed below the lower height of breadth, the upper part, or top-sloe, may be laid off by transferring the upper height of breadth line F from the sheer-plan, fig. 1, at each timber from dead-flat to X, to the body-plan, fig. 3, and striking level lines across at each height. Continue upwards each timber parallel to the middle line, from the lower to the upper height of breadth. Then, with the radius of the upper-breadth swept taken from the body-plan, Plate I., sweep upwards every timber from its respective upper-breadth line, from dead-flat to O.

Transfer the height of the top timber-line, I, from the sheer-plan, fig. 1, at every timber, to the fore body-plan, fig. 3, and strike in level lines at each height; then take the top-timber half-breadth from the half-breadth plan, fig. 2, at every timber, from dead-flat to X, and let them off from the middle line of the body-plan, fig. 3, upon their respective heights. Then, by a mould made to the hollow or tumbling-home of the top-sloe, and upper-breadth sweep at dead-flat, and a few feet above the top-timber-line, every timber from dead-flat to O may be formed on the floor by lowering or raising the mould so as to agree with the upper-breadth sweep, and the half-breadth, as set off on the top timber-line. But the timbers before O must gradually par-

take of the hollow of top-timber X, which falls outwards considerably from a perpendicular at its main-breadth, though parallel to the middle line above the height of the top timber-line to the top of the side, which must be transferred from the sheer-plan, fig. 1, to each timber respetively in the body-plan, Plate VII., fig. 3. Pin a batten to those several heights, which will form the curves O and P, as in fig. 3. Take square from the middle line in the body-plan, fig. 3, the half-breadths of all the timbers at the top of the side, and let them up on their corresponding timbers from the middle line in the half-breadth plan, fig. 2; seeing that it makes a fair curve. The fore-body may now be laid to be laid off above the main-breadth, which completes the whole of the square fore-body, fig. 3.

The correct height of the knuckles of the timbers at the beak-head requires some attention; for if they were carried too high, the sheer of the ship must be lifted; or, if kept too low for the sheer, the timbers must be reduced to raise the knuckles; therefore determine what part of the sheer-strakes shall come well with the knuckles; for if the knuckle was to come in the middle of either sheer-strake, the foreshaft of it must then be wrought, taking a large piece of timber and much labour. In Plate VII., the upper edge of the sheer-strake is well with the knuckle. Another consideration to be taken into this account is the lifting the sheer forward, that it may have the fame appearance on the ship as is designed on the draught; for if not lifted gradually some inches higher towards the item, the curvature of the bow will make it appear to drop below a fair curve.

To know how much the sheer of the ship requires to be lifted forward has sometimes been resolved in this manner. Prolong the sheer of the wale before the item in the sheer-plan, fig. 1, at pleasure; then pin a batten to the round of the bow at the main half-breadth, in the half-breadth-plan, fig. 3, and mark on the batten the slanting of the square timbers and the side of the item; then pin the batten to the sheer of the wale in fig. 1, keeping the slanting of the timbers, as marked on the batten, well with those near dead-flat, where they will not alter; then mark the other timbers, and the item on the sheer of the wale line prolonged, and level them at, to intersect their corresponding timbers and the item; then a batten pinned to those interections will give the curve for lifting the sheer of the ships round the bow. But as the forms of the bows of ships are so very different, it cannot be recommended as an undervailing rule, and therefore must be referred to practice; however, it is requisite to make an allowance for it in the laying-off of all ships, as the decks, sheer-strakes, and consequently the knuckles of the timbers, all partake of this considerable additional height.

The square body afore dead-flat being now laid-off, proceed to lay-off the after-body abait dead-flat; but it is only necessary to point out such differences as occur at the extremities of the ship, the midship part being similar in both bodies.

On the mould-loft-floor it is customary to set off as many of the perpendiculars abait the fore-body already laid off, as to have sufficient room for the item-poit, using as many of those in the fore-body as will answer to the regular room and space of the timbers, which will be as far as B, which will extend in the after-body as far as 14, consequently from 14 strike up from the line A A all the remaining perpendiculars to 36.

Strike in the aft-side of the item-poit on the floor from the sheer-plan, Plate I., and the aft-side of the rabbet; and strike a line parallel thereto, on the fore-side, to the thickness of the bottom plank.
SHIP-BUILDING.

Transfer from the floor-plan, Plate I., the heights of the centres of the floor-sweeps, lower and upper heights of breadth, top timber-line, and top of the side, as before.

Transfer from the half-breadth plan, Plate I., the half-breadths of the floor-sweeps, main half-breadth, and top-timber half-breadths. But to end the main-breadth, and likewise the top-timber half-breadth in the half-breadth plan, fig. 2, the side-counter-timbers must be laid off in the floor-plan and body-plan, and where they intersect the side-counter-timber in the floor-plan, must be squared down to the half-breadth plan.

In the plan of the after-body on the mould-loft-floor, its middle line is made by the side-line of the fore-body, consequently the bodies at the lower part cross each other. This would have appeared very confused in the plate, but it is always a maxim in laying-off on the floor to use as few lines as possible.

The lower height of breadth and sweeps, and the centres of the floor-sweeps in the after-body, fig. 5, may all be obtained exactly in the same manner as directed for the fore-body. The diagonals struck in, and the several half-breadths of the timbers let off thereon, form the after-body plan, Plate I. These timbers which come near the after-end of the keel, must be ended by tapers from the inner-thickens of the keel, as far as it tapers from the stern-post in the half-breadth plan, fig. 2; and within the half-thickens of the keel, fet off the thickens of the bottom plank. Then take off the half-breadth of each timber to the inside of the rabbet, and cut off on the base line from the middle line of the body-plan, fig. 5, which is the true ending of every timber at the upper edge of the keel.

The top-side of the after-body, fig. 5, is laid off in the same manner as directed for the fore-body at dead-flat, even to the after-timber.

When the bodies are thus far laid off on the floor, it is usual to make the moulds, and take the bevellings of all the timbers in the square body; that is, from O forward to 28 abaf.

Moulds for the Timbers in the Square Body.

The moulds for the midship floors are generally made first in the following manner: take fir-board, about three-quarters of an inch thick, and lay the outer edge to the floor-timber dead-flat, in the body-plan, fig. 3, from the keel to the floor-head, and make it of a parallel width, about four inches. Provide another board, and lay it to the foremost square floor O, from the head to the sides of the keel, and make it of the fame width. Then tack them both down in their places, and nail a piece of board made parallel to the half-breadth of the keel, its midship edge well with the middle line, and lower end cut square, and be well with the base line, or upper edge of the keel: the upper end is to extend a few inches above the cutting-down of O. Now nail a straight batten, about four inches wide, at the floor-head, from dead-flat to O; the upper edge well with the direction of the floor-head C. Let battens of the same width be nailed aros, with their upper edges kept well with the floor-ribband B, and one at the lower diagonal A, and as many between as may be thought necessary. Let these battens be one inch narrower than the others, which will distinguish them, as the former shew the proper flattens of the diagonals, and likewise the direction of the floor-heads. Then, upon the cross battens shall be marked the intermediate floor-heads from dead-flat to O. There must be outside pieces and battens put together, exactly in the same manner, for the other side; and the lines for the moulding edges of the floors correctly transferred to the other side.

These two moulds may then be united together at the middle line by hinges, so as to shut together, and be more handy for use.

The cutting-down line being transferred from the floor-plan, fig. 1, to the floor, as at M, Plate VII. fig. 1, take its height above the upper edge of the keel at every floor from dead-flat to O, and let them upon the middle line of the mould from its lower edge, and square them across, marking each floor's name respectively. Fix one or two battens horizontally across, from the cutting-down board in the middle to the foremost floor, as braces, to prevent the mould from racking. The mould is now finished for moulding the floors of the fore-body thus far.

Now lay the blank side of the mould upwards in the after-body, fig. 5, and mark thereon, as before, the moulding edges of as many of the after-floors from dead-flat as the mould will contain, and the heights of their cutting-down, which will be found to extend to 21.

Then to the floors from 22 to the after-square floor 28, another similar mould must be made.

The lower futtock-moulds are held made of feathered board of the above thickens, the outer edge being faced to the frame-futtock, and the inside edge to the adjoining filling, from a few inches within the side of the keel to the firft futtock-head. Then when the mould is in its place, mark thereon the side of the keel, lower diagonal A, floor-ribband B, firft futtock-ribband D, and firft futtock-head E; or a shorter way, the diagonals numerically, 1st diag. 2d diag. &c.

But if saving of stuff and time be considered as an object, make the edges of the mould lay to the two adjoining frames, and set down splittings to the corresponding fillings at every diagonal, and also at the head and heel.

The second futtock-moulds may be next made similar to the above, from the floor-head to the second futtock-head, marking thereon the keel C, firft futtock-ribband D, second futtock-head E, second futtock-ribband F, and second futtock-head G.

The third futtock-moulds may be next made in the same manner from the firft futtock-head to the second futtock-head, marking thereon the keel E, second futtock-ribband F, second futtock-head G, third futtock-ribband H, and third futtock-head I.

The fourth futtock-moulds differing in their shape, and being much longer than the others, the belt and readiest method is to lay this mould to dead-flat, from the second futtock-head to the top of the side, and two or three feet longer, as the heads run higher afofe and abaft dead-flat. The inside of the mould towards the upper part may be made to the scantling line, but at the heel, and a few feet above it, should be made as broad as possible; so that by this one mould may be moulded nearly all the fourth futtocks in the fore-body. Lay the mould in its place at dead-flat, and mark thereon the keel G, third futtock-ribband H, third futtock-head I, lower and upper heights of headdith K and L, gun-deck port-fill M, upper deck port-fill N, top timber-line O, and top-side P.

Next place the upper part of this mould to the foremost fourth futtock, O, of the square body, and it will be found to lay to the main-breadth upwards (as it will likewise lay to all the timbers between O and dead-flat, in consequence of the radii of the upper-breadth sweeps being all of one length); then, while the mould is in this position, if it covers that part of the timber from the main-breadth downwards to the fourth futtock-head, the fourth futtock of this timber may be moulded by this mould, as it may then be conveniently marked on it; but if not, then the mould shall...
must be moved to the next timbers aft, placing it after the same manner, until the timber is found to which it will mould, as described above: while the mould lies well to the timber above the breadth, take its corresponding third futtock-mould, keeping the heel of the third futtock-mould well with the heel of its timber, then raise or mark its moulding edge on the fourth futtock-mould. In the same manner place it to the other timbers, marking thereon its corresponding third futtock, at the same time marking all the respective heights of the ribsbands, &c., as at dead-flat. Observe, should the mould not lay towards the head of some of the foremost timbers, (as the tumble-home is left forward abaft than in midships,) measure the distance from the mould to the line of the timber or a square, and mark it on the mould; this being done to all the intermediate timbers, they may be laid to be complete on that side; and when so done, it will be necessary to have a small hole bored square through the mould at every firmark, or height, upon every timber, by which means the true shape of the timbers, and places of the firmarks, may be transferred to the other side of the mould, and likewise upon the timbers when moulding.

In the same manner must be formed another mould to dead-flat for the timbers in the after-body, marking thereon all the timbers it will take. Thse timbers of the square body afore or abaft the timbers already marked on the mould made to dead-flat, on account of there being more compasses at the heel, may be marked upon one mould to each body, proceeding as before, only making the lower end of the mould sufficient to be as good as any compasses timbers thereon. But should the heels differ so much as to cause the lower end of the mould to be cumberfome; in that case, make moulds to each timber, as described above.

The top-timber moulds may be made in the same manner as those for the fourth futtocks, from the top of the side to the heel I, or third futtock-head.

Method of taking the Bevellings of the Timbers in the Square Body.

The moulds for the timbers of the square body being made, it is necessary to shew in what manner their bevellings may be taken; for, until then, the timbers which have bevellings cannot be cut out.

Provide a bevelling-board for the floors, in breadth as much as the floors are laid; and, in length, sufficient to take all the floor-bevellings thereon, as Plate VII. fig. 8. The first bevelling to be taken is from the cutting-down line for trimming the throat of the floors; but from dead-flat to floor E, they will be found to be square, or as far forward and aft as the cutting-down is parallel with the keel. They will be all represented by a square line on the board. Then, for the throating of floor F, apply the flock of the bevel to the perpendicular, or joint below the cutting-down line, and the tongue well with the cutting-down line M, as at N, Plate VII. fig. 1, and that will give the bevelling for the throat of floor F. Proceed in the same manner with every floor, till all those bevellings be taken and marked on the board, as a, fig. 8, distinguishing them by writing their respective names, as A, to E, F, G, H, &c., to O. These will be all standing bevellings, both in the fore and after-bodies. In the next place, the bevellings for the outides of the floors must be taken, which are always under-bevellings in both bodies, in consequence of the floors being always placed on that side of the joint from which the body declines; these bevellings are taken at the lower diagonal b, fig. 8, the second diagonal, or floor-ribband, c, fig. 8, and floor-head d, fig. 8. To take these bevellings, let off the fiding of each floor from its joint, or perpendicular, on each diagonal in the half-breath plan.

Plate VII. fig. 2, (observing, as before, that the floors in the fore-body are before the joint, and those in the after-body abaft it,) the diagonal formed by the heads of the timbers being laid off in the half-breath plan, as far as the square bodies, for that purpose, as at M, fig. 2; then take the distance of each diagonal on the fiding line square from the middle line of the half-breath plan, and set them down on their corresponding diagonals from the middle line in the body-plan, making spots in Plate VII. fig. 3. Then fix one leg of a pair of compasses on those spots of the lower diagonal, beginning with the firt floor before dead-flat that has any bevelling, which is A, and, with the other leg, sweep the nearest distance to the line of its corresponding timber. That will determine when it is within a square in the breadth of the bevelling-board; and so proceed with every floor alternately at O, as at B, fig. 8; thus the bevellings may be taken for every floor at each diagonal, and be thence marked on the board, as Plate VII. fig. 8.

In the next place provide bevelling-boards, one for each futtock, and one for the top-timbers, observing that the breadth of each board corresponds with the fiding of its respective futtock and top-timber; then, to take the bevellings for each, we must act as before explained for the floors; only observing which futtocks are standing bevellings, and which are under: for futtocks that have standing bevellings, the fiding of the timber must be fet off upon each diagonal, abaft the joint of its respective timber in the fore-body half-breath plan, and before the joint in the after-body, and so contrarywise for those which are under-bevellings.

Therefore observe, that floors have under-bevellings, lower or first futtocks standing bevellings, second futtocks under, third futtocks standing, fourth futtocks under, and top-timbers standing bevellings. The bevellings of each may now be taken at every diagonal for every timber, and marked on their respective boards, the fore-body on one side, and the after-body on the other.

The bevellings to be taken for each futtock and top-timber are as follows: for the lower or first futtock, lower diagonal a, second diagonal or floor-ribband b, third diagonal or first futtock-ribband, and first futtock-head d, Plate VII. fig. 7. For second futtocks, floor-head, which is second futtock-heel, third diagonal or first futtock-ribband, and second futtock-ribband, and second futtock-head. For the third futtocks, first futtock-head, which is the third futtock-heel, fourth diagonal or second futtock-ribband, second futtock-head, fifth diagonal or third futtock-ribband, and third futtock-head. For the fourth futtocks, second futtock-head, which is fourth futtock-heel, fifth diagonal or third futtock-ribband, third futtock-head, main-breath, port-fill-line, top-timber-line, and top-side. For the top-timbers, third futtock-head, which is the top-timber-heel, main-breath, port-fill-line, top-timber-line, and top-side. The bevellings for the main-breath, and all above, may be taken from the half-breath plan, by fixing the flock of the bevel to the joint of the timber, and moving the tongue to the respective half-breath lines.

It is necessary, in the practical application of the moulds, to have the size of the timbers the moulding-way; this must be either set off on the bevelling-boards, or on the moulds. As the latter may be reckoned the belt way, first set off the beveling of the timbers the moulding-way at every head, &c., at dead-flat; thus, at the top of the sides, 6 inches, Plate VII. fig. 3; at the upper deck ports, N, 14 inches; at the gun-deck ports, M, 14 inches; at the third futtock-heads, I, 14 inches; at the second futtock-heads, G, 12 1/2 inches; at the first
SHIP-BUILDING.

First futtock-heads, \( E \), 15 inches; and at the floor-heads, \( C \), 13. Then pinning a batten to all those spots, making it fair to the cutting-down of dead-flat at the middle line, will give the scantling-line, or inner edge of timber dead-flat; then take the fixe or moulding at the head or heel of every timber, and let off on their respective moulds.

Then to mould the floors, the mould is laid on the timber, and the moulding edge of the intended floor is brought towards the outside of the piece; then fixe if there is cutting-down in the piece sufficient for bevelling, and sufficient below it for seating, which should be no less than sixteen inches, increasing forward and aft, as the strength may require. When that is done, if there remains sufficient wood to mould the floor agreeably to its line on the mould, which is readily seen by marking spots on the piece corresponding with the lines on the battens, and then observing whether there is wood sufficient to mould the inside agreeably to the scantlings marked on the mould. The above-mentioned spots may be made conspicuous on the piece, and the cutting-down also marked from the mould; then its corresponding first futtock-mould will finish its moulding edge, or a pliable batten may be pinned to the spots, and the moulding edge formed as low as the piece will admit (so that it is not within the given subflance below the cutting-down), the batten being fair raised by its edge; then raise up the firmarks for the diagonals to apply the bevellings. Set off on a square from the outside the given scantlings, and pin the batten thereto, as also to the cutting-down, and rake by the edge; the inside of the floor will then be completed, and the deficiency, if any, below the seating is made good by chocks.

To mould all the futtocks except the fourth, the mould need only be laid off to the outside edge of the piece; and if the piece comes near enough to the mould to allow for the scantlings and bevellings outside and inside, rake by the edge of the mould likewise the firmarks, head, and heel; then from the moulding edge set off the scantlings square from their respective places, and try if the edge of the mould will not form the inside by moving up or down; if not, it must be finished by a pliable batten, as before directed. Observe, should any of the timbers be a few inches short in the length, let them be made good by the next timber upon it, as through chocks are not to be admitted.

The fourth futtock-moulds are laid upon the piece, and should be in an horizontal position (as indeed all moulds should to try the bevellings); then see if the piece forms agreeably to the line on the mould of the timber intended to be moulded, by making a hole with a gimlet through the hole at the various firmarks belonging to the main-breadth; observing, at the same time, that the piece is strictly conformable to the head of the mould above. When both are found to agree, and there is wood in the piece sufficient for the bevellings, rake by the side of the mould inside and out as low as the main-breadth; below that it may be completed by the upper part of the corresponding third futtock-mould, keeping it well to the holes made by the gimlet at the heel and third futtock-ribband, which firmarks must be also raked up on the piece, likewise the heights of breadth, port-fill lines, top-timber line, and top-fide. The inside towards the head is finished by the scantlings given, and a batten as before described. But when fourth futtock-moulds have spiling at their heads, owing to the difference in the tumbling-home of the side, then, as the mould lies upon the piece, and the heel is found to answer, it must be seen that the upper part of the piece answers to the spiling marked upon the mould; then, towards the heel may be finished as before; but the upper part above the upper-breadth sweep must be completed by a mould made to the top-timber hollow. The top-timber line marked thereon must be placed to that given by the fourth futtock-mould, with its edge there fixed to the spiling, and its heel to the back of the upper-breadth sweep; its edge may be then raked by, and the fourth futtock will be formed up to the head or top of the side from the moulding-edge; then set off the scantling at the different firmarks, and the top-timber hollow placed to those spots will form the inner edge of the said fourth futtock, and so will the timber be completed.

Top-timbers are moulded so much like the fourth futtocks, as to render a further description unnecessary.

The moulds for the square body being finished, proceed to make moulds for the flem, fern-poll, &c. The mould for the flem is made to the lines representing the fore and after sides, or moulded breadth, from the head to the heel; but in pieces, according to the number the item is to be composed of. The flem is defcribed on the mould, which is readily seen by marking spots on the piece corresponding with the lines on the battens, and then observing whether there is wood sufficient to mould the inside agreeably to the scantlings marked on the mould. The above-mentioned spots may be made conspicuous on the piece, and the cutting-down also marked from the mould; then its corresponding first futtock-mould will finish its moulding edge, or a pliable batten may be pinned to the spots, and the moulding edge formed as low as the piece will admit (so that it is not within the given subflance below the cutting-down), the batten being fair raised by its edge; then raise up the firmarks for the diagonals to apply the bevellings. Set off on a square from the outside the given scantlings, and pin the batten thereto, as also to the cutting-down, and rake by the edge; the inside of the floor will then be completed, and the deficiency, if any, below the seating is made good by chocks.

The fern-poll mould is made to the lines representing the fore and after sides of the fern-poll, from the head to the heel, and a batten to the flem; then, across the mould may be marked the height of the upper side of the wing, filling, and deck-tranfoms at the middle line, also the heights of the harpins. Another mould is also made for the bearding-line on the poll, the aft-fide of which must be raked to the beard line from the upper side of the wing-tranfom down to where the beard-line intersects the fore-side of the inner poll, and the fore-side of the mould to the fore-side of the inner poll; then upon the mould must be marked the stitutions of the upper sides of all the tranfoms, marking their respective names thereon. By many, the use of this mould is superceded by marking the whole of the heights, &c., upon the fern-poll mould.

Another mould may be made to the thwartship bearding of the fern-poll, thus: square down the intersection of each water-line, with the fore-side of the inner poll in the flem-plan, to its corresponding water-line in the half-breadth plan; then throw the several half-breathths from the middle line in the half-breadth plan, and let them off from a straight line at their corresponding heights in the fern-plan; and a curve made to pass through those spots will be the thwartship bearding of the poll, at the fore-side of the inner poll, from the middle line, to which the mould is to be made; the same may be done, and a mould made to the fore-side of the fern-poll.

A mould should be made to the dead-wood abscit, which is limited on the upper part by the cutting-down line, on the lower part by the upper edge of the keel, the after end by the fore-side of the inner poll, and the forenoon end by the aft-side of the after-floor. The mould for the dead-wood knee is represented on it; and so likewise are the several pieces that compose the whole, as they can be gotten to as to give shift to each other. Upon this mould are fastened battens, with one edge freight to the middle line: they correspond with the flutions of the square timbers; and the other edge...
is hollowed to the moulding of the timbers, which gives the half-thickness of the dead-wood below the stepping or bearding-line, as marked on the mould, as all above that line the dead-wood is trimmed perpendicular to the siding of the keelson. To make this mould more conveniently, it may be made in two parts, separating lengthways at about half its depth.

To Lay-off the Cant-timbers, Plate VII. Laying-off, Plate A.

The necessity and utility of canting the timbers forward and aft, have been already explained in constructing the sheer-draught, Plate I. But that the reader may have as clear an idea as possible of the design of the cant-timbers, and their disposition when canted, observe then in the half-breadth plan, Plate VII., fig. 4, where the lines representing the joints of the cant-timbers, as transferred from the sheer-draught, Plate I., intersect the middle line, there may be supposed the hinge of a door; and the lines for the cant-timbers may be supposed to represent the door, which may be swung forward at pleasure; so that if the ship was on an even keel, the sides of the cant-timbers (though trimmed to their proper form) would become perpendicular, similar to the door; or supposing the form of the cant-timber was drawn on the door and fawed out, it would be perpendicular as before. The diagonal ribbands are similar to the cant-timbers in this respect; and as the cant-timbers at the middle line become perpendicular, making one straight section in the direction of the cant-timbers; so the cant-ribbands at their intersection of the middle line in the body-plan, fig. 3, become horizontal, that is, parallel to the keel at the middle line all fore and aft, provided that the ribbands for the fore and after bodies meet at the middle line, as the floor-ribbands do in fig. 3. Or otherwise, as the cant-timbers are represented by a door that is hung perpendicular, so may the cant-ribbands be represented by any plain surface, like the flap of a table, that may be hung horizontal to the side of a room; then will the side of the room become the middle line of the ship, equal to the middle line in the half-breadth plan, fig. 2, and the flap of the table may be cut down to the direction of the diagonal lines in the body-plan, fig. 3.

To understand it clearly, suppose the edge of the flap of the table to be cut in the form of one of the diagonal ribbands laid off in the half-breadth plan, fig. 2; let it be the floor-ribband; then within the floor-cant-ribband in the half-breadth plan, fig. 4, is the square or horizontal ribband B, which is the same or distance from the middle line which the flap of the table makes when canted down, as in fig. 3.

The cant-ribband in the half-breadth plan, fig. 4, is the same as the flap of the table, if lifted up till its level, shewing the extreme half-breadth of the ship, were it cut in the direction of the cant-line in the body-plan, fig. 3. The cant-ribband in the half-breadth plan, fig. 4, is the proper line to make the mould to for the harpin. But the intersection of the cant-timbers in fig. 4, with the cant-ribband, is not the proper flation of the timbers; because the cant-ribband is now raised from its proper place, and the timbers remain as before. Therefore, where the cant-timbers cross the square ribbands, square them up to their corresponding cant-ribbands, as may be readily seen in fig. 4, which are the proper flations of the cant-timbers on the harpin-moulds. For if the flap of the table, which is the cant-ribband-line, and hinged at the middle line, was to fall down in its proper place, it would then be exactly under the long ticked line B, which is the square ribband. The flations of the square timbers on the harpin-mould will make no alteration, because the mould falls in the direction of the square timbers. Strike a straight line from the intersection of the cant-timber with the middle line, to their corresponding flations on the harpin-mould; as at cant-timber S, fig. 4. This will give the direction as the cant-timbers stand on the harpin-mould.

Before we proceed any further in laying-off the cant-timbers, the fore cant-body, that is figs. 3 and 4, should be proved by the square timbers and water-lines, as far aft as timber M at least; for it is possible that the ribband-lines may have a fair appearance on the floor, and yet not produce a fair body in the ship; but if the water-lines and ribband-lines agree, there need be no fear of producing a fair bow, as the lines cannot be altered after the cant-timbers are laid off.

Therefore, transfer the water-lines from the body-plan, Plate I., to the body-plan on the floor, and then they may be all run from timber M, and ended forward, as directed in the constructing the sheer-draught, Plate I. These lines laying with a more acute angle with the timbers, any unfaiths in the body is more readily seen; but when the ribband-lines and water-lines produce fair curves in fig. 4, and likewise fair timbers in fig. 3, we may proceed to lay-off the square ribband-lines, which may be done in the following manner: mark on the edge of a batten the distances taken square from the middle line of the fore body-plan, fig. 3, to where the floor-ribband intersects each of the square timbers O, Q, S, U, X, and Y. Then fit them off from the middle line on their corresponding timbers in the half-breadth plan, fig. 4. The ending of it may be performed as the ending of its corresponding diagonal or cant-line, with only this difference, that, instead of taking the half-breadth of the item in the direction of the diagonal line, it must be taken square from the middle line in the body-plan, fig. 3, to where the floor-ribband intersects each of the square timbers O, Q, S, U, X, and Y. Then fit them off from the middle line on their corresponding timbers in the half-breadth plan, fig. 4. Now proceed to the operation, where the cant-timbers in fig. 4, intersect the square ribbands A, B, C, D, E, or 1, 2, 3, 4, and 5. Take the nearest distance or square from the middle line, and set them off square from the middle line to intersect their corresponding ribbands in the body-plan, fig. 3, and from thence level out lines at pleasure, as may be seen in fig. 3. Then take the distance from the middle line in fig. 4, in the direction of the cant-timbers, to the intersection of the square ribband with the cant-timbers, and carry them to their corresponding timbers in the body-plan, fig. 3, setting them off square from the middle line on the lines before levelled out. This will give the spots for the timbers, and likewise the proper flations of the harpins to be croffed on the timbers.

Square up from the half-breadth plan, fig. 4, where the cant-timbers cross the half-thickness of the dead-wood H, to the bearding-line R in the sheer-plan. Likewise from fig. 4, where the cant-timbers cross the main half-breadth line, port-fill line, top-timber half-breadth, and half-breadth at top-side, let them be squared to their corresponding lines in the sheer-plan.

Take the heights in the sheer-plan, where the cant-timbers cross the bearding-line, likewise the lower and upper main-breadths,
SHIP-BUILDING.

breadths, the port-fill line, the top timber-line, and top of the side, and let them in up the body-plan, fig. 3, striking lines thereto parallel to the base line; then take the distance from the middle line in the half-breadth plan, fig. 4, in the direction of the cant-timbers, to the line for the half-breadth of the dead-wood at each timber, and let them off from the middle line in the body-plan, fig. 3, on the heights let up for the bearding. This will give the ending of the cant-timbers on the bearding-line.

Take the distance from the middle line in the half-breadth plan, fig. 4, in the direction of the cant-timbers, to the main half-breadth, port-fill half-breadth, top-breadth, and top-side, and let them off in the body-plan, fig. 3, square from the middle line, on their corresponding heights. This will give the spots through which the curves of the timbers are to pass by pinning a batten, and likewise the proper heights of the harrpins on the timbers.

To Lay off the Bevellings of the Cant-Timbers.

Let the bevelling of cant-timber u be required, and this will suffice for all, as the process is alike. Strike a line afoxe and likewise abaft the joint of cant u in the half-breadth plan, fig. 4, to the fecting of the timber, which should be the breadth of the bevelling-board. Square a line from the interfeftion of the joint with the middle line, to crofs the edges or fiding of the timber u in the half-breadth plan, as at L, fig. 4; then take the neareft distance or fquare to the middle line, from where the ticked line afoxe crofses the square ribbands A, B, C, &c. and set it off square from the middle line in the body-plan, fig. 3, on each corresponding ribband, in the fame manner as was done for the joint of the timber, and level them out on each side of the diagonal ribbands, because the distance taken in the direetion of the bevelling edge in fig. 4, will sometimes be without and sometimes within the diagonal. Then take the distance from the square line, which crofses the middle line at the joint in fig. 4, to the square ribbands A, B, C, &c. in the direetion of the ticked line, before the joint or fore edge of u, and let them off square from the middle line in the body-plan, fig. 3, on their corresponding spots before levelled out. Where the same ticked line, in fig. 4, interfefts the half-breadth of the dead-wood, square it up to the bearding-line in the fheer-plan, and transfer that height to the body-plan, fig. 3. Then take the distance in fig. 4, from the fquare line, as before, to the line for the half-breadth of the dead-wood, in the direetion of the ticked line; and let it off square from the middle line in the body-plan, fig. 3, on the height of the bearding-line, which gives a spot to fimplify the lower end. Where the fame ticked line, in fig. 4, interfefts the main half-breadth line, square it up to the lower height of breadth line in the fheer-plan, and transfer that height to the body-plan, fig. 3. Then take the distance in fig. 4, from the square line, as before, to the main half-breadth, in the direetion of the ticked line, and set it off square from the middle line in the body-plan, fig. 3, on the height laid off. Then, by pinning a fatten through those spots, the fore edge is produced in the body-plan from the heel to the lower height of breadth.

Proceed exactly the same with the edge abaft the joint of u, and the two edges will be run in the body-plan, fig. 3, as the ticked lines there reprefent, the neareft distance of which, taken with compaflies, to the joint at every ribband, shows how much bevelling the timber requires at each place in the breadth of the bevelling-board; that is, if the ticked line, which is the bevelling edge of the timber, come within the joint of the timber (or nearer the middle line), then the bevelling of the timber would be fo much within (or under from) a fquare, confequently the ticked line without the joint will be fo much without (or branching from) a fquare.

Figs. 5 and 6, exhibit the form of the fashion-ice and cant-timbers of the after-body, which being laid off and bevelled in the fame manner as cant-timber u in the fore-body, it is ufeless to explain them; nevertheless, cant-timber 35 is completely laid off, that it may be referred to at leisure. It may be neceflary to add, that the greater parts are required to prove the correellines of the after-body, not only by the water-lines, but by the vertical leetions or buttocke-lines, and by introducing one or more square timbers abaft 36, to prove the butocke quite aff, and hence called proof-timbers. When there are all found to agree, it will not only produce a fair cant-body, but likewise a fair ftern-frame. See Plate IX. Laying-off C.

Observe, the diagonal H, fig. 5, or third buttock-ribband, ends up on the aft-side of the wing-tranfonm, which requires the following method to end it. Transfer the height from the line A, the upper edge of the keel, where the diagonal H interfefts the margin-line of the tranfonm in the body-plan, fig. 5, to crofs the margin-line in the fheer-plan; and where it crofses, square it down to the margin-line in the half-breadth-plan, fig. 6; then take the distance from the middle line in the body-plan, fig. 5, in the direetion of the diagonal H, to where it interfefts the margin-line of the wing-tranfonm, and let it off from the middle line in the half-breadth-plan, fig. 6, on the line squared down from the margin-line, which ends the diagonal H, or third buttock-ribband. To end it as a fquare ribband, take the neareft distance, or fquare, from the middle line in the body-plan, fig. 5, to where the diagonal H interfefts the margin-line, and let it off square from the middle line, fig. 6, to interfeft the margin-line there; and if truly squared down for ending the cant-ribband, the ending of the fquare ribband will also interfeft the margin-line in the fame place in fig. 6.

Moulds are generally made to each timber, or buttock, in the cant-bodies; and in frolling or marking them, it must be obferved, that the itations of the heads and ribbands are where the lines levelled out interfeft the lines of the cant-timbers. On the heels of the double buttock and half-timber moulds, nail on a batten to the lepping and fide of the dead-wood, by which the heel is to be cut off. To perform this, let off on the half-breadth plan, fig. 6, the thicknefs of the lepping, or dead-wood, above the lepping-line, which may be the half-thicknefs of the keel, from and parallel to the middle line, as there ticked; then from the middle line in the half-breadth-plan, fig. 6, take the distance in the direetion of the cant-line to the ticked line, and let it off in the middle line in the body-plan upon the line levelled out for the heel of the fame cant-timber; and from that spot square up a line to the upper fide of the cutting-down, which will give the height of the inide of the timber, and will reprefent the fide of the dead-wood to which the batten is to be nailed. A firnark, crofsed on this batten at any certain height above the keel, and carefully crofsed on the fide of the timber, when trimmed to correspond to a line gotten upon the dead-wood at that fame height above the keel, will be the fureft and beft method of keeping the cant-timbers to their exact height on the fhip.

Bevellings.—To take the bevellings, provide a board as broad as the fecting of the timber, and long enough to take all the bevellings of the fore-side of the joint, and likewise abaft it, as Plate VII. fig. 9. Begin with the fore-side of cant-timber u, fig. 4; the heel-bevelling is the firft to be taken, which gives the direetion to trim the heel of
the futtock the fore and aft-way, or faying to the dead-wood; therefore, the outside of the dead-wood being parallel to the middle line, apply the flock of a bevel in the direction of the joint of cant-timber \( u \) in the half-breath plan, and place the tongue well with the middle line, or at the half-thickness of the dead-wood, as at \( F \), fig. 4; letting the tongue teach forward, which will be an under bevelling, and may be thence marked on the board. The bevelling of the heel, to trim it to the beveling or bearding-line, is next taken. Thus, where the joint of cant-timber \( u \) intersects the half-thickness of the dead-wood, in fig. 4, square it up to cross the bearding-line in the sheer-plan; and, at that place, let the tongue of the bevel be placed to the bearding-line, teaching forward, and move the flock till it is perpendicular, as at \( O \) in the sheer-plan, which will give the above bevelling, which may be the next marked on the board.

The outside bevelling of the heel is best obtained by trimming the heel parallel to the inside, where it fays to the side of the dead-wood, to the thickness of the beveling. Then, to take the bevelling at the lower diagonal, fix one leg of a pair of compasses in the line of the cant-timber \( u \), in the body-plan, fig. 3, where the level line intersects, and extend the other leg to the ticked line, representing the fore edge of the timber \( u \), sweeping it till you get the nearest distance, and that will shew how much the bevelling is within or without a square in the breadth of the bevelling-board; if the former, the ticked line must be towards the middle line of the joint, and of course the latter without it; then do the same with the diagonal lines, and the bevellings of each, so taken, may be marked on the board.

To take the bevellings at the main and top-breathths, and at the port-fill line between them, apply the flock of the bevel to the joint of the cant-timber \( u \), in the half-breath plan, fig. 4, as at \( G \), and place the tongue in the direction of the respective half-breath lines, as at top-breath, observing to let the tongue teach forward: these bevellings are set off on the board, as taken, and the whole kept at a regular distance of about three-quarters of an inch on the left-hand side of the board; and, to complete them, mark their respective names and fore-side of cant \( u \), as \( a, \) fig. 9.

The bevellings may now be taken for the aft-side of cant \( u \); but the operation is performed like the former, only observing that the square line at the heel comes within side of the middle line of the half-breath plan, and likewise when the bevel is applied to take the bevellings at mainbreadth and above, the tongue of it must teach aft; these bevellings may then be marked on the same side of the board below the others, and the board for cant-timber \( u \) will be complete, as \( b, \) Plate VII, fig. 9.

In like manner may the bevellings be taken for cant-timber \( 35 \) at the aft-side, and marked on another board, as \( a, \) fig. 10; likewise for the fore-side, as \( b, \) fig. 10; and so on for all the other cant-timbers, both on the fore and after cant-bodies, and also for the fashion-pieces, and marked on their respective boards.

Making the Moulds, and taking the Bevellings of the Harpins.
Plate VII. Laying-off, Plate A.

The ribbands to which the harpins are connected reach along the ship fore and aft; but in the wake of the cantbodies, or at the fore and aft parts of the ship, they are termed harpins, and are trimmed to the shape of the ship’s body by moulds and bevellings from the mould-loft. The reader, in the foregoing section, being made acquainted with the nature of cantiing the ribbands, it may only be necessary to observe, that the ribbands at the port-fill line would be placed better about eight inches below the upper side of the lower fill, so that they may be let out above the ribband; and likewise the ribband at the top timber-line should be so placed, that one of the sheer-frakes should be wrought before it is disturbed. This is commonly a larger ribband, like that at the floor-head, to keep the top-side fair.

The harpin-moulds are made of fir-board, to the diagonal or cant-ribbands lines in the cant-bodies, figs. 4 and 6; from the stem or stern-pole, to the adjoining square timber, as \( O \) and \( 28 \), to be about seven inches broad; and as they lie in their places on the floor, mark the flations of the cant-timbers upon them thus. Where the cant-timbers intersect the square ribbands, square them up to their corresponding cant-ribbands; then striking a straight line from the intersection of each cant-timber, at the middle line of the half-breath plan, to the corresponding flations latt, squared up, will give the direction of the cant-timbers as they stand with the harpin-mould, as at cant-timber \( r, \) fig. 4.

The method of taking the bevellings is at every square timber, which must be likewise marked on the harpin-mould before it is displaced. The flations of the square timbers make no alterations, because the harpin is lowered to its cant in a perpendicular direction. Fix the flock of a bevel in the direction of the diagonal, say the upper one, or third futtock-ribband \( H \), in the body-plan, fig. 3; and the tongue against the outside of the square timber \( O \); then mark it on a board (the board to be as broad as the harpin is deep or sided), and so on with the other square timbers before \( O \), marking each of them, and its respective timber, as before; then fix the flock of the bevel upon the same harpin-line in the body-plan, fig. 3, and the tongue against the side of the item, and mark that likewise upon the board; and by that bevelling the foremost end of the harpin must be trimmed, to say against the item. The fore and aft part of the harpin against the item is obtained by the foot, or swell on the fore-end of the harpin-mould, which is cut off well with the half-thickness of the item, taken diagonally, and parallel to the middle line, in the half-breath plan, fig. 4. Another bevelling is taken and applied over the end, after it is cut off to the fore and aft-line, and belved against the item, thus; fix the flock of a bevel upon the horizontal line of the harpin upon the item, and teach the tongue down the aft-side of the rabett; then mark it on the board, and the bevellings are completed. To complete the harpin-mould, square down from the sheer-plan, where the fore-side of the rabett of the item crosses the upper side of the harpin, to the mould on the half-breath plan, and make a firmark, which being kept to the fore-side of the rabett of the item on the ship, is the guide to fix the harpin to.

To Lay-off the Hawse-Pieces, Plate VIII. Laying-off B.

This plate represents the lines on the floor, as before observed, but made separare here for clearnels. The hawse-pieces, in figs. 1 and 2, are supposd to stand perpendicular when in their places, and their sides to look fore and aft. They may be called square timbers, only they look fore and aft, instead of athwartships. This being the first method of laying-off the hawse-pieces, will be easiest understood.

Strike in straight lines as much adenser, and parallel to the middle line in the half-breath plan, fig. 3, as the knight-head and hawse-pieces are to be sided, marking them \( K, \) \( H, \) 1, 2, 3, and 4.

Where the edges of the foremost cant-timbers, marked \( E, F \) in the half-breath plan, fig. 3, cross the water-lines,
SHIP-BUILDING.

main-breadth, and level line, at their heads A, square them up parallel to any of the square timbers, to their corresponding lines in the heer-plan, fig. 1, and likewise do the fame with the bearding-line, which will give the ending of the timbers on the bearding-line; then, by pinning a batten to all those spots, this shews the thwartship view of those cant-timbers when in their places, as F G.

Where the lines for the knight-head and hawse-pieces, in the half-breadth plan, fig. 3, cross the water-lines, main-breadth, and heads, let them be likewise squared up to their corresponding lines in the heer-plan, fig. 1; a batten pinned to those spots, making a fair line, and the edge rasied or chalked by, gives the form of the knight-head and hawse-pieces, and shews them in their proper places; and where the lines for the knight-head, and 1, 2, and 3 hawse-pieces, meet the fore-side of the short cant-timber, before cant y, in the half-breadth plan F, fig. 3, let them be squared up to the fore-edge, G, of the same timber, in the heer-plan, fig. 1; likewise the heel of hawse-piece 4 crossing the fore-edge of cant y, which gives the heeling of the knight-head and hawse-pieces.

The midship side of the knight-head connecting well with the side of the item, the rabbit being in the middle of it, makes the aft-side of the rabbit the fore-side of the knight-head. But when the rabbit is not in the middle of the item, it connects well with the side of the apron and dead-wood, consequently the bearding-line represents the fore-side.

Before the moulds for the knight-head and hawse-pieces can be crossed, if made, the hanging of the harpins must be described in the heer-plan, fig. 1. Thus, their heights perpendicularly from the base line, where they intersect the square timbers, and at the side of the item, in the body-plan, fig. 2, and transfer them respectively to the heer-plan, fig. 1; then, by pinning a batten to those heights, we have the lines A, B, C, D, and E, or hanging of the harpins in the heer-plan, fig. 1.

The heels of the knight-head and hawse-pieces, where they intersect the cant-timber in the heer-plan, fig. 1, are lined up perpendicular, in which direction they must be cut off, to fay against the side of the cant-timbers F and G. The moulds may now be made of inch-board to the lines marked K, or knight-head, and 1, 2, 3, and 4 hawse-pieces in the heer-plan, fig. 1, from the heads to the heel, and the moulds at the heels to be cut off in the direction of the perpendicular line theret, and while in their places mark a firmark on the moulds, wherever the harpins intersect the moulding edge of the knight-head and hawse-pieces, also the main-breadth and head, and as many between as it may be thought necessary to apply bevellings, as may be seen at the hawse-piece 4. The firmarks on the harpins also shew the height to keep the harpins on the ship.

The bevellings may be next taken, and marked on a board, which should be as broad as the fiding of the hawse-piece, having a board to the knight-head, and each hawse-piece, or all on one board, if not thought unhandy, as fig. 4. The first bevelling taken from the knight-head or hawse-pieces to the side of the cant-timber in the half-breadth plan, fig. 3, as G for the knight-head, and H for the hawse-piece 4, is the under bevelling. To cut off the heels to fay against the cant-timber thwartships, the bevel should be applied square from the heel, as cut off, to the perpendicular lines at the heels in the heer-plan, fig. 1. But to get the bevelling at the heel to counter-mould them, when the heel is cut off and trimmed to the above bevelling, the foremost edge of cant y must be laid off on the square, as i, and on the cant, as h, in the body-plan, fig. 2, as the joint of any of the cant-timbers were in Plate VII.; and so must likewise the fore-edge of the cant-filling before y, the latter being introduced only to shorten the heel of the knight-head and foremost hawse-pieces. Then strike in the body-plan, fig. 2, the fiding of the knight-head and hawse-pieces parallel to the middle line; and where the moulding edge at the heel intersects the square edge, or fore and aft view of the cant-timber, as g in the body-plan, fig. 2, level it out to intersect the cant edge b. To do this with less trouble, take the height in the heer-plan, fig. 1, of the heels of the knight-head and hawse-pieces at their intersection of the thwartship view of the fore edge of the cant-timbers, as F and G, and set them up in the body-plan, on their respective cant edges, marking them up perpendicular; then place the flock of the level against the perpendicular lines, and the tongue to the cant edge of the timber, as G for the knight-head, and F for hawse-piece 4, which will give the exact bevelling to be applied on the heel when cut off for the counter-moulding of the knight-head or hawse-pieces.

The side of the knight-head and hawse-pieces being parallel to each other, they will serve, in the heer-plan, fig. 1, for the bevellings of each other, similar to parallel lines laid down for the cant-timbers; for, as much as the moulding edge of the hawse-piece, 1, is within or abaft the moulding edge of the knight-head, from the head to the heel, so much is the bevelling of the knight-head within or under from a square, in the distance between the knight-head and the hawse-piece, 1, in the half-breadth plan, fig. 3; therefore with compasses sweep the nearest distance at each harpin, &c. from the moulding edge to the after edge of the knight-head and each hawse-piece, as may be seen at hawse-piece 4, in the heer-plan, fig. 1, and set it within a square upon the board, as at e, fig. 4; and so on for the others.

The bevellings of the knight-head and hawse-pieces, if taken from the water-lines, main-breadth, &c. in the half-breadth plan, fig. 3, would be found to alter but little; yet they are not so true in their application as when taken on a square.

But was the counter-moulding bevelling at the heel correctly set off, and another at the head for the knight-head, then the mould for hawse-piece 1, being kept well at the head and heel, and to its proper height, must consequently counter-mould the knight-head exactly, if the knight-head could be gotten long enough to reach to the heel, or if the chock was fayed before it was moulded, and the knight-head properly fided.

In the same manner, the mould that is made to the moulding edge of the hawse-piece 2, would counter-mould the hawse-piece 1, and so on of the rest.

There is no necessity to run the water-lines in the half-breadth plan, fig. 3, on purpose to lay off the hawse-pieces, because there is a sufficient number of square harpins already run; for in the half-breadth plan, fig. 3, where the knight-head and hawse-pieces cross the square harpins, let them be squared up to their corresponding harpins in the heer-plan, fig. 1, which will give the exact form of the knight-head and hawse-pieces; and, if the work is correct, will agree with the former by the water-lines.

To Lay off the Hauwse-Pieces, where the Sides are required to look fore and aft, and likewise to be fided left at the Heels.

Every timber in the ship which is fided straight, must appear, either in plan or elevation, as one straight line; therefore it is necessary, before any operation can be performed, to have a clear idea of the disposition of the timber when in its place. The hawse-pieces are intended to look fore and aft, that is, at any particular height the sides of them...
them are to be parallel to the middle line; but as the heels of them are to be fixed less than the heads, they will consequently be nearer the middle line; therefore they will not appear in a straight line in the half-breadth plan, fig. 7, as they did in fig. 3, and cannot be viewed in a straight line, unless by supposing them really in their places in the body-plan, fig. 6.

Proceed to dispose of the knight-head and hawfe-pieces as in the body-plan, fig. 6, where they will appear straight lines. The moulding edges are the thin lines, except the outside of hawfe-piece 4, which is intended to be laid off, in order to get the bevellings of No. 4 hawfe-piece.

The thwartship view of the foremost edge of cant-timber y, and the cant-filling before it in the half-breadth plan, fig. 7, which the knight-head and hawfe-pieces end against, must be squared up and represented in the sheer-plan, fig. 5, as in the preceding operation.

The fore and aft view of the foremost edge of cant-timber y, and the cant-filling before it, both on the square and cant, must be laid off as b, i, in the body-plan, fig. 6, as before explained.

Now proceed to lay off the hawfe-pieces, or to shew the form in which they will appear in the half-breadth plan, fig. 7. The knight-head is already laid off, because it is the same as the half-thickness of the item in the half-breadth plan, fig. 7. Therefore take the distance square from the middle line to the heels of the hawfe-pieces, where they intersect the fore and aft view of the cant-timbers i and G in the body-plan, fig. 6, and set them off square from the middle line in the half-breadth plan, fig. 7, on the edges of the cant-timbers F and E, which gives the heels of the hawfe-pieces in fig. 7. Take the distance square from the middle line in the body-plan, fig. 6, to where the hawfe-pieces cross the hawfe-pieces A, B, C, D, and E; and set them off square from the middle line, on their corresponding square hawfe-pieces in the half-breadth plan, fig. 7. Likewise, in the same manner take the half-breadths in the body-plan, fig. 6, for the main breadth and the hawfe-piece at the head; and set them off in the same manner as before in the half-breadth plan, fig. 7. Then pin a batten to those spots, and mark the curves in the half-breadth plan, fig. 7, which shews the form they will appear in, were you right over them, and looking down upon them; occasioned by the different curves of the body when cut by these sections.

The next operation will shew the form of the body, supposing it to be cut by the different sections of the hawfe-pieces, to which form the moulds are to be made to trim the hawfe-pieces. Proceed in the following manner:

Where the hawfe-pieces 1, 2, 3, and 4, in the half-breadth plan, fig. 7, cross the square hawfe-pieces c, d, e, f, and g; and likewise the main-breadth B, and hawfe above A; let them be squared up to their corresponding hawfe-pieces in the sheer-plan, fig. 5, where they end against the edge of the cant-timbers F and E in the half-breadth plan, fig. 7; they may be likewise squared up to intersect the thwartship view F and G of those cant-timbers in the sheer-plan, fig. 5, to give the heels of the hawfe-pieces. But this is not so true, as to take the heights of the heels where they intersect the fore and aft view of the cant-timbers i and G, in the body-plan, fig. 6, and transfer them to the sheer-plan, fig. 5, on the thwartship view of the half-timbers F and G; this is the proper height of the heels; yet if both ways agree, it shews the truth of the work. Then pin a batten to those spots squared up, and mark the curves 1, 2, 3, and 4; this gives the moulding edges of the hawfe-pieces, and shews them as they appear when in their places. This method is usually practised when required to be laid off in this manner, and will suffice for practice; but by explaining the situation of those at present laid off, it will sufficiently shew they are not exact, therefore we shall point out a method the most accurate.

Consider the hawfe-pieces as they are now laid off, and as they appear in the sheer-plan, fig. 5; you there see the exact form of them, supposing them to be in their places, and that you are looking level at them. You may therefore observe the exact form of the hawfe-pieces, when you are looking level at them, where they appear at their proper heights: consequently, then, you have the exact length and form of the hawfe-pieces only as they appear in a level view. And because they do not stand perpendicular, you cannot have the exact length nor form properly to mould them.

In order to shew the proper method that may be depended on, lay-off the moulding edge of hawfe-piece 4, or the outside of No. 3, which will make the most difference, because it stands most from a perpendicular.

There must be supposed one given point to work from; therefore, it being the most proper, let it be the heel. Strike the level line from the heel in the body-plan, fig. 6, to the heel in the sheer-plan, fig. 5, as f. If the hawfe-piece 4 was not laid off in the sheer-plan, fig. 5, the moulding edge must be gotten up, as before, from the half-breadth plan, fig. 7. Therefore, as it is, strike lines upwards, perpendicular from the separate hawfe-pieces in the sheer-plan, fig. 5, where the moulding edge of hawfe-piece 4 intersects them. Then take the distance from the heel of No. 4 hawfe-piece, in the body-plan, fig. 6, to each hawfe, main-breadth, &c. taken in the direction of the moulding edge of hawfe-piece 4; and let them up perpendicular from the heel of hawfe-piece 4, in the sheer-plan, fig. 5, on the lines before squared up, at their corresponding hawfe-pieces: then pinning a batten to those spots, mark the curve in fig. 5, which will give the exact moulding of the hawfe-piece, and the heights for the flations of the hawfe-pieces to be crossed on the hawfe-piece moulds.

Though the exact and proper method to lay-off the hawfe-pieces is described by laying off No. 4, the explanation must suffice for this, being too minute to be drawn on the plate. Yet the first method is not entirely to be condemned, as they are shewn in the sheer-plan, fig. 5, because it makes but little difference in the moulding, that the error is not to be regarded in the practice. The greatest difference it makes is in the length, which, in No. 4, does not make it two inches longer. But the certainty of the latter method being the most correct, must be proved by working at extremes; that is, suppose the head of hawfe-piece 4 to stand where it is in the body-plan, fig. 6, and the heel to be fixed at the middle line, then, if laid off by both methods, the difference would be readily seen, which method is best to be depended on.

The moulds for the knight-head and hawfe-pieces are made to the lines in the sheer-plan, fig. 5, as before directed.

The bevellings, supposing the hawfe-pieces to be properly laid off in the sheer-plan, fig. 5, are taken in the same manner as was shewn in fig. 1; for though they do not appear in the same manner in the half-breadth plan, fig. 7, yet in the sheer-plan, fig. 5, (their sides looking fore and aft,) you there see the form of them square from the plans of their respective sides; therefore the distance, as they appear from each other in the sheer-plan, fig. 5, at each hawfe, is the proper bevelling of them, agreeable to their distance from each other taken at their corresponding hawfe-pieces in the body-plan, fig. 6.

Where the heels of the hawfe-pieces step on the thwartship view of the cant-timbers in the sheer-plan, fig. 5, line them
them up perpendicular; which gives the disposition of the heels of the hawse-pieces to lay against the fore-side of each cant-timber.

The bevelling of the hawse-pieces must likewise be done as in fig. 3; for though in the half-breadth plan, fig. 7, the form of the moulding edges of the hawse-pieces appear in this view, yet the sides of them, at level heights, are exactly fore and aft; therefore the bevellings to trim the heels to lay against the side of the cant-timber, is the same for all the hawse-pieces, and must be taken with the floor of the bevel looking fore and aft, or parallel to the middle line, as is expressed by the bevel G, which is applied in the half-breadth plan, fig. 7, to take the bevelling of No. 4 hawse-piece.

To take the bevelling of the heel, to be applied when the heel is trimmed by the last bevelling, in order to counter-mould the hawse-pieces, transfer the heels of the hawse-pieces from the sheer-plan, fig. 5, to the cant-timber in the body-plan, fig. 6, as for taking the bevelling of the hawse-piece 4, and strike up a perpendicular line, to which apply the floor of the bevel, and the tongue to the fore cant-edge, as at e, fig. 6. This gives the bevelling of the heel, in order to counter-mould the hawse-pieces.

As the most accurate method of moulding the hawse-pieces has been treated of, it is requisite it should be referred to respect the disposition of the heels, and the bevelling of the heels. As the bevelling of the heel is shewn for No. 4 hawse-piece, the following will explain the difference that may be expected, if the hawse-pieces were required to be laid off on extremes, or if a section of the body were required in such direction.

Set up any particular height on the hawse-piece 4, in the body-plan, fig. 6, and suppose it to be the height where the harpin C intersects it; then take that height from the heel of the hawse-piece No. 4, in the direction of the line of the hawse-piece, and set it up perpendicular from the heel of No. 4 hawse-piece, in the sheer-plan, fig. 5. Take the distance square from the middle line at the proposed height in the body-plan, fig. 6, and set it off square from the middle line in the half-breadth plan, fig. 7, on the cant edge E; there make a spot, and carry it square up to the ticked level line in the sheer-plan, fig. 5, and strike the line from thence to the heel of No. 4 hawse-piece, which gives the exact form of the heel to lay against the fore-side of cant-timber y.

From the spot before mentioned in the half-breadth plan, fig. 7, take the distance to the middle line in the direction of the cant-timber, as E, and set it off from the middle line in the body-plan, fig. 6, on the ticked level line, and draw it down to the heel of the timber; which is the proper line to which the floor of the bevel should be applied to take the bevelling of the heel, in order to counter-mould the hawse-pieces. The explanation of the above must suffice, as it would not only interfere with the method laid off, but also be too minute to be deferred on the plate.

Where the hawse-pieces in the half-breadth plan, fig. 7, cross the square harpins c, d, e, f, and g, square them up to their corresponding cant-harpins, as at h, which gives the proper stations of the hawse-pieces on the cant-harpins; but the direction of the hawse-pieces to be marked on the harpin-moulds will be fore and aft, as well on the cant-harpins as on those which lie level; such are the harpins at the port-fell and head; for where the hawse-pieces cross those harpins in the half-breadth plan, fig. 7, is the proper station of the hawse-pieces on the aforesaid harpins; or otherwise it is the proper distance from the middle line which the hawse-pieces will be on each harpin, when the harpins are in their places; because those harpins are shewn in the half-breadth plan, fig. 7, as they really appear when they are in their places.

To Lay-off the Hauue-pieces when canted.

The method of laying off and disposing of the hawse-pieces when canted, is the most complete of any, as it is the rule for the length of the ship, and will likewise afford the conversion of the timber; for by canting them, they will not only be diminished at the heels, whereby a less piece of timber will make them, as in the foregoing method, but the bevellings will be less acute; and as the canting and diminishing of them at the heels are performed by one operation, they consequently must appear as straight lines when viewed in the half-breadth plan; and, as before observed, that all timbers, when canted nearer to a square with the body, add more to the security of the plank, and the timbers are not wounded so much by that securit. The canting of the hawse-pieces is also some advantage to the hawse-holes; for although the hawse-holes are generally cut nearly parallel to the middle line, yet cantiug of them leaves most wood at the outside of the hawse-hole, which is the farthest from the middle line, as it is the wearing side of the hawse-hole.

Dispoae of the hawse-pieces in the half-breadth plan as in fig. 11, on which plan they will be straight lines, similar to the cant-timbers. Strike in likewise the fore-side of the cant-timbers marked E, F, as before, against which the heels of the hawse-pieces are to be cut off.

Lay off the thwartship view of the hawse-pieces and fore-side of the above cant-timbers E, F, in the sheer-plan, fig. 9, in the following manner. Where the fore-side of the cant-timbers E and F in the half-breadth plan, fig. 11, croises the half-thickness of the dead-wood C, square them up to the bearding-line in the sheer-plan, fig. 9, and in the same manner proceed at every-water-line, 1, 2, 3, 4, 5, and 6; likewise with the main-breadth and harpin at the beak-head; then pin a batten to those spots, and mark the curves, as F, G, which gives the thwartship view of the fore-side of the cant-timbers the hawse-pieces heel against.

In the same manner proceed with the hawse-pieces: where, in the half-breadth plan, fig. 11, they intersect the water-lines, main-breadth, and harpin above, square them up to their corresponding lines in the sheer-plan, fig. 9; and where they intersect the fore-edges of cant-timbers E and F in the half-breadth plan, fig. 11, square them up to intersect the thwartship view of the said cant-timbers, as E and G in the sheer-plan, fig. 9. This shews the exact height of the heels of the hawse-pieces, where they slope against the cant-timber, when they are in their places. Then by pinning batten to all the spots squared up, mark the curves 1, 2, 3, and 4, which will give the exact thwartship view of the hawse-pieces, supposing they were in their places; but as the sides do not look fore and aft, these are not the proper lines to make the moulds to; but will be serviceable hereafter, to get the proper height of the harpins to be croised upon the hawse-piece moulds. The moulding edge of the knight-head is the aft-side of the rabbet of the stem.

Where the knight-head and hawse-pieces intersect the fore-side of the cant-timber, marked E in the half-breadth plan, fig. 11, to a batten in the direction of the line of the knight-head, or hawse-pieces; mark thereon the points where they are intersected by the water-lines; and let them off from the middle line in the body-plan, fig. 10, on their corresponding water-lines. Then take the heights, where the heels of the knight-head and hawse-pieces intersect the thwartship view of cant-timber F in the sheer-plan, fig. 9, and transfer them to the middle line in the body-plan, fig. 10.
Having the lower height of breadth and harpin at the
beak-head laid off in the sheer-plan, fig. 9, take the heights
where they intersect the thwarts view of the knight-
head and hawfe-pieces, and transfer them to the body-plan,
fig. 10. Then take the distances in the half-breadth plan,
fig. 11, from the intersection of the knight-head and hawfe-
pieces, with the cant-timber marked E, to the main-breadth
and harpin at the beak-head, in the direction of the fiding
and ticked line, and set them off from the middle line in the
body-plan, fig. 10, on their corresponding lines, marking spots.
Then by pinning a batten to these spots, mark the curves
K, H, I, 1, 2, 3, and 4, which are the proper moulding edges
of the knight-head and hawfe-pieces, and consequently those
to which the moulds are to be made. Now to give the direc-
tion for cutting off the heels to lay against the side of the
cant-timber, the mould of No. 4 hawfe-piece must be cut
off well with the middle line in the body-plan, fig. 10; but
as the knight-head and the other hawfe-pieces cut off against
the timber, before that which No. 4 heels against, take
the height in the sheer-plan, fig. 9, where the heels of the
knight-head, and 1, 2, 3 hawfe-pieces intersect the thwarts
view of the foremost cant-timber at G, and transfer them to
the body-plan, fig. 10; and where they intersect their re-
spective hawfe-pieces, strike up a perpendicular line, as
at No. 3 hawfe-piece, which will also give the direction to
cut off their heels against the said cant-timber.

But now, since they are laid off by the water-lines, the
proper stations of the harris below the main-breadth can-
not be marked on the moulds. Therefore the thwarts
view of the harris must be laid-off in the sheer-plan,
fig. 9, as before, which is the exact height of them when they
are in their places; consequently, then, the points where they
intersect the thwarts view of the knight-head and hawfe-
pieces, shall the exact height be transferred from the sheer-
plan, fig. 9, to their corresponding lines in the body-plan,
fig. 10, which gives the exact stations of the harris to be
crooked on the knight-head and hawfe-pieces moulds.

The beevlings are to be taken thus: Strike a line in the
half-breadth plan, fig. 11, to the fiding of the knight-head
and hawfe-pieces, as was done for bevelling the cant-timbers,
as the ticked line at No. 4 hawfe-piece, it being the clearest
of all to be understood. Then square a line at the heel, where
the moulding edge of No. 4 hawfe-piece crooks the can-
timber marked E. Then take the distance from the squared
line in the direction of the fiding or ticked line to the separate
water-lines, where they intersect the ticked line, and set them
off from the middle line in the body-plan, fig. 10, on their
behalfing water-lines. Where the ticked line in the half-
breadth plan, fig. 11, intersects the cant-line E, square it up
to intersect the thwarts view F, in the sheer-plan, fig. 9,
as marked with a star, and from thence transfer it tt the
body-plan, fig. 10, as far as the middle line. Then take the distance
from the squared line at the heel in the half-breadth plan,
fig. 11, to the cant-line E, in the direction of the ticked line,
and set it off from the middle line in the body-plan, fig. 10,
at the height last mentioned. Continue the ticked line or
fiding of the hawfe-piece to intersect the water-lines 1, 2,
and 3, in the half-breadth plan, fig. 11; then take the dis-
tance from the squared line at the heel to those water-lines
in the direction of the fiding or ticked line, and set them off
from the middle line in the body-plan, fig. 10, on their corre-
sponding water-lines to the left-hand, which serves to prove
the spot at the heel by continuing the bevelling edge to the
lowest water-line. Where the ticked line or fiding of the
hawfe-piece 4, in the half-breadth plan, fig. 11, intersects the
main half-breadth and beak-head harpin, square them up to
their corresponding lines in the sheer-plan, fig. 9, and trans-
fer them to the body-plan, fig. 10, striking level lines. Then
take the distance from the squared line at the heel in the
half-breadth plan, fig. 11, to the main half-breadth and
beak-head harpin in the direction of the fiding or ticked
line, and set them off from the middle line in the body-
plan, fig. 10, on their corresponding heights, which gives
the spots to which a batten must be pinned, and the curve
marked out thereby will be the bevelling edge of the hawfe-
piece 4, and at whatever distance the bevelling edge in the
body-plan, fig. 10, is from the moulding edge of the hawfe-
piece 4, so much is the hawfe-piece under a square in the
distance from the fiding or ticked line, to the joint of the
hawfe-piece in the half-breadth plan, fig. 11.

The bevel G, as shewn in the half-breadth plan, fig. 11,
gives the direction to cut off the heel. When the heel is cut
off, in order to find the bevelling of the heel to counter-
mould the hawfe-pieces, the fore-lides of the cant-timbers, as
E and F, in the half-breadth plan, fig. 11, must be laid off
in the body-plan, fig. 10, which may be done by the water-lines.
Then transfer the height of the heel of the hawfe-piece
No. 4, from the sheer-plan, fig. 9, where it cuts the thwarts
view of the cant-timber marked F, to its corresponding
cant-timber in the body-plan, fig. 10, and strike a perpendi-
cular line; to which apply the flock of a bevel, and the
tongue, to the cant-timbers, as at M; the fame likewise for
hawfe-piece No. 1, as at L, and so on for the others. This
gives the exact bevelling to be applied when the heel is cut
off, in order to counter-mould the hawfe-pieces, if it should
be so required. The bevellings of No. 4 hawfe-piece are
all taken at their heights, as may be seen in the body-plan,
fig. 10, and marked on the bevelling-board, as at a in fig. 12:
the laid heights to be all croosed upon the hawfe-piece
mould.

To Lay-off the Hawfe-Pieces by the Square Harpins taken
off.

The square and cant-harpins being of necessity laid off in
the half-breadth plan, fig. 11, it is necessary to explain the
method of laying off the cant-hawfe-pieces by the square
harpins, which are marked E, F, in the half-breadth
plan, fig. 11. The point where the knight-head and hawfe-
pieces intersect the fore-lide of the cant-timber marked E
in the half-breadth plan, fig. 11, is supposed to be in the
middle line in the body-plan, fig. 10, which middle line will
serve for laying off the knight-head and hawfe-pieces, as it
did for the foregoing operation by the water-lines. By being
laid off in the same body-plan, fig. 10, it will be a convincing
proof that both methods may be depended upon, because
they will be found to agree, as near as can be expected on
so small a scale as the plate.

To explain the laying off the knight-head and all the
hawfe-pieces would be too tedious; (though they are all
laid off in the same body-plan) for laying off and bevelling the
cant-hawfe-piece No. 4, the ticked lines (which are
transferred from the sheer-plan, fig. 9, to the body-plan,
fig. 10, in order to give the proper stations of the harpins
on the hawfe-piece moulds, when laid off by the water-
lines) will now be proved to agree with the operation by the
harpins.

Now the knight-head and hawfe-pieces are intended to
be laid off together by the harpin-lines. There is no ne-
cessity to lay-off the thwarts view of them in the sheer-
plan, fig. 9; but the thwarts view of the fore-lide of the
cant-timber they heel against will be wanted, to find the
height of the heels. Having the plane height of the har-
pins laid off before in the sheer-plan, fig. 9, where the
fore-lides of the cant-timbers, marked E, F, intersect the
square
square harpins \( c, d, e, f, g \), in the half-breadth plan, fig. 11, square them up to their corresponding harpins in the sheer-plan, fig. 9. This gives the thwartship view of the cant-timbers; and if the work be true, it will answer the fame as by the water-lines. The exact height of the heels should be found, in order to prove the rest of the work; and as the lines of the hayse-pieces in the half-breadth plan, fig. 11, are continued abaft the fore-side of the cant-timbers, as \( E, F \), to intersect the square harpins \( c, d, e \), then by having spots in the body-plan, fig. 10, beyond the middle line, (when the batten is continued to the spots beyond the middle line on those harpins,) it would intersect the middle line at the proper height of the heel of the hayse-piece.

To prove the hayse-piece No. 4, as laid off by the water-lines, let it be laid off by the level or square harpins: thus, where the moulding edge intersects the fore-edge of the cant-timber, marked \( E \) in the half-breadth plan, fig. 11, square it up to their intersecting thwartship view \( F \), in the sheer-plan, fig. 9; and transfer that height to the middle line in the body-plan, fig. 10. This gives the heel of the hayse-piece No. 4, exactly similar to the method by the water-lines.

Observe in the half-breadth plan, fig. 11, where the hayse-piece No. 4 crosses the square harpins, and from thence take the nearest distance to the middle line; and let them off on their respective harpins square from the middle line in the body-plan, fig. 10, there striking a level line, in the same manner as was done for the cant-timbers. Then take the distances in the half-breadth plan, fig. 11, from the intersection of the hayse-piece No. 4, with the cant-edge marked \( E \), to where it intersects each of the square harpins, in the direction of the line for the said hayse-piece; and let them off square from the middle line in the body-plan, fig. 10, on their respective level lines before mentioned; observing to let off the distance to the left hand of those which were taken abaft the cant-line \( E \). This gives the spots for the moulding edge of the hayse-piece No. 4; and is likewise the exact elevation of the harpins to be crossed on the moulds.

Proceed in the same manner to find the spots for the moulding edges of the other hayse-pieces; as those for the main-breadth and beak-head harpin are found in the very same manner as by the water-lines.

The beveling-edge is laid off in the very same way as the moulding edge; only the distance taken in the direction of the tied or fising-line is taken from the squared line at the heel, instead of its intersection at the cant-edge \( E \), in the half-breadth plan, fig. 11. The plate will shew that the difference of laying-off, between the water-lines and harpins, is in the performance only.

To find the proper latitons of the knight-head and hayse-pieces on the harpin-moulds, we need only square up the intersections of them with the square harpins to the cant-timbers, in the same manner as was done for the cant-timbers. And the points where the knight-head and hayse-pieces in the half-breadth-plan, fig. 11, cross the harpins at the ports and beak-head, shew the proper latitons of them, as they appear when the harpins are in their places, they lying level in a thwartship direction to the sheer of the ship, the fore and aft-way. The main breadth is only used as a beveling spot; for it was required to place a harpin to that height, its great value would require a very different operation to form the line to make the mould to.

To Lay-off the Tranforms, Plate IX. Laying-off C.

The trantsoms and fashion-pieces compose the stern-frame. The upper ones are the wing, filling, and deck-tranforms; and there may be as many under the deck-transform as the form of the body will admit, of kindly growth. The uppermost is called the wing-transform, which is the base of the stern.

This may be admitted the strongest and best method of uniting the after-part of the ship together: the strongest, because every transform crossing the after-part of the ship, and bolting through the stern-poll, they may be confidered similar to the breast-hooks; so that when the planks are wrought on the buttock, and the wing-transform knees, and fleerers or diagonal knees are bolted, it may be allowed to be as strong as the fore-part or bow is with the breast-hooks, because the fore-part of the ship has no other asistance to keep the bows together.

As there are several operations required to lay-off the stern-frame, Plate IX. Laying-off C, is made a separate plate for that purpose; though it represents the lines on the floor, as before observed.

The fashion-pieces being struck in the half-breadth plan on the floor, and the water-lines run as in Plate I., square up the intersection of the fashion-pieces with the bearding-line, water-lines, the end of the wing-transform, and main half-breadth line in the half-breadth plan, to their corresponding bearding-line, water-lines, wing-transform, and height of breadth line in the sheer-plan; then a batten pinned to those spots will represent the thwartship view of the aft-sides of the fashion-pieces \( T, F, P \), Plate IX. fig. 1.

Where the aft-sides of the fashion-pieces intersect the before-mentioned lines in the half-breadth plan, take the distances square from thence to the middle line; and let them off square from the middle line, on their corresponding lines in the body-plan. A batten pinned to these spots will give the fore and aft view of the fashion-pieces, generally called the square fashion-pieces, which are marked \( S, F, P \), Plate IX. fig. 2.

Transfer from the sheer-plan of Plate I. the heights of all the trantsoms to the sheer-plan on the floor; likewise the fiding or depth of each transform, as \( W, F, D, 1, 2, 3, 4, 5, 6 \), Plate IX. fig. 1.

In the body-plan, fig. 2, describe the upper side of the wing-transform \( a \), by a segment of an are to its round-up, till it intersects the aft-side of the foremost square fashion-piece \( S \); and below that a parallel curve \( b \), where the ends of the planks of the buttock are intended to be cut off, which is called the margin-line. Square down from the sheer-plan the aft-side of the wing-transform to the middle line of the half-breadth plan; and from thence descibe the aft-side of the wing-transform at its upper side, by a segment of an arc to its round-off, which shews the line to which the mould is to be made. Take the height of the margin-line \( e \), at the middle line in the body-plan, fig. 2, and transfer it to the fore-part of the rabbet of the stern-poll, in the sheer-plan, fig. 1; and from thence square it down to the middle line in the half-breadth plan, marking a parallel are to the aft-side of the wing-transform, which is likewise called the margin-line. Continue to shew the level view of the moulding edges of all the trantsoms in the body-plan, fig. 2, in the following manner: the wing-transform, the filling under it lying level, then form the segment of an arc to their round-up, as above. This is the proper curve to which the round-up mould is made for fiding those trantsoms. The next is the deck-transform, which is generally laid off to the round-up of the gun-deck beams; the other trantsoms below the deck lying straight and level, are represented by level lines only.

Transfer from Plate I. the buttock-lines \( 1, 2, 3, 4, 5, 6 \), and
and let them be struck on the floor in the body-plan and half-breadth plan. Then proceed to run the buttck-lines in the sheer-plan, fig. 1, as directed in the construction of the sheer-draught, Plate 1. The buttck-lines, the square timbers, and likewise the water and ribbont-lines, should be made to agree to the greatest exactness.

The moulding edges of the other transoms may now be laid off from the buttck-lines in the sheer-plan, fig. 1; but if they are laid off in the half-breadth plan, then only half or one side can be represented. The best method, therefore, will be to lay them off in some convenient place on the floor by themselves, whereby both sides may be represented, and there will not be then such confusion in the lines. This, for distinction, may be termed plan of the transoms, as Plate IX. fig. 3.

The moulding edge of the wing-transom is already described to which the mould is to be made; the filling-transom is next, which lies between the wing and deck; and as it lies horizontally, the description of it will suffice for all the other transoms that come under the deck, which also lie horizontally.

As there is no more trouble in laying-off a transom which is fined straight, and lies level, than in laying-off a water-line, strike on each side of the middle line M, in the plan of the transoms, Plate IX. fig. 3, the half-thickness of the dead-wood or bearding-line, where, at the bottom of the body-plan, fig. 2, and as low down as the deck-transom the inner poft is fined the same; likewise the buttck-lines. Take from the half-breadth plan the square timbers 32, 33, 34, 35, 36, and the proof timbers 1 and 2, and strike them in the plan of the transoms, fig. 3, at right angles with the middle line; also strike in the cant of the fashion-pieces P, M, A. Then strike a perpendicular line, P, in the sheer-plan, fig. 1, at the intersection of the upper edge of the wing-transom, at the fore-part of the rabbit; likewise another at right angles with the middle line, at the after-side of the wing-transom, as PP, in the plan of the transoms, fig. 3.

Now from the perpendicular P, above mentioned, called perpendicular of the transoms, take the distance in the sheer-plan, fig. 1, to where the upper side of the filling-transom, E, intersects the fore-side of the rabbit of the poft or bearding-line B, and set it off from the same line P, in the plan of the transoms, fig. 3, at the middle line, squaring a line across to each bearding-line; which line will be the after-part of the filling-transom at the middle line. Observe where the bearding-line, C, of the poft, in the sheer-plan, fig. 1, comes before the fore-side of the rabbit, to take the aforesaid distance to the bearding-line of the poft, as that terminates the after-part of all the transoms; then take the distances in the sheer-plan, fig. 1, from the perpendicular line P, to where the line representing the upper side of the filling-transom intersects the different buttck-lines 1, 2, 3, 4, 5, and 6, and get them off from the same line P, in the plan of the transoms, fig. 3, on their corresponding buttck-lines on each side of the middle line. Then take the distances in the body-plan, fig. 2, from the middle line, to where the upper side of the filling-transom, E, intersects the square timbers, and get them off on both sides of the middle line on their corresponding timbers, in the plan of the transoms, fig. 3; then by pinning a batten through the spots on the buttck-lines and square timbers, to its after-part at the side of the bearding C, the moulding edge or upper side of the filling-transom will be described on one side the middle line; the mould may then be made to that side, and canted over, and the opposite side marked thereby, being faire thus to have both sides alike. This filling-transom having been laid off horizontally, of course, when moulding the filling-transom, the mould must lie in an horizontal position; but having to little room between the wing and deck-transoms, it becomes necessary to give the filling-transom a round-up between both. Those who would be more correct in laying-off transoms, that have a round upwards, may see the full details farther explained in the following methods.

To lay-off the deck-transom, strike a straight line in the sheer-plan, fig. 1, at its under-side of the deck, at the middle line, to take that part of the hang of the deck only, which is terminated between the rabbit of the ftem-poit and the fashion-piece, as E, fig. 1. Then take the round of the deck R, at every buttck-line, as under the body-plan, fig. 2; and let them off below and square to the straight line H, in the sheer-plan, fig. 1, marking parallel lines thereto, to intersect their corresponding buttck-lines, which gives the moulding edge of the transom. Proceed in the same manner with the lower edges, by striking a line for the lower side of the transom at the middle line parallel to the former; and set the round down, as before, upon any buttck-line.

The upper and lower sides of the deck-transom being obtained on the buttck-lines, in the sheer-plan, fig. 1, transfer their heights from the sheer-plan, fig. 1, to the body-plan, fig. 2, respectively; then by pinning a batten to those heights, the upper and lower sides of the deck-transom, d d', may be represented in the body-plan, fig. 2.

The lines above mentioned, in the sheer-plan, fig. 1, parallel to the sheer of the deck, at the intersection of the buttck-lines and fashion-piece, should be continued ast to the perpendicular P; then take the distances from that line, in the direction of the parallel lines, to the buttck-lines and fashion-piece, and let them off square from the said line P, in the plan of the transoms, fig. 3, on their corresponding buttck-lines and fashion-piece. Next take the half-breadth from the body-plan, fig. 2, at the intersection of the deck, at the side, with the square timbers, and let them off on their corresponding timbers from the middle line, in the plan of the transoms, fig. 3; then by pinning a batten to those spots, this forms the moulding edge of the deck-transom D D. The transoms under the deck, all lying horizontally, may be laid off by taking the distances of the buttck-lines and bearding-line from the perpendicular P, in the sheer-plan, fig. 1, on the upper edge of each transom, and setting them off on their corresponding buttck-lines from the same perpendicular P, in the plan of the transoms, fig. 3; and also at the timbers from the middle line in the body-plan, fig. 2; and let them off from the middle line on their corresponding timbers in the plan of the transoms, fig. 3; a batten pinned to those spots will represent the moulding edges of all the transoms.

To prove the intersection of the transoms with the side of the fashion-piece, which is the end of each transom, as already laid off in the plan of the transoms, fig. 3. Thus, where the upper side of the wing-transom in the body-plan, fig. 2, intersects the foremost square fashion-piece S, level it out to intersect the cant-fashion-piece C. Then take the nearest distance from the cant-fashion-piece at that place to the middle line, and set it off from the middle line in the plan of the transoms, fig. 3, in the direction of the line of the foremost fashion-piece F. In the same manner prove the filling and deck-transoms. Take the distances from the middle cant-fashion-piece to the middle line along the upper side of Nos. 1, 2, and 3 transoms in the body-plan, fig. 2, and set them off on the middle cant-fashion-piece M, from the middle line in the plan of the transoms, fig. 3, as before. Take likewise the
SHIP-BUILDING.

the distances from the aftermost cant-fashion-piece to the middle line for the transoms 4, 5, and 6, and let them off, as before, on the line for the aftermost cant-fashion-piece $A$, in the plan of the transoms, fig. 3; to which spots the transoms in fig. 3. must agree.

Cut off the ends of the wing, filling, and deck-transoms, at the joint or aft-side of the foremost fashion-piece $F$, and transoms Nos. 1, 2, and 3, under the deck at the aft-side of the middle fashion-piece $M$, and Nos. 4, 5, and 6, at the aft-side of the after-fashion-piece $A$, as is clearly shown in the plan of the transoms, fig. 3, where the middle fashion-piece is represented as sloping at the under side of the deck-transom, and the after-fashion-piece at the under side of the transom No. 3.

To make the Moulds and bevel the Transoms.

The moulds are made of fir battens fayed to the lines already laid off in the plan of the transoms, fig. 3, for their aft-sides; and another to their fore-side, at their moulding or breadth at the upper side; which are confined together by battens at each buttock-line, and one at each end to the direction of the fashion-piece, allowing what they are intended to be let into the fashion-pieces; and a broad piece in the middle, to the size of its leant $c$, with the middle line correctly marked thereon.

The bevelling of the transoms are frequently taken from the buttock-lines in the sheer-plan, fig. 1, in the following manner. Apply the flock of the bevel $E$ to the upper side of the transom, in the sheer-plan, fig. 1, and the tongue to the buttock-line; but let the tongue be off at the upper and lower sides of the transom, as at the filling-transom in the sheer-plan, fig. 1, which gives the exact bevelling of the transoms at their corresponding buttock-lines.

The bevellings for the wing-transom are taken from the margin-line to the under side of the wing-transom, as above. The under side of the wing-transom is transferred from the body-plan, fig. 2, to the sheer-plan, fig. 1, by the buttock-lines.

The bevelling for the deck-transom may be taken by applying the flock of the bevel parallel to the hang of the deck, at the middle line, and the tongue to each buttock-line; keeping the tongue well at the upper and lower sides of the transom, as before observed, and must be applied on the transom, by placing the bevel at each corresponding buttock-line, and keeping the flock out of winding with the upper side of the transom at the middle line.

The transoms under the deck may be bevelled by the buttock-lines in the sheer-plan, fig. 1, and the bevellings may be taken very exact; but it requires to be very particular in applying the bevel on the transoms; to do which, the flock of the bevel must be kept in the direction of the buttock-lines, at the upper side of the transom, and the tongue teaching to the buttock-line below, which ought to be marked at the lower side of the transom, and not trusting to the bevel's canting promiscuously, for then the bevel may not be exactly square.

When this trouble is taken to bevel the transoms, then they may, when trimmed, be depended upon.

This is a method not to be recommended to those who would be particularly exact, because there can be no more bevellings on the transoms than the number of buttock-lines which intersect the transoms; as for instance, there are only two buttock-lines which cross the lower transom in fig. 3, and one of them is close to the end, which is not sufficient to get the exact form of the lower side of the transom. Therefore, the best way to find the bevellings of those transoms is to lay-off their lower sides, which is very easy to be effected here, because all the transoms lie level. Proceed in the sheer-plan, fig. 1, at the under side of the lower transom, to take the distance from the perpendicular of the transom $P$, to the intersection of each buttock-line, and likewise the bearding-line; and let them off from the line $PP$, on their corresponding buttock-lines and bearding-line, in the plan of the transoms, fig. 3. Then from the middle line of the body-plan, fig. 2, take the distances at the lower side of the said transom to the square timbers, in the same manner as the moulding edges were done, and let them off on their corresponding timbers, in the plan of the transoms, fig. 3, which gives the spots; to which a batten pinned will give the form of the lower edge $L$, which is ticked, to distinguish it from the moulding edge. In the same manner may be laid off the lower or bevellings of edges of all the transoms.

The distance from the upper or moulding sides of the transoms, to the ticked line for the lower sides, shews how much the transoms are under from a square; only in the distance from the upper to the lower sides of the transoms, in the sheer-plan, fig. 1, must be supposed the breadth of the beveling-board.

By having the lower sides of the transoms laid off, we have an opportunity of taking as many bevellings as may be thought sufficient, without any confinement; therefore, on the lower transom may be placed three bevelling spots, which should be divided equally between the beech and the fashion-piece; then take the nearest distance from the spots on the moulding edge, (which must be firmarked on the moulds,) to the ticked line for the lower edge, by sweeping it with a pair of compasses, which shews how much the transom is under from a square at each bevelling spot, as at $a, b, c$, in the plan of the transoms, fig. 3, agreeable to the depth of the transom. In the same manner may the bevellings of all the transoms below the deck be taken.

The bevelling for the breech of the transom is taken from the upper side of the transom, and the tongue to the bearding-line in the sheer-plan, fig. 1; for the transoms are all supposed to be cut off in the direction of the bearding-line $C$. The ends of all the transoms, when moulded, are trimmed square from the upper side. But the square, when applied to the end of the wing, filling, and deck-transoms, must be lifted up as much as the transom rounds down, and appears out of winding with a batten in the middle line.

To find the bevelling for the ends of the transoms, when cut off, let the flock of the bevel be placed to the lines of the upper sides of the transoms in the body-plan, fig. 2, and the tongue to the cant-fashion-piece, which gives the proper bevelling over the end of the transoms when cut off.

But to find the bevelling for the end of the wing-transom, take the distance square from the middle line to the intersection of the joint, or aft-side of the foremost fashion-piece, with the end of the wing-transom, in the plan of the transoms, fig. 3; and let it off square from the middle line on the upper side of the transom in the body-plan, fig. 2, and level it out till it intersects the cant-fashion-piece. Then apply the flock of the bevel on the line bevelled out, and the tongue to the cant-fashion-piece, as at $B$. This gives the bevelling for the end of the wing-transom, when cut off. But the bevel must be lifted up as much as the wing-transom rounds down at the end, and appears out of winding with a batten kept well with the middle of the wing-transom. The same must be also done for the bevelling at the end of the filling and deck-transoms.

The points where the transoms under the deck-transom in the body-plan, fig. 2, intersect the cant-fashion-pieces, are the proper stations to be crossed on the fashion-piece mould. And where
where the lines (before mentioned) levelled out intersect the cant-fashion-piece, is the proper section of the wing, filling, and deck-tranoms on the fashion-piece mould for the moulding edge, but not for the direction in which those tranoms strike the fashion-piece, because of the round of those tranoms; which will be more explained in the following method.

When the lower sides of the tranoms are laid off, it is but little trouble to make a flight mould to counter-mould the under sides of all the tranoms, by making it only to one arm of the tranoms, and then canting it over, to mould the opposite arm. Then, when the breech of the tranom is trimmed to the bearding-line, set off the distance from the middle line each way, as far as the bearding-line e is from the middle line in the plan of the tranoms, fig. 3; to which the tranom-mould is made. Then trim the end of the tranom square, and set off the bevelling for the end of the tranom; then cant the tranom over, and applying the mould made for the under side to the breech and bevelling at the end, you have the tranom counter-mould, without the assistance of any other bevelling; or they may be set off, to see if they agree with the mould; and if they do, you may be sure the work is correct.

To Lay-off the Tranoms when canted.

The utility of canting the tranoms is, that it greatly affords the conversion of timber, is better for fastening the plank of the bottom, and bolts square to the ftern-poll. When the tranoms have a very great bevelling, it is difficult at the upper edge to get sufficient fastening for the planks, which sufficiently points out the utility of canting them: proceed therefore to the operation, which will require the reader’s particular attention; as those minute particulars which cannot so conveniently be displayed on the plate, can only be explained in words.

Dipose of the tranoms in the sheer-plan, fig. 4; let the wing and filling-tranoms be placed level, and the upper side of the deck-tranom to the proper hang of the deck; and the other tranoms below at the fashion-piece, as much above a level as represented in the sheer-plan, fig. 4; so as to make them nearly of an equal opening at the ftern-poll, and likewise at the fashion-piece. These show the disposition of the tranoms at the middle line.

Now proceed to shew the level view of the moulding edges of all the tranoms in the body-plan in the following manner: the wing-tranom a, and the filling e, lying level, they form a segment of a circle in the body-plan, fig. 5, to their given round-up. This is the proper curve to which the round-up mould is made for fixing these tranoms, as before observed. The next is the deck-tranom d, which being confined to the hang of the deck, and the round of the beam, is the most difficult of any, if executed in a proper manner: it ought to undergo the following operation. The ticked line H, in the sheer-plan, fig. 4; is the under side of the deck at the middle line, and is intended to be the upper side of the deck-tranom at the middle line. Transfer the heights of the ticked line H, or upper side of the deck-tranom, in the sheer-plan, fig. 4, at every square timber, to their corresponding timbers in the body-plan, fig. 5; and where the deck at the middle line in the sheer-plan, fig. 4, intersects the buttock-lines, transfer them to their corresponding buttock-lines in the body-plan, fig. 5; a batten pinned to these spots shews the interjection of the deck at the square timbers, as H, in the body-plan, fig. 5; supposing the deck had no round-down at the side. Under the line A A, for the upper side of the keel, in the body-plan, fig. 5, mark the round-up of the gun-deck beam R; and where the ticked line H for the deck, at the middle line, in the body-plan, fig. 5, intersects the square timbers, square them down to the round of the deck R, under the body-plan. The timbers and the buttock-lines are there marked and numbered in the same manner with those from which they were squared down. Take the distance at each place on the round of the deck, under the body-plan, fig. 5; square up to the line A A, or upper side of the keel (which is the round of the deck at each timber), and set them down below their corresponding timbers, in a perpendicular direction, from the interjection of the deck at the middle line with the square timbers H, in the body-plan, fig. 5; and from those spots direct them towards the middle line M, parallel to the round of the deck under the body-plan, till they intersect the square timbers, which are the proper sections on the square timbers the curve I of the deck will make, supposing it to be continued to the outside of the timbers; which is required, in order to find the exact form of the moulding edge of the deck-tranom.

Let the buttock-lines in the body-plan, fig. 5, be continued down to the round of the deck R, under the body-plan; then take the round of the deck at each buttock-line, and set it down below the deck at the middle line H, in the sheer-plan, fig. 4, on their corresponding buttock-lines, and transfer those spots to the buttock-lines in the body-plan, fig. 5; then to those spots on the buttock-lines, and those on the timbers, pin a batten, and it will shew the curve the deck-line at the side will make, if continued to the outside of the timbers, as I, in the body-plan, fig. 5.

To find the deck at the side in the sheer-plan, fig. 4, take the heights at every square timber in the body-plan, fig. 5, where they intersect the deck at the side, and transfer them to their corresponding timbers in the sheer-plan, fig. 4: by pinning a batten to those spots, with those made before on the buttock-lines, you have the deck at the side, as I, in the sheer-plan, fig. 4, which is the level view of the moulding edge of the deck-tranom.

To find the lower side of the deck-tranom in the sheer-plan, fig. 4, and likewise in the body-plan, fig. 5; this should be done in the same manner as the upper side. If it is intended to be very correct, run the ribband-lines, which will be a proof to the rest of the work, in laying-off the tranoms.

To find the level view of the tranoms below the deck, in the body-plan, fig. 5, observe where the lower and upper sides of the tranoms in the sheer-plan, fig. 4, intersect the buttock-lines, square timbers, and fashion-pieces; transfer those heights to the body-plan, fig. 5, on their corresponding lines, which give the level view of the tranoms in the body-plan, fig. 5.

To lay-off the cant-tranoms, proceed, as before, to make a separate plan, as fig. 6. The moulding edges of the wing, filling, and deck-tranoms, are laid off so similar to the former, as not to need repeating here. But should the deck-tranom have much flier, and a great round, it would be a further proof of correctness, to take the distance from the perpendicular line P, in the sheer-plan, fig. 4, to timber 32, in the direction of the flier of the deck I, and set it off from the line P P, in the plan of the tranoms, fig. 6, which will be further forward than the said timber, as before laid off; then pin a batten to the round of the deck under the body-plan, fig. 5, marking the middle line, and the spot that was squared down from the deck at the side, at timber 32, to the round of the deck, and set it off on the new timber 32, in the plan of the tranoms, fig. 6. This would give the exact spot on timber 32, if the deck was required to hang and round to extremities, in the same manner.
as by pinning a battcn to the round of the wing and filling-transoms in the body-plan, fig. 5, and marking the square timbers, buttock-lines, and square fashion-pieces on the batten; then let the batten lie straight, and it will be the exact half-breadth at every square timber, buttock-line, and fashion-piece, and will give the exact length of the wing-transom.

To lay-off the transoms under the deck, take the distance from the line P, in the sheer-plan, fig. 4, to the buttock-lines in the direction of the transoms, and set them off from the line P P, in the plan of the transoms, fig. 6, on their corresponding buttock-lines. Take the half-breadths in the body-plan, fig. 5, square from the middle line to the intersection of the transoms Nos. 1, 2, 3, 4, 5, and 6, with the square fashion-piece, and set them off square from the middle line in the plan of the transoms, fig. 6, to intersect the fashion-piece, marking a line parallel to the middle line, as a a, transom No. 6. Then take the distances from the line P, in the sheer-plan, fig. 4, in the direction of the transoms, to the fashion-piece, and set them off square from the line P P, in the plan of the transoms, fig. 6, on the lines a, a, at the intersection of the fashion-piece. Take the half-breadths square from the middle line in the body-plan, fig. 5, where the transoms intersect square timber 36, and set them off square from the middle line, in the plan of the transoms, fig. 6. Then take the distances from the line P, in the sheer-plan, fig. 4, to square timber 36, in the direction of the lines of the transom, and set them off square from the line P P, in the plan of the transoms, fig. 6, to intersect their several half-breadths, as at b, c, d, e. In the same manner proceed to find all the spots for the square timbers, in order to prove the buttock-lines. This will give the exact form of the moulding edge of all the transoms below the deck, and the flatness of the fashion-piece on the transom, with the length of the transom at the moulding edge.

To find the direction of the end of the transom, to lie against the side of the fashion-piece, observe in the half-breadth plan where the fashion-pieces intersect the middle line, and square them up to the sheer-plan, as may be seen ticked, and marked K, M, L, calling them the fashion-pieces at the middle line in the sheer-plan, fig. 4. Take the distance from the line P, in the sheer-plan, fig. 4, to the middle line of the aftermost fashion-piece K, in the direction of the transoms No. 6, and set it off from the line P P, in the plan of the transom, fig. 6, on the middle line, and mark the ticked line g, from the spot on the middle line, to the spot on No. 6 transom. This will give the direction to cut off the end of the transom, in order to lie against the side of the fashion-piece.

To bevel the Transoms when canted.

Those transoms which are not sided straight, as the wing, filling, and the deck, are generally bevelled by the buttock-lines, as before observed; but rather than trust to the bevelings only (it being rather difficult to apply them truly as they should be), lay-off the underside of all the transoms, and make a slight mould to them. This will correct the bevelings, and make greater dispatch in trimming the transoms. Then there need only (except for proof fake) be taken the beveling at the bearding-line, and the beveling at the end; for the mould will give the roll. But observe to be careful in the bevelings at the ends of the transoms; for instance, the ends of the wing and filling-transoms, when they lie level, are to be cut off square; but keep the square as much above the end of the wing and filling-transoms, as they round in their length, and let the square look out of winding with the middle of the transom. Alfo the bevel (when applied on the end after it is cut off, in order to bevel the end for counter-moulding) must be kept as much above the end of the transom, and look out of winding with the middle of the transom.

As the bevelling for the end of the deck-transom is taken against the cant-fashion-piece by a level line in the body-plan, fig. 5, it must be observed how much the transom at the middle line in the sheer-plan, fig. 4, is below a level (fupposing one foot). Then place a batten at the middle line on the transom, and lift the foremost end of the batten up till it becomes level, as supposing the transom to be in its place: then proceed with the square and the bevel for the end of the transom, in the same manner as for the wing and filling, looking out of winding with the batten at the middle line.

To bevel the transoms, which are cut in the sheer-plan, fig. 4, proceed in the same manner as in beveling the cast-timbers, by making a parallel line to the moulding edge. Therefore lay-off the bevelings of the transoms, by squaring a line from the upper side, where it intersects the line P, in the sheer-plan, fig. 4, to the under side, as the ticked line a at the lower transom. Take the distances from where the squared line, a, crosses the lower edge in its cast direction, to the bearding-line c, and to all the buttock-lines, and set them off square from the line P P, on their corresponding lines, in the plan of the transoms, fig. 6. Where the bearding-line c, in the sheer-plan, fig. 4, proves to be square from the direction of the transom, as it is, or very nearly so, at the lower transom, then the bearding for the moulding edge, and likewise for the bevellings, will come as near together in the plan of the transoms, fig. 6. This may sufficiently prove that the method of bevelling is correct.

Where the under side of the lower transom intersects the square timbers and square fashion-piece in the body-plan, fig. 5, take the nearest distances from thence to the middle line, and set them off square from the middle line, in the plan of the transoms, fig. 6, striking lines parallel to the middle line, as at ii. Then take the distances from the squared line a, in the sheer-plan, fig. 4, in the direction of the under side of the lower transom, to the square timbers and fashion-piece T, and set them off square from the line P P, on their corresponding lines last struck, in the plan of the transoms, fig. 6. To these spots, and those on the buttock-lines, pin a batten, and it will represent the ticked line, b b, within the lower transom, which will shew how much the lower transom is under from a square, agreeable to the depth of the transom. Take the distance from the squared line a, in the sheer-plan, fig. 4, to the ticked perpendicular K, which is the after-fashion-piece at the middle line; and set it off from the line P P, on the middle line, in the plan of the transoms, fig. 6, and mark the ticked line m, from thence to the spot on the fashion-piece, which will be a line parallel to the ticked line g, before marked to cut off the end of the transom; and the distance between the two ticked lines shews how much the end of the transom is under from a square, agreeable to the depth of the transom.

The ticked line b b, in the plan of the transoms, fig. 6, which is for the bevellings, is the line to make the temporary mould to, in order to counter-mould the transom; and by cutting off one end of the mould to the thwartship-line for the brecch of the transom, and cutting off the others to the ticked line m for the end of the transom, when the mould is applied to the under side of the transom, it will be easily perceived if the work be true.

To find the exact bevelling to be applied over the end of
of the tranom, after the end is cut off, in order to counter-mould the tranom, proceed in the following manner.

Where the upper and lower sides of the lower tranom intersect the after-cant-fashion-piece P, in the body-plan, fig. 5, level them out to intersect the after-cant-fashion-piece O. Where the upper side of the lower tranom intersects the perpendicular ticked line K (which is the after-fashion-piece in the sheer-plan, fig. 4), transfer that height to the middle line, in the body-plan, fig. 5; and from thence draw a straight line to the upper side of the lower tranom, on the cant-fashion-piece, as the ticked line e; to which line fix the block of a bevel, as at B, and the tongue to the cant-fashion-piece O, as low down as the spot for the lower side of the tranom. This is the proper beveling to be applied on the end of the tranom, after the end is cut off, in order to counter-mould the tranom. The ticked line e, to which the block of the bevel is placed, is the direction of the tranom to be crooked on the fashion-piece mould. The bevel B, which is represented in the body-plan, fig. 5, ruling the beveling of the end of the lower tranom, sufficiently proves the utility of canting the tranoms; for, by having so little beveling, it greatly affists the convection of timber, as well as that it must certainly be better for the security of the plank of the buttock.

To Lay-off a Square-Tuck, Plate IX. Laying-off C.

We have already explained the utility of the tranoms in composing the stern-frame, by which method most ships are inclosed abaft. But yachts and cutter-built vessels are, owing to their clearness of run abaft, enclosed by a square tuck, by which room is gained; and, when properly put together, this mode of construction is, perhaps, stronger than tranoms would be in vessels of this description.

The tuck proposed to be laid off is that of the royal yacht, Plate XI. But that the reader may be led progressively on from the caffet to the most difficult part of the operation, we shall first propose a square tuck, the sides of which are to be out of windings, or in the same direction as the rabble of the posts, in consequence of which the wing-tranom must be strait athwartships, and the whole will be one flat surface (similar to the tranoms of boats), or a section of the vell cut athwartships, but not in a perpendicular direction, which is the only difference between it and the square timbers; and as the section is agreeable to the rake of the stern-post, it consequently follows, that the laying it off must differ from the square timbers in the operation.

The horizontal view of the tuck must first be represented in the body-plan, fig. 8, which is done in the following manner: Strike a horizontal line in the sheer-plan, fig. 7, at the height of the wing-tranom at the side, as at 5; and likewise as many horizontal lines below that as may be thought sufficient; and where they intersect the aft-part of the rabble of the post a, square them down to the half-breadth plan, fig. 9; then transfer their heights to the body-plan, fig. 8; and where they intersect the square timbers 23, 23, 24, 25, and P, in a horizontal direction, take those distances from the middle line, and let them off upon their corresponding timbers from the middle line, in the half-breadth plan, fig. 9; then by pinning a batten to those spots, the horizontal lines 1, 2, 3, 4, 5, and 6, will be represented; then take their distances from the middle line, in the half-breadth plan, fig. 9; then by interfleting the lines squared down from the sheer-plan, and let them off from the middle line on their corresponding horizontal lines, in the body-plan, fig. 8; then by pinning a

batten to those spots, the horizontal view of the tuck, a, will be represented in the body-plan, fig. 8, as high as the wing-tranom at the side. But when the fashion-piece required to run up, to take a bolt or two through the heel of the side counter-timber, proceed in the same manner to run a horizontal line or two above that at the side of the wing-tranom; say, one at the upper side of the wing-tranom at the middle line; then run the main half-breadth line in the half-breadth plan, fig. 9; then, where the half horizontal line and main height of breadth line intersect the aft-side of the rabble a in the sheer-plan, fig. 7, square them down to the half-breadth plan, fig. 9, and take their distances from the middle line in the half-breadth plan, fig. 9, to where they intersect the horizontal line 6, and the main half-breadth line, and let them off from the middle line on their corresponding horizontal lines, in the body-plan, fig. 8; then by continuing the curve, a, upwards through these spots, the horizontal view of the tuck will be continued up to the height of breadth.

Now, where the horizontal view of the tuck in the body-plan a, fig. 8, intersects the bearding-line 6, that height, and transfer it to the sheer-plan, fig. 7, striking there the horizontal line 8, which represents the raising of the tuck; then take the distance from the raising of the tuck, in the sheer-plan, fig. 7, on the rake, in the direction of the rabble of the post a, to the respective horizontal lines and height of breadth, and let them up the middle line, from the horizontal line 8, at the raising of the tuck, in the body-plan, fig. 8; striking a horizontal line to the rake, at every height, as shown by the fine-ticked lines; then, where the horizontal view of the tuck, a, intersects the horizontal lines first struck, carry it up parallel to the middle line, to their corresponding horizontal lines on the rake; which will give the spots through which the fine-ticked curve is to pass, that will represent the proper shape of the tuck, agreeably to the rake, as e; and the line to which the fashion-piece mould must be made.

The bevellings for the fashion-piece may next be taken, by proceeding as follows. The aft-side of the rabble of the post a, in the sheer-plan, fig. 7, represents the aft-side of the fashion-piece of the tuck; therefore, take the side of the fashion-piece, and let it off above the rabble, and square there to; then, by striking a parallel line to the aft-side a, the fore-side of the tuck b will also be represented; next, from the raising of the tuck 8, on the aft-side, square the line C from the rabble to the fore-side; and from its intersection at r, take the heights of the horizontal lines up the fore-side, and let them up on the middle line from the horizontal line 8, at the raising of the tuck, in the body-plan, fig. 8; strike horizontal lines for the fore-side of the fashion-piece, as distinguished by the long-ticked lines; then, where the fore-side of the fashion-piece b, in the sheer-plan, fig. 7, intersects the horizontal lines and height of breadth, square it down to their corresponding horizontal line and main half-breadth, in the half-breadth plan, fig. 9; at which intersections take the distances square to the middle line, and let them off from the middle line on their corresponding horizontal lines, for the fore-side of the fashion-piece, in the body-plan, fig. 9. Continue the fore-side of the fashion-piece down to the bearding-line d, as you see ticked in the sheer-plan, fig. 7; then take the distance from the intersections of the squared line at the raising r, down the fore-side of the fashion-piece to the horizontal line 1, and where it intersects the bearding-line d, and let it off in the body-plan, fig. 8. Below the horizontal line 8, at the raising of the tuck down the bearding-line, strike a horizontal line for No. 1, and proceed as before directed to obtain the half-breadth
SHIP-BUILDING.

breadth spot on the half-breadth and body-plans, figs. 9 and 8; then to all those spots pin a batten, and mark the curve which shall intersect the bearding-line, and the fore-side or bevelled-edge, d, of the fashion-piece will be represented in the body-plan, fig. 8.

The aft-side and fore-side appear now in their proper shape, in the body-plan, fig. 8, and of the same form as the fashion-piece, when trimmed and laid flat with the aft-side upwards, as then both edges will be seen, in consequence of its being a standing beveling; therefore, the distance from the line represents the aft-side to the line of the fore-side, taking the nearest distance, as at $c$, which will show how much the bevelling is standing, or without a square, in the breadth of the bevelled-board, which should be equal to the fiding of the fashion-piece.

When the mould is made to the ticked line, $c$, of the aft-side, the heel of it must be cut off well with the line for the fecting of the tuck, and likewise well with the middle line, in order that it may dovetail and bolt into the stern-poll. Mark also on the mould the bearding-line, or side of the inner poll. The different firmarks for the ribsbands must be marked on the moulds; but, in order that the stations of the ribsbands may be correctly marked, observe where the diagonal lines intersect the horizontal view of the tuck $a$, in the body-plan, fig. 8, and carry them up parallel to the middle line, to the line for the aft-side of the fashion-piece $c$, to which the mould is made. This will be their proper stations or upper sides, and may thence be marked on the mould.

The bevelling may be taken at the different firmarks or ribsbands, and set off where taken, as the bevel at the seventh ribband, which will shew it more clearly. The ticked line $g$, drawn parallel to the stock of the bevel, is the same distance from the outside of the bevel, as the fashion-piece is fided. Then draw a line square from the stock of the bevel to the ticked line $g$; and where it intersects the ticked line $s$, as at $h$, set off from $h$ to $i$ the same distance as the fore-side is from the aft-side at that place, as before directed, and open the tongue of the bevel to $i$. This will shew the bevelling of the fashion-piece at that place. The bevel is to be applied square from the moulding edge.

Run in the half-breadth plan, fig. 9, the diagonal $j$, although the ending of it only differs from thofe explained before, and need only be described. Transfer the height from the body-plan, fig. 8, where the diagonal $j$ intersects the horizontal view of the fashion-piece $a$, and set it up in the stern-poll, fig. 7, at the aft-side of the fashion-piece; and from its intersection there, square it down to the half-breadth plan, fig. 9; then take its distance in the body-plan, fig. 8, from the middle line to the horizontal view of the fashion-piece $a$, in its diagonal direction, and set it off from the middle line, in the half-breadth plan, on the line squared down, which gives its ending at the fashion-piece. In the same manner transfer its height where it intersects the upper side of the wing-transform, in the body-plan, fig. 8, and set it up in the stern-poll, fig. 7; and where it intersects the aft-side of the fashion-piece, square it down to the half-breadth plan, fig. 9; then take the distance from the middle line, in the body-plan, fig. 8, as before, to the upper side of the wing-transform, and set it off from the middle line, in the half-breadth plan, fig. 9, on the line half squared down; then mark a line through those spots, as the long-ticked line $a$, in the half-breadth plan, fig. 9, which will be the true ending of the diagonal $j$, or any diagonal crossing the wing-transform and fashion-piece.

Square tucks of lighters are like thofe above described, and the transforms of boats are laid off in a similar manner, but composed of only one piece athwartships, and their upper side is bounded by the upper side of the sheer. But the tucks of yachts (or frigates, if built of sir) partake of the round-forward of the wing-transform, which causes the fashion-pieces to take a part of it also the whole of their length, which makes them rather more difficult to be laid off. But, supposing the former to be clearly understood, we shall give a description of a tuck, the outside of which is to round-forward, in its finished state.

Suppose a flat surface, of thin deal (in length from the head of the fashion-piece or height of breadth to the fecting of the tuck, and in breadth to the outside of the transform) was placed with one edge to the rabbe of the poll, and the other edge bent round to a curve, as much as the outside of the tuck is intended to round-forward, in which position suppose it to be confined; then draw the shape of the outside of the tuck or fashion-piece down to the poll, and cut it out. The true shape of the tuck or fashion-piece is now shown as it is to be trimmed, and as it will appear in its finished state. Then take it from its position, and lay it flat, letting the round be unconfined; and it will then appear as it is required to be laid off in the body-plan, in order to make the mould therefrom.

The fashion-pieces for the square tuck being already laid off, the same horizontal lines, &c. may be transferred to the sheer and body-plans, figs. 10 and 11; then proceed to lay it off upon the flat, agreeable to the rake of the rabbe of the stern-poll, as before directed, with this difference, having no round- aft made, but one straight line in the thwartship view, in the sheer-plan, fig. 7, which was the aft-part of the rabbe of the stern-poll; but, in the present square tuck, where the head of the fashion-piece is carried forward, to connect with the end of the wing-transform, the moulding edge of the fashion-piece forms a serpentine line.

Therefore, where each horizontal line intersects the aft-part of the rabbe of the poll $a$, in the sheer-plan, fig. 10, square down the distances to the middle line of the half-breadth plan, fig. 12, making of spots; then upon the horizontal line, No. 5, at the height of the wing-transform, at the side, set off from the aft-side of the rabbe of the poll $a$, the round-forward of the wing-transform, in the sheer-plan, fig. 10, and square it thence down to the half-breadth plan, fig. 12; upon which set off the half-breadth of the wing-transform, and thence sweep a curve, the centre of whose radius being in the middle line, shall cut the spot for the said horizontal line, in the middle line of the half-breadth plan, fig. 12, which will represent the aft-side of the wing-transform $a$, at the height of the horizontal line at the side. Now, from the other spots squared down on the middle line of the half-breadth plan, sweep curves with the same radius, and they will be parallel to the curve of the wing-transform $a$. The horizontal lines being transferred from the half-breadth plan, fig. 9, to fig. 12, take the distances square from the middle line in the half-breadth plan, fig. 12, to where the horizontal lines intersect their respective curves for the aft-side of the tuck, and set them off from the middle line on their corresponding horizontal lines, in the body-plan, fig. 11; a batten pinned to those spots will shew the horizontal view of the tuck $a$, in the body-plan, fig. 11. Also, where the horizontal lines in the half-breadth plan, fig. 12, intersect their respective curves, square the distances up to their corresponding horizontal lines in the sheer-plan, fig. 10; and by drawing a curve to pass through those spots, the thwartship view of the aft-side of the fashion-piece, $b$, will be represented in the sheer-plan, fig. 10; and what the thwart-
SHIP-BUILDING.

thwartship view of the aft-side of the fashion-piece leaves the rabbet of the stern-post, in order to be conformable to the wing-tranform at the side, is easily perceived by the shaded lines.

Till this thwartship view of the aft-side of the fashion-piece, \( b \), be shown in the sheer-plan, fig. 10, the ribband

lines cannot be truly ended, although the operation is the same as before described.

Though the aft-side of the fashion-piece \( b \), in the sheer-

plan, fig. 10, leaves the rabbet of the stern-post at the head

conformable to the end of the wing-tranform, yet a square

line at the scepting must be drawn as before, to lay-off the

tuck on the flat; therefore, take the nearest distances from

the square line \( a \), in the sheer-plan, fig. 10, to where each

horizontal line crosses the aft-side of the fashion-piece \( b \), and

let them up from the horizontal line \( S \), in the body-plan,

fig. 11, striking horizontal lines, as distingued by a fine
tick.

Then take the half-breath of the wing-tranform, in the

body-plan, fig. 11, square from the middle line, and let it

off from the middle line, on the line \( A A \). Next, fix one

leg of the compasses at the end of the wing-tranform, in the

sheel-plan, fig. 10, and take the nearest distance to the aft-

part of the rabbet of the stern-post \( a \), which is square from

the rabbet, as the line \( e \), and let it off square from the line

\( A A \), at each end of the tranform \( b b \); and sweep the arc

\( c, e \), which gives the round-aft of the tuck at any height,

square from the rabbet of the stern-post. Square down the

fine-ticked lines, or horizontal lines, \( 2, 3, 4, 5, 6, \) and \( 7, \)
on the rake where they intersect the horizontal view \( a, b \), of the

fashion-piece in the body-plan, fig. 11, to the round-aft line,
on a square under the body-plan. Then take their

distances from the middle line, on the curve \( c, e \), or round-
aft, on a square, and let them off from the middle line of the

body-plan, fig. 11, on their corresponding horizontal lines;

then pin a batten to these spots, and to where the scepting

intersects the polt, and it will give the form of the aft-side

of the fashion-piece \( d \), to which the mould is to be made,

that will agree with the other timbers, when in their

places.

To be correct with the length of the wing-tranform on the

flat, take the half-breath from the body-plan, fig. 11, on the

round for the upper side of the tranform; then continue the

end of the tranform in the half-breath plan, fig. 12, square out from the middle line, as at \( e \); on which (square from the middle line) let off the half-breath taken on the round from the body-plan, fig. 11, and from that spot sweep an arc to break into the middle of the tranform, at the middle line, as represented by the dotted line \( a \); then from the before mentioned spot, or end of the wing-tranform at \( c \), take the half-breath round the dotted curve to the middle line, and let it off from the middle line in the body-plan,

fig. 11, round the curve, for the upper side of the tranform.

This will give the exact length of the tranform on the round-aft of the tuck.

Previous to the laying-off of the fore-side of the fashion-
piece, it will be proper to understand in what manner the

fashion-piece is to be moulded and trimmed, particularly on the fore and after-sides.

Make a mould to the moulding, or outer edge of the fashion-piece laid off on the flat, as the fine ticked line \( d \) in the

body-plan, fig. 11. The upper end may be made as high as the height of breadth, or horizontal line \( 7, \) and the lower end may reach to the scepting on the post. Let the upper end of the mould be cut off well with the direction of the horizontal line \( 7, \) and let the heel be exactly perpen-
dicular at the side of the inner post. Make another mould to the round-aft, on a square \( e, \) as shown under the body-

plan, fig. 11, and of a parallel breadth, like part of a beam-
mould. Make it as broad as the fashion-pieces are intended to be fided, and let the midhip-end be well with the side of the inner post, and cut off parallel to the middle line. Let the side-end correspond well with the moulding edge of the fashion-piece, and cut off agreeable to the round of the side when the mould lies in its proper place, underneath the body-plan, fig. 11. Let the fashion-piece be fided suffi-

ciently for the wing-tranform to dovetail into the aft-side of it, and let the fore-side of the fashion-piece, that runs above the wing-tranform, be of sufficient length to receive the bolts of the side stern-timber, and long enough at the heel to meet at the middle line.

When the fashion-piece is roughly fided on the aft-side, as to lay the mould on the aft-side, to mark the upper and lower end nearly, then cut off the head by the mould for the thwartship-way, and the fore and after-way, square. Then

faken the round-aft mould, that is made to the fiding, on the head of the fashion-piece, by which may be trimmed the fore and after-sides of the fashion-piece out of winding, by lines parallel to the middle line. This will have the belt opportunity of seeing how to convert the piece, by seeing both sides at once. Then will the fashion-piece be of a parallel thickness from one end to the other, by all lines that are parallel, whether perpendicular or horizontal.

To Lay-off the Fore Side of the Fashion-Piece.

Having the fiding of the fashion-piece on a square, set it off in the sheer-plan, fig. 1, square from the rabbet of the stern-post \( a \); then with compasses take the fiding of the fashion-piece in the direction of the horizontal lines, and set it off square from all the aft-sides of the horizontal lines, prolonged in the half-breath plan, fig. 12, on each horizontal line, and square them up on their corresponding lines in the sheer-plan, fig. 10. Then pin a batten to those spots, and the fore-side of the fashion-piece \( e \) will be represented.

Take the heights above and below the squared line \( d \), in the

sheer-plan, fig. 10, to the interference of each horizontal line

with the fore-side of the fashion-piece \( e \), in the same manner as the aft-side was done; and set off above and below the ticked line \( S \), in the body-plan, fig. 11, and strike horizontal lines, as there distingued by long-tick. Then take the

half-breaths in the half-breath plan, fig. 12, to the fore-side

of the fashion-piece on the horizontal lines, square from the

middle line; and let them off square from the middle line

on to the line for the round-aft, on a square \( e, \) under the

body-plan, fig. 11. Then take them off again on the round-
aft line, and let them off from the middle line, on their

corresponding horizontal lines in the body-plan, fig. 11.

Then pin a batten to those spots, and the form of the fore-

side of the fashion-piece \( e \) will be agreeable to the fiding

proposed.

The aft-side of the fashion-piece not being straight, will

render it more troublesome than useful, to run lines in order to trim the outide of the fashion-piece by bevellings; therefore, would it be better to make a mould to the fore-side, and trim a spot to fay to the side of the inner post or dead-

wood, and set off a bevelling for the outide at the main-

breath, as at \( B \), fig. 12.

Mark the line at the fating \( S \), in the body-plan, fig. 11, on the mould for the aft-side, and on the mould for the fore-

side; and when the aft-side is moulded, and the side trimmed to fay to the inner post, mark the spot \( 6 \) square from the

aft-side.
aff-side to the fore-side, to which place the spot b, on the mould for the fore-side, must properly correspond; and the head of the mould must be kept well with the spot to the bevelling at the main-breadth. The mould lies then in its proper place to mould the fore-side of the fashion-piece.

It is customary, in boats, for the planks of the bottom to run through to the aff-side of the tranform, and sometimes to the aff-side of the fashion-piece of lighters; but in larger vessels it is better to rabbet the fashion-piece; for when the planks of the bottom are rabbeted into the fashion-piece, and the inside of the butts left longer than the outside, the planks are apt to be pressed to the timbers on caulking their ends; while, on the contrary, when the planks run through the fashion-piece, they are not able to bear the force that is required to be made by caulking their ends sufficiently. In vessels of this class, likewise, the ends of the planks would be liable to be flar'd off by accident.

The fashion-piece, as it is laid off, both fore and aff-sides, is conformable to the timbers of the body, being for that reason easier undertook; but when the fashion-piece is moulding, be careful to leave enough without the lines for the thickness of the plank; which may be found exactly by holding a batten at the outside of the fashion-piece, at several places, parallel to the lines for the fore and aff-sides of the fashion-piece, and square from the lines.

Then extend the compasses to the thickness of the bottom plank, or otherwise run as many fictitious diagonal lines as shall be necessary, and square from the moulding edge of the fashion-piece. Then set off the thickness of the plank of the bottom, and lay off the extreme outside of the fashion-piece, likewise the aff-side, observing the round in the direction of the diagonal line, whereby a mould may be made to the aff-side, at the extreme breadth; and the outside may be trimmed by bevellings from the diagonal lines. But great care must be taken to place each diagonal line square from the moulding edge of the fashion-piece; and then, as the fashion-piece at the aff-side will wind or twist in the direction of the diagonal lines, the tongue of the bevel may not cast at all the bevelling spots, exactly in the direction wherein the diagonal lines were laid off; for the diagonal lines at the middle line (suppose in the sheer-plan) are parallel to the upper side of the keel; and are canted down similar to the flap of a table, as before observed; in which direction the tongue of the bevel ought to cast, when the bevellings are taken from the diagonal lines.

The fashion-piece are rabbeted on their aff-sides, to receive the planks of the tuck; but do not take the rabbet too low down as where it intersects the polt, but leave it square some inches above it, that the midship piece may be gotten in its length as it rabbets into the polt, and it will also leave a better butt for caulking, as shewn in the body-plan, fig. 11.

The wing-tranform mould must be made to the fine ticked curve d, in the half-breadth plan, fig. 12. The bevelling of the wing-tranform will be the same athwartship on the aff-side, which bevelling is the rake of the rabbet of the polt; and the wing-tranform is rabbeted at the aff-side at the lower edge for the planks of the tuck, and at the upper edge for the planks of the lower counter, (if thought proper,) therefore the heels of the flern-timbers should be placed as much before the aff-part of the wing-tranform as the thickness of the planks of the lower counter.

To prevent any error in the true height of the fashion-pieces, let the firmark c, in the body-plan, fig. 11, be correctly marked on the mould and side of the flern-polit, so that when the heels of the fashion-pieces are letting-on the polt, those firmarks must exactly agree.

To Lay-off the several Parts of the Head, Plate X. Lay-off D.

The knee, cheeks, rails of the head, and block for the figure, must be laid off to their full size on the floor from Plate I., which is the horizontal and thwartship view, when the cheeks, rails, &c. are fixed in their places.

To make the Mould to the Knee of the Head.—The lower part of the knee at the fore, as at X, Plate X. fig. 1, Laying-off D., may be made of fir-board about an inch thick, and up the fore-part of the knee and item, as high as the cutting-down and feeling of the figure; but these need be no broader than about five inches for lightness, as at 39, 39, fig. 1. Then across the mould are fastened battens, which not only keep the mould together, but the manner of sliding the knee is expressed thereby. Thus, take any perpendicular, as at 24, fig. 1, and level out the several heights 13, 14, 15, 16, and 17; and at 13 and 17 set off the half-fiding of the item, striking a line thereto. Then let fall a perpendicular from the fore-side of the knee at the upper part, as at 25, fig. 1, and set off the half-fiding of the knee at 4, and at 12, and strike a line. Strike the lines across the knee of the head, where it is intended to have the upper side of the battens, as at 1, 2, 3, &c. to 12. Then, to determine on the fiding of the knee at the fore part, pin a batten from the upper part of the knee round the fore-side, marking thereon the lines 1, 2, 3, &c. Then apply the batten to the perpendicular 25, fig. 1, keeping it fast at the upper end, and mark on the perpendicular the spots 1, 2, 3, &c. Then from the perpendicular 25, fig. 1, take the half-fiding of each spot, and set them off on their corresponding lines at the fore-side of the knee; proceed in the same manner for the half-fiding of the item at 24, fig. 1, and strike in the lines as ticked across the knee. Then battens being made to those lines, and nailed across the mould, the half-fiding of the knee may be readily set off at the upper side of each batten, and the knee, when put together, may be trimmed straight from the fore-side to the item or aff-side of the knee: the cutting-down, as at 1, 2, 3, and 4, fig. 1, is fided in the same manner.

To make the Mould to the Grize, G, fig. 1.—The grize is only the completion of the knee to the keel, and the mould is made so similar to the knee above as to need no further description.

To make the Moulds to the Cheeks.—The cheeks must be laid off to their moulded size on the half-breadth plan, fig. 3, as at C, C, to the main half-breadth line, allowing the thickness of the plank, as at R, and against the side of the knee. Another mould must be made to the flight of each cheek, in the sheer-plan, fig. 1, at C, or upper cheek; and L C, the lower cheek, from the heel of the figure Z, to reach as far aft as the cheeks are there shewn, marking a firmark at the fore-side of the item. Then, to mould the cheeks to their proper flight, draw off the knee-arm to the mould made in the half-breadth plan, marking on the piece the fore-side of the item from that mould: then failling the flight-mould to the knee-arm of the cheek, observing to keep the firmark on the fore-side of the item, and keeping the mould parallel to the middle line, let the cheek be trimmed out of winding by the thwartship lines, or lines which are square from the mould. Then there is a certainty, when the cheek is threated, no angle will appear in the throat, as there will be sometimes by the usual method, particularly in full-bowed ships, where the sheer springs more than the flight of the cheeks. When the side-arm of the cheek is trimmed...
SHIP-BUILDING.

trimmed by a mould made to the sheer of the ship, and the fore and aft-arms by the flight of the cheeks laid off on the floor, there will sometimes be a very disagreeable throat, which cannot happen when trimmed by the above method. Although the side-arm may not hang so much as the sheer of the ship, yet it will not look disagreeable, because the throat of the cheek is the only part that takes the flight.

To lay-off the Head-Rails.—Strike in the perpendiculars Z and Y from the fore-side of the figure, and foremost end of the upper rail in the sheer-plan, fig. 1, down to the half-breadth-plan, fig. 2. Determine on the half-breadth of the lacing, as at 1, 2, fig. 2, as the foremost end of the upper rail comes against it. The after end falls against the plank at the back-head timber, from whence strike a straight line to the lacing at its fore end. Then set off the riding of the rail, allowing the thickness of the lining, and strike the line P, or outside; which being the fight-edge of the rail when in its place, is the proper edge to be laid off.

Strike the horizontal line 32 at the upper part of the foremost end of the upper rail, in the sheer-plan, fig. 1. Then square up to the line 32 the aft-side of the stem-timber 20, and as many lines at equal distances as may be needful, and number them 1, 2, 3, &c. above the line 32, as shown in fig. 1. Set off the fame frications from perpendicular Y, on the middle line in the half-breadth plan, fig. 2, and square them out to the line P, or outside of the main-rail, numbering them, as before, at the middle line; then square them out from the line P. Take the distances from the line 32 in the sheer-plan, fig. 1, to the upper and lower parts of the main-rail at each perpendicular line, and set them off on their corresponding numbers in the half-breadth plan, fig. 2, which was squared out from the line P; and then, by pinning a batten to these spots, it will give the form of the main-rail, and it will shew the fame form, when in its place, as that in the sheer-plan, fig. 1. Where the lines squared out from the middle line in the half-breadth plan intersect the inside of the main-rail, strike them from thence square from the line P to the rail already laid off, and take the distances on these lines from the line P to the upper part of the rail, and let them down from the line 32 in the sheer-plan, fig. 1, on their corresponding perpendiculars; which will give the inside of the main-rail in the sheer-plan, fig. 1, as the ticked line, which rifes above the middle of the rail forward, being the upper line, and below towards the after end as the after part, falls below the outside. The inside of the rail at the lower edge must be set off in the same manner in the sheer-plan, in order to lay off the timbers exactly.

Strike the ticked line in the plan of the rails in the half-breadth plan, fig. 2, which is the line to which the chamfer at the under side of the rail the mouldings are intended to be wrought to. This must likewise be laid off in the sheer-plan, because in a thwartship view this is the proper edge of the lower edge of the rail: for the lower part of the rail in the sheer-plan (which was first laid off in order to lay off the rail to its proper cant in the half-breadth plan) may now be rubbed off, when the rail is supposed to be chamfered or wrought.

In the half-breadth plan, fig. 2, where the lines squared out from the middle line intersect the ticked line before-mentioned, strike them from thence square from the line P to the lower part of the rail laid off; then take the distances on these lines from the line P to the lower part of the rail, and let them off from the line 32 in the sheer-plan, fig. 1, on their corresponding perpendiculars. This gives the lower part of the rail in the sheer-plan, at the chamfer, being the fight part of the rail when trimmed and in its place.

Before the main-rail is canted, as in the half-breadth plan, fig. 2, the proper form of it cannot be ascertained in the sheer-plan, fig. 1, for the rail, when canted in order to make the mould, must be gradually diminished from one end to the other, and from thence transferred to the sheer-plan; for instance, the middle line at the after part of the rail in the sheer-plan, is the ait-part of the rail at the outside; so that from thence to the fore-side of the rail shews less than the rail in the middle; also, at the foremost end the rail will not shew so much as it does in the half-breadth plan; whereas in the middle it shews the fame.

Before the middle rails can be canted in the half-breadth plan, fig. 2, to their proper spread, proceed in the following manner; strike an horizontal line from where the ait-side of the stem-timber 20, in the sheer-plan, fig. 1, intersects the upper side of the upper cheek, as the line 27, in fig. 3. Take the heights from the upper side of the upper cheek, at the perpendicular line 7, in the sheer-plan, fig. 1, to the upper and lower parts of the three rails L, M, and N; and let them up from the horizontal line before-mentioned in fig. 3, as you see ticked at L, M, and N. Then take the distances from the middle line in the half-breadth plan, fig. 2, at the line 7, to the outside of the main-rail; likewise to the inside, and the ticked line for the chamfer of the rail at the under side; and set them off on their corresponding lines in fig. 3, and draw the thwartship section of the main-rail. Set off in the half-breadth plan the half-thickness of the knee S Y of the head, and the moulding of the upper cheek C C; then take the half-thickness of the knee at 7, or ait-side of the stem-timber in the half-breadth plan, fig. 2, and set it off from the middle line in the plan of the timber, fig. 3, on the line 27. Then determine the breadth of the timber at the upper side of the cheek, and pin a batten to the curve for the outside of the timber. Then in the plan of the timber, fig. 3, determine on the half-breadths of the middle rails L and M; and transfer them from thence to the half-breadth plan, fig. 2, at the ait-side of the stem-timber. Then set off the distance of the foremost end of the rails from the middle line, and strike in the two lower or middle rails N, O, in the half-breadth plan, fig. 2.

The middle and lower rails being determined in the half-breadth plan, fig. 2, the outsides of them, being the fight-sides, are the propered to be laid off. The outside of the middle rail is marked O, and the outside of the lower rail N. Where the upper sides of the middle rail M, and lower rail L, in the sheer-plan, fig. 1, intersect the ait-side of the hair-bracket H, strike the horizontal lines 33 and 34, answerable to those in the half-breadth plan, fig. 2.

Where the lines 1, 2, 3, &c. which are square from the middle line in the half-breadth plan, fig. 2, intersect the lines O and N, let them be squared out from the lines O and N, in the same manner as was performed for P. Then take the distances from the lines 33 and 34, in the sheer-plan, fig. 1, (at the same perpendiculars as before,) to the upper side of the middle and lower rails, and set them off in the half-breadth plan, fig. 2, from their corresponding lines O and N, on the lines squared out. This gives the form of the upper sides of the middle and lower rails, which is sufficient to shew the method of laying off each rail, agreeable to their different cant or spread. The lower side of the rails is formed by a diminishing line to the moulding or depth of the rail at each end.

It is very seldom that the middle and lower rails are laid off on the floor only; the main or upper rail, when trimmed, is gotten up into its place, and moulds are there made to the head-timbers, and then the middle and lower rails are spread and equally divided thereon between the upper rail.
SHIP-BUILDING.

determined at in order the tie and the tie 2, interfaced every view before them fet the down the making Jig.

it insides.

spots, of the in and rail, taken each of the timbers at the timber side of the timber, which ticked. Then take the distances from the upper side of the rails, and strike the in- sides of the middle and lower rails, let them be drawn square from the lines N and O, to intersect the lines of the rails laid off. Then take the distances from the lines N and O on the lines squared out, to the lines of the rails laid off, and set them down from the lines 33 and 34, at the aft-sides of their respective timbers in the sheer-plan, fig. 1, making spots which form the upper side of the rails at the in-side, the same as was performed for the upper rail. Take the distances from the upper side of the cheek in the sheer-plan, fig. 1, at the aft-side of the timbers, to the spots last mentioned, and likewise to the line for the upper side of the rail at the in-side, and set them up from the base line of each respective timber in fig. 3, and strike a faint line. Then take the distances from the middle line in the half-breadth plan, fig. 2, at the aft-side of each timber, to the in-side of the before-mentioned rails, and set them off from the middle line u, in the plan of the timbers, fig. 3, on their corresponding faint lines. This gives the upper part of the rails at the in-side. The same operation may be performed to find the lower part of the rails at the in-side; or you may draw the in-side of the rails perpendicular, and set down the depth of the rails agreeable to what they measure on the moulds, taken in the direction of the timber. This may determine the under side of the rails at the in-side.

As the line of the chamfer of the upper rail N (being the right-side of the rail when it is trimmed, and in its place) is before represented in the sheer-plan, fig. 1, take the height from the upper side of the cheek to the chamfer of the rail, at the aft-side of each timber, and set it up from the base line of each corresponding timber, fig. 3, striking faint lines parallel to the base line. Then take the half-breadths at the aft-side of each timber in the half-breadth plan, fig. 2, to the ticked line of the upper rail, (which is supposed to be where the rail is also to be chamfered,) and set them off from the middle line u, in fig. 3, on their corresponding lines last drawn, and from thence draw the under side of the rail to the in-side.

Having the upper side of all the rails, inside and out-side, in the plan of the timbers, fig. 3, set off, draw the line for the upper side of the rails, which shews how much the in-side of the rails is higher than the out-side, if cut off in the direction of the aft-side of the timber. Then having the spots, as before mentioned, for the out-side of the rails, (being on the ticked lines first drawn,) the under side of the rails may be drawn parallel to the upper, or to intersect the spot before-mentioned for the in-side, which was set down agreeable to what it measures on the mould, taken in the direction of the rail, as it is marked on the mould.

Having the scores for the timbers, the half-thickness of the knee of the head at the aft-side of each timber, set off from the middle line u on the base line of its corre-

fponding timber in fig. 3. Like wise take the height from the upper side of the upper cheek in the sheer-plan, fig. 1, to the ticked curve, representing the cutting down or facing of the knee, and set it up from the base line of each timber in fig. 3. This will give the score to be cut out, in order to let the timber meet its opposite at the middle line. Then set off the sublance at the upper side of the upper cheek, and draw the in-side and out-side of the timber as represented in the plate. This will be the exact form of the timbers, or more particularly, of the scores of the middle rails; and if laid off in the grofs, might be performed to the greatest nicety.

To bevel the Timbers in the Head.—In the sheer-plan, fig. 1, set off the fiding of the timbers, and strike in their fore-sides. Then square a line from the aft-side to the fore-side, from where the aft-side intersects the upper side of the cheek, as at 18, 19, 20, in the same manner as was done to find the bevellings of the cant-timbers.

Take the heights at the fore-side of each timber from its heel, as squared, to the upper and lower sides of the rails, in the same manner as directed for the aft-side, and set them up on the plan of each respective timber, fig. 3; then set off the fore-side of each timber in the half-breadth plan, fig. 2, and take the distances from the middle line to the out-side of each rail at the fore-side of each timber, and set them off on the plan of each respective timber, fig. 3, on their corresponding horizontal lines last mentioned. Where the fore-side of each timber in the half-breadth plan, fig. 2, intersects the in-side of the middle and lower rails, let them be squared out from the lines N and O, to intersect the lines of their corresponding rails laid off. Then take the distances from the lines N and O in the half-breadth plan, fig. 2, agreeable to the lines squared out, to the lines of the rails laid off, and set them down below their corresponding lines 33, 34, 1, at the fore-side of each corresponding timber in the sheer-plan, fig. 1, making spots. Then take the heights from the square line at the heel up the fore-side of each timber in the sheer-plan, fig. 1, to the spots last mentioned, and set them up in the plan of their respective timber, fig. 3, striking new horizontal lines. Then take the distances from the middle line in the half-breadth plan, fig. 2, at the fore-side of each timber to the in-side of the rails, and set them off on their corresponding horizontal lines last drawn, in the plan of each respective timber, fig. 3. This will give the direction of the upper side of the rails, and, if rightly performed, will be parallel to the upper side of the rails laid off for the aft-side.

In the same manner every operation performed for the fore-side as was directed for the aft-side, the heights being taken from the heel as squared in the sheer-plan, fig. 1, instead of the upper side of the cheek, which shews how much the rails lift at the fore-side from a square; and the half-breadths being taken at the fore-side of the timbers in the half-breadth plan, fig. 2, shew how much the scores at the fore-side of the timbers are under from a square with the aft-side, because the timbers in the half-breadth plan are square from the middle line.

Having the disposition of the rails for the fore-side of the timbers, set off the same distance from the rails as it is from the rails of the aft-side, both inside and out-side, and mark the curves as ticked for the in-side and out-side of each timber, in the plan of the timbers, fig. 3. Then whatever distance the ticked lines of the fore-side are from the lines of the aft-side, so much is the out-side of the timber under, and the in-side standing from a square, agreeable to the fiding of the timber. Or, having the aft-sides of the timbers laid off exactly, the fore and aft bevellings might be taken more cor-

Vol. XXXII.
rect from the half-breadth plan, fig. 2. The bevelling for the heel of the timbers may be taken agreeable to the flight of the upper check, because the check flands fore and aft; but it will not answer exactly to the other bevellings agreeable to the flight of the rails in the sheer-plan, fig. 1, unless they are taken to the lines of the rails when laid off in the sheer-plan; and then the bevellings must be applied close to the scores that are trimmed for the cant of the rails.

To Lay-off the Rails to the Cant in the Sheer-Plan.—The perpendicular lines must be drawn in the sheer-plan, fig. 1, the same as before, and likewise those in the half-breadth plan, fig. 2, answerable to them. Let fall a perpendicular from the intersection of the upper part of the upper rail N, with the aft-side of the hair-batten H, in the sheer-plan, fig. 1, down to the upper rail P, as before canted in the half-breadth plan, fig. 2, to which point the rail must be supposed fixed. Then place a batten to the inside of the rail, as canted in the half-breadth plan, fig. 2, and mark on the batten the perpendiculars as at 12, and the intersection of the lines 1, 2, 3, &c.

Then in the sheer-plan, fig. 1, where the perpendiculars 1, 2, 3, &c. intersect the upper side of the upper rail, level after-lines at pleasure, as you there see fit; then place the batten to each level line, marking thereon its corresponding perpendiculars, observing always to keep the foremost perpendicular marked on the batten to the perpendicular Y. This gives the spots to which a batten pinned will form the upper side of the upper rail O, and is exactly answerable in form to the upper side of the rail N, in the half-breadth plan, fig. 2. While the batten is pinned to the form of the rail, mark thereon the stations 1, 2, 3, &c.; and when it is straight, place it to any perpendicular line, and mark the extremities of the rail, and the several stations, as at 26, fig. 1; then set off the moulded size at each end, and strike a straight line, which will give the tapering at every perpendicular, and a batten pinned thereto will form the under-side of the rail.

In the same manner are the other rails to be performed in the sheer-plan. The aft-side of the after-timber being already laid off, and the cant of the middle and lower rails being determined on the half-breadth plan, fig. 2; let fall the perpendiculars 35, 36, where the lines 33, 34, intersect the aft-part of the hair-batten H, in the sheer-plan, fig. 1, down to the half-breadth plan, fig. 2, and proceed as above.

It may be necessary to notice here, that when Plate I. was engraved, all vessels above a frigate in the royal navy had head-heads, which mode has lately been discontinued: but such of our readers as may be desirous of knowing the method of laying-off the beam-head timbers, are referred to the "Elements and Practice of Naval Architecture," by Steel.

To Lay-off the several Parts of the Stern.

To Lay-off the Side Stern-Timber.—The side stern-timber must be laid off on the floor, and a mould made to it, so that when trimmed and put up in its place on the ship, that is, to the tumble-home of the side, it should appear as its ticked line in the sheer-plan, Plate I. from whence it is transferred to the floor.

Strike the horizontal lines from the stern-timber in the sheer-plan, Plate VII. fig. 11. Laying-off A, to square-timber 56, at the wing-tranform, at the side, at the knuckles of the upper and lower counters, at the top-breadth, and at the top-side. Likewise strike as many between the wing-tranform and lower counter as may be thought necessary, that part being the most critical to obtain the exact form of the timber. Then transfer these horizontal lines to the after-body plan, fig. 5, as you see ticked in the plate, and number them accordingly. Then take off the half-breadth of each horizontal line in the body-plan, fig. 5, at every square timber, as far forward as timber 28, and transfer them to their corresponding square timbers in the half-breadth plan, fig. 6. To these spots pin a batten, and mark the curves, or half-breadths, and continue them as far aft as the stern-timber in the sheer-plan, fig. 11, and number them in the half-breadth plan, fig. 6, as in the plate.

Where the horizontal lines in the sheer-plan, fig. 11, intersect the aft-part of the stern-timber, square them down, or let fall perpendiculars to their corresponding lines in the half-breadth plan, fig. 6, as shown in the plate. This gives the ending of the after-part of the half-breadth lines. Then take off the half-breadths of the horizontal lines in the half-breadth plan, fig. 6, at their ending, as above-mentioned, and set them off on their corresponding horizontal lines in the body-plan, fig. 5. A batten pinned to these spots forms the aft-side of the stern-timber A, agreeable to the form in the sheer-plan. But if these half-breadths, when set off in the body-plan, should not make a fair line, then those in the half-breadth plan, fig. 6, which seem most to require it, must be altered at the after-end, till they all correspond to make a fair line in the body-plan.

Now set off the moulded size of the stern-timber upon each horizontal line, in fig. 11, to which pin a batten, and the fore-side of the timber will be represented, because the mould is to be made broad enough to be answerable to the fore-side of the timber.

Then, where the horizontal lines in the sheer-plan, fig. 11, intersect the fore-side of the timber, transfer them to their corresponding lines in the half-breadth plan, fig. 6, parallel to the other lines, which are ticked down from the aft-side, and on the half-breadth lines make the spots as you see in the plate. Then take the half-breadth of each horizontal line in the half-breadth plan, fig. 6, at the spots last-mentioned, and set them off on their corresponding horizontal lines in the body-plan, fig. 5. Pin a batten to these spots, and mark the line B, which is the fore-side of the timber, agreeable to the line for the fore-side in the sheer-plan.

Having in the body-plan, fig. 11, the form of the aft-side and fore-side of the stern-timber, as it appears upon a horizontal view when in its place, it follows next to point out a method to make a mould, in order to mould the timber, so that it shall have the same appearance when it is in its place upon a horizontal view, as it now shews in the sheer and body-plans. Unless there be a method which may be depended upon for the exact heights of the counters, it can be to no purpose to design a view of the stern, in order to dispose of the decks, the lights, and all other heights, in such a manner, that each part may bear a just proportion to the rest.

Strike the line C in the body-plan, fig. 11, the thicknesses of the mould from the side of the timber, to which place a batten, and keep one end well with the horizontal line at the end of the wing-tranform, and mark on the batten all the horizontal lines in the body-plan. Then carry the batten to the sheer-plan, fig. 11, and keeping the end of the batten well with the horizontal line A of the wing-tranform at the side, set up all the heights on the batten perpendicular, and strike them through the stern-timber parallel to the horizontal lines first struck, as you see in the plate. Where the ticked horizontal lines in the sheer-plan, fig. 11, first struck intersect the fore-side and aft-side of the stern-timber, square them up to the horizontal lines last struck. This will give the spots, to which a batten pinned will give the ticked
ticked lines I and H, to which the mould is to be made. The left heights which were set up are the proper heights of the knuckles and horizontal lines to be marked on the mould.

The ticked lines I, H, in the sheer-plan, fig. 11, to which the mould is to be made, are supposing to be the straight line C in the body-plan, fig. 11, standing half at the wing-tranform, and the head lifted up till it stands perpendicular; which, if lowered again to the direction of the straight line C, in the body-plan, fig. 11, will appear exactly the same as the stern-timber fir1 laid off in the sheer-plan, fig. 11, which is the form of the timber required when trimmed and in its place.

In the next place, the mould should be so made, that the stern-timber shall be trimmed both ways by this one mould; that is, to the shape as it appears in the sheer-plan, fig. 11; and likewise to the fore-side and aft-side thwartship appearance in the body-plan, fig. 11.

Proceed to make the mould of dry seasoned inch-deal to the ticked lines I, H, fig. 11, in the sheer-plan, from the upper side of the wing-tranform at the side to the head G; then, when the mould is in its place, mark on it the upper horizontal lines, in the same direction as they are laid off, distinguishing them by their proper names on the mould, as the lower counter at D, upper counter at E, heel at A, No. 1 at B, No. 2 at C, No. 5 at F, and head at G. Then take the distances from the straight line C, in the body-plan, fig. 11, to the fore-side of the stern-timber B, at every horizontal line, and in the direction of the horizontal lines, and set them down in figures at the fore-side of the mould on their corresponding horizontal lines; then proceed in the same manner, and let down the dilutions or spillings on the aft-side of the mould from the lines C and A. But to mould the timber from these spillings requires much trouble, and without great care taken, the stern-timber will not be exactly moulded.

Therefore, the most correct method of finishing the mould, and the easiest in application when moulding the piece, is, instead of having the spillings marked on the mould, to have brackets made of 2-inch deal, agreeable to the spillings (dodging the thickness of the mould) at each horizontal line, having their ends at the fore-side and aft-side cut exactly square from the mould, or their aft-edges may teach to the round-afi; then fall all the brackets to the under side of the mould, keeping the middle of their thicknesses exactly well with their respective horizontal lines, as they appear shaded in the sheer-plan, fig. 11, observing to keep the side of every bracket in the same direction from the mould as the bevel at F, fig. 11, in the body-plan, that is, to the inclination which the straight line C has from an horizontal plane in representing the tumbling-home of the stern-timber.

To be more exact, let the half-thickness of the brackets be gauged down to their ends, and the sides chamfered away therefo, which will direct upon the timber, when trimmed, the exact stations of the knuckles, and also of the horizontal lines.

The brackets may be so fixed on either side, as to mould the timber for both sides of the ship.

The mould, thus made, may be applied in any direction in moulding the timber, provided its upper side is kept straight, and out of winding. Then examine where the timber, in its rough state, deviates most from the under side of the brackets, and make that the general spiling to be applied from the under side of the brackets. Wherever this spiling must be applied beyond the brackets, owing to the inequalities of the piece, let a straight-edged batten, of sufficient length, be kept well to the under side of the bracket; from which let down the spiling required, wherever it may touch the piece. Then by boring holes with a small gimlet, exactly in the direction of the gauge-line, at the ends of the brackets, and full as much below the brackets as the general spiling, you will preserve the exact moulding of the timber, after the rough wood is sawn off, agreeable to the mould.

To take the bevelings of the aft-side of the timber, the round-afi of the stern at the counters, and top-timber line, must be laid off thus in the half-breadth plan. Take the distance from the midship to the side stern-timber, on a square in the sheer-plan, Plate I., and set it off upon the middle line, Plate VII. fig. 6, and to its corresponding perpendicular, as squared down from the counters, &c. at the side, sweeping curves to the said round-afi on a square; thus, fix the tongue of a bevel to the different round-afi lines, and the flock parallel to the middle line will be the beveling of the round-afi at each place, to be applied square from the mould.

Take the beveling as cut off from the fore-side of the body-plan, Plate VII. fig. 11, thus: fix the block of a bevel to the line C, and the tongue to the round-up of the wing-tranform, as at D; and apply it over the heel of the mould, when it lies in its proper place, to where the lower bracket strikes the timber.

Supposing the heel of the timber to be carefully trimmed, as above directed, a thin mould may be made to the section of the heel on the wing-tranform, and the bevelings taken to carry it to the fashion-piece from the stern-frame, as that is generally in its place before the stern-timbers are trimmed.

The bevelings for the round-up of the knuckles of the lower and upper counters may be taken from the body-plan, Plate VII. fig. 11, by fixing the block of a bevel to the aft-side of stern-timber A, and the tongue to the round-up, as at E, and so applied from the timber when it is trimmed.

To Lay-off the Stern and Quarter-Galleries, Plate X. Laying off D.

In Plate VII. Laying off A, the laying-off of the side stern-timber to make the mould to, is represented in its proper situation, that the reader might have a clearer idea of the operation. But we are not to suppose that any mould-loft is broad enough to admit of the stern to be laid off in that manner; neither would it appear clear enough, if laid off in the body-plan.

Therefore, in some convenient part of the floor, lay off the horizontal (or level) view of the stern, as Plate X. fig. 6, from Plate I.; and likewise the quarter, as far forward as timber 32, as fig. 4.

Strike an horizontal line at the upper side of the wing-tranform at the middle line, which will be a base line to the stern; likewise the lines 17 and 18 parallel to the base line, to intersect the knuckles of the lower and upper counters, at the side stern-timber 33; in fig. 4; continuing them through their respective timbers in fig. 6. Then take the heights from the base line, in fig. 4, to the knuckles of the lower and upper counters at the midship stern-timber 32, and let them up the middle line above the base line, in fig. 6. Then spring the arc of a circle through those heights in fig. 6, and as far as the quarters project, as B, B, which will be the knuckles of the timbers. Design the lower and upper counter-rails in fig. 4, and let off the projection of the plank of each counter, thus: square out a line from the knuckle of each counter at the midship-timber 32, as a and b, and draw the thickness of the plank of each counter parallel
parallel to the timber, which gives the under side of the
rails; then transfer the upper and under sides of those rails
from fig. 4, to the middle line, fig. 6, and describe parallel
curves to the knuckles 42 and 43; and the upper counter-ruil B, and lower counter-rail A, will be also represented in
the plan of the stern, fig. 6, and that will shew how
much the right-part of the rails will be on a level view
below the knuckles of the timbers.

But the round-up and round-aft of the counter-rails, to
make the moulds for trimming the rails, must be laid off
on a square, thus: from the fore-side of the rails at the mid-
ship-timber 34, in fig. 4, square in a line from the knuckle
to the fide-timber 33; then take the distance from the
knuckle of the upper counter from the midship-timber 32,
to the fide-timber 33, in the direction of the above square
line, and set it off from any straight line, as AA, at CC,
fig. 9, which is the knuckle or breadth of the upper
counter, squared down from fig. 6. Then spring the arc
BB, which is the round-aft of the upper counter, on a
square.

Next take the distance from the knuckle of the upper
counter, at the fide-timber 33, to the line squared in from
the knuckle of the midship-timber, and set it off as before
at CC, above the line AA, in fig. 9, and spring another arc,
which will be the round-up of the upper counter, on a
square. Proceed in the same manner with the lower coun-
ter, and we shall have both rails laid off to the round-up
and round-aft on a square.

This is the best way to make the moulds for the round
of the rails; because if the rails were cut out of a lying
plank, or piece of thick-fulh, the round-up would be the
same; that when put in the boiler, and set to the round-aft,
they would then have their proper round-up on a level
view; or, were they cut out of a small piece of timber, it
would answer the same purpose, and be most expeditious
and exact.

The counter-rails may be cut out of a straight piece of
timber, without kiling them, as they are apt to fly after
that proceeds, thus: take the round-up and round-aft to-
gether, that is, from the knuckle of the fide-timber to the
knuckle of the midship-timber, and spring an arc thereto,
as before; then when the rails are trimmed to the fher,
and the fore-side canted to the timber, they will exactly
conform to the round-up and round-aft, when put in their
places.

Having the round-up of the lower and upper counter-
rails in fig. 6, and continued them far enough out for the
projection of the quarter-galleries, round up the quarter-
deck in the stern, agreeable to the upper counter-rail, in
the following manner: take the height from the upper
counter-rail, in fig. 6, to the quarter-deck, in the direction
of the fide-timber at the infide; and set it up the middle
line of the stern. This makes the quarter-deck round more
than the upper counter-rail, and adds life to the stern; for
the upper part of the lights in the stern should be parallel
to the ftranom. And if they were to round by the fame
mould as the upper counter-rail, the bars in the fakes next
the fide would be longer than those in the middle line, and
would appear as if the top of the lights rounded less than
the upper counter-rail. In the fame manner dispose of the
round of the poop, or round-house.

This should determine the round of the decks abaft; and
the beams of those decks, as they approach aft in fig. 4,
must be gradually increas’d in their round-up, to correspond
with the ftranom.

Observe that the above lines, in fig. 6, for the quarter-
deck, fhow the round of the deck at the stern-timbers,
without considering at present the projection of the bal-
cony.

Set off within the stern-timbers, in fig. 6, the
thickens of the clamp, and the projection of the cornice in
the cabin, and let that be the side of the light. Then
determine on the breadth of the munions, allowing sufficient
for the weights and pulley-pieces, and divide the other lights
equally. Set off likewife the mock-light in the aft-part of
the quarter-galley, the fame size as the reft. About half
the breadth of the munions from the mock-light, place the
infide of the quarter-piece; then determine on the breadth
of the quarter-piece at the head. About the middle of
the quarter-piece place the outside of the gallery, which de-
termines the outside of the gallery on the quarters, fig. 4.
Having the breadth of the lower part of the lights in the
clear, let the depth be one-third more than the breadth at
the lower part; set off upon the rake of the stern-timbers,
in fig. 4, and transfer that to fig. 6, which makes a good
proportional light. But obferve, between the upper coun-
ter-rail and the lights must be room allowed for the falt-fiils,
and about one inch and a half between their heads and the
ftranom above. Then determine on the out-bound of the
taffrail and quarter-pieces, and lower finifhing.

Next dispose of the quarter-gallery in fig. 4, having the
out-lines of the quarter-piece and taffrail, thus: let fall a
perpendicular from the knuckles of the lower and upper
counters of the midship-timbers, in fig. 4, as you see ticked
and numbered 14 and 15; then where the horizontal lines
17 and 18, from the knuckles of the fide-timber, interfeft
the perpendiculars 14 and 15, take those distances, and set
them off from the knuckles of the fide-timber, in fig. 6,
down the perpendiculars, c c, f f; from thence spring the
arcs 24, 24, and 26, 26, to touch the horizontal lines 17
and 18, at the middle line, which are called round forward
on a level. Then will the ticked curves 24, 24, and 26, 26,
be anfwerable to the ticked perpendiculars 14, 15, which fall
from the knuckles of the midship-timber in fig. 4.

Take the heights from the base-line, in fig. 6, to the
knuckles of each counter, at the outside of the gallery, at
the ticked perpendiculars d d, and e e, and let them up from
the base line in fig. 4, striking the ticked horizontal lines
c c and d d. Then from the horizontal ticked lines 17 and 18,
in fig. 6, take the length of the perpendiculars d d and e e,
to where they interfeft the ticked curves 24 and 26, or round
forward on a level, and set them off forward from the per-
pendiculars 14 and 15, in fig. 4, on the horizontal lines
c c and d d respectively, which will give the exact knuckles
at the timbers, in fig. 4, at the outside of the gallery.
Then take the heights of the ends of the rails from the base
line at A and B, in fig. 6, and set them off from the base line in
fig. 4, at the knuckles of the timbers last mentioned, and
continue them forward, agreeable to the fheer of thehip.
This will give the exact heights of the lower and second
counter-rails, as they will appear on the ship, if the work
be conformable to the floor.

To Lay-off the Foot-Rail of the Balcony.

Here we may again repeat the obfervation, which was made
about laying-off the beak-head timber, that since Plate I.
was engraved, the timbers of all ships of the line are now
continued upwards to the round-aft of the second counter-rail,
without any balcony, as they are much longer; yet
more useful, if guns are wanted to be used right-aft occa-
ionally. Nevertheless, ships of 50 guns have at present
a balcony or walk in the stern.

To understand the exact form of the balcony-rails, as
they appear in the fheer-plan, and likewife in the plan of the
stern,
SHIP-BUILDING.

In the plan of the stern, as far as the heads of the timbers as at 24, for the convenience of the joiners in the quarter-deck, and abaft that allow three or four times for the ballasts in the aft part of the quarter-deck, and let that be the aft part of the quarter-deck at the stern. Then design, in fig. 3, the midship part of the ends of the deck. That part, from the side-timber to the outside of the gallery, being the aft part of the taffrail, must be parallel to the taffrail line A.

Strike the perpendicular line 43 abaft fig. 4 and 5, and where the ticked line I, which is the round-at the heads of the timbers in fig. 5, intersects the outside of the taffrail, take that half-breadth, and let it off on the perpendicular 43 from the middle line. Then take the round-up of the quarter-deck on a perpendicular, in fig. 4, at the taffrail, and let it off on the half-breadth line taken from the perpendicular 43, and spring the arc H, which is the round-up of the quarter-deck, on a perpendicular.

Let the quarter-deck, at the middle line in fig. 4, be continued as far ast the ends of the deck c, in fig. 5: then from the line for the under side of the deck, drop as many perpendiculars as may be thought sufficient to find the true form of the under side of the deck, from the side to the midship, as may be seen numbered 23, &c. in fig. 4. Carry down those perpendiculars parallel to the line 43, to intersect the ends of the deck c, in fig. 5, and from thereon carry them ast parallel to the middle line, to intersect the round-up of the deck H. Then take the distance from the line 43 to the curve H, for the round of the deck at 4, fig. 5, and let it down the perpendicular 3, from the under side of the deck, fig. 4, (for per. 2 was too small a round to be received in the plate); continue the same regular to 20, fig. 5, which answers to per. 9, in fig. 4. Take the half-breadth in fig. 6, to the outside of the quarter-deck taffrail, and let it off square from the middle line to intersect the ends of the deck c, in fig. 5. Then carry ast, as before, to the curve H, the intermediate lines 21, 22, with 23, at the outside of the taffrail, and also carry them up to the under side of the deck in fig. 4, as 10, 11, 12. Then take the distances from the line 43 to the round of the deck H, in fig. 5, at 21, 22, 23, and let them off below the under side of the deck, on the perpendiculars 10, 11, 12. Then through these spots, and those before let off, draw the taffrail curve to the ast part of the quarter-deck at the middle line. This will be the exact form of the under side of the quarter-deck, if cut off agreeable to the plan, fig. 5, from the outside of the taffrail in fig. 4. Draw the taffrail line 40, in fig. 4, agreeable to the taffrail of the ship, and let off below the line 40 about one inch and a half, or as much as the joiners require for the pannelling which is at the under side of the balcony; and from that take up the depth of the rail. This will give the exact height of the foot-rail in the taffrail, fig. 4.

To find the proper height of the aft part of the quarter-deck at the under side, answerable to that in the taffrail, fig. 4, take the half-breadths at the ticked lines 14 to 23, on the line 43, in fig. 5, and let them off from the middle line on the base line, as on the left-hand, in fig. 6, and erect perpendiculars as high as the under side of the deck. Then take the heights from the base line, in fig. 4, to the under side of the deck, at Nos. 2, 3, &c. and let them up on their corresponding perpendiculars in fig. 6. Through these spots get in a ticked line, which will give the under side of the deck in fig. 6; then let off the thickness of the deck, and get in the parallel line above it. Likewise let off the foot-rail, as before directed, in fig. 4. This will give the exact form of the foot-rail, in fig. 6, agreeable to the round-ast in the plan of the quarter-deck, fig. 5.

To Lay-off the Breast-Rail of the Balcony.

It has been customary to mould the breast-rail of the balcony with the same mould as the foot-space-rail is done with. But to complete the range of balusters in the balcony, so as to make them have an agreeable rake in the taffrail, fig. 4, and likewise a proper diminution of tumbling-tongue in the plan of the stern, fig. 6, the following method only can be relied on.

In the plan of the stern, fig. 6, let the side-timber be produced upwards till it intersects the middle line; and from that point to the above-mentioned stations at the under side of the quarter-deck, in fig. 6, make ticked lines as high as the breast-rail. Whatever height the upper side of the breast-rail is intended to be at the middle line, in fig. 6, take that height from the deck at the middle line, and let it up from the deck at the several ticked lines in the direction of the said lines, as well as at the side-timber. Through these spots get in the upper side of the breast-rail D, in fig. 6. Supposing these ticked lines to be ballasters, they should all be of an equal length. Where the perpendicular ticked lines 2, 3, &c. in fig. 4, intersect the ticked line for the deck at the side, draw them upwards parallel to the side stern-timber; then take perpendicularly the heights of each of the ticked lines at the upper side of the breast-rail from the base line in fig. 6, and let them, as taken from the base line, fig. 4, to intersect their corresponding lines here-mentioned. Through these spots draw the curve K, which is the upper side of the breast-rail, as it will appear in the taffrail, fig. 4.

Drop the ticked perpendicular 1, from the ast-side of the breast-rail, fig. 4, to the middle line, fig. 5, and parallel to that the ticked perpendiculars 2 to 11, which will be found to intersect the ticked lines at the upper side of the breast-rail in fig. 4. Then take the distances (or half-breadths) from the ticked lines afore-mentioned at the upper side of the breast-rail in fig. 6, to the middle line; and let them off on their corresponding perpendiculars 2, 3, &c. from the middle line in fig. 5: a batten pinned through these half-breadths forms the line G, or upper side of the breast-rail. But observe, it only gives the form of the breast-rail corresponding with the ast part of the deck c; therefore, if the balusters are laid off in this manner, the fore-side of the mould is the reader to apply on the deck, in order to cut off the deals, and what the rail is intended to rebate on the ends of the deals must be added thereto, and as much wood as is necessary to raise the members of the rail must be left on the mould abaft the line c.
line c. Whatever is left abaft the foot-rail mould must be also left abaft the line G for the mould of the breast-rail, upon a supposition that both moulds are made to suit the aft part of the ballasters. The half-breath of the rails only being laid off is the most correct, for then the moulds will be made in two halves exactly alike, and may be scarfed and nailed together in the middle from any straight line. The middle line and outside of the timber should be marked on each mould.

To Lay-off the Taffrail and Quarter-Piece.

The form of the taffrail and quarter-piece, in fig. 6, being laid off from the plan of the stern, Plate I., square up from fig. 5, what the stern projects at 23, to the quarter-deck in fig. 4, and continue it upwards parallel to the side stern-timber to the top of the side, as you see ticked; then set off the half-breath of the stern at the quarter-deck, and likewise at the top of the side on the ticked line 25, fig. 6, taking the round-oft at each place, and set it apart the corresponding heights from the above ticked line in fig. 4. This will give the ticked line T, being the midship-timber at the upper part of the stern, or the fore-side of the taffrail at the middle line. Let this ticked line T be answerable to the line A A, fig. 9.

Drop as many perpendiculars from the top of the taffrail and outide of the quarter-piece, as in the left-hand of fig. 6, as may be thought necessary. Take the perpendicular heights from the base line in fig. 6, to the several perpendiculars last mentioned on the taffrail and quarter-piece, and set them up from the base line in fig. 4, and strike in the horizontal lines 22 to 31, the last being the height of the taffrail at the middle line. Take square from the middle line in fig. 6, where each perpendicular intersects the upper part of the taffrail and outside of the quarter-piece, and let them off from the middle line on the ticked line 25, fig. 6; then take the distances from the ticked line 25, to the round of the stern on a level 26, 26, at each line squared down, and set them off on their corresponding lines last struck in fig. 4, from the ticked line T, forward in the direction of the ticked lines. A batten pinned to these spots will give the ticked curve Q in the middle of the quarter-piece, (which, in a thwartship view, is the aft-part of the timbers, supposed to be continued to the heel of the quarter-piece); then abaft this ticked line set off the aft-side of the taffrail, and continue it to the heel of the quarter-piece; that will determine the aft-side of the quarter-piece, from which set forward the side of the quarter-piece, and that gives its fore-side, as it will appear when in its place.

The rims and tools might be all laid off on the floor; but it would appear confused on the plate, and perplex the reader. And, indeed, the making of a handsome quarter-gallery depends chiefly on the performance on the ship; therefore an explanation may give more useful information than a drawing.

The length of the rims and tools being determined in fig. 4, the breadth abaft need only be taken from fig. 6, and let the floor at the quarter-deck serve for all the rims and tools in the quarter-gallery, keeping the foremoat end well. At least, the fame mould that moulds the taffrail at the upper parts of the lights, may mould the rim at the lower part of the same lights, because the munions in the quarter-gallery should be all out of winding; and in order to make them so, the floor at the quarter-deck will require to be longer than the rim at the lower part of the lights, more or less, according to the winding of the top-side. This might be allowed for exactly in laying-off the floors; but it is better to leave the floor at the quarter-deck long enough, and proceed in the following manner.

Suppose the rim at the second counter-rail to be trimmed agreeable to the form of the floor at the quarter-deck, and to be in its place on the ship; and suppose the floor at the quarter-deck to be fayed to the side; then set off the breadth of the floor at the aft part, and nail a batter from thence to the rim. Then set off the munions on the rim, and at every munion on the rim hold a straight batter from thence to the under side of the floor, and look them out of winding with the batter at the aft part, or with each other, observing to set off the same distances at the under side of the floor from the aft part as they are on the rim. Then the wood may be dapped away, or the floor taken down, and mould the under side (which will nearly agree) to every spot, with the same mould as the rim was moulded with. Then you may be certain the batties will be out of winding, and, if required, would slide from one end of the gallery to the other. Then, when the munions are let off, you may find a greater distance from the form-mould on the floor, than there will be on the rim; but this cannot be avoided, and is of but little consequence; because the casting-livres, or confide-bracket, is introduced on purpose to intercept the finishing of the gallery with the ship-side; for if the floor at the quarter-deck was to be no longer than the rim at the second counter, it would fall into the hollow of the top-side at the foremoast end, and the foremoast munions in the view of the sheet, fig. 4, would appear to rake more than the after ones; and when looking from before the gallery, the munions in the lower and upper gallery would not appear out of winding, but the whole gallery would seem in confusion; therefore the upper gallery must undergo the same operation, and then it will bear to be viewed in any direction.

It is requisite, at least, to lay off the floor and rim of the lower gallery, and allow for the winding of the top-side, in order to mould them nearly; but by following the above method in the performance of the work, any little error that may happen will be corrected.

To lay off the upper rim B, and middle floor, fig. 4, to make the moulds to, transfer the height of the upper side of the lower rim, B, and upper floor 6, in fig. 4, continued forward to square timber 32, to the body-plan, Plate VII., fig. 5, upon its corresponding square timbers. Then take the half-breath as far forward as square timber 32, and set them off from the middle line on their corresponding timbers in Plate X., fig. 5, and produce the half-breath lines, and thicken of the planks A and B without it, as far ast in the plan, fig. 5.

Then square down the knuckles of the upper counter from fig. 4 to fig. 5, and spring an arc to the round-oft, which will be the fore-side of the upper counter-rail. Next sweep another arc to the thickness of the upper counter-rail, parallel to and abaft the ticked curve, and the upper counter-rail will be thrown in the plan, fig. 5. Then take the half-breath of the upper side of the upper counter-rail to the outside, B, in fig. 6, and set it off from the middle line in fig. 5, on the ticked perpendicular 13, as squared down from the outside knuckle. Thence form the curve F, or outside of the lower rim. The ticked parallel line within is the outside of the munions, upon which set off the flatings of the lights, making them all alike, and the munions 44, 45, 46, 47, between. Square up the munions to the upper side of the lower rim in fig. 4; and from the spots squared up strike lines parallel to the side stern-timber, to the under side of the middle floor. The aft part of the middle floor is already laid off in fig. 5, and the form of the outside may be
be determined by the inside of the mould of the lower rim, keeping the fore end well, and allowing the additional length required by the winding of the top-side, &c. Then to prove that the outer edge of the rim and floor are out of winding, square down the sides of the munion from the under side of the middle floor in fig. 4, to the outside of the middle floor in fig. 5; and at the after-sides of the musions, take their half-breadths from the middle line, and set them off square from the middle line in fig. 6, upon the under side of the middle floor. In the same manner take off the half-breadths of the musions on the rim, and set them off on the upper side of the upper counter-rail. Then strike lines to those spots in fig. 6, and they will be parallel to the side timber and each other, consequently out of winding. The upper gallery rim and floors may be laid off in the same manner, and the moulds also made; observing to take the musions of the upper lights agreeably to those below, which may be set off as follows. Determine on the fore-part of the upper gallery, and continue it upwards as the ticked line \( H \), in fig. 4; then with a batten, fitted as square as possible from the fore-side of the foremost munion, mark on it the sides of all the musions. Then fit the fame end of the batten to the ticked line \( H \), and move it diagonally, till the after-side of the after-munion touches the fore-side of the quarter-piece, and mark all the sides of the munion as on the ticked line \( 41 \); then striking lines through those spots parallel to the rake of the lower munion, the lights and musions will be represented in the upper gallery.

The upper and lower finishings may be formed at pleasure, making them as light as possible, to please the eye, and containing sufficient room in the upper finishings to hold a cittern.

To Lay-off the Stern upon the Rake.

The horizontal plan of the stern being laid off, proceed to lay off the stern upon the rake; or, at least, the taffrail and quarter-pieces. For, were moulds made to them as already laid off, it is easy to conceive that they would be too low and too narrow, when fixed upon the stern, to its round-af on rake; which must be the case upon the ship. In the plan of the stern, fig. 6, strike up lines in the middle of each munion, one in the middle of the side timber, one up the inside of the quarter-piece, and one between, to rake upwards to the centre of the stern, at the middle line, as marked 35, 36, 37, and 38, as on the right hand.

Draw the horizontal line \( B \) through figs. 7 and 8, which will correspond with the ticked lines 25, 25, at the upper counter in fig. 6. Take the perpendicular heights of all the timbers, from 35 to 38, and at the inside of the quarter-piece in fig. 6, from the lines 25, 25, to the ticked curve for the knuckles of the upper counter, and set them from the line \( B \) in fig. 8, and draw parallel lines thereon, as you see ticked, and numbered \( 9, 10, \&c. \) Take likewise the perpendicular heights from the lines 25, 25, fig. 6, to the intersections of all the timbers, with the under and upper sides of the taffrail and quarter-piece; and set them from the line \( B \), in fig. 8, where they are ticked and numbered as before.

Strike lines to the rake of the midship and side counter-timbers above the upper counter-rail, taken from fig. 4, and transferred to fig. 8, as the ticked lines 32 and 33. Draw a line square from the midship stern-timber 33, in fig. 8, to intersect the knuckle at the upper counter at the side-timber, as the ticked line 30; then continue the midship-timber 32 down to the line 30; then take the distance from the midship to the side-timber in the direction of the ticked line 30, and let it off from the line \( A, A \), in fig. 9, on the ticked lines \( C, C \), and raise the arc \( B, B \), which shews how much the stern rounds aft on a square, agreeable to the breadth of the upper counter, which round-af governs all the stern above, as before observed.

Where the timbers 35, 36, 37, 38, and inside of the quarter-piece, fig. 6, lie on the ticked line \( 42 \), or knuckles of the upper counter, square them down to fig. 9; then take the round-af of each timber from the line \( A, A \), fig. 9, and set them off square from the midship-timber 32, so as to intersect their corresponding level lines in fig. 8. Then where the above timbers in fig. 6, intersect the upper part of the taffrail and quarter-piece, let them be squared down as before; and transfer the round-af to their corresponding level lines in fig. 8, setting them off square from the midship-timber, as before. Then from those spots, down to the spots on the level lines of the knuckle of the upper counter, strike the lines of the intermediate timbers, and mark them \( 1, 2, 3, \&c. \) which shews the thwartship view of the timbers, as stationed in fig. 6.

If the side-timber 33, and midship-timber 32, were prolonged in fig. 8, till they intersect each other, that would be the centre for the intermediate timbers, as disposed in fig. 6, and prove the work.

It will be necessary to have one spot at the outside of the quarter-piece, as 39, fig. 6, and squared down, as before, to the round-af, fig. 9; then take its round-af at 11, fig. 9, from the line \( A, A \), and set it off square from the midship-timber 32, in fig. 8, on its corresponding level line 16, as transferred from fig. 6.

Square down the heel of the quarter-piece where it intersects the knuckle-line, 42, fig. 6, to fig. 9, to the round-af \( B, B \). Then pin a batten to the round-af on a square \( B, B \), fig. 9, and keeping it fast at the middle line, mark spots on the batten, where the ticked lines 2, 4, 7, 10, 12, and outside of quarter-piece, are squared down from the knuckle-line 42, fig. 6. Then fit the same end of the batten well to the middle line, fig. 7, keeping it straight along the line \( B \), and thereon mark the several spots on the right hand, and likewise on the left. Then, if the floor will admit of it, continue upwards the spots in the middle of the side counter-timber, as at 13, fig. 7, till they intersect the middle line, and from thence, as a centre, may all the other spots be continued upwards, as in the plate. But if this cannot be performed, the heights of the timbers 35, 36, \&c. must be taken up their perpendicular lines, from the line 25, 25, fig. 6, to where they intersect the upper side of the taffrail and quarter-pieces, and set up from its corresponding line 25 the middle line in fig. 7, striking horizontal lines; then pin a batten, as above, to the round-af \( B, B \), fig. 9, and mark spots thereon at the middle line, and perpendicular lines 1, 2, 3, 5, \&c. squared down from their heads; and set them off upon their corresponding heights laid set off in fig. 7; then lines struck through those spots to the spots before set off on the line 25, or \( B \), the timbers will have their regular tumble-home, as from the centre in the plate. Then take the distance square from the line 30, fig. 8, up each separate timber, to the spots on the level lines for the upper part of the taffrail and quarter-pieces; and set them off square from the line \( B, B \), fig. 7, to intersect their respective timbers, and in like manner the spot at the outside of the quarter-piece; then a batten pinned to those spots will represent the boundary of the stern or taffrail \( T \), and quarter-pieces \( Q, Q \), on the rake, fig. 7. Then take the heights square from the line 30, fig. 8, up the separate timbers, to the heights for the lower part of the taffrail and inside of the quarter-pieces, and set them up, as before, on their corresponding timbers in fig. 7; then by pinning a batten
SHIP-BUILDING.

batten to those spots, the under side of the taffrail I, and inside of the quarter-pieces, will be completed to make the moulds to. The cover-rail D may be also marked on the taffrail mould, and likewise upon the quarter-piece mould.

Practical Directions for the actual Building.

Having now explained the usual methods of forming the draughts, and laying off the several parts of the ship, it remains only to describe the progressive manner of its actual building, or putting together the several parts.

A ship being provided, the blocks on which the keel is laid are usually about five feet asunder. Each block is laid upon a ground-way in the middle of the ship, unless a smaller vessel is intended to be built where the launch has been laid for a large ship. In this case, by keeping the blocks towards one side, the fiding-planks may be preferred for that side.

The blocks, being the foundation of the whole, must be very carefully fixed, and their upper surface to a declivity of five-eighths of an inch to every foot in the length, observing that there may be water enough to launch the ship into, and keeping them high enough at the fore-part to clear the fore-foot of the ground-ways in launching, and to admit of the fiding-planks to be laid with a declivity of about seven-eighths of an inch to a foot.

The caps or upper blocks should be more in depth than the false keel; and they should be clear-grained oak, that they may split out the easier when the false keel is put under.

The upper sides of the blocks are made straight fore and aft, and level athwartships; sometimes the after-blocks are raised above a straight line, as the great weight of the stern and overhanging generally settle in building.

Keel is generally elm, fawn straight and square, and is scarfed together with coaks, with tarred flannel between each scarf, which are firmly bolted together and caulked.

The rabbit for receiving the plank of the bottom may be trimmed out, leaving about a foot at each end of the scarfs, for the better caulking the butts. In the navy, the rabbit is lined parallel to the upper side of the keel to the thickness of the bottom plank; but, in most merchant-ships, the rabbit is taken out of the middle of the keel, to prevent its caving, should the ship take the ground. The keel is left fair and straight along the middle of the blocks; and, to keep it in that position, tree-nails are driven along its sides into the blocks.

Dead or rising-wood is of oak timber, and fayed upon the upper side of the keel. The pieces along the midship are of a parallel thickens, and in breadth to overhang the keel about two inches on each side. The dead-wood afore and abaft, for the security of the half-timbers, is as high as the cutting-down. This part of the dead-wood below the keel is trimmed to the shape of the body, and above the keel, perpendicular to the fize of the keel. The scarfs or butts of the dead-wood should give scarf to the butts of the keel, and to each other.

Stem is composed of two or more pieces of oak timber, of the belt quality, as shifting it is very expensive. It is fayed to its fiding and moulding, then trimmed and scarfed together as the keel, and the rabbit taken out likewise.

On the stem should be marked, from the mould, the heights of the harpins, decks, casks, &c. and a line square from the keel, and a middle line as a guide to set it by.

Apron is also oak fawn to its fiding and moulding, and fayed to the aft-side of the stem, to fuccour it at the scarfs, which are bolted through the apron, observing to place the bolts within the rabbits.

Bollard-timbers are oak fawn to their fiding and moulding, their heads in wake of the bowsprit to be left the thickness of the plank inside and out; they are fayed and coaxed to the sides of the stem and apron, and bolted through, where practicable, observing to place the bolts clear of the deck-hooks. Sometimes oak fillings are fayed between the stem and bollard-timbers, to keep them more open in wake of the bowsprit.

Hawse-pieces are oak fawn to their fiding and moulding, and are fayed to the bollard-timbers, and to each other, in wake of the hawse-holes; and are opened above and below the hawse-holes, for the admittance of air, to about one inch and a half. When in their places, they are to be bolted to the bollard-timbers and each other, clear of the hawse-holes and deck-hooks. Let it be observed, that the hawse-pieces should be so disposed as to be equally cut by the hawse-holes.

Stern-post is oak fawn to the fiding and moulding, and should be provided for the top, and to work upwards, if to be got. The rabbit is trimmed out on each side, to receive the plank of the bottom, to the shape of the body; and a tenon left on the keel, one-third the depth of the keel.

Inner-post is oak fawn to a parallel breadth, and fided, as the shape of the body may require, below the head: it is fayed to the fore-side of the stern-post, and a tenon made on the heel as on the main-post, and the head left long enough to tenon an inch into the tranfom next above it.

Tranfoms are oak fawn to their fiding, whether rounding upwards or straight; and to the moulding by their respective moulds. The wing-tranfom, if faved only to the margin bevelling, may be brought in for other ues, if sound defective; for tranfoms require much trouble and expence to shift them; the quality of the timber ought, therefore, to be of the best, and quite free from any defect whatever. In converting the tranfoms, let care be taken to work them top and butt alternately.

The tranfoms are to be trimmed with the greatest nicety, and then let on the pott, with scores on each side of about an inch; observing the greatest exactness in letting them down, and that they stand at right angles with the middle line on the pott. The ends, when cut off to the mould, are left one inch and a half longer, to tenon and face on to the aft-sides of the fashion-piece. The ends may be opened or mouthed, to admit the air.

Fashion-pieces are oak fawn to their fiding, then to the mouldings and bevellings; and, when trimmed, let on to the ends of the tranfoms, in the manner already described.

Frame-timbers are oak fawn to their fiding, straight, and out of winding, then moulded and fawn to their respective bevellings, except the cant-floors, which are fided to their proper cant.

The frame-timbers should be converted of sound well-grown timber, without sap or vein appearing in wake of the posts, and fawn full to their fodings, so that their fastening may remain after the posts are trimmed out. Every timber should also be provided to its length, consequently each should stand upon its proper head; or if one timber happens to be short, provide the next long enough to make good the deficient length, as through-checks should always be rejected, or only admitted on extraordinary occasions. The heads and heels of all the timbers to have one-third of the substance left the moulding way, when trimmed; and the feet of the checks should not exceed once and a half the fiding of the timber.

In providing the floors, care should be taken to reverse the butt end of each succeeding floor, because the tops may sometimes
sometimes be feasty; and, when short of the floor-head, may be admitted, if the second futtock runs down and meets upon its respective floor.

All floors are required to have sufficient wood to feast themselves on the dead-wood, and the throats to run up to the cutting-down or under side of the keelson; then any wood wanting below the feating may be made good by a chock.

The floors, when correctly trimmed, are let down into foors cut in the dead-wood, to the exact height of the cutting-down from the upper edge of the rabbit of the keel, in their respective situations; set precisely level, and at right angles with the middle line of the keel. The floors are then ribbanded and flored, securing the foors at the head and heel to prevent any alteration; for the truth and precision of the whole fabric may be laid to depend upon the accuracy of the floors, when got into the ribsbad.

Futtocks.—The several futtocks are trimmed straight, and out of winding on the joint side; and the lower futtocks in the navy run down to the side of the dead-wood, but in merchant-ships they are from nine to twelve inches short of the keel, that water may not lie above the ceiling. The wood wanting on the inside of the lower futtocks, in the navy, is made good by cross-chocks up to the cutting-down.

The timbers that compose a frame, or bend, are bolted together, either close or opened, as required; the joint-side of the second futtock to the joint-side of the lower futtock, to the middle of its length or flaring, and bolts thereto with three bolts of square iron. The heel of the third futtock joins the head of the lower futtock, and bolts, as the former, to the second futtock; the heel of the fourth futtock joins to the head of the second futtock, and bolts to the third; and the heel of the top-timber fearns on the head of the third futtock, and is bolted or fastened with tree-nails to the fourth futtock, taking care that no bolts are driven in wake of the ports or port-fills.

They are railed into their places by sheers and tackles, and great care should be taken that the frame be not strained in hoisting, as its form would be altered, and of consequence the true shape of the body loft; to prevent which, the joints of the chocks and heads are secured by nailing quarter over them, and a flore fitted on the inside or bag of the frame.

The frames, as hoilled, are kept to their true breadth, and equally distant from the middle line, by the cross pales, which are nailed at the main height of breadth, or in the ports: the latter is preferable, if not thought too high, because the ends need not be cut, and they may remain till the hull is plank'd, and the beams in and kneed.

The frames are next ribbanded thus: the cant-frames may be gotten near to their flations by the harpin-moulds, then the harnpinned gotten up; and, if the frames come fair, may be nailed and flored to their framework.

The square frames, correponding at the floor-mark or guide, must be levelled, and the joints let at right angles with the middle line, observing that the spacing of the ports agrees. The ribbands may then be nailed and flored, and the lower futtocks bolted to the floors.

Filling-timbers, or the timbers between the frames, are trimmed and hoilled into their places separately; then equally spaced asunder, and nailed to the ribbands; then chocked at their heads and heels, and the whole frame dubbed fair inside and out to its scantlings for planking.

Keelson is oak fawn to its fiding and depth, or moulding, then fayed along the middle of the floors, and bolted through every floor and the keel, with three or more douls on each scarf, which should give as much shift as possible to the fearns of the keel. For some years a three-inch oak plank has been fayed upon the upper side of the keelson, and the bolts driven through that likewise.

Stem-fan is oak fawn to its fiding and moulding, then trimmed and fayed to the apron, and fearns with a hook or douls into the fore part of the keelson. The bolts through the braid-books must be consider'd, and one or two bolts may then be driven through between them.

Stem-fan-knee is oak fawn to its fiding and moulding, then trimmed and fayed against the transoms and upper side of the dead-wood, and fearns with a hook, or douls into the after-piece of the keelson. It is bolted to the transoms and stern-pont as the keelson, of which it is a continuation.

Wales are next wrought, and the thick-stuff below them: they should be fastened with dumps only for the present, as the tree-nail holes, which are double and single alternately in every timber, and should be left open as long as possible, for the admission of air. A doul in the timber next each butt in the wales, in the strake above and below it, has been lately introduced in the navy, as an additional securitv. The wales and diminishing strakes are then dubbed down fair, and large cleats nailed at the fore part of every port, to which the hup is substantially flored.

Planking.—The bottom is next plank'd down sufficiently low to work the orlop-clamps. See Planking expanded, Plate VIII.

Inboard Clamps, Thick-stuff, &c.—These are wrought similar to the outside stuff above. The clamps to the sheer of the deck, and their upper sides to the round-up of the beam, and the lower edge, square to the timbers, unless they work down to the ports; then in, in wake of the ports, the lower sides are trimmed level, and between the ports square to the timbers. Clamps over ports are beared from half their depth to one inch less in thickens on the under side, excepting over the ports, where the wood is left on, for the muzzles of the guns to houset to; and the butts are douelled as the wales.

The thick-stuff is to be wrought with a square close edge over the joints of the timbers; and the spirkings are to have a seam allowed, agreeable to the thickens with the outside stuff, which should be a full sixteenth to every inch in the thickens.

Beams are fawn to their fiding, and to the moulded depth square to the fiding. Beams of two, three, or four pieces are fearned together; and if in three or four pieces, the middle pieces may be sir, excepting in the hatchways. Beams in two pieces have a scarf one-third the whole length of the beam. Beams in three pieces have the middle pieces and the end pieces each half the length of the whole beam, the middle piece having a scarf each way to take the arms. Beams made of four pieces have two middle pieces, each similar to the former; the arms and middle pieces are each to be in length three-sevenths of the whole length of the beam. See Gun-deck, Plate VI.

Beams are either tabled or douelled, and bolted together at the fearns: if tabled, the lengths of the tables are one and a half the moulded depth in length, and divided at the middle of the depth; and where the wood is taken out on the upper side, it is left on the lower side, and so alternately; taking the wood out on the upper side at the table next the butt, as it will the better hang and support the lip. At each lip, beyond the tables, is a coak about six inches long; and next to that is a straight lap, about the same length.

The beams, when cut off to their length, have their ends moulded and charred, and then are let down about one inch into
into the clamps, at their several stations, at right angles with the middle line; keeping their upper sides out of winding with the beam line.

Knees.—The beams, at their ends, are connected to the sides by knees, or other substitutes for knees. The knees are fawn or trimmed to their sides, and fayed to the side, taking as little wood as possible out of the throat the moulding way, as the greatest strength of the knee is there. Each knee tapers towards the toe to which it is fided; and the surface in the throat should be about twice and a half the fiding, and not to admit of any chock that would reduce the knee at any part less than the fiding.

Each knee should have two douls in the beam-arm, and from three to four bolts; and the two upper bolts in the side-arm of the hanging-knees should be kept up as high as possible, and the others equally spaced to the toe, and bored as square to the sides as the beams outside will allow.

In those parts of the ship aforesaid, where wooden knees cannot be procured of kindly growth, (for upon that depends the strength,) knees of iron are generally placed. These, although much used, particularly in merchant-ships, cannot be so fully depended upon as those of wood, because they cover less surface, are no wise flexible, nor can the bolts be driven so tight in iron as in wood. If, therefore, the ship strains, they must inevitably work loose. Again, the holes must be bored in the direction in which the knees are punched, so that where iron knees are intended to be placed, oak fellungen should be driven between the timber; otherwise the bolts may come in the openings, which is inadmissible. Besides this, the bolts may come in the beams of the outside plank; when it so happens, the belt way is to cut out a piece, and clench the bolt upon the timbers.

Bolts in wooden knees are mortly driven from the outside, and clenched upon the knees inside; but bolts in iron knees are driven from the inside, with collar or flout heads, because upon the head depends its fastening; or if the bolts be of copper, they must have a ring under the head, and the head spread or made large in driving. All bolts driven from the inside should be carefully clenched upon a ring, let fluff into the plank, by means of a machine or centre-bit for that purpose, and the points under water carefully caulked after the ring is let in.

Wooden knees having become scarce for some years past, many substitutes have been attempted; and iron knees, or rather knees formed of iron and wood conjointly, are certainly bent when properly applied. See Substitute.

Standards, either on the deck or to the sides of orlop beams, are so similar to knees, as to require no further description.

Breast-hooks, steps, and crutches, are oak fawn to their fidings, then moulded. The deck-hooks are fayed to the timbers, the others to the inside fluff. The holes for the bolts are bored alternately, near the edges, equally and square with the body. Breast-hooks, steps, and crutches, are affixed in the moulding by chocks; and the deck-hooks may be affixed by large eakings, worked behind them. All the chocks, &c. are douelled or tabled, and ought on no account to have lefs wood or substance than their fiding, clear of the check.

Riders are oak fawn to their fidings, moulding, and bevellings; then fayed to their respective places, as follows.

Floor-riders in two pieces have a cross-chock fayed over the heels, with a hook and butt fcarf; their heels run down to the timber-strake, and the heads run upwards between the joints of the floor-heads and first futtock-heads.

First futtock-riders stay close to the sides of the floor-riders, and their heels extend downwards within four feet of the keelson; their heads run upwards between the joint of the first futtock-head and under side of the orlop-beams, with a cross-chock fayed over the heels as the floor-rider.

Second futtock-riders stay close to the sides of the first futtock-riders, and scar with a hook-scarf under the head of the floor-riders, or connect thereto with a chock. Their heads run up within two inches of the under side of the gun-deck beam, and are fawn with a swell at the orlop-beam, to which they tail sideways; and they bolt through the beam and the adjoining riders fore and aft.

Third futtock-riders stay and bolt to the sides of the second futtock-riders, and are fawn with a swell, as the above, at the gun-deck beam. The heads run up within two inches of the under side of the upper deck beam, or middle deck, in three-deck ships; and the heels come within two inches of the under side of the orlop-beam.

Ships in the navy at present have no inside fluff below the clamps, but have their timbers filled in between with dry slices of oak, driven in tight and caulked; and the riders are fayed over the timbers, and stand diagonally at the angle of forty-five degrees.

The knee of the head is oak, each piece fawn to its sizing, agreeable to the tapered battens, where they intersect. The main piece should make the lower part of the knee, and run up to the top part of the stem, to which it says high enough for a hole to be cut in it to receive the main-tay collar. The front piece runs up to fit the figure, and should be broad enough to take the bow-deck holeways, and the lower end step in the main piece about one foot below the load draught of water. Another piece must be provided to make the lacing to secure the figure. The other pieces between may then be provided, as most convenient, marking on the mould the shape of each piece, as provided; the surface of each piece is then fayed close together, and douelled. The knee is hoisted up into its place, and then bolted with seven or more bolts through the stem-end and apron, and sometimes through the deck-hooks.

Cat-heads are now fawn straight, sideways, and plumb, moulded to flight, in ships of the line, to five inches in a foot above a level line without the bow; and in frigates and smaller vessels, to the angle of forty-five degrees. The inner end fays up to the under side of two or more of the forecastle beams, fo as to angle square with the bow.

Supportors of the cat-heads are knees of oak fayed to the under side of the cat-head, and the arm to the side to stand perpendicular; the upper arm bolted through the cat-head, and the other through the side.

Rudder.—The main piece to be oak fawn to its sizing, and the upper part to the given dimensions, and the lower part to be moulded as broad as the piece will admit. Whatever the main piece may require to complete its fore-side may be elm, fayed close to the main piece, and douelled. The other pieces to complete the surface of the rudder may be fir, fayed close to the main piece and each other, and douelled. The whole is then trimmed straight through to its thicknesses, and bolted together between the flaps of the pintles. The back is then fayed on, and fastened to the aft-side, and the sole at the heel, when cut off to its length, which is nine inches short of the under side of the keel. The fore-side may be then bearded from the middle to twofifths the thickness, lined down on each edge; but this has been found to cut or wound the main piece so much at the upper pintle, that, lately, the aft-side of the stem-poll is likewise bearded at the upper end; and consequently the fore-side of the rudder to much the lefs. The pintles may next be let on thus: the braces being let on to the stern-poll, and square from the aft-side, a staff of the whole length
length is run down through the holes of the braces. Now mark the upper sides of the braces correctly on the staff with a pencil, or both under and upper sides will be bent. Then mark on the staff the upper side of the wing-tranom, and the under side of the deck-tranom above; also the upper side of the deck; and, lastly, the under side of the keel. Next apply the staff on the foré-side of the rudder, and exactly mark off the upper sides of the braces in the middle line, likewise the transoms and deck. Then square down, from the fore-side of the rudder, the upper side of each brace, which, it may be observed, is the under side of the pinteles. Now set upwards the breadth of the flaps of the pinteles, and the scores may be taken out till their crowns come flush with the bearding, and the middle of the pinteles ranges well with the middle line: thin copper is dint in the scores under the pinteles. Scores or throatings are then gouged out, under the pinteles, sufficiently large for hanging the rudder, which may be formed by a piece of sheet-lead made to the crown of each brace, and traversed round its respective pintle. Let there be sufficient room in the scores to allow for the head of the bolts; and that the rudder may hang easily, all the scores must be made to the length of the lower one; that pintle being two inches longer than the others. The score nearest the load water-line is opened on one side to fit in the wood-lock, which prevents the rudder from unshipping. Ships built in the North have the pinteles put into the braces, and the rudder put together in that situation, so that it cannot be unhang until throatings are cut to clear it of the braces.

After the braces are let on to the stern-post, it is best to try all the pinteles in them, and see that they work easily in the braces, and square from the stern-post. Then their upper sides may be marked on the stern-post, and set off on the rudder, as before directed, without the possibility of error.

The head, if not round-headed, is thinned and bearded back about three-quarters of an inch, and the edges taken off to a bold round. The holes for the tellers may now be cut through the lower hole three inches clear of each tranom, and the lower part of the upper hole three inches clear of the deck: lastly, the head-hoops may be driven on.

Amongst other useful machines for drawing bolts out of ships (see BOLTS), the following was invented by Mr. William Hill. See Transactions of the Society for the Encouragement of Arts, &c. vol. x.

"First, The use of this machine is to draw the keel-van and dead-wood bolts out, and to draw the knee of the head bolts. Secondly, The heads of the keelbolts heretofore were all obliged to be driven through the keelson, floor-timbers, and keel, to get them out: by this means the keelson is often entirely ruined, and the large hole the head makes materially wounds the floors; and frequently, when the bolt is much corroded, it tears, and the bolt comes out of the side of the keel. Thirdly, The dead-wood bolts, that are driven with two drifts, are seldom or never got out, by which means the dead-wood is condemned, when some of it is really serviceable. Fourthly, In driving the knee of the head bolts, sometimes the knee starts off, and cannot be got to again, but is furled up; but with this machine it may be drawn to again."

In Plate XIV. Ship-building, fig. 3, A, A represent two strong male scres, working in male scres, near the extremities of the cheeks, against plates of iron. E, E. C C is the bolt to be drawn, which, being held between the chaps of the machine at D, is, by turning the scres by the lever B, forced out of its hold. F, F are two dogs, with hooks at their lower extremities, which, being driven into the plank, serve to support the machine till the chaps have got fast hold of the bolt. At the upper part of these dogs are rings passing through holes in a collar, movable near the heads of the scres.

Fig. 4. is a view of the upper sides of the cheeks, when joined together; a, a, the holes in which the scres work; b, the chaps by which the bolts are drawn. Fig. 5. the under side of the cheeks; a, a, the holes in which the scres work; b, the chaps by which the bolts are drawn, and where the teeth that grip the bolt are more distinctly shown. Fig. 6. one of the cheeks separated from the other, the letters referring, as in figs. 4 and 5.

SHIPFUND, SHIPSEND, or Schifffund, in Commerce, a large weight in Holland, Germany, Denmark, and Sweden, containing a different number of pounds in different places. At Amsterdam the shipfund contains 3 centners, 20 lyponds, 37½ tare or tines, and 330 lbs. A lypond is 15 lbs., and a tine 8 lbs. At Berlin a ship-lift contains 12 shipfunds, each of 20 lyponds, or 280 lbs.; in all 3360 lbs.: but a salt of salt is 3260 lbs. At Hamburgh a shipfund contains 2½ centners, 20 lyponds, or 280 lbs.: a lypond is 14 lbs., and a centner 112 lbs. Hamburgh weight. At Copenhagen the shipfund contains 3 centners, 20 lyponds, or 320 lbs.; a lypond is 16 lbs., and a centner 101 lbs.

SHIPLEY, JONATHAN, in Biography, an English prelate, was born in the year 1714, and was educated at Christ-church, Oxford, where he wrote some verses on the death of queen Caroline; and in 1738 he took his degree of M.A. Soon after this he entered into holy orders, and obtained a living. In the year 1743 he was installed prebendary of Winchelner, and in 1748 appointed chaplain to the duke of Cumberland, whom he accompanied abroad. In 1749 he became canon of Christ-church, and in 1760 dean of Winchelner. In 1769 he was advanced to the bishopric of St. Asaph. He died in 1783. He was author of poems, and sermons on public occasions.

SHIP-MONEY, an imposition which was anciently charged upon the ports, towns, cities, boroughs, and counties of the kingdom; by writes commonly called ship-writs, under the great seal of England, for the providing and furnishing certain ships for the king's service.

This imposition was revived by king Charles I. in the years 1635 and 1636; but by Stat. 17 Car. I. it was declared to be contrary to the laws and statutes of the realm, claim of right, liberty of the subject, &c.

SHIPPANDTOWN, in Geography, a town of Virginia, on the south side of the Patowmack; 40 or 50 miles from Alexandria.

SHIPPENSBURGH, a post-town of Pennsylvania, in Cumberland county, on a branch of Conadoguinet creek, which discharges itself into the Susquehannah; containing about 200 houses, chiefly built of stone, 1595 inhabitants, and three meeting-houses, one for Seceders, one German, and one Methodist. It derives its name from its proprietor John Shippin, esq. of Philadelphia, who leased out the place in small house-lots on ground-rents from two to four dollars a year; 146 miles W. of Philadelphia.

SHIPPER, SKIPPER, or Schipper, a Dutch term, signifying the master of a ship.

We also use the word, popularly, for any common seaman.

SHIPPISANADAN ISLAND, in Geography, an island in the gulf of St. Lawrence, on the south side of Chaleur bay, S.W. of, and separated by a narrow channel from, Miscow Island.

SHIPPING denotes a multitude of vessels.

SHIP-SHAPE, in Sea Language, denotes the fashion of a ship, or the manner of an expert sailor: thus, they say,
SHI

fay, the mast is not rigged shipshape, and trim your sails shipshape.

SHIPSTON-UPON-STOUR, in Geography, a market-town in the upper division of the hundred of Owlefield, and county of Worcestershire, England, is situated in a district entirely detached from the body of the county, and close to the left bank of the river Stour, whence it derives the latter part of its name. The houses here are chiefly built of stone; but notwithstanding this advantage, the town cannot boast much of its appearance, many of them being small, and thatched with straw. Several attempts have been made to establish manufactures here, but without any permanent success. The market-day is Friday, weekly, and there are two annual fairs, one on the 22d of June, and the other on the 1st Tuesday after the 10th of October; both of them for horses, cows, and sheep. The Manor of Shipton formerly belonged to the priory of Worcester, and is now part of the possessions of the dean and chapter. The church is only a chapel of ease to the mother church of the parish of Tredington, which extends about nine miles in length and two in breadth. According to the population returns of 1811, the parish contains 297 houses, and 1377 inhabitants, of whom about 1000 reside within the township of Shipton-upon-Stour. Naft's Survey of Worcestershire, 2 vols. fol. Beauties of England and Wales, vol. xv. by Mr. Launc. 8vo. 1813.

SHIPTON, a flourishing township, of excellent land, in Lower Canada, on the east bank of the St. Francis; 20 miles N.W. of Acicot, and containing about 350 inhabitants.

SHIPWRECK. See Wreck.

SHIRALDO, in Geography, a town of Perdz, in the province of Ghilan; 30 miles S. of Aftara.

SHIRBAY, a town of Syria, the residence of a sheikh; 15 miles E. of Aleppo.

SHIRBOY, a river of England, in the county of Warwick, which runs into the Sow.

SHIRE, SYVRA, originally Saxon, seir, or seires, formed from sfurvan, to divide; a part or portion of the land, called also a county; which fee.

SHIRE-CLerk, he who keeps the county court; and his office is so incident to that of the sheriff, that the king cannot grant it away.

SHIRE-MAN, was anciently the judge of the shire, by whom trials for land, &c. were determined.

SHIRE-MOTE, in our Old Writers, an assembly of the county or shire at the alizes, &c. See SYRECEMOT.

SHIRE-REVE, See Sheriff.

SHIRE, Knight of the. See Knight.

SHIREWOOD or SHERWOOD FOREST, in Geography, is an ancient and extensive forest, comprehending a large portion of the county of Nottingham, England. Thoroton, in his History of Nottinghamshire, says that it extends into the hundreds of Broxton, Thurgarton, and Baffletlaw; and measures about twenty-five miles in length, by from seven to nine in breadth, an extent which seems to agree with its ancient boundaries, as stated in a perambulation made in the sixteenth year of Henry III. The period when this forest was originally constituted a forest is unknown, but that event must have occurred previous to the time of Henry II, as in the first year of that monarch's reign, it appears from official records, that William Peverel was called upon to answer "De Placitis Forestal in Comitatu Nottingham." At that time Peverel had the whole profit and command of this forest; but it must soon afterwards have reverted to the crown, for in 1151 the sheriff of the county prays to be discharged of "4L in valo foresta," and in 1163 he prays for a similar discharge, and for the discharge of "40L paid to the canons of Shrewsbury for alms." In the Forest book is inserted a copy of a charter by king John, granting to Matilda de Caux, and Ralph Fitzlethen her husband, and their heirs, all the liberties and free customs which any of the ancestors of the said Matilda, lords of Laxton, had held in Nottinghamshire, including the forest of Shrewsbury. The same rights afterwards fell to John Birking, as heir-general to Matilda de Caux; and in 1226 the forest is mentioned as being then in possession of his son; but this line failing, it descended to the family of the Everinghams, who having lost their possessions by forfeiture in the reign of Edward I., reverted to the crown. Since that event, its civil jurisdiction has been generally vested in the sheriffs of the county, and its forest jurisdiction only granted to various individuals among the nobility and gentry, as special marks of royal favour. An inquisition taken before Geoffrey de Langley, in the reign last mentioned, illustrates the customs of this forest. By it the chief keeper appears to have been obliged to have three deputy keepers for a like number of districts, in order to attach all trespassers, and prevent them at the attachment before the verdurers. In the first keeping, which lay between the rivers Lene and Doverbeck, he was to have one forester riding with a page, and two foresters on foot; two verdurers, and two agitators. This keeping contained the three hays of Balkwood, Lindeby and Willay. The High Forest, including the hays of Barkland and Bilhagh, and the park of Clifton, formed the second keeping; and here were two foresters riding, with two pages and two agitators. The third keeping, Rumwode, had one forester on foot; two woodwards, one at Carbunton, and the other at Budby; and the number of verdurers and agitators. The chief keeper was further bound to have a page bearing his bow, whose duty it was to gather "chimnage," which is usually supposed to have been a tax for the formation and preservation of roads.

By the late survey made of this forest in 1609, it was parcelled out into three walks, called the north, middle, and south walks. The forest officers, under the superintendence of the chief justice in eyre north of Trent, are a lord warden, a bow-bearer and ranger, four verdurers, a steward, and nine keepers, besides two sworn woodwards for Sutton and Carleton. The surveyor-general of the woods has likewise a jurisdiction over this forest, as far as regards the wood and timber of the crown. He has a deputy in the forest, who has a fee-tree yearly, and a salary of 20L. Thorney-wood Chace, though a branch of this forest, is distinct from it in jurisdiction, having been granted by queen Elizabeth to John Stanhope, esq. and his heirs, as hereditary keepers. This chace comprehends a large portion of the south walk, and was formerly well flocked with fallow deer; but these, of late years, have greatly diminished in number.

Of the ancient woodland in this extensive tract, little remains except in the hays of Barkland and Bilhagh, which form an open wood of large old oaks, covering about 1500 acres of ground; but modern plantations have lately increased rapidly, and there are, in different districts and parks, a few trees, remarkable alike for their great age and magnitude. In Clifton park is an immense oak, called the Parliament oak, from a tradition that a parliament was assembled here by Edward I.; and in the same park is another tree, felled by the Broad oak, the bough of which measures 234 feet in circumference. Many of these venerable oaks may likewise be seen in Welbeck park, on the skirts of the forest, where some of them are upwards of 34 feet round. Rooker, in his "Sketch of the Forest," mentions a recent discovery of a very curious mode of ascertaining the great antiquity of some of these trees. He tells us, that in cutting down some timber in Birkland
Birkland and Bilhagh, letters were found cut or stamped in the body of the trees, denoting the king's reign in which they were so marked. The cyphers were of king John, James I., and William and Mary. The mark of John was eighteen inches within the tree, and about a foot from the centre; it was cut down in 1790; but the middle of John's reign was 1207, from which, if we substract 120, the number of years requisite for a tree of two feet diameter to arrive at that growth, it will make the date of its planting 1087.

The forest of Shirewood was, in ancient times, frequently the scene of royal amusements. As early as the reign of Henry II., Mansfield was the general residence of the court upon these occasions, and it was in this vicinity, according to tradition, that Henry made acquaintance with the miller of famous memory, Sir John Cockle. This forest was likewise the retreat of another personage, equally celebrated in the chronicle of ballad, the illustrious Robin Hood, who, with little John, and the rest of his associates, making the woody scenes of it their asylum, laid the whole county under contribution. Thoroton's History of Nottinghamshire, republished, with additions, by John Throoby, 3 vols. 4to. 1790. Beauties of England and Wales, vol. xii. by Mr. Laird, 8vo. 1813.
