SHIRINKI, one of the Kurile islands, about 26 versts from Poromushir. On it it rives a round mountain-top; and about it, on the coast, walls of rock and loofe brittle bone, but it has no sandy bay, nor any safe inlet for shipping. The island is nearly as broad as it is long, and may be about 40 versts in circumference. It is only inhabited by sea-lions and other marine animals, with some red foxes and sea-fowls that have been carried thither with the ice. There is no wood on the island, except a few stumps of the mountain pine and some elder bushes; and it has neither a stream nor a spring of water. The rocks are very much disposed to break and fall in fragments. N. lat. 50° 40'. E. long. 138° 3'.

SHIRLEY, Anthony, in Biography, second son of Thomas Shirley of Welton, in Snifle, a celebrated traveller, was born in 1565. He studied at Oxford, where he took his bachelor's degree in 1581, after which he joined the English troops, which, at that time, were serving in Holland. In 1596 he was one of the adventurers who went to annoy the Spaniards in their settlements in the West Indies, and on his return he was knighted. After this he was sent by the queen into Italy, in order to affright the people of Ferrara in their contumely with the pope: before, however, he arrived, all the disputes were accommodated, and peace was signified; he accordingly proceeded to Venice, and travelled from thence to Perlia, where he came in great favour with Shah Abbas, by whom he was sent ambassador to England in 1612. By the emperor of Germany he was raised to the dignity of count, and by the king of Spain he was appointed admiral of the Levant seas. He died in Spain about the year 1630. There is an account of his vast Indian expedition in the third volume of Hakluyt's Collection, under the following title: "A true Relation of the Voyage undertaken by Sir Anthony Shirley, Knight, in 1596. intended for the Island San Toma, but performed to St. Jago, Dominica, Margarita, along the Coast of Sierra Firma to the Isle of Jamaica, the Bay of Honduras, Thirty Leagues up Rio Dolce, and homeward by Newfoundland, with the memorable exploits achieved in all this Voyage." His travels into Persia are printed separately, and were published in London in 1613; and his travels over the Cape of Goza, and through Ruffia, were inserted in Purchas's Pilgrimages.

Shirley, James, a poet and dramatic writer, was born in London about the year 1594. He received the early part of his education at Merchant Taylors' School, from which place he was removed to Oxford. He was, on ac-

count of his talents, patronized by Dr. Laud, who, however, would not consent to his taking orders, by reason of his being disfigured by a large mole on his cheek, which, in his ellimation, according to the canons of the church, rendered him unfit to officiate in clerical duties. Shirley therefore left Oxford without a degree; but he afterwards removed to Cambridge, and meeting with no farther obstacle, he took orders, and obtained a curacy. His religious creed was not sufficiently settled, and he went over to the church of Rome, abandoned his cure, and opened a grammar school at St. Alban's. After some time he deserted this employment, and became a writer for the stage. His productions were successful, and he acquired a reputation which enabled him to be taken into the service of queen Henrietta Maria. When the civil war broke out, he accompanied the earl of Newcastle in his campaigns, and also assisted him in the composition of several of his plays. On the ruin of the king's cause he came to London, and resumed his occupation of a schoolmaster, in which he met with considerate encouragement, and he showed his attention to the duties of his office, by publishing some works on grammar.

During the Commonwealth, theatrical amusements being suspended, Shirley had no room in which he could display his dramatic talents; but after the Restoration, several of his pieces appeared again on the stage. The death of this author is thus described: his house 'in Fleet-street being burnt in the great fire of London, in the year 1666, he was forced with his wife to retreat to the suburbs; in consequence of the loss and the alarm which this occasioned, both himself and wife died within a few hours of each other, and they were buried in the same grave.

Mr. Shirley was author of thirty-seven plays, confounding of tragedies and comedies, and of a volume of poems, published in 1646. He had the reputation of being the chief among the second-rate poets of his time, but his works have long since disappeared from the stage, and they are scarcely ever referred to by more modern authors, yet there have been critics who thought highly of them. Dr. Farmer, in his Essay on the Learning of Shakespeare, says the imagination of Shirley is sometimes fine to an extraordinary degree.

He alluded Mr. Ogilvie in his translation of Homer and Virgil, by writing notes on them.

Shirley, in Geography, a township of America, in Massachusetts, in the W. part of Middlesex county; 41 miles N.W. of Boston, incorporated in 1753, and containing 814 inhabitants,—Also, a township of Pennsylvania, in Huntingdon county, containing 862 inhabitants.

Shirón, or Shirvón, a town of Thibet; 120 miles N. of Catmandu. N. lat. 35° 10'. E. long. 85° 5'.

Shirvan. See Shirván.

Shisniew, a town of Poland, in Volhynia; 12 miles N. of Conflantina.

Shitakoontha, a name of the Hindoo deity Siva. It means the blue-throated; and the fable accounting for the name is often alluded to in the writings of that fanciful people. It relates, that when the ocean was churned, in the manner described under our article KurmaVatara, poison was produced among the fourteen precious articles resulting from that marvellous operation. The word, as well as poison, means medicinal drugs. This was swallowed by Siva.

"To soften human ills, dread Siva drank
The poisonous flood that irrigated his azure neck."

In the fongs of Jaydeva, translated by Sir W. Jones, in praise of Vishnu and Lakhmi, under their names of Krithna and Radha, the following passage occurs, which we are in-
Hindoo poetries, and the prevalence of mythological allusions, in all their writings. Heri and Narayana, we may presume, are names of Vishnu; and Padma, or the Lotus, of Lakshmi.

"Whatever is delightful in the modes of music; whatever is divine in meditations on Vishnu; whatever is exquisite in the sweet art of love; whatever is graceful in the fine strains of poetry— all that let the happy and wise learn from the songs of Jayadewa, whole soul is united to the foot of Narayana. May that Heri be your supporter, who expanded himself into an infinity of bright forms, when eager to gaze with myriads of eyes on the daughter of the ocean, he displayed his great character of the all-pervading deity, by the multiplied reflections of his divine perfon in the numberless gems on the many heads of the king of serpents, whom he chose for his couch: that Heri, who, removing the lucid veil from the bosom of Padma, and fixing his eyes on the delicious buds that grew on it, diverted her attention by declaring, that when she had chosen him as her bridgroom, near the sea of milk, the disappointed husband of Parvatि drank in despair the venom which dyed his neck azure."—Jones's Works, vol. x. Af. Ref. vol. iii.

The many-headed king of serpents is named Sefha, a frequent subject of poetical exuberance. See Seshä.

Of the blue-necked Siva, Nalakantha is another name, of familiar meaning as that at the head of this article; and which indeed occurs oftener than Shitakantha, or Shitakoontha.

SHITTAT, in Geography, a town of Arabia Deserta; 50 miles N.W. of Melched Ali.

SHITTEN BAY, a bay on the W. coast of the island of St. Christopher.

SHIVAL, a town of Hindoostan, in Vifapour; 25 miles E. of Baddammy.

SHIVERAPILLY, a town of Hindoostan, in the cîrcar of Cicacle; 20 miles W. of Cicacle.

SHIVERS, in a Skip, the seamen's term for those little round wheels in which the rope of a pulley or block runs. They turn with the rope, and have pieces of brass in their centres, which they call the coek, with holes in them, into which the pin of the block goes, and on which they turn.

These shivers are usually of wood, but some are of brass, as those in the heels of the top-masts. See Sheave.

SHIVERS, in Rope-making, the foul particles taken from the hemp, when hatchelling.

SHIVERING, the rate of a sail when the wind is too oblique to fill it, so that it flutters about. This must be the case when a vessel is put about, till the sails are filled again with the wind.

SHIVERY SALT, a name given by the salt-workers to a fort of salt, very little different from the common brine-salt. See Salt.

SHIUMLA, in Geography, a town of Bulgaria, in the fangiac of Drihtra. In this place, thought by the Turks to be impregnable, they were defeated by the Ruslians with terrible slaughter; 62 miles E. of Varna. N. lat. 43° 10'. E. long. 26° 27'.

SHIZAR, a town of Syria, in the pachalie of Aleppo; 15 miles S.E. of Famieh.

SHOAD, in Mining, a term for a train of metalline stones mixed with earth, sometimes lying near the surface, sometimes at considerable depths, but always serving to the miners as a proof that the load or vein of the metal is thereabout. The deeper the shoad lies, the nearer is the vein.

SHOAD-Stones, a term used by the miners of Cornwall, and other parts of this kingdom, to express such loose mailes of stone, as are usually found about the entrances into mines, sometimes running in a straight course, from the load or vein of ore to the surface of the earth.

These are stones of the common kinds, appearing to have been pieces broken from the strata, or larger mailes, but they usually contain mangan or marastic matter, and more or less of the ore to be found in the mine. They appear to have been at some time rolled about in water, their corners being broken off, and their surface smoothed and rounded.

The antimony mines in Cornwall are always easily discovered by the shoad-stones, these usually lying up to the surface, or very nearly so; and the matter of the stone being a white spar, or debased crystal, in which the native colour of the ore, which is a lashing blueish-black, easily discovers itself in itsexits and threads.

Shoad-stones are of so many kinds, and of such various appearances, that it is not easy to describe or know them: but the miners, to whom they are of great use in the tracing, or searching after new mines, distinguish them from other stones by their weight; for if very ponderous, though they look ever so much like common stones, there is great reason to suppose that they contain some metal. Another mark of them is their being spungy and porous; this is a sign of especial use in the tin countries, for the tin shoad-stones are often so porous and spungy, that they resemble large bodies thoroughly calcined. There are many other appearances of tin shoads, the very hardest and firmest stones often containing this metal.

When the miners, in tracing a shoad up hill, meet with such odd stones and earths, that they know not well what to make of them, they have recourse to wounding, that is, they calcine and powder the stone, clay, or whatever else is supposed to contain the metal; and then washing it in an instrument, prepared for that purpose, and called a waving showel, they find the earthy matter washed away, and of the remainder, the stone, or gravelly matter lies behind, and the metallic matter at the point of the showel. If the person who performs this operation has any judgment, he easily discovers not only what the metal is that is contained in the shoad, but also will make a very probable guess at what quantity the mine is likely to yield of it in proportion to the ore. Phil. Trans. No 69. Price’s Mineralogia, p. 124, &c.

SHOAL, in Sea-Language, is the same as shallow, and is applied to flats in the water.

They say it is good floating, when a ship failing towards shore, they find by her founding it grows shallower and shallower by degrees, and not too suddenly; for then the ship goes in safety.

SHOAL INLET, in Geography, a channel between two small islands on the coast of North Carolina. N. lat. 34° 54'. W. long. 77° 58'.

SHOALNESS, a low cape on the west coast of North America. Captain Cook met with some Indians on the coast, near this cape, who came off to the ships in canoes, expressing, as he conceived, their pacific intentions by hailing and opening their arms, as they cautiously advanced. At length some of them approached near enough to receive some trifles that were thrown to them. This brought on, says Captain Cook, "a traffic between them and our people, who got drestes of skins, bows, arrows, darts, wooden vessels, &c.; our visitors taking in exchange whatever was offered them. They seemed to be the same kind of people that we had lately met with along this coast; wore the same ornaments in their lips and noses, but were far more dirty, and not so well clothed. They appeared to be wholly unacquainted with people like
...knew not even the use of tobacco; nor was any foreign article seen in their possession, unless a knife may be considered as such. This indeed was no more than a piece of common iron fitted into a wooden handle. They however knew the value and use of this instrument so well, that it seemed to be the only article they wish'd for. Most of them had their hair shaved or cut short off, leaving only a few locks behind, or on one side. As a covering for the head they wore a hood of skins, and a bonnet apparently of wood. One part of their dress was a kind of girdle, very neatly made of skin, with trappings depending from it, and paffing between the legs, so as to conceal the adjoining parts. By the use of such a girdle, it should seem that they sometimes go naked, even in this high latitude, for they hardly wear it under their own clothing. The canoes were made of skins, like all the others we had lately seen; except that these were broader, and the hole in which the man was wider than in any I had before met with." N. lat. 60°. E. long. 108° 12'.

...SHOALS, /les of, or, as they were formerly called, Smith's Islands, a group of small islands, situated on the coast of New Hampshire, in America. The line that divides the district of Maine from New Hampshire pafes between these islands, leaving part in one of these states and part in another. They contain about 140 poor fishermen, who are supplied with a religious teacher by the society for propagating the gospel. They have a meeting-house, which serves as a landmark for seamen, and a parolour-house, erected by charity. These islands consist chiefly of a barren rock, with little foil. N. lat. 43° 59'. W. long. 70° 33'.

SHOAL-WATER BAY, a bay on the N.E. coast of New Holland, W. of Cape Townshend.—Alfo, a bay on the W. coast of North America. N. lat. 46° 50'. W. long. 124° 10'.

SHOAR, or Shore, a prop, or counterfort, set up to support any thing of weight which leans on one side. See Buttress.

Shoars, or Shores, in Ship-building, are fir-valks, spars, or pieces of timber, fixed under the ribbands, or against the sides and bottom of the ship, to prop or support her whilly building or repairing.

SHOBA, in Geography, a town of some note in Africa, in the kingdom of Dar-fur; 42 miles or 24 days' journey W.S.W. of Cobbe. This place is said to be well supplied with water, and has near it some chalk-pits, which, when Mr. Browne visited them, were almost exhausted for the purpose of adorning the royal reliquary, and some others, with a kind of white-wash. In Shoiba reside fome Jolahs; the reb of the people are Ferians, and occupied in other purpofes.

SHOCK, or Schock, in Commerce, a German word exprefling 60 pieces.

SHOE, in Geography, a small island in the Pacific ocean, near the coast of Waygwo. S. lat. 60° 11'. E. long. 170° 53'.

SHOE, Indians, Indians of North America, in an island of lake Milliouri. N. lat. 48° 15'. E. long. 105° 45'.

Shoe, a covering for the foot, usually of leather. Its structure, though the object of a particular art, is too popular to need explaining.

Its history is more obscure. Bend. Baudoin, a shoe-maker by profession, has learned treatise of the ancient shoe, "De Solea Veterum," where the origin, matter, form, &c. thereof, are particularly inquired into.

Baudoin maintains, that Gofd, in giving Adam skins of beasts to clothe him, did not leave him to go bare-footed, but gave them shoes of the fame matter; that, after raw skins, men came to make their shoes of rubles, broom, paper, flax, silk, wood, iron, fliver, and gold; so different has their matter been. Nor was their form more flable, with regard either to the shape, colour, or ornaments; they have been square, high, low, long, and quite even, cut, carved, &c.

Pliny, lib. vii. c. 56, tells us, that one Tycheius, of Barotia, was the firft who used shoes.

M. Nilant, in his remarks on Baudoin, observes, that he quotes Xenophon wrongly, to shew that even in his time they fill wore shoes of raw skins.

Xenophon relates, that the ten thousand Greeks, who had followed the young Cyrus, wanting shoes in their retreat, were forced to cover their feet with raw skins, which occasioned them great inconveniences.

Nilant will not even allow, that the shoes of the country people, called carbatine, and perone, were of crude skin, without any preparation.

The patricians, among the Romans, wore an ivory crefcent on their shoes: Helogabalus had his shoes covered over with a very white linen, in conformity to the prefts of the fun, for whom he profefled a very high veneration; this kind of shoe was called coaft, udo, or ado. Caligula wore shoes enriched with precious flones. The Indians, like the Egyptians, wore shoes made of the bark of the papyrus. The Turks always put off their shoes, and leave them at the doors of the mosques.

Shoes made by rivetting instead of fewing. A patent was taken out for this invention in 1809, by Mr. David Mead Randolphi, an American. In his specification, he describes that the rivetting which he proposes to subftitute for fewing, is only applicable to the foles and heels of boots or shoes, all the other parts being made in the ufual manner. The lat which is used for this method is the only implement which demands a particular description. It is firft made in wood, of the fame figure as the common lat, and adjusted in the ufual manner to the fize and shape of the shoe which is intended to be made or put together upon it. The lower part or fole of the lat is then covered with a plate of iron or steel, about the fame thickness as a lat fole leather: this plate, being formed to the exaft shape which is defired, is flattened down upon the wood by fcrews or rivets. The iron plate has three circular holes made through it, one at the toe, another about half way between the toe and the heel, and a third at the heel: the holes are about an inch in diameter, and being filled up with wooden plugs, and cut down even with the furface of the iron, they will admit the points of temporary nails to be driven through the leather fole to penetrate into the wood, and fix the fole upon the lat whilst the work goes on.

The making of the fhoe is conducted in the ufual manner, until it is ready for putting on the lat. To do this, the inner fole is put upon the iron fole of the lat; then the upper-leathers are put upon the opposite part, and the edges of the leather are turned down over the edges of the inner fole; the outer fole is then applied over the turning-down, and flattened in a temporary manner upon the lat, by driving one or two nails, through both foles, into the wooden plugs before mentioned, which fill up the holes in the iron face of the lat. Now, to unite the two foles to the upper-leathers, holes are pierced all round the edges of the fole, and small nails are driven in, which are of sufficient length to penetrate through the fole and the turning-in of the upper-leathers, and also through the inner fole, fo as to reach the metal face of the lat, and be forcibly driven, their points will be turned by the iron, fo as to clench within fide, or rivet through the leather, and ferve instead of the fewing or stitching commonly employed to unite the fole to the upper-leathers.

Shoes,
**SHOES.**

**Shoes, Machines for making.** These are the invention of Mr. Brunel, of whose mechanical genius we have had frequent occasion to speak in this work. He has lately established at Battersea an extensive manufactory of shoes, chiefly intended to supply the army, where all the operations are performed by the aid of machines, which act with such facility, that they can be managed by the invalid soldiers of Chelsea Hospital, who are the only workmen employed, and most of them disabled by wounds, or the loss of their legs, from any other employment.

The shoes made by these machines are different from the common shoes, in the circumstance of the sole being united to the upper-leathers by a number of small rivets instead of sewing, in the same manner as those we have mentioned in the preceding article. To facilitate the description we intend to give of the machines, we shall first describe the structure of one of these shoes. Its upper-leathers are the same as any other shoes, and consist of three pieces; viz. the vamp, or part which covers the upper part of the foot, and the two quarters which surround the heel, and are fewed together behind it; they are also fewed to the vamp at about the middle of the length of the shoe. The sole part of the shoe is composed of the real or lower sole, with its welt, the heel, and the inner or upper sole.

The lower sole has an additional border, which is called the runner, or welt, fixed upon its upper side, all round the edge, by a row of rivets, so that it makes a double thickness to the sole towards the edge; but this additional piece is only of small width from the outside of the sole inwards, and gradually diminishes away in thickness to nothing, as it recedes from the edge of the sole, so that the middle part of the sole is only of the same thickness as the single leather. The upper-leathers are made sufficiently large to turn in, all round, beneath the foot, under the edge of the inner sole, for about three-quarters of an inch wide, and the outer sole, reinforced by the welt, is applied beneath, so that the turning-in is included between the two soles; that is, it is included between the edge of the inner sole and the welt, or extra thickness which surrounds the lower sole. To hold the shoe together, a row of rivets is put through the sole, all round the edge, and they are of sufficient length to pass through all the four thicknesses, viz. the lower sole, the welt, the upper-leathers, (where they are turned in,) and also through the inner sole; and these rivets being made fast, unite the parts of the shoe together in a much firmer manner than sewing. The rivets have no heads, but are made tapering, and the largest ends are on the outside of the sole, which prevents them from drawing through; and at the same time, the strength of the rivetting will not be materially impaired by the gradual wearing away of the sole leather.

These rivets prevent the wear in a very great degree, and for this reason there is a greater number of rivets put into the sole than merely those which hold the shoe together. The different nails are, first, the short nails, or rivets, which only penetrate through the single thickness of the lower sole; these are arranged in parallel rows across the tread of the foot, that is, about two-thirds of the length from the heel; there is likewise a double row of short nails, which is carried round parallel to the outline of the toe, at about three-quarters of an inch from the edge, and extends as far as the middle of the foot. Next, the tacking nails, which are of a sufficient length to reach through both the sole and the welt, and thus fix the two together: of these, there is a row all round the edge of the foot, nearer to the edge than the row of short nails before mentioned. Lastly, the long nails, which, as before described, fasten the shoe together: these form also a complete row round the edge of the whole shoe, and nearer to the edge than any of the preceding rows. The heel is also fastened on by a row of long nails round its circumference. The heads or thick ends of all these nails appear on the lower surface of the sole, and all contribute to preserve the leather from wearing. We shall now proceed to a description of the ingenious instruments and machines used in this manufactory, beginning with those for

**Cutting out the Leather.**—This is performed by flamps, each of which is an iron frame or ring, bent to the size and figure of the sole, or other part to be cut out by it: one edge of the frame is edged with steel, and ground sharp, so that it will cut the leather: the sharp edge of this frame being placed upon the skin, and driven with a mallet, will cut out a piece from the skin, which is exactly of the same size as the interior opening of the frame. The leather for the soles is first softened, by soaking it in water; the skin is then spread out on a block or table of lead about two feet long and eighteen inches wide, and the flamp or knife for the soles is placed upon the skin in the most advantageous position to cut out the piece; then two or three blows upon the top of the knife with a beetle or large wooden mallet, forces its edge through the leather, and cuts out the piece, which remains in the opening of the knife, but being taken out another is cut in a similar manner.

A knife of this kind is provided for all the pieces which are used to form the shoe, and they are called after the names of the respective pieces, which are as follow: 1. The sole, which is not cut out the full size for the sole of the shoe, but wants a piece at the heel. 2. The piece-piece is a semicircle, to be joined to the sole to make up the heel. 3. The heel: these two last pieces are cut out of the small pieces, or scraps of leather. 4. The runner, or welt, which is applied upon the sole, all round the edge, to make the extra thickness where the upper-leather is to be joined to the sole. All these parts are cut out from the strong hides. 5. The inner sole. The upper-leathers are, 6. the vamp, or part which covers the toes and upper part of the foot; 7 and 8, the right and felt quarters, which surround the heel, and are fewed to the vamp, being also fewed together behind the heel.

All these parts, except the soles, are cut out by knives of the above description, there being a set of knives for every different-sized shoe which is made in the manufactory. For cutting out the inner soles, the knife is fixed horizontally, with its edge upwards, beneath a heavy cast-iron lever, which moves on a centre pin, supported in the same framing which sustains the knife. The lever has a plate of lead attached to it near the centre, so that when it is brought down horizontally the lead will depend upon the knife, the edge of which being imprinted into the lead, will cut through the leather which is previously spread upon the knife. To use this cutting-out machine, the sole is first cut out roughly from the skin by a common cutting-knife, round a wooden pattern, and the lever being being raised nearly to a vertical position, the rough sole is laid fairly upon the edge of the knife; then, by letting fall the lever, its weight, and the leverage upon the plate of lead, causes a sufficient nseur upon the leather to force it upon the edge of the knife, and cut it to the exact shape required. The lever is guided in its descent, to ensure that its lead shall fall precisely upon the knife.

Immediately after the soles are cut out, they are stamped on the under-side of the leather with a number which designates the size of the shoe to which they belong. The flamp is engraved on the face of a small hammer, so that one blow makes the desired mark. The heels and other parts are also marked,
marked, that the workman may make no mistakes in putting the shoes together.

The leather for the welt is cut into strips of about an inch wide: for this purpose, the piece is spread on a flat table about two feet square, the surface of which is covered with small iron rulers the width of the intended strips, and screwed down upon the wooden table, leaving between them sufficient spaces to admit the point of a knife. Several small pins project from these iron rulers to penetrate the leather and hold it fast. To confine the leather down whilst it is cut, a frame of iron is fixed to the table by hinges at one end, so as to fold down horizontally upon the leather, and the frame is covered all over with similar rulers, the intervals between them corresponding exactly with those between the rulers on the table. The cutting is performed by a hooked knife, fixed into a long handle. The workman holds down the frame upon the leather, and introducing the hooked point of the knife between the bars, draws it towards him; this cuts through the leather, and he repeats it at every interval between the rollers, and thus divides the whole leather into strips of the same breadth as the rulers.

To prepare these strips for use, each one is split lengthways into two other strips, by an oblique cut along the middle of it; thus producing two strips, which have bevelled or feathered edges, similar to a ruler for drawing. The splitting of the strips is performed by a very complete machine, consisting of a pair of brass rollers, one of which is turned by a winch, and the other receives its motion from it by means of a pair of equal cog-wheels, one wheel being fixed upon the ends of each of the rollers. The rollers are mounted one above the other in an iron frame, in a similar manner to those used for laminating; the lower one has a groove formed round it, which is of a proper size to receive the strip of leather before it is divided, and the preserve of the upper roller compresses it into the groove. A guide, consisting of an iron item, with a square hole through it, is fixed up before or in front of the rollers, to conduct the leather into the groove; and on the opposite side, or behind the rollers, is an item, or standard, which receives a cylindrical steel pin, and holds it fast in a horizontal position, in the direction in which the strip of leather will move when it comes through the rollers. The end of this steel pin is flattened and ground to a fine sharp edge, like that of a chisel, and precluding itself to the end of the strip of leather as it passes through the rollers, will evidently divide the strip longitudinally into two pieces, when the leather is forced forwards against the edge of the cutter by the motion of the rollers. This edge is placed obliquely to the axis of the rollers (or to the surface of the leather which passes between them), and therefore will divide it by an oblique cut, so as to produce two narrow feather-edged pieces from each strip. The preserve of the rollers upon the leather tends to condensate its texture, and supply the place of hammering.

Preparation of the Soles.—The leather is hardened by passing it between rollers, to produce the same effect as hammering does in the ordinary method of shoe-making. The rollers used for this purpose are made of brass, about five inches diameter, and as much in length; they are mounted in the usual kind of frame, except that instead of screws to hold down the upper roller, and regulate its distance from the lower one, two plain cylindrical pins are inserted into the holes which usually receive the screws, and these pins have a strong lever bearing upon their upper ends, to press the upper roller down upon the lower, by the action of a weight at the extremity of the lever. These pins are only about four inches distant from the centre or fulcrum of the lever, and the weight (of about 100 pounds) is at a distance of four feet from the centre, it therefore presses down the upper roller upon the lower, with a force of nearly 1200 pounds. The lower roller has a cog-wheel upon the extremity of its spindle, which is moved by a pinion upon the end of an axis turned by a winch; one man turns this winch and another puts the soles between the rollers. Two soles are presented together, being laid one upon the other, with the flesh sides of the leather towards each other, and an iron plate is placed between them, which is made thick in the middle, and diminishes every way to the edges, where it is thin. The grain or hair side of the leather of the two soles is outsie, so as to be in contact with the rollers when the soles are presented to the machine which draws them in; and when they have nearly passed through, the man who turns the winch reverses the motion, and rolls them back again, then forwards, and so on for four or five times, in the same manner as the motion for mangleing linen. After this operation the leather becomes hard and solid, and much reduced in thickness, particularly at the middle part.

The heels being so small cannot conveniently be rolled; but to produce the same effect they are stamped in a fly-pres: for this purpose, a heel-piece is put into a small box or cell of cast-iron, of a proper shape to receive it, and a thick plate, which is fitted to the box, being laid upon it, the whole is laid beneath the fcrews of the press, one blow of which is sufficient to press the iron plate upon the leather, with a force which will render it hard and solid.

The soles are made complete by joining to it the small semicircular piece at the heel; for this purpose, the parts which are to be joined together are cut bevelled, so that they will overlap without increasing the thickness, and then three or four nails are driven through the bevelled parts, to hold them together. To cut the joints bevelled, a simple press is used: the sole is laid flat upon the edge of the bench, and a piece of iron is pressed down upon it by a lever, upon which the workman leans his elbow. The edge of the bench is bevelled, and faced with iron, and this, together with the upper piece of iron, guides the knife, so that it will cut the joint bevelled: the heel-piece is then cut in the same manner, but reversed.

Application of the Sort Nails.—The leather for the sole is next laid in with short copper or iron nails, which are put through holes in the leather, in the broad part of the foot, where the greatest wear will take place; and there is also a double row of similar rivets, laid round the toe part, at about three-quarters of an inch within the edge of the sole. The holes for these nails are first punched in the leather of the sole by a punching machine, and then a second machine cuts the nails, and inflicts them into the holes.

The punching machine is moved by the foot of the workman, who is seated before a small semicircular table of cast iron, on which he places the leather. This table is supported by a strong column, rising from the floor to a height of about two feet above the table, which is joined to the column by a projecting bracket, so that the column is on the opposite side to that where the workman is seated. The upper part of the column has two arms, projecting forwards from it towards the workman, and extending over the table; at their extremities they are formed into sockets, to sustain a square iron rod or perpendicular slider, which at the lower end has the piercer or awl screwed into it: one of the sockets guides the upper part of the slider, and the other the lower part, so that it has a freedom of motion in a perpendicular direction, but no other. The slider is caused to descend by means of a treadle moving on a centre pin, attached to the foot of the iron column, beneath the bench; from this treadle an iron rod ascends through a hole in the
SHOES.

bench (and also through holes in the arms, which project from the column to sustain the slider), and at the upper end this rod is connected with a lever, which moves on a joint at the upper end of the iron column, whilst the extreme end of the lever is connected with the top of the perpendicular slider. By this arrangement it is clear, that the foot, being pressed upon the treadle, will communicate motion by the iron rod and upper lever to the slider and piercer, and force its point through the leather, which is placed upon the small iron table. A short lever and counterpoise are provided to raise up the slider again when the pressure is removed. To prevent the piercer striking upon the iron of the table, and breaking the point, a screw is inserted in a piece projecting from the slider, and its point in descending comes to rest upon the upper of the two arms which sustain the slider, and thus prevents the descent of the slider at the proper place.

The piece of leather for the sole is fixed upon a pattern made of iron plate, cut to the same size and shape as the sole, which is united to it by two sharp gauge pins, which are fixed in the pattern, one at the middle of the tread, and the other in the centre of the heel; and these pins project so far, that they will just penetrate through the leather, to hold it fast against the pattern, which is perforated with all the holes which are intended to be pierced in the sole. The leather is applied upon the pattern, and struck with a mallet, so as to force the gauge pins into the leather, and unite the sole and the pattern together; the pattern is then laid flat upon the table of the machine, with the leather uppermost, and is brought beneath the joint of the piercer, so that it will penetrate in the desired place. To ascertain this place, a small fluid or pin is inserted into a hole in the table, in the exact spot where the point of the piercer descends; the fluid projects a little above the surface of the table, but is only held up by a spring, so that it can easily be pressed down. The pattern being placed so that any of the holes therein receive the point of the fluid, it is evident that when the pressure of the foot makes the piercer descend, its point will make a puncture in the leather which is fastened upon the pattern, which puncture will be opposite to the hole in the pattern; and though it perforates the leather quite through the thickness, the point of the piercer cannot be blunted against the iron, because it is placed in the hole in the pattern, and the fluid descends by the pressure, so that the pattern will lie quite flat upon the surface of the table. In this manner the workman pierces any number of holes in the leather, placing it beneath the joint of the piercer by the aid of the pattern, and then pressing the foot to bring the point down and pierce the hole. As soon as the piercer rises, he removes the pattern to another hole, and so on. A small piece of iron is fixed just above the leather, which prevents its being lifted up, and following the piercer when it rises. The piercer paras through a hole in this piece.

Nailing Machine for the Short Nails.—The sole being thus pierced with holes, the short nails are put into it by a very curious machine, which at the same time forms the nails, by cutting them off from the end of a strip of iron or copper, of the same breadth as the length of the intended nails.

The sole is presented to the machine by laying it upon a small table, similar to the lathe machine, and is directed by means of the same pattern; so that each of the holes in the leather will be successively brought beneath the point of a blunt piercer, which descends by the action of a lever. In the upper part of the machine is a pair of scissors, to cut the nails; they conflict of a lever, loaded at the extremity with a weight, and connected with the treadle, so that the end of the lever is lifted up when the treadle is depressed by the foot. Near the centre of this lever is a cutter, which is fixed to it, and moves with it. Another cutter is supported by the frame, so as to be stationary, and in the proper situation to come in contact with the edge of the moving cutter, when the end of the lever is lifted up. The cutters act in a manner similar to a pair of shears, to cut off a small piece from across the end of a strip of iron, which is introduced between the cutters. This piece forms the nail or rivet, which is to be put into hole in the leather; and immediately after it is cut, it falls into a tube, by which it is conducted down to a small cell or tube, situated immediately over the leather. In this the nail stands perpendicular, and ready, when the piercer descends, to be forced down into the hole in the leather; because the cell which receives the nail is exactly beneath the point of the piercer, so as to hold it perpendicularly in the proper position. The workman is seated before the machine, and with his right hand directs the sole, with its pattern beneath the piercer, in the same manner as before described. In his left hand he holds the strip of iron or copper which is to make the nails; and he introduces the end of it through a small hole, which conducts to the cutters, pushing it forward with a gentle force: this causes the end of the strip to enter between the cutters, when the shears are open. Then adjusting the sole by the pattern, so that one of the holes in the leather will be beneath the nail contained in the cell, he presses down the treadle; this forces the nail down from the cell into the leather, by the descent of the piercer, and at the same time closes the shears, and cuts off a nail across the end of the strip. The nail immediately descends by the tube into the cell, where it places itself perpendicularly, and ready to be put in its place in its turn. Thus the machine, at every stroke, cuts a fresh nail to supply the place of that which it puts in the leather by the same stroke. The strip of copper is turned over every time, to form the nails alternately head and point.

When all the nails are put in, they are hattered down with a hammer; and as they are but very little longer than the thickness of the sole, this reduces them to an even surface.

Application of the Welt to the Sole.—The welt, or runner, is a narrow slip of leather applied upon the sole, round its edge, to make the sole of a double thickness round the edge, where the upper leather joins to the sole, although the sole is only single within. The welt is made from the feather-edged slips which we have before mentioned, and is fastened to the sole by tacking nails of sufficient length to pass through both the sole and the welt. These nails are arranged all round the circumference of the sole, and the holes are first pierced through the sole by the punching machine, which we have before described, but by a different pattern of iron, which is attached to the sole by its two gauge pins entering the same holes which were made through the leather in the first operation. This pattern is pierced with a row of holes all round the circumference, which are arranged within the former row of rivets, or farther from the edge of the sole; but around the toe and tread of the foot, for half its length, the holes are in double number, or at half the distance that they are in the heel part. This pattern being used in the same manner as before described, the punching machine pierces the sole with holes, exactly corresponding to it; which holes are filled with tacking nails in a separate machine, something similar to the nailing machine before described. But as the nails are longer, it would be too laborious to cut them by the same motion; the nails are, therefore, cut by a machine made on purpose, and applied to the leather by
The nailing Machine for long Nails.—This is made exactly like the same as the punching machine before described, but with additional apparatus to supply the nails, and put them into the holes. Thus it has a vertical column, with a table and two projecting arms to support the perpendicular slider, which is caused to descend when the foot is applied upon the treadle, and to re-ascent by the action of the counter-weight. The piercer at the lower end is not sharp-pointed, not being intended to penetrate the leather, but only to force the nails into the holes previously pierced by the preceding operation. The additional parts are as follow: a circular plate, or wheel of brass, about nine inches diameter, and of a thickness nearly equal to the length of the nails; it is perforated with a great number of holes, to contain the same number of nails; the holes being made round its circumference, as close together as convenient, and arranged in four circles, one within the other. The interior space within the circles is formed with four arms, like a wheel; and in the centre is a hole, which fits loosely upon an upright centre pin, standing in the centre of a small circular table, which is fixed sideways to the upper end of the arms, which, as before mentioned, project from the vertical column of the machine, and fulfill the upper end of the perpendicular slider. Upon this circular table the wheel is supported in a horizontal position, at the height of 18 or 20 inches above the table on which the leather is placed, and with liberty to turn upon its centre pin. The wheel is filled with nails when it is used, one being put into every hole of its circumference, with the points downwards; and the holes are sufficiently large to let the nails drop through the wheel, except when their points rest upon the circular table which supports the wheel. At one part of the circumference of this table an opening is cut through it, and a small tube descends from it, to conduct a nail down to the point of the piercer. The motion of the wheel upon its centre brings the nails successively over the opening or mouth of the tube, and therefore each nail, in its turn, drops by its weight through the hole in the wheel into the tube, which is made so small, that the nail must descend with its point downwards, and fall into a small cell, so situated that the nail will stand exactly beneath the point of the piercer, when the same is at its highest position. But when the piercer is depressed by the action of the treadle, its point will act upon the head of the nail, and force it down through the cell into the leather placed upon the table of the machine; the hole in the leather having been previously pierced by the punching machine. The cell which receives the nail is very ingeniously contrived to hold it in a perpendicular direction, beneath the end of the piercer. It is situated immediately above the leather, and is conical within, so that the nail drops down into it until it becomes fixed fast; but when the nail is to be forced down by the piercer, the cell opens in two halves, being formed by notches in two pieces of steel, which are only held together by being screwed together at one end, and are made so thin as to spring together, and form a cell for the reception of the nail, although they will readily separate when the piercer forces down the nail. It is during the ascent of the piercer that another nail is dropped down from the wheel through the tube, and received into the cell, whilst its two halves are still kept open by the piercer; or rather as the piercer at this moment occupies the interior of the cell, the nail is received in the space, or open joint, at which the two halves of the cell separate, so that the nail lies close by the side of the piercer. But when the piercer has risen up completely out of the cell, its two halves spring together, and the joint in which the nail is placed being formed with faces inclining inwards, they throw the nail into the cell itself, in which it drops down till it ticks fast; because, as before stated, the cell is smaller at the bottom; and in this situation the nail is certain to be held perpendicular, with its head under the point of the piercer.

To turn the wheel round, so as to supply a fresh nail every time that one has been put into the leather, the edge of the wheel is cut into ferrated or flaring teeth; the number of teeth being equal to the number of holes made in each of the four circles to contain the nails. A small detent or click takes into these teeth by a hook, so that it will turn the wheel when moved in one direction, but slide over the teeth when moved in the other direction. The click is jointed to a short lever, fixed upon the upper end of an upright axis, which slips down through the two projecting arms of the main column, so as to be very near the perpendicular slider; and a short lever, fixed to this axis, bears, by the action of a spring, against a wedge fixed to the slider. The action of this mechanism is to turn the wheel round one tooth at a time; thus, when the slider descends, its wedge forces the end of the short lever farther away from it; this movement is communicated by the upright axis and upper lever to the click, which slides over the flaring sides of the teeth of the wheel; but on the re-ascent of the slider, the wedge allows the lever and click to return by the action of a spring, and the hook of the click, having caught a tooth of the wheel, will turn the wheel round the space of one tooth. In this manner, at every descent of the slider, the click engages a fresh tooth of the wheel; and at every ascent, the wheel is turned round upon its centre pin; the weight of the wheel, resting upon the flat circular table, being sufficient to retain it as it is placed.

The nailing machine acts with the rapidity as the other machines, to put a nail into every one of the holes previously made; and for this purpose the leather is kept upon the same pattern by which those holes were pierced, not only for the purpose of placing the leather so that the nails shall be inserted into those holes, but that the thickness of the pattern may allow the nails to penetrate and be project through the leather on the under side. When the nails are all put in, they are beat down with a hammer, to drive all the heads to a level with the surface. The leather is then prepared from the pattern, and put into a frame called the striking frame.

The stitching machine is a small square frame of cast iron, fixed upon the top of the pedestal, in which it is capable of turning round, for the convenience of the workman, and to enable him to work at the different sides, as he remains seated before the table. An iron frame is connected with the table by hinges at one side, so that it can be lifted up or turned down, to lie flat upon the surface of the table; and in this situation it can be fastened down by means of a simple clamp. This frame is intended to hold the leather which is placed beneath the frame; the interior opening of the iron frame is nearly to the same size and shape as the cell of the sole. The sole is placed flat upon the frame, in the proper position, which is determined by two gauge pins fixed into the table, and entering the holes made in the sole; then the iron frame being turned down upon the leather, will incline the sole as it were with an iron hoop or raised border, all round the edge; and the frame being clamped fast down, the sole is confined, as if lying in the bottom of a cell of iron, of the same figure as itself, and with the nail points projecting upwards from the frame. In this frame the sole is applied, by laying the strip of leather upon the edge of the sole in contact with the inside of the iron frame, and bending it to follow the curves of the outline of the sole. As fast as any part of the length of the
Itrip is fastened to its position, it is attached to the sole by striking it down with a mallet upon the points of the nails. The thin or feathered edge of the itrip of leather is put inside, so that the edge of the sole, for about the breadth of half an inch, is of a double thickness; but within this, the extra thickness diminishes away to nothing, leaving only the thickness of the sole. The ends of the itrip of leather which compose the welt, where they join and complete the circuit of the sole, are cut sloping, so as to lap over each other, and make a joint, without any increase of thickness, or apparent division. When the sole is taken out of this frame, the welt and sole are beat down together, to make a good joint; it is then carried to the cutting press, in which the edge or outline of the sole and welt are cut smooth, and to the fame size; because, as the frame of the welt machine must be rather less than the sole, in order that the frame may bear upon the edges of the sole all round, and thus hold it fast, the welt, which is moulded or bent round within the frame, will be a small quantity less all round than the sole. To guide the knife in cutting round the edge of the sole, it is confined between two iron patterns, which are made exactly to the size to which the edge is to be pared. They are attached to the sole by two gauge pins, fixed into one of the plates, and passing through the holes in the sole, project far enough on the opposite side for the other plate to be fastened on, in its required position, by two holes which receive the ends of the pins.

The cutting press very much resembles a common lathe: a horizontal spindle is supported in a frame, consisting of two standards, erected from a horizontal plate, to sustain the spindle, which passes through a collar in one of these standards, and projects some inches beyond it, having at the extremity a piece of wood flat on the surface, and of the same shape as the sole. Against this flat surface the two iron plates, with the sole between, are placed, and they are forcibly pressed together by the action of a screw, fitted into a third iron standard, erected from the same horizontal plate, and pressing by means of a lever upon the iron plates exactly opposite the end of the spindle. This pressure causes the spindle to retreat a small quantity in the direction of its length, and then a flat circular plate, fixed upon the spindle, (in the same situation as the pulley of a common lathe,) is made to press against a similar flat plate, which is fastened to the frame, and therefore cannot turn round. By the friction between these two surfaces, the spindle becomes immovable, and the press holds the sole firm, whilst the workman, who is seated before the machine, cuts all round the edge with a drawing-knife, which is made sharp in the middle, and is worked with both hands by having a handle at each end. When he has with this tool pared down that part of the edge which is uppermost, he releases the screw of the press, and a spring then causes the spindle to advance so far as to relieve the flat circular plate, which is fixed upon the spindle, from its contact with the fixed plate. This leaves the spindle at liberty to be turned round, and the sole turns with it, so as to bring up a new part of the edge of the leather to a convenient situation to be pared or cut; and the screw is then turned to fasten the spindle as before described, and at the same time to press the sole between the two patterns.

When the edge of the sole is thus cut, it is carried to a grindstone, and ground smooth: the iron is turned with a quick motion, by means of a band and large wheel; the leather is afterwards polished by applying it to the edge of a wooden wheel, on which a little bees-wax is spread.

Application of the long Nails.—The sole, thus reinforced by the welt, is returned to the punching machine, and being attached to another pattern, a range of holes is pierced all round the outer edge, through both, just within the former row of tacking nails; after which, by the nailing machine, these holes are filled with nails which project through the upper side of the sole, being longer than any of the former, and being also intended to penetrate through the upper-leather and inner soles, and thus fasten the shoe together. In this state the sole is ready to be put to the upper-leathers.

The upper-leathers are prepared for applying to the sole, in the same manner as the ordinary shoe, viz. by sewing the vamp, or piece which covers the upper part of the foot, to the two quarters which go round the heel, and also sewing these two quarters together behind the heel. The workmen do not hold the work upon their knees to sew it, but four men work at a square table, the corners of which are cut off, and a small piece of wood projects from each angle: the two pieces of leather which are to be sewed together are laid upon one of these pieces of wood in the proper position to be sewed, and are held fast by an endless strap, which is laid over them, and the workman binds it fast down, by prefling his foot in the strap, like a stirrup. This method of sewing, which is far superior to the common mode, might, from its simplicity, be used by all shoe-makers, and would render their buskins less unhealthy; whereas at present they are subject to many diseases from sitting in the awkward and unnatural posture which is necessary to reach their work, when they hold it upon their knees.

Operation of Clampine or riveting the Shoe together.—The upper-leathers are put upon a lafli, and held tight thereupon whilst the sole is applied. This is done in

The Clamping Machine.—It is a small oval table, supported on a column, but capable of turning round upon the column, to enable the workman to work at any side. In the centre of the table a lafli is fixed, with the sole upwards; it is supported at a height of about six inches from the table. The sole is made of cast-iron, in a solid piece, with the stem or part by which the lafli is supported; but the other part, upon which the upper-leathers are to be moulded, is made of wood, for the convenience of altering the figure when necessary. The lafli is fixed upon the table by means of two steady pins; and a strong pin, which projects from the lower part of the lafli, and passes through the table, is bound fast by a wedge, which confines the lafli firmly upon the table, in the same manner as if it were made in a piece therewith. The table has a number of pieces of brasses attached to it by hinges, and arranged all round the lafli in such a manner, that they can be turned up against the lower part of the lafli, and then form clamps, which are exactly adapted to the figure of the lower part of the lafli, and will therefore clamp or bind the leather firm upon the lafli at the toe, heel, and every part thereof, except at the flat part of the sole. The clamps are of such dimensions, that they will touch each other when turned up, and thus form a complete cell or box, in which the lower part of the lafli will be contained, and the leather confined upon it; but the cell being made in several pieces, or clamps, they can be removed one by one, as found necessary. The clamps are forced up to their situation by means of an independent screw for each, which is tapped in an oblique direction through the edge of the table, and the point forces up the end of a small rod, which is jointed to the clamp near the part where it acts upon the leather; by this means the force of the screw acts to turn the clamp up upon its hinge, and at the same time presses it against the leather. When the clamp is released by displacing the end of the small rod from the point of the screw, the clamp will be suffered to fall back upon the table; and this being done
done to all the clamps, the last flanks insulat'd in the middle of the table, from which it can be detached by withdrawing the wedge which confines it. The inner sole of the shoe is first put upon the sole of the last, being tightly fastened thereto by two short pins, one of which is driven through the gauge hole in the toe of the sole, and enters a hole made in the heel; and the other pin is fixed in the heel part of the last, and enters the hole in the sole. The upper-leathers are now put upon the last in the true position. In this state, the last is taken to the clamping machine, and fastened into its place in the centre of the table; the clamps are then turned up, one by one, beginning at the heel, and the upper-leathers being pulled up all round by a pair of pincers, so as to make them fit tight upon the last, the clamps are ferreved tight. In this state, the upper-leathers are made to take the form of the last, being firmly attached thereto, except at the sole part: at this part the leather stands up all round about three-quarters of an inch, which quantity is turned down flat upon the edge of the inner sole (previously fastened upon the sole of the last), and a small quantity of paste is put in to make it stick fast: four or five notches are cut out in the leather at the toe and at the heel, to make the part which is turned down lie flat upon the sole, without folds or overlapping, and then, to make a close contact, the leather is beaten down. Parings of leather are likewise paled, and fluck flat upon the inner sole for levelling, to make up the sole to the same thickness in the centre as it acquires towards the edges all round by the turning-in of the upper-leathers. In this state, the nail which fastened the inner sole to the last is withdrawn, being now unnecessary, and the real sole is applied, an iron frame, or faddle, being employed to determine its proper position upon the last. This frame is made of thin iron, and its figure within is similar, and of the same size as the row of nails which project through the sole, and by which the sole is to be rivetted into its place: it is made in two halves, which are united by a joint or hinge at the heel part; and at the toe part are two holes, through which a pin can be put to hold the frame together. This pin, as well as the joint pin of the hinge at the heel, projects downwards sufficiently to enter into a hole made in each of the two clamps at the toe and heel, in such a position as to guide the frame, so that it will apply the sole exactly in the proper position.

The sole, when prepared as before described, by infenting all the long nails in the holes, so that their points project through the leather, is put into an iron box or mould, and a plate being laid upon it, is put into the fly-prest, and by a single blow the sole is rendered conveave within, so as to adapt itself to the last. When it is taken out of the mould, the iron frame, before-mentioned, is put together round the row of nails, at the base of the sole: the size of the inside of the frame being made exactly upon the proper size to receive the projecting points of the nails, and retain them perpendicular to the leather, and prevent them from spreading out. The sole is then applied in its place by the two guide pins of the frame, and by driving upon the ends of the nails, their points penetrate through the turning-in of the upper-leather, and also through the inner sole. When they are well entered the iron frame is taken away, by withdrawing its pins, and opening its two halves on their joint, and the nails are driven down into their places. This causes them to project through the inner sole into the shoe, and the points meeting the iron last are turned back, and thus clenched into their places. To render this more certain, the sole of the last is made with a flight groove all round, where the points of the nails will fall, and the groove being of a semicircular figure, the points are more readily turned thereby, and are all turned the same way, so that they will not interfere.

The shoe is now put together, and the clamps being relieved and turned down, the shoe is taken off the last; for which purpose the heel of the last is made in a separate piece, and jointed to the other by inclined fittings, and with a tongue or rebate, so that it can be held fast in its place by a single hook or spring catch; but this being relieved, the shoe draws off the last with the greatest ease, the heel part remaining within the shoe, and is taken out afterwards. The shoe is now carried to the rivetting left, where it is put upon a last exactly similar to that of the clamping machine, but fastened down upon a bench, and the sole is smooth without the groove, which caues the points of the nails to turn up. Upon this last the nails are beaten down, to rivet all fast, and make the sole smooth within: the heel is then put on by laying it in its place, and driving down the long nails which have been put through it by the nailing machine, in the same manner as for the sole.

The sole of the shoe is now rasped with a coarse file, to level all the nail-heads, and render the leather smooth; the shoes are then carried to the grindstone, by which they are polished, and finished up in every part, the soles blacked, and polished by the wheel with a composition of bees-wax and ivory black, which renders them glossy: the upper-leathers are then brushed by a circular brush, which is turned by the lathe, and the shoes are rendered fit for sale, except those which require binding and lining, with a lining of thin leather, in which case they are finished in the same manner as common shoes.

Nail Machine.—This is equally deserving of notice with any other part of this ingenious manufacture. In our article Nail, we have described some nail machines; but we consider this as a much better machine for cutting brads or nails without heads. The nails are cut from sheet-iron, the plates being first reduced into slips, of a breadth equal to the length of the intended nails, by a large pair of shears, acting in the same manner as those described in the article CANTEEN, but are constructed in a superior manner, by employing cast-iron for the framing and for the lever. The iron plate is presented to the machine by one man, whilst another works the handle, and at a single stroke cuts off the desired slip of iron: the sheet of iron is cut so that the direction of the grain, or fibrous texture which the iron acquires by rolling, will be across the length of the slip. From this it follows, that when the nails are formed by cutting off narrow pieces from the end of the slip, the grain of the iron will be the lengthwise of the nail.

The cutting of the nails is readily performed by the machine, which is turned by the foot of the workman, whilst he supplies the iron by his hands. The motion of the treadle turns a crank and its heavy fly-wheel; similar to the turning of a lathe: from the crank a rod proceeds to the longer end of a front lever, the axis of which is supported on pivots in the upper part of the frame, so as to be above the wheel and crank. At a small distance from the centre of the lever, and at the opposite side of the axis to the long lever, a fixed cutter is fixed, which acts against a fixed cutter supported by the frame; the fixed cutter has an edge on the upper side, and the moving cutter, which is fixed to the lever, is made sharp on the lower side. The revolution of the wheel and crank causes the lever to rise and fall, and the edges of the two cutters in this motion pass as close together as possible, without touching. At the most elevated position of the moving cutter, its edge rides above the edge
of the fixed cutter so far, that the thickness of the flrip of plate can be admitted between them; the end of the flrip is pushed back, so that a small portion of the end of it overhangs the edge of the fixed cutter; therefore the edge of the fixed cutter, when it descends, meets this overarching piece, and pricking it down upon the edge of the fixed cutter, cuts it off, and the piece so separated forms a nail. When the moving cutter re-ascends, the iron is pushed forwards again to overhang the fixed cutter, and another nail is thus cut off. The nails are narrow at one end to form the point, but at the other end are about as broad as the thickness of the plate, so as to be of a square figure; but at the point they are, in one direction, as broad as at the head; this is the direction of the thickness of the plate, so that in reality the nail is the figure of a small wedge instead of a pyramid, the point being in fact a sharp edge. To effect this, the cut which the machine makes across the end of the flrip of iron is not perpendicular to the length of the flrip, but rather inclined thereto; and at every successful nail which is cut, the inclination of the cutter is reversed, so that the head of one nail is cut from the same side as the point of the next, and so on alternately of the whole length of the flrip of iron. The thickness of the nail is regulated by the quantity which the end of the flrip is allowed to project over the edge of the fixed cutter, and the angle of inclination by two fllops, against which the edge of the flrip is always brought to bear, when the workman places it ready for the cut. To flrop the end of the iron, a part projects from the lever beneath the edge of the moving cutter, and is curved to the arc of a circle described from the axis; this fllop is as far removed behind the edge of the cutter as the thickness of the nail intended to be cut off by the defect of the moving cutter. In working the machine, the workman keeps the wheel constantly revolving by the motion of the treads; and holding the flrip with its edge in contact with the two fllops, so as to give it the proper inclination, he pushes it forwards, with a gradual pressure, against the moving cutter; then the instant the cutter is sufficiently raised to admit the flrip, it will advance forwards, until the end of the flrip touches the fllop which is beneath the cutter; on the defect of the cutter, the nail is cut off, and the workman immediately turns the flrip with the other side upwards, which has the effect of reverting the inclination of the cutter; and pushing it forwards, another nail is cut as the former, and thus the operation continues with the utmost rapidity.

There are several suits of machines in this manufactory, so that a great number of shoes are proceeding at the same time through the different stages of their fabrication; and the rapidity of the execution is such, that a given number of workmen will here make a far greater number of shoes than by the common method, and they are more durable, particularly for the strong shoes which are desirable for soldiers. Several of the machines were constructed by Mr. Maudslay, with his usual accuracy of execution.

Shoe-makers' Machine.—This is a simple contrivance, to enable those artificers to perform their work in a standing posture; by which means they will avoid the diseases incident to those who follow sedentary employments.

In the common method of working, the shoe-maker is obliged to sit and floop in the most awkward posture imaginable, sometimes in order to hold the shoe and lift between his loins and his thigh, whilst he fews the sole to the upper leather; at other times he must hold the last between his knees; and to few the leathers together whilst he holds them upon his knees, he must lean very much forwards. In all these operations he acts as it were doubled up, so as to impede the action of his lungs, and ultimately produce many diseases. The machine is a kind of vice, to hold the shoe in any position whilst it is fewed.

The Society of Arts have shown a laudable desire to recommend these machines to the trade; and to induce their general adoption, they have given several rewards to those who have produced machines. The first of these was Mr. Holden, then Mr. Parker, and next Mr. Stafes, whose machine, being more improved than the preceding, demands some description. A small bench, or table, is firmly supported on four legs, at about two feet from the ground; a circular cushion is placed upon the bench, having a hollow or calon in the centre of it, with a hole from the bottom of the hollow, quite through the cushion, and also through the centre of the bench. This hole receives a flrip, which is doubled, and the two ends fewed together. The last is put into the double of the flrip, and it is drawn down by a treads, so as to hold the last firmly in the hollow of the cushion, which is stuffed with withinside; and as the hole through the cushion is too small for the shoe to pass through, the last can be set in any direction which is most convenient for the fewing; but by relieving the treads, it can be removed in an instant, turned round, and fixed again to few another part. A seat can be applied in front of the machine, for the workman to rest himself occasionally: this seat is supported by only two legs, and a piece of wood, which projects horizontally from beneath the seat, and enters into a mortise, made in a part of the frame. Upon this the workman sits upright, as if upon a saddle; and as his work is held before him at a proper height, he sits in an upright posture, which is not attended with the fame prejudicial effects as fliping to work upon the knee. The machine is provided with a small tray, or box, behind the cushion, to contain all the small articles which the work requires; also a drawer beneath it for tools, &c.; a whetstone fixed up at a convenient height; and an anvil, which fits into the hollow of the cushion, so as to lie firmly, to hammer the leather upon instead of a lapstone.

Shoe-makers are to make their shoes of sufficient leather, or forfe 3. 4d. (1 Jac. I. c. 21.) and journeymen shoe-makers embezzling leather shall make satisfaction for damage, or be ordered by judges to be whipped, &c. Perfon buying or receiving such leather, are to make reasonable recompense, to be levied by diftreffes, &c. and search is to be made after the fame: also leaving their work undertaken, or neglecting it, to be sent to the house of correction for a month. 9 Geo. I. cap. 27. 13 Geo. II. c. 8. See Leatiers.

Shoe, in the Mange. A horf-shoe is a piece of flat iron, with two branches or wings, which being commonly forged according to the form of the hoof for which it is designed, is made round at the toe, and open at the heel.

A shoe for all feet, is one that is cut at the toe into two equal parts, which is joined by a rivetted nail, upon which they are moveable in such a manner, that the shoe is enlarged or contracted less or more at pleasure, in order to make it fit all sorts and sizes of feet.

To floe a horfe after the form of a lunette, a patin, &c. see LUNETTE, PATIN, &c. See also SHOEING of Horses, &c.

Berenger observes, that the ancients did not floe their horfes, that is to say, they did not nail upon their hoofs any pieces of iron, or of other metal, in the form of the modern horf-shoes: but when they intended to defend them from any thing that might annoy them in travelling, they flattened upon their feet, by means of straps and ligatures, a fort of fondal, flocking, or what we call boots. Thefe
SHO   SHO

There were made of fedges twisted together like a mat, or else of leather, and were sometimes strengthened with plates of iron, and adorned by the rich and ostentations with silver and gold, as in the infinaces of Nero and Poppaea.

It does not appear in what era, or in what country, the modern art of shoeing took its rise. The earliest proof which the above mentioned writer has met with is the shoe said to have belonged to the horse of Chideric, who lived in the year 481, and is preserved in Montfaucon's Antiquities of France. It perfectly resembles the shoe now in use, Berenger's Horsemanship, vol. i. p. 234.

Shoes of the Horse and other Animals. The crooked pieces of iron attached to the hoof of the horse or other beast, by means of nails. There are various forms and shapes of shoes in common use, and others which are adapted and accommodated to the particular purposes and circumstances of the hoofs. Different sorts of animals, likewise, require different forms in their shoes. In speaking of the shoe which is concave on its lower surface, it has been remarked by some, that there are certain proportions to be observed in its different parts. Its breadth should be considerably less than the breadth of the common shoe; it is totally unnecessary to cover any part of the sole, especially when care is taken to preserve its natural hardness. The breadth of the shoe at the heels should be one-half of its breadth at the toe. Its thickness should decrease gradually from the toe, so as to be reduced one-half at the extremity of the hoofs. As to the distribution of the flamp-holes, every person acquainted with the subject knows, that in shoes for the fore-feet, they should be at the toe and quarters, because the wall, or crust, of the fore-feet is stronger at the toe than at the heels. The reverse of this is to be observed in the hind shoes, because the heels and quarters of the hind-feet are commonly stronger than the toe. It is impossible to lay down any general rule for disposing of these holes in bad feet; it must be the business of the farrier to distribute them in such a manner, as to be able to fix the nails in these parts of the crust where the horn is found and firm. Farriers generally multiply these flamp-holes too much, which brings the nails too close together, occasions the horn to break in splinters, and at length destroys the crust.

The following number is recommended for good feet; viz., for race-horses five, that is three on each side; for saddle-horses seven, four on the outside and three within, the quarter on this side being weaker than on the other; the same number for coach-horses of the middling size; for large coach-horses four on each side; and for cart-horses, five on the out and four on the inside. It is also of principal importance to determine the weight of the shoe, for it is matter of astonishment, to see some horses with shoes weighing each five pounds, making together a burden of twenty pounds of iron attached to their four feet. It is obvious to common sense, that such an additional weight, fixed to the extremity of the leg, must be productive of some inconvenience or other; and, in fact, the muscles are thereby compelled to greater exertion; the ligaments are stretched, and the articulations continually fatigued; and, besides all these evil consequences, the shoe by its weight forces out the nails, and to entirely spoils the texture of the wall or crust, that it becomes often extremely difficult to fix the shoe to the hoof. Why then, it is asked, do not practitioners of the present day, who are daily witnesses of these facts, and indeed are the principal authors of them, apply themselves to the correction of their own errors? The answer, it is feared, is obvious; because he who is uneducated and destitute of sound principles in his art, cannot turn to real profit the experience he has acquired, nor abandon the path of prejudice and custom, in which he has so long journeyed, but satisfies himself with continuing to imitate and repeat whatever he has been done by others.

The weights which are propounded, for shoes of different kinds, are nearly as follow:  

<table>
<thead>
<tr>
<th>Description</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>For the strongest of cart-horses</td>
<td>7</td>
</tr>
<tr>
<td>For the smaller horses of this kind</td>
<td>5.5</td>
</tr>
<tr>
<td>For the largest coach-horses</td>
<td>6.5</td>
</tr>
<tr>

</tbody>
</table>

And by reducing the superfluous breadth of these shoes, their thickness may, it is supposed, be increased without making any addition to their weight. See Shoeing.

Shoes of Cattle, the small plates of iron that are fastened upon the feet of oxen, or other cattle employed in field or road labour. Shoes of this sort consist, according to some, of a flat piece of iron, with five or six flamp-holes on the outward edge, to receive the nails; at the toe is a projection of some inches, which palling in the cleft of the foot, is bent over the hoof so as to keep the shoe in its proper place. This projection is not, however, employed in the general practice of making these shoes, nor can it in common be of any utility. See Shoeing of Oxen.

Shoe of Gold, in Commerce, an ingot used as money in China. Gold is here considered as merchandise; it is sold in regular ingots of a determined weight, which the English call shoes of gold; the largest of these weigh 10 taels, and the gold is reckoned 94 touch (that is 94 parts fine in 100), though it is really only 92 or 93. Formerly, 10 taels of silver were given for one tale of gold of the same degree of fineness; but of late, from 100 to 110 taels of silver of 94 touch have been given for 10 taels of gold of 92 or 93 touch; and sometimes from 110 to 120 taels, or even more, of Spanish dollars, reckoned at 92 touch, have been paid for 10 taels of gold. It must be observed, that when gold is exchanged for silver, its price is always valued by the 10-tale weight; and it is sold either above or below touch, as follows: if the gold be 96 touch, and sold at 5 under touch, subtract 5 from 96, and 91 remains; then 91 taels of silver are paid for 100 tael of gold; if gold be sold at 10 above touch, the fineness being full 96, add 10 to 96; and 106 taels of silver are paid for 100 tael of gold.

We shall here observe that there is but one kind of money made in China, called cash, which is not coined but cast, and which is only used for small payments; it is composed of six parts of copper and four parts of lead; it is round, marked on one side, and rather raised at the edges, with a square hole in the middle. These pieces are commonly carried, like beads, on a string or wire. A tale of fine silver should be worth 1000 cash; but on account of their convenience for common use, their price is sometimes so much raised that only 750 cash are given for the same. See Tale.

Shoe, Horse, in Fortification, Mining, &c. See Horse-shoe.

Shoe, Horse, Head. See Horse-shoe Head. See Horse-shoe.

Shoe of the Anchor, in Sea Language, a small block of wood, convex on the back, and having a small hole sufficient to contain the point of the anchor-fluke on the fore-side. It is used to prevent the anchor from tearing or wounding the planks on the ship's bow, when ascending or descending; for which purpose the shoe slides up and down along the bow, between the fluke of the anchor and the planks, as being prefixed close to the latter by the weight of the former. Falconer.

SHOEING, See Shoering the Anchor.

SHOE Blocks, are two simple blocks, cut in a solid piece transferably to each other. They are used for legs and falls of the bunt-lines, but are seldom employed.

SHOE-Hoofing, See Hooping.

SHOEBURY Ness, in Geography, a cape of England, on the south coast of the county of Essex, at the mouth of the Thames. Here King Alfred erected a fortress against the Danes. There are two villages near North and South Shoebury, both containing together about 200 inhabitants; 5 miles N.E. from the Nord. lat. 51° 32'. E. long. 0° 45'.

SHOEING of Horses, a term applied to the operation of softening the pieces of iron on the bottom parts of the hoofs, or that of fixing shoes to the feet. These, and some other animals defined to labour, are found with iron, in order to defend and preserve their hoofs. The shoes of horses should differ according to the feet, as has been already seen. The common form of shoes, and the method of shoeing, are wholly condemned by some, as Mr. Clark, and a new method recommended, which appears founded on just principles, and to have been sanctioned by much experience. It is remarked, that in preparing the shoe for the foot, according to the common method, the frog, the sole, and the bars or binders, are pared so much that the blood frequently appears. The common shoe by its form (being thick on the instep of the rim, and thin upon the outside), must of consequence be made concave or hollow on that side which is placed immediately next the foot, in order to prevent its refting upon the sole. The shoes are generally of an immoderate weight and length, and every means is used to prevent the frog from resting upon the ground, by making the shoe-heels thick, broad, and strong, or raising cramps or causers on them. From this form of the shoe, and from this method of treating the hoof, the frog is raised to a considerable height above the ground, the hoofs are deprived of that substance which was provided by nature to keep the crust extended at a proper width, and the foot is fixed as it was in a vice. And by the pressure from the weight of the body, and resiliency from the outer edges of the shoe, the hoofs are forced together, and retain that shape imprinted upon them, which is impossible ever afterwards to remove; hence a contraction of the hoofs, and of course lameness. But farther, the hoofs, as has been observed, being forced together, the crust prevails upon the processes of the coffin and extremities of the nut-bone: the frog is confined, and raised so far from the ground, that it cannot have that support upon which it ought to have: the circulation of the blood is impeded, and a wasting of the frog, and frequently of the whole foot, ensues. Hence, it is contended, proceed all those diseases of the feet known by the names of founder, hoof-bound, narrow-heels, thrushes, corns, high foles, &c.

And it has likewise been frequently observed, that there arises from this compression of the internal parts of the foot, a swelling of the legs immediately above the hoof, attended with great pain and inflammation, with a discharge of thin, ichorous, fetid matter: from which symptoms, it is often concluded that the hoofs are in a bad habit of body (or what is termed a greaet falling down), and must therefore undergo a course of medicine, &c. The bad effects of this practice are still more obvious upon the external parts of the hoof. The crust towards the toe, being the only part of the hoof free from compression, enjoys a free circulation of that fluid necessary for its nourishment, and grows broader and longer; from which extraordinary length of toe, the hoofs flumples in his going, and cuts his legs. The smaller particles of

SHO

fand infinuate themselves between the shoe and the heels, which grind them away, and thereby produce lameness. All this is entirely owing to the great spring the heels of the horse must unavoidably have upon the heels of a shoe made in this form. This concave shoe in time wears thin at the toe, and, yielding to the pressure made upon it, is forced wider, and of consequence breaks off that part of the crust on the outside of the nails. Infinates of this kind daily occur, ininfum that there hardly remains crust sufficient to fix a shoe upon. And further, it is generally thought, that the broader a shoe is, and the more it covers the sole and frog, a horse will travel better. But, as it has been remarked, the broader a shoe is of this form, it must be made the more concave; and, of consequence, the contracting power upon the heels must be the greater. It is likewise to be observed, that, by using strong broad-rimmed concave shoes in the summer season, when the weather is hot and the roads very dry and hard, if a horse is obliged to go fast, the shoes, by repeated froths (or friction) against the ground, acquire a great degree of heat, which is communicated to the internal parts of the hoof, and is the cause of that disease in the feet so fatal to the very belt of our horses, commonly termed a founder. This is also the reason why horses, after a journey or a hard ride, are observed to shift their feet so frequently, and to lie down much. And if we attend further to the convex surface of this shoe, and the convexity of the pavement upon which horses walk, it will then be evident that it is impossible for them to keep their feet from slipping in this form of shoe, especially upon declivities of the streets. It is also a common practice, especially in this place, (Edinburgh,) to turn up the heels of the shoes, into what are called cramps or causers, by which means the weight of the horse is confined to a very narrow surface, viz. the inner round edge of the shoe-rim and the points or causers of each heel, which foorn wear round and blunt; besides, they for the most part are made far too thick and long. The consequence is, that it throws the horfe forward upon the toes, and is apt to make him slip and stumble. To this cause we must likewise ascribe the frequent and sudden lamenes of horses are subject to in the legs, by twisting the ligaments of the joints, tendons, &c. It is not affirmed that causers are always hurtful, and ought to be laid aside; on the contrary, it is granted that they, or some such-like contrivance, are extremely necessary, and may be used with advantage upon flat shoes where the ground is slippery; but they should be made thinner and sharper than those commonly used, so as to sink into the ground, otherwise they will rather be hurtful than of any advantage.

It is suggested that the Chinese are said to account a small foot an ornament in their women; and for that purpose, when young, their feet are confined in small shoes. This no doubt produces the desired effect; but must necessarily be very prejudicial to them in walking, and apt to render them entirely lame. This practice, however, very much resembles our manner of shoeing horses; for, if we looked upon it as an advantage to their feet to have long feet, with narrow low heels, and supposing we observed no inconvenience to attend it, or had consequence to follow it, we could not possibly use a more effectual means to bring it about than by following the method already described. It is supposed that in shoeing a horse, therefore, we should in this, as in every other case, study to follow nature; and certainly this shoe which is made of such a form as to resemble as nearly as possible
SHOEING.

possible the natural tread and shape of the foot, must be preferable to any other. But it is extremely difficult to lay down fixed rules with respect to the proper method to be observed in treating the hoofs of different horses: it is equally difficult to lay down any certain rule for determining the precise form to be given to their shoes. This will be obvious to every judicious practitioner, from the various conftructions of their feet, from diseafe, and from other caufes that may occur; fo that a great deal must depend upon the discretion and judgment of the operator, in proportioning the shoe to the foot, by imitating the natural tread, to prevent the hoof from contracting a bad shape. In order, therefore, to give some general idea of what may be thought most necessary in this matter, it is endeavored to describe that form of shoe, and method of treating the hoofs of horses, which, from experience, has been found most beneficial. And in this it is to be remembered, that a horse's shoe ought by no means to rest upon the sole, otherwise it will occasion lameness; therefore it must rest entirely upon the crouft: and, in order that we may imitate the natural tread of the foot, the shoe must be made flat (if the height of the sole does not forbid it); it must be of an equal thickness all around the outside of the rim; and on that part of it which is to be placed immediately next the foot, a narrow rim or margin is to be formed, not exceeding the breadth of the crouft upon which it is to rest, with the nails-places placed exactly in the middle, and from this narrow rim the shoe is to be made gradually thinner towards its inner edge. And that the breadth of the shoe is to be regulated by the fize of the foot, and the work to which the horse is accustomed; but in general, it should be made rather broad at the toe, and narrow towards the extremity of each heel, in order to let the frog rest with freedom upon the ground. The necessity of this has been already shewn. The shoe being thus formed and shaped like the foot, the surface of the crouft is to be made smooth, and the shoe fixed on with eight or at most ten nails, the heads of which should be sunk into the holes, so as to be equal with the surface of the shoe. The sole, frog, and bars, as has been already observed, should never be pared, farther than taking off what is ragged from the frog, and any excrescences or inequalities from the sole. Mr. Ofmer has remarked, that the shoe should be made so as to stand a little wider at the extremity of each heel, than the foot itself; otherwise, as the foot grows in length, the heel of the shoe in a short time gets within the heel of the horse; which preffure often breaks the crouft, and produces a temporary lameness, perhaps a corn. But this method of shoeing horses has been followed long before Mr. Ofmer's treatize on that subject was published; and for these several years past it has been endeavored to introduce it into practice. But so much are farriers, grooms, &c. prejudiced in favour of the common method of shoeing and paring out the feet, that it is with difficulty they can even be prevailed upon to make a proper trial of it. They cannot be satisfied unless the frog be finely shaped, the sole pared, and the bars cut out, in order to make the heels appear wide. This practice gives them a show of widendes for the time; yet that, together with the concave form of the shoe, forwards the contraction of the heels, which, when confirmed, renders the animal lame for life.

It is contended, that in this flat form of shoe, its thickest part is upon the outside of the rim, where it is most exposed to be worn; and being made gradually thinner towards its inner edge, it is therefore much lighter than the common concave shoe; yet it will last equally as long, and with more advantage to the hoof; and as the frog or heel is allowed to rest upon the ground, the foot enjoys the same points of support as in its natural state. It must therefore, it is supposed, be much easier for the horse in his way of going, and be a means of making him sure-footed. It is likewise evident, that, from this shoe, the hoof cannot acquire any bed form: when, at the same time, it receives every advantage that possibly could be expected from shoeing. In this respect it may very properly be said, that we make the shoe to the foot, and not the foot to the shoe; as is but too much the case in the concave shoes, where the foot very much resembles that of a cat's fixed into a walnut-shell. But it is to be observed, that the hoofs of young horses, before they are shod, for the most part are wide and open at the heels, and that the crouft is sufficiently thick and strong to admit of the nails being fixed very near the extremities of each. But, as has been formerly remarked, from the constant use of concave shoes, the crouft of this part of the foot grows thinner and weaker, and the nails are fixed far too back, especially upon the inside, the horse becomes lame; to avoid this, they are placed more towards the fore part of the hoof. This causes the heels of the horse to have the greater spring upon the heels of the shoe, which is so very detrimental as to occasion lameness; whereas by using this flat form of shoe, all these inconveniences are avoided; and if the hoofs of young horses from the first time that they were shod, were continued to be constantly treated according to the method here recommended, the heels would always retain their natural strength and shape. By following this flat method of shoeing, and manner of treating the hoofs, several farriers now under this management, that were formerly tender-footed, and frequently lame, while shod with broad concave shoes, are now quite sound, and their hoofs in as good condition as when the first shoes were put upon them. It is thought that if farriers considered attentively the design of shoeing horses, and would take pains to make themselves acquainted with the anatomical structure of the foot, they would then be convinced, that this method of treating the hoofs, and this form of shoe, is preferable to that which is so generally practised. But it has been alleged, that in this form of shoe, horses do not go so well as in that commonly used. This objection will easily be set aside, by attending to the following particulars. There are but few farriers that can or will endeavour to make this sort of shoe as it ought to be. The iron, in forming it, does not easily turn into the circular shape necessary, as in the common shoe; and perhaps this is the principal reason why they object to it, especially where they work much by the piece. And as many horses that are commonly shod with concave shoes have their foles considerably higher than the crouft, if the shoe is not properly formed, or if it is made too flat, it must unavoidably rest upon the sole, and occasion lameness. Further, that the practice of paring the sole and frog is also too prevalent, and thought so absolutely necessary, that it is indiscriminately practised, even to excess, on all kinds of feet; and while this method continues to be followed, it cannot be expected that horses can go upon hard ground, on this open shoe, with that freedom they would do if their foles and frogs were allowed to remain in their full natural strength. Experience teaches us, that in very thin-soled shoes, we feel an acute pain from every sharp-pointed sole we happen to tread upon. Horses are sensible of the same thing in their feet, when their soles, &c. are pared too thin. Hence they who are prejudiced against this method, without ever reflecting upon the thin slate of the sole, &c. are apt to condemn it, and draw their conclusions more from outward appearances than from any reasoning or knowledge of the structure of the parts. From a due attention likewise to

Vol. XXXII. 4 1
the structure of a horse’s foot in a natural state, it will be obvious, that paring away the sole, frog, &c. must be hurtful, and in reality is destroying that sub stance provided by nature for the defence of the internal parts of the foot: from such practice it must be more liable to accidents from hard bodies, such as sharp stones, nails, glases, &c. From this consideration we shall likewise find, that a narrow piece of iron, adapted to the shape and size of the foot, is the only thing necessary to protect the crust from breaking or wearing away; the sole, &c. requiring no defence if never pared. But there is one observation farther necessary to be made; which is, that the shoe should be made of good iron, well worked, or what smiths call hammer-hardened, that is, beaten all over lightly with a hammer when almost cold. It is well known, that heating of iron till it is red softens it greatly; and when the shoes thus softened are put upon horses’ feet, they wear away like lead. But when the shoes are well hammered, the iron becomes more compact, firm, and hard; so that a well-hammered shoe, though made considerably lighter, yet will last as long as one that is made heavier; the advantage of which is obvious, as the horse will move his feet with more activity, and be in less danger of cutting his legs. The common concave shoes are very faulty in this respect; for, in fitting or shaping them to the foot, they require to be frequently heated, in order to make them bend to the unequal surface which the hoof requires from the constant use of these shoes; they thereby become soft, and to attempt to harden them by beating or hammering when they are shaped to the foot would undo the whole. But flat shoes, by making them when heated a little narrower than the foot, will, by means of hammering, become wider, and acquire a degree of elasticity and firmness which it is necessary they should have, but impossible to be given to them by any other means whatever; so that any farrier from practice will soon be able to judge, from the quality of the iron, how much a shoe, in fitting it to the circumference of the hoof, will stretch by hammering when it is almost cold: this operation in fitting flat shoes will be the less difficult, especially when it is considered, that as there are no inequalities on the surface of the hoof for, or, at least, ought not to be which require to be bended thereto, shoes of this kind only require to be made smooth and flat; hence, they will press equally upon the circumference or crust of the hoof, which is the natural tread of a horse. And a preference has lately been given by Mr. Moorcroft to this kind of shoe, which he calls the “feated shoe,” and which he has formed in a die, in the same manner as money is struck in coinage. The upper surface of this shoe consists of two parts; an outer part, which is a perfect plane near the rim, corresponding with the breadth of the crust, and called the flat; and an inner part, sloping from the flat, and distinguished by the name of the bevel. The flat is obviously intended to support the crust in its whole extent, the bevel to lie off the sole; and this part being more or less broad, according to the kind of work proposed to be done, will give the requisite strength to the shoe. At the whole of the crust bears on the flat, it is less liable to be broken than when only a small part of it rests on the shoe. In consequence, likewise, of the crust reposing on the flat, the weight of the body has a tendency to spread the foot wider in every direction, rather than to contract it, as has been observed to happen with the common shoe, and when afterwards phox with the seated one, it has become wider without the horse having been taken from his usual work; and again, it is observed, that a foot being of a full size and proper form when first shod with the seated shoe, has retained the same size and form without the slightest alteration, as long as the seated shoe was used. By the slope or bevel in the shoe, a cavity is formed between it and the sole, sufficient to admit a picker, and to prevent preflure on this part, without the sole itself being hollowed, and consequently weakened. For if it be one of the functions of the horny sole to defend the sensitive sole, of which, from its situation and nature, no one can doubt, it must be evident that the more perfect it is left, the stronger it must necessarily be, and of course the more competent to perform its office. And though he cannot be so sanguine as to suppose that this shoe will prevent lameness in every case, there is nevertheless sufficient proof from experience to attest, that it will diminish its frequency. Some strong objections have however been made to this form of shoe by Mr. Coleman. If it should be found, where the shoe is applied, that the sole very frequently receives preflure, then we shall demonstrate that the practice is incompatible with the principle. If it be good practice for the sole to receive preflure, then the principle must be erroneous that attempts to make the shoe reft totally on the crust; and if the principle be well founded for the crust only to support the shoe, then, if the sole be in contact with the shoe, the practice must be imperfect. Except a model is taken to every horse’s foot, it is impossible for the resting-place of the shoe precisely to fit the crust; for the crust not only varies exceedingly in different horses, but in the same hoof at different parts. The flat surface, therefore, that is only broad enough for the toe, is frequently too broad for the quarters and heels. And in all the shoes he has ever seen of this description, the flat part of the shoe is made of the same breadth at the quarters as at the toe. It is farther to be observed, that this surface very generally exceeds the crust at every part. In the same proportion as the seat of the shoe exceeds the breadth of crust, exactly so much of a flat surface is opposed to an equal quantity of sole. The principle of this shoe is therefore defeated by the practice; for, instead of the seat resting on the crust, it projects over the edge of the sole. It is therefore a fact, that while great pains have been taken to make a flat seat on the shoe, in order to support the crust only, and the web concave, in order to remove preflure from every part of the sole, that the feet has nevertheles been very rarely fitted the crust; and consequently the foles of all flat rods, at their connection with the crust, must receive more or less of preflure from the seat of the shoe. Where the sole is concave, this shoe will only rest on the crust; but a shoe that is flat on its whole internal surface would answer the same purpose; for the concave part of the sole opposite to the concavity of the web of the shoe would receive no preflure, even from a shoe wholly flat. He therefore recommends a shoe which has been found free from theoe and other objections, and which indeed bids fair to supercede the use of every other kind. But before this is noticed, it may be necessary to mention curiously the shoes proposed by Mr. St. Bel, and Mr. Taplin; but in fact the changes they have introduced are rather novelties than improvements. Mr. St. Bel has indeed committed a great error, that of promoting the arched form of the horse’s foot, and thus raising the frog out of the way of preflure, a practice highly injurious to the animal.

It is indeed observed, in respect to Mr. St. Bel’s mode of shoeing, by Mr. Coleman, that he employed a shoe with a flat upper surface; but, from not attending to the very important operation of removing the sole under the heels of the shoe, to every kind of hoof, it frequently failed of success. But that the best form of the external surface of the shoe is a regular concavity, that is, the common shoe reversed. This shoe leaves the hoof of the same figure when shod, as before its application. And it is evident, that a concavity has more points of contact with pavement and other
SHOEING.

convex bodies than a flat or convex surface, and that the horse is consequently more secure on his legs. A shoe that is flat externally, may preserve the hoof equally well in health; but this form is not so well calculated to prevent the horse from slipping as a concavity.

And in explaining the principles and practice of shoeing, it is supposed there are two circumstances necessary to be attended to, viz. to cut the hoof and apply the shoe. Before the hoof is protected by iron, some parts require to be removed, and others preferred. This is even of more importance than the form of the shoe. But many have attended chiefly to the shoe, and not to its application or to the hoof; and this error has produced more mischief and more enemies to the Veterinary College, than all the prejudices and calamities of groovers and farriers. The first thing to be attended to, is to take away a portion of the sole between the whole length of the bars and crust with a drawing-knife; for the heels of the sole cannot receive pressure without corns. To avoid this the sole should be made concave, so as not to be in contact with the shoe. If there be any one part of the practice of shoeing more important than the rest, it is this removal of the sole between the bars and crust. When this is done, the horse will always be free from corns, whatever may be the form of the shoe. Besides this, the heels of the shoe should be made to rest on the junction of the bars with the crust; whereas, if the bars are removed, the shoe is supported by the crust only, and not by the solid broad basis of crust and bars united.

And it is added, that it is necessary that the sole should be cut before any other part of the hoof be removed. If the heels have been first lowered by the butteris, then possibly there may not be sufficient sole left to enable a drawing-knife to be applied without reaching the fenible sole; whereas, by cutting the sole in the first instance, we can determine on the propriety of lowering the heels and shortening the toe. The sole can then descend, without the motion being obstructed by the shoe; and any foreign bodies that may have got into this cavity are always forced out when the sole descends, without producing any mischief. When the shoe is applied, the cavity between the sole and shoe should be sufficiently large, at every part, to admit a large horse-picker, and particularly between the bars and crust. If the sole is naturally concave, a shoe with a flat surface applied to the crust, will not touch any part of the sole; and if the sole be flat, or even convex in the middle, or towards the toe, the quarters and heels of the sole will generally admit of being made concave with a drawing-knife, so as not to receive any pressure from a flat shoe. If a shoe with a flat upper surface does not leave ample space for a picker between the sole and shoe, then it is requisite to make either the sole or the shoe concave. When the sole appears in flakes, and thick in substance, it will be better to make the whole of the sole concave by a drawing-knife; and this operation should always be performed before the toe is shortened or the heels lowered. When we have made the sole hollow, then a shoe with a flat surface will rest only on the crust: but if the sole be flat, or convex, and thin towards the toe and middle of the hoof, so as to prevent the possibility of removing the sole at these parts, to form a concavity, then it is necessary to employ a shoe sufficiently concave to avoid pressure, and to admit a picker. In this case, however, the sole at the heels and quarters, even in convex feet, will generally allow of removal with a drawing-knife, and then the quarters and heels of the shoe may be flat. It therefore follows, that where the sole can be made concave, a shoe with a flat surface may with safety be applied; but where parts of the sole, from diseased or bad shoeing, become flat, a shoe with a concave surface is required. As the hoof is always growing, and as the shoe preserves it from friction, the toe of the crust requires to be cut once in about twenty-eight days. The more horn we can remove from this part, the sooner it will be proper to apply a shoe thin at the heels, without mischief to the muscles and tendons, and the horse will be less liable to trip.

And it is stated that the bars and frog should never be removed. What is ragged and detached had better be cut off with a knife by the groom than left to the farrier, who will perhaps remove some of the found parts. Where the frog is not large and projecting, the heels may be lowered by a rasp, or the butteris, for in every case we are to endeavour to bring the frog in contact with the ground. The frog must have pressure, or be deformed. Nevertheless, when the frog has been diffused for a considerable period, and become soft, it must be accustomed to pressure by degrees. If the quarters are high, and much exceed the convexity of the frog, we should gradually lower the heels, and endeavour to bring the frog and heels of the shoe on the same parallel line. Where work is required of the horse, while the frog is soft and deformed, it may be gradually used to pressure, by lowering the hoof about the tenth of an inch every time of shoeing, until the frog be hard, and equally prominent with the heels; or if the horse is not wanted, great advantage would be derived from his standing without shoes on a hard pavement. But the feet of horses are so variously deformed by their management, it will be requisite in shoeing to attend to each particular kind of hoof. If any form of shoe be indiscriminately applied for all kinds of feet, it must frequently fail of success: but by proper attention to the different hoofs, we can generally improve the whole foot, so as to employ the shoes recommended at the Veterinary College. And, after the hoof has been properly prepared, then it is requisite to apply a shoe, and to vary its length, breadth, and thicknesses at the heel, surfaces, &c. according to the hoof. If the heels of the fore-feet are two inches and a half, or more, in depth, the frog is prominent, and the ground dry, then only the toe of the hoof requires to be shortened, and after wards protected by a short shoe made of the usual thickenes at the toe, but gradually thinner towards the heel. For a common sized saddle-horse, it may be about three-eighths of an inch thick at the toe, and one-eighth at the heel. The intention is, to bring the frog completely into contact with the ground, to expand the heels, prevent corns, thrufhes, and canker. If applied in May or June, when the ground is dry, it may be continued all the summer; and in warm climates, where this is the case, no other protection for the hoof is requisite. And he adds, that so long as the wear of the hoof is not greater than the supply afforded by nature from the coroneit, so long may the short shoes be worn; but in wet weather this is not the case: he has known some light horses to wear them the whole year; but such instances are not common. Nevertheless, the short shoe can be employed on most horses with advantage in summer, when the heels are from two and a half to three inches in depth, and the frog equally prominent: but, unless the hoof has been properly preferred, the heels and frog are generally too low for the short shoe. The toe of the horse requires to be shortened as much as possible; but if the frog touches the ground, no part of the heels should be cut; and, by pursuing this practice, the heels will frequently grow sufficiently high to receive the short shoe. After speaking of the application of the short shoe to running horses, it is stated, that during the wet months, we protect the whole crust by a long shoe; and if the heels of the hoof are low, we employ the same shoe in summer. In winter, when the heels are too high,
high, it is better to lower them moderately with a rasp, than to wear them down with a short shoe, as the wet may cause more horn to be destroyed than is necessary to be removed; but it cannot be too often repeated, that the feet between the bars and crust should be taken out before the heels are cut. If the heels are first removed, then possibly the horn left will be insufficient to afford a proper degree of concavity between the bars and crust. Where very high-heeled shoes have been worn, the horse would be liable to injury, as well as the muscles and tendons that bend the leg, from the sudden application of a shoe made thin at the heels. Indeed, whether the shoe or hoof be the cane that elevates the frog, the attention is required to bring it gradually into contact with the ground. We therefore thin the heel of the shoe by degrees, that the frog may become accustomed to hard pressure. The thicknefs of the flat shoe at the heel will always furnish a proper criterion for that to be next applied. If only a small portion of the hoof can be taken from the toe, the heel of the new shoe should be about one-tenth of an inch thinner than the shoe removed; and the growth of the crust will generally be equal to this diminution of iron. By reducing the heels of the shoes in the same proportion as the hoof grows, a thin-heeled shoe may, in a few months, be employed; and yet the horn being preferred at the heels, and cut at the toe, every time of shoeing, the heels (shoe and hoof together) will be as high, and frequently higher, than when the former thick-heeled shoes were employed. The crust that defends at the heels we allow to remain; but subtract an equal quantity of iron from the heels of the shoe, and as much horn as possible from the toe of the hoof. This system should be continued till the heels of the shoe are about one-third the thicknefs of the toe. In proportion as the crust from the coronet to the toe increases, and the heels decrease in depth, the back lines and muscles will be put on the stretch. And the converse of this must be equally true, that as the heels are high and the toe short, the muscles and lines are relieved. It therefore follows, that every atom of horn or iron taken from the toe of the crust, or shoe, tends to relax the parts behind, and that the removal of horn or iron from the heels produces the opposite effect. If these simple facts are kept in view, there can be no difficulty in ascertaining the quantity of iron that may be removed with safety from the heels of any shoe, without danger of mischief to the muscles and tendons.

But in the shoeing of horses that are liable to cut, the following useful directions have been given by Mr. Moorcroft. It is contended, that in order to prevent a horse from striking the foot or shoe against the opposite leg, by which it is often bruised or wounded, is an important point; inasmuch as this accident occurs very frequently, and it not only blemishes and disfigures the leg, but also endangers the safety of the rider. The parts struck in the hind leg, are the inside of the fetlock-joint, and the coronet; in the fore leg, the inside of the fetlock-joint, and immediately under the knee; which latter is called the speedy cut, from its happening only when a horse goes fast. Young horses, when first backed, generally cut their fore-legs, although naturally they may be good goers. This arises from their placing the foot on the ground too much under the middle of the breast, in order the better to support the burden to which they are unaccustomed; but by degrees they acquire the method of balancing the weight, with the foot in the same direction it would naturally have were they without it. It may, therefore, he thinks, be laid down as a general rule with such horses, that, till they regain their natural method of going, the edge of the inner quarter of the shoe should follow exactly the outline of the crust, but should not be et

within the crust, nor should the crust itself be reduced in thicknefs; as both these practices tend to weaken the inner quarter, and to deform the hoof. And here it must be observed, that the outer edge of the shoe should, in all cases of found feet, follow exactly the outer edge of the crust, except just at the heel, where it should project a little beyond the line of the hoof. Also, that horses with narrow heels, having their legs placed near together, are apt to cut when they begin to tire; and with the practice just mentioned should always be employed. Horses that turn their toes much outwardly are, of all others, most subject to cut. But in reply to the assertions of some, that this accident also happens to such horses as turn the toes much inwardly, he denies having met with a single instance of the kind. In horses of the firft description, it has been long observed, that the inner quarters of the hoof were lower than the outer, and that the fetlock-joints were nearer each other than in horses whose feet pointed straight forwards. These two facts probably led to a conclusion, that if the inner quarters were raised to a level with the outer, and so much the more as they were made proportionally higher, that the fetlock-joints would be thrown farther apart, so as to admit of the foot passing by the supporting leg without striking the joint. Accordingly, for the next half centuries, at least, it has been usual to make the inner quarter of the shoe higher than the outer; and not only has this been the general practice, but it has been regularly recommended by almost every writer from that time to the present. And notwithstanding this method has very frequently failed of success, yet repeated disappointment appears never to have led to the circumstance of questioning the truth of the principle. Nay, indeed, the reliance placed upon it has been so strong, probably from the simplicity of the reasoning on which it was founded, that in the cases where it most particularly disappointed expectation, its failure was generally attributed to the practice not being carried sufficiently far; and accordingly the shoe has been still more raised on the inner quarter, and the edges of the crust and shoe have been filed away. When these expedients likewise failed, the last resource has been, a circular piece of leather placed round the joint to receive the blow of the foot.

It is noticed, that about four years ago, a shoe, with the outer quarter thick and the inner one thin, was applied in a case which had baffled many attempts on the old plan. On the first trial the horse ceaied to cut, and has ever done it since; which can only be attributed to his having constantly worn the same kind of shoe. And other bad cases, which have occurred occasionally since that period, have been treated in the same way, and with the same success, although for a long time he was at a loss how to explain them. If the action of cutting principally depends on the faulty position of the fetlock-joints, and of the feet with respect to each other, and it seems generally agreed that such is the fact, it should seem that a means which, by raising the outer quarters, will throw the fetlock-joints still nearer to each other, would necessarily increase the defect in question; but as the reverse of this actually takes place, it might induce a supposition that there exists some other cause of cutting which has hitherto been overlooked. For horses which cut their hind-legs, the shoe, at the outer heel, should be from half an inch to an inch in thicknefs, according to the kind of horse, and to the degree in which he may cut. The web of the shoe should gradually become thinner till it reaches the toe, which should be of the ordinary thicknefs, and from which it should slope off, and end like a tip in the middle of the inner quarter. For horses which cut only in a slight degree, a shoe of the same thicknefs throughout, but reaching on the inner quarter only as far as the middle of the foot, will
SHOEING.

will in most instances be found sufficient. This shoe, in point of effect, would be equally proper for the fore-feet, were it not that in such horses as are used for the faddle, the fore-feet, being more charged with weight than the hind-feet, are more particularly subject to be injured, and a horse thus shod on the fore-feet might go unsafe: therefore, it is expedient to let the inner quarter of the shoe be thin, and reach to the heel; but the outer edge should be bevelled off, so as to slope inwards. The fame kind of shoe is equally well calculated to prevent the speedy cut; observing to bevel off more gradually the part which strikes, and not to put in any nails thereabouts. And here it may be proper to remark, that in found feet, the heel of the shoe should reach as far on the heel of the hoof as to admit of the angle formed by the cruff, and the bar resting fully upon it; but it should not be carried quite so far as the end of the heel of the hoof. But in order to ascertein what would happen to a horse shod with different kinds of shoes, the following trials were made.

Experiment 1. A horse with a narrow chest, who had never cut, and having parallel shoes on his fore-feet, was trotted at about the rate of eight miles an hour, in a straight line, over ground sufficiently soft to retain slightly the impressions of the shoes, but not to admit the feet to sink into it. Then two parallel lines were drawn along the track, including between them the prints of the shoes. By these it was found, that there was regularly a distance of nine inches and a half between the outer edge of the near fore-shoe and that of the off fore-shoe.

2. Shoes thick in their inner quarter, and like a tip, reaching only half way on the outer quarter, were then used; and it appeared that the distance between the outer edges of the prints of the shoes, taken as before, was regularly reduced to eight inches and a half.

3. The same shoes were afterwards placed on the opposite feet, so that the thick heel was on the outer quarter; and the result, under circumstances exactly the same as in the foregoing experiments, was, that the distance between the outer edges of the prints of the shoes was regularly increased to eleven inches. To account for this result, it is necessary to attend closely to the different effects produced by the weight of the fore part of the body acting upon the two fore-feet, when raised on the inner or outer quarters, during the opposite states of rest and action. And first, with regard to the feet raised on the inner quarter: whilst a horse fo shod is landing full, the fetlock-joints are certainly thrown farther apart than when any other kind of shoe is used. Hence it was concluded, that the limb which supported the body would have its fetlock-joint thrown much outwards, as to keep it completely out of the way of the foot in motion. But it appears that the impressions made on the ground by such shoes are an inch nearer together, than those made by parallel shoes, and two inches nearer together than those made by shoes raised on the outer quarter. And this may be thus explained: when the horse is at rest, the weight is supported equally by the two fore-feet; but the instant one foot quits the ground, the weight is suddenly transferred to the other; and by the outer quarter being lower than the opposite one, the fore part of the horse has a tendency to fall over to the outside. To prevent this, the moving foot is suddenly brought close to the fetlock of the supporting foot, in order to relieve it by catching the weight; and the foot itself is placed on the ground too much under the middle of the breast. The same circumstance occurs to both feet in their turn: and the horse, being thus in constant danger of falling to one side or to the other, is contrived to bring his feet near together to preserve his balance; and in doing this, strikes the foot against the opposite fetlock. And it frequently happens, that the more the toes are turned outwards, the nearer the fetlock-joints are brought together, and the more the horse is disposed to cut. However, this is true only to a certain extent; for if this faulty position of the lower part of the leg be carried artificially beyond a given point, instead of producing an increased degree of cutting, in most instances it remedies the defect altogether. The reason of this is just the reverse of what takes place when the inner quarter is raised; that is to say, when the weight of the fore part of the body rests only upon one leg, it bears too much upon the inner quarter, from its being lower than the outer quarter; and thus the horse has a tendency to fall over to the inside of the supporting leg. To prevent this, the moving foot is thrown farther from the supporting leg, in order to maintain the balance; and thus the foot muffles the fetlock-joint.

In cafes where the roads are covered with ice, it becomes necessary to have the heels of horses' shoes turned up, and frequently sharpened, in order to prevent them from slipping and falling; but this cannot be done without the frequent moving of the shoes, which breaks and destroys the crust of the hoof where the nails outer. To prevent this, it has been recommended to those who are willing to be at the expense, to have wheel points screwed into the heels or quarters of each shoe, which might be taken out and put in occasionally. And the method of doing this properly, as laid down by Mr. Clark, is first to have the shoes fitted to the shape of the hoof, then to make a small round hole in the extremity of each heel, or in the quarters, about three-eighths of an inch diameter, or more, in proportion to the breadth and size of the shoe; in each of these holes a screw is to be made. The wheel points are likewise to have a screw on them, exactly fitted to that in the shoes. Care must be taken that the screw on the points is no longer, when they are screwed into the shoe, than the thickness of the latter. The wheel points are to be made sharp; they may either be made square, triangular, or chisel-pointed, as may be most agreeable. The height of the point above the shoe should not exceed a quarter of an inch, for a saddle-horse; they may be made higher for a draught-horse. The key or handle, that is necessary to screw them in and out occasionally, is made in the shape of the capital letter T, and of a sufficient size and strength. At the bottom of the handle a socket or cavity must be made, properly adapted to the shape of the wheel point, and so deep as to receive the whole head of the point that is above the shoe. In order to prevent the screw from breaking at the neck, it will be necessary to make it of a gradual taper. The same is likewise to be observed of the female screw that receives it: that is, the hole must be wider on the upper part of the shoe than the under part. The sharp points may be tempered or hardened, in order to prevent them from growing too soon blunt; but when they become blunt, they may be sharpened as at first. These points should be unscrewed, when the horse is put into the stable; as the shoes will do them more injury in a few minutes than a day's riding on ice. A draught-horse should have one on the point of each shoe, as that gives him a firmer footing in drawing on ice; but for a saddle-horse, when points are put there, they are apt to make him trip and stumble. And when the shoes are provided with these points, a horse will travel on ice with the greatest security and readiness, much more so than on caufeway or turnpike roads, as the weight of the horse presses them into the ice at every step. And in addition to the common shoe for horses that have found feet, there are also others
others of various shapes, determined by the necessity of the cafe, as by the different derangements and diseases to which the horfe's foot is liable. See Shoe.

Shoeing of the Ass and Mule. With respect to what concerns the shoeing of other animals, Mr. Clark thinks that the mule, being an animal uncommon in this country, the ass of no great value, and the ox not generally employed in labour, it is needless to say much on the subject. The shoe for the fore-feet of the mule is very similar to that which the farriers call the bar-shoe. It is very wide and large, especially at the toe, where it sometimes projects four inches and upwards beyond the hoof. This excess is given it with a view to enlarge the basis of the foot, which is in general exceedingly narrow in this animal. The shoe for the hind-feet is open at the heels, like the horfe's shoe; but it is lengthened at the toe, like the preceding one. And it is added, that the foot of the ass, having the same shape as that of the mule, requires the same kind of shoe, with this only difference, that the shoe of the fore-foot is not closed at the heels, and that its edges do not project so much beyond the hoof. The fame form of shoe is used for the hind-feet of this animal.

Shoeing of Oxen, the business of fixing shoes upon animals of this kind, and which is constantly necessary wherever they do any sort of field or road labour; but it is a practice which is yet far from being performed in a perfect manner. Mr. Clark remarks, that in many parts of France, where the ox is used for draught, it is sometimes necessary to employ eight shoes, one under each nail; or four, one under each external nail; and sometimes only two, one under the external nail of each fore-foot. In this country two pieces, or shoes, to each foot are generally, however, made use of; being mostly fixed on, especially in the northern districts, with three or four large-headed nails to each shoe. They are fitted on in a similar manner to those of the horfe. But from the shoes of these animals being, from the smallness of the pieces, so liable to break, it has been suggested to have them fixed with whole shoes, in the manner of the horfe; but how far this is a practice that will answer, must depend upon future trials. It is probable, that in this way the foot will be too much confined to succeed in any very perfect manner. Where oxen are left without shoeing, they are continually liable to become lame, and to be incapable of going on with their work. As there is much trouble in the shoeing these animals, from its being necessary to call them each time, it has been found requisite to have recoupe to contrivances for shoeing them standing. See Ox-shoeing Machine.

Shoemakers' Chips, in Agriculture, the refuse cuttings pared off in making shoes, which, when collected in sufficient quantity, are found useful as a manure. See Manure.

Shoenich, in Geography, a Moravian settlement in Pennsylvania, near Nazareth, begun in 1757.

Shoesharo, a town of Little Bucharia; 60 miles S.W. of Acre.

Shole. See Shou.

Shoolcampet, a town of Hindooftan, in Coimbatore; 5 miles S.S.W. of Caroeor.

Shoods, in Rural Economy, a provincial term applied to hulls.

Sholaramboor, in Geography, a town of Hindooftan, in the province of Dindigul; 17 miles N.N.W. of Dindigul.

Shoolaramcottta, a town of Hindooftan, in the province of Dindigul; 7 miles N. of Dindigul.

Shoomshra, one of the Kurile islands, the nearest to Kamtschatka. The channel between the Lopatka and this island is 17 miles broad. The length of the island from N.E. to S.W. is 50, and the breadth 20 versts. The land is low, with moderate ridges of hills. The caffon coasts, about the middle of the island, form steep shores and rocky shelves, and are for some way into the sea fluddled with rocks. Here is one, and it is said that a vein of silver has been formerly worked. In the centre of the island is a lake, five versts in circuit, which flows by a streamlet into the sea. In this are caught fine salmon, and several other kinds of fish. There are no island trees upon the island, but merely bushes of alder, willow, and an efparier kind of pine, or Siberian cedar, on which grow little cedar-nuts. The inhabitants are not genuine Kuriles, but of Kamtschadal descent; of these 45 persons pay tribute. N. lat. 51° 25' to 52°. E. long. 156° 14'.

Shoor, a town of Hindooftan, in Lahore; 15 miles S.E. of Koolhaub.

Shoot, in Agriculture, the young branch of any sort of plant, which is afforded in one season. It also signifies a young animal of the cattle kind, in some districts.

Shoot, in the Sea Language. They lay the ballast floats, when it runs over from one side to another.

Shoote, among neat cattle, an affection of the bowel kind, with which calves are often attacked a few days after calving. The usual symptoms are, a colic or pain that is more or less violent, and is frequently very severe and dangerous, especially when it is contagious. This colic is terminated, and the calf relieved, by a discharge taking place from the bowels; though this sometimes proves fatal before the shoote appears. Secondly, a loathing and refusing of food, even previous to the discharge; which decreases and increases according to the duration and violence of the disorder. Where the discharge prevails, the beet medicine which can be administered is that of eggs and flour properly blended with oil, melted butter, and aniseed, linseed, or similar mucilaginous vegetable matters; and milk finely mulled with eggs may be often given with much advantage.

Shooter's Hill, in Geography, a hill in the county of Kent, between London and Dartford.

Shooting of Bombs. See Bomb.

Shooting with Air. See Wind-gun.

Shooting, Malicious, in Law. See Mahim.

Shooting of Salts. It is to be observed, that the figures arising from the floating of dissolved salts are not conftantly the same, but vary according to different circumstances, such as when they happen to float more or less halftly, or in different proportions of liquor. See Salt.

Shooting Point, in Geography, a cape of Scotland, on the south coast of the county of Fife, and east side of Largo bay.

Shouts, Hot. See Hot.

Shout Water. See Water.

Shop-lifter, a person who, on pretence of buying goods or otherwise, takes an opportunity to steal them; and if the goods amount to the value of five shillings, though
though no person be in the shop, he is guilty of felony without benefit of clergy, by 10 & 11 W. III. c. 22.

SHOKAB, in Geography, a town of Perfia, in the province of Segelan; 30 miles W. of Meimend.

SHORAY, a town of Hindoostan, in the circar of Chandree; 22 miles N. of Trumalla.

SHORE, Jane, in Biography, the concubine of king Edward IV., was the wife of Mr. Matthew Shore, a goldsmith in Lombard-Street, London. Historians represent her as extremely beautiful, cheerful, and generous. The king, it is said, was no less captivated with her than her person; she never made use of her influence powerfully in the prejudice of any one; her importunities were always in favour of the unfortunate. After the death of Edward, she attached herself to the Lord Hasting; and when Richard III. cut off that nobleman as an obstacle to his ambitious schemes, Jane Shore was arrested as an accomplice, on the accusation of witchcraft. For this she was doomed to a public penance, and to the loss of her property. She was alive, but probably in a very wretched state, under the reign of Henry VIII., when she was seen by Sir Thomas More, poor and old, and without the smallest trace of her former beauty. Mr. Rowe, in his tragedy of Jane Shore, has adopted the popular story, related in the ballad, of her perishing with hunger in a place where Shoreditch now stands. But Stow assures us, that this place had its name long before her time.

SHORE, John, a famous performer on the trumpet. Matthias Shore, the father of John, and Colley Cibber's wife, was performer-trumpet, in which office he was succeeded, first by his brother William Shore, and afterwards by his son John. His daughter, Mrs. Cibber, had been a scholar of Purcell in singing and playing on the harps-chord; in the exercise of which talents at home, her conquest over the heart of Colley Cibber first began. Purcell, from his connexion with the family, and his admiration of John's performance on the trumpet, took every opportunity in his power to employ him in the accompaniment of his songs and other theatrical compositions; and this accounts for the frequent use he made of that martial and field instrument, even when the subject of the poetry was pacific. John Shore lived till the year 1753, when he was succeeded as performer-trumpet, by that admirable performer the late Mr. Valentine Snow, whose exquisite tone and fine shake must be still remembered by many persons living, who have heard him at Vauxhall, and in Mr. Handel's oratorios.

SHORE, among Builders, &c. See SHOR.

SHORE, or Common Shore, a corruption of sewer. See SEWER.

SHORE, in Agriculture, a fort of artificial drain or course formed in low flat lands for the purpose of freeing and relieving them from the collected surface-waters. The want of shores is now most common in waste and unreclaimed lands; but it occasionally occurs in those of other kinds, in wet seasons, to the great injury and prejudice of the prevailing crops, and the future productiveness of the land, as the lodging surface-water can get off in no other way. There are very great extents of even appropriated lands, in some cases, that are greatly damaged and inconvenienced by water lodging and stagnating in the furrows of the ridges and the ditches, for want of having sufficient proper shores, or public drains, for drawing it off; and of public proper laws and regulations for enforcing the re-opening and the cleansing, from time to time, of those which have been formed at former periods; as well as for the preserving of the whole always in a suitably open state.

It is extremely probable, that a large proportion of the low flat lands of this country, which are now in a somewhat dry condition, were, in their natural state, liable to be at times covered with water. This appears to have been the case, from the compact, gelatious composition of the soil, and the flight covering of black vegetable earth which still forms the surface of them, where the work of tillage has not been performed upon them. And, from many of such low flat grass lands now lying in a tolerably dry state, from large tracts of those of the arable kind, whole fields and now barely out of the reach of water, which, in wet seasons, fill their drains and ditches to the brim, as well as from the less admirable evidence of tradition in low-lying districts, it would seem, is fairly, to be equally probable, that much industry and exertion have at former periods been employed, to free the lands of this fort in the country from the lake in which nature and time had placed them.

The feudal system is supposed to have been particularly favourable to undertakings of this useful kind, and that since its decline, the courts of the manorial description, which succeeded and survived it, have contributed to enforce its beneficial regulations. But that as they have now for the most part lost their power, existence, and authority, or where they are still continued and retain them, what relates to the business of public drains and water-courses, in their management, is too often neglected and overlooked. Hence it is noticed by a late writer, that, "...relative to this important department of rural economics and internal policy, the country may be said to have been moving, and, in a general view of it, still continues to move, in a retrograde direction."

In a great number of situations, vast injury and inconvenience are at present sustained from the want of the shores, drains, ditches, and other outlets for drawing off the water being kept properly open and sunk for its discharge into the adjoining rivers, brooks, or seas.

Some sufficient power and authority for the regulation of all matters of this nature should certainly exist in every district of the kingdom; which is not now the case, at least to any full and effectual extent, as many most important benefits and advantages would necessarily result from it, in the management and improvement of lands, as well as in the increasal of the produce of the same.

It has been suggested, that a great deal may be effected in this way, by the having recourse to the appointment of justices for the conducting of the business of shores and water-courses, wherever there are the slightest remains of the existence of manorial courts. And that, even where there is nothing of this sort to be met with, it would not fail to have a good effect, in many cases, where the lands are considerable, to have landing inquests, chosen from among the neighbouring tenantry in an annual or other manner, for the purpose of directing the proper regulation of the public shores, drains, water-courses, and other modes of conveying away the superabundant water from the land.

SHORE, Sea, is a general name for the sea-coast of any country. A bold shore is a coast which is steep and abrupt, so as to admit the closest approach of shipping without exposing them to the danger of being stranded.

The shores of the sea are divided, by count Marigli, into three portions, according to which, all his descriptions, in his account of the bason of the sea, are given. The first part of the shore is that tract of land to which the sea just reaches in storms and high tides, but which it never covers; the second part of the shore is that which is covered in high tides and storms, but is dry at other times; and the third is the desert from this, which is always covered with water.
The first part is only a continuation of the continent, and suffers no alteration from the neighbourhood of the sea, except that it is rendered fit for the growth of some plants, and wholly unfit for that of others, by the saline fluids and impregnations; and it is scarcely to be conceived by any but those who have observed it, how far inland the effects of the sea reach, so as to make the earth proper for plants, which will not grow without this influence, there being several plants frequently found on high hills and dry places, at three, four, and more miles from the sea, which yet would not grow, unless in the neighbourhood of it, nor will ever be found elsewhere.

The second part or portion of the shores is much more affected by the sea than the former, being frequently washed and beaten by it. Its productions are rendered salt by the water, and it is covered with sand, or with the fragments of shells in form of sand, and in some places with a tartaraceous matter deposited from the water, and the colour of this whole extent of ground is usually fufky and dull, especially where there are rocks and stones, and these are covered with a fliny matter.

The third part of the shores is more affected by the sea than either of the others, and is covered with an uniform crust of the true nature of the bottom of the sea, except that plants and animals have their residence in it, and the decayed parts of the sea alter it a little.

Shore of Sussex, in Geography, a cape of Scotland, on the E. coast of the county of Kincardine, so called from a village near the coast; 3 miles N. of Stonehaven.

Shoreditch, St. Leonard, a parish in the hundred of Oldcastle, and county of Middlesex, England, is situated in the northern suburbs of London, and forms one of the twenty-three out-parishes of Middlesex and Surrey, which are mentioned in the bills of mortality. This parish is of great extent, and is divided into four liberties, called the liberties of Churchend, Hoxton, Holywell, and Moorfields. The church, a modern edifice, was opened for divine service in August, 1740, having been erected in place of a very old church, which Ellis, author of the "History and Antiquities of Shoreditch," states to have been of Saxon origin. The ascent to the church is by a double flight of steps leading under a portico, supported by four Doric columns. The body is plain in its architecture, but is well lighted by spacious windows. The steeple, which rises to a very considerable height, has rather a handsome appearance. In the old church were a variety of monuments and brasses in memory of persons of distinguished rank; among whom were the countesses of Welforland (daughter to Edward, duke of Buckingham), who died in 1553; Eleanor, countess of Rutland, who died in 155; and two sons of the said countess of Rutland, but none of those in the new church possess any interest. This parish abounds with alms-houses, established either by public cities or by private individuals. In Holywell was anciently a priory for nuns of the Benedictine order, which was founded early in the twelfth century, and possessed a revenue of 293l. per annum at the time of the disolution. According to the parliamentary returns of 1811, this parish contained 765 houses and 43,030 inhabitants. The History and Antiquities of the Parish of St. Leonard Shoreditch, by Henry Ellis, quarto, 1797.

Shoreham, New, a borough and market-town in the half hundred of Fishergate, rape of Bramber, and county of Sussex, England, is situated upon the coast of the English Channel, at the dillance of about 6 miles W. from Brighthelmstone, and 55 miles S. by W. from London. This town is indebted for its origin to the decay of Old Shoreham, which is now a very trifling village, but appears to have been a place of considerable importance in ancient times. New Shoreham is a borough by prescription, and has sent members to parliament since the year 1255, the 23d year of the reign of Edward I. In 1771 it became conspicuous in the annals of electioneering, by the development of a remarkable scene of corruption practised in the election of members for the parliament then assembled. The returning officer having returned a candidate with only 37 votes, in prejudice to another who had 87, of which he had rejected 76, without assigning any satisfactory reason for so doing, was called upon to account for his conduct at the bar of the house of commons; when he defended himself, by stating that those whom he hadqueried formed part of a society, called the Christian club, the ostensible object of which was only a cloak to cover its real one, the letting the borough to fall to the highest bidder. In consequence of these affections, the house resolved itself into a committee to inquire into the truth; and being fully satisfied on that head, after a patient investigation, it was resolved to incapacitate the members of the club from voting at elections in future. An act was accordingly passed soon afterwards, by which 60 persons were disfranchised, and the right of voting was declared to belong to every freeholder, above 21 years of age, "who shall have, within the rape of Bramber, a freehold of the clear yearly value of forty shillings, and in such persons as by the usage of the borough have, or shall hereafter have, a right to vote at such elections." By this extension of the elective franchise, the number of voters has increased from about 200 to 1200 persons.

The church of New Shoreham is a curious and interesting specimen of ancient Norman architecture. At present only the east end is fitted up and appropriated to divine service, as the nave, or part westward of the tower, has been entirely destroyed. It consists of a nave, transept, tower, and choir; and by its style of architecture, appears to have been built near the end of the twelfth century. See a beautiful engraving of it in Cooke's "Southern Coast of England."

New Shoreham is governed by two constables, annually elected, who are the returning officers. The market-day is Saturday, weekly; and there is a fair on the 25th of July. It was formerly a town of more relative note than at present, and had a priory of Carmelite or White Friars, founded by Sir John Mowbray, kn.; as also an hospital dedicated to St. James. It is chiefly remarkable, however, for having been built upon the spot where Ellis, the Saxon, landed, with supplies from Germany in aid of his countrymen, Hengist and Horfa. According to the parliamentary returns of 1811, the parish contains 168 houses, and 770 inhabitants. History of the Boroughs of Great Britain, and the Cinque Ports, 3 vols. 8vo. 1792. Beauties of England and Wales, vol. xiv. by F. Shoobler, 1815.

Shoreham, a township of America, in the state of Vermont, and county of Addison, on the E. side of lake Champlain; containing 2033 inhabitants.

Shorehaven, a sea-port on the south coast of the island of Stromloe, with a good harbour, called Bros. N. lat. 61° 40'. E. long. 11° 3'.

Shore, in Mineralogy. See Shore.

Shorling and Morling, in our Old Writers, words used to distinguish fells of sheep; shorling being the fells after the fleeces are shorn off the sheep's back; and morling the fells flaid off after they die or are killed. In some parts of England they are termed by a shorling, a sheep whole
whole fleece is shorn off; and by a morling, a sheep that dies.

SHORN VELVET. See Velvet.

SHORT, Thomas, in Biography, a physician of the early part of the last century, and the author of many works relating to chemistry, meteorology, and medicine. Few particulars are recorded of his life, which seems to have been spent more in the pursuit of science, than in the exercise of his profession. He was a member of the Royal Society. The following are the principal works which he left. "Memoir on the Natural History of Medicinal Waters," 1725. "A Dissertation on Tea," 1730. "Natural History of the Mineral Waters of Yorkshire, Lincolnshire, and Derbyshire," 1733. "A General Chronological History of the Air, Weather, Seafsons, Meteors, &c. for the Space of 250 Years," 1740. "Discourses on Tea, Sugar, Milk, made Wines, Spirits, Punch, Tobacco, &c. &c." 1749. "New Observations, Natural, Moral, Civil, Political, and Medical, on Bills of Mortality," 1750. See Eloy, Dict. Hill. and the Works of Short.

SHORT, James, an eminent optician, was born at Edinburgh in the year 1710. At the age of ten he lost his parents, and being left in a state of indigence, he was admitted into Heriot's Hospital, where he soon shewed a fine mechanical genius, by constructing for himself a number of curious articles with common knives, or such other instruments as he could procure. At the age of twelve he was removed from the hospital to the High-school, where he shewed a considerable taste for classical learning, and he soon became at the head of his forms. He was intended for the church, but after attending a course of theological lectures, he gave up all thoughts of a profession, which he found little fitted to his talents, and from this period he devoted his whole time to mathematical and mechanical pursuits. He was pupil to the celebrated Mac Laurin, who perceiving the bent of his genius, encouraged him to prosecute those particular studies for which he seemed best qualified by nature. Under the eye of his preceptor he began, in 1732, to construct Gregorian telescopes; and, as the professor observed, by attending to the figure of his specula, he was enabled to give them larger apertures, and to carry them to greater perfection, than had ever been done before him.

In 1756 Mr. Short was invited to London by queen Caroline, to instruct William, duke of Cumberland, in the mathematics; and on his appointment to this office, he was elected a member of the Royal Society, and patronized by the earls of Macclesfield and Morton. In the year 1739 he accompanied the former to the Orkney islands, where he was employed in making a survey of that part of Scotland. On his return to London he established himself as an optician, and in 1743, he was commissioned by lord Thomas Spencer to make a reflector of twelve-feet focus, for which he received 600 guineas. He afterwards made several other telescopes of the same focal distance, with improvements and higher magnifiers: and in 1752 he completed one for the king of Spain, for which, with the whole apparatus, he received 1200L. This was the noblest instrument of the kind that had ever been constructed, and has probably not been surpassed, unless by the grand telescopes manufactured by Dr. Herschel.

Mr. Short was accustomed to visit the place of his nativity once every two or three years during his residence in London, and in the year 1766 he paid his last visit to Scotland. He died in June 1768, after a very short illness, when he was in the 58th year of his age. His eminence as an artist is universally admitted, and he is spoken of by those who knew him from his youth upwards, as a man of virtue and very amiable manners.

SHORT Accent, in Grammar. See Accent.

SHORT Crooks, in Agriculture, are a sort of crooks, which are formed of bent pieces of wood of the oak or elm kind, and so contrived as to be fixed on the horse's back, the ends or crooks turning up, so as to secure the loads on them. They are in use in the counties of Devon and Cornwall, in the latter of which they have both short and long crooks, as they are termed, which are made of for carrying heafn-corn, hay, faggot, hallett, flat, and flag-stones. They are a relic of the old mode of carrying loads in hilly districts. Single-horfe carts would probably answer the purpose in a far better way. See Cart.

SHORT Grass, in Gardening, a term applied to the pieces of gras which are kept in a continually mown, short, close flate, as on lawns, and in pleasure-grounds, or other situations about country residences. The portions of mown or short gras about feats and houses of the above fort in the modern improved modes of laying out pleasure-grounds, are mostly much more confined in their limits than was formerly the cafe; as they are not only troublesome, but very expensive in keeping in that proper order and neatness which is necessary for the purpose of ornamental effect, and the utility of walking upon them as occasion may require; and because a much better and more natural effect is found capable of being produced without them; while at the same time the lands can be rendered useful in supporting animals, and of course no lofs be sustained.

Where pieces of short gras are, however, formed, and to be kept in order, it will be necessary to roll, mow, and sweep up the grasy litter in a clean neat manner from them once or oftener in the course of the week during the spring feasan, and frequently at other times. The refuse litter, thus procured, may be employed for different garden purposes, where it cannot be converted to better ufe. See Lawn and Pleasure-Ground.

It is moiily in too dirty a flate to be applied as food for any fort of cattle flock.

SHORT Grazs Scythe, that fort of tool of this kind which is employed in moving short grass. Scythes for this ufe should be rather short, and laid in the fhaft with the edges low, in order that the gras may be cut in a close neat manner, without leaving any fcythe ridges or bulks, as they are usually termed. The fwarts or fcythe cafles, in performing this fort of moving, are commonly made narrow, in the intention, that the gras may be well and levelly cut out of the hulks or parts under the fwarts, and by such means have a more neat and even appearance. See Scythe.

SHORT Smalls, in Agriculture, a fort of oat, which is fo named on account of its remarkable fhortneas. It is much grown in the county of Ellif, and is a thick, full, weighty fort, that succeeds well on moft lands of the more dry kind. See Oats.

SHORT Sail, in a Man of War, are the fame with fighting fails, being the fore-fail, main-fail, and fore-top-fail, which are all that are used in fight, left the relit should be fired and spoiled; besides the trouble of managing them when a ship gives chase to another.

If a chafe flews a disposition to fight, they fly the chafe frigs into her short fells, i.e. puts out her colours in the poop, her flag at the main-top, and her streamers or pendants at the yard's arms; furls her spirt-fail, peeks her mizen, and flings her main-yard.

To shorten Sail. See Sail.
SHORTFORD, q. d. fore-cloes, an ancient custom in the city of Exeter, when the lord of the fee cannot be answered rent due to him out of his tenement, and no diltrees can be levied for the fame. The lord is then to come to the tenement, and there take a stone, or some other dead thing, off the tenement, and bring it before the mayor and bailiff, and thus he may do even quarter-days successively, and if on the twentieth quarter-day the lord is not satisfied his rent and arrears, then the tenement shall be adjudged to the lord to hold the same a year and a day; and forthwith proclamation is to be made in the court, that if any man claims any title to the said tenement, he must appear within the year and day next following, and satisfy the lord of the said rent and arrears: but if no appearance be made, and the rent not paid, the lord comes again to the court, and prays that, according to the custom, the said tenement be adjudged to him in his demeane as of fee, which is done accordingly, so that the lord hath from thenceforth the said tenement, with the appurrances, to him and his heirs.

SHORT-JOINTED, in the Manege. A horse is said to be short-jointed, that has a short pattern; when this joint, or the pattern, is too short, the horse is subject to have his forelegs from the knee to the cornet all in a straight line. Commonly short-jointed horses do not manage so well as the long-jointed; but out of the manege, the short-jointed are the best for labour or fatigue, especially those of the farm breed.

SHORT-SIGHTEDNESS, Myopia, a defect in the conformation of the eye, wherein the crystalline, &c., being too convex, the rays reflected from different objects are refracted too much, and made to converge too soon, so as to unite before they reach the retina, by which means vision is rendered dim and confused. See Myopia.

A learned author thinks it probable, that out of so great a number of short-sighted persons as are daily to be met with, few are born so, for it generally grows upon young people at the age of twenty or twenty-five, and therefore might possibly be prevented by using their eyes, while young, to all sorts of conformatons, that ill by often looking through glasses of all sorts of figures, and by reading, writing, or working with spectacles of several degrees of convexity; or whatever be the powers by which the eye conforms itself to distinct vision, they may possibly grow weak, or lose their extent one way or other, for want of variety of exercise. It seems an opinion without foundation, to think that such an exercise of the eyes can anywise injure them, provided due care be taken to avoid looking at objects that are too bright.

Short-sightedness may come by accident; of this we have a remarkable instance, mentioned by Dr. Briggs in his Ophthalmographia, of a person upwards of seventy years old, who had used spectacles for ten years, and yet by catching cold, he suddenly became so short-sighted, that he could not distinguish objects three feet off, and after the cold and delusion were cured, he continued to read the smallest print without spectacles for many years.

Dr. Smith mentions a young gentleman, who became short-sighted immediately after coming out of a cold bath, in which he did not totally immerse himself, and has ever since used a concave glass for many years.

It is commonly thought that short-sightedness wears off in old age, on account of the eye becoming flatter; but the learned doctor questions whether this be matter of fact, or hypothesis only.

It is remarkable, that short-sighted persons commonly write a small hand, and love a small print, because they can see more of it at a view. That it is customary with them not to look at the person they converse with, because they cannot well see the motion of his eyes and features, and are therefore attentive to his words only. That they see more distinctly, and somewhat farther off, by a strong light than by a weak one; because a strong light causes a contraction of the pupil, and consequently of the pencils, both here and at the retina, which lessens their mixture, and consequently the apparent confusion; and, therefore, to see more distinctly, they almost close their eye-lids, for which reason they were anciently called myopes. Smith's Optics, vol. ii. Rem. p. 10. &c.

Dr. Jurin observes, that persons who are much and long accustomed to view objects at small distances, as students in general, watch-makers, gravers, painters in miniature, &c. see better at small distances, and not so well at great distances, as the rest of mankind. The reason is, that in the eye, as well as in other parts, the muscles, by continuous exercise, are enabled to contract themselves with more strength, and by diffuse are brought to less strength. Hence, in the persons before-mentioned, the greater muscular ring of the eye contracts more easily and strongly, and the cornea more readily obeys the contraction of the ring, whence they see better at small distances. And the cornea, by being thus often and long bent into a greater convexity, does by degrees lose something of its elasticity, so as to return to its natural elasticity, when the muscular ring ceases to act upon it. This is one cause of their not seeing so well at great distances: also the ligamentum ciliaris, being seldom employed to lessen the convexity of the capilla, does by degrees become less capable of performing that office: and the capilla being seldom drawn out, and put into tension, must lose something of its diftensible quality, so as less easily to comply with the action of the ligament. And this is another cause of their not seeing so well at great distances. Jurin, Essay on diff. and indict. Vision.

The ordinary remedy for short-sightedness is a concave lens, held before the eye, which making the rays diverge, or at least diminishing much of their convergency, makes amends for the too great convexity of the crystalline.

Dr. Hook suggests another remedy. Finding that many short-sighted persons are but little helped by concaves, he recommends a convex glass, placed between the object and the eye, by means of which the object may be made to appear at a greater distance from the eye: and consequently, all objects may be thereby made to appear at any distance from the eye, so that the short-sighted eye shall contemplate the picture of the object in the same manner as the object itself were in the place. It is true, the image will appear inverted, but we have expedients to remedy this too: for, in reading, there needs nothing but to hold the book upside down. To write, the best way, in this case, will be, for the person to learn to do it upside down. For difficult objects, the doctor afferts, from his own experience, that with a little practice in contemplating inverted objects, one gets as good an idea of them as if seen in their natural posture.

SHOSTACK, in Commerce, a money of account in Poland and Hungary. In Hungary, a shottack is 2 imperial florin, or 6 kreutzers; an imperial florin, or kayer florin, is 2 potturats, 3 kreutzers, or 12 pennings; a potturat is 6 pennings, and a kreutzer 4 pennings. A Hungarian florin is worth 2 kreutzers in Upper Hungary; but 2½ kreutzers in Lower Hungary: thus, 5 florins in Upper Hungary, or 6 florins in Lower Hungary, = 1 kayer florin. A rixdollor of account is worth 1½ imperial florin, 15 Hungarian florin, 15 shottacks, 30 imperial florin, or 90 kreutzers. An imperial florin is 10 shottacks, or 20 imperial florin, and a Hungarian florin, 8¾ shottacks.
8½ shotacks, or 17½ imperial grofchen; thus, 7 florins of the empire = 8 Hungarian florins.

In Poland, the florin of 30 grofchen or grosz, each of which is divided into 18 pfenings, contains 2½ shotacks, 90 shillings, or 270 pfenings. A shotack is worth 12 groschen, or 36 pfenings; a grofchen, 2 pfenings; a shilling, 3 pfenings. Kelly's Cambist.

SHOT, INDIAN, in Botany. See CANNA.

SHOT, in the Military Art, includes all sorts of ball or bullets for fire-arms, from the cannon to the pistol. See BULLET, CANNON, &c.

Thee for cannon are of iron; those for muskets and pistols are of lead.

SHOT, for ordnance, especially in the sea service, are of several sorts as:

SHOT, Round, balls or globes of iron fitted to the bore of the piece.

SHOT, Bar, is formed of two bullets, or rather half bullets, joined together by an iron bar, serving to cut down masts, sails, &c.

SHOT, Cafer, Chain, Grape, Langrel, Random, Star, and Trundle, see the respective articles. See also Fire-Arms.

SHOT, for fouling, is otherwise called hail, by reason of its figure and size.

The method of casting it is as follows: the lead being melted, flared, and skimmed, a quantity of powdered yellow orpinment is stirred in it, as much as will lie on a shilling, to twelve or fifteen pounds of lead; the whole being well flared, the orpinment will flame.

To judge whether there be orpinment enough in, a little of the lead is dropped into a glass of water, and if the drops prove round, and without tails, there is orpinment enough, and the degree of heat as it should be.

This done, a copper plate, hollow in the middle, and three inches in diameter, bored through with thirty or forty small holes, according to the size of the shot, is placed on an iron frame, over a tub of water, four inches above the water; the hollow part is to be very thin; on this plate are laid burning coals, to keep the melted lead in fusion. The lead is now poured gently, with a ladle, on the middle of the plate, and it will make its way through the holes in the bottom of the plate into the water in round drops.

Great care is taken to keep the lead on the plate in its proper degree of heat: if too cold, it will lop the holes; and if too hot, the drops will crack and fly.

The shot, thus made, are dried over a gentle fire, always stirring them that they do not melt; this done, the greater are separated from the smaller by passing them through sieves for that purpose.

SHOT, Fresh. See Fresh Shot.

SHOT, Hip. See Hip Shot.

SHOT, Water. See Water Shot.

SHOT of a Cable, or Ship-board, is the splicing of two cables together, that a ship may ride safer in deep waters and in great roads, for a ship will ride easier by one shot of a cable, than by three short cables out a-head.

SHOT-FLAGON, a sort of flagon somewhat bigger than ordinary, which, in some counties, particularly Derbyshire, it is the custom for the host to serve his guests in, after they have drank above a shilling.

SHOTS, in Agriculture, a term provincially applied to young flaro-fwine.

SHOTT, in Geography, a town of Egypt; 3 miles S. of Siut.

SHOTT, a large valley or plain of Africa, in the country of Sahara, on the borders of Algiers; 50 miles in length, and about 12 in breadth. The word commonly signifies the sea-shore, or the banks of some lake or river; but the meaning here is somewhat varied, and denotes the borders or area rather of such a plain, as, according to the seasons of the year, is either covered with salt, or overflowed with water. Several parts of the Shott consist of a light oozy foil, which, after sudden rains, or the overflows of the adjacent rivers, are changed into so many quicksands, and occasion no small danger to the unwary traveller. La Croix was badly informed, in affirming that all the rivers of this kingdom run from south to north: since, besides several others in a quite contrary direction, we have no fewer than five, and those very considerable streams, which empty themselves from the northward into the Shott; 106 miles S.W. of Conflantina.

SHOTTEN HERRINGS. See HERRING.

SHOTTEN, Blood. See Blood-Shotten.

SHOTTSOOD, in Geography, a town of America, in New Jersey, on the Rariton; 4 miles E. of Brunswick.

SHOVEL, Sir Cloudesley, in Biography, a British naval hero, was born about the year 1650, of parents in rather humble circumstances, but who having expectations from a relation, whose name was Cloudesley, they thought fit to bellow that name on their son, as a probable means of recommending him to his relation's notice. Nevertheless, being perhaps disappointed in their plans, they put out his son apprentice to a shoe-maker, to which business he applied some years, when he betook himself to the sea, under the protection of Sir John Narborough, with whom he went out in no higher capacity than that of cabin-boy. He soon, by talents and Ready application to the art of navigation, became an able seaman, and obtained preferment, through the favour of Sir Christopher Myngs. After the close of what is called, in history, the second Dutch war, Shovel went out with Sir John Narborough, who was deputed to check the piratical state of Tripoli. In the spring of 1674 Sir John arrived before Tripoli, and being ordered to try negotiation rather than force, he sent Shovel with a message to the Dey, defining separation for the evils already fulfilled, and security for the time to come. The Dey, despising his youth, treated him with disrespect, and sent him back with an equivocal answer. Mr. Shovel, on his return, proved that he had not been an unoblivious spectator on shore; and the admiral, pleased with his remarks, sent him again with a second message. He was treated with more rudeness than before, which he bore with apparent submission, and made use of it as an excuse for remaining longer on shore; and on his return he afforded the admiral, that it was very practicable to burn all the ships in the harbour. Sir John immediately appointed him to the enterprize, which he executed with the most complete success. The account which the admiral sent home respecting the conduct of this young man was so honourable to his talents and courage, that in the course of a few months he had the command of the Sapphire, a fifth-rate, given him; and soon after was raised full higher in the service, by being appointed to the James Galley, a fourth-rate, in which he continued to the death of King Charles II., by whom he had been raised.

By James II. captain Shovel was preferred to the command of the Dover, a fourth-rate, in which he was at the time of the revolution. This event was fortunate for captain Shovel, as well as very agreeable to his way of thinking; for being in almost every engagement during the reign of William, he became conspicuous, and made his rife in the service as quick as it was possible to be effected. He was in the battle of Bantry-Bay, in the Edgar, a third-rate, and 
large was the fend Scilly, fir Cloudefley Shovel employed in conveying the king and his army into Ireland. William, for his good conduct on this occasion, appointed him rear-admiral of the blue, and delivered to him the commission with his own hands.

In the following year fir Cloudefley Shovel attended the king to Holland; and in 1692 he was declared admiral of the red, and again accompanied his majesty to Holland; and on his return he joined admiral Russel with the grand fleet, and had a large share in the danger and glory of the celebrated battle of La Hogue. When it was thought requisite that the fleet should be put under command of joint admirals in the succeeding year, he was one; and, says the judicious and cautious Campbell, "if there had been nothing more than this joint commission, we might well enough account from the chance for the misfortunes which happened in our affairs at sea, during the year 1693." The joint admirals were of different parties; but as they were all good seamen, and probably meant well to their country, though they did not agree in the manner of serving it, it is most likely "that, upon mature consideration of the publick things, they were in the order they had received from court, and the condition of the fleet, which was not either half manned or half victualled, the admirals might agree that a cautious execution of the instructions which they had received was a method as safe for the nation, and more so for themselves, than any other they could take." On this occasion fir Cloudefley Shovel was at first an object of popular odium; but when the affair came to be strictly investigated in parliament, he gave so clear and satisfactory an account of the matter, that it satisfied the people that the commanders were not to blame; and that if there was treachery, it must have originated in persons in office at home. The character of fir Cloudefley remaining unimpeached, we find him again at sea, in 1694, under lord Berkley, in the expedition to Camaret-bay, in which he distinguished himself by his dextrous embarkation of the land forces, when they failed on that unfortunate expedition; as also when, on their return to England, it was deemed necessary to send the fleet again upon the coast of France, to bombard Dieppe, and other places. From this time till 1702, Shovel was not engaged in any expedition of moment, when he was sent to Vigo, after the capture of that place by fir George Rooke, to bring home the spoil of the Spanish and French fleet. He arrived on the 16th of October, and carried off whatever could possibly be brought home, burnt the ref, and arrived safely in the Downs on the 7th of November; which was considered as so remarkable a service by the court, that, though he was no favourite at court, it was resolved to employ him in affairs of the greatest consequence; and he so effectually crushed the power of the French at sea, that they did not afterwards dare to meet the British fleet; and on account of the great share which he had in the victory obtained the 13th of August 1704, he was appointed rear-admiral of the fleet of England in the January following. He performed many other acts, which were useful to his country, and important to the cause in which it was then engaged. His last act was the defence of the coasts of Italy, of which, when he had taken due care, he left a sufficient force at Gibraltar for the purpose, and set sail with ten ships of the line, five frigates, four fire-ships, a flag, and a yacht, for England. On the 22d of October, 1707, he came to foundings, and in the following morning he had ninety fathom water. About noon he lay by, but at six in the evening he made sail again, and stood away under courser, believing that he saw the light on St. Agnes, one of the islands of Scilly. Soon after this several of his ships made signal of distress, as he himself did. It was with difficulty that fir George Byng, in the Royal Anne, saved himself, having one of the rocks under her main chains. Several others run the most imminent risks; but the admirals' ship, and some more, perished with all aboard. How this accident happened has never been properly accounted for. The body of fir Cloudefley Shovel was thrown ashore the next day upon the island of Scilly, where, falling into the hands of some fishermen, he was stripped and buried. Among their plunder was an emerald ring of great value, which, being thrown about, made a great noise all over the island, and led to the discovery of the body. This was now taken up, and conveyed to London, when it was interred with great solemnity in Westminster Abbey. To his memory an expensive monument of white marble was erected, by direction of his majesty, on which were the following inscriptions: "Sir Cloudefley Shovel, knight, rear-admiral of Great Britain, admiral and commander-in-chief of the fleet; the just rewards of long and faithful services, he was deservedly beloved of his country, and esteemed, though dreaded, by the enemy, who had often experienced his conduct and courage. Being shipwrecked on the coasts of Scilly, in his voyage from Toulon, on the 22d of October 1707, at night, in the 57th year of his age. His fate was lamented by all, but especially the sea-faring part of the nation, to whom he was a very worthy example. His body was flung on the shore, and buried with others in the sands; but being soon after taken up, was placed under this monument, which his royal mitres has caused to be erected, to commemorate steady loyalty and extraordinary virtues." See Stockdale's edition of Campbell's Lives of the Admirals.

Shovel, in Agriculture, a well-known implement, consisting of a long handle, and a broad blade, with raised edges.

Shovel, Cafting, a tool somewhat of the wooden shovel kind, which is sometimes employed in cleaning or dressing corn. It is very useful in this mode, where the wind is trusted to for managing the busines.

Shovel, Draining, a sort of tool of this nature, frequently employed for the purpose of clearing out the loose crumby earthly materials from the bottom parts of drains. It is formed with a crooked handle, the edges of the shovel part being turned up on the sides, in order to prevent the materials which are scraped up from falling off. In consequence of the crookedness of the handle, the workman is prevented from slopping so much as would otherwise be the case, in performing the work. There are different constructions of this implement made use of, in managing busines of this fort.

A scoop is likewise sometimes made use of, both with and without this implement, for the purpose of scooping up and clearing out all the crumbs, loose mould, and other similar materials, from the bottom parts of drains, before they are laid or filled with spray, brushwood, or any other substance, in order that they may be quite clear and free of any sort of obstruction. The tool is formed in a crooked, scoop-like manner at the head, and of different shapes, sizes, and breadths, according to the nature of the drains and openings in which it is to be employed; being, in working, drawn or pulled through the bottoms of the cuts or drains.
The handle has also occasionally a crooked form, in order to ease the workman in using it.

**SHOVEL, Paring**, that sort of tool of this kind, which is employed in some places for paring off the fward or turf from the surface of ground, in order to burn it. The shovel which is used in Devonshire for this purpose has a hollow heart-shaped form in the fwovel part, with a long handle, which makes it a very powerful implement. The plate of the mouth part is from nine to ten inches in width, where the handle is inserted, which is made with a considerable curve upwards; the blade is about twelve inches in length, terminating with a broad angular point, which, with its sides, are constantly kept very sharp and keen for cutting; on the left hand, or land side of the tool, a sharp wing, comb, or coulter, rise up in an oblique manner, to cut and divide the flice part from the whole ground. This, however, in consequence of the toughness of the surface, and the impediments presented by the roots of furze, flags, heather, and other similiar matters, is not unfrequently dispensed with; the slice being rent or torn off by the workman from the side of the whole ground, while it is cut up and separated from the earth below. When a foot or fifteen inches of the slice rises upon the handle of the shovel, it is separated from the uncet part of the surface by a sudden effort or exertion with the tool, and by a turn of it it is whelmed or laid over the mould side upwards. Where the flate and circumstances of the surface will permit, as by not being too much loaded and encumbered with the above forts of plants, the effort of separating the cut from the uncet fward may in all cases be more lengthened, by having the slice, which is next to be parred, cut or nicked in such lengths as may be most convenient to the workmen. And in some particular places and situations of land, the regular nicking of the slice to be parred from the ground is indeed found indispensably necessary, as where the ground is of such a moory quality as to render the operation impracticable without it. In all such instances it is, however, probably much better, as being more convenient and expeditious, to have the shovel formed with a cutting wing, by which the whole may be done at once, without any fort of delay in the business. This fort of shovel may be seen at fig. 9, in the plate of paring ploughs.

**SHOVEL, Spit**, an useful tool for some small purposes. It is that fort which is often employed in setting small roots or plants, as offe of the cultivated furflon, and some others of a similiar nature.

**SHOVELER, in Ornithology.** See Broad-beaked Duck.

**SHOVELING, in Agriculture,** a term used in Ireland to signify the throwing the mould of furrows, in cleaning them out, over the rides.

**SHOULDER, Humerus, in Anatomy.** See Extremities.

**SHOULDER, Fracture of,** in Surgery. See Fracture.

**SHOULDER, Luxation of.** See Luxation.

**SHOULDER-Blade, in Anatomy,** a bone of the shouder, of a triangular form, covering the hind part of the ribs, called by anatomists the Scapula and Omoplate. See Extremities.

**SHOULDER-Bone.** See Extremities.

**SHOULDER, in the Mange,** is the joint of a horse's fore-quarters, that joins the end of the shoulder-blade with the extremity of the fore-thigh.

**SHOULDER of a Branch,** is that part of it which begins at the lower part of the arch of the bouquet, over-againist the middle of the fonceau or chaperon, and forms another arch under the bouquet. The shoulder of a branch calls a greater or lesser circumference, according as it is designed to fortify or weaken the branch. See BRIDLE, BANQUET, and BRANCHES.

**SHOULDER-Pigged Horses, called in French chevilles,** are such as have their shouders groundy, fliff, and almost without motion. A horse charged with shouders, is one that has thick, Sony, and heavy shouders.

**SHOULDER of a Bajion, in Fortification,** is where the face and the flank meet.

**SHOULDER-DRAIN, in Agriculture,** a sort of under drain, constructed with a shouder on each side of the cut or opening, so that some sort of strong subsance may be laid over it, and form an opening or drain for the water below. See Drain.

**SHOULDER, in Block-Making,** a projection made upon the surface of blocks, pins, &c. by reducing one part to a lets subsance.

**SHOULDER-Block,** a large sngle block, left neary square at the lower end, or arfe of the block, and cut sloping in the direction of the fheave. Shoulder-blocks are used on the lower yard-arms, to lead in the topfail-sheet, and on the topfail-yards, to lead in the top-gallant-fheets; and by means of the shoulder they are kept upright, and prevent the fheets jumbling between the block and the yard: they are also used at the lower outer end of the boomkins, to lead in the fore-tacks.

**SHOULDER-of-Mutton Sail,** a triangular sail, similar to the lateen sail; but attached to a mail instead of a yard.

**SHOULDERING, in Fortification.** See EPAULEMENT.

**SHOULDERING-Piece,** in Building. See Bracket.

**SHOULDER-KNOTS.** See EPAULETTES.

**SHOULDER-PITCH,** in Farriery, is a diseafe in a horfe, when the pitch or point of the shouder is displaced, which makes the horfe halt downright.

**SHOULDER-SPLAIT, or SHOULDER-TORN,** is a hurt which befalls a horfe by some dangerous slip, by which the shouder is parted from the hread.

**SHOULDER-WRENCH,** is a strain in the shouder.

**SHOUT, Clamor, in Antiquity,** was frequently used on ecclelciatical, civil, and military occasions, as a sign of approbation, and sometimes of indignation. Thus as Cicero, in an assembly of the people, was expoling the arrogance of L. Antony, who had had the impudence to cause himself to be inerited the patron of the Romans, the people, on hearing this, raised a shout to shew their indignation.

In the ancient military discipline shouts were used, 1, upon occasion of the general's making a speech, or harangue, to the army from his tribunal; this they did in token of their approving what had been proposed. 2. Before an engagement, in order to encourage and spirit their own men, and fill the enemy with dread.

This is a practice of great antiquity, besides which, it wants not the authority of reason to support it, for as mankind are endowed with two fenfes, hearing and seeing, by which fear is raised in the mind, it may be proper to make ufe of the ear as well as the eye for that purpose.

Shouts were also raised in the ancient theatre, when what was acted pleased the spectators. See ACCLAMATION.

It was usual for those present at the burning of the dead to raise a great shout, and call the dead perfon by his name before they let them to the pile. See BURIAL.
SHOWEL, in Agriculture, a term applied to a blind for a cow's eyes.

SHOWER, a cloud resolv'd into rain, and discharged on a certain tract of ground.

In Natural History we meet with abundance of instances of extraordinary and preternatural flowers; as flowers of blood, mentioned by Galenius; a brimstone flower, mentioned by Wormius; flowers of frogs, mentioned by Pliny, and even by Dr. Plott; a flower of millet-fed in Sicilia, mentioned in the Ephemer. German.; flowers of offices, frequent in the Archipelago; a flower of wheat, in Wiltshire; a flower of witlings, mentioned in Philolog. Transact. The natural reasons of many of which may be seen under Rain.

SHOWOOR, in Geography, a town of Hindooftan, in Mylore, where, in 1790, a bloody battle was fought between the British and Tipoo, and in which the latter was defeated; 15 miles S. of Sattimugulam.

SHOWS, or SHAWS, in Agriculture, a term applied to the haulm or tops of potatoes. See Potatoes and SOLANUM.

SHRAHEEN, in Geography, a mountain of Ireland, in the county of Mayo; 11 miles N.E. of Castlebar.

SHRAVEY LAND, in Agriculture, a term used in some districts, as that of Suffolk, and some others, to signify that of a strong, gravelly, or flinty nature. The fears or holes on the sides of steep hills, where the turf or sward has slipped away, and laid bare the soil on the South Down, are sometimes called thraves. See Soil.

SHREW, or SHREW-MOUSE, in Zoology, the common name of the creature called by authors Mus araneus, and Sorex araneus of Linnaeus. It is an animal of a mixed brown and reddish tawny colour: the belly is white; its tail is about one inch and a half long, and covered with short hairs; its body is about two inches and a half in length; and its eyes black and very small; they are indeed little larger than those of the mole, and do not exceed the size of the head of the smallest pin; it is no wonder, therefore, that the creature is almost blind; the nose long and slender; the ears short and rounded; the teeth are very small, and differ in shape and situation from those of all other creatures in the world; and seem as if nature had in one creature made a sort of mixture of the teeth of the mole and the snake kind.

It has two long fore-teeth, as all the mole kind have: but these are not single, as in mice, but have two or three other small and sharp teeth growing out of them; these, to an accurate observer, might either be wholly unseen, or taken for distinct teeth; and the anterior long teeth are not separated from the rest by any gap or space, as in the mole kind, but make one continued series with the others. The upper jaw in this creature is longer than the under, and the teeth sharp and serrated, some with two, some with three points, and these so small, that they might easily not be seen, but that the tips of them are reddish. Their whole number is twenty-eight.

It is very common in many parts of the world, and is met with in almost all dry grounds, in old walls and holes in the earth; near hay-ricks, dung-hills, and necessary houses; it lives on corn, insects, and any filth; the cats will kill it, but never attempt to eat it. It brings four or five young at a time.

Its whole body has a fetid and offensive smell. The ancients erroneously believed it was injurious to the cattle. There seems to be an annual mortality of these animals in the month of August, numbers being then found dead in the paths.

It is distinguished at first sight from the common mouse, in that it is smaller; its nose longer, and like a hog's; it has five toes on the hinder as well as the fore-feet; its eyes are extremely small; its ears very short; its claws are long and whitish, and its feet short. Ray and Pennant.

SHREWSBURY, in Geography, the Water, Sorex fodiens of Pallas, is much larger than the common mouse; its length from nose to tail being 3½ inches; its tail two inches; the upper part of the head and the neck are of a black colour; the throat, breast, and belly, of a light ash-colour; and beneath the tail there is a triangular dusky spot.

This animal inhabits Europe and Siberia; was lost in England till the year 1768, when it was discovered in the Lincolnshire fens; it burrows in the banks near the water, and is said to swim under water; it is called in some places the blind mouse, on account of the smallness of its eyes; and it chirrups like a grasshopper. Pennant.

SHREWSBURY, in Geography, an ancient and market-town in the hundred of the same name, and county of Salop, or Shropshire, England, is situated on two hills, pinulated by the river Severn, at the distance of 112 miles from Bath, and 162 miles from London. It is the chief town, or capital, of the county, and, from its historical importance, is particularly deserving of an extended description, even in a work like the present. According to the parliamentary returns of 1811, it is divided into the nine parishes of St. Giles and Holy Cross, St. Chad, St. Mary, St. Julian, St. Alkmund, and Meole-Brace, which united, contain 3299 houses, and 16,666 inhabitants. It must be remarked, however, that some of these parishes extend a short way into the country. The liberties of Shrewsbury comprise six other parishes, four townships, and two chapels.

Origin and Historical Events.—Although no doubt can be entertained of the high antiquity of Shrewsbury, it being frequently mentioned by our earliest historians, there is no authentic record of its origin. Probable conjecture, however, has ascribed that event to the fifth century, when the Britons were forced by the Saxons to abandon all the country to the eastward of the river Severn. It is supposed that, after the destruction of the Roman Uriconium, the fortifications of which enabled the poleflora for a time to check the progress of their enemies, that they established themselves on the site of Shrewsbury, on account of the natural security afforded by its lofty and peninsular position. At that period this spot was called the Pengweyne hill, whence the town received the appellation of Pengwern, to which Powis was subsequently added, when it had become the capital of Powiland, and the seat of its princes, whole palace occupied the same ground with the old church of St. Chad. Here the Britons maintained themselves for several centuries, notwithstanding the repeated efforts of the Mercian Saxons to dispossess them; but at length the arms of the warlike Offa proved too powerful for further resistance, and they were compelled to retire to Mathrafael, among the mountains of Montgomeryshire, where they preferred their ancient dignity and independence, till finally subdued by Edward I. of England.

The Saxons, having obtained possession of this ancient capital, changed its name from Pengwern to Scrubbibryg, or Scrubbcbyri, which words have nearly the same signification, viz. "the head of the elder groves." Instead of levelling it with the ground, as was their custom when they seized upon any British town, they seem to have protected it with care, and probably even increased its opulence and extent. In the reign of Alfred it was numbered among the principal cities in his dominions: and in that of Edward the Elder...
Elder it had the privilege of a mint. In 1066, king Ethelred kept his Christmas here; but in about ten years thereafter, the inhabitants having declared against that prince in favour of his rival Canute the Dane, his son, prince Edmund, afterwards king Edmund Ironside, attacked and took the town after a short siege. On this occasion Shrewsbury seems to have infurped greatly; as in the reign of Edward the Confessor, its houses only amounted to 252 in number. Posterity to the Conquest, it was beleaguered upon Roger de Montgomery, who was created earl of Shrewsbury, Arundel, and Chichele; and appears from Domesday hook to have then paid 26s. in taxes to the king and sheriff. Earl Roger, on acquiring possession of this city, (for so it was styled in his time,) fixed his residence in it, and founded both a castle and an abbey. He did not, however, long possess them undisturbed, for in 1067, Owen Gwynedd, prince of Wales, assaulted it with formidable a force, that the conqueror deemed it advisable to repel the invasion in person. He accordingly marched hither from York, rallied the forces, and overthrew the Welsh with prodigious slaughter. Shrewsbury was again besieged in the reign of Henry I., in consequence of his having defeated Robert, son to Earl Roger, having united his forces to those of the rebellious barons; and it was probably only faved from the horrors of an assault by the submission of the earl, who was banished to Normandy, and had all his immense estates forfeited to the crown.

Shrewsbury being esteemed the most important town and fortress on the marches of Wales, continued, during several centuries, to be one of the principal places of rendezvous for the English armies, and hence was often visited by its monarchs. Numerous conflicts took place in its immediate vicinity, and its inhabitants frequently suffered the evils incident to foreign war. During the wars between Stephen and the empress Matilda for the succession to the crown, William Fitz-Alan, a powerful baron, then governor of Shrewsbury castle, supported the claims of the latter. Stephen, however, early obtained possession of it, and un generously put to death many of the brave knights by whom it was defended. Fitz-Alan fled to the continent, where he remained an exile till the accession of Henry II., who restored him to all his honours and possessions. In the reign of king John, the royal council assembled here to confer the better means of checking the inroads of the Welsh; when the prince of Powis came, and frankly offered terms of accommodation; but to the disgrace of the English lords, instead of receiving him with respect, they threw him into prison. Soon afterwards, however, he was released, and a treaty with the Welsh was concluded, for the performance of which twenty-nine children were delivered as hostages, all of whom were most inhumanly hanged by king John, in consequence of some infringement of its terms by the prince of Wales. But this barbarous massacre did not long remain unpunished; for in 1215, the Welsh having dispersed all the armies of the lords marchers, suddenly appeared before Shrewsbury, which submitted without resistance. How long the Welsh held their conquest, or how they lost it, is uncertain; but in 1221 Shrewsbury had again fallen into the possession of the English. In the seventeenth year of Henry III. it was plundered and burnt by the earl of Pembroke and other factional barons, who had joined their arms to those of prince Llewellyn. The rebel Simon de Montfort, earl of Leicester, likewise seized upon this town; but it soon reverted to the king; and in 1257, Henry assembled a large army here, with the design of crushing the Welsh power, but the interference of the pope prevented the execution of his views. Edward I., who, during his father's life-time, had been invested with the government of Shrewsbury, made it in 1277, the principal seat of his court, and removed hither the courts of exchequer and king's bench, that he might the more easily accomplish his favourite object, the subjugation of Wales.

During the rebellion which the infatuated attachment of Edward II. to the Spencer family gave rise to, the king was received at Shrewsbury with great military parade, and a tournament was held here, attended by the knights and followers of the marches. Afterwards, when Edward was deprived of his liberty and throne by his queen, and her paramour, Roger Mortimer; Edmund Fitz-Alan, earl of Arundel, who had been faithful to his allegiance, was feized by the inhabitants, and put to death; for which service Mortimer, in the name of the king, granted to the burgesses of Shrewsbury, whom he calls "the good men of Salop," all the goods and chattels found upon the earl. Richard II. held a parliament here in the 20th year of his reign, on which occasion he gave a sumptuous feast to the members in the abbey of St. Peter and St. Paul. The next event of importance which occurred at this town was the famous battle of Shrewsbury, in which Henry V., then prince of Wales, found distinguished himself in the field, and the gallant Hotspur fell, after performing, in conjunction with his rival Douglas, the most brilliant acts of prowess.

Throughout the whole of that eventful period, marked by the communications of the rival houses of York and Lancaster, the inhabitants of Shrewsbury zealously adhered to the interests of the former. The learned author of the "Account of the ancient and present State of Shrewsbury," contends that it was here, and not at Salisbury, as commonly supposed, that Henry Stafford, duke of Buckingham, was executed by order of Richard III., who was chiefly indebted to him for his usurped crown. When Henry VII. landed in Wales, he marched directly towards Shrewsbury, where he was received "with raptures of joy" by all except the "head bailey," who for a time refused him admittance. Here he was first proclaimed king of England, and here he collected and organized the greater part of those forces with which he achieved the signal and decisive victory of Bosworth Field. In consequence of these circumstances, Shrewsbury was greatly favoured by that monarch, and was frequently visited by him during his reign.

From this period till the reign of Charles I., no event of historical importance happened here. When the parliamentary war broke out, however, the king came hither, and was cordially welcomed by the inhabitants, though they had been strongly prejudiced against him by the commissioners for the parliament. The greater part of the army with which he first took the field was composed of persons resident in this town and the adjoining counties. After the king left Shrewsbury, it was garrisoned in his cause; but the bad health of the governor having prevented him from enforcing the discipline of the soldiers with sufficient vigour, they became negligent and debauched. The parliamentary officers, colonel Mitton and Bowyer, being informed of the state of the garrison, made several attempts to purify the town, and at length succeeded in their object, in February 1645. By this event the parliament gained the important advantage of cutting off the king's communication with North Wales, and a formidable association, which was on the point of being formed between the loyal inhabitants of the counties of Salop, Worcesters, Chester, and Flint, was destroyed in the bud.

In Cromwell's lifetime, and also immediately after his death, two attempts were made to gain possession of Shrewsbury in favour of Charles II.; but both of them were frustrated. The last circumstance which history records worthy of notice, occurred
occurred in August 1687, when James II. held his court here. On this occasion, the "sentiments of loyal attachment, for which Shrewsbury has ever been conspicuous, burst forth with chivalrous enthusiasm."

**General Appearance of the Town.**—Shrewsbury, from its lofty and peninsular situation, presents, at every approach, a pleasing variety of views; and the noble sweep of the river, which seems to embrace it, heightens at every turn the charms of the scene." Except on the north and west sides, where the streets approach close to its banks, a narrow margin of meadow, or of garden ground, interposes between the houses and the river. The exterior circle of the town is lined with an unbroken range of well-built houses, most of which command beautiful views over the adjacent country. On its western side is a public field, called the Quarry, which occupies about twenty acres of ground, and is adorned with avenues of trees. At one extremity of this field are the remains of a rural amphitheatre, where the Augustinian friars of the adjoining convent were probably wont to exhibit the ancient sacred dramas called mysteries, or Whitfiun plays; which were certainly acted here in the reign of Queen Elizabeth.

Such is the exterior aspect of Shrewsbury; but it is to be regretted that its interior appearance is far from corresponding with the external aspect. The streets are ill arranged, and some of them narrow and steep, and but indifferently paved. The houses are extremely mixed in their architectural character, exhibiting a strange contrariety of ancient and modern buildings. This circumstance is in part to be attributed to the happy freedom which Shrewsbury has enjoyed, from those general conflagrations which have occasionally devastated other towns within the last two centuries.

**Civil Government and Corporation.**—Shrewsbury is a corporation, both by charter and prescription. The first charter was granted by Henry I.; but other princes have since altered and extended the privileges it conferred. By the charter now in force, granted by king Charles I., the corporation consists of a mayor, recorder, serjeants-at-law, town-clerk, 24 aldermen, 43 aldermen, or common councilmen, two chamberlains, a serjeant-at-law, judges at assize, &c. Four general quarter-juries are held in the course of the year, and the mayor and some of the aldermen, who are magistrates, hold a court every Tuesday. The charter includes the general corporations, are sixteen in number, of which those of the drapers and mercers are the most considerable.

Shrewsbury sent members to parliament from its earliest establishment. They are chosen by the inhabiting burgesses, who have been legally admitted to the parish rates. The mayor is the returning officer. The markets are on Wednesday and Saturday, weekly; and there are eight annual fairs.

**Public Buildings and Institutions.**—The public structures of Shrewsbury are, the castle, the town-hall, the churches, the charitable institutions, the town and county gaol and Bridewell, the market-house and courts, the theatre, and the bridges.

The Castle stands on a narrow neck of land, about five hundred yards in breadth, which is formed by the windings of the Severn. It was founded by Roger de Montgomery, as before mentioned, and became the chief seat of his baronial power. As all the transactions of interest connected with this edifice have been noticed under the head Historical Events, &c. it is unnecessary to repeat them. This structure has evidently undergone so many alterations, and is so greatly dilapidated, that it is difficult to form any probable idea of its ancient state. The buildings of it now remaining consist of the keep, the walls of the inner court, and the great arch of the interior gate-way. The keep, which is converted into a handsome dwelling-house, consists of two round towers of equal size, embattled and pierced, and connected by a square building, about one hundred feet long, and nearly of the same height. The inner court is now a garden, "on a circular grass-plot in which, the newly elected knights of the shire have been girt with their swords by the sheriff, from perhaps the first foundation of our invaluable constitution." The arch of the gateway is clearly part of the original castle. It is eighteen feet high, massive, and semi-circular, and appears to have supported a tower, from which hung the portcullis. On the opposite side of the court is a small pattern, probably built in the time of Charles I.; and on its south side is a lofty mound, the summit of which is surrounded by a ruined wall, at one part of which rises a small watch-tower, now a beautiful summer room, much restored to on account of the fine views which it commands. This castle was defended by ramparts of stone thrown across the peninsulas, from the castle to the river, on each side. One of them was formed by Robert de Balezigne, and the other by order of Oliver Cromwell. Ramparts and walls with towers likewise defended the town on its northern and eastern sides, but few traces of them remain. The principal gates were three in number, and called the Castle or North-gate, the East or Abbey-gate, and the Welsh-gate, the latter of which stands on the Welsh bridge. The Town-hall is a modern structure, finished in 1786. It was designed by Mr. Haycock, a native of the town, and exhibits a handsomè stone front. Here are held all meetings of the corporation, and grand juries, likewise the courts of justice for the town and county. The grand jury room is decorated with portraits of George I. and II., and of admiral Benbow; and another room is appropriated to the reception of a valuable collection of books.

The **established churches** are St. Giles's, St. Chad's, St. Mary's, St. Alkmund, and St. Julian's. St. Giles's is a small plain building, and appears, from some remains of massive square piers, and a semi-circular arch, to have been partly built in the Norman era, and probably on a larger scale than it is at present. Most of the other piers are round, and supported pointed arches. St. Chad's church is of modern erection, having been built between 1750 and 1752, in lieu of the old collegiate church, which fell down in the first mentioned year, in consequence of its repair having been too long neglected. It is, "upon the whole, a splendid, and, in many respects, an elegantly ornamented structure." In this church the mayor and corporation are accustomed to sit on festivals and other public days. Here are but few monuments, and none of note; but in the church-yard is a chapel, in which many of the tombs and inscriptions refuted from the ruins of the old church are deposited; the principal of them, however, were removed to the respective parish-churches of the families to which they belonged. St. Mary's church was likewise collegiate, and had the privileges of a royal chapel, of which advantages it was deprived in the reign of King Edward VI. It is a venerable pile, in the form of a cross, and comprises a nave, side-aisles, transept, choir, and chapels, with a tower at the west end. Its architecture embraces almost every style prevalent from the Norman conquest to the reign of Henry VIII. The nave is divided from the side-aisles by semi-circular arches; but those separating it from the choir are lofty and pointed. The ceiling here is of oak, and rifes in an extremely flat arch, divided by its principal beams into square panels, including circles richly adorned with quatrefoils and foliage; the ribs and bosses being carved into double rosettes, with devices and knots at their interconnection.
Shrewsbury.

derfection. The chancel, choir, &c. display chiefly the pointed style. At the extremity of the former is a spacious window, in the later pointed style, which is nearly filled with stained glass, brought from the ruins of old St. Chad's church. The principal piece represents Jesus in a deep sleep. The spire of this church rises 217 feet above the summit of the tower, upon which it rears. The monuments are numerous, and some of them curious; but we shall only notice one inscription, which is remarkable, from the circumstance of its commemorating a person named Cadman, who was killed in defending from the summit of the spire, by a rope flung from thence to the opposite side of the river from that on which the church stands. The parochial church of St. Alkmund's, like the two last mentioned, was formerly collegiate, but its college was dissolved as early as the reign of King Stephen. The old church was taken down about the year 1793, and the present building raised in its stead; which is a clumsy imitation of our ancient architecture. St. Julian's church, which closes the list, is a plain subintellectual edifice, rebuilt in 1759, on account of the ruinous condition of the former edifice.

In addition to the above established churches, there are in Shrewsbury several dissenting places of worship, viz. a Roman Catholic chapel, a Presbyterian meeting-house, also one for Methodists, and another for Quakers.

The Charitable Institutions belonging to Shrewsbury are, a small hospital, formerly dedicated to St. Giles, another called Millington's hospital, several almshouses, an infirmary, a hospital of industry, and the free and charity-schools.

The infirmary is among the earliest provincial institutions of the kind in England, having been opened in 1747. It is supported by voluntary subscriptions, and by bequests. The house is plain but respectable building of brick, with a large portico in front. The house of industry was originally a foundling hospital, connected with that in London, and was only converted to its present purposes in 1784. It is governed by directors chosen from among the inhabitants of Shrewsbury, and maintains, on an average, about 275 poor, including children, partly by a rate levied on the six parishes, and partly by the produce of the labour of the paupers. The free grammar-school was founded and endowed by King Edward VI., at the request of Henry Edwards and Richard Whitaker, and was afterwards augmented by queen Elizabeth, at the instance of Thomas Aiton. The school-house is a large and lofty structure, forming two sides of a square court. The government of this school is vested in the bishop of Lichfield, and the corporation, who appoint two schoolmasters, one of whom is superior to the other. Several of them have been men of great talents and erudition, and have cherished the seeds of knowledge in many individuals afterwards distinguished in society. Among the latter, were Sir Philip Sydney; lord Brook, lord chief justice; lord chief justice Price; Dr. Bowers, bishop of Chichester; Dr. John Thomas, bishop of Salisbury; and the learned Dr. John Taylor. The learned Dr. Butler is the present head master.

The other public schools in this town are Bowdler's charity-school, founded in 1724, by Mr. Thomas Bowdler, alderman, for the education and clothing of poor children of St. Julian's parish; Allart's charity-school, founded in 1798, under a bequest by Mr. John Allart, one of the chamberlains of the corporation: and a subscription charity-school, instituted in 1708, for instructing poor children of the town at large.

The Town and County Gaol and Bridewell, which now form one building, stands near the castle, where the sheriff probably had his gaol in former times. Its situation is at once beautiful and salubrious, and though it cannot boast much elegance of exterior appearance, it is spacious and airy, and possesses every convenience requisite for its different purposes. In front is a free-stone arched gateway, containing a butt of Howard, by Bacon.

The Market-house is one of the largest and most magnificent buildings of its kind in England. It is of the age of Queen Elizabeth, whose arms, sculptured in high relief, decorate the portal, on each side of which is an open arcade, consisting of three large circular arches, supported by columns. The north and south ends of the building are likewise ornamented with large open arches, over which stands a statue of Richard, duke of York, removed from the Well bridge in 1791. Adjoining this building is a conduit, which supplies a great part of the town with water. The Market-croft is a strong structure of brick and stone, having a refectory over it. The old crofts was destroyed in 1707. The Theatres, according to Phillips, the old historian of the town, is part of the palace formerly belonging to one of the later princes of Powis, but though evidently an ancient structure, it seems improbable that its date should be so remote as such a fact would necessarily imply. It is fitted up in the interior in an appropriate manner.

The Bridges over the Severn at this town are called the Welsh bridge, and the English, or Earl, bridge. Both of them are new structures, erected in place of older ones, which had gone to decay, and were, from their narrowness, unsuitable to the rate of commercial advancement Shrewsbury and the county at large now enjoy. The Welsh bridge consists of five elegant arches, about 260 feet in aggregate length, 30 feet high, and 30 broad. Adjoining to it is a quay, faced with stone, and accompanied with warehouses. The English bridge extends 400 feet in length, and consists of seven semi-circular arches, built of fine freestone. The central arch is 200 feet span and 40 high from the low-water mark: and the two on each side 35 feet wide and 20 high. The breadth between the ballustrades is 25 feet: and the ornaments are at once light and graceful.

Monastic Institutions.—The principal monastic establishment in Shrewsbury was the abbey of St. Peter and St. Paul, which stood in the suburb that still bears its name. It was founded, or, as some have it, re-founded and endowed by Roger de Montgomery, and a nobleman named Warin, who filled it with monks of the Benedictine order. These having subsequently obtained possession of the relics of St. Winefrid, their abbey became the favourite resort of various classes of people from all parts of the kingdom, who, according to their circumstances, offered donations on the shrine of the saint. This society, at its disolution, consisted of an abbot, fourteen monks, and three novices, whose annual revenues, according to Dugdale, amounted to 532l. 4s. 10d., but Speed rates them as high as 656l. 4s. 3d. The remains of the abbey are very inconsiderable, the ground which it occupied being in great part converted into a garden. There is, however, a very curious little structure, which has puzzled the learned in antiquities as to its use: by some it is regarded as a pulpit for preaching. Its plan is an octagon, six feet in diameter, but considerably higher. Over it is an obtrude dome of stone, supported by six narrow pointed arches. The roof within is vaulted on eight ribs, which spring from the side walls, and form a bower at their crossing in the centre, bearing a representation of the crucifixion. The arches on the south side are without ornament, but three of them on the north side are filled with stone panels, adorned with different figures of angels and saints. The abbey church was built in the form of an cross, and was a spacious and magnificent edifice; but at present is in a state of dilapidation, except the western aisle, which is now used as a parish-church, instead of St. Giles's. The other reli-
gious houses here were, a convent of Augustine friars, founded about the year 1256; a second of Franciscan or Grey friars, the date of which is unknown; and a third of Dominicans, founded by lady Genevile in the reign of Henry III. The queen of Edward IV. twice lay in at this monastery. Befides these, there were chapels dedicated respectively to St. Michael, St. Nicholas, St. Catherine, St. Blaise, and St. Mary Magdalen.

Shrewsbury contains several ancient private structures, which would claim notice, did the limits of our article permit of a commensurate extension. One of them, ill called the Council-House, was formerly the residence of the court of the marches of Wales, on their annual visits to this town. For some account of this court, see LUDLOW.

The eminent natures of Shrewsbury, heides Dr. Thomas and Dr. Taylor, before-mentioned, were Thomas Churchyard, a poet of some note, admiral Benbow, and the Rev. Hugh Farmer, author of several learned and critical works.

The objects in the vicinity of Shrewsbury, most worthy of notice, are the Shelton oak, which is remarkable from a tradition, that Owen Glyndwr ascended it to reconnoitre, previous to the battle of Shrewsbury, and for its great size, Battelfield, where the battle was fought; and Haughton Abbey, which stands about four miles to the eastward of Shrewsbury. It is situated on a rising ground, which commands beautiful and extensive views, and owes its foundation and endowment to William Fitz-Alan, in the year 1100. The inhabitants were canons regular of St. Augustine, who enjoyed at the dissolution a yearly revenue, stated by Dugdale at $125l. 13s. 7d. and by Speed at $28d. 12s. 6d. Of the abbey church, scarcely a vestige remains, but considerable portions of the other buildings are yet standing. Phillips' History and Antiquities of Shrewsbury, 4to. Some Account of the ancient and present State of Shrewsbury, 12mo. 1808, an interesting and judicious topographical work. Beauties of England and Wales, vol. xiii. by J. Nightingale and R. Rylands.

SHREWSBURY, a town of America, in the state of New Jersey, and county of Monmouth, on the sea board, having Middletown on the N., Freehold W., and Dover S.W. It is divided from Middletown by North river, which is navigable for a few miles. The compact part of the town is pleasant, and contains an Episcopal and Presbyterian church, and a meeting-house for Friends. The number of inhabitants is 3773. This place is frequented in summer by genteel company from Philadelphia and New York, for health and pleasure; 79 miles N.E. of Philadelphia.—Also, a township of America, in Rutland county, Vermont, between Clarendon on the W., and Saltash on the E., containing 900 inhabitants.—Also, a township of York county, Pennsylvania, containing 1702 inhabitants.—Also, a township in Worcestershire county, Massachusetts, incorporated in 1727, and containing 1210 inhabitants; 6 miles E. of Worcesters.—Also, a town of Pennsylvania, in Codorus creek; 10 miles S. of York.

Shrewsbury, a river of New Jersey, which runs into the Atlantic, N. lat. 40° 22'. W. long. 74° 2'.

SHRIKE, in Ornithology, an English name for several species of the Lanius; which see.

SHRILLA, in Geography, a town of Africa, in Luda-mar; 38 miles E.S.E. of Benown.

SHRIMP, in Natural History, is the Cancer Crangon of Linneus; which see.

This shell-fish inhabits the sandy shores of Britain in vast quantities, and is reckoned the most delicious of the genus. Some writers have elabated it under the genus of Squilla.

The white shrimp, or cancer squilla, is the prawn. (See Cancer Squilla.) It inhabits the coast of Kent. (a)

By Geo. II. c. 21. white shrimps in the river Thames and Medway are only to be taken from Bartholomew day to Good Friday; and red shrimps in the river Medway only from April 25 to July 1.

SHRINE, formed from ferinium, a desk, or cabinet, a cafe to hold the relics of some saint.

SHRITE, in Ornithology. See MISSEL-BIRD.

SHROFF, a sort of banker or money-broker in the East Indies. See RUPEE.

SHRONDO, in Geography, a town of Africa, in the kingdom of Dentila, in which are considerable gold mines.

SHROPSHIRE, one of the midland counties of England, is situated between 52 and 53 degrees N. latitude, and 2 and 3 degrees W. longitude, from London. It is bounded on the S. by the counties of Worcester and Hereford; on the E. by Staffordshire; on the N. by Chester, a detached part of Flintshire, and by Denbighshire; and on the W. by the county of Shropshire, and those of Radnor and Montgomery. According to archdeacon Plymley's "General View of the Agriculture of Shropshire," it extends about 44 miles in length, 28 in breadth, and 134 in circumference, comprising an area of 890,000 acres, or about a 45th part of England and Wales united. In shape it approaches to that of an oval, and is separated into two almost equal divisions by the river Severn. The parliamentary returns of 1811, state the number of houses it contains at 36,553, and its population at 104,209 persons, of whom 99,842 were males, and 8,467 females.

Historical Events.—When the Romans invaded this island in the reign of the emperor Claudian, this county was inhabited by two British tribes, called the Ordovices and Cornavii, whose respective territories were bounded by the Severn. The Ordovices, who appear to have been a most warlike and enterprising people, joined with the Silures, under the renowned Caractacus, to defend their country. Among the hills of Shropshire, that great chiefman for a time successfully strove against the overwhelming tide of Roman conquest; and here, several antiquities contend, was fought the unfortunate conflict which terminated his military career, and led to his captivity. After that event, Shropshire formed part of the province called Flavia Caesariensis, and seems to have been held in undisturbed tranquillity so long as the Romans remained in Britain; but when they withdrew their forces to the continent, it again became the theatre of war between the Britons and the Saxons. For some centuries it constituted part of the kingdom of Powiiland, of which Pengwern, now Shrewsbury, was the capital (see SHREWSBURY); but in the reign of the great Offa it fell under the dominion of the Saxons, when the British princes retired to Mathrafael, in Montgomeryshire. To secure his conquests, Offa formed an immense rampart of earth, extending about 100 miles in length along the confines of Wales; but the utility of this work, for the purposes of defence, seems to have been very inconsiderable, as we find the Welsh constantly making inroads into the Merian territories.

In the ninth century, when the Danes invaded this island, Shropshire shared in the calamities which their ferocity brought upon the kingdom, but in a much less degree than most other counties. During the reign of Edward the Conqueror, Gruffydd, prince of North Wales, became the terror of the English by his incursions into this county. Harold undertook an expedition against him, in which he was so successful, that the Welsh were glad to purchase peace by
the massacre of their chief. After the conquest, nearly the whole of Shropshire was bequeathed to Roger de Montgomery, a relation of the conqueror; but the inroads of the Welsh frequently disturbed him in the enjoyment of his splendid acquisitions. In 1067 they laid siege to Shrewsbury, the seat of his baronial power, with so formidable a force, that the king found it necessary to march against them in person, when they were defeated with great slaughter.

This disposition, however, only served to increase the warlike spirit of the Welsh; and William, finding himself foiled in his repeated attempts to reduce those high-spirited foes by submision by open combat, adopted a more politic mode of warfare. He inflicted grunts to certain of his favourites of all the lands they should be able to conquer from the Welsh; and endeavoured to divide and weaken the Welsh border obtained themselves, by promitting a confirmation of all the rights and privileges to fuch of them as would simply acknowledge the sovereignty of the English crown. Hence appears to have originated the feignories and jurisdictions of the lord marches, whose power was even more arbitrary and despotic than that of the monarch himself. They constructed and repaired fortresses at their pleasure, and garrisoned them with fiders of their own. They likewise built towns, and exerced the most absolute authority, both civil and military, within their respective territories. In later times, however, this power was considerably controlled by a chief court of the marches of North Wales, which was generally held at Ludlow, but sometimes also at Shrewsbury and other towns; and was still more limited after the union of Wales with England, from which period no lord marcher could exercise any prerogative not confirmed to him by charter, without a special licence from the crown. During the various revolts which occurred subsequent to the death of Edward I., and also during the contentsions for the crown between the houses of York and Lancaster, Shropshire was occasionally the scene of military conflicts, of which the most celebrated was the battle of Shrewsbury. When the civil war broke out in the 17th century, this county was peculiarly distinguished for its loyalty; but except the taking of the county-town by the parliamentary forces, no tranfaction of peculiar interest happened within its limits throughout that unfortunate era.

General Aspect, Soil, and Climate.—Shropshire presents within its boundaries almost every variety of natural charm; the bold and lofty mountain; the woody and secluded valley; the fertile and widely cultivated plain; the majestic river, and the sequestered lake. The soil is no lefs various. In the hundred of Offwerty, a deep loam and gravelly soil prevail; and in those of North Bradford and East Burmley, a light or sandy loam. Pinhill hundred contains a mixture of "boggy land, and of sandy soil, with a greater proportion of found wheat land." In the other hundreds, clays of different consistence form the most general soil; but there are numerous patches and extensive tracts both of deep and sandy loam, gravel, &c. The climate of course partakes of the character of its surface and soil. On the eastern side of the county, where the land is warm and flat, harvest frequently commences a fortnight sooner than near the middle of the county, where the vales are extensive, but the surface lefs light, and the bottom often clayey; and hay and grain are both gathered earlier there than on the western side, where the vales are narrow, and the high lands frequent and extensive, although the soil is not in general so stilt. The easterly winds prevail moft in spring, and those from the west in autumn; but the easterly winds are the moft regular; those from the west blowing for a series of months five or six perhaps) long and frequent, and then for nearly a similar period less often and less violent. The climate may be said of the wet and dry seasons in this county, but the periods of both appear to be much shorter.

Rivers and Lakes.—Shropshire abounds with rivers as much as any county in England. The principal among them is the Severn, which, after bounding the county for several miles, enters it near Melverley, and flows on in an irregular serpentine channel to Shrewsbury, which it nearly encircles. At this town it turns towards the north, but soon again weeps to the southward, passing by Wroxeter, Madeley, and Bridgnorth, to Bewdley, where it enters Worcestershire. Its course within Shropshire is estimated at nearly seventy miles in length, throughout the whole of which, with a few navigable for barges, trows, wherries, and boats, and is abundantly supplied with fith of various denominations. The contributory streams to this great river, belonging to the county, are the Camlet, the Vyrnyw, the Morda-Brook, the Perry, the Mecole-Brook, the Rea, the Tern, the Bell-Brook, the Cund-Brook, the Worf, the Marbrook, and the Bore-Brook, all of them considerable waters. Those of most importance, which do not join the Severn, are the Morles, which falls into the Dee, the Teme, the Shelbrook, the Elf-Brook, the Weever, the Clun, the Ony, which discharges itself into the Teme, in Herefordshire, and the Corve; but besides these, there are nearly a hundred streams of minor extent, which our limits will not permit us to mention. The lakes here are numerous, but none of them are very extensive. That of Ellesmere, which is the largest, covers about 116 acres of ground.

Minerals.—Shropshire is well supplied with minerals. The mines of lead-ore, on the western side of the county, are extremely producive, and their product is reckoned to be of excellent quality. Copper and calamine are likewise found here in great quantities, but neither of them has hitherto been mined with any degree of success. Coal of a superior kind is wrought on the eastern side of the county, particularly in the parishes of Wellington, Lilleghall, Wrockwardine, Wombridge, Stirsley, Dawley, Little Wenlock, Madeley, Barrow, Bonthall, and Broseley. It is likewise found in the hundred of Stottesden, and to the southward of the Clee hills; also on the north and north-west confines of the county. Iron-stone, as is usually the case, accompanies the coal strata, as well as lime-stone, which is quarried in various places, but particularly at Liddlehall, Torth-y-Wain, and Llanymynech, and in the parishes of Cardifon and Alberbury. This county further contains abundance of building-stone, and ises for covering roofs. At Pitchford, about seven miles S.E. from Shrewsbury, is a red sand-stone, approaching the surface in many places, which exudes a mineral pitch. This from this rock is extracted an oil, known by the name of Betton's Britifh oil. Mr. Arthur Aikin is preparings an interting ejection on the mineralogical stratification of this county.

State of Property, &c.—The extent of edates in this county is very various. While the posessions of a few noblemen and gentlemen include from 10,000 to 25,000 acres each, there is an infinite number of freeholders' and yeomen's edates of all inferior sizes. The number of freeholders entitled to vote amount to above 3000; and the total rental of the county, tithes inclusive, to about 900,000l. There is much copyhold tenure, but of easier cullm and than in most of the neighbouring counties. The lords of some customary manors have enfranchised the copyholders, upon receiving an equivalent in money; but the cullums of the greater number are still preferred and acted upon. In the manors of Ford, Cundover, Wem, and Lop-
pington, the lands descend to the youngest son; and in the
manors of Cardigan and Stretton, (where the eldest son suc-
cceeds,) in default of sons, the daughters are co-heiresses.

Agriculture.—The extent of farms is nearly as various as
that of estates; but in general they are of a large size, and
are, in some instances, held on leases for life; in others, for
seven, ten, or twenty-one years; and, in many cases, from
year to year only. The crops commonly cultivated are
wheat, barley, oats, pease, turnips, and potatoes; hops,
hemp, flax, and cabbages, are only raised in small quan-
tities. The growth of hay and the improvement of pature
lands are rather neglected branches of Shropshire agricul-
ture; but on the borders of the Severn, and in the vicinity
of several of the lesser streams, there are many excellent
tracts of meadow land, which produce grases in great luxu-
riance, without the aid of any other manure than what is
deposited by the floods. The grases most common in
the county are the following: the sweet-scented vernal
grases, Timothy gras, meadow box-tail, and some species
of the agroins; but the latter flower too late to be of much
use for cultivation. Several varieties of the poa and fentua
are likewise common.

Woods and Plantations.—Notwithstanding large yearly
falls of timber, there still remain in Shropshire some fine
woods of oak, and a vast number of good hedge-row trees,
chiefly ash and oak. Birches, both as trees and as fences,
are common in the south-west district. There are beides,
in this county, many large tracts of coppice-wood, and se-
veral extensive modern plantations; but the former suffer
much by the demand for charcoal, which the numerous iron
works in this and the adjoining counties occasion.

Of wattle lands, Shropshire is comparatively free. Al-
most all the lands in cultivation are inclosed; and the com-
mons are every day decreasing, so that few of any great
extent remain, except that of Mort, near Bridgenorth,
which measures five miles in length, and nearly three in
breadth; and the high lands between Church-Stretton and
Bishop’s-Castle, and from Clun to the borders of Radnor-
shire, which are solely occupied as sheep-walks, and perhaps
could not be better employed. There are several large
moles, and many smaller ones, in Shropshire. The chief
district of moor-land is that in the vicinity of
Kinnerley.

Roads and Canals.—The turnpike-roads of this county
are excellent; but the parish roads are in general bad, and
the repair of them much neglected, from the want of pro-
per surveyors. Canals, though late of introduction into
Shropshire, are now frequent. The chief cuts are the
Shropshire canal, which commences at Donnington wood,
and terminates at Coal Port on the Severn, running through
an extensive assemblage of coal and iron works; the Ketley
canal, which joins that of the Shropshire; the Shrewsury
canal; and the Ellesmere Navigation, which forms in itself
a fylem of canals, extending through that large and fertile
tract of country which lies between the Severn on the south
and the Mersey on the north, and between the confines of
North Wales on the west and the borders of Stafford-shire
on the east, a space of 50 miles in length, and upwards of
20 in breadth, exclusive of the valleys which open into
North Wales. Its grand object is to unite the Severn, the
Dee, and the Mersey, and by that means open a communi-
cation between the districts above mentioned and the ports of
Liverpool and Bristol.

Manufactures and Commerce.—Among the manufactures
of Shropshire, those of Ketley and other places in the iron
district are the most considerable. Garden-pots, and other
coarse earthen vessels, are made at Broseley, which is likewise
noted for the manufacture of excellent tobacco-pipes. At
Caulkey, in the same neighbourhood, is a china manufac-
ture of great excellence, and at Coal Port is another of the
same kind; besides one of that species of earthenware called
the Queen’s or Wedgwood ware. Shropshire also contains
several mills for dyeing woollen cloths, and some cotton and
linen manufactories. These various products of course form
a considerable share in the commercial means of Shropshire,
but its principal traffic is probably the staple trade of Shrew-
bury, in flannels and Welsh webs, which are bought in large
quantities at the markets of Pool and Ofwell, and are not
only sent to every part of the kingdom, but are exported to
different quarters of the world, particularly to the West
Indies and to South America.

Civil and Ecclesiastical Division and Government.—Shro-
shire, like every other county in England, is governed by
a lord lieutenant and cultus rotulorum, a high sheriff, and
a number of justices of the peace, besides the magistrates of
the privileged towns. It is divided into fifteen hundreds, or
districts, answering to that denomination; namely, Ofwell,
Pennington, Pennhill, North and South Bradford, Brim-bridge,
the liberty of Shrewsbury, the franchises of Wenlock, and
the hundreds of Stottesden, Ford, Chirbury, Cnndon, Mun-
slow, Overy, Purlow, and the honour of Clun. These again
are subdivided into 259 parishes, part of which are
within the diocease of Lichfield and Coventry, and part
within those of Hereford and St. Asaph.

Parliamentary Representation and Chief Towns.—Shro-
shire sends twelve members to parliament, two knights of
the shire, and two burgesses for each of the boroughs of Shrew-
bury, Ludlow, Bridgnorth, Wenlock, and Bishop’s-Castle.
The principal landed proprietors who have an influence in
the representation, are the earl of Powis, the lord Bradford
and Berwick, the Hills, the Corbets, and colonel Forester.
The market-towns in the county are, Church-Stretton, Cleo-
bury-Mortimer, Ellesmere, Hales-Owen, Madeley, New-
port, Wen, Great-Wenlock, Ofwell, Whitchurch, and
Wellington.

Antiquities.—Shropshire contains a great many objects of
antiquarian interest. The chief Roman stations within its
limits were Uriconium, now Wroxeter, Mediolanum, near
Drayton, and Rutunium, near Wen. Antiquaries differ
respecting the precise position of the two last, but with re-
gard to the former, there is little doubt but it was a chief-
city of the Cornavii, founded and fortified by the Romans.
Walling-street enters the county on the east, between Crack-
ley-wood and Welton, and pails through it in a bending
line to Leintwardine, in Herefordshire, on the southern
borders. Of the Saxon period no certain remains exist;
but of the Norman era, and of subsequent times, there are
many; as the castles of Shrewsbury, Ludlow, Bridgnorth,
Clun, and Red Castle, and the abbies of Shrewsbury, Haugh-
mond, Buildwas, Wenlock, and Hales-Owen, several priories,
and a great number of curious churches. The most remark-
able encampments are those of Bury Ditches and the Walls,
and at Purlow, Basford Gate, and Hawkitone. A General
View of the Agriculture of Shropshire, by Joseph Plym-
ley, M.A. Archdeacon of Salop, 8vo. 1803. Beauties of
England and Wales, vol. xiii. by J. Nightingale and Ralph
Ryland, 8vo. 1811.

SHROUD, from the Saxon freond, a shelter, or cover, is
used to denote the drefs of the dead. This is required by
fate to be made of sheep’s wool only. See Burial.

If any one, in taking up a dead body, steals the freond,
the property of which remains in the executor, or the person
who was at the charge of the funeral, it is felony.

SHROUDS, in Sea Language. See Shrouds.

SHROVE-
SHROVE-TIDE, the time immediately before Lent; thus called by our ancestors, because employed in feasting, that is, in confessing their sins to the priest, in order to a more devout keeping of the ensuing Lent fast.

Shrove-Tuesday is the day next before the first of Lent.

SHROWING of Trees, the cutting or lopping off the top branches; this is only practised to trees that are not fit for timber, but designed for fuel, or some other prevalent use.

Such trees the husbandmen find much preferable to coppice, as they need no fence to inclose them; because they stand in no danger from the brownings and rubbings of cattle, which too have the benefit of grazing under them.

As for the time of shrowing, it is not to be practised till the trees have flopped three or four years; and then it must be done either at the beginning of the spring, or the end of autumn.

Tho' of the harder sorts are not to be lopped above once in ten or twelve years, and that at any time in the winter. The pithy and soft woods are best shrowed in the spring. The stamps left should always be cut off, and smooth, in order to call the water off, and prevent its sinking in, and rotting the tree.

SHROWS, or Shrubs, in Sea Language, are great ropes in a ship, which go up on both sides of all masts, except the bowspirt.

The shrubs are always divided into pairs, i.e., one piece of rope is doubled, and the two parts fastened together at a small distance from the middle, so as to leave a sort of noose or collar to fix upon the main-head.

They are fastened below by chains to the ship's sides, and aloft, over the head of the mast; their pennants, fore-tackle, and swivellers, being first put under them; and they are served there, to prevent their falling the mast. The top-mast shrubs are fastened to the puttocks, by plates of iron, and by what they call dead-men's eyes, and laniers also, as the others are. See Puttocks.

The shrubs, as well as the falls, are denominated from the mast to which they belong. Thus they are the main, fore, and mizen shrubs, the main-topmast, fore-topmast, or mizen-topmast shrubs, and main-top-gallant, fore-top-gallant, or mizen-top-gallant shrubs.

The number of shrubs by which a mast is fastened, as well as the size of the rope of which they are formed, is always in proportion to the size of the mast, and the weight of the fall it is intended to carry. The two fore-mast shrubs, on the starboard and larboard side of the ship, are always fitted first upon the main-head; and then the second on the starboard, and the second on the larboard, and so on till the whole number is fixed.

The intention of this arrangement is to brace the yards with greater facility, when the falls are clove-hauled, which could not be performed without great difficulty, if the fore-mast shrubs were laid fitted on the main-head, because the angle which they would make with the mast would then be greatly increased. Falconer.

Bowspirt shrubs are those which support the bowspirt. Bumkin shrubs are those which support the bumkin. Puttock shrubs are those which connect the efforts of the topmast shrubs with the lower shrubs. Bentinnick shrubs are additional shrubs to support the masts in heavy gales. Preventer shrubs are similar to Bentinnick shrubs, and are used in bad weather to ease the lower rigging.

The terms are, cafe the shrubs; that is, flacken them. Set taught the shrubs; that is, fasten them fast. See Shrubs Trucks. See Trucks. See Shrubs Trucks. See Shrubs.
the winter season, as for their contrast with the yellow and russet tints of the deciduous kind, and trees of the same nature, in the autumnal and spring seasons. They ought, generally, according to him, to be the prevailing sorts planted near the houses and buildings of country-seats, not only for the reasons suggested above, but because they are capable of concealing some part or parts of the edifices, disguising their real extents, and thus blending them at all seasons with the surrounding scenery. There is also another circumstance in their favour, which is the superiority of their shelter and shade.

It is thought, also, that the cypresses are seldom planted in such situations, as it has the capability and power of giving a rich classical appearance and effect to them; as is seen in some cases, as at Foxley and Yoxal Lodge.

And the holly, it is suggested, should be planted still more than any other shrub, in particular cases; as no other is capable of affording and producing such an excellent and diversified effect in wooded scenery, as is exemplified in some forest situations.

The ivy is capable, it is said, of answering three important uses, and of course deserving of more frequent growth. These are the varying of the items of single trees, and small groups of them; the giving of effect to old decaying trees, and the rendering of ugly trees interesting, as well as other similar rural purposes; the producing of variety in different forts of buildings; and the giving of ornament and utility to works of the country kind.

In the frill of these intentsions, in different cases, where the number of trees of the same kind are considerable, and very much alike, which are in the fore-ground, one or several of them may be varied and diversified by the ivy shrub, in probably as happy a manner, and with as good an effect, as in any other way, and better than by the use of any fort of deciduous climbing plant. Single trees can always be rendered interlardingly different by these means, as well as old and ugly trees of different forts.

In the second use, where cottages, ruins, irregularly formed buildings, old houses, and other similar structures, are to be varied, partially concealed, and rendered different in their external appearance, but which cannot be cheaply enough done in other ways, they may be highly and richly diversified and decorated by the simple planting of the ivy shrub, and directing it so as to cover in different places or parts. The expence of such works would also be less, in many instances, it is remarked, if the external appearance of them were contrived so as to admit this plant; which would not only vary and alter them generally, but might occasionally be substituted for, and supply the place of, particular parts, as is exemplified in many instances.

The last of these intentions is that of planting the ivy shrub against walls of the late kind, dikes, and fence fences between fields, and other similar purposes, in the view of rendering them more ornamental and durable. The chequering of them in this way, on their sides, with shades of green, and little ribs or columns, and richly mantling their tops, have, it is said, much effect in producing variety, and at the same time in rendering them more lasting. Mortared and unmortared walls are likewise preferred and secured by it. This creeping shrubby plant may consequently be of extensive utility in various ways; as, besides affording beauty, shelter, and durability, it may be beneficial in thickening hedges in the vicinity of the sea-coast, when joined with the elder. It should, in all cases, be carefully planted, either by fets or young seedlings, which last is by much the readiest mode of raising it and providing it. Nothing more is wanting, as it succeeds well in moist foils, situations, and exposures. Where tall plants are wanted for particular uses, they must be provided with good roots.

In the deciduous kind of shrubs, the modes of varying and planting are very different, according to their nature, habits, and other qualities and circumstances. For the most part, however, the larger sorts are put more out of the way, in order that the smaller and more curious kinds may be more fully exposed to view. The peculiar properties in some of this description of shrubs also direct the modes and manners of planting them, as that of the time of flowering, and several others. They are varied and planted differently, likewise, for a great variety of other different reasons.

In planting the laburnum, as there are two sorts, which differ greatly in their sprays or small twigs and foliage, that with the smaller and more delicate branches and flowers should conjoinly be chosen for putting out with other shrubs; the other, which is of much larger growth, is well suited for poor gravelly soils, rocky banks, and the rocky margins of water, where, in the two latter situations, the plants may sometimes be seen in great perfection.

Shrubs of these different kinds are raised and produced in many different ways, as may be seen under their different particular proper heads.

Some sorts of shrubs, particularly in the early state of their growth, fland in need of not merely a foil and situation, but a mode of cultivation which is adapted to their different natures and habits. And though all shrubs require to have the earth or foil about them either frequently stirred, or kept clean and free from all plants of the weed kind, there are some that succeed best when the surface of the ground is over-run with low plants of the moss kind.

In all cases, shrubs are to be preferred in a neat and perfect order, by the removal of the decayed and withered parts, and the proper cutting in of particular shoots and branches where necessary, especially in some of the deciduous kinds. In the evergreen clays, the knife or shears, however, are very seldom to be applied, except for the removal of the delroyed parts, which are conjoinly to be carefully taken away.

SHRUB, Fruit, that sort of low shrubby plant which bears fruit of some kind or other. Shrubs of this kind are mostly very useful, and not few in number. The sorts are various, as the gooseberry, the currant, the rasperry, and some others, cultivated in garden situations; and the blackberry or barberry, and a few other kinds, in some of the shrubbery. Shrubs of this description, in most cases, require careful attention in cutting, managing, and keeping the ground in proper order, by due cultivation, and the proper use of suitable manure. See Small Fruits, and Standard Fruit Trees.

In planting them, those of the garden sort are most properly and usefully put out in situations by themselves, and not in the usual mode, on the sides or borders of the different cultivated compartments of the garden ground. Those which produce ornamental, as well as fruit, are to be placed out in variety with other shrubs, in the more open parts of shrubberies, or alone in particular cases.

SHRUBS, Stealing of. See Larceny. Wilfully spoiling or destroying them is a species of that malicious mischievous, which subjects the offender to pecuniary penalties for the first two offences, and for the third, if it be committed in the day-time, and even be the fifth at night, to the guilt of felony, and transportation for seven years. 6 Geo. III. cap. 36. and 48.

SHRUBBERY, in Gardening, a tract, portion, or space of ground, which is planted with shrubs, trees, and flower plants,
plants, for the purpose of ornament. The term is, however, perhaps the most properly applied to narrow belts and strips of ground, planted with shrubs and flowers, which are sometimes the principal ornaments of small seats, and other similar contrivances and conveniences. They are contrived in different forms and modes, for the purpose of giving the desired effect; and the notion of such schemes of planting shrubs and flowers is considered by Mr. Loudon as good and proper, as when executed according to the principles of nature and good taste, they must produce effects of the interesting as well as the pleasing kind; but that from the reverse having been so frequently the case, their tardy insipidity has been justly reproved by some, as Mr. Knight, in the following line, &c.

"Curle on the shrubbery's insipid scenes."

It is supposed that shrubberies are, in general, made and contrived with the intention of procuring walks, which may either conduct or direct to some particular place or scene, such as the kitchen garden, the farm, a wood, or any other similar object; or they may lead and extend merely through the shrubberies, for their own sake, and such views of external objects as can be produced from them, or as are deserving of attention. In designing and forming shrubberies, therefore, keeping the above in view, these three points will, it is thought, require to be particularly attended to: first, the arrangement, distribution, and grouping of the shrubs, which ought to be that of general nature; in the second, the intermixing of the glades and pastures, which, in most cases, is an essentially requisite consideration; and in the third or last, the judicious introduction of the views of the more distant scenery, which is generally defirable, unless in such parts as, by way of utility or contrast, are preferred in a flat of umbrosity.

The two latter requisites are, it is said, naturally connected with picturesque improvements, the general principles of which are blended and intermixed with this branch of ornamental gardening.

The directions which this able designer of rural works of this nature has given for the forming of shrubberies with proper taste, in different cases, situations, and circumstances, are, that when such groups of shrubs and flower plants are small and placed upon lawns, they should always be of very irregular shapes; but that, when upon gravel, their forms must depend upon circumstances. In cases where they are in a part in which art is avowed and ought to prevail, then the more artificial the forms are, so much the better; but that if merely a group for separating, dividing, or varying a road, walk, or natural path at a distance from artificial scenes, then the shape should be as irregular as in those upon lawns. Whether such shrubbery groups are made in a regular or irregular manner, they almost in every case require to be cultivated or wrought over for some years afterwards. This, in the mode of digging and working them which has been usually had recourse to, produces, it is said, a harsh and disagreeable boundary line; which, in addition to the means of proper arrangement, suitable grouping, and the natural connection of surface, may be improved principally, it is supposed, by the destruction of such lines of separation in as complete a manner, as high a degree, and as extensively as possible. Nothing, it is thought, can be more readily or more easily accomplished, as it is only requisite to keep the earth on the margins or borders of such groups of the same level as the surfaces of the lawns or pavilions, and to suffer both to unite and blend harmoniously together, or with each other. And as all groups of this shrubbery kind are only dug or wrought over during a certain period of time, as until the shrubs become so large as to render further culture unnecessary; the pailure should be allowed to gradually encroach and spread itself among the shrubs and flower plants, until at last it wholly covers the surface. After this, the shrubry group becomes rough and picturesque; the flower plants, still continuing to grow among the shrubs, will, it is supposed, be productive of exactly what is seen to happen in natural groups; with this elegant difference, that in place of nettles, thistles, and such coarse Gros weeds, which, however, it is remarked, are as good to the painter as the finest flower plants, there will be had the Narcissus, faxifrage, faponaria, and others, which are quite in character with the rest of the pleasure-ground, and thrive among pailure. It is suggested, that in planting the shrubs in such groups, the great art consists in putting them in irregularly; for though the outline of the ground to be cultivated must, even under the best taste, be somewhat formal, yet the shrubs can always be planted as irregularly as if no outline or form of group existed. This, however, said to be a plan or manner of distribution, which has never been put in practice; as whatever the form of the ground may be which is to be dug and planted, the shrubs are distributed in a regular manner over every part of it; even when digging is no longer attended to, till these of the shrubs are thinned out, but the whole left a formless clump of vegetation, an appearance, it is observed, as different from the irregular group-thickets of nature, as a green ballock is from a rocky precipice. It is stated, however, that the groups of this nature, or rather those masses of formal shapes which are placed in particular situations, such as ovals in the fronts of small villas, or baskett-work patches upon the lawns in the fronts of residences of the mansion kind, should always have determinate outlines; as being devoted, in a great measure, to tender flower plants and flowering shrubs, they will require to be confiningly in a cultivated state. Their outlines or boundaries may, it is supposed, be properly formed, according to circumstances, either of elegant masonry, wood, baskett-work, or of plants of the flower kind, such as thrift, the daily, and some others, and not unfrequently, when surrounded by gravel, by a broad margin of turf. In regard to the general forms of such shrubbery planted masses, it is said that they may be oval, circular, pentagonal, or fanciful, according to pleasure; and that their surfaces may either be kept level with the lawns or other parts, or be gradually raised from their margins to their centres. It is however noticed, that when raised in this way the sides should always be made to present a concave slope, and not that of a convex one, as is most commonly the case, and which has a very bad effect in different situations, as in the public squares of the metropolis, &c. Baskett-work shrubbery groups have not unfrequently, it is remarked, a very pretty effect when covered with moss. Others which are unconnected among themselves, and which have forms that are rather unuitable to the nature of the situations in which they are formed, are likewise productive of variety. In all cases, some sort of agreeable effect ought to be afforded in as striking a manner as possible.

It is conclusively remarked, that though the connection of surface in such shrubbery groups is always of importance, neither those of the irregular or regular shapes ought ever to be placed in any situation, except where they have a proper relation and union with what surrounds them.

In the larger and more extensive works of the shrubbery kind, the same rules and principles will be necessary to be had recourse to, but with a greater attention to the production of variety and effect. These are to be accomplished by such...
fuch means as have been already fuggelled, and by giving
them a more natural conformity, as well as by the introduc-
tion of greater diversity in the shrubs, trees, and other farts
of plants that are made ufes in the formation of them. It
is indeed observed, that one of the moft effectual means of
rendering rural fenes still more interefting than they com-
monly are, is by introducing a more extensive variety of
shrubs than is ufually employed, a vast number of which
are capable of anfwering the purpofe. They are not, how-
ever, to be planted in fuch situations in the common in-
difcriminate manner, but with much regard to the effect
which they are to produce. In fhort, it is concluded, that it
is in the shrubbery, or thefe parts of pleasure-gounds
which contain flower plants, shrubs, and trees,—which occupy
considerable space,—exhibit views of the country or of other
parts of the ground, that ornamental gardening and pic-
turefe view improvement blend themselves together in produc-
ting thofe happy effects which fof much intereft the feelings
and fancy.

SHRUBBY-Howk-Weed, in Agriculture, a plant of the
shrubby weed kind, which is often troublesome and injurious
in woods and plantations. See Hieracium, and Weeds.

SHRULE, in Geography, a river of the county of
Tyrole, Ireland, which joins the Moyle near New Town
Stewart. There are also feveral rafhes of this name in
Ireland, but none called from a town now extifiting, except
Shrule in the county of Mayo, on the borders of the county
of Galway; 106 miles N. by W. from Dublin.

SHUKA, a powerful tribe or kabyle in the province of
Sufe, in the southern division of the empire of Morocco.
inhabited by Shellucks, amounting in number to 350,000.

SHURIF, a fmall low ifland in the Red Sea, near the
coast of Africa. N. lat. 24° 22'.

SHUBENACADIE, a river of Nova Scotia, which
rises within a mile of the town of Dartmouth, on the E.
fide of Halifax harbour, and difcharges itself into Coba-
quid bay, receiving in its course the Slewink andiais
rivers. The large lake of the fame name lies on the E. fide
of the land that leads from Halifax to Windsor, and about
7 miles from it, and 121 from Halifax.

SHUK, in Agriculture, provincially a flock, or twelve
sheaves of corn fet up together in the harveft field.

SHUD, in Rural Economy, a word fometimes provincially
used to feign fheafed.

SHUG, in Agriculture, a term used to imply the fhaking
of any thing, as hay, &c.

SHUGGINGS, a word fignifying that which is fheaf or
fcattered, as grain at harveft, &c.

SHUHUSHU, in Geography, a village of the pahalic
of Bagdad, one day's fial from Korma, and fited on the
bank of the Euphrates. It is as large as Samavat (which
fee), but much more flourishing; for the Euphrates, which
is navigable, even in the drieff feafon, for boats of con-
iderable burthen as far up as this place (where the effects
of the tide are too felt), enables the inhabitants to carry on
a trifling trade with Baffora. Shuhushu is a great mart
for borlcs, and is famed for the richnefs of the cloves raised
in its vicinity.

SHUK, in Agriculture, a term fometimes provincially ap-
plied to a bulk or shell.

SHUKER, in Geography, a town of Thibet; 42 miles
S. of Gangotre.

SHULA, or Shuli, in Mythology. See Sula.

SHUMAN, in Geography, a town of Grand Bucharia;
30 miles W. of Valiherd.

SHUMBERG, a town of Ifria; 5 miles N.N.E. of
Pedena.

SHUME, or Ashume, a violent hot wind of Africa,
or, as they are called, Ondas, which, in the intermediate
journeys between several parts of the Defart or Sahara, oc-
casions great incofience and diftrefs to travellers. It
sometimes wholly exhales the water carried in skins by
the camels for the ufe of the passengers and drivers: on which
occasions the Arabs and people of Soudan affirm, that 500
dollars have been given for a draught of water, and that 10
or 20 are commonly given, when a partial fubfipation has
occurred. In 1805, a caravan proceeding from Tombuctoo
to Taiflet was disappointed in not finding water at one of
the ufual watering-places, when, as it was faid, all the perfonns
belonging to it, 2000 in number, defides 1800 camels,
perifhed by thirst. The intense heat of the fun, aided by
the vehement and parching wind that drives the loofe fand
along the boundles plains, gives to the Defart the ap-
pearance of a fea, the drifting fands refeembling exactly the
waves of the fea, and hence aptly denominated by the Arabs
"el Bahar billa mia," a fea without water. During the
prevailing of this wind, it is impoffible to live in the upper
habitants of the houfes; fo that the inhabitants retire to
erraneous apartments, cellars, or warehouses on the ground-
floor, eating only fruits, as the water-melon or prickly pear,
as the animal food at this time is loathfome and hot, and
has scarcely time to cool before it becomes tainted. The
walls of the bed-chambers, being of stone, are moftened
by throwing upon them buckefts of water, in order to render
the rooms habitable towards the night; and fo great is their
heat, that in doing this, the effect is fimilar to that which is
produced by cafting water on hot iron. Mr. Jackfon fays
that he has felt the fhume 20 leagues out at fea. When in N.
l. lat. 30°. W. long. 12° 30', a quantity of land fell on the
deck. He adds, that he never found any extreme incofience
from the fhume N. of the province of Sufe, although at
Mogodor it is fometimes felt, but not fo fervently, during
three days.

The Akkaabahs, or accumulated caravans, which erois
the great defart of Sahara, and conflit of feveral hundred
loafed camels, accompanied by the Arabs who let them to
the merchants for transporting their merchandise to Fez,
Morocco, &c. are fometimes obliged fuddently to frike
their tents, and proceed on their journey, when the fhume
rises and drifts the loofe fand along the plains, which atches
to every fixed objeft in its courfe, and foon buries it. We
fhall here add, that the guides of thefe accumulated car-
avans were being enabled by the two pointers to acfertain
the polar flar, fler their courfe with crefible precifion, and
that they often prefer travelling in the night to endurining
the fuffocating heat of the fcorching meridian fun. When
the Akkaabah reaches Akka, the firft flation on this fide of
the Defart, and fitated on its confines, in Lower Sufe, which
is a part of Bledulgerid, the camels and gufes are dif-
charged, and others are there hired to proceed to Fez, Mo-
rocco, Teredant, Taiflet, and other places. The Akka-
bahs perform the travels of the Defart, including their jo-
ourments at El-wahs, or Oafes, in about 130 days. Pro-
ceding from the city of Fez, they go at the rate of 35
miles an hour, and travel seven hours a day: they reach
Weflinno, Tatta, or Akka, in 18 days, where they remain
a month, as a grand accumulated Akkaabah proceeds from
the latter place. In going from Akka to Tagaafi, they
employ 16 days, fojourning here 15 days more to replen-
fh their camels; then they proceed to the Oafes and well of
Taudya, which they reach in seven days; and after dwelling
there 15 days, they proceed to Tombuctoo, which they
reach the fith day, making a journey of 54 days actual
travelling, and of 75 days' repofe; being altogether, from Fez
Rennell in favour of his opinion are, 1st, the similarity of
name, and the situation, which agrees better with the
distance between Sardis and Sufa, mentioned in the tablets of
Ariflagoras, than that of Shuflter; 2dly, the legend of
the prophet Daniel, whole coffin was found at Shus; and
3dly, that Sufa ought to be placed on a river, which has
its source in Media. Dr. Vincent, in reply, says, that the
similarity of name is a corroborating circumstance, when
we are sure of our position. But till the position be ascer-
tained, it is only a presumptive proof, and often fallacious;
and that Shufter approaches still nearer than Shus to Shussian,
which is its title in Scripture, and Shufian differs not from
Sufa, but by the invention of a dot in the letter Sebin. To
the legendary tradition of the tomb of Daniel, little more
relative is due, as the learned doctor conceives, than to the
legends of the church of Rome and the Mahomedan tra-
ditions. Sufa, he adds, was on the river Euileus; Shuflter
is more ancient than Shus; Sufiana, the name of the
province, approaches nearer to Shufian; and Kuzialtan, its
modern appellation, derived from the mountains which
surround it, is evidently connected with the Kihi, Kufi,
and Kofli of the Greeks. Nearhus failed up to Sufa, with-
out entering the Shat-ul-Arab, which he would not have done,
if that city had stood on the Kerah; and when Alexander de-
scended the Euileus, he sent his disabled ships through the cut
of the Hafar, into the Shat-ul-Arab; and, finally, a strong
reason for placing Sufa at Shufter occurs in Ebn Hakul,
who says, that there is not in all Kuzialtan any mountain,
except at Shufter, Jondi Shapour, and Ardz; and as the
castle of Sufa is represented by historians as a strong place,
it is reasonable to suppose that it stood upon a hill. Mr.
Kinneir, in his "Geographical Memoir on the Persian
Empire," has examined with critical skill and great
courteous the objections of Dr. Vincent, and the principles on
which they are founded; and the result is, that he inclines
to favour the opinion of major Rennell, in support of which
he cites the authority of Strabo, who says, that the
Persian capital was entirely built of brick, there not being
a stone in the province; whereas the quarries of Shuflter
are very celebrated, and almost the whole of the town is
built of stone, but there is no such thing in the environs of
Shus, which was entirely formed of brick, as appears
from our author's description of the pyramids that still
remain. However the question concerning the site of
the city of Shus be determined, it is now a gloomy wilder-
sens, infested by lions, hyenas, and other beasts of prey.

SHU

Vol. XXXII.

...
Sabla, are uninhabited, and consequently almost wholly uncultivated, and covered with brush-wood, the resort of lions, wild bears, and other animals. Morals are common. The Chab country is watered by three rivers, viz. 1. the Karoon, fupposed by some geographers to be the ancient Choapaces, but Kinneir disputes their identity; it rises 22 furlongs S.W. of Ifpahan, and after receiving many tributary streams in the mountains of Laurilfan, flows through the city of Shuffer to the village of Bundakeel, eight furlongs to the S. of that city, where it meets the Abzal; pursuings thea a fowther course, as far as Sabla, N. lat. 30° 32', and 30 miles E. of Bailoro, it divides itself into two branches, one of which discharges itself into the sea at Goban, and the other, affuming the name of Hafar, separates, after a course of 14 miles, into two branches, one of which passes through an artificial canal, three miles in length, into the Shat-ul-Arab, and the other enters the sea by the name of the Bannahir. 2dly. The Tab, which fee; and the 3d is the Jerahi, or ancient Pattigiris, which descends from the mountains behind Bebahin, in the province of Fars, and paffing within a few miles of the walls of that city, runs through the vale of Ram Hormuz to old Dorak, in the territory of the Chab Sheikh. Here it is divided in various directions for the purpose of agriculture; and the water afterwards is loft, or occasions the vall morales in the vicinity of modern Dorak. The principal towns in the district of Chab Sheikh are, Dorak or Felahi, Ahwaz, Endian, Mahboor, Goban, and Jerahi, whence the river, so called, derives its name. The revenues of the Chab Sheikh amount to five lacs of piafiers, or about 50,000 florins a-year; and he can bring into the field 5000 horse, and 20,000 foot.

The territories attached to the government of Shuffer confitute the fairest portion of Susiana. It derives its fertility from four noble rivers, and from a multitude of smaller streams. This wealthy province, which, according to Strabo, yielded to the hufbandman 100 or even 200 fold, and was rich in its productions of cotton, fugar, rice, and grain, is now, for the greatft part, a forfaken waste. The only indications to the contrary occur between Bundakeel, Dezphoul, the vicinity of Hawezaa, and the vale of Ram Hormuz. From the Abzal to the Tigris, and the river Gyndes, on the western fide, and from the banks of the Karoon to thofe of the Shat-ul-Arab, all is dreary and defolate, and on the E. fide of Shuffer a lonely wild, upwards of 60 miles in length, extends from that city to the entrance of the valley of Ram Hormuz. Although the inhabitants of the towns and villages groan under the arbitrary fway of the governor of Shuffer, his authority is hardly acknowledged by the wandering tribes, both Perian and Arabian, of Kuridftan. Of the four great rivers which embellish and ftrillize the dittrict of Shuffer, Karoon defferves the firit mention. Next in magnitude is the Abzal, which has two fources, one in the Shutter Koh, near Booroojerd, and the other in the mountains of Laurilfan: these form a junction N. of Dezphoul, and after paffing under the walls of that city, empty themselves, after a winding course, into the Karoon, at Bundakeel. The third river is the Karaf, or Hawezaa river, called by the Turks the Karafu, which is formed by the junction of many streams in the province of Ardalan, in Kuridftan: it runs through the plain of Kermanhaw, meeting the Kazawur and the Gamafu. The Karafu, increafed in magnitude by tributary streams, flows with a furious course towards Kuridftan, and fupplied with an accifion of water, it paffes on the W. of the ruins of Shus to the city of Hawezaa, and enters the Shat-ul-Arab, about twenty miles below Korna. The fourth river is that fupposed by Mr. Kinneir to be the ancient Gyndes, which proceeds from an unknown source in the mountains of Laurilfan, and joins the Tigris between Koot and Korna.

Shuffer, the capital of Kuziftan, and the residence of a Beglerbeg, is situated in N. lat. 32°. E. long. 48° 59', at the foot of the mountains of Bundariari, on an eminence commanding the rapid course of the Karoon, across which is a bridge of one arch, upwards of eighty feet high, from the fummit of which the Perians often throw themselves into the water, without the flight of injury. On the welfern fide it is defended by the river, and on the other fide by the old fience wall, now fallen into decay. The houses are good, being principally built of stone, but the streets are narrow and dirty. The population, confifting of Perians and Arabianis, exceeds 15,000 souls; and it has a considerable manufacture of woolen fllufs, which are exported to Bafiora, in return for the Indian commodities brought from thence. This city is generally believed to be the ancient Sofa; but fome approved geographers entertain a different opinion. (See Sufus.) Shus, in the old Perian language, means pleasing, or delightful, and Shuffer fill more delightful; and the name is said to be given to this city by Sapor, the fon of Artaxeres Babegan, by whom it was founded, and caufed to be built under the inspection of his prifoner, the Roman emperor Valerian. It was once, without question, a place of vall extent, and no inconfiderable magnitude. The castle, dyke, and bridge, are moft worthy of notice. The castle occupies a small hill at the welfern extremity of the town, commanding a fine view of the river, mountains, and adjoining country. This fortress is, on two fides, defended by a ditch, now almoft choked up with fand, and on the other two fides by a branch of the Karoon. It has one gate-way, formerly entered by a draw-bridge. The hill is almost entirely excavated, and formed into furdals and fubterraneous aqueducts, through which the water fill continues to flow. Near the castle is the dyke, or "Bund," built by Sapor across the Karoon, with a view of turning a large proportion of the water into a channel more favourable for agriculture, than that which nature had assigned it. This dyke is confructed of stone, bound together by clamps of iron, about 20 feet broad, and 400 yards long, with two small arches in the middle. It has lately been rebuilt by Mahomet Ali Meerza, governor of Kermanhaw, and its beneficial effects are already experienced. The artificial canal, occasioned by the construction of this dyke, difembogues, after a long winding course, into the Dezphoul, half a mile from Bundakeel. Near the canal is a bridge, built of hewn fline, consisting of 32 arches, 28 of which are yet entire. The city of Shuffer is so remarkable for its fatality, as to be the continual refort of invids from the surrounding territories. In summer the heats are excessive from nine in the morning to the fame hour at night, when the air is refreshed by a gentle breeze from the N.W. During the day the inhabitants take refuge in fubterraneous chambers, and pafs the night on the flat roofs of their houses. The winters are mild, and the springs temperate and delightful. Shuffer affords excellent springs. Kinneir's Geog. Mem. of the Perian Empire.

SHUT in Land. See LAND.

SHUTESBURY, in Geography, a township of America, in Hampshire county, Massachusettts, on the E. side of Connecticut river; 90 miles W. by N. from Bolton, containing 939 inhabitants.

SHUTTING, in Anchor-Making, denotes joining or welding one piece of iron to another.
SHUTTING-UP, in Rural Economy, a term applied to
woods and plantations, which signifies the inclosing and
securing them from the injuries which are done to them
by neat cattle and other sorts of live-flock getting into them,
and the keeping of them secure and safe for a certain period of
time before they are cut over and converted to use in their
different intentions. See Wood.

It also implies the removing of live-flock from the
patters and other grazed lands, for the purpose of closing
them in the view of having the former of a more full, suit-
able, and better growth or bite, as it is called, and the
latter more productive of grazs for hay. See Meadow,
and Pasteure.

SHUTTLE, in the Manufatures, an instrument used by
the weavers, which, with a thread it contains, either of
woollen, silk, flax, or other matter, serves to form the woofs of
fluffs, cloths, linen, ribbands, &c. by throwing the shuttle
alternately from left to right, and from right to left, across
between the threads of the warp, which are stretched out
lengthways on the loom.

In the middle of the shuttle is a kind of cavity, called
the eye of chamber of the shuttle; in which is inclosed the
spool, which is a part of the thread defined for the woof;
and this is wound on a little tube of paper, ruff, or other
matter.

The ribbon-weaver's shuttle is very different from that
of most other weavers, though it serves for the same pur-
pose: it is of box, fix or seven inches long, one broad,
and as much deep; flood with iron at both ends, which terminate
in points, and are a little crooked, the one towards the right,
and the other towards the left, representing the figure of an
circle horizontally placed.

SHUTTLE, in Inland Navigation, a term expressing a small
fluece, paddle, &c.

SHUTTLEWORTH, Obadiah, in Biography, or-
granit of St. Michael's church, Cornhill, was elected, on the
resignation of Harte, for St. Dione's Back-church, who was
succeeded by Burney in 1749. Shuttleworth, soon after his
election at St. Michael's, was appointed one of the organists
of the Temple church. He was the son of Shuttleworth of
Spitalfields, the father of a remarkable musical family, and
had acquired a small fortune by teaching the harpsichord,
and transcribing the compositions of Corelli, before they were
printed in England. He had three sons and a daughter,
all good musicians; and had frequent concerts at his house for
the amusement of his friends, in which the sons played the
violin and tenor, the daughter the harpsichord, and the old
gentleman the viol da gamba. His son Obadiah, particularly,
was so admired a performer on the violin, as to be ranked
among the first masters of his time. He led the band at the
Swan concert, from its first institution to the time of his death,
about the year 1735; when he was succeeded by Featling.
His brothers were excellent performers on the violin, and
employed in all the city concerts. But Obadiah is almost a
single instance of the fame musician being equally admired for
his performance on two different instruments. He was
such a favourite player on the Temple organ, that great
crowds went thither to hear him of a Sunday evening, when,
after service, he frequently played near an hour, giving a
movement to each of the folio stops previous to his final fugue
on the full organ.

SHWAN-PAN, the name of a Chinesce instrument, com-
pofed of a number of wires, with beads upon them, which
they move backwards and forwards, and which serves to affill
them in their computations. See Anacus.

SHWAYEDONG, in Geography, a small but neat town
of the Birman empire, on the Irawaddy, containing about
300 houses, ranged in a regular street; each dwelling
having a small garden, fenced with a bamboo railing. Its
two monasteries and a few small temples did not engage
the particular notice of Col. Symes and his companions; but
the tall and wide-spread trees that overshadowed them
were objects of pleasing contemplation. Symes's Embassy

SHY, in Agriculture, a provincial term, signifying high-
melted or head-argong, in the manner of wild colts, &c.

SHYAMULA, in Mythology, a name of Parvati, the
confort of the Hindoo deity Siva. It means with a blue
body; and is, with many other names of similar derivation,
given to that goddes, and to Vishnu, Krishna, and Rama,
who are describ'd and represent'd of "hyacinthine hue."
Among these names are Syama, Shyamala, &c.

SI, in Geography, a town of China, of the third rank, in
Ho-nan; 50 miles N.W. of Kowang.

St. or Sia, a town of China, of the second rank, in
Chan-fi. N. lat. 36° 40' E. long. 116° 31'.

S1, in Music, a name in singing, given by the French to
the sharp 7th of the key of C, to preclude the embarrassment of
the mutations in folvation. (See HEXACHORD, and Mu-
tations.) A similar expedient had been often attempted
by various authors; but none had been so generally adopted
as this, which however was long solely confined to France;
nor is it yet general all over Europe. And we think that
the manner in which the French syllabize not only vocal
but instrumental music, is subject to very material objections;
but only provides for one key. if the new syllable fi had been
used for the sharp 7th of every key, as well as that of ut or C
natural, and la for every key-note or tonique in minor keys,
it would have exempted the principants in singing from
much perplexity. There is no certain name for any note,
except in the key of C, ut, re, mi, fa, sol, la, fi, ut; and whether
B is flat, natural, or sharp, it is equally denominated fi;
as C, whether natural, flat, or sharp, is always called ut.
When D is the key-note, it is named re; when it is the 3d
of the key of B♭, or 4th of A, it still retains the name of
re.

Malcolm, in the year 1721, was the first who openly cen-
tered the hexachords, which Dr. Pepusch, in 1731, defended
with some warmth, by giving the best and clearest explana-
tion of their use and importance, not only in singing but
composition, in regulating the answers to fugues. Foucha,
Padre Martini, Sala, and the most respectable Italian and
German theorists, still adhere to the folivation which has
produced so many great composers and fingers during the
two last centuries. We have given our opinion fully on the
subject in the article Serra, a Roman master, who proposed
a new method of naming the intervals in cultivating the
voice. See Serra.

The original introduction of this syllable is attributed by
Merfennus and other writers to one Le Maire, a French
musician, who laboured for thirty years to bring it into
practice; but he was no sooner dead than all the musicians of
his country made use of it. However, it has been the
more general opinion, that the syllable fi was introduced into
the scale by Eriacus Putzcaus of Dort, who lived about the
year 1580. M. Bourdect ascribes the introduction of this
syllable into the scale to a Cordeliers, about the year 1675;
and he adds, on the testimony of the abbé de la Louette,
that it was invented, or a second time brought into practice,
by one Metru, a famous singing-maister at Paris, about the
year 1676; and Bonet inclines to think, that the honour of
the invention might be due to the Cordeliers, but that the merit
of reviving it is to be ascribed to Metru. Bourdect in-
tributes, that though the use of the syllable fi is much ap-
proved
proved of by the French musicians; yet in Italy they disdain to make use of it, as being the invention of a Frenchman. Hawkins's Hist. of Music, vol. i. p. 435.

The French are not yet agreed to whom they are obliged for the syllable $\beta$; some say it was Nevers, some Le Mairé, and other claimants are mentioned by Rouleau; but not being quite satisfied with its utility, we shall below no pains in verifying the claims of an imperfect invention.

S. Actio, in Lavis, the conclusion of a plea to the action, when the defendant demands judgment, if the plaintiff ought to have his action, &c.

SIABE, in Geography, a town of Persia, in the province of Segeltan, or Seiftan.

SIABISCH, a river of Russia, which runs into the Abakan, near Bankalova, in the government of Kolyvan.

SIADY, a town of Samogitia, seated on a lake; 33 miles N. N. W. of Miedniki.

SIAGNE, a river of France, which runs into the Mediterranean, N. lat. 43° 31'. E. long. 7'.

SIAGONAGRA, a name given by some medical writers to the gout in the jaws.

SIKA, in Geography, a town of Japan, in the island of Ximo; 12 miles W. of Tafiero.

SIA-KOH, a mountain of Persia, in the province of Irak; 50 miles E. N. E. of Kom.

SIAL, a small island near the coast of Egypt, which forms a harbour in the Red Sea. N. lat. 24° 30'. E. long. 35° 2'.

SIALACOORY, a town of Hindoostan, in Cochin; 30 miles N. E. of Cranganore.

SIALISMUS, formed from $\sigma\alpha\lambda\sigma$, saliva, a word used by the ancients to express a discharge of saliva, brought on by the holding hot things in the mouth; and by us for a salivaition by mercury.

SIALO, in Geography, a town on the E. coast of the island of Sibu. N. lat. 5° 53'. E. long. 123° 30'.

SIALOCHI, a term used by the ancients to express such persons as had a plentiful discharge of saliva, by whatever means. Hippocrates uses it for a person having a quinsy, who discharges a very large quantity of saliva. Others express by it persons, whose mouths naturally abound with a bitter saliva; and others, such persons as, from having a very large tongue, spit into people's faces while talking with them.

SIALAGOGUES, in Medicine, from $\sigma\alpha\lambda\sigma$, saliva, and $\gamma\nu\zeta$, I excite, comprehend all such medicines as increase the flow of saliva.

The sublubtes which operate upon the salivary glands, so as to excite them to pour out their fluid in increased quantities, are of two kinds; namely, those which may be called external, and which, when applied within the mouth, stimulate the excretories of saliva and mucus, opening thereby their acrid qualities; and those which are administered internally, and operate through the medium of the circulation.

It seems to be a salutary provision of nature, that when any acrid matter is applied to the sensible parts of the tongue and internal surface of the mouth, a quantity of saliva and mucus should be poured out to wash it off, or to defend those parts from its irritating effects. Whence, by the continued application of acrid substances, a considerable evacuation of the vessels of those parts is produced. By emptying the salivary glands and mucous follicles, they produce an afflux of fluids from all the neighbouring vessels to a considerable extent. Whence it will be readily understood, that these malacitories may relieve rheumatic congections, not only in the neighbouring parts, as in the case of tooth-ache, but also congections or inflammatory dispositions in any part of the head, supplied by the branches of the external carotid.

Many sublubtes are reforted to for this purpose, and chiefly the warm and acrid vegetables; indeed every sublubt that proves sharp and heating to the tongue, or internal surface of the mouth, will answer the end. The angelica is a mild and agreeable salagogue; the imperatoria more acrid; and the pyrethrum more acrid still, and therefore more commonly employed. Other sublubtes might be enumerated, but it may be enough to add, that a bit of fresh horse-radish root, held in the mouth, and chewed a little there, is as effectual as any.

The only medicine which we pollute, that is capable of exciting a flow of saliva when taken internally, is mercury. In its crude and simple Rate of quicksilver, however, it is perfectly inert, and exerts no influence whatever upon the living body, until it is oxidised, or combined with other materials. Its operation then, as Dr. Cullen has ably demonstrated, is not, as was formerly supposed, by any chemical action on the fluids of the body, by which they are attenuated, and thus made to pass off more readily through the excretory ducts; but by a general stimulant effect upon the vascular system, and especially upon the various excretories of it. When blood is drawn from a perfon under the full influence of mercury, it exhibits no appearance of any diminution of confluence; but, on the contrary, it is always found in the same condition as in inflammatory diseases.

It will not be necessary to enter into detail in this place respecting the mode of administering mercury as a salagogue, since that has already been done under the head of Lues venerea, for which disease principally it is exhibited. In this disease, indeed, as well as in diseases of the liver, in hydrocephalus, and some other maladies, it is not administered with a view to the evacuation from the salivary glands; its operation as a salagogue is rather looked upon as the pretext of its full influence on the constitution, than as the means of its remedial power. See Cullen, Materia Medica, part ii. chap. 17.

During the prevalence of a chemical theory, to which the discovery of the importance of oxygen in the animal economy gave rise, and when it was supposed that the nitric acid had been found to be a substitute for mercury in the cure of syphilis, it was even maintained that this acid acted in a similar manner upon the salivary glands, and was, in fact, a powerful salagogue. Farther experience, however, while it disproved the antirenal powers of this acid, disproved also its virtues as a salagogue, except indeed it might influence the excretory ducts of the glands externally, that is by its acrid qualities in the act of being swallowed.

SIALUSSEIB, in Geography, a town of the Arabian Irak, on the Euphrates; 8 miles E. of Sura.

SIAM, a country of Afa, the name of which is of uncertain origin; but probably derived from the Portugeuse, in whose orthography Siem and Siaö are the same; so that Siam, or Siang, might be preferable, as Loubere has suggested, to Siam; and the Portugeuse writers in Latin call the natives "Stones." The Siamese style themselves "Tai," or freemen, and their country "Meuang Tai," or the kingdom of freemen. The Portugeuse might possibly derive the name Siam from intercourse with the Pegueze. "Sian," however, is the oriental term. Before the recent extension and encroachments of the Birman empire, the rich and flourishing monarchy of Siam was regarded as the chief state of exterior India; but some of its limits are not now easily ascertained. On the west of the Malayan peninsula some few possessions may remain to the south of Tanaferim; and on the eastern side of that Cherifonne, Ligor may
may mark the boundary. On the west, a chain of mountains divides Siam, as formerly, from Pegu; but the northern province of Yunnan seems to belong to the Birmans, who extended their territory, in this part, to the river May-kang; and the limits may perhaps (says Pinkerton) be a small ridge running E. and W. above the river Anan. To the S. and E. the ancient boundaries are fixed; the ocean, and a chain of mountains, dividing Siam from Laos and Cambodia; so that, according to the ancient description of this kingdom, it may be considered as a large vale between two ridges of mountains. The northern boundaries, as defined by Loubere, evince that Siam has lost little in that quarter. His city Chiamai is probably Zamee, fifteen days' journey beyond the Siamee frontier. The northern limit is therefore at 19°, and not at 22°, as he erroneously states its latitude; and therefore the length of the kingdom may be about 10°, or near 700 British miles, and about one-half of this not above 70 miles in medial breadth. Or its admeasurement may be more accurately fixed from about 11° of N. lat. to 19°; being in length of about 550 British miles, by a breadth of 240.

This kingdom is divided into ten provinces, viz. Supthisa, Bancok, Porcelon, Pipili, Camphine, Rappri, Tanaferim, Ligor, Cambouri, and Concacea, each of which has its governor respectively. Of these provinces we have the following short notices. Bancok is situated above seven leagues from the sea, and in the Siamee language is called Fon. Its environs are embellished with delicious gardens that furnish the natives with fruit, which is their chief nourishment. See BANCOK.

Tanaferim is a province abounding in rice and fruit-trees; it has a safe and commodious harbour, admitting vessels of all nations; and in this province the people find more ample resources of subsistence than in the other parts of the monarchy. (See TANASEERM.) Cambouri, on the frontiers of Pegu, carries a considerable trade in the commodity called by the French eagle-wood, elephants' teeth, and horns of the rhinoceros. The finest varnish is also procured from this province. Ligor affords a kind of tin, called by the French celain, the celain of the Portugueze. (See LIGOR.)Porcelon was formerly a distinct sovereignty, and produces dyeing woods and precious gums.

The capital city of the kingdom has been called Siam, by the ignorance of Portugueze navigators. In the native language the name approaches to the European pronunciation of Yuthia, or Juthia; it is situated on an isle formed by the river Menam or Meniam. Its walls in Loubere's time were extensive; but not above a sixth part was inhabited. Its condition, since it was delivered from the Birman conquest in 1756, has not been derelied. The royal palace was on the north, and on the east there was a caufeway, affording the only free passage by land. Different quarters were inhabited by the Chinee, Japanee, Cochinchinee, Portugueze, and Malacca. The temples, pyramids, and royal palaces seem to have been much inferior in all respects to those of the Birmans. See JUTHIA.

The other chief towns in the Siamee dominions are Bancok, at the mouth of the Meniam, Ogmo, and others on the eastern coast of the gulf of Siam. On the western, D'Anville marks Cham, Cinii, and others as far as Ligor. Along the banks of the great river are Louvo and Poriclous, with others of inferior note. Louvo was a royal residence for a considerable part of the year. In general, these towns were only collections of hovels, sometimes surrounded with a wooden blockade, and rarely with a brick wall. In the south-west, Tanaferim and Merchul may be regarded as polleiffions belonging to the Birman empire, and the remaining fragment of the Siamee territory in that quarter presents no considerable town; though villages appear in Junkeylon and some of the other isles. Kemptner, in an account of his voyage to Japan in 1690, describes two remarkable edifices near the capital: the first is a famous pyramid, and called Puka Thon, erected for the commemoration of a victory obtained, on the spot where it stands to the N.W., over the king of Pegu. This magnificent structure is enclosed by a wall, and is 120 feet high, varying in form at its different stages, and terminating in a slender spire; the second edifice consists of two squares to the east of the city, surrounded by a wall, and separated by a channel of the river. These squares contain many temples, convents, chapels, and columns, particularly the temple of Berkam, with a grand gate ornamented with statues and various carvings; the other decorations appear by Kemptner's account to have been exquisite.

Our principal sources of information with regard to Siam are the publications of La Loubere, who went as ambassador from Louis XIV. to the king of Siam, and those of the French missionaries, of which, that from the papers of the bishop of Tabraca by Turpin, in 1771, is the most important. According to the account of the latter writer, the people of Laos and Pegu have established a considerable colony in Siam, since their countries were ravaged by the Birmans. Here are also many Malays, and the ancient kings had a guard of Japanese, which exhibits, in a striking point of view, the intercourse that subsisted among oriental nations.

With regard to the history of Siam, we shall content ourselves with observing, that previously to the Portuguese discoveries, this country was unknown to Europeans. According to Loubere's account, the first king of the Siamee commenced his reign in the year 1300 of their epoch, or about 756 years after the Christian era. Since the Portuguese discovery, their wars with Pegu, and occasional usurpations of the throne, constitute the principal topics of their history. In 1568 the Peguee king declared war on account of two white elephants, which the Siamee refused to surrender; and after prodigious slaughter on both sides, Siam became tributary to Pegu; but about the year 1626, raja Raji delivered his crown from this servitude. In 1680, Phacson, a Greek adventurer, being highly favoured by the king of Siam, opened an intercourse with France, for the purpose of supporting his ambitious designs; but they were punished by his decapitation in 1689, and the French connection was thus terminated. From Turpin, who has extended the history of Siam to the year 1770, we learn, that the first king began to reign about 1444 years before Christ, and that he had forty succedors before the epoch of the Portugueze discovery, or the year 1546, many of whom were precipitated from the throne on account of their depopulus. Nevertheless, these forty kings cannot be supposed to have reigned more than ten years each, at a mean computation, the first historical date cannot ascend beyond the year 1100 after Christ, instead of 1444 years B.C. One of the most remarkable events, after the French had evacuated Siam, is the war against the kingdom of Cambodia, which was reduced to the necessity of seeking the protection of Cochinchina. The Siamee army, having advanced too far into the country, was destroyed by famine; and their fleet, though it destroyed the town of Ponteams, with 200 tons of elephants' teeth, had little success. In 1760 a signal revolution happened in Siam, preceded by violent civil wars between two rival princes. According to Turpin's statement, the Birmans, a people of the kingdom of Ava, had, in 1754, languidified five years under the Peguee domination. Having lost by death their
their king, queen, and most of their princes, they lamented their humiliation and servitude, and anxiously fought for a deliverer. With this view they selected one of their companions, named Manlong, a gardener, who, singularly qualified for the office they devolved upon him, by corporeal and mental endowments, undertook to rescue them from the yoke of tyrants, on condition of their cutting off the heads of all the little feudatory tyrants whom the Peguene had sent to oppress them. They readily submitted to his terms; and after the massacre, Manlong was proclaimed king. Having prepared a force, and established a discipline which rendered the Birmans almost invincible, he began by the capture and complete ruin of the city and port of Siriam, which took place about the year 1759; and advancing to Martaban and Tavil, the new monarch received information of the riches of Siam, and formed the design of its conquest. He began by sending 30 ships to pillage the cities of Merghi and Ta-naferrim, and this success led him to flatter himself that he should be able, with great ease, to subdue the whole kingdom of Siam. The court of Siam, hearing of this irruption, sent to the bishop of Tabraca, to request that he would arm the Christians, who amounted only to the number of 100, and yet acquitted themselves with greater honour than the pusillanimous multitude. The Burman sovereign, being at the distance of three days' march from Yuthia, the capital, died in consequence of an abscess. The suburbs, however, on the Dutch quarter were ravaged and burnt; and the surrounding country was exposed to a thousand cruelties. The death of Manlong delivered the Siamese capital; the youngling of his sons having assumed the sceptre, found himself under the necessity of regaining his own kingdom, in order to stifle any revolt. The Siamese sovereign, however, having rashly pronounced a sentence of death against the favourite of his brother, was forced to abdicate the throne; and in consequence of this event he became a Talapoin, or monk, in May 1762, and many of his nobles followed his example. Siam remained in a state of insecurity, upon the report that the new prince of the Birmans had been dethroned upon his return to Ava; and that his elder brother, who had succeeded, had no wish to make conquests. This pacific monarch dying suddenly, a pretence was made of war was afforded by the affianced which the Siamese had given to a rebel Birman governor. In January 1765, the Birmans attacked Merghi and took it; and then proceeded to Tanaferin, which they reduced to ashes. Flushcd with success, the general of the Birmans marched against Yuthia, not doubting that the conquest of the capital would induce other cities to submit. The provinces on the north-west of the royal city were ravaged; and the inhabitants faved themselves from death or slavery by dispersion into forests, where they participated the food of wild beasts. The Siamese, threatened with speedy and total destruction, reunited their forces; but though they fought with ardour, their fanguinary defeat subjected their country to the power of their conquerors. The fields, ravaged by the confuming flames, presented nothing to them but ashes, and famine became more terrible than war. The victorious Birmans built, at the confluence of two rivers, a town, or rather a fortified station, which they called Mouchou. The Siamese, on their part, attempted to fortify the capital, and earnestly solicited the affianced of two English vessels which happened to arrive. The captain of one of them confessed to defend the capital, on condition of being supplied with cannon and ammunition: but the jealous Siamese informed that he should first lodge his merchandise in the public magazine. With this condition he complied, and going on board his ship, harried the enemy, and destroyed their forts, so that every day was marked either by their defeat or flight. But demanding more ammunition, the daftardly court became afraid, that the English captain, with his single ship, would conquer this ancient monarchy. Its indignant captain withdrew, after feizing fix Chinefe vessels, whose officers received from him orders upon the king of Siam to the amount of the merchandizes which had been lodged in the public treafury. Upon his retreat, the Birman, finding nooppofition,spread universal deforation, and configned even their temples to the flames. Instead of recurring to arms, the superfluous monarch and his miniflers repofed their whole confidence in their magicians. A Siamefe prince, indeed, who had been banifhed to Ceylon, railed a little army, and returned to the affianced of his couniry; but the diftracted court of Siam fent forces to oppofe their deliverer. Many of the Siamese, forcibly provoked by this conduct, joined the Birman, who in March 1766 again advanced, after having been repulfed by the English captain, to within two leagues of the capital. In September 1766, the Birman feized a high tower, at the di- fame of about a quarter of a mile from the city, and railed a battery of cannon, which gave them an absolute command of the river. In this state of urgent danger, 6000 Chinefs were charged with the defence of the Dutch factory, and of a large adjacent temple. The Birman, in confequence of previous skirmishes and a fubsequent affault, feized on five considerable temples, which they converted into fortresses; but in another affault they were compelled to retire. The Siamese officers, eager to secure the magazines of grain, as a future refeurce, produced an immediate famine; which, followed by a contagious disorder or pestilence, occasioned the most dreadful devastation. The Dutch factory was in vain defend by the Portuguefe and Chinefe; and after a siege of eight days, it was taken and reduced to ashes. The whole Chrif- taium quarter of the city shared the fame fate; and the virgins were obliged to marry the firft young men that prefented themselves, in order to be protected by the matrimonial tire, which the Birman reverenced. The Birman, demanding an unconditional surrender, affaulted the city, and captured it on the 28th of April 1767. The wealth of the palaces and temples was consumed by the flames, or abandoned to the foidiers. The golden idols were melted; and the victors, finding that their avarice had been facrificed to their fury, recurred to acts of violation and cruelty. The great officers of the kingdom were loaden with irons, and condemned to the galleries. The king, attempting to escape, was maffacred at the gate of his palace. When nothing remained for thefe conquerors to deftoy, they refumed their march to Pegu, accompanied, among other captives, with the remaining princes and princes of the royal blood of Siam. In June the Birman quitted Siam, after having burnt the town of Michoug, soon after its construction. When the Birman evacuated their conquer, the Siamese flued from their forests, and superflitiously directed their first rage against their gods, for having abandoned them to a defeuctive enemy. Availing themselves of the wealth which accrued from the fluates, filled by superflitious perfons with gold and fliver, who expected to find them when they re- visited this world, they proceeded to elect a leader; and Phaiba-Thae, an officer of acknowledged ability, was the object of their choice. This new prince displayed considerable bravery and talents; and in the year 1768 suppressed a rebellion that was infligated against him. The Birman in vain attempted to renew their incursions into the Siamese terri- tory: they were repulfed, and afterwards obliged to turn their arms against the Chinefe, who were defeated in their turn. For further particulars with regard to the history of Siam, see Birman Empire. Indeed, if the Birman empire
maintains its present extent, Siam, we can have little doubt, will ere long be deprived of its independence. But it is an event not, perhaps, less probable, that the Birman empire itself will fall into confusion, and be dismembered.

Everything we are told respecting the government, the laws, the literature, the arts, and personal qualities of the Siamese, indicates a corresponding state of advancement with that of the Birman. That the religion of the Siamese is the same with that of the Birman, and derived from the same origin as that of the Hindus, there seems to be sufficient evidence. Sommone-Codam, mentioned by Loubere as the chief idol of Siam, is interpreted by competent judges to be the same with the Boodel of Hindoostan. The sacred language called Bal is of the same origin; the most esteemed book feems to be the Vinae, and the precepts of morality are chiefly five; viz. not to kill, not to steal, not to commit uncleanness, not to lie, and not to drink any intoxicating liquor. Loubere has given a translation of a more minute code of morals, chiefly compiled for the use of persons dedicated to religion, whom he calls Talapoins. Their laws are said to be in high reputation all over the East; and it is not certain, whether, like those of the Birman, they are of Hindoo, or of indigenous origin. Their system of legislation is represented by all writers on this country, as extremely severe in its functions; death or mutilation being punishments of unimportant offences. The Siamese imitate the Chinefe in their festival of the dead; and in some other of their rites. The government of Siam is despotic, and the sovereign, as among the Birman, is revered with honours almost divine. The succession to the crown is hereditary in the male line. The population has not been accurately ascertained, nor have we any documents for this purpose. Allowing to the Birman empire more than fourteen millions, as some have stated, the Siamese dominions may probably be peopled by about eight millions. However, Loubere affirms us in his time, that from actual enumeration, there were only found, of men, women, and children, 1,900,000. Loubere says that the Siamese had no army, except a few royal guards; but Mandello; the army, which may be occasionally raised, at 60,000, with no less than 3000 or 4000 elephants. The navy is composed of a number of vessels of various sizes, which display a singular fantastic elegance, like those of the Birman; and naval engagements frequently occur. The revenues of this sovereignty are of uncertain computation. Mandello describes them as arising from the third of all inheritances, from trade, conducted by royal agents, annual presents from the governors of provinces, duties imposed on commerce, and the discovery of gold, which seems to be a royal claim. Tin is also a royal metal, except that found in junkleyon, which is abandoned to the adventurers. Loubere adds a kind of land tax, and other particulars, among which is the royal domain.

Siam appeared to the French, in the reign of Louis XIV., to be of considerable political importance; for this monarch was ambitious of forming permanent settlements, by rendering it a rich part of Indian commerce. If we had any apprehension that the Birman would become dangerous to our possessions in Bengal, our alliance with Siam might be highly serviceable. In a merely commercial point of view, it may be difficult to preserve the friendship of both the Birman and the Siamese, it is not easy to determine from which state superior advantages might be derived. If directed by European policy, Siam would form strict alliances with the more eastern states of exterior India, as a common defence against the growing preponderance of the Birman.

As to the manners and customs of the Siamese, as they have embraced a branch of Hindoo faith, they are rather Hindoo than Chinefe; though its situation is central between the vast countries of China and Hindooistan. Loubere has given a detailed account of the Siamese manners. The females are under few restraints, and marry at an early age, and are past parturition at forty. Marriages are conducted by female mediators, and a priest or magician is usually consulted concerning the propriety of an alliance. On the third visit the parties are considered as wedded, after the exchange of a few presents, without any further ceremony, civil or sacred. Polygamy is allowed, more from affection than any other motive; and one wife is always acknowledged as supreme. Royal marriages, from considerations of pride, are sometimes incestuous; nor does a king hesitate to elope with his own sister. Divorce is seldom practiced; but the rich may chuse a more compliant wife without disdaining the former. Few women become nuns, till they are advanced in years. The Siamese funerals resemble those of the Chinefe. On this occasion, the Talapoin sing hymns in the Bal tongue. After a solemn procession the body is burnt on a funeral pile of precious woods, erected near some temple; and the magnificence of the spectacle is enhanced by theatrical exhibitions, in which the Siamese are said to excel. The tombs are pyramidal, and those of the kings are large and lofty. The common food of the Siamese consists of rice and fish; they also eat lizards, rats, and several kinds of insects. The buffaloes yield rich milk; but butter would melt and become rancid; and cheese is unknown.

In Siam little animal food is used; the mutton and beef being very bad. The doctrine of the Boodel inspires the Siamese with horror at the effusion of blood. The houfe is small, and constructed of bamboo, upon pillars, in order to guard against inundations, which are common. The palaces only exceed common habitations by occupying a wider space, and being constructed of timber, with a few ornaments. They are also more elevated, but have never more than one floor. With regard to their perfumes, the Siamese are rather small, but well made. The figure of the countenance, says Kamper, both of men and women, has less of the oval than of the lozenge form, being broad, and raised at the top of the cheeks; and the forehead suddenly contracts, and is almost as pointed as the chin. Their eyes, rising towards the temples, are small and dull; and the sublim is commonly completely yellow. Their cheeks are hollow; mouths very large, with thick pale lips, and teeth blackened by art; the complexion coarle, brown mixed with red, to which the climate greatly contributes. From this description the Siamese appear to be much inferior in personal appearance to the Birman, and to approach rather to the Tartar or Chinefe features.

The dress of the Siamese is slight, clothes being rendered almost unnecessary by the warmth of the climate. A muffin shirt, with wide sleeves, and a kind of short drawers, are almost the only garments of the rich, a mantle being added in winter, and a high conie cap upon the head. The women use a scarf instead of the skirt, and the petticoat is of painted calico; but with this slight dress they are extremely modil.

The Siamese are said to excel in theatrical amusements; the subjects being taken from their mythology, and from traditions concerning their ancient heroes. Their ordinary amusements consist of races of oxen, and those of boats, the combats of elephants, cock-fighting, tumbling, wrestling, and rope-dancing, religious processions, illuminations, and beautiful exhibitions of fire-works. The men are generally very indolent, and fond of games of chance; while the
the women are employed in works of industry. Although the Siamese are indolent, they are ingenious, and some of their manufactures deserve praise; nevertheless, the ruinous and depopulous avarice of the government crushes industry by the uncertainty of property. They are little skilled in the fabrication of iron or steel, but excel in that of gold, and sometimes in miniature painting. The common people are mostly occupied in procuring fish for their daily food, while the superior classes are engaged in a trifling traffic.

The language of the Siamese, called "THAY," according to Dr. Leyden's account of it (Asiaitic Researches, vol. x. p. 244.), appears to be in a great measure original; but there is reason to conjecture, that it is not different from that of the Burmans. To this purpose it is alleged, that Siamese dramatists used to perform in the Burman dominions, which is not probable, unless the language were common. Dr. Leyden says, that it is more purely monosyllabic, and more powerfully accented, than any of the Indo-Chinese languages. It certainly is connected, in some degree, with some of the Chinese dialects; especially the Mandarin or Court language, with which its numerals, as well as some of its terms, coincide, but these are not very numerous.

It borrows words freely from the Bali, but contrasts and disguises more the terms which it adopts, than either the Ruk'heng or the Barma. In its finely modulated intonations of sound, in its expression of the rank of the speaker, by the simple pronouns which he uses, in the copiousness of the language of civility, and the mode of expressing esteem and adulation, this language resembles the Chinese dialects, with which also it coincides more nearly in construction than either Barma or Ruk'heng. Its construction is simple and artificial, depending almost solely on the principle of juxta-position. Relative pronouns are not in the language; the nominative regularly precedes the verb, and the verb precedes the case which it governs. When two substantives come together, the last of them is for the most part supposed to be in the genitive. This idiom is confonant to the Malayu, though not to the Barma or Ruk'heng, in which, as in English, the first substantive has a possessive signification. Thus, the phrase, a man's head, is expressed in Barma and Ruk'heng, by lu-k'haung, which is literally man-head; but, in Siamese, it is kwa-thon, and in Malayu, kapala orang, both of which are literally head-man. A similar difference occurs in the position of the accusative with an active verb, which cafe in Barma and Malayu generally precedes the verb, as tumming cha, literally rice eat; but in Siamese follows it, as ken kau, literally eat rice, which corresponds to the Malayu, makan-nap. The adjective generally follows the substantive, and the adverb the word which it modifies, whether adjective or verb. Whenever the name of an animal, and, in general, when that of a species or clafs, is mentioned, the generic, or more general name of the genus to which it belongs, is repeated with it, as often happens in the other monosyllabic languages, as well as in the Malayu. In the position of the adverbial particle, the Malayu often differs from the Siamese; as Mana parji, literally where go, but in Siamese, tai hnei, go where. The Siamese composition is also, like that of the Barma, a species of measured prose, regulated solely by the accent and the parallelism of the members of the sentence; but in the recitative the Siamese approaches more nearly to the Chinefe mode of recitation, and becomes a kind of chant, which different Brahmins altered Dr. Leyden is very similar to the mode of chanting the Samaveda.

The THAY coincides occasionally, even in simple terms, both with the Barma and Malayu; but these terms bear to small a proportion to the mass of the language, that they seem rather the effect of accident or mixture, than of original connection.

The THAY or Siamese alphabet differs considerably in the power of its characters from the Bali; though it not only has a general semblance to it in point of form, but also in the arrangement of the character. The vowels, which are twenty in number, are not represented by separate characters, but by the character corresponding to the short shar, variously accented; excepting the vocalic ru and lu, which are only variations of the r and l consonants.

The confonants are thirty-seven in number, and are not arranged by the series of five, like the Deva-nagari and Bali, but the first series, ka, consists of seven letters; the second series, cha, of six; the third series, ta or da, of six; the fourth series, ba or pa, of eight; the fifth series, ja, of four; and the last series, ja, of six, including the vocalic akar, though two of them are not in common use. Each of these letters is varied by fourteen or more accentuations, and by thirty-five or more complex ones. The letters ka, nga, ta, or da, na, ma, ba or pa, are also final confonants. Hence it is easy to perceive the near approximation of the Siamese to the delicacy of the Chinefe accentuation; while in other respects, the alphabet is considerably more perfect, than in the Mandarin or Court language of the Chinefe, which has neither the same variety of confonants, nor admits so many, in the close of a syllable. The Siamese pronunciation, even of confonants, corresponds very imperfectly to the European mode; r and l are generally pronounced n in the close of a syllable; b is often prefixed to a confonant; but from the total suspension of the voice in pronouncing syllables which terminate in a confonant, no aspiration can be pronounced after them; ma and ba, tya and chya, are often difficult to be distinguished in pronunciation, as are ya and ja, kyé and chyé, with other combinations. From this circumstance, many combinations of letters are pronounced in a manner somewhat different from that in which they are written.

The first European who attempted the study of Siamese literature, was the learned Gervaife, but his labours have never been published. The learned indefatigable Hyde procured from the Siamese ambassador at London, an imperfect copy of the Siamese alphabet, which has been published by Greg. Sharpe, in the "Syntagma Dissertatium," 1767. It is inferior to Loubere's alphabet in accuracy, though it contains a greater number of compound characters. Loubere's alphabet contains three forms of the ja, corresponding to the Nagari; but the ja and ja la, being diffused in common pronunciation, are commonly omitted both in the alphabet and in modern MSS.

The Siamese or THAY language contains a great variety of compositions of every species. Their poems and songs are very numerous, as are their Cheritras, or historical and mythological fables. Many of the Siamese princes have been celebrated for their poetical powers, and several of their historical and moral compositions are still preferred. In all their compositions, they either affect a plain simple narrative, or an unconnected and abrupt style of short, pithy sentences, of much meaning. The books of medicine are reckoned of considerable antiquity. Both in science and poetry, those who affect learning and elegance of composition, sprinkle their style copiously with Bali. The laws of Siam are celebrated all over the East, and La Loubere has mentioned three works of superior reputation, the Pra-Tam-non, the Pra-Tam-Ra, and the Pra-Raja-Kam-manot. Of these, the first is a collection of the institutions of the ancient kings of Siam; the second is the constitutional code of
of the kingdom, and contains the names, functions, and prerogatives of all the officers; the third, which is about 150 years old, contains additional regulations. Of these, the first is the most celebrated and the most deserving the attention of Europeans.

The Thay exhibits considerable variety of measures in composition, and frequently introduces several of them in the same manner as is frequently done in Brij'hi, Punjabi, and Sik'h compositions. The most frequent measure, however, among the Thay, as among the Ruk'hong and Barma, seems to be that determined rap, which consists of four long syllables, but admits occasionally of one or more intercalary short ones: the Jâni, which consists of five syllables, the Chô-bang of six, the Pat'tamang of seven, the Jefauta of eight, are also frequently employed. The Siamese are not deficient in literature, and their modes of education are well explained by Loubere.

From Mandello we learn, that the commerce of the capital of Siam consisted in cloths imported from Hindooftan, and various articles from China; in exports of jewelled, gold, benjoin, lacca, wax, tin, lead, &c. and particularly deer-skins, of which more than 150,000 were fold annually to the Japanese. Rice was also exported in great quantities to the Asiatic islands. The king was a ruinous policy, the chief merchant, and had factors in most of the neighbouring countries. The royal trade consisted in cotton cloths, tin, ivory, salt-petre, rack, and skins fold to the Dutch. A late writer informs us, that the productions of this country are prodigious quantities of grain, cotton, benzamin; sandal, aquello, and Japan woods; antimony, tin, lead, iron, load-tones, gold, and silver; sapphires, emeralds, agates, crystal; marble, and tambac. Siam, in respect of fertility, loco-position, and productive labour, possesses commercial advantages of the same nature with those of the Birman empire; but on the coast at least, the climate is far from being healthy.

The two first months of the Siamese year, corresponding with our December and January, form their whole winter; the third, fourth, and fifth, belong to that portion which is called their little summer; and the seven others to their great summer. As they lie north of the line, their winter corresponds with our's, but it is almost as warm as a French summer. The little summer is their spring; autumn is unknown in their calendar; the winter is dry, and is distinguished by the course of the wind, which almost constantly blows from the north, and is refreshed with cold from the snowy mountains of Thibet, and the bleak wates of Mongolia.

We have already described this country as a wide vale between two high ridges of mountains; but compared with the Birman empire, the cultivated land is not above half the extent either in breadth or length. Less insidious than the Birman, the agriculture of the Siamese does not extend far from the banks of the river, or its branches; so that towards the mountains there are vast aboriginal forests filled with wild animals, whence they obtain the skins which are exported. The rocky and variegated shores of the noble gulf of Siam, and the lize and inundations of the Meinam, confine with the rich and picturesque vegetation of the forets, illuminated at night with crowds of brilliant fireflies, to impress strangers with admiration and delight.

The soil towards the mountains is parched and infertile; but on the slopes of the river confines, like that of Egypt, of a very rich and pure mould, in which a pebble can scarcely be found; and the country would be a terrestrial paradise, if its government were not so despotic as to be justly reckoned far inferior to that of their neighbours the Birmans. Rice of excellent quality is the chief product of their agriculture; wheat is not unknown; peas and other vegetables abound; and maize is confined to their gardens. The fertility of Siam depends in a great degree, like that of Egypt on the Nile, on their grand river Meinam, and its contributory streams; for an account of which, see MEINAM.

Of the lakes of this country little is known: a small one, however, lies in the east of the kingdom, which is the source of a river that flows into that of Cambodia. To its extensive ranges of mountains, including the kingdom on the east and west, we have already referred. A small ridge also passes from east to west, not far north of Yuthia, called by Loubere Taramamon. The forests of the country are large and numerous, and produce many valuable woods. Its chief animals are elephants, buffaloes, and deer. The elephants in particular are distinguished for their fragacity and beauty; and those of a white colour are treated by the Siamese with a kind of adoration, as they believe the soul of such is royal. Wild boars, tigers, and monkeys, are numerous. The reports of the mineralogy of Siam are various. Mandello, or rather his translator Wiequefort, who added, about the year 1670, the accounts of Pegu, Siam, Japan, &c. informs us, that Siam contains mines of gold, silver, tin, and copper; and Loubere suggests, that they were anciently more diligently wrought, as the ancient pits indicate; not to mention the great quantity of gold, which must have been employed in richly gilding the idols, pillars, cirelions, and even roofs of their temples. In his time no mine of gold or silver, worth the labour of being wrought, could be found. The mines chiefly wrought by the Siamese were those of tin and lead. The tin, called "calin" by the Portugueze, was sold throughout the Indies; but it was soft and ill refined. Near Louvo was a mountain of load-tones, and another of inferior quality in Junkfionlon; which see. Pinkerton'sGeog. vol. ii.

The Siamese, though of a melancholy turn, have no objection to lively music. They have often parties on the water, which they render very pleasant by a number of voices, and the clapping of hands, with which they beat time.

The instrument in the highest favour with them produces a found similar to two violins perfectly in tune, played at the same time. But there is nothing more disagreeable than its diminutive, the kit of this instrument, which is a kind of rebecc, or violin with three brass strings.

Their copper trumpets very much resemble, in tone, the cornets with which the peafants of France call their cows. Their flutes are not much sweeter. They make likewise a kind of cornet with small bells, which are lively, and not disagreeable, when not accompanied by their iron drum, which is made by every one that is not accustomed to its noisy harshness. They have drums made of terra cotta, a baked clay, with a long and very narrow neck, but open at the bottom: they cover the drum with a buffaloe's hide, and beat it with the hand in such a manner, that it serves for a bass in their concerts. Their voices are not disagreeable, and if we were to hear them sing some of their airs, we should not be displeased. Laborde.

Siam, a name sometimes given to the country above described. See JUTHIA, and the preceding article.

Siam, Gulf of, a large bay of the East Indian sea, between Cambodia and the peninsula of Malacca, having to the north Siam.

SIAMODEL, a town of Hindooftan, in the Carnatic; 13 miles N. of Nellore.

SIAMPA. See CHIAMPLA.
SIA, S. of Cio, a town of Africa, in Melinda.
SICANAS, a town of South America, in the province of Tucuman; 30 miles E.S.E. of St. Salvador de Jugui.
SIANDUPADA, a town of Hindooftan, in Myfore; 13 miles S.W. of Bangalore.
SIANELLY, a town of Hindooftan, in Myfore; 13 miles S.W. of Bangalore.
SIANG, a city of China, of the second rank, in Quang-fi. N. lat. 23° 58'. E. long. 109° 08'.
SIANG-CHAN, a town of China, of the third rank, in Tche-kiang; 25 miles S.E. of Ning-po.
SIANG-HIAN, a town of China, of the third rank, in Hou-quang; 40 miles S.W. of Tchang-techa.
SIANG-TAN, a town of China, of the third rank, in Cban-fi; 20 miles S.E. of Tsing.
SIANG-YANG, a town of Corea; 28 miles N.N.W. of San-pou.
SIANG-YANG, a city of China, of the first rank, in Hou-quang, on the river Han. N. lat. 32° 5'. E. long. 111° 39'.
SIANG-YN, a town of China, of the third rank, in Hou-quang, on the Heng river; 27 miles N.N.W. of Tcheng-techa.
SIANKE, or SYNKE, in Natural History, a name given by the people of some parts of the East Indies to the Caryophyllus, or clove-hipace. The people of the Moluccas, according to Garcias, call it change, which is only a small difference of pronunciation. The Turks and Persians call the same spice calafur.
SIAO, in Geography, a town of China, of the third rank, in Kiang-nan; 22 miles W. of Pefu.
SIAO, an island in the East Indian arch, about 30 miles in circuit, which belongs to the sultan of Ternate. The Dutch maintain in this island a corporal, a few soldiers, and a school-master for the instruction of the children of the natives. It abounds with provisions. N. lat. 20° 44'. E. long. 125° 5'.
SIAO-CHAN, a town of China, of the third rank, in Tche-kiang; 17 miles N.W. of Chiao-king.
SIAO-HE-CHAN, a small island near the coast of China. N. lat. 37° 54'. E. long. 120° 34'.
SIAO-HO-TCHAN, a town of Chinefe Tartary. N. lat. 41° 43'. E. long. 121° 42'.
SIAO-NON-HOTUN, a town of Chinefe Tartary. N. lat. 41° 24'. E. long. 126° 53'.
SIAO-PI-HOTUN, a town of Corea. N. lat. 40° 24'. E. long. 125° 26'.
SIAO-TEIN, a river of China, which runs into the Eastern sea, N. lat. 37° 21'. E. long. 118° 41'.
SIARA, a small town of Braili, and capital of a district or captaincy of the same name, so called from a river which rises in the mountains, and discharges itself into the ocean in S. lat. 5° 30'. The captaincy is small, not being above 54 miles in compass. It has two fortresses, one on the north, joining to the town of Siara, and situated on a small hill on the right side of the haven, which is so shallow as to admit only small vessels; and the other, called Fort St. Luke, situated on the coast, at the mouth of a small river, navigable only by barges. This district abounds in cotton, fugar, tobacco, and Braili wood, the usual food of the country. The trade of the town, consisting chiefly of fugar and tobacco, is incomconsiderable. S. lat. 3° 15'. W. long. 39° 46'.
SIARDEHUI, a town of Hindooftan, in the Carnatic; 8 miles N.E. of Uedgeserry.
SIARMAN, a town of Peruia, in the province of Ma-
SIB

25. t. 6. f. 1. Scotch Cinquefoil: Petiv. Herb. Brit. t. 41. f. 7.)—Leaves wedge-shaped, three-toothed.—Native of the summits of the highest mountains of Lapland, Scotland, Switzerland, Siberia, and North America. Tournefort gathered it also in Cappadocia. The plant thrives best in a mouldering mucaceous soil, flowering in June and July. The root is perennial and woody, throwing out many short, spreading, leafy, herbaceous, round, downy stems, which are slightly branched, and procumbent, except sometimes at their flowering extremities. Leaves on long stalks, whose base bears a pair of oblong, acute filipula, like those of a rofe; their leaflets three, on short partial stalks, wedge-shaped, inclining to ovate, green, hairy, entire, except their three large terminal teeth. Flowers in small terminal leafy corymbs, inconspicuous, with minute yellow petals and filaments, inserted into the thickened rim of the green leafy calyx. Seeds dry, hairy. We have noticed in Fl. Lapp. that Plukkenet's t. 212. f. 3, cited by Linnaeus, and recently copied by Pursh, belongs rather to the Pentaphylloides pubescent; nor does this figure, in essential points, resemble our Sibbaldia.

3. S. alata. Large-flowered Sibbaldia. Linn. Suppl. 191. Willd. n. 3. "Pall. Act. Petrop. for 1773. 526. t. 18. f. 2." (S. n. 42. var. j.; Gmel. Sib. v. 3. 187.)—Leaves in numerous linear segments. Stems slightly branched. Petals roundish-heart-shaped.—Found by Pallas very abundantly on the rocks of Dauria. The flowers are but about three inches high, slender, often simple, and slightly leafy. Flowers, especially their petals, three or four times the size of the leaf, of which neither the sepals nor at one time Pallas himself, thought this plant a variety.

SIBBENDS, or SIVVENS, in Medicine, an infectious disease, of a chronic nature, somewhat resembling lycophyll, prevalent in the western parts of Scotland. It is said to be too denominated from the appearance of a fungous exudation from some of the cutaneous foetor, not unlike a raspberry; the word filben, or fevin, being the Highland appellation for a wild raspberry. Whence it has also been sometimes confounded with the yaw, a disease of the Highland climates, brought from Africa, and so denominated by the Negroes from the same fruit. See FRAMBOISE and YAW.

This malady is not of ancient date in Scotland. The first writer on the subject was Dr. Gilchrist, who, in the year 1765, distributed a short description of the filben among the people of Ayrshire, which was afterwards published by the Philosophical Society of Edinburgh. (See Essays and Observations Physical and Literary, vol. iii. art. 11.) According to tradition in the Highlands, the disease was introduced there by the soldiers of Oliver Cromwell, who laboured under the venereal disease, when garrisoned in that country. From thence it is said to have been carried to Dumfries by a party of soldiers, who had been stationed in the north Highlands; and it is perfectly ascertained, according to Dr. Paterson, that it was introduced into Ayrshire, about the year 1745, by people who went thither from Dumfries to buy cattle. Since that period, it has constantly prevailed in different places in that district, sometimes at different times; sometimes abating so much, both in virulence and frequency of occurrence, as to give hopes that it would entirely disappear; then breaking out again with greater violence, generally in the harvest season, and spreading over several parishes. (See Dr. Paterson's Letter, in Beddoes's Contributions to Physical and Medical Knowledge, p. 408.) At its first appearance, it occasioned little uneasiness or apprehension to those affected with it; but it was soon discovered to be a formidable disease, resembling in character the venereal disease, and to be propagated extensively by its contagion, insomuch that, as Dr. Gilchrist expresses it, "great are the perplexity and diffrets, the suppuration and terror, caused by it, wherever it comes; and hitherto nothing has been able to prevent the spreading of it." The disease differs, however, materially from incurable venereal, though it is cured by the same remedy; the poison being introduced into the system not through the medium of the organs of generation, but commonly by the mouth and throat, in which the primary ulcerations occur.

The filben is almost always begins with an inflammation of the throat, fist on the uvula and velum pendulum of the palate, and afterwards on the tonsils, of a dark red colour, which is succeeded in one or two days, and sometimes so late as to end, by small pimples, or vesicles, which terminate in ulcers, with a white surface, and red abrupt edges. There is often also an aphthous appearance, or a series of white specks and floghs, upon the roof of the mouth, and inside the cheeks and lips, which commonly fills itself also at the corners of the mouth, in a small rising of the skin, of a pearl or whey-colour; upon which part also a small fungous excrecence often appears, not unlike a raspberry, which changes to a scab, and is a pretty sure sign of the disease, although there be no aphthae or sore throat. The uvula is sometimes destroyed by the ulceration; and children at the breast, when thus affected in the mouth and throat, have perished from hunger, not being able to suck or swallow.

In a little time the constitution is contaminated by the absorption of the poison, and a series of secondary symptoms appears. In some, and especially in adult persons, dark red spots, or sometimes fungous excrecences, arise about the anus and perineum, which gradually increase and ulcerate. But the most common appearances are eruptions of a pustular character on the skin, containing, however, little fluid, and soon terminating in a dry scab, surrounded by a livid margin, and ultimately in ulceration. In some, and especially in children, these eruptions occupy chiefly the belly, groins, and sides, and are sometimes seen on the face. The ulcers, into which they pass, usually make but small progress, not exceeding in general the point of the finger in size, and being irregular in their forms, and pretty clean, with slightly inflamed edges. In some instances, however, they have been seen to become confluent, and to unite into one large foul ulcer over a great part of the abdomen, exhibiting a most intolerable and peculiar stench. In some children, indeed, the whole scalp has gauged, and the ears have nearly fallen off. Smaller ulcers have also formed on the breast and face, covered with a purulent flogh, remaining inert, without pain or inflammation, and seldom increasing in size.

In other cases, where the primary symptoms have been moderate,
SIBBENS.

moderate, and have subsided, the secondary symptoms, affecting the skin superficially, assume different forms. The whole surface of the body, Dr. Gilchriff says, has been observed to be mottled, of a dusky copper colour, or a dirty hue, as the discolorations of the skin in this disease commonly are. Infants of the month have had a redness in the lower part of the belly, buttocks, thighs, and part of the legs, where sometimes it terminates abruptly in a ring. In some of these there was an inflammation, and a watery film covering the pudenda. A more certain appearance in such subjects somewhat older are broad red patches, as large as the palm of the hand, over all the trunk, as well as the limbs, attended with inflammation. A cluster, or clusters, of small pustules come out; the skin grows dry, and peels off, leaving a new tender skin beneath; and this will happen a great many times, sometimes in one place, sometimes in another. Scabous eruptions are often met with on the scalp, forehead, inside of the thighs, groins, and parts contiguous; where frequently small hardnecsses, rising just within the skin, excite a very troublesome itching. Besides the inflammation and excrences about the fundament already noticed, other appearances of the disease present themselves on the breast, shoulders, and elsewhere, especially a sort of herpes exudens, or spreading tetter, healing in one part, while it breaks out in another adjoining, and leaving a great deformity of the skin, after it cicatrizes. In a few cases, an eruption of tubercles occurs upon the face, rather numerous, and in figure and size resembling the small-pox at the height, but being of a reddish colour. These are attended with great heat and tumour of the face, so as sometimes to close up the eyes. In some cases they have spread thickly over the whole body, and suppurred, not unlike the confluent small-pox, and have even proved fatal, as the swelling subsided; but in others, when not so numerous, they gradually decay, without coming to suppuration. In some persons there is a swelling of the surface, without any appearance of tubercles; in which case, the cuticle exfoliates from time to time in fine white reticulated flakes, as often as it is renewed. In other cases, tubercles arise from small bright red spots, of a more intense redness than those just mentioned, which in some places become confluent, and form a flat smooth elevation, which soon becomes of the usual colour of the skin, and sometimes slightly ulcerates. The face, too, is often affected with different kinds of eruption, sometimes alone, and sometimes together with the rest of the body.

Where the disease assumes still greater malignity, larger boils appear dispersed over the arms, shoulders, face, legs, and feet, which suppurate, and form ulcers, which penetrate to the muscular parts, laying them quite bare, and seeming even to corrode them superficially. These ulcerations are of a high florid colour, with scarcely any discharge upon their surface, except a little ichor, which renders them exquisitely tender and painful, and scarcely bear- ing the mildest applications. Their edges are hard and ragged, their size various, and their appearance very malignant; so that Dr. Gilchriff says, when viewed finely, they might have been mistaken for real cancers; but the number of them, the manner of their coming out, and other circumstances, soon determine the disease to which they belong.

There is one symptom, not yet particularly described, but from which the disease takes its name, which remains to be mentioned. An itchy tetter, or a sort of ring-worm, breaks out in a circular form, which either spontaneously, or from being scratched, becomes raw and excreted, and does not scab, but continues to ooze out an ichorous hu-
pipe in soaking. When the body is warm, and the pores open, the tender skin of the lips and mouth is most disposed to receive the infection, which the heat, in labouring, will render more active and apt to be communicated. A girl, who had the thral to a great degree, at this season, spread the disease through a whole parish, where it was not formerly known."

Contagions of this sort are not usually communicable by effluvia; but it seems to be believed, by those who have witnessed the progress of fibbens, that it may be propagated without actual contact. Dr. Gilchrist says, "nor is it unlikely, that, in certain circumstances, the breath may become infectious!" implying, however, his want of positive evidence on the subject. But Dr. Paterfon afferts, that "it is perfectly ascertained, that the breath of people, labouring under the sore throat, is loaded with infection, and communicates the disease, without the contact of ulcers." Beddoes' Contributions, loc. cit.

It will be obvious, from the preceding detail of the symptoms and causes of fibbens, that it is the result of a morbid poison, operating first locally, and afterwards constitutionally, and producing phenomena exceedingly analogous to those of the venereal disease. There is also the farther analogy, as we shall see, that the cure is effected principally, if not exclusively, by mercury: whence several writers, and apparently Dr. Gilchrist among the rest, have deemed it a modification of syphilis. It was soon discovered, says this writer, "to be of the venereal kind, or the soul disease." Dr. Paterfon, however, has pointed out several circumstances which mark a difference between the two. In the first place, he observes, the venereal disease was common in Scotland long before the fibbens appeared; and he had never been able to trace the latter to any person affected with syphilis. Secondly, it is much more infectious than common syphilis, for it seldom gets into a family without infecting every person in it, and frequently spreads rapidly over a village. If the common lues were to spread in a similar manner, its progress in all large towns would be truly dreadful. Thirdly, the fibbens is a more purely cutaneous or superficial affection than the common lues, for it very rarely indeed occasions buboes, and almost never affects the large bones. And, lastly, the fibbens is much more readily cured than the ordinary form of syphilis; for a much less quantity of mercury removes blisters and extensive ulcers, than is required to cure the secondary symptoms of syphilis, contracted in the ordinary manner. Its ordinary commencement in the organs of deglutition, and its never appearing in a primary form on the genital, nor being propagated by contagion, appear also to establish a distinction between the two maladies.

Cure of Fibbens.—We have partly anticipated this subject in the preceding paragraph, where we have stated that mercury is found to be the specific remedy. It appears that, like syphilis, the disease is perhaps never cured by the unassisted efforts of the constitution; and that mercury, as in the other affection, does not fail to cure it, except in those deplorable cases, where, from the long continuance of the disease, hectic symptoms have come on, and the constitution is so broken down as to be unable to bear the remedy.

It seems to be a well ascertained fact, that, of all the preparations of mercury, the corrosive sublimate, or oxymuriate, is the most adapted for the cure of fibbens; that is, it cures it more speedily, and with equal certainty with any other mercurial preparation. This circumstance also constitutes a point of distinction between the two maladies, and may serve, according to Dr. Paterfon's suggestion, from the fibbens being a more superficial or cutaneous affection than syphilis. Dr. Gilchrist, however, considers it better to adopt the ordinary course of mercury, though not carried to the extent of high salivation, for the purpose of infusing regularity by means of confinement, without which, he says, it often fails, and the symptoms returned, rendering another course of medicine necessary. Experience shows, he says, that the disease is proof against all light administrations of the remedy; that it will sooner or later return with greater force, or in a worse form; and that it is only to be eradicated by a regular course of medicine, judiciously adapted to the several degrees and circumstances of the malady.

As the extensive propagation of the disease in Scotland was ascribable to the uncleanly practices which prevailed among the lower classes of the people, such as using the same utensils in eating and drinking, passing the same pipe from mouth to mouth, sleeping in the same bed, using the same towel, &c.; so the most effectual check to the progress of the malady was to be expected from a system of prevention, which consisted in adopting a more decent and cleanly proceeding. Dr. Gilchrist recommended the persons employed in harvest-work, each to carry with him a dith, cup, knife, spoon, and a cloth to wipe them with, that all the party might not eat with the same utensils, and transfer contagion to one another. He also strenuously urged the impropriety of admitting that common familiarity, which every one claims by custom to kins and kindred children, and especially to deny it to strangers, and those of low rank. By attending to these, and similar means of prevention, the disease appears to have been materially controlled, and its prevalence diminished.

SIBBIKITTIN, in Geography, a town of Africa, in Neola. N. lat. 12° 38'. W. long. 11° 35'.
SIBBO, a town of Sweden, in the province of Nyland; 10 miles S.W. of Borgo.
SIBBOLETH. See Shibeboleh.
SIBBUL, in Geography, a town of Africa, in the country of Barca; 25 miles W. of Augela.
SIBDA, in Ancient Geography, a town of Asia Minor, in Caria; one of the six towns which Alexander the Great placed in dependence on that of Halicarnassus.
SIBELLA, in Geography, a mountain of Calabria; 9 miles E.S.E. of St. Severna.
SIBENEN, a river of Switzerland, which runs into the Kander, 4 miles W. of Spiez.
SIBENTAAL, a town of Austria; 8 miles W. of St. Polten.
SIBERIA, or, as it is sometimes denominated, Asiatic Russia, is that part of the immense territory of the Russian empire, which lies to the E. of the Ural chain of mountains, by which the empire is interjected from N. to S. and thus divided into two parts, differing from each other both as to dimensions and quality. Siberia is described as a flat tract of land of considerable extent, declining imperceptibly towards the Frozen ocean, and by equally gentle gradations rising towards the south; where at last it forms a great chain of mountains, constituting the boundary of Russia on the side of China. The large portion of the habitable globe, now distinguished by the appellation of Asiatic Russia, extends from about the 37th degree E. longitude to more than 150° or 160° W. long.; and assuming the degree in this high northern latitude at 50 miles, the length may be computed at 4590 geographical miles. The greatest breadth from the cape of Cevro Vollochini, called in some maps Taimara, to the Altai mountains S. of the sea of Baikal, may be estimated at 28°, or 1680 geographical miles. In British miles the length, at a gross computation, may be
Slated at 5350, and the breadth at 1960, which extent exceeds that of Europe. The vast country of Siberia, says Mr. Tooke, contains, by calculation, upwards of 104 millions of square miles, comprehending within itself several kingdoms, taken by roving Kozaks (Colfacks) on their own account, and then surrendered to the tzar, who completed the conquest; at present this country consists of several of the most extensive governments. The farther eastern boundary is that of Asia, and the seas of Kamtchatka and Ochotók, and the northern is the Arctic ocean. On the W. the frontiers correspond with those between Asia and Europe, and the southern limits may be slanted more or less large in the following manner: The river Cuban, part of the Caucasian chain, and an ideal line, divide the Russian territory from Turkey and Persia. The boundary then ascends along the north of the Caspian through the Caspian, or desert of Tiflin, and the eastern shore of the river Ob, to its source in the Altaiian mountains, where it meets the vassal empire of China, and proceeds among that chain to the sources of the Onon, where it includes a considerable region called Dauris, extending about 200 miles in breadth, to the south of the mountains called Yablónoy; the limit between Russia and Chinese Tartary being partly an ideal line, and partly the river Argoon, which joined with the Onon constitutes the great river Amur. Thence the boundary returns to the mountainous chain, and follows a branch of it to a promontory on the north of the mouth of the Amur.

The population of Asiatic Russia may be regarded as primitive, except a few Russian colonies recently planted; and the Techuks in that part which is opposite to America, supposed to have migrated from that continent, in their persons and customs are different from those of the Asiatic tribes. Next to the Techuks, most remotely north, are the Yukaghs, a branch of the Yakuts, and further west the Samoyedes. South of the Techuks are the Koriaks, and further south the Kamtchadalas, who are a distinct people, and speak a different language. The Lamutes are a branch of the Mandhires or Tungus, who are widely diffused between the Yenisei and Amur, and the southern tribes, ruled by a khan, conquered China in the 17th century. The Ostiaks, and other tribes of Samoyedes, have penetratedconsiderably to the S. between the Yenisei and the Irtisch, and are followed by various tribes of the Monguls, as the Kalmucks, Burats, &c. and of those of the Tartars or Huns, as the Teluts, Kurgufes, and others. The radically different languages amount to seven, independently of many dialects and mixtures.

The vast extent of northern Asia was first known by the name of Sibir, or Siberia; but the appellation is gradually passing into disuse. When the Monguls established a kingdom in these northern regions, the first residence of the princes was on the river Tura, on the site of the town now called Tiumen, about 180 miles S.W. of Tobolsk; but they afterwards removed to the eastern shore of the Irtisch, and there founded the city of Iker near Tobolsk. This new residence was also called Sibir, of unknown etymology, and the name of the city passed to the Mongul principality. Although this is doubted by Coxe, Pallas says that the ruins of Sibir are still visible 23 versts from Tobolsk, and that it gave name to the rivulet Sibirka, and the whole of Siberia. When the Russians began the conquest of the country, they were unappreciated of its extent; and the name of this western province was gradually diffused over the half of Asia. The principality established by the Monguls under Shebunin in 1242 in the western part of Siberia, around Tobolsk and the river Tura, from which it has been sometimes called Tura, has been already mentioned. The actual conquest of Siberia commenced in the reign of Ivan Vassiliievitk II., who ascended the Russian throne in 1534. Induced by the prospect of establishing a traffic for Siberian furs, he determined to undertake the conquest of the country, and in 1558 added to his titles that of lord of Sibir, or Siberia. Yarmak, a Collack chief, being driven, by the Rusillian conquests in the south, to take refuge, with 6000 or 7000 of his followers, near the river Kama, afterwards marched down the Ural chain, defeated the Tartar Kutchun, khan of Sibir, and pressed forwards to the Tobol and the Irtisch, and also to the Ob, and in this astonishing expedition, subdued Tartars, Vogules, and Oltiaks. Finding it impossible to maintain and complete his conquests with his small army, he surrendered them in 1558, by a formal capitulation, to the tzar Ivan Vassiliievitch, who nobly rewarded his magnanimity and exertions. This conqueror of Siberia, however, did not live to witness the full accomplishment of this enterprise. He died in 1584; and after his death the discovery and conquests which he had made were prosecuted by regiments of Donnikol Collacks, sent thither for that purpose, as far as the eastern ocean and the mountains of China; and in the middle of the 17th century this whole part of the world had become a Russian province. A person, whose name was Cyprian, was appointed first archbishop of Sibir in 1621, and at Tobolsk, where he resided, he drew up a narrative of the conquest. About the middle of the 17th century the Russians had extended east as far as the river Amur; but Kamtchatcha was not finally reduced till the year 1711. Behring and other navigators afterwards proceeded to discover the other extreme parts of Asia. In his first voyage of 1728, Behring coasted the eastern shore of Siberia as high as latitude 67° 18', but his important discoveries were made during his voyage of 1741. The Aleutian isles were visited in 1745; and in the reign of the empress Catharine II. other important discoveries followed, which were completed by captain Cook. In the south the Mongul kingdom of Kazan was subdued in 1552, and that of Astrakhan in 1554, and the Russian monarchy extended to the Caspian sea. In 1727, after previous conflicts, the Russian limits were continued westward from the source of the Argoon to the mountain Sabystantab, near the conflux of two rivers with the Yenisei; the boundary being thus ascertained between the Russians and the Monguls subjected to China. The trade with China has been conducted at Zuruchait, on the river Argoon, N. lat. 55° E. long. 170°, and at Kichta, about 90 miles S. of the sea of Baikal, N. lat. 51° E. long. 168°. This boundary between two states is the most extensive on the globe, reaching from about the 65th to the 145th degree of longitude; 80° (lat. 50°) yielding, by the allowance of 39 geographical miles to a degree, 3120 miles.

The most curious antiquities in Siberia seem to be the stone tombs which abound on some lakes, particularly near the river Yenisei, representing rude sculpture human faces, camels, horses with lances, and other objects. Here are also found, besides human bones, those of horses and oxen, with fragments of pottery and ornaments of dews. The most singular ancient monument in Siberia is found on the river Ahakan, not far from Tomsk, being a large tomb with rude figures.

The religion of the Greek church, which is professed by the Russians, has made no great progress in their Asiatic dominions. Many of the Tartar tribes in the S.W. are Mahometans, and others are vassals of the sultan of Sibir. But the religious sentiments of the Chinese are the most prevalent; particularly among the Tartars, Finns, Samoyedes, Ostiaks, Mandhirs, Burats, and Tunguses;
SIBERIA.

gues; and they have been adopted by the Koriaks, Tchucks, and people of the eastern isles. On the eastern coast of the sea of Baikal is the rock of the Schamans, an idol of a peculiar shape: whilst the Schamanists admit one chief infernal deity and his subalterns, authors of evil, they also believe in one supreme uncreated beneficent being, who commits the management of the universe to inferior deities, and they delegate portions of it to sublmal spirits. See Schamans.

The archiepiscopal see of Tobolsk is the metropolis of the Russian Aia in the north, and that of Altarakhan in the south. There is another see, that of Irkutsk and Nerhinfs, and some others of more recent origin.

Siberia is divided into two great governments, those of Tobolsk in the west, and Irkutsk in the east. The smaller provinces are Kolivam, Nerhinfs, Yakutsk, and Ochotsk. In the S.W. is the government of Caucasus, with one or two other divisions, blending Europe and Asia.

The population of Siberia cannot be computed at above 3½ millions. The political importance and relations of this part of the Russian empire principally relate to China and Japan. The manners and customs of Asiatic Russia vary with the numerous tribes by whom it is peopled. The Tartars are the most numerous; next to these in importance are the Monguls, one tribe of whom, viz. the Kalmucks, are found to the W. of the Caspian, while the others, called Burats, Torgats, &c. are chiefly round the sea of Baikal. Further to the east are the Mandhurs or Tungusas. See these denominations respectively.

The languages of all the original nations of Asiatic Russia are radically different; and among the Tungusas, Monguls, and Tartars, there are some traces of literature, and not a few MSS. in their several languages.

The principal city of Asiatic Russia is Altarakhan, which see. Azof (which see) derives its importance chiefly from its being a fortified port. The chief towns on the Asiatic side of the Volga, are Samara and Stauropol. At the mouth of the river Urals, & Jaik, stands Guriief; but the chief place after Altarakhan is Orenburgh, founded in the year 1740, and the seat of a considerable trade with the tribes on the E. of the Caspian. Beyond the Ural chain the first city that occurs is Tobolsk; which see. Kolyvan is a town of some consequence on the river Ob, having in its vicinity some silver mines of considerable produce, and north to this is Tomisk. Farther to the E. the towns become of less consequence. On the river Yenisei is a small town of the same name, and another called Sayanik. On the river Angara stands Irkutsk, supposed to contain 12,000 inhabitants, the chief mart of the commerce between Russia and China, and the seat of supreme jurisdiction over eastern Siberia. On the wide and frozen Lena stands Yakutsk; which see.

The chief commerce of this part of the Russian empire consists in fables and other valuable furs, for which the Chinese return tea, silk, and nankeen. That with the Kirgusses consists in exchanging Russian woollen cloths, iron, and household articles, for horses, cattle, sheep, and beautiful flocks.

On the Black sea there is some commerce with Turkey, the exports being furs, kaviar, iron, linen, &c. and the imports wine, fruit, coffee, milks, rice. In the trade on the Caspian the exports are the same, and the return chiefly silk. The principal Russian harbours are Altarakhan, Guriief, and Kiliari, near the mouth of the Terek, but the belt haven is Baku, belonging to the Persians. The Tartars, on the eall of the Caspian, bring the products of their country and of Bucharas, as cotton-furs, furfls, hides, and rhabarb; but the chief article is raw flilk from Shirvan and Ghilan, on the W. of the Caspian.

In Asiatic Russia the climate extends from the vine at the bottom of the Caucasus, to the solitary lichen on the rocks of the Arctie ocean. Through the greater part of Siberia, the most southern frontier being about 50°, and the northern ascending to 78°, the general climate may be considered rather as frigid than temperate; being in three quarters of the country on a level with that of Norway and Lapland, untempered by the gales of the Atlantic. To the S. of the sea of Baikal, the climate corresponds to that of Berlin, and the N. of Germany. The chains of high mountains, which form the southern boundary of these provinces, contribute also to incrase the cold; so that the sea of Baikal is commonly entirely frozen from December till May. The finest climate in these eastern parts is that of Daouria, or the province around Nerhinfs; and the numerous towns on the Amur exhibit the great superiority of what is called Chinese Tartary, which is comparatively a fertile and temperate region. The change of the feasons is very rapid; the long winter is almost instantaneously succeeded by a warm spring; and the quicksets and luxuriance of the vegetation exceed description.

The greater part of Siberia, that is, the middle and southern latitudes of it, as far as the river Lena, is extremely fertile, and fit for every kind of produce; but the northern and eastern parts, being encumbered with wood, are delimitative of this advantage, being unfit both for pasturage and culture. The whole of this part, as far as the 60th degree of N. latitude, and to the Frozen ocean, is full of bogs and morafles covered with moss, which would be absolutely impassible, if the ice, which never thaws deeper than seven inches, did not remain entire beneath it. In the central parts vegetation is checked by the severe cold of so wide a continent. Towards the S. there are vall forests of pine, fir, larch, and other trees, among which is a kind of mulberry, which might thrive in many climates that are now delimitative of it. The sublme scenes around the sea of Baikal are agreeably contrasted with the marks of human industry, the cultivated field and the garden. Many parts of Siberia are totally incapable of agriculture; but in the southern and western districts the soil is remarkably fertile. North of Kolyvan barley generally yields more than twelve-fold, and oats commonly twenty-fold. Exclusive of winter wheat, most of the usual European grains grow in southern Siberia. In some parts flax grows wild, and hemp is prepared from the nettle. Wood is found in Siberia, and fashion near the Caucasus. The belt rhabarb abounds on the banks of the Ural or Jaik, in the southern districts watered by the Yenisei, and in the mountains of Daouria. But it is not possible that agriculture should flourish while the peafany are flaves, and fold with the foil. Nevertheless, an intelligent traveller was surprized at the abundance of buck-wheat, rye, barley, oats, and other grain which he observed to the S. of Tobolsk; where the cattle were also very numerous, and in the winter fed with hay. The large garden strawberry, called hauibois, is found wild in the territory of Irkutsk; and on the Altai mountains the red currant attains the size of a common cherry, ripening in large bunches of excellent flavour. Near the Volga and the Ural are excellent melons of various kinds.

Some of the largest rivers of Asia belong to the Russian empire; such as the Ob, of 1,500 British miles in course; the Yenisei, about 1,750; and Lena, 1,570. To these we may add the Irtilf, the Angara, the Selenga, the Yaik, &c. The lakes of this country are numerous. The most considerable in the north of Siberia is that of Piaznikof; that of Baikal, described under that article; a large lake between the rivers Ob and the Irrilf, 170 miles long, divided by an island into two parts, called the lakes of Tchang and Soumi.
In this quarter there are many smaller lakes, and others to the N. of the Caspian, some of which are salt, particularly that of Bogdo. To these we may add the Altan Nor, or golden lake, and the lake of Altyn, called by the Russians Teletako. The mountains are the Uralian, the Altaian, Bogdo Alim, or the Almighty mountain, Sinina-Sekpa, Schlangeberg, which is the richest in minerals, the Sayanick mountains, the mountains of Nerhink or Russian Daoria, the chain of Stanvooi or mountains of Ochotchik, and Caucasus. For the fleapes of Russia, see Steppe.

Siberia has hitherto been found to possess scarcely any genera of plants; and even all the species of any considerable importance, are those trees which are common to it with the north of Europe. Under the head of the zoology of Asiatic Russia, we may enumerate the rein-deer, which performs the office of the horse, the cow, and the sheep; the dog, Kamtschatka, which are used for carriage; the horse, which is found wild, a species of As, the urus or bilon, the argali or wild sheep, the ibex or rock-goat, large stags, the musk or civet, and wild boar; wolves, foxes, and bears; the fable, several kinds of hares, the catter or beaver, the walrus, and the common seal. But it would be superfluous to enlarge. Siberia is so rich in zoology and botany, that, as Mr. Pennant observes, even the discovery of America has scarcely imparted a greater number of objects to the naturalist. The mineralogy of Siberia is equally fertile, and displays many singular and interesting objects. The chief gold mines of Siberia are those of Catherinburg or Ekatherinburg, on the E. of the Uralian mountains, about N. lat. 57°; the mines of Nerhink, discovered in 1704, are principally of lead, mixed with silver and gold; and those of Kolyvan, chiefly in the Schlangeberg, or mountain of serpent, so called by the Germans, began to be wrought in 1748. The gold mines of Berefot are the chief in the empire; those of Kolyvan and Nerhink being denominated silver mines. Besides the copper mines in the Uralian mountains, there are some in those of Altai. But the iron mines of Russia are of the most solid and lapping importance, particularly those which supply the numerous foundries of the Uralian mountains. Rock-salt is chiefly found near the Iek, not far from Orenburg; Coal is scarcely known; but sulphur, alum, mal amniconic, vitriol, nitre and natron, are abundant. Siberia possesses a variety of gems, particularly in the mountain Adunfollo, near the river Argon, in the province of Nerhink or Daoria. Common topazes are found here, and also the jacinet. The kind of jade called mother of emerald is a Siberian product; and beryl or aqua marina is found in Adunfollo, and in greater perfection in the gems mines of Mourfintsey, near Catherinburg, along with the chrysolite. Red garnets abound near the sea of Baikal. The ruby-coloured schorl has been discovered in the Uralian mountains. The greenSIBIBOLOO, in Geography, a town of Africa, in the latitude of Mason, the government of which is a republic, or rather an oligarchy; 40 miles N.E. of Kamalia. SIBIL-EL-MULSIH, a town of Arabia, in the province of Hedja; 120 miles N.W. of Mecca. SIBILI, a town of Africa, in the kingdom of Bambara; 25 miles N.E. of Sego. SIBILIAKOVA, a town of Russia, in the government of Tobolik, on the Irtisch; 28 miles N. of Tar. SIBIRIXOA, a town of New Mexico, in the province of Cinaloa; 45 miles N.W. of Cinaloa. SIBINBAS, a town of Hindooftan, in Bengal; 10 miles E.N.E. of Kihenagur. N. lat. 23° 25'. E. long. 88° 50'.

SIBOOCKO, a town on the E. coast of the island of Borneo. N. lat. 4° 24'. E. long. 117° 12'. SIBOURNE, a town of France, in the department of the Lower Pyrenees, on a small river opposite to St. Jean de Luz. SIBRAIM, or SABARDI, in Ancient Geography, a place which terminated the land of promive towards the north. Ezekiel says (xlvii. 16.) that this city was between the confines of Hamoth and Damaucus, probably the same which Abulheda calls Houren, a village of the country of Emir, or Hamoth, S.E. of that city. SIBSIB, in Zoology, an animal of the empire of Morocco, abounding in the mountains of the province of Sufa; of an intermediate species between the cat and the fquirrel; somewhat similar to the ichneumon in form, but not half its size; it inhabits the Atlas, and lives in holes, among the flowers and caverns of the mountains; it has brown hair, and a beautiful tail, resembling that of a fquirrel, about the length of its body. The Shellufakes and Arabs eat this animal, and consider it a delicacy. This is the only animal which the Mahometans torment before its death, which they do by taking hold of its hind-legs, and rubbing it on a stone, or flat

The islands belonging to Asiatic Russia may be distributed into the Aleutian, Andrenovian, and Kurilian groups, with the Fox isles, which extend to the promontory of Alaka in North America. See these articles respectively. For further particulars respecting Siberia or Asiatic Russia, see RUSSIA. See also Cooke's Russian Discoveries; Cooke's Russ. Emp.; and Pinkerton's Geog. vol. ii.

SIBERIAN Kozaks, or Cofuck, a branch of the Don, so called by the Germans, who, intimidated, in the year 1577, a considerable army, and got together a fleet of ships to chastise these audacious robbers. These robbers, intimidated by these hostile preparations, dispersed and fled into the neighbouring regions. See the preceding article.

Siberian Barley, in Agriculture, a hardy fort of grain of the barley kind. See Barley.

Siberian Oat, an useful fort of hardy oat brought from that country. See Oat.

It has been found by some as much superior to the common black oat as the Poland fort is to others. It has the advantages of being capable of being found with safety in December, and of being fit to cut as soon as sooner than early peas; the produce is greater than the usual forts; and rain, instead of injuring, rather improves the colour, which is of the pied kind. The kernel is plump and large, and the straw is said to make excellent fodder for live-flock of the next cattle kind.

SIBIVOLOO, in Geography, a town of Africa, in the latitude of Manding, the government of which is a republic, or rather an oligarchy; 40 miles N.E. of Kamalia. SIBIL-EL-MULSIH, a town of Arabia, in the province of Hedja; 120 miles N.W. of Mecca. SIBILI, a town of Africa, in the kingdom of Bambara; 25 miles N.E. of Sego. SIBILIAKOVA, a town of Russia, in the government of Tobolik, on the Irtisch; 28 miles N. of Tar. SIBIRIXOA, a town of New Mexico, in the province of Cinaloa; 45 miles N.W. of Cinaloa. SIBINBAS, a town of Hindooftan, in Bengal; 10 miles E.N.E. of Kihenagur. N. lat. 23° 25'. E. long. 88° 50'.
SIB

flat surface, for a few minutes, which operation causes the animal to scream out. They then cut its throat, according to the Mahometan custom. In that it is said to resembach a rabbit; but friction, as they pretend, is necessary to render it tender and palatable.

SIBTHORP, John, in Biography, an eminent botanist and traveller, was the youngest son of Dr. Humphry Sibthorp, professor of botany at Oxford, where the subject of the present article was born, October 28, 1758. He received the first rudiments of his education at Magdalen School, from whence he was removed to the school at Lincoln. In due time he entered at Lincoln college, Oxford; but upon obtaining the Radcliffe travelling fellowship, he became a member of University college. Being intended for the medical profession, he was necessarily sent to Edinburgh, to complete that branch of his education; but he took the degree of doctor of physic in his own university. The tale he had early imbibed for natural history, especially botany, was cultivated at Edinburgh, and indulged in a tour to the Highlands of Scotland. After his return from thence, he visited France and Switzerland, spending a considerable time at Montpellier, where he formed an intimacy with the amiable Brouillonet, (see PAPYRUS,) collected many plants of that country, and communicated to the Académie des Sciences of Montpellier, of which he became a member, an account of his numerous botanical discoveries in the neighbourhood. The death of an elder brother of his father, by which a considerable estate devolved on the latter, occasioned Dr. J. Sibthorp to return to England in 1783, when, on his father's resignation, he was appointed to the botanical professorship. For this his Oxford degree of M.D. was necessary. (See SHERARD, and SIBTHORP.) It was perhaps the last service he expected from it, for he was a favourite son, and had besides an ample independence of his own in prospect, from the estate of his mother, who was his father's second wife. These expectations, and his academical appointments, though they releaved him from the calls of his profession, only rivetted more firmly his ardent attachment to botany; his passion for which became, by those appointments, a duty; nor was he ever, to his last hour, disposed to shrink from the task he had undertaken, or to prefer any relaxation, or any indulgence, to this laborious pursuit.

During the stay of professor J. Sibthorp at London, in the winter of 1783, the museum and library of the celebrated Linnaeus were sold, by private contract, to the writer of this article. The professor was commendably desirous of adding so great a treasure to the collections, already famous, at Oxford; but the acquisition depended on a resolute and decisive step, which was already taken, and not on any management or negotiation, to which the person entrusted with the sale was superior. This competition occasioned no interruption in the friendship, just then formed, between the parties concerned, which continued increasing during their joint lives.

Dr. Sibthorp passed a portion of the year 1784 at Gottingen, where he projected his first tour to Greece; the botanical investigation of which celebrated country, and especially the determination of the plants mentioned by its classical authors, had, for some time past, become the leading object of his pursuits. He first visited the principal seats of learning in Germany, and surveyed some of its mountains and forests; but it was impossible to quit this part of the world without a considerable stay at Vienna. There he cultivated the friendship of the two professors Jacquin, father and son; studied with peculiar care the celebrated manuscript of Dioscorides, which has so long been preserved in the imperial library; and procured a most excellent draughtsman, Mr. Ferdinand Bauer, to be the companion of his expedition. On the 6th of March, 1786, they set out together from Vienna, and passed through Carniola to Trieste, Venice, Bologna, Florence, Rome, and Naples, examining every thing that was curious, and keeping an exact record of their botanical observations. After viewing the celebrated environs of Naples, they failed from thence early in May, and touching at Melfina, as well as at the isle of Mikon, they proceeded to Crete. Here, in the month of June, our botanical adventurers were welcomed by Flora in her gayest attire. The snowy covering of the Sphacete mountains was withdrawing, and a tribe of lovely little blossoms were just peeping through the veil.

Having narrowly escaped shipwreck, in returning to Mikon by one of the country vessels, Dr. Sibthorp and Mr. Bauer touched successively at several islands of the Archipelago, visited Athens, and remained for a while at Smyrna. Here they traced the folk of Shera and Harfeqquq, proceeded by land to Burfa, climbed the Bithynian Olympus, and at length reached Constantinople, where they spent the ensuing winter, in the course of which Dr. Sibthorp devoted himself to the study of modern Greek. In a botanical excursion to Belgrad, on the 17th of February, 1787, and another to Bujukerdi, March 5, the plants found in flower were almost entirely the same as are met with, at the same season, in England. Dr. Sibthorp's residence at Constantinople, or in the neighbouring isle of Karke, proved favourable to his investigations of the flies and birds of those regions, by which he was enabled to throw much light on the writings of ancient naturalists.

On the 14th of March, 1787, having joined company with captain Emery and Mr. Hawkins, Dr. Sibthorp and his draughtsman failed from Constantinople in a Venetian merchant-ship for Cyprus, taking the islands of Mytilene, Scio, Cos, and Rhodes, and touching at the coast of Asia Minor, in their way. A stay of five weeks at Cyprus enabled Dr. Sibthorp to draw up a Fauna and Flora of that island. The former consists of 18 Mammalia, 85 Birds, 19 Amphibia, and 100 Fishes; the latter comprehends 616 species of plants. The particular stations, domestic and medical tisues, and reputed qualities of these last, are amply recorded; and the vernacular names of the animals, as well as of the economical plants, are subjoined. The same method is pursued, in a subtile part of this journal, respecting the plants and animals of Greece, with every thing that could be collected relative to the medicine, agriculture, and domestic economy of that country and the circumjacent isles. The illustration of the writings of Dioscorides, in particular, was Dr. Sibthorp's chief object. The names and reputed virtues of several plants, recorded by that ancient writer, and still traditionally retained by the Athenian shepherds, served occasionally to elucidate, or to confirm, their synonymy. The first sketch of the Flora Graecae comprihes about 850 plants. "This," says the author, "may be considered as containing only the plants observed by me in the environs of Athens, on the snowy heights of the Grecian Alp Parmaus, on the steep precipices of Delphi, the empurled mountain of Hymettus, the Pentele, the lower hills about the Pirus, the olive grounds about Athens, and the fertile plains of Boeotia. The future botanist, who shall examine this country with more leisure, and at a more favourable season of the year, before the summer sun has scorched up the spring plants, may make a considerable addition to this list. My intention was to have travelled by land through Greece; but the disturbed state of this country, the eve of a Russian war, the rebellion of its bashaws, and the plague at Larissa, rendered my project impracticable." Of the Mammalia of 4 N Greece,
Greece, 37 are enumerated, with their modern names, 25 reptiles and 82 birds. All these catalogues were greatly augmented by frequent observations, in which the number of species, collected from an investigation of all Dr. Sibthorp's manuscripts and specimens for the materials of the Prodrumus Florae Graeciae, amounts to about 3000.

We shall not particularly trace our traveller's steps through Greece, or the various islands of the Archipelago. His health, which suffered from the confinement of a ship, and the heat of the weather, was restored at Athens, where he arrived on the 19th of June, 1787. From thence he proceeded to the mountains of Delphi, in Negropont, in a storm of wind and rain, on the 30th of August, was one of his most laborious, if not perilous, adventures; but his botanical harvest was abundant. With regard to scenery, mount Athos, which he visited a week after, seems to have made most impression on his mind. This spot also greatly enriched his collection of rare plants. From hence he proceeded to Thessalonica, Corinth, and Patras, at which last place he embarked with Mr. Bauer, on board an English vessel, for Brindisi, on the 24th of September. After a tedious and stormy voyage, they arrived in England the first week in December.

The constitution of Dr. Sibthorp, never very robust, had suffered materially from the hardships and exertions of his journey. But his native air, and the learned leisure of the university, gradually receded his strength. The duties of his professorship were rather a recreation than a toil. The superintendence of his exquisite draughtsman, now engaged in making finished drawings of the Greek animals, as well as plants; and his occasional visits to the Limnean and Bankian herbariums, for the removal of his difficulties; all together filled up his leisure hours. He was ever where welcome and admired for his ardour, his talents, and his acquisitions. His merits procured an augmentation of his stipend, with the rank of a Regius professor; both which advantages were, at the same time, conferred on his brother professor at Cambridge. He became a fellow of the Royal Society in 1789, and was among the first members of the Limnean Society, founded in 1788. In the spring of the year last mentioned, the writer of this, with Sir Joseph Banks and Mr. Dryander, passed a week at Oxford, which was devoted to a critical survey of the professor's Grecian acquisitions; nor was the honey of mount Hymettus, or the wine of Cyprus, wanted at this truly attic entertainment. But the greater these acquisitions, the less was their possessor satisfied with them. No one knew, so well as himself, how much was wanting to the perfection of his undertaking, nor could any other person so well remedy these defects. Though he was placed, a few years after his return, in very affluent circumstances; and though his necessary attention to his landed property, and to agricultural pursuits, of which he was passionately fond, might well have turned him, in some measure, aside from his botanical labours; he steadily kept in view the great object of his life, to which he finally sacrificed life itself. No name has a fairer claim to botanical immortality, among the martyrs of the science, than that of Sibthorp.

On the 20th of March, 1794, Dr. Sibthorp set out from London, on his second tour to Greece. He travelled to Constantinople in the train of Mr. Lifdon, ambassador to the Porte, and was attended by Francis Borone, of whom an account may be seen at the end of the article Rutaceæ, as a botanical assistant. They reached Constantinople on the 19th of May, not without Dr. Sibthorp's having suffered much from the fatigues of the journey, which had brought on a bilious fever. He soon recovered his health at Constan
tinople, where he was joined by his friend Mr. Hawkins from Crete. Towards the end of August they made an excursion into Bithynia, and climbed to the summit of Olympus, from whence they brought a fresh botanical harvest. Dr. Sibthorp discovered at Fanar an aged Greek botanist, Dr. Dimitri Argyraí, who had known the Danish traveller Forskall, and who possessed some works of Linnaeus.

Recovered health, and the accession of his friend's company, caused Dr. Sibthorp to set out with alacrity on his voyage to Greece, on the 8th of September. Palling down the Hellepont, on the 12th, with a light but favourable breeze, they anchored at Koom Cale, in the Troad, spent two days in examining the plains of Troy, and then proceeded to the isles of Imbras and Lemnos. On the 25th they anchored at mount Athos, and passed ten days in examining some of the convents and hermitages, with the romantic scenery, and botanical rarities, of that singular spot, on all which Dr. Sibthorp descants at length, with great delight, in his journal. Their departure was, for some time, prevented, by a few Barbary pirates hovering on the coast, whom the monks, unlike the priests of the Athenian Bacchus, were not potent or valiant enough to defeat, or to turn into dolphins. Our voyagers sailed on the 7th of October, and on the 17th landed at Skiatho. From hence, on the 11th, they proceeded down the strait of Negropont, and on the 13th passed under the bridge of five arches, which connects that island with the mainland of Greece. On the 15th, at noon, they entered the harbour of the Pyrrus, and proceeded to Athens, where the four succeeding weeks were employed in collecting information relative to the present state of the government, the manufactures, and the domestic economy of that celebrated spot. Here Dr. Sibthorp left his assistant Borone, who perished by an accidental fall from a window, in his sleep, on or about the 20th of October.

November 16th, Dr. Sibthorp and Mr. Hawkins left Athens by the ancient Eleusinian way, while the classical streets of the Cephissus, the heights of Helicon and Parnassus lay before them. They proceeded to Patras and to Zante, where they arrived in the middle of December, enriched with a large collection of seeds, the only botanical tribute that could, at this season, be collected from those famous mountains. An apothecary at Zante furnished Dr. Sibthorp with an ample and splendid herbarium, of the plants of that island, with their modern Greek names; nor did the winter pass unprofitably or unpleasantly in this fecular spot; where neither agreeable society, nor copious information relative to our learned travellers' various objects, was wanting. The fea was sufficiently favourable in the middle of February, 1795, to allow them to visit the Morea, of which peninsula they made the complete circuit in somewhat more than two months. The Violet and Primrose welcomed them in the plains of Arcadia; and the Narcissus Tazetta, which Dr. Sibthorp was disposed to think the true poetical Narcissus, decorated in profusion the banks of the Alpheus. The barbarian horse, under whose charge they were obliged to travel, had taile enough to collect nosegays of these flowers. The oaks of the Arcadian mountains presented them with the true ancient Mifeltoe, Loranthus europæus, which fill serve to make birdlime; whilst our Mifeltoe, Pifium album, in Greece grows only on the Silver Fir. May not this circumstance account for the old preference of such Mifeltoe as grows on the oak, among the ancient Britons, and consequentlv help us to trace the origin of their superstitious to Greece? (See Druids.) The Jay, still called by its ancient

SIBTHORP.
ancient name Kexa, which is generally taken for the Magpie, was feeding among these oaks; and the Water Ouzel, Sturnus Cinclus, flying along the rocky sides of the alpine rivulets of Arcadia, prefixed itself to Dr. Sibthorp's collection, as probably the White Blackbird, which Ariosto says is peculiar to the neighbourhood of Mount Cyllene. In vain did our classical travellers look for the beauty of Arcadian shepherdesse, or liften for the pipe of the sylvan swain. Figures emaciated, and features furrowed, with poverty, labour and care, were all that they met with. The vermin of the Pachas court, with other vermin, who presume to call themselves Christian bishopps, and whole places are all bought of the Turks, devour the substance of these poor people, and drive many of them to a precarious and predatory life among the mountains.

Proceeding to Argos, and thence to Mycenæ, the travellers were highly gratified by finding, on the gate of the latter, those ancient lions, which Paulusiana describes as the work of the Cyclops; and near it the reputed tomb of Agamemnon, a circular building, formed of immense masses of stone, placed with such geometrical precision, though without mortar, that one who had given way, that it forms the tomb, is described to Dr. Sibthorp as the largest stone he ever saw employed in any structure. A number of fragments of vases, like those commonly called Etruscan, lay among the ruins of Mycenæ. At Hermione, now called Caltris, in the Argolic peninsula, famous for the purple dye newly prepared there, a vast pile of the shells from which that dye was obtained, and still denominated Perpbyri, served to ascertain the species, which is Murex trunculus of Linnaeus, figured by Fabricius Columba in his rare and learned work, de Purpura, under the name of Purpura nostra vio- lacea. (See Purple Fish.) From this place Dr. Sibthorp and his friend intended to have coasted along the bay of Argos in a boat, but the sea was then infested with pirates, which obliged them to give up that project, and to return by land to Argos, whence they proceeded to Corinth, Patras, and by way of Elis to Pyrgos. Here they obtained another escort from Said Aga, to whose protection they had before been indebted, and safely reached Calamata, on the gulf of Corone, where they were detained by the celebration of Easter, on the 12th of April, amid a profusion of sky-rockets and crackers. Proceeding in a boat along the barren and craggy shore, covered with bushy and prickly Euphorbia, they reached Cardamoula. Here the Greeks are tolerably free from the tyranny of the Turks, and their persons and demeanour exhibit less marks of degrancy. Panagiote, a popular character, nephew of the Cherife, came down, with a train of followers, to welcome the strangers, and conducted them to his tower-like castle, where a narrow entrance, and dark winding stair case, led to a chamber, whose thick walls and narrow loop-holes seemed well prepared for defence. The country of Maira, though governed by a Bey, is under the control of eight subordinate, but partly independent, native chiefs, who, like our old feudal lords, often make war on each other, when they bring not only men but women into the field. No Turk is allowed to live in this district. The land is extremely billy, and lately defenced. Taygetus, the highest mountain in the Morea, and almost rivaling Paros, was ascended by our adventurous travellers; but the quantity of snow, and the great distance, prevented their reaching the summit. Panagiote and fifty of his followers accompanied them, and he displayed his botanical knowledge by shewing Dr. Sibthorp danel, still called aupa, among the corn, which he said occasioned dizziness; and a wonderful root, the top of which is used as an emetic, the bottom as a purge. This proved Euphorbia Apias, to which the very fame properties are attributed by Dioscorides.

From Cardamoula the travellers were escorted by the dependant of this hospitable Grecian chief, along a precipitous road, to Miltia, where they had the unexpected pleasure of meeting a party of their English friends, in the garb of Tartars, with whom they explored the site of ancient Sparta. After returning to Calamata, and surveying from the summit of a neighbouring precipice the ruins of Melissia, with the rich plains watered by the Panipes, and bounded by the hills of Laconia, Dr. Sibthorp and Mr. Hawkins hastened to Corone, where a Venetian vessel waited to convey them to Zante, which place they reached on the 29th of April. Here Dr. Sibthorp parted from the faithful companion of his tour, whom he was desirous never to see again, but in whose friendship he safely confided in his last hours. Mr. Hawkins returned to Greece; while the subject of our memoir, leaving Zante on the 1st of May, experienced a most tedious voyage of twenty-four days to Otranto, though five days are the most usual time for that passage. He touched at the isand of Cephalonia, and next at Preverfa, on the Grecian shore, where being detained by a contrary wind, he employed the 7th of May in visiting the ruins of Nicopolis. The weather was unfavourable, and Dr. Sibthorp here caught a feverish cold, from which he never recovered. It seems to have proved the exciting cause of that disease, which had long been latent in the mesenteric and pulmonary glands, and which terminated in a consumption. Being obliged by the weather to put in at the little isand of Fanno, May 11th, the violent north-west wind continued, as he too expressively says in his journal, "to nurse his cough and fever." He was confined to his bed, in a miserable hovel, to which, after frequent attempts to fail, he was driven back fix times by the unfavourable wind. At length, the vessel was enabled to cast anchor in the port of Otranto on the 24th of May. Here he was obliged to submit to a quarantine of three weeks, part of which, indeed, was allowed to be spent in proceeding to Ancona. Thence he passed through Germany and Holland to England. Of the precise time of his arrival we find no mention. It was in the autumn of 1795, and his few succeeding months were chiefly marked by the progress of an unconquerable disease, for which the climates of Devonshire and Bath were, as usual, reforted to in vain. He died at Bath, February 8th, 1796, in the thirty-eighth year of his age, and lies interred in the abbey church, where his executors have erected a neat monument to his memory.

We have now to record the posthumous benefits which Dr. Sibthorp has rendered to his beloved science, and which are sufficient to rank him amongst its most illustrious patrons. By his will, dated Ashburton, January 12th, 1796, he gives a freehold estate in Oxfordshire to the university of Oxford, for the purpose of first publishing his Flora Graeci, in 4to folio volumes, with 100 coloured plates in each, and a Prodromus of the same work, in 8vo. without plates. His executors, the honourable Thomas Wenman, John Hawkins and Thomas Platt, Esqrs., were to appoint a sufficiently competent editor of these works, to whom the manuscripts, drawings, and specimens, were to be confided. They fixed upon the writer of the present article, who has now nearly completed the Prodromus, and the second volume of the Flora. The plan of the former was drawn out by Dr. Sibthorp, but nothing of the latter, except the figures, was prepared, nor any botanical characters or descriptions whatever. The final determination of the species, the difficulties of such as were new, and all critical remarks, have fallen to the lot of the editor, who has also revised the references.
ferences to Dioscorides, and, with Mr. Hawkins's help, corrected the modern Greek names, which last were necessarily taken down but incompletely, from many iliterate and imperfect authors, on the spot. When these publications are finished, the annual sum of 300l. is to be paid to a profess of professor of rural economy, who, is, under certain limitations, to be the Sherardian professor of botany, and who is, very properly, obliged to read lectures, that the appointment may not become a reproach, instead of an advantage, to the university. The remainder of the rents of the estate above mentioned is defined to purchase books for the professor; and the whole of the tellator's collections, with his drawings, and books of "Natural History, Botany, and Agriculture," are given to the university. This bequest rivals the munificence of Sherard and of Sloane, in the service of natural science, and has only been exceeded by that of the late Mr. Roberton of Stockwell, whose ill-made will was set aside by the common law of the land.

The only work which professor John Sibthorp published in his life-time is a Flora Oxoniensis, in one volume 8vo, printed in 1794. It has the merit of being entirely founded on his own personal observation. The species enumerated amount to 1200, all gathered by himself, and difpofed according to the Linnaean system, with the alterations of Thunberg, which were then new, but which are now not admitted as improvements. The adoption, though imperfect, of Hedwig's genera of mosses in this Flora, must be epenmed a more fortunate measure. S.

SIBTHORPIA, in Botany, was so called by Linnaeus, in compliment to Dr. Humphrey Sibthorp, for about forty years professor of botany at Oxford, and the immediate successor of Dillenius. He is said to have delivered but a single lecture in all that time, which was not a successful one, nor do we know of his having enriched the science with any publication. A short letter from this gentleman, announcing the death of his predecessor, is extant among the Epistles ad Hallerum. In this he modestly expresses a wish that he were equal to the task before him. However imperfect his claims to botanical celebrity, his fon has conferred more honour on the above name than either of them could derive from it; see the preceding article.—Linn. Gen. 320. Gen. Ch. Cal. Periánth inferior, of one leaf, turbinate, in five deep, ovar., spreading, slightly unequal, permanent segments. Cor.: of one petal, bell-shaped, in five deep rounded segments; the three uppermost largest, equal to the calyx; two lower ones shorter, and less coloured. Stams. Filaments four, awl-shaped, not half the length of the corolla, scarce visibly unequal, spreading, two at each side, opposite to its lateral stigmas; anthers roundish, two-lobed. Pet. Germen superior, roundish, compressed; ryle cylindrical, very short, thicker than the filaments; stigma peltate. Peric. Capsule compressed, orbicular, notched, swelling at each side; acute at the margin, of two valves and two cells, the partitions from the centre of each valve. Seeds: few, roundish-oblong, convex on one side, flat on the other, inferted into a globose central receptacle.

1. S. europaea. Sibthorpsia, or Cornish Money-wort.
of their enterprise, and who lived, according to Eusebius, not in the time of the Trojan war, as Varro believes, but under the reign of Romulus; Samian, called, according to Suidas, Pitto, or Perfusion, and according to Eusebius, Erikeph; Cumæan, named Amalaeth by some authors, and by others Demophilus or Hierophylus, who is said to have offered to Tarquin the Elder a collection of Sibylline verses, in nine books; Hellepontic or Troyad, born at Marpeus, near the town of Gorgis, in Troas, who lived, according to Heraclides, in the time of Cyrus and Solon; Phrygien, who gave her oracles at Ancrea, the place of her residence; and Tiburtine, named Albunea, and honoured as a divinity in the vicinity of the river Anio. Of these, the most celebrated are, the Erythrean, Delphic, and Cumæan Sibyls.

Some modern authors, without regarding the authority of Varro, or that of the other ancients, are for uniting all the Sibyls in one; so that, according to them, different names were given to one and the same Sibyl from the different places where she uttered her oracles. She first published her predictions in the city of Erythrea, the place of her nativity; then rambled about the world, and closed her life at Cumæ, in Italy. Dr. Hyde (De Relig. Persar.), shocked at the contradictions and fabulous adventures with which the Pagans filled the history of the Sibyls, accounts for them in the following manner. He observes in the constellation Virgo a bright star, which the Persians called Sambula, denoting, in their language, a serpent, or an ear of corn; and remarks, that the Persians, who were fond of judicial astrology, looked on the sign of the Virgin as having a greater power than all the other celestial bodies, for discovering future events. The Greeks, having learnt the sciences of the eastern nations, soon adopted these trifling opinions, and, agreeably to their genius, embellished them with their fictions. Their poets soon invented a Sibyl virgin, in allusion to the term Sambula, carried her into several countries, and made her act the part of a prophetess. So that, according to this eminent writer, whatever has been said both by the ancients and moderns of the Sibyls and their prophecies, is entirely fabulous. This conjecture, though ingenious, is contradicted by the testimony of antiquity, which allows that there were, in different times and countries, such extraordinary persons, who were reputed to have a particular fore-knowledge of futurity, and whose predictions, carefully collected, were consulted upon important occasions. The Perian Sibyl might, indeed, owe her original to the circumstance above-mentioned, but that is no sufficient argument against the existence of other Sibyls. The Romans had the highest possible veneration for the Sibyls; and if they did not always regard them as divinities, they at least reputed them of a middle nature between gods and men; and some of them received divine honours. Laetanius says, with confidence, that the Tiburtine Sibyl was worshipped as a goddess at Thibur. Some of them also had temples. Julius Martyn mentions that of the Sibyl of Cumæ, in Italy, built over the cave where she delivered her oracles. Virgil mentions this temple, or rather he considers it as a temple the grotto where the Sibyl delivered her oracles, because in after-times there was one actually built there. "Vocat alta in Templum Sacertos," Æn. 1. 6. We may here add, that the inhabitants of Gorgis, in the Leisyr Phrygia, had a custom of representing upon their medals the Sibyl who was born in that city, as being their great divinity. As a farther proof of the worship paid to the Sibyls, they had statues erected to them, which were placed in the temples.

The Sibylline oracles were held in great veneration by the more credulous among the ancients; but they were much suspected by many of the more knowing. The books in which they were written were kept by the Romans with infinite care; and nothing of moment was undertaken without consulting them. Tarquin first committed them to the custody of two patrician priests, instituted for that purpose. (See Duumviri Sacrum.) How, when, or by whom this collection was made, are circumstances which authentic history has not ascertained. It is not likely that the Sibyls prophesied in verse, for lest that they themselves kept their predictions, and digested them into order. All that we know concerning them is, that a woman came to Tarquin the Elder, as Varro says, or, according to Pliny, to Tarquin the Proud, offering him a collection of these verses in nine books, or three according to Pliny; and that she demanded for them 300 pieces of gold; that when the prince refused to give that sum, she threw three of them into the fire, and asked the fame sum for the remaining six, which being refused, she turned three more, and perfisted in asking the same sum for those that were left; at length the king, fearing that she would burn the other three, gave her the sum which she demanded. Although this story has very much the air of a romance, it is attested by many authors; and it is certain that the Romans had in their possession a collection of the Sibylline verses.

These books were carefully kept till the civil wars of Sylla and Marius: when the Capitol being accidentally set on fire, and burnt down to the ground, these books were burnt with it. This happened in the year before Chrîst 83. But the Capitol being again rebuilt about seven years after this period, the Senate determined to restore the Sibylline oracles; and having procured many that were said to be of this kind, laid them up in the Capitol, in order to supply the place and office of those that were lost. However, the books thus obtained had been dispersed in the hands of many, and were, therefore, by being thus vulgarly known, unuit for the use which the Romans proposed to make of them. On this account a law was passed, which required the surrender of them, and prohibited any from retaining copies of them, under pain of death. Augustus, when he assumed the high-priesthood of Rome, revived this law, and defrayed a great multitude of copies which were brought in. Tiberius caused many more to be burnt, and preserved only those which were found most worthy of approbation for that service of the state for which they were originally intended; and to these, as long as Rome remained heathen, they had constant recourse; till at length Honorius the emperor, A. D. 399, issued an order for destroying them; in pursuance of which, Stilicho burnt all these prophetic writings, and demolished the temple of Apollo, in which they were reposed. Nevertheless, there is still preserved, in eight books of Greek verse, a collection of oracles, pretended to be the Sibylline. Dr. Cave, who is well satisfied that this collection is a forgery, supposes that a large part of it was composed in the time of Adrian, about the year 130; that others were added in the time of the Antonines; and the whole work completed in the reign of Commodus. Dr. Prideaux says, that this collection must have been made between the year of our Lord 138, and the year 167. It could not be earlier, for mention is made of the next successor of Adrian, i.e. Antoninus Pius, who did not succeed him till the year 138: and it could not be later, because Julius Martyn, in his writings, often quotes it, and appeals to it; and he did not outlive the year 167. Fabricius supposes that this collection does not contain all the Sibylline oracles which were used by the ancients; and that the most ancient

Christian
Christian writers, who have quoted the Sibylline oracles, had only a part of the collection which is transmitted down to us. Some of the fathers, not apprized of the imposture, have often cited the books of the Sibyls in favour of the Christian religion; and hence Celsus takes occasion to call the Christians Sibyllists. It must be allowed that St. Clement, St. Theophilus, and some other Greek fathers of the second century, had a much greater respect for the Sibyls than they deferred; for Dr. Lardner says, that he is well satisfied that the Sibyline veris quoted by them are the forgery of some Christian. The ancient Sibylline veris did not recommend the worship of the one God, condemning all manner of idolatry, as those do which are cited by Julian, Theophilus, and Clement. It must be owned, however, that Clement calls the Sibyl a prophetess, and seems to quote her veris as Scripture, in the strictest sense of the word, together with the Scriptures of the Old Testament; so that if there be any books improperly advanced by him into the rank of sacred Scripture, they are the Sibylline books; but Dr. Lardner does not think that he esteemed them of equal authority with the books of the Jewish canon. It is a circumstance that deserves to be mentioned, that the Heathen people knew nothing of these Sibylline veris till they were found out, or rather forged, by some Christian, and then incanunently and imprudently recommended by others. Julian Martyr seems to have been the first Christian writer who quoted the collection now existing of Sibylline oracles, or any Sibylline veris whatever, containing the peculiar doctrines of Christianity. The more ancient writers preceding him, who have mentioned the Sibyls, have quoted nothing but what might be found in Sibylline writings among the Heathens. In the collection above-mentioned, which appears, for the chief part of it, to have been a work of the second century, we have many unquestionable evidences that the writer, who calls himself a Christian, was acquainted with the New Testament, and that in several places he recites the same facts in the same or similar language. The pretended prophecies of this collection are undeniably taken from the New Testament. Whatever was the particular view of the author in composing this work, says Dr. Lardner, and however improperly some ancient writers have produced testimonies from it in their defences of the Christian religion, it is now of use to us, as it affords an argument that our gospels were extant, and in much repute, in the author's time. See farther on this subject, Prideaux's Conn. vol. iv. p. 885, 8c. Lardner's Credib. of the Gospel Hist. vol. iv. book i. cap. 29, or Works, vol. ii.

**SICABA**, in Geography, a town on the north-west coast of the island of Negroes. N. lat. 11° 26'. E. long. 123° 2'.

**SICAE**, in Ancient Geography, a town of Thrace, called in the time of Steph. Byz. Julitianae. — Alfo, a town of Asia, in Cilicia. — Alfo, the name of a place in the vicinity of the town of Alexandria.

**SICAL**, or **SISAT**, in Geography, a town of Mexico, on the north coast of the province of Yucatan; 60 miles N.W. of Merida.

**SICAMINUM**, in Ancient Geography. See **CAIPHA**.

**SICAN**, in Geography, a town of Peruia, in Khoraffan; 15 miles S.W. of Zauzan.

**SICANDERAB**, a town of Hindoostan, in Doob; 36 miles W.N.W. of Pattiany.

**SICANE**, in Ancient Geography, a town of Spain. Steph. Byz. — Alfo, a river of Sicily, which ran near Agrigentum.

**SICANUS**, a town of Spain, according to Ptolemy.

**SICAPHA**, a town of Africa Proper, being one of those which were situated between the two Syrtis. Ptol.

**SICARD**, **CLAUDE**, in Biography, a Jesuit missionary, was born at Aubergne, near Marleilles, in 1677. He entered into the society of Jesus in the year 1699, and for several years taught the classics and rhetoric in their schools. He was at length sent on a mission to Syria, and thence to Egypt, where he died at Cairo in 1726. He was a man of deep as well as extensive learning, and an exact observer of what was remarkable in the countries he visited. His first publication was "An easy Method of learning Greek," translated into French from the Latin of Peter Gras, with additions. When abroad, he sent home several curious letters, which were published in the "Nouveaux Memoires des Millions de la Compagnie de Jefus dans les Levant," in which are likewise published his "Plan of a Work on Egypt, ancient and modern," and "A Differtation on the Passage of the Red Sea, and Journey of the Israelites."

**SICARIO**, in Ancient History, affilains of Judea, who went about the country for the accomplishment of their nefarious purposes, with short swords concealed under their clothes. Josephus has described them in the most odious colours. Eleazar, he says, the chief man among them, was a descendant of Judas, who had perfidled not a few of the Jews not to enrol themselves, when Cyrenius the censor was sent into Judea. For then the Sicarii conspired against all who were willing to submit to the Romans. They treated all such as public enemies. But other pretences were proffed, in order to cover their cruelty and avarice. These hypocritical villains were hired to murder Jonathan, the high priest, at the instigation of Felix. Accordingly, some of the affilains, coming up to Jerusalem, with an apparent purpose of worshipping God; and having short swords under their coats, mixed themselves with the multitude, and killed Jonathan. This murder paffing unpunifhed, the robbers afterwards attended the feats with no fome concern, and carrying, as before, swords under their clothes, and mixing with the multitudes, killed several people, and whom they reckoned their enemies, and fome whom they were hired by others to deflroy. This they did, not only in other parts of the city, but within the bounds of the temple itself. Joseph. De Bell. Jud. l. vii. c. 8. § 1-5.

**SICASICA**, or **CICASICA**, in Geography, a town of South America, and chief place of a jurisdiction of the fame name, in the government of Buenos Ayres, 240 miles in extent; 40 miles N.N.W. of Oruero.

**SICAYAP POINT**, a cape on the north-west coast of Mindanao. N. lat. 8°. E. long. 123° 32'.

**SICCA**, a town on the north coast of the island of Sumbatra. N. lat. 1° 32'. E. long. 110° 40'.

**SICCA**, a town, in the island of Sumatra. N. lat. 35° 68'. E. long. 13° 53'.

**SICACOLLOM**, a city of Hindoostan, in the cir- cock of Conadipally, on the Kilkhan; 35 miles S.S.W. of Ellorc.

**SICCAPILLY**, a town of Hindoostan, in Myfore; 25 miles N.N.W. of Chinda Balabaram.

**SICCA-VENERE**, KEFF, in Ancient Geography, a town of Africa, situated about five leagues S.W. of Lusibus Colonia, and 25 leagues W.S.W. of Tunis. It was built upon the declivity of a hill. Valerius Maximus says, that it had a temple of Venus, at which young females prostituted themselves, in order to obtain a portion that might enable them to marry.
SICCHASIA, a word used by some writers to express that uncainis at the stomach, and lodging of food, which women are often afflicted with in their pregnancy.

SICCHOS, in Geography, a town of South America, in the audience of Quito; 20 miles W. of Latacunga.

SICCINNIS, in Antiquity, a mixed kind of dance.

SICERA, in the Jenoa Antiquities. The Hellenistic Jews give this name to any intoxicating liquor. St. Chrysostom, Theodore, and Theophilus of Antioch, who were Syrians, and who therefore ought to know the significance and nature of sicera, allow us, that it properly signifies palm-wine.

Pliny acknowledges, that the wine of the palm-tree was very well known through all the East, and that it was made by taking a buffet of the dates of the palm-tree, and throwing them into three gallons of water; then squeeving out the juice, it would intoxicate like wine.

The wine of the palm-tree is white; when it is drank new, it has the taste of the cocoa, and is sweet as honey; when it is kept longer, it grows strong, and intoxicates. After long keeping, it becomes vinegar.

SICHAR, in Ancient Geography. See the next article.

SICHEM, or SHECHM, called also NEopolis, Sicar, or Sychar, and Mahaneth, a town of Judea, in the tribe of Ephraim, which took up the south side of Samaria. This town was situated on the summit of a mountain, and became one of the strongest and most celebrated towns of this tribe. It was at this place that Abraham lodged, on his way to Canaan (Gen. xii. 6); and it afterwards became the abode of Jacob, who bought a field in its vicinity, which he gave to his son Joseph, who was buried here. (Gen. xlvii. 2.) Near the same city was Jacob's well or fountain, at which Jesus discourse with the woman of Samaria. (John, iv. 7.) Joshua gave it to the Levites of the tribe of Ephraim, who belonged to the family of Kohath, the first of the Levites; and it was appointed to be one of the cities of refuge. (Josh. xxiv. 1.) It was at Sichem that Joshua assembled the tribes of Israel (Josh. xxiv. 1), to renew the engagement of fidelity to God. Sichem was destroyed by Abimelech; but it appears to have been afterwards re-established, because it is said (1 Kings, xii. 2.) that Rehoboam came hither, after the death of Solomon his father; and it was fortified and inhabited by Jeroboam. (1 Kings, xii. 25.) After the ruin of Samaria by Shalmanezer, Sichem was the capital of the Samaritans; and Jophesus says (Antiq. lib. xi. cap. 8.), that it was in the time of Alexander the Great. It was distant, according to Eusebius and Jerom, 10 or 12 miles from Shiloh, 40 from Jerusalem, and 52 from Jericho. Jerom says, that Paul visited the church built on Jacob's fountain; and others, who wrote in the eighth century, speak of this building; but it is not mentioned by Pocas, who wrote in the twelfth century. Sichem or Sichar is now Napluo, or Nabul; which see.

SICHEM, or SHECHM, in Geography, a town of France, in the department of the Dyle, on the Domm; 30 miles N.E. of Bruxelles.

SICHERFREUTH, a town of Germany, in the principality of Bayreuth; 3 miles S.E. of Bayreuth.

SICILL. See SICILLI.

SICILLIAN, a river of Russia, which runs into the Ochotkoi sea, N. lat. 50° 28'. E. long. 152° 14'.

SICHIIOU-LI-HOTUN, a town of Corea, in the sea of Japan. N. lat. 42° 20'. E. long. 135° 29'.

SICHOW, a town of Bohemia, in the circle of Bohelin; 3 miles N.N.W. of Turnau.

SICTELEN, See SUCHTELEN.

SICHU, a town of Mexico, in the province of Mechoacan; 120 miles N.N.E. of Mechoacan.—Also, a town of Mexico, in the province of Guadalou, 150 miles W.S.W. of Panuco.

SICIGNANO, a town of Naples, in Principato Citra; 10 miles W. of Cagnano.

SICILIAN Mefasures, Silk, and Veffers. See the Subtainties.

SICILIANA, in Botany, a name given by Donouzeus, and some other authors, to the great arthrofeum, called tufion, and park-leaves.

SICILIANA, a pastoral movement in a flow jing-time of . The character of this movement requires a point to the third note of almost every triplet. Nothing is more pleasing than the Sicilian strains of great masters. Handel hardly ever fails rendering them characteristically, touching, and pleasing; such as "He shall feed his Flock like a Shepherd;" "Let me wander not unseen," &c.

SICILIANE, or PASTORALE, a kind of simple rural music, refounding in Chrismas time through all quarters of Naples, and executed by Abruzeze or Calabrian shepherds, upon a species of bag-pipes, called in Abruzzo zampane, and ciarameli in Calabria. The tunes vary, according to the provinces: in the south, they have three different airs; the northern shepherds have only two, to which they add any variations which the boldness of their own genius inspires. The boys learn of their fathers to play upon this instrument, as the means of subsistence. The waits, still kept up in the pay of some corporations in England, are counterparts of these shepherds.

SICILICUM, the name of a weight in use among the ancients; which, some say, was equal to three drachms of our weight; others say only to two.

SICILY, in Ancient and Modern Geography, an island in the Mediterranean, the largest of all the islands in this sea, being about 170 British miles in length, and 70 in medial breadth. Swinburne reckons its greatest length at 210 miles, and breadth 133; and places it between N. lat. 36° 25' and 38° 25', and E. long. 12° 50' and 16° 5'. Sicily is separated from the continent by the straits of Messina, which, in some parts, are about four miles broad. (See CHARYBDIS, MESSINA, and SCYLLA.) At Messina, and at the mouth of the straits between the promontories of Pelorus in Sicily and the Lode di Volpe, or Foxes' Tail, in Calabria, is nearly a mile. Many of the ancient historians and poets have stated that this island was formerly joined to the continent, and severed from it, at an unknown period, by some extraordinary convulsion; nor is this opinion at all improbable. Accordingly Pomponius Mela observes, "Sicilia, ut ferunt, aliquando agro Brutio adnexa." To the fame purpose Virgil (Aen. i. iii. v. 414) says:

"Hae loca vi quondam, et valls convulsus ruina
Diluvii ferunt, cum protinus utraque Tellus
Una fortis. Venit medio vi pontus et undis
Helpefum feculo latus abfcidit."

Sibus Italicus details this event more at large (lib. xiv.):

"Autem pars magna jacet Trinacria Tellus
Ut femel expugnata nata, et vallatibus undis
Acceptid frete curulis propilia tradente,
Namque per occultum carca vi turbinis olim
Impactum Pelagus lacera viridex terrae
Difidet, et medio primum arva profundo,
Cum populus pariter convultas tranquillit urbes."

Claudian affirms poetically,

"Trinacria quondam Italici pars fuit."

Pliny,
Pliny, Strabo, Diodorus, and many others, both historians and philosophers, are of the same sentiments, and pretend that the Ærata on the opposite sides of the Ærata agree perfectly; and some imagine, that this separation is recorded in the name given to Rhegium, a town of Brutium.

With regard to the breadth of the Ærata that separates Sicily from Italy, Silius fays, ubi supra:

"Sed spatium, quod diversaùm constricta terre,
Latras fama elt (sic arcta intervenit unda),
E: mutatius voluerunt transeunte cantho."

And some persons have even affirmed, that not only the crowning of a cock might be heard from one shore to another, but that a strong voice might be heard through this distance.

Mariners have asserted that this canal is not two miles broad.

Sicily, on account of its somewhat triangular form, has been called Trinacria, or Trinacia, and Trinquetra. Its ancient name was Sicania, derived from its inhabitants the Sicani; but when the Siculi took possession of the greatest part of the island, it assumed the name of Sicilia. The interior of Sicily is full of mountains. The ancients, proceeding from the west to the east, enumerated the following:

1. Eryx, near the sea and Drepanum, celebrated for a temple of Venus; Cratas, towards the north, in which are the fountains of the Eleutherus and Himera, and those of Hypa, which flows towards the south; the Gemelli colls, more southerly than the chain of Cratas, in which is the source of the Camicus, and of other rivers; the Nebrodes, northwards and east of the preceding; Maro, still more to the east; the Herae, from south to north, between the sources of the Himera to the west, and those of Simathus to the east; and also the famous mount Ætna; which fee.

Among the rivers of Sicily noticed by the ancients, we may enumerate, on the eastern coast, the Simathus, which rises west of Ætna, and south of the town called Engyum, runs towards the south-east, receiving in its course the Chryfas, and discharges itself into the sea near to and north of Murgentium; and the Mela, south of the preceding, and running in a straight direction from west to east; and on the southern coast, the Himera, which has its source in mount Artemus, in the environs of Enna, and flows into the sea at Phθgia; and the Hypa, which proceeding from the interior of the island, flowed into the sea near to and east of Selinus.

The principal places in ancient Sicily are enumerated and briefly described under their proper names in different parts of the Cyclopædia.

Sicily was celebrated among the ancients for its extraordinary fertility. Its mines of lead, copper, and silver, and its variety of stones and volcanic productions, have been recorded by ancient and modern writers; and it has been observed, that the summits of its highest mountains have furnished a great number of different marine productions.

This island has undergone a variety of revolutions: it has been denominated, in very remote times, the island of the Sun, and the land of the Cyclops, and of the Leltrygons. It was afterwards called Sicana and Sicily, from the names of its possessors. The Phaenicians also had establishments in this island, and carried on with it a considerable commerce, in the advantages of which the Trojans are said to have participated. The Greeks established themselves in Sicily for the first time after the siege of Troy, and kept possession of it for a long period, forming different republics, and transporting hither their manners and arts, and different opinions, and erecting temples of Ærone of the Doric order; and, in the progress of time, they shared the government of it with the Carthaginians. These new conquerors, who about 510 B.C. gained possession of it, brought with them their commerce, their arms, and their gods. They occupied the western and northern shores, whilst the Siculi retained the midland country; and the southern and eastern coasts were inhabited by the Greeks. The Mamertins arriving hither from Italy took possession of Messina, and called over the Romans, who, urged by their ambition, wanted only a pretext of taking up arms against the Carthaginians. After a variety of successfu contests, they took possession of the island. The Romans occupied themselves for some years in establishing peace, abundance, and even splendour; and they erected during the time of the republic superb edifices of marble; their power and ambition setting no limits to their magnificence. Under their dominion Sicily became more flourishing than it had been in the time of the Greeks, when it was considered as free. The Sicilians, under the government of the Romans, lost their military genius, and those mutual jealousies which served only to accelerate their own destruction. When the Romans made themselves masters of Sicily, they permitted the inhabitants to retain the temples, the deities, and the forms of worship which the Greeks and other nations had established among them, and till the division of the Roman empire, they maintained a certain character of elegance and refinement. But at this period the monuments of antiquity sunk into neglect; the arts were no longer held in estimation; and talents disappeared on the access of ignorance and barbarism. Towards the end of the fourth century, Syracuse was the first town of Sicily that received Christianity, and soon after other towns and the whole country followed its example; and this event was followed by a neglect of their temples and public monuments. The ignorance of the priests, no less notorious than the fervour of their zeal, induced them to make war against the sciences and the arts, that they might thus the more effectually and speedily destroy Paganism, which cultivated them.

The Sicilians, having relinquished all martial ideas during a long series of generations, turned their attention solely to the arts of peace, and the labours of agriculture. Their position in the centre of the empire preserved them from both civil and foreign foes, except in two instances of a servile war. But the incapacity of their governors was a more constant and insupportable evil. In this state of apathy and opulence, Sicily remained till the seventh century of our era, when the Saracens began to disturb its tranquillity. The barbarous nations of the North had previously invaded and ravaged its coasts, but had not long kept possession. The Saracens, however, were more fortunate. In the year 827 they availed themselves of quarrels among the Sicilians to subdue the country; and they chose Palermo for their capital. The standard of Mahomet triumphed about 200 years. In 1038 George Maniaces was sent by the Greek emperor with a great army to attack Sicily. He made good his landing, and pushed his conquests with vigour, and, aided by the value of some Norman troops, with success. Maniaces recompensed them with ingratitude; and by his conduct allowed the Minilmen an interval of tranquillity, and the Normans an opportunity and pretext of invading the imperial dominions in Italy. Robert and Roger of Hauteville afterwards conquered Sicily on their own account. After a struggle of ten years, the Saracens, in 1072, as Swinburne says, surrendered the rich prize; though others say, that they lost the possession of it A.D. 1048. Robert ceded it to his brother Roger, who assumed the title of great earl of Sicily. This first sovereign fayed the sceptre with wisdom and glory, and defervely ranks among the greatest charac-
ters in history. He was succeeded by his son Simon, who, after a short reign, made way for a second son called Roger, the first king; who, in 1127, joined to his Sicilian dominions the whole inheritance of Robert Guiscard, and assumed the regal title. Roger, it is said, was named king of Sicily by the pope, A.D. 1130. During his reign, Sicily enjoyed profound peace. The reign of his son William I, who ascended the throne in 1154, was a period of war and confusion. During the reign of Frederick I, a German, the Saracens, who had revolted, were removed to Puglia, 400 years after the conquest of Sicily, by their ancestors. The Norman line continued till their kingdom was subdued by Henry VI. emperor of Germany. After the battle of Benevento, Sicily submitted to Charles of Anjou, a prince of the French line, A.D. 1266, and having endured quietly for a considerable time oppression and wanton cruelty, at length determined to emancipate itself from its tyranny. Accordingly an insurrection took place in 1282, and after the Sicilian vassals, the insurgents offered their crown to Peter I, king of Aragon, who accepted and defended it against all the efforts of his antagonist, and the thunders of the Vatican.

On the death of Alphonso the Magnificent, who succeeded his father Ferdinand I of Castile, Naples was added to his other dominions; and after his decease in 1458, the history of Sicily becomes interesting. At the peace of Utrecht, Sicily was ceded to Victor, duke of Savoy, who soon after was compelled by the emperor Charles VI. to relinquish it, and accept Sardinia as an equivalent.

For further particulars relating to the history of Sicily, we refer to Naples.

The climate of Sicily is very hot; the thermometer at Palermo varying in June and July from 73° to 86°, and when the fierce wind blows, rising suddenly to 112°, March is the only month in which any chilling winds are felt, and even in the beginning of January the shade is refreshing. The appearance of winter is only seen in the snow that falls on the summit of Mount Etna. (See that article.) Although the island, in many parts of it, the aspect of a rock, the soil is singularly fertile, but it is not now cultivated as it was formerly, when it was reckoned the granary of Rome. The crops of wheat are still so abundant, notwithstanding the opprobrium of the government, as not only to supply the wants of its own inhabitants, but to afford a large surplus for exportation; and if this island enjoyed the blessing of a free government, it might become one of the richest and most flourishing in the world; for even in its present wretched state of cultivation, one good crop, says Brydone, would be sufficient to maintain the island for seven years; but when he visited the island, the exportation of this commodity had been prohibited for several years past, or, at least, to all such as were not able to pay most exorbitantly for that privilege. The sugar-cane was formerly very much cultivated in this island, but the duties imposed were so enormous, that it has been almost totally abandoned. Silk afforded formerly a profitable branch of trade, but this has very much declined. Besides wheat, which has at all times contributed the riches of this island, they cultivate many other branches of commerce, though none that could bear any proportion to this, were it under a free government, and exportation allowed. Their granaries are so contrived, by excluding the air and keeping the grain dry, as to preserve it for many years. Large quantities of barley and pulse grow in Sicily, but very little oats or millet. Canary-bird feed is exported to a large amount, and is almost peculiar to this island. Large quantities of oil are exported from places on the north side of the island. Wine and brandy are exported in great abundance; and the wines are very various. The fisheries, also, are very productive, and great quantities of tunny, anchovies, and sardines, are fished, and sent from the vicinity of the places where they are caught.

The art of manufacturing silk, and of the management of the silk worms that produce it, was established here by Roger, king of Sicily, and it was communicated from hence to the western countries of Europe.

Silk is considered as the second great source of riches to Sicily, corn being undoubtedly the first: a quantity of silk, equal in value to a million of ducats (187,500l.) is annually exported. Palermo and Messina alone lend it out; a considerable quantity of the materials is manufactured in both places; but Palermo, which employs nine hundred looms, exports very little, most of its silks being used at home. Messina employs twelve hundred looms, and Catania rather more. In the Messine manufactures a variety of silks is made, but the silk is seldom well made, dyed, or matched, and the work is apt to prove hard and to rub. Most of it goes to the Levant.

A large quantity of barilla is shipped from the southern coast. The white and heavy felt is produced at Trapani. This island also furnishes licorice, hare and rabbit-skins, rags, sulphur, &c. for exportation.

Soda is a commodity of which they have an ample supply, and they every year lend great quantities of it to the glass-works at Venice. They have likewise a considerable trade in liquors, rice, figs, raisins, and currants, the bulk of which grow among the distinguished volcanoes of the Lipari islands.

Their honey, which is gathered three months in the year, viz. July, August, and October, is very highly flavoured, and in some parts of the island superior to that of Minorca.

Although sugar is now no article of Sicilian commerce, enough is made for home consumption; and the sugar-cane is said to thrive very much in several parts of the island. It is said, that towards the north of Sicily they find the shell-fish that yields a kind of wax, of which gloves and stockings are made. Their plantations of oranges, of which 2000 chests are shipped annually from Messina, lemons, bergamots, almonds, &c. afford no inconsiderable branch of commerce. The pistachio-nut is likewise much cultivated; their manna and alum are likewise very profitable. The cantharides fly, which is found on several trees of Etna, is also a Sicilian commodity. These cantharides are said to be preferable to those of Spain. Sicily abounds with mineral springs of both hot and cold water; some of which throw up an oil that is applicable to various purposes. The marble of Sicily would afford a great source of opulence, if there were any encouragement to work the quarries; and they have also other stones that are serviceable in a variety of ways.

It would, however, be endless to give an account of all the various commodities and curious productions of this island; Etna alone affords a greater number than many of the most extensive kingdoms, and it is the epitome of the whole earth in its fossil and mineral climate, than in the variety of its productions. Besides the corn, the wine, the oil, the silk, the spice, and delicious fruits of its lower region,—the beautiful forests, the flocks, the game, the tar, the cork, the honey, of its second,—the snow and ice of its third; it affords from its caverns a variety of mineral and other productions; cinabary, mercury, sulphur, alum, nitre, and vitriol; so that this wonderful mountain at the same time produces every necessary, and every luxury of life.

Its first region covers its tables with all the delicacies that the earth produces; its second supplies them with game, cheese, butter, honey; and not only furnishes wood of every kind
kind for building their ships and houses, but likewise an inexhaustible store of the most excellent fuel; and as the third region, with its ice and snow, keeps them fresh and cool during the heat of summer, so this contributes equally to keep them warm and comfortable during the cold of winter.

The principal trade of this island is carried on at Palermo and Messina; the former confines of imports four or five times more than the latter; but on account of lighter duties, Messina exports a greater quantity of silk, and supplies the inland towns with more commodities. The buxomity of other places on the coast confines solely in shipping corn, wine, salt, &c. Trapani, on account of its famous salt-panes and the shipping belonging to it, is one of the busiest commercial towns in the island.

According to the enumerations made in 1714, says Swinburne, Sicily contained 1,133,163 inhabitants, including 40,000 ecclesiastics, and 110,000 inhabitants of Palermo. In 1615 it contained 1,107,234; in 1595, 488,500, without reckoning the inhabitants of Palermo or Messina. When Mr. Brydone visited the island in the year 1770, he says that the inhabitants, by the last enumeration, amounted to 1,123,163, of which number there were about 50,000 that belonged to the different monasteries and religious orders: the inhabitants of Palermo were computed at 150,000. The number of houses in the island were estimated at 268,120; so that allowing the enumeration and the estimate to be just, the number to a house appears to have been between five and six. The vicissitudes and commotions that have more recently occurred have not been favourable to an increase, but must rather have contributed to a diminution of the population.

The provinces in this island are three: viz. Val di Noto, 260 miles in circumference; Val di Mazara, 302 miles in circumference; and Val Demona, 313 miles in circumference: they contain 42 towns belonging to the demeane, and 310 baronial.

Sicily is governed by a viceroy, in whose absence the archbishop of Palermo is regent. The general assembly of parliament is composed of 66 archbishops, bishops, abbots and priors, which form the braccio ecclesiastico: 58 princes, 27 dukes, 37 marquises, 27 counts, 1 viscount, and 79 barons, form the militaire; and the demaniale consists of 43 representatives of free towns. Out of each braccio four deputies are chosen to conduct public business; but the viceroy, the prince of Butera, and the prator of Palermo, are always the three first. N.B. There are many titled persons that have no seat in the assembly, viz. 62 princes, 55 dukes, 87 marquises, 1 count, and 282 other feudatories.

The ecclesiastical government consists of three archbishops and seven bishops.

The following tables shew the coins, weights, and measures of Sicily.

**Tables of Sicilian Coins.**

**Gold Coins.**

1. Piece of 6 ducats, or double ounce.
2. Piece of three do. or onza.
4. Piece of one ditto and a half.

**Silver Coins.**

- Scudo, equal to 12 taris.
- Ducat - 10.
- Mezzo scudo - 6.
- Terzo di scudo - 4.
- Piece of three tari - 3.
- Of two tari, equal to the tari of Naples.
- Of one tari, equal to the carlini of Naples.

**Bronze Cents.**

- Grano, equal to six Neapolitan calli, or half a grano.
- Mezzo-grano, equal to three calli of Naples.

Other subdivisions are seldom met with.

- The ounce, or onza is equal to 3 ducats, or 30 taris.
- The scudo - 12 taris.
- The ducat - 10 taris.
- The tari - 20 grano.
- The grano - 6 piccoli.

Accompts are kept in onza, tari, and grano. As an average, the ducat is worth forty-five pence English money.

**Weights and Measures.**

There are two sorts of weights used in Sicily.

1. Grande.
   - 1 Cantaro contains 110 rotoli.
   - 1 Rotolo - 33 ounces.
   - 1 Pound - 12 ounces.
   - 1 Ounce - 30 trapezi.

   This cantaro is equal to 1714 pounds avoidupois weight.

2. Common.
   - 1 Cantaro contains 100 rotoli.
   - 1 Rotolo - 30 ounces.

   This cantaro is equal to 178 pounds weight avoidupois.

**Dry Measure.**

- 1 Salma generale contains 16 tomoli—equal to 26 Wincheller bushels, used in measuring wheat.

- 2 Salma a la groffa contains 16 tomoli—equal to 24 Wincheller bushels, used for barley, beans, &c.

**Liquid Measure.**

- 1 Califis weighs 18 pounds avoidupois.

**Wine.**

- 1 Salma contains 8 quartari.
- 1 Quart contains 12 quartari.

**Lineal Measure.**

- 12 Oncia make 1 palmo, equal to 10 inches 3 lines.
- 8 Palmi make 1 canna, equal to 6 feet 8 inches.

Besides the obligations which the Romans had to the Etruscans and Greeks for their tale and knowledge in the fine arts, the conquest of Sicily 200 years before the Christian era, contributed greatly to their acquaintance with them. Indeed, there was no state of Greece which produced men of more eminence in all the arts and sciences than Sicily, which was a part of Magna Grecia, and which having been peopled 719 years B.C. by a colony of Greeks from Corinth, their descendants long after cherished and cultivated science of all kinds, in which they greatly distinguished themselves, even under all the tyrants of government with which they were oppressed. Fabricius gives a lift of seventy Sicilians who have been celebrated in antiquity for learning and genius, among whom we find the well-known names of Æclitus, Diocorus Siculus, Empedocles, Gorgias, Euclid, Archimedes, Epicharmus, and Theocritus. To the Sicilians is given not only the invention of pastoral poetry, but of the wind instruments with which the shepherds and cowherds used to accompany their rural songs.

After the conquest of Greece, the Romans had the tale to admire and adopt the Greek arts. And the president Monteflequin remarks, with respect to the military art, that one of the chief causes of the Roman grandeur, was their method...
method of abandoning their ancient customs, and adopting those of the people whom they had vanquished, whenever they found them superior to their own.

SICIMA, in Ancient Geography, a town of Palestine, in Samaria, according to Josephus.

SICINOS, or PHELEGANDROS, the name of one of the Cyclades islands; situated S.E. of Siphnos, E. of Melos, and W. of Ios, and very near it.

SICION, in Geography, a small island in the Indian sea, near the coast of Africa. S. lat. 12° 35'.

SICK HERRINGS. See HERRING.

SICKHERY, in Geography, a town of Hindoostan, in the circuit of Gohud; 5 miles N. of Lahaar.—Also, a town of Hindoostan, in the circuit of Gohud; 10 miles S.E. of Kooch.

SICKLE, in Agriculture, a toothed hook, with which corn is reaped.

There is considerable variety in the construction of the tools which are employed for this purpose in different places; and which, in some, are denominated sickles, but in others hooks. Some of them are also used in one part of the country, and some in another, being wholly unknown in others.

The common sickle is a fork of semicircular piece of wrought iron faced with steel, which in general is from about twenty to thirty inches in length, and about half an inch in breadth, having a sharp toothed-edge cut in the filed part, from twenty-six to thirty teeth being formed in every inch in length. The teeth all incline towards the handle of the tool, so that it only cuts when it is drawn towards the person using it, and not when introduced through the standing corn in the act of reaping. The Farnese sickle, a valuable tool of this kind, made use of in a district of that name in the northern part of Lancashire, has a blade two feet five inches long, edged with fifteen teeth in every inch, and in the span of its curvature, measures two feet from the heel to the point. It is a powerful tool, and capable of doing much work in a given time when in good hands, as seen below.

The finest-edged sickle, or reap-hook, has a shape and length which are much the same as those in the common sickle, only a little broader; but the edge is smooth or sharp and without teeth.

The bagging or bagging sickle or hook is a tool of the same kind, but which is a great deal larger and heavier, as well as broader at the point. It can, however, be used with great effect and expedition by those who are accustomed to this mode of reaping.

The fickle-hook is also another tool of this nature, which is made use of in some districts. It is only toothed from about the middle to the point end, by which the waste of grain in cutting is said to be prevented.

By much the most ancient of these tools is the common fickle, and it is probably, on the whole, the best of them, though it is getting much out of use in many parts of the country, being now even feebly known or employed in the counties of Devon, Cornwall, and Somerset, and many other places in the more western districts of the kingdom, having long since given place to the hooks, the reaon of which seems to be the greater ease of performing the work by them, as is commonly supposed, but by no means proved. The fickle is by far the most frugal and economical tool for accomplishing the work with, as causing the least loss of grain. Trials made with the fickle and the reap-hook, have indeed shown that the latter tool is more expeditious, but at the same time that the loss of grain is far greater, being estimated at not less than five-sixths of the whole in scattered corn.

This difference is supposed to be produced by the hook having a sharp smooth edge, which cuts the stems, as it is put into the standing corn, before it is gathered into the left hand of the workman; while the fickle having a fine-toothed edge inclining towards the heel part, as has been already seen, does not cut the straw as it is put into the standing crop. Thus, though the hook will execute the work with greater facility, where the workman takes care to have the same buckle, the mode will probably be to have recourse to the fickle-hook, by means of which, from the manner of it being edged, it will much prevent the above enormous loss of corn which is caused in other ways of doing the business.

It is necessary for the farmer to be aware of this difference in the use of the different tools of the fickle kind, as at the hooks are fast introducing themselves into the eastern and even the northern parts of the kingdom, as well as into Ireland, where they were formerly unknown, and prevails much in many other places.

In the above district of Furnes, the reaping is wholly and most excellently performed by means of the fickle. At an easy rate of working, three men, it is said, with this tool, will cut a customary acre of fix yards and a half to the pole or perch, of long, light, slender corn, bind, and flout the fame in the course of a day, or less than twelve hours; and five men with these tools will perform the fame quantity of work in a field of the strongest corn, when laid and much entangled. By hard labour from light to dark, three men with this sort of tool will reap, bind, and flout above a customary acre of any kind of grain. See Harvesting and Reaping of Corn.

Sickle-Fix. See FALK.

Sickle-Wort, in Botany. See Coronilla.

SICKLUPEN, in Geography, a town of Prussia, in the province of Siamland; 5 miles N. of Tilkat.

SICKNESS. See Disease.

Sickness, Falling. See Epilepsy.

Sickness, Green. See Chlorosis.

Sickness, Sweating. See Sweating Sicknes.

SICKREE, in Geography, a town of Bengal; 26 miles W.N.W. of Ramgur.

SICLOS, a town of Hungary, having a castle on a mountain, in which the emperor Sigismund was imprisoned; 64 miles S.E. of Canificha.

SICLYGULLY, a town of Bengal; 15 miles N. of Rajenial.

SICON, a town of the island of Cuba; 125 miles W.S.W. of Havanna.

SICUB, or Sicup, in Natural History, a name given by the inhabitants of the Philippine islands to a species of hawk, of the birds of their common hawk, or hawk, which is somewhat larger than our sparrow-hawk. This bird is very elegantly variegated all over its body with yellow, white, and black. See Layin.

SICULI, in Ancient Geography, a people originally of Dalmatia, who established themselves in Italy about the 16th century B.C. They formed a numerous nation, and had possession of a considerable extent of country; as they peopled Umbria, Sabina, Latium, and all the cantons, the occupants of which were afterwards known under the name of Opici. The Siculi fell into Italy, and gave it their name. This event is said to have taken place, according to Hellanicus of Lesbos, 80 years b.f the siege of Troy, or 1364 years B.C. according to the chronology of Titurel. The name of Siculi, which comprehended all the people who diffused themselves from the Tiber to the eastern
extremity of Italy, the country occupied by the Liburni excepted, was gradually abolished by the separate leagues and disjunctions of the Sabines, Latins, Samnites, Omantrians, and Italians. Herodotus, Thucydides, Plato, and Aristotle, mention these people.

SICULIANA, in Geography, a town on the S. coast of Sicily, containing 5000 persons, and belonging to the prince of La Catholica, to whom it yields an annual income of 14,000 crowns. It is remarkable for not having a single convent within its precincts, owing other to the danger of a visit from the Mahometans, or to the recent foundation of the town. The ignorance of the inhabitants, at least with regard to philosophy, is remarkably evinced by an anecdote mentioned by Swinburne. On the wall of his apartment he found notice of a thesis to be maintained in the school of Girgenti by a native of Siculiana: in which he undertakes to prove, "that the Copernican system is absurd, and contradictory to Holy Writ, from which it is evident, that the earth stands still, and the sun moves round it, like the tail of a windmill round the pivot." Siculiana is pleasantly situated on two hills joined together by a long street; the vale below being full of orange and other fruit-trees, and the view of the sea very extensive; 12 miles N.W. of Girgenti.

SICULONES, in Ancient Geography, a people who inhabited the Cimbric peninsula, according to Ptolemy.

SICULOTÆ, a people of Dalmatia, who, according to Ptolemy, were divided into 24 deurice.

SICUM, a town of Illyria, on the coast of Dalmatia, between Scardona and Salone, according to Ptolemy and Pliny. The latter says, that the emperor Claudius sent his famous order there to the Emperor Maximinus, and the emperor had a body of men, of which the Emperor Claudius sent his order to them, and they were called by his own name. Accordingly it was not one of the nobilest cities in Greece, on account both of its magnificent edifices and ingenious workmen, but it was a considerable place when the Venetians were masters of Morea, under the new name of "Bafficca," though it has been near for the last two centuries reduced to a heap of ruins, containing only three Turkish, and about as many leaning walls. The town was situated on the top of a hill, about three miles from the gulf of Lepanto; and has still several monuments of its ancient as well as modern grandeur, particularly the walls of its famous citadel, of some fine churches and mosques, and a large ancient edifice, called the royal palace, with aqueducts to supply it with water, all which, with other old remains, are described by Sir George Wheeler, Vox.

After the death of Zephyrillus, the last king of Sicily, this state is said to have been governed by the priests of Apollo Carneus, five of whom held the sovereignty only during one year each; after which the Aegyptians swayed the sceptre nine years succedently, and Charidemus, the last of them, continued in it 18 years. After this hierarchy had lasted 32 years, the Heracleidae, who were at that time returned from Peloponnesus, became masters of it, or, according to Paulianus, the kingdom was incorporated with the Dore, and became subject to that of Argos, the next kingdom to that of Sicily in respect of antiquity. Anc. Un. Hist. vol. v.

SICYONE, a word used by Hippocrates to express colocyth, and by others for a species of hard-shelled gourd, in the shape of a pear, and by some for a cupping-glass.

SICYONIUM OLEUM, a word used by the ancients to express a medicinal oil, of which there were among them three kinds in use. The first was called *ficoonum simplex*. This was composed of two ounces of the root of the wild cucumber, boiled several hours in a pint of oil. The second oil was called *compound ficoonum*, and was made of the root of the same plant, with many other ingredients. The third was another compound kind, made not with an infusion of the root, but with the juice of the fruit of the wild cucumber.

SICYONII, among the Romans, were shoes of a more delicate

Gen. Ch. Male. Cal. Perianth of one leaf, bell-shaped, with five small awl-shaped petals. Cor. bell-shaped, in five deep ovate segments, united to the calyx. Stam. Filaments three, awl-shaped, short, connected at the base; anthers two on each of five filaments, one on the third. 

Female on the same plant. Cal. Perianth as in the male, superior, deciduous. Cor. as in the male. Pet. German inferior, ovate; style cylindrical; stigma tumid, three-crested. Peric. Berry ovate, belted with spines, of one cell. Seed solitary, nearly ovate.

Female, Calyx superior, with five teeth. Corolla in five deep segments. Style three-crested. Berry with one seed.

1. *S. angulata*. Angular Single-seeded Cucumber; or Chocho Vine. Linn. Sp. Pl. 1439. Wildl. n. 1. Att. n. 1. Pursh n. 1. (Bryonioides flore et fructu minore; Dill. Ell. 88. t. 51. f. 59.) Cucumis bryonioides bifinagrarica, fructu parvo, glorum calyce maturico; Pluck. Phyt. t. 26. f. 4. C. canadensis monopomeros, fructu echinato; Herb. Parad. t. 133; ibid. p. 108. Bryonioides canadensis, &c.—Leaves five-angled, minutely toothed, heart-shaped, with an obtuse finus, at the base.—On the banks of the Mississippi, from Canada to Carolina, flowering in June and July. Purfla. The root is annual. Stem branched, hairy, weak, climbing by means of long, spiral, divided tendrils. Leaves alternate, on long flanks, pointed, more or less toothed, minutely rough, or three or four inches broad. Flowers white, marked with green lines, axillary; the male ones racemose, on a long flaks; female on a much shorter flaks, and capitate. Fruit ovate, pale, spinous, half an inch long, about eight or ten to an inch round. Seed large, ovate, smooth.

2. *S. parviflora*. Small-flowered Single-seeded Cucumber. Wildl. n. 2. —“Leaves five-angled, minutely toothed, smooth; heart-shaped, with a roundish finus, at the base.” —Native of Mexico. Communicated to professor Willdenow, by the celebrated Baron Humboldt, from whose seeds it was raised at Berlin. Annual, like the last, and much resembling it, but the leaves are not so long, nor is their finus an obtuse angle, but round. The male flowers are not so large as in *S. angulata*; the female ones about a quarter the size of that species. The fruit however is but little smaller. Wildenow.

3. *S. vitifolia*. Vine-leaved Single-seeded Cucumber. Wildl. n. 3.—“Leaves five-lobed, toothed, hairy and vifcid; heart-shaped, with a roundish finus, at the base.” —Willdenow saw this species in a living state, but was unacquainted with its native country. He describes it as annual, differing widely from both the preceding in having the leaves divided half way down into five lobes, clothed, like the whole plant, with fine vifcid hairs, and smelling like *Sisymbium vaccinum*. Male as well as female flowers half the size of the first species.

4. *S. laciniata*. Jagged-leaved Single-seeded Cucumber. Linn. Sp. Pl. 1439. Wildl. n. 4. (Sicyoides fructu echinato, foliis lacinio; Plum. Ic. 239, t. 243, f. 1.)—Leaves deeply five-lobed, laciniata.—Native of South America.—By Plummer’s figure, this species seems to differ from all the foregoing in its deeply divided and jagged leaves, which are rather rough on the upper side. The fruit appears more rounded and obtuse than in *S. angulata*.

5. *S. Garritii*. Linn. Mant. 297. Burm. Ind. t. 57. f. 3. —Is rightly, we believe, referred to *Bryonia* by Willdenow, in his Sp. Pl. v. 4. 625. Burmane mišook the flipula for the fruit, a rare instance of the kind!

SID, in Geography, a small river of England, which runs into the English Channel, at Sidmouth.

Gen. Ch. Cal. Perianth inferior, simple, of one leaf, angular, cut about half way down into five segments; in some, a short, dilated, upwards, emarginate, attached by their claws to the tube of the flammen. Stam. Filaments numerous, united below into a tube, separating at the upper part of the tube into capillary segments; anthers roundish. Pet. German orbicular; stigmas five, ten, or more, or less combined below; stigmas capitata. Peric. Capsule roundish, angular, deprest, as of many cells, as there are stigmas, more or less combined at the base, each with two pointed valves, bursting at the upper part. Seeds one or more in each cell, roundish, generally pointed; convex at the outer side; angular at the inner, by which they are attached to the central column.

Obi. This genus includes the *Malvinda* of Dillenius, which has five cells only, with solitary seeds, as well as his and Tournefort’s *Abutilon*, whole cells, as well as seeds for the most part, are more numerous. *Anoda* of Cavanilles is very insufficiently distinguished, by the cells of the capsule being rather more united than usual; but there is no clear or decided difference. For the distinctions of *Napaea*, referred to *Sidon* by Cavanilles, Schreb., &c. see that article. The fruit of the Linzaean *S. periplacifolia* seems peculiar, having two series of cells, according to Schreb.

An extensive genus, including most of the columiniferous or malaceous order, that have no external calyx. Cavanilles and L’Heritier have considerably added to the quantity of species. Their number in the 14th edition of Linn. Syll. Veg. is only 27; from which the half of all, being Schreb’s *Palavia*, is to be expunged. (See that article.) Willdenow reckons up 99, but from these are to be deducted the two *Napaea* of Linnaeus, which undoubtedly constitute a distinct genus, as we have shown in its proper place. In their stead, however, there are two or three from North America. Most of the species are tropical plants, natives of the Ear or West Indies. Several are found in Mexico and Peru; eight in North America; a few at the Cape of Good Hope, the Mauritius, &c.; none truly wild.
in Europe, though S. Abutilon is reported to grow in Siberia and Switzerland, where it may perhaps have been naturalized; as has happened to various tropical annuals in colder climates than what is natural to them. Abyssinia has afforded one new species to our gardens; besides which, 34, exclusive of the Napea, are enumerated in Mr. Aiton's valuable work.

The habit of all is more or less shrubby, though several have annual roots. The leaves are alternate, flaked, simple; either entire, toothed, or lobed. Inference mostly axillary. Leaves yellow, reddish, or white. The species are divided in sections, according to the shape of the foliage. We shall give various examples.

Seët. 1. Leaves lanceolate, more or less narrow, oblong, or ovate. Seventeen species.

S. bipinata. Prickly Sida. Linn. Sp. Pl. 960. Willd. n. 6. Ait. n. 2. Pursh n. 1. Cavan. Diff. 11 n. 1. f. 9. (Alcea carpinifolia, americana frutescens, floccus luteus, femine duplex rostro donato ; Comm. Hort. v. i. 3. t. 2.) — Leaves ovato-lanceolate, serrate; somewhat heart-shaped at the base. Stipulas fetaceous, with axillary spines. Flower-flasks simple, mostly solitary. Capsules with beaked valves. —Native of the East and West Indies, Senegal, Arabia Felix, and North America. Mr. Pursh says it is found among rubbish, and by road-sides, from Pennsylvania to Carolina, flowering in July and August. This was one of the earliest species cultivated in England, but rather for curiosity than beauty. The broader leaves principally distinguishing it from the former, for their flowers appear are nearly similar. The root is annual or biennial.

S. bipinata. Haploid Sida. Pursh n. 2. — "Rough with bristly hairs. Leaves lanceolate, serrate. Flower-flasks axillary, the length of the footstalks. Outer calyx thread-shaped."—Described by the above author, from the herbarium of Mr. Lyon, who is said to have met with this plant in the sandy plains of Georgia in North America. The flowers are yellow. If they have really an external calyx, the plant can be no Sida; but perhaps a simple fetaceous bract is all that is meant by the above definition. We have seen no specimen.

S. carpinifolia. Hornbeam-leaved Sida. Linn. Suppl. 307. Willd. n. 8. Ait. n. 3. Jacq. Lea. Rar. t. 135. Cavan. Diff. 274. t. 134. f. 1. — Leaves ovato-oblong, smooth, closely serrate. Stalks axillary, about four-flowered. Capsule with beaked valves. —Mr. Maffon met with this shrub in the garden of a Franciscan convent, in Madeira, and sent it to Kew garden in 1774, where it is treated as a green-house plant, flowering most part of the summer. The native country has not been ascertained. The branches are hairy, spreading, like the leaves, in two directions. The latter are two or three inches long, and nearly half as broad, smooth, with crowded, acute, somewhat unequal, or doubled, serrations, each tipped with a bristle, as in the genus Carpinus. Calyx smooth. Petals yellow, oblique, and partly notched. Capsule of eight cells, each having two spinous beaks. S. plantifolius, Cavan.
though more elongated. This last plant being reckoned a
*Periplaca* by Tournefort and Dillenius, cauied the above
specice name. The flowers are yellowish, small, and fuga-
cious, opening in bright funfime only.

riplacifolia b; Linn. Sp. Pl. 963. S. tellata; Cavan. Dill. 27 and 349. t. 5 f. 4. Abutilon amphiplo foio, cau-
se villofo; Plum. f. c. 2. t. 3.)—Leaves roundifh-heart-
shaped, pointed, obtuseuly crenate; downy bonth:

*S. purpureas*. Naked-flowered *Sida*. L'Herit. Stirp. 177. t. 63. (S. peruviana; Cavan. Dill. 35. t. 7. f. 8, and 276.
t. 130.)—Leaves orbicular, heart-shaped, crenate, finely
downy, with short points. Flower-flalks orbicular, foltary,
flower-flaked, longer than the foot-flalks. Capsules orbicu-
lar, of numerous abrupt cells. *Native of Peru*. A green-
houfe rather than a fove-plant, both at Paris and Lon-
don, flowering in the latter part of funmer. This is
much larger in all its parts than the foregoing, to which it is,
in many respects, nearly aliied. The leaves however dif-
der in their short points, greater breadth, and more orbil-
cular form, the lobes at the bafe folding over each other,
so as to give the leaf a peltate apect. The foot-flalks are
six inches long in the lower leaves, two or three in the
upper. From the bofoms of the latter proceed the flower-
flalks, twice the length of their correpoding foot-flalks,
always foltary, as far as we have observed, though Wil-
denow says they are in pairs. We fupofe he confounded
this species and the hall. The flowers are full twice the
fize of *S. fwnbmata*, and of a pale sulphur-colour, or yel-
low-bihle.

935. Abutilon Avenaceum; Bell. Hort. Eyll. Diff. 6. t. 10. f. 1.)—Leaves roundifh-heart-shaped, pointed,
toothed, downy. Flower-flalks axillary, foltary, shorter
than the foot-flalks. Capsules orbicular, of numerous,
abrupt, double-baked cells. *Native of both Indies*; long
cultivated in the gardens of Europe, and partly naturalized
in the warmer parts, fo that Haller admits it as a Swiss
plant, under his n. 1077. Gerard raifed it every year,
from Spanifh or Italian ffeeds; fo he fays it hardly ripened
any in his garden, not flowering till September. The
root is annual. Stems much branched. Leaves not unlike
the *Arboria* in shape, but more pointed, more coarfly
notched, often obliquely lobed, and fels lofty pubefcent.
Flowers yellow, not an inch wide, foltary, except that
each is frequently accompanied by a young flowering branh.
Capsules downy, with a sharp, double, incurved leaf to each
cell. This, like many other old garden plants, of which no
coloured plates exit, ought to be figured in periodical pub-
lications.
Sida.

Lecto. heart-shaped, indented. Stalks many-flowered or racemose.

Flowers small, yellow, five or six in each long-flaked axillary solitary umbel. The upper umbels are many of them, unattended by leaves. The valves of the calypode have each a sharp, Iter, erect beak.

S. paniculata. Panicled Sida. Linn. Sp. Pl. 592. Willd. n. 78. Ait. n. 32. Cavan. Diff. 16. t. 12. f. 5.; Swartz Obi. 259. (S. astro-funguea; Jacq. Coll. v. 1. 49. t. 1. 136. C. capillaris; Cavan. Diff. 10. t. 1. f. 7.).—Leaves ovate or heart-shaped, toothed, downy on both sides. Flowers pinnate, with capillary stalks. Capsules rough, with double-beaked cells.—Native of calcareous rocks in Jamaica, as well as Peru and Brazil. Sir Joseph Banks is recorded as having sent it, in 1795, to Kew, where it flowers in the clove from July to September.

Mrs. Aiton marks this species as biennial. Jacquin describes it as an evergreen shrub, eighteen feet high, almost always in bloom. Our wild Peruvian specimens appear woody, with rough round branches. The leaves are stalked, of a roundish-ovate, partly heart-shaped figure, various in length from one to three inches, strongly serrated, clothed on both sides, but more densely beneath, with stellate pubescence.

Flowers small, crimson, copious, on long, very slender, pinnate stalks. Corolla more or less reflexed.

S. terminalis. Terminal-stalked Sida. Cavan. Diff. 29. t. 6. f. 6. t. 195. f. 2.; Willd. n. 82.—Leaves heart-shaped, deeply crenate, somewhat lobed, very soft and downy. Clusters simple, somewhat corymbose, on very long, solitary, terminal stalks. Capsule hairy.—Gathered at Monte Video, by Commoner, whose specimen is before us. The stem is shrubby, much branched, downy, apparently of rather humble growth. Leaves dependent, shorter than their flower, heart-shaped, bluish, very, scarcely an inch long, extremely soft, their nerves broad, round, and very unequal. Flower-stalks terminal, though the branches are often subequently elongated beyond them, solitary, simple, naked, four or five inches in length, round, downy, each bearing four or five rather large, flat-topped, corymbose, yellow, flowers, externally purplish, with linear bracteas, which soon fall off. The calyces, twice as long as the flowers, are thickly clothed with long upright hairs. The curious reader may observe how Wilkenden, without any other guide than the description and plates of Cavanilles, has altered his specific character for the worse. Wilkenden terms the leaves "ovato-lanceolate" and "toothed," for neither of which there is any foundation; but it may serve us, in any other doubtful case, to understand his phaenology, for which reason, chiefly, we here point it out.

Sect. 5. Leaves heart-shaped, three-pointed, or angular at the base.

S. crassifolia. Thick-leaved Sida. L'Herit. Stirp. 125. t. 60. Willd. n. 84. (S. tricuspidea; Cavan. Diff. 30. t. 6. f. 5.).—Leaves heart-shaped, toothed, pointed, obscurely lobed, downy on both sides. Stalks solitary, flowered, about equal to the flowerstalks. Capsules with double-beaked cells, rather longer than the calyx.—Gathered in Hispaniola by Thirry de Menonville. A flore-plant at Paris, unknown in our collections. The stem is shrubby, branched, round, downy. Leaves three inches long, strongly scented, bordered with tooth-like serrations, and furnished with one or two flat lobes at each side. Flowers yellow, an inch broad, on long, simple, axillary flabellae.

S. pectinata. Shuttlecock Sida. Sims in Curt. Mag. t. 164.—Leaves heart-shaped, pinnate, pointed, downy on both sides, somewhat angular; the upper ones heart-shaped. Pinnate racemose. Petals emarginate, nearly erect, shorter than the flowers. Capsule without a beak.—Supposed to be a native of Mexico. It flowers nearly throughout the year, in the collection of John Walker, eq. of Arno's grove, Southgate; but we are not informed whether it is a greenhouse or flore-plant. The stem is tall and shrubby, with round hipid branches. Leaves green, alternate, flaked, divergent; the upper ones elongated, and deeply lobed. Flowers elegant, bright scarlet, near an inch long, of a shuttlecock form, as the inerely heart-shaped, oblong petals spread but very little. The column of filaments rises considerably above them.

S. xylola. Halberd-leaved Mexican Sida. Willd. n. 89. Ait. n. 33. Andr. Repol. t. 588. Curt. Mag. t. 154. S. crassifolia; Linn. Sp. Pl. 964. Anoda hakata; Cavan. Diff. 38. t. 11. f. 2.)—Lower leaves heart-shaped, lobed; upper halate. Stalks axillary, solitary, flowered, longer than the leaves. Petals oblong, spreading, entire. Native of Mexico. Its seeds were brought from Spain by the late marchioness of Bute. An annual or biennial flore plant, which may be raised on a hot-bed early in the spring, and planted out in the open border. It is scarcely however likely to be added to the list of tropical annuals, generally so cultivated, being much inferior in beauty to most other plants, of the Mallow tribe, that are quite hardy. Its flowers are light purplish-blue, about an inch wide, on long, fraggling stalks. The divisions and shape of the leaves vary greatly. The valves of the calypode have no beaks.

S. crassifolia. Crested Sida. Linn. Sp. Pl. 594. Willd. n. 90. Curt. Mag. t. 350. (Anona trifolia; Cavan. Diff. 39 and 55. t. 10. f. 3.)—Leaves crenate, pointed; the lower ones angular; upper halate. Stalks axillary, solitary, flowered, longer than the leaves. Petals inerely heart-shaped, thrice the length of the calyx.—Native of Mexico; long since known in our gardens. We have however ascertained the synonymy of Cavanilles, by seeds received from himself, and raised by the late lady Amelia Hume, in whose flower this plant flowered in July 1866. It may probably succeed, as Mr. Curtis observes, if raised on a hot-bed and planted out in a flower-border. This is distinguished from the last by its very large crimson flowers, rendering it far more worthy of cultivation. Few plants vary more in the shape of their foliage, so that we are satisfied of the S. Dililentiana, Willd. n. 91. Ait. n. 34; figured in Cavanilles, t. 11. f. 1; and in Dill. Hort. Ethn. t. 2, being a mere variety; so little defined indeed, that we can hardly distinguish it as even such.

Sect. 6. Leaves heart-shaped, three-pointed, or angular at the base.

S. trifolia. Three-leaved Cape Sida. Cavan. Diff. 11. t. 1. f. 11. very bad; and 274. t. 131. f. 1. Willd. n. 92. Thumb. Prod. 117. Jacq. Hort. Schonbr. v. 2. 9. t. 142.—Leaves heart-shaped, toothed, with three or five lobes; the middle one longest and sharpest. Stalks axillary, solitary,
...and the leaves are white, and the flowers are red. The plant is often cultivated for its beautiful flowers and is a popular ornamental in gardens. The leaves are divided into several leaflets, and the flower clusters are large and showy. The flowers are usually white with red or purple centers.

The plant is easy to grow and requires little care. It thrives in full sun and well-drained soil. Propagation is usually done by division of the rhizomes or by root cuttings. The plant is hardy and can survive in a variety of climates, making it a popular choice for gardeners around the world.

This table will not differ the 279,936,000,000th part of a second of time.

If the equinoctial points were at rest in the heavens, there would be exactly 366 revolutions of the stars from the meridian.
But to the meridian again in 365 days. But the equinoxial points go backward, with respect to the stirs, at the rate of fifty seconds of a degree in a Julian year; which caueth the stirs to have an apparent progressive motion eastward fifty seconds in that time. And, as the sun's mean motion in the ecliptic is only 11 figs 29 degrees 48 minutes 40 seconds 15 thirds, in 365 days, it is plain, that at the end of that time he will be 14 minutes 19 seconds 45 thirds short of that point of the ecliptic from which he set out at the beginning; and the stirs will be advanced 50 seconds of a degree with respect to that point.

Consequently, if the sun's centre be on the meridian with any stirr on any given day of the year, that stirr will be 14' 19" 45" + 50', or 15' 9" 45" east of the sun's centre, on the 365th day afterward, when the sun's centre is on the meridian; and therefore that stirr will not come to the meridian on that day till the sun's centre has passed it by 1 minute 0 second 38 thirds 57 fourths of mean solar time; for the sun takes so much time to go through an arc of 15' 9" 45"; and then, in 365 days 0 hour 1 minute 0 second 38 thirds 57 fourths, the stirr will have just completed its 366th revolution to the meridian.

This table was calculated by Mr. Ferguson; and it is the only table of the kind in which the reckoning of the equinoctial points has been taken into the calculation.

Siderite, in Mineralogy, a name given by Bergman to a fopped peculiar metallic substance, which is the principal cause of the Brittleness of certain kinds of bar iron.

It has since been discovered to be phosphofate of iron.

Siderites, a name which some authors give to the loadstone. See Magnet.

Sideritis, in Botany, supposed to be the σιδερίτης of the Greeks, of which Dioscorides describes three species, all celebrated for staunching blood, and healing wounds. The first quality they might very well possess, being, according to his account, rough herbs, akin to Marrubium, in which also there might be somewhat of an allriginous or tonic quality. They answer indeed to the general idea of the genus to which modern botanists have applied the name, whose etymology is to be sought in σιδερός, iron; but whether it alludes to that metal as the cause of wounds, to the ruffly colour of the flowers, as De Theis imagines, or to any other circumstance, nothing but conjecture can be offered.—Linn. Gen. 290. Schreb. 387. Wild. Sp. Pl. v. 3. 63. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 384. Sm. Prod. Fl. Grec. Sibth. v. 1. 400. Jull. 113. Tourn. t. 90. Lamarck Illutr. t. 505. Clafs and ord. Didyma Gymnosophm. Nat. Ord. Verticillata, Linn. Labiate, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, oblong, cut nearly half way down into five acute, almost equal, segments. Cor. of one petal, nearly equal; tube cylindrical, oblong; throat oblong, somewhat cylindrical; upper lip erect, narrow, divided; lower in three segments, of which the lateral ones are more acute, and scarcely to large as the upper lip, the middle one rounded. Stam. Filaments four, within the tube of the corolla, and shorter than the throat, two of them smaller than the rest; anthers roundish, two of them with two distinct lobes. Pyl. German four-cleft; style thread-shaped, rather longer than the stamens; ligulas two; the uppermost cylindrical, concave, abrupt; the lower membranous, shortish, sheathing the other. Peric. none, the seeds being lodged in the base of the calyx. Seeds four.

Ell. Ch. Calyx five-cleft. Corolla ringent; its upper lip erect, divided; lower deeply three-cleft. Stamens within the tube of the corolla. One stigma shorter, encompassing the other.

2. S. candidiss. Mullen-leaved Iron-wort. Ait. n. 2. Wild. n. 2; excluding the synonymy.—Shrubby and downy. Leaves densely downy, ovato-lanceolate, taper-pointed; heart-shaped at the base; snow-white beneath. Spikes compound. Whorls remote, each of about eight flowers. Calyx obtuse, pointless.—Native of Madeira; long known in the gardens of England, as well as Holland; flowering from April to July, and sheltered in the greenhouse in winter, with moderate supplies of water. Akin to the preceding, with which Limnæus confounded it; but differing in the peculiar dense snow-white clothings of the leaves, which almost resemble thick white leather. The flowers are larger, and fewer, with an obtuse, very woolly, calyx, deltiform of awns, and grow in compound, whorled, leath'ry spikes. The inflorescence is so different from Commelin's figure, cited by Aiton and Wildenow, that we rather follow Limnæus in applying that synonymy to the following species; though not quite without a suspicion of its really belonging to S. canariensis.

3. S. cretica. Cretan Iron-wort. Linn. Sp. Pl. 801, excluding the reference to Tournefort. Wild. n. 3. (Stachys canariensis frutescens, var. foliosa; Commel. Hort. v. 2. 197. t. 99.)—Shrubby and downy. Leaves densely downy, heart-shaped, bluntish, broadly crenate, on long stellae; snow-white beneath. Spikes simple, whorled. Calyx obtuse, pointless.—Native of Crete and Greece. This has the very dense white pubescence of the last species, but differs in its larger, blunter, more strongly crenate leaves, and especially its solitary unbranch ed leaflets spikes. The whorls consist of each of eight or more flowers, whole calyx, though less woolly, nearly agrees with the preceding, being totally unlike the spinous-pointed calyx of S. canariensis. If Commelin's plate had been executed with any care, this circumstance would have determined his synonymy, which certainly belongs either to our first or third species, and not to the second.

SIDERITIS.

8. Corolla undoubtedly a

ference and woody. Stems erect, mostly simple, herbaceous, a foot high, clothed, like the whole of the herbage, with long, soft, silky, dense, white wool. The radical and lower flat-leaved are oblong, or elliptic-lanceolate, obscurely crenated; those which accompany the flowers are generally much shorter, ovate, and acute; sometimes they nearly resemble the rest of the foliage, evincing that they are not bracteas, as some esteem them, but real leaves. Whorls about eight, a little dilated, each of five bright yellow flowers. Calyx obvate, densely woolly, with five sharp teeth, but no awns or points. Corolla twice as long, contracted at the mouth, downy externally, its segments acute, all entire.

5. s. lyciica. Tartarian Iron-wort. Willd. n. 8. ("S. Lyciica; Pallas Nau. Act. Petrop. v. 10. 312."")—Somewhat shrubby, downy. Leaves lanceolate, crenate. Whorls crowded. Floral leaves heart-shaped, pointed, reticulated with elevated veins.—Native of Tartary. The branches are a foot long, subdivided, clothed with white down. Radical leaves falcate, flat-leaves sessile, all crenate, rugged with veins, covered with fine wooliness; the floral ones roundish-ovate, pointed, ribbed, reticulated, shorter than the calyx; woolly, like the other leaves, till the flowers are past, when they become nearly smooth, except the edges. Corolla yellow. Willd.

6. s. difusa. Distant-woolly Iron-wort. Willd. n. 9. —"Somewhat shrubby, hoary. Leaves lanceolate, acute, entire. Whorls dilated. Floral leaves heart-shaped, sharp-pointed, reticulated with elevated veins."—Supposed to be a native of the Levant. Willdenow obtained it from some old herbarium, with the name of Sideritis folia conjugata amplexicaulis rigidis. He describes it as like the former, but different, having acute, entire, less downy leaves, the stem alone being villous. Whorls very dilated, accompanied by nearly smooth leaves, with sharp points. Tube of the corolla longer than the calyx; the middle segment of its lower lip obtuse, but not emarginate. We are unacquainted with any thing answering to this description.

7. S. perfusata. Perfusate Iron-wort. Linn. Sp. Pl. 802. Willd. n. 10. Ait. n. 7. Prodr. Fl. Græc. n. 1332. (S. orientalis, philomidis folio; Tourn. Cor. 12?)—Herbaceous, rough with bristly hairs. Upper leaves ovate-lanceolate, obscurely toothed, clasping the stem; floral ones heart-shaped, sharp-pointed, reticulated, fringed.—Native of the Levant. Dr. Sibthorp gathered it in some part of Greece, or the neighbouring isles, but omitted to mark the precise spot. No figure is extant of this species. The herbage is green, hairy, and bristly, not downy. Leaves reticulated with copious veins; the floral ones crowded, short, and broad, with spinous points, their disk pale, and semi-pellucid. Flowers six in a whorl. Calyx tubular, round, without angles, glandular and hairy; its teeth long, erect, ribbed, spinous. Linnæus says the corolla is white, with some red veins.

9. S. montana. Mountain Iron-wort. Linn. Sp. Pl. 802. Willd. n. 4. Ait. n. 3. Jacq. Anh. v. 5. 16. t. 434. Sm. Fl. Græc. Sibth. t. 551, unpublished. (S. montana, parvo flos nigro-purpureo; Column. Edpl. 198. t. 196.)—Herbaceous, decumbent, hairy. Leaves deflexed, spinous-pointed. Calyx-teeth spreading, spinous, nearly uniform.—Native of Italy and the Levant. A hardy annual, cultivated by Miller in Chelsea garden, where it still springs up spontaneously every year, flowering in June and July. The stem is branched from the bottom, hairy, rather rigid, a foot long, diffuse, clothed all the way up with ovate, concave, deflexed, slightly notched, green, hairy leaves, each accompanied by a whorl of six flowers. The calyx is tubular, very hairy, except its lip, which spreads in two divisions; the upper three-lobed, with three spinous teeth; the lower deeply divided, rather narrower, with two; mouth hairy. Corolla with a yellow slender tube, the length of the calyx; limb various, sometimes very small, yellow, bordered with brown on all sides; sometimes, as in our garden plants, and in Dr. Sibthorp's Greek specimens, the upper lip only is small and brown, the lower dilated, yellow, obtusely three-lobed. This does not at all answer to the figure and description of Columna. We are not without a suspicion of two species being here confounded, and yet we are not able to trace a permanent distinction between any of the specimens we have seen.

10. S. romanæ. Simple-beaked Iron-wort. Linn. Sp. Pl. 802. Willd. n. 6. Ait. n. 5. Cavan. Ic. v. 2. 69. t. 187. Sm. Fl. Græc. Sibth. t. 552, unpublished. (Sideritis genonis spinifinis verticillatis; Bawh. Hist. v. 3. 428.)—Herbaceous, decumbent, hairy. Calyx-teeth spinous; the uppermost largest, solitary, ovate.—Gathered by Cherler first near Rome, whence the specific name. It has however been found in fields and waste ground in many other parts of the south of Europe. Dr. Sibthorp observed this plant to be common in Greece and the isles of the Archipelago, and we have suspected it might be the real oedys of Dioscorides, to whose description, as far as any thing can thence be determined, it answers well. The habitat of the plant is much like the last, but the leaves are more notched, shorter and broader. Tube and upper lip of the corolla pale red; lower lip white, dilated as in the larger-flowered variety of the preceding. The most striking difference is found in the calyx, whose upper lip is erect, large, and ovate, the lower of four slender teeth, spreading downward.

11. S. lanata. Dark-flowered Iron-wort. Linn. Sp. Pl. 804. Willd. n. 20. Prodr. Fl. Græc. n. 1333. (S. elegans; Murray in Comm. Gott. for 1778. 92. t. 4. Willd. n. 5. S. nigricans; Lamarré Dict. v. 2. 168.)—Herbaceous, diffus, hairy. Leaves elliptical, obtuse, crenate, without spines. Calyx-teeth spreading, spinous, hairy, nearly uniform.—Native of Egypt, Caria, and Palæstine. Murray first described it at Gottingen, from garden specimens, without knowing whence they came. Nor was he blamable for not discovering his plant to be S. lanata of Linnæus, whose specific character, made from a flavished wild specime, is calculated to mislead those who had no other guide. Yet the great Swedish botanist appears, by his herbarium, to have rightly understood the cultivated plant of Murray, of which he poissled a very old and luxuriant morrel, apparently from some Dutch collection. This species is undoubtedly most akin to montana and romanæ, nor has it any real bracteas. The whorls, as in those, are all axillary, fix-flowered. Calyx involuted all over with long silky hairs, its teeth tipped with spines, the upper one rather longer than the others, but all nearly equal in breadth. Corolla with a white tube; the front of the limb dark purplish-brown, nearly black, of a very striking appearance; its
its upper segment cloven; lower in three rounded lobes. The leaves vary greatly in size, but are rounded, pointed, crenate, or dentate and distinctly crenate; the lower ones stalked.

12. *S. incana*. Lavender-leaved Iron-wort. Linn. Sp. Pl. 382. Willd. n. 12. Ait. n. 8. Cavan. Ic. v. 2. 69. t. 186. (Hyphopus montana verticillata major; Barcel. Ic. t. 239. H. verticillata minor; Bocc. Muf. 77. t. 67. f. 2).—Somewhat thrybbly, downy, hoary. Leaves linear-lanceolate, entire. Bracteas ovate, palmate, with many spiny teeth. —Native of Spain. Cultivated by Miller in 1752, being tolerably hardy, flowering in July and August. The habit of the plant is much like Lavandula. Whorls claret, four or five in each spike, with a pair of close, firm, ribbed, thorny bracteas, cut into many spiny segments, under every whorl. Calyx clothed with white cottony down; its teeth erect, spiny, nearly equal. Corolla twice as long as the calyx, yellow, white, or pale blue; both its lips dilated and spreading.

*S. virgata*, Desfont. Atlant. v. 2. 15. 125. Willd. n. 13. seems the very same plant, not even a variety. We venture to remove Barrelier's synonym, cited by Desfontaines, to the following, as Willdenow has done.

14. *S. hyophylophila*. Hyophylla-leaved Iron-wort. Linn. Sp. Pl. 803. Willd. n. 15. Ait. n. 9. (S. alpina; Villars Dauph. v. 2. 373. S. alpina hyophylophila; Ger. Em. 606. S. montana, &c.; Barcel. Ic. t. 171. 172.)—Leaves lanceolate, smooth, nearly entire. Bracteas heart-shaped, with spiny teeth, as long as the calyx.—Native of the mountains of Switzerland, Dauphiny, Italy, and the Pyrenees. Cultivated by Gerard in his garden, and still preferred in curious or general collections, being a hardy perennial, flowering throughout the summer and autumn. The flowers are somewhat woody, throwing up many leafy squarish branches, a span high, hairy at the two opposite sides, in lines crossing each other at every joint. Leaves numerous, opposite, flaked, green, elliptic-lanceolate, two or three of the upper ones only occasionally toothed. Whorls more or less crowded into an ovate or oblong, solitary, terminal spike, each whorl accompanied by two broad, reticulate, hairy bracteae, with strong spiny furrows. Calyx-teeth long, spiny, erect, nearly equal. Corolla straw-coloured, with two dilated lips, longer than the calyx.

16. *S. spinosa*. Spinous-leaved Iron-wort. Vahl. Symb. v. 1. 41. Willd. n. 17. Lamarck Dict. v. 2. 169. (S. subspinosa; Cavan. Ic. v. 3. 5. t. 209.)—Leaves lanceolate, pointed, with strong spiny teeth, as well as the reticulated heart-shaped bracteas. Stem equally hairy on all sides.—Native of mountains in Spain, flowering in June. We received it from the late abbé Cavanilles. The habit of the plant, as well as its inflorescence and flowers, all seem to agree with the two last; but the sharpness of the leaves, and their strong spiny teeth, as well as the more strongly reticulated, and deeply cut, bracteas, indicate an essential difference, confirmed perhaps by the pubescence of the stem, which is generally, though sparingly, diffused, not collected into two dense opposite lines. The leaves moreover are very strongly ribbed.

17. *S. hispida*. Hairy Procumbent Iron-wort. Linn. Sp. Pl. 803. Willd. n. 18. Ait. n. 11. (S. teretia; Cluf. Hilt. v. 2. 40. Tetralit herbatarium; Lob. Ic. 523. Herba judaeica Lobelia; Ger. Em. 690.)—Leaves oblong, obtuse, strongly toothed. Bracteas with spiny teeth. Stems hairy all round, decumbent at the base.—Native of Spain, Italy, and the south of France. —Very much akin to the three last in its flowers, bracteas, &c. but more hairy. The form and teeth of the leaves agree with scrophularioides, a hairy variety of which, we suspect, is sometimes taken for the true hispida. The latter however appears essentially to differ, in having the copious hairiness of its stem equally diffused all round, not collected into decussating lines. The whorls vary much in being crowded or remote, and are very hairy. The wooden cut cited above, which is the same in all the three authors, does not well represent the inflorescence, nor distinguish the bracteas from the leaves. It seems taken from an axillary-whorled species, like montana, romana, &c.

18. *S. ovata*. Ovate Peruvian Iron-wort. Cavan. Ic. v. 1. 36. t. 48. Willd. n. 19.—Herbaceous, downy. Leaves flaked, elliptical, obtuse, crenate. Whorls crowded. Bracteas ovate, spinous-toothed, imbricated in four rows.—Native of Peru. It flowered in the gardens of Madrid, in July. The root is fibrous and perennial. Stems scarcely a foot high, square, slightly hairy. Leaves about two inches long, on flanks about the same length; rough on the upper side, with hairs proceeding from minute tubercles; smooth and shining beneath spike solitary, terminal, about three inches long, quadrangular. Bracteas crowded, in four rows, ovate, acute, rigid, spreading, beset with strong spiny furrows. Flowers fix in a whorl, three to each bractea. Calyx with five slender, sharp, nearly equal teeth. Corolla yellowish-white; its upper lip entire, lower three-lobed, the middle lobe three-crested.

**Sideritis**, in *Gardening*, contains plants of the under-shrubby, and shrubby exotic kind, of which the species cultivated are, the Canary iron-wort (S. canariensis); the Cretan iron-wort (S. cretica); and the sage-leaved iron-wort (S. lyracea). But there are other species that may be cultivated for the sake of variety.

**Method of Culture.**—These plants may be increased by seeds, cuttings, and layers. The seeds should be sown in pots in the spring, planting them in a moderate hot-bed; when the plants have had some growth, they should be removed into separate small pots, filled with light mellow mould, being afterwards treated as other shrubby greenhouse plants. The cuttings and layers may be planted out or laid down in the summer season, and when sufficiently rooted managed as the other sorts. Also, the third sort may be increased by planting the clipped heads, either in pots or in a shady border, to be afterwards removed into pots for potting in the winter in a frame.

They afford variety in greenhouse collections, among other evergreen potted plants of similar growth.

**SIDERO.** in *Geography*, a town of Naples, in Calabria Ultra; 48 miles S. of Catanzaro.
SIDERO-CAPSA, a town of European Turkey, in Macedonia: 32 miles E.S.E. of Saloniki.

SIDEROCHITA, in Natural History, a class of crustated ferruginous bodies, of a moderately firm and compact texture, composed of ferruginous mixed with earthy matter, and formed of repeated incrustations, making so many coats or crusts round a softer or harder nucleus, or round loofe 
earths, or an aqueous fluid.

Under this class are comprehended the emphretia, heteropera, goads, and enhydris.

SIDERODENDRUM, in Botany, from sidero, iron, and dendro, a tree, a species given by Schreber to the Sideroxyloloides of Jacquin, which the latter had called for a while only, till he should be more certain of the genus, by ascertaining the true nature of the fruit. This Schreber has determined; and the name he has chosen alludes to the hardines of the wood, known to the French in Martinique by the appellation of Bois de fer, or Iron-wood. The analogy of the neighbouring genus Sideroxylon is also thus kept in mind.—Schreb. Gen. 71. Wild. Sp. Pl. v. 1. 612. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 245. (Sideroxyloloides; Jacq. Amer. 19.)—Clas and order, Tetrandria Monogynia. Nat. Ord. Dumafo, Linn. Sapotes, Juff.

Gen. Ch. Cal. Perianth inferior, of one leaf, minute, with four acute teeth. Cor. of one petal; tube cylindrical, incurved, many times longer than the calyx; limb in four oblong, obvate, flat, reflexed segments, half the length of the tube. Stam. Filaments four, very short, inserted under the divisions of the limb; anthers oblong, erect. Pet. four, oblong roundish, inferior; style thread-shaped, the length of the tube of the corolla; stigma oblong, obtuse, thickish. Peric. Berry two-lobed, crowned with the calyx, two-celled, with a transverse partition. Seeds solitary, convex and rugged at the outer side, flat on the inner, bordered, attached to the partition.

1. S. triflorum. Three-flowered Iron-tree. Wild. n. 1. Ait. n. 17. Sideroxyloloides ferreum; Jacq. Amer. 19. t. 175. f. 9. Sideroxylon americanum, five lignum duritiae ferrum zemulans; Pluk. Almag. 346. Phyt. t. 224. f. 2.)—Native of mountainous woods, in the islands of Martinico, Montserrat, Barbadoes, &c. A tall branching tree. Leaves opposite, flat, ovato-lanceolate, acute, entire, shining, five inches long. Flower-flats axillary, very short, mostly three-flowered, chiefy on the older and leafless branches. Flowers small and slender, about half an inch long, roselike at the outside, white within. Mr. Ryan observed the corolla to be often changed, possibly by the attack of some insect, into an oblong, hollow, pearly bag, pointed at the top, half an inch in length, resembling a fruit.

SIDEROMANTIA, Σιδερόμαντια, in Antiquity, a kind of divination performed with a red-hot iron, upon which they laid an odd number of straws, and observed what figures, bendings, sparklings, &c. they made in burning.

Gen. Ch. Cal. Perianth inferior, small, erect, in five segments, permanent. Cor. of one petal, wheel-shaped, in five concave, erect, roundish segments, with a little pointed inflexed scale, at the base of each segment. Stam. Filaments five, awl-shaped, the length of the corolla, into which they are inserted alternately with the scales; anthers oblong, incurved. Pet. four, roundish, inferior; style awl-shaped, the length of the flaments; stigma simple, obtuse. Peric. Drupa roundish, pointed, of one cell. Seed. Nut ovate, large, of one cell.

Obi. SER SHELLIA of Mr. Brown, see that article, differs in having a berry, with from one to five seeds; but in the former case we know not how to distinguish it from the present genus. Sideroxylon amurense, Linn. Sp. Pl. 279, according to Mr. Brown, constitutes a very distinct genus of the same natural order.

1. S. mite. Harmless Iron-wood. Linn. Syll. Nat. ed. 12 v. 2. 178. Wild. n. 1. Jacq. Coll. v. 2. 249. (S. amurense; Mill. l. t. 299.)—Thorns none. Leaves acute.—Native of Africa. Jacquin describes its plant, which appears to be the same with Miller's, as an elegant evergreen tree from the Cape of Good Hope, flowering abroad in summer, sheltered in the greenhoue in winter. The leaves are scattered, flafted, lanceolate, pointed, entire, coriaceous, smooth; of a shining deep green above; paler beneath. Foot-flats short, purple. Flowers white, on simple or branched axillary flats.—We know nothing of this species but from the above authors. Linnaeus defines his plant as having fowle flowers, but we find no specimen in his herbarium to ascertain what he meant.

2. S. amurense. Smooth Iron-wood. Linn. Sp. Pl. 278. Wild. n. 2. Ait. n. 1. Jacq. Coll. v. 2. 250. (Sideroxylon amurense, De Corne indorum nomine data arbore; Dill. Elth. 357. t. 25. f. 544.)—Thorns none. Leaves obovate, obtuse. Flower-flats simple, round.—Native of the Cape of Good Hope. This shrub has long been known in the greenhoues of Europe, but has no beauty to boast, at least in its flowers, which are small and inconspicuous, growing on short, cylindrical, simple, axillary, generally aggregate flats. The leaves are thick and coriaceous; rounded at the end, and often emarginate; somewhat tapering at the base; two or three inches long.

3. S. mlanophyllum. Laurel-leaved Iron-wood. Linn. Mant. 48. Wild. n. 1. Ait. n. 2. Jacq. Hort. Vind. v. 1. 29. t. 71. (Padus foliis oblongis, fructu foliario: Burm. Afr. 238. t. 84. f. 2. Laurifolia africana; Coll. Hort. v. 1. 95. t. 100.)—Thorns none. Leaves lanceolate. Flower-flats simple, angular.—Native of the Cape of Good Hope. Communicated by Linnaeus in 1761, by the late professor David Van Royen; and sent to Kew in 1783, by Mr. Graesser. This has dark purplish branches, and elliptic-lanceolate leaves, longer and more acute than the last. The flowers and their flats are altogether of a palish red hue. Linnaeus says the scales between the flaments are wanting, which Jacquin finds to confirm. The frut is blue, the size of a pea.

5. S. fericeum. Silky Iron-wood. Ait. n. 3. Wild. n. 5. (Sideroxylon fericea; Brown Prod. Nov. Holl. v. 1. 530.)—
530.—Thorns none. Leaves ovate, obtuse; downy, like the calyx and flower-flalks, beneath. Corolla villous externally. Gathered by Mr. Brown, in the tropical part of New Holland; and by Sir Joseph Banks, who sent it to Kew in 1773, in New South Wales. The style is flender, hairy at the base.

6. S. obvolutum. Ovulate iron-wood. (Serbalia obo-vata; Brown tab. n. 2.)—Leaves obovate; somewhat tapering at the base; scarcely silky beneath. Calyx nearly smooth. Corolla smooth. Style very short.—Gathered by Sir Joseph Banks, in the tropical part of New Holland.—In both thefe the feeler between the flaments are lancelolate.

8. S. tectum. Downy iron-wood. Roxb. Coromand. v. 1. 28. t. 28. Willd. n. 7.—Thorns none. Leaves elliptic-oblong, with a blunt point; downy when young. Flower-flaks downy, axillary, aggregate, the length of the footflalks. Found chiefly on the tops of the mountains in Hindoostan, flowering during the hot feason. This is a small tree. The leaves, three inches long and one broad, are smooth when full grown, but in a young flake are covered with rusty down. Flowers numerous, of a dirty white. Fruit yellow, the size of a small cherry. Dr. Roxburgh says there are the rudiments of five feels, though only one or two come to perfection. Hence it seems that the generic character, in that refpect, is but precarious.

10. S. decandrum. Linn. Mant. 48. Willd. n. 9. Thorns axillary. Leaves effetial, deciduous.—Native of North America. In shady woods from Carolina to Georgia, flowering in July and August. A small tree, with minute greenish flowers. Pursh. The branches are round, minutely warty, with strong, spreading, tapering, axillary, solitary thorns, three-quarters of an inch long, accompanying the flowers, on the lower part of each branch. Leaves alternate, flaked, elliptic-oblong, about three inches in length, and more than one in breadth, entire, somewhat pointed, smooth, light green, finely reticulated with veins, deciduous. Flower-flalks axillary, several together, simple, about the length of the spines, and rather longer than the footflalks. Segments of the calyx deep, oval, concave, smooth, obtuse, unequal, folding over each other. Corolla twice as long as the calyx, but little spreading. We are unable to find any distinction between S. lecyoides and decandrum. A specimen in the Linnaean herbarium from Kalm, under the latter name, has a pentapetalous flower, and is otherwise totally different from the species in question. Our description is taken from the specimen lent by Baron Munch-haufen to Linnaeus, and marked lecyoides by the latter, though described in his Hortus under the appellation of decaandrum.

10. S. spinifum. Thorny iron-wood, or Argan. Linn. Sp. Pl. 279, excluding the synonynm. Dryand. in Ait. Hort. Kew. n. 5. (Eriodendrum Argan; Willd. Sp. Pl. v. 1. 1148. Rhamnus ficulif; Linn. Syll. Nat. ed. 12. v. 3. 229.)—Thorns lateral. Leaves obovate-oblong, deciduous.—Native of Morocco. This has strong, almost conical, thorns. Leaves aggregate, flaked, obovate, simple, entire, smooth; a few of them, like coarse roots, or tufks. Rhamnus siculus pentaphyllus, Bocc. Sic. 43. t. 21. must be a very different plant, having really five leaflets on a common stalk, as Mr. Dryander observes in Tr. of Linn. Soc. v. 2. 225. This learned writer justly remarks, that many East Indian synonynms have erroneously been referred to Linnaeus to his Sideroxylum spinifum; but he errs respecting the specimen under this name in the Linnaean herbarium, which is evidently the plant belonging to those synonynms, though not to the original specific character, being Placourtia sepertia, Willd. Sp. Pl. v. 4. 831. Roxb. Coromand. v. 1. t. 68.

The reader will perceive that there is considerable uncertainty about the species of this genus; nor is there least difficulty respecting its generic character, which is not yet clearly contrasted with that of Bumelia; see that article.

Sideroxylum, in Gardening, contains plants of the shrubby, evergreen, exotic kinds, of which the species cultivated are; the smooth iron wood (S. infemc); and the willow-leaved iron-wood (S. lycioides).

The wood of these shrubby plants having great solidity, hardens, and ponderosity, so as to sink in water, they have obtained the appellation of iron-wood.

Method of Culture.—These plants may be increased by seed procured from abroad, which should be sown in the spring in pots filled with fresh mould, and plunged in the tan-bed of the flove; when the plants have some growth, they should be removed into separate pots, and be replanted in the bank-bed. They are also sometimes raised from flit-layers and cuttings in the summer season; but they are tedious in forming roots in this way, and the plants are not so good in general.

The first fruit is tender, affording variety in the flove; but the leaf is more hardy, and may sometimes be introduced in the shrubbery borders in warm sheltered situations.

SIDERS, in Geography, a town of Switzerland, and principal place of a dixain in the Valais; 8 miles E. of Sion.

SIDES-MEN, properly called fynd-men, or quest-men, persons who, in larger parishes, are appointed to affult the church-wardens inquiring into the manners of inordinateivers, and in preventing offenders at visitations. In the ancient episcopal synods, the bishops were wont to summon divers creditable persons out of every parish to give information of, and to attest the disorders of clergy and people. These were called "tellers synodals"; and in after-times, they were a kind of impanelled jury, consisting of two, three, or more persons in every parish, who were upon oath to present all heretics and other irregular persons. These, in process of time, became standing officers in several places, especially in great cities, and hence were called "synod-men," and by corruption "sides-men." They are also sometimes called "quest-men," from the nature of their office, in making inquiry concerning offences. And these sides-men or quest-men, by Can. 90, are to be chosen yearly in Easter-week, by the ministers and parishioners (if they can agree); otherwise to be appointed by the ordinaries of the diocefe. But for the most part this whole office is now devolved upon the church-wardens; which see. The sides-man's oath, agreed upon by the civilians and common lawyers, is as follows: "You shall swear that you will be affiant to the church-wardens in the execution of their office, so far as by law you are bound; so help you God." Gib. 216.

SIDEWAYS, in the Measure. To ride a horse side-ways, is to passage him, or make him go upon two treads, one of which is marked by his shoulders, and the other by his haunches.

SIDGUR, in Geography, a town of Hindoostan, in Baglana; 50 miles E.N.E. of Bussien.

SIDI, in Hindo Mythology, is the name of one of the two
two wives of Ganea or Pollear, the god of prudence and policy. (See Pollear.) The name of the other was Budh; and both were daughters of Vifhawarp. which see. Their names occur in the Hindoos writings.

Sid Efo, a town of Algiers; 30 miles S. of Boujeliah.

Sid Gazi, a town of Afiatic Turkey, in Natolia; 4 miles N.E. of Kintaia.

Sid Ibrahim, a town of Algiers; 30 miles W. of Tnbah.

Sid Medhab, a town of Africa, in Tmias; 20 miles N. of Gabs.

Sid Schiri, a town of Afiatic Turkey, in Caramania, on a lake; 6 miles E. of Beifheni.

SIDIALIEL, a town of Nubia; 55 miles N. of Sennaar.

SIDIBISCHIR, a town of Africa, in the country of Fezzan; 16 miles E. of Monrouk.

SIDIN, or VATISA, a river of Afiatic Turkey, which runs into the Black sea, at Vatifa.

SIDLA, SIDLAW, or Sudlauc Hills, a range of mountains in the counties of Perth and Angus, Scotland, which form the southern boundary of the great valley of Strathmore, whence they derive their name; Sudlaws signifying, in Erse, the south hills. This ridge commences on the east, in the vicinity of the town of Perth, and extends in a north-easterly direction to Redhead, a promontory on the coast of the German ocean, between Aberbrothick and Montrofe. The mountains which compose it vary considerably in elevation; some of them not exceeding 800 feet in height above the level of the sea, while others are upwards of 1400 feet high. The following are the heights of several of the principal of them, as ascertained by barometrical measurements:

Sidlaw hill, 1406 feet; Kinglet, 1238; Kipnicnie hill, noted for an ancient tower on its summit, 1151; and Dunfinnan hill, 1024. The last mentioned hill is remarkable for being on that on which the usurper and tyrant, Macbeth, built a castle, with a view to secure his life against any attempt which might be made to murder him. Sinclair's Statistical Account of Scotland, vol. i. 1791.

SIDMOUTH, a market-town in the hundred of East Budleigh, and county of Devon, England, is seated in a valley on the banks of the river Sid, between high hills, at the distance of 14½ miles S.E. of Exeter, and 158 miles S.W. of London. Sidmouth was formerly a sea-port of some confluence; but the harbour has been so clogged with sand and pebbles, that pleasure-boats and fishing smacks are the only vessels which can now approach the shore. Of late years the buildings and population have increased, in consequence of the number of persons who frequent the place in the summer, for the purposes of bathing and recreation. Good accommodations have consequently been provided, and a ball-room, billiard-room, and tea-rooms erected for the convenience of the visitors. According to the population report in the year 1811, the number of houses in the parish was 549, inhabited by 1688 persons. A weekly market is held on Saturdays, and two fairs annually. Near the beach is an ancient stone building, with very thick walls firmly cemented, traditionally said to have been a chapel of ease, when Otterton was the mother-church; and in a path leading from Sidmouth to Otterton, called Go-Church, is an ancient stone cros. At Sidmouth was formerly an alien priory, a cell to Mountborow in Normandy, or rather to St. Michael in Per cula Maria; for to this last mentioned monastery the manor was given by king William the Conqueror. It was sometimes reckoned as a part of Otterton priory, and, with that, after the dissolution of the foreign houses, was given to Sion abbey; and at the time of the surrender, devoted to the crown. The scene on this coast, between Sidmouth and Seaton, is grand and romantic; prefenting a succession of lofty cliffs, sloping ridges, and narrow valleys. In some places the cliffs are composed of sand, tinged by a red oxyz of iron, and is partly calcareous. On the edge of a hill, north-west of Sidmouth, is an ancient encampment, called Woodbury castle, which is of an irregular form, with deep ditches; at some places the foss is double. Observations on the Western Counties, by George Maton, M.D. 2 vols. 8vo. The History of Devonshire, by the Rev. Richard Polden, vol. 3 vols. fol. 1797. The Chorographical Description, or Survey of the County of Devon, by Trithram Ridson, 8vo. 1714, 2d edit. 1811. Beauties of England and Wales, vol. iv. 1803, by J. Britton and E. W. Brayley.

SIDNA-BINES, a town of Fez, near the sea-coast.

SIDNEY, PHILIP, in Biography. See SYDNEY.

SIDNEY, ALGERNON. See SYDNEY.

SIDNEY, in Geography, a town of the island of Cape Breton; 20 miles N. of Louisburg.—Allo, a town of New York, on the Sufquechanna; 50 miles W. of Hudfon.—Allo, a port-town of the county of Maine, on the Kennebeck; 30 miles N.E. of Portland, situated in the county of Kennebeck, and containing 1558 inhabitants.

SIDNEY COVE. See SYDNEY COVE.

SIDODONA, in Ancient Geography, a barren place on the coast of Carmania, in the Persian gulf, where Near- chus is said to have refreshed himself, in his voyage from the isle of Oarafta to that of Cara, according to his journal of the navigation.

SIDOLOUCUM, or SODOLEUCUM, a town of Gallia Lyonnaensia, on the route from Lugdunum to Gefloriaecum, between Angluodium and Abellone, according to the Itinerary of Antonine.

SIDON, a town of Phoenicia, 30 miles from Berytus, according to the Itinerary of Antonine. This town was for a long time the metropolis of Phoenicia, till Tyre became more powerful, and contended with it this dignity. Justin says, that the Phoenicians, being obliged to abandon their country on account of an earthquake, established themselves in the vicinity of the lake of Allysia, which they afterwards deserted, and established themselves on the neighbouring coast of the sea, where they built the town, which they called Sidon. Mofes informs us that this town had been built by Sidon, the elder son of Canaan, the father and founder of the Phoenicians. Josuha (ch. ii. v. 8.) says, that the town of Sidon was rich and powerful when the Israelites took possession of the land of Canaan. St. Jerom says, that it fell to the lot of the tribe of Asher. In the year 1015, Sidon was dependent on Tyre, for Solomon induced Hiram, king of Tyre, to give orders to the Sidonians to procure from Libanus the wood which he wanted for the temple at Jerusalem, which he proposed to build. The Sidonians shook off the yoke of the Tyrians 720 years B.C. and surrendered themselves to Salomon, when this prince entered into Phoenicia. Josephus (Antiq.) relates, that about 150 years afterwards, Aprics, king of Egypt, invaded Phoenicia with powerful armies, took Sidon by force, and burnt the city, which event was followed by the submission of all the other towns of Phoenicia to the conqueror. Cyrus conquered this city, but the Sidonians obtained permission of the Persians to have their own kings; and they took part in all the expeditions of their new masters, according to Heraclitus (i. iii.); and in the war of Xerxes against the Greeks, the king of Sidon, according to Diodorus Siculus (i. xiv.) commanded
commanded a fleet of forty-eight ships, which very much contributed to the victory which that prince obtained over the Lacedæmonians. The city of Sidon was ruined in the year 351 B.C. under the reign of Ochus, king of Persia. When the inhabitants saw the enemy in the city, they shut themselves up in their houses, with their wives and children, and were there massacred by a conflagration. Dio-Dorus Siculus (l. xvi.) says, that the Sidonians, who were absent during this massacre, and thus escaped destruction, returned thither and rebuilt it, after Ochus had withdrawn to Persia. Arrian (De Exped. Alex.) says, that the Sidonians offered to submit to Alexander, when that prince entered into Phœnicia after the battle of Ilius, 333 years B.C. This prince charged Hephaestion to appoint a king for this city; accordingly this officer raised to the throne of Sidon the hoft with whom he had lodged; but this person declined the charge, and procured the crown for a person of the royal family, called by Diodorus, Ballonymus. After the death of Alexander, Sidon was transferred to the kings of Egypt, and afterwards to those of Syria, until at length it fell under the power of the Romans. This city, according to Strabo, suffered the effects of an earthquake, which demolished half the city. See SAID.

SIDONA. See Sidoena.

SIDONEY, in Geography, a town of Hindoostan, in Oude; 42 miles W. of Kurrabat.

SIDONIUS, Caius, SOllius Apollinaris, in Biography, was born at Lyon in or about the year 430, of a distinguished family, his father and grand-father having ex-received the office of praetorius-prefect in Gaul. He was liberally educated, and obtained great reputation for his literary talents, and especially his skill in the poetical art. Coming to the capital he was raised to the highest offices by several successive emperors. He married Papianilla, daughter of the emperor Avitus, whose ecelebration he celebrated by a long panegyric in verse, which was rewarded by a brafs statue of him placed in the portico of Trajan. On the deposition of that prince, he was made a prisoner at Lyon by the emperor Majorian; whose favour he afterwards obtained by a new panegyric. He was now employed by Majorian to negotiate a treaty with Theoderic, king of the Visigoths, of whose person and manners he has left us a curious description. For this service he was rewarded with the title of count. Under Severus Rikler he defended with the most complete successes Auerenge against the incursions of the barbarians. On the accession of Anthemius he was ready with another panegyric, and was in this requited by the government of Rome, and the dignity of patrician was conferred upon him. In the year 472 he renounced all his secular employments, and became a bishop. He is said to have conducted himself with singular piety in his new office, to have been exemplary for charity, and all the episcopal virtues, and to have fed 4000 Burgundians, when under the prelude of famine. He was a great sufferer at the siege of Clermont, and was forced to fly at its surrender, but was very soon restored to his see. He afterwards underwent some trouble from two factions priests, who contended with him the government of the church, and also from some who were deemed by him as heretics; and to this has been ascribed his death, in 487, which has been called a martyrdom. Of the writings of Sidonius, there are extant twenty-four pieces in verse, marked with the debated character of the age, and nine books of Epistles, containing much curious information relative to the learning and history of his times. The best editions of his works are those by Savaron in 1609, and by Sirmond in 1652.

SIDOWLY, in Geography, a town of Hindoostan, in Bahar; 12 miles E. of Safaran.

SIDRA, a town of Hindoostan, in Bahar; 18 miles N.W. of Palamow.

SIDRA, Gulf of, a large bay of the Mediterranean, on the coast of Tripoli, anciently called "Syris," extending from N. lat. 30° 30' to 32° 30', and E. long. 15° 30' to 19° 30'.

SIDRONA, in Ancient Geography, a town of Illyria, in the interior of Liburnia. Ptol.

SIDUS, a small borough of the territory of Corinth, E. of Schenus, which served as a port to Megara. Steph. Byz.—Allo, a small borough of Afa Minor, in Ionia, in the vicinity of the town of Clazomene.—Allo, another in the vicinity of the Erythrea sea.—Allo, a place of Afa Minor, in Pamphylia. Steph. Byz.

SIDUS, Georgium, in Astronomy. See Georgian Planet.

SIDUSA, in Ancient Geography, an island of Afa Minor, upon the coast of Ionia. Pliny.

SIEBELN, or Siebenlihn, in Geography, a town of Saxony, in the circle of Erzgebirg; 4 miles N. of Freyberg.

SIEBENKEES, John Philip, in Biography, professor of philology and the Oriental languages in the university of Altdorf, and member of the Society of Volsci, at Velletri, was born in 1759 at Nurnberg, where his father was organist to one of the churches. Being intended for the church, he was initiated in the Latin and Greek languages under very able masters, and he applied also with great diligence to the Hebrew and Chaldee. In the year 1778 he repaired to the university of Altdorf, where he attended lectures on the holy scriptures, and where, in conjunction with some of the other students, he established a private literary society, the first-fruit of which was a dissertation on the religion of the ancient Germans, and other Northern people. This piece was published in 1781, and it was so highly esteemed by Morelli, that he added it to his translation of Tacitus "De Moribus Germanorur," which was printed in 1791. He now became the tutor to some young people, and not only performed the duties attached to the office for six years with high reputation, but was able by diligence and affability to apply himself, at the same time, to refarches in the literature, history, and arts of the ancients. He collected materials to compose memoirs of the life of Bianca Capello de Medici, grand duches of Tuscany, which was published in one volume octavo at Gotha, in the year 1759. But the chief part of his attention was directed to the MS. treasures contained in the library of St. Mark, from which so many of the classical authors have been printed and improved. His refarches here were much facilitated by Morelli, the librarian, who assisted him greatly in the art of deciphering and reading manuscripts, a branch to which he himself had been unaccustomed. Here he examined with great attention the valuable manuscripts of Strabo; and studied with the utmost care the two celebrated manuscripts of the Iliad, of which, before the appearance of Vallofon's edition, he gave a circumstantial account in the German work entitled "Bibliothek der Alten Literatur und Kunf." In the same work he published an extract from the Chirilothamia of Proclus; collated some MSS. of Heliodorus; and made selections from the unprinted fehola on Plato and other authors. With the same eagerness he examined and studied the remains of ancient art preserved in different collections at Venice. In 1788 he quitted Venice, and made a tour through many parts of Italy, and at Rome he remained fifteen months, entirely occupied in surveying the works of art, or in studying the manuscripts in different
libraries; and here he was much indebted to Reggio, the learned librarian of the Vatican, who allowed him the use of all those highly valued manuscripts, the greater part of which has been, since that, carried to Paris by the French. From there, Siebenkees made copious extracts for the improvement of Strabo and other ancient authors; and here he transferred the Vatican MS. of the characters of Theophratus, which is reckoned the complete and most perfect in existence. He collected likewise from this library a large mass of critical matter for the illustration of the classics, in extracts, fragments, and observations. Cardinal Borgia interested himself very much in favour of Siebenkees, and allowed him the free use of his museum at Velletri, where he wrote an explanation of a "Tellera Hospitalis," prefaced in it, which was published with the following title: "Expositio Tabulae Hospitalis ex varie antiquissimo in Museo Borgiano Veltrii alteram." For this work, which was considered as extremely ingenious, he was elected a member of the learned society of Velletri. On his return to his native country, he visited the most celebrated libraries at Augsburg and Memingen, as well as in various monasteries in Swabia, and formed an acquaintance with many of the German literati. In the year 1790 he returned to Nurnberg, and in the following year he was appointed extraordinary professor of philosophy and of the Oriental languages at Altdorf; after this he was made regular professor of philosophy and history. Between the years 1791 and 1796, besides giving academic lectures on the Oriental as well as the Greek and Latin languages, on mythology, archaeology, geography, universal history, the history of literature and of the German empire, he found leisure to publish the following works: "An Essay on the History of the Inquisition in the Venetian States," "A Plan for Prosecuting the Study of Roman Statuaries, for the Use of His Lectures," "On the Temple and Statues of Jupiter at Olympia," an antiquarian essay. But his most important undertaking was his edition of Strabo, amended and corrected from various readings, and an improved translation, with the following title: "Strabonis Rerum Geographiarum Libri XVII. Graeco a Opt. Codd. MSS. recensuit var. lec. ad notationibusque illustravit Xylandri Verlinom emendavit I. P. Siebenkees." He contributed to many periodical works, such as the "Journal des Luxus," in which he was not distinguished a picture of Venice; Harles' edition of "Fabrii Bibliothecae Graecae," &c. He died in 1796. He was not distinguished by any uncommon strength of genius; but extraordinary diligence, and a most ardent attachment to literary pursuits, enabled him to acquire a very extensive knowledge of languages and literature in general. He was an excellent draughtsman, and this talent was of great assistance to him in his archaeological researches in Italy. His writing, in his own language, was exceedingly elegant, but his Latin is neither pure nor correct. His service to literature would have been more important had he lived to finish his Strabo, a great part of the second volume of which was left unprinted at the time of his death. Some other works, on which he had been employed, were also left incomplete, viz.: an edition of Theophratus, from a MS. copy in the Vatican, and his valuable "Anecdota Graeca," selected from the best MSS. in the Italian libraries. Both these works were completed after his death, and published at Nurnberg in 1798. Gen. Biog.

SIEBER, in Geography, a river of Germany, which runs into the Oder, 5 miles S. of Olerode.

SIECHAM-HOTUN, a town of Corea, in the sea of Japan. N. lat. 41° 24'. E. long. 127° 24'.

SIEDABAD, a town of Hindoostan, in Benares, on the Ganges; 15 miles N.E. of Benares.

SIEDE, a small river of Germany, which runs into the Wefer, 2 miles S. of Benares.

SIEDENBERG, a town of Germany, in the county of Hoya; 9 miles S.S.W. of Hoya.

SIEG, a river of Germany, which rises in the east part of Naflau-Siegen, falls by Siegen, Blankenberg, Siegburg, &c. and runs into the Rhine, two miles below Bonn.

SIEGBURG, a town of the duchy of Berg; 14 miles S.E. of Cologne. N. lat. 50° 53'. E. long. 7° 18'.

SIEGBURG. See Synberg.

SIEGE, in War, the encamping of an army around a place, with design to take it, either in the way of batteries and famine, by making lines all around it, to prevent any relief from without; or by main force, as by digging trenches, and making formal attacks.

The word is French, and signifies, literally, seat; alluding to the army's taking its seat before a town, till the reduction of the place.

The most celebrated sieges of antiquity are those of Troy, Tyre, Alexandria, and Numantium; and, among the moderns, those of Olland, Candia, Grave, Bergen-op-Zoom, Gibraltar, &c. See Line, in Fortification.

SIEGE, To raise a, is to give over the attack of a place, quit the works thrown up against it, and the posts formed about it.

SIEGE, To turn a, into a blockade, see Blockade.

SIEGE-PIECES, in Coinage, a division of modern coins, consisting of those that have been minted upon urgent necessity, during a siege, by any city or town. Patin has published a remarkable one of thick paper or parchment, struck at Leyden in 1574, when that place was besieged by the Spaniards. It has a lion rampant, PUNO PRO PATRIA; and on the reverse this inscription, LUGDUNI BATAVORUM. Various siege-pieces of gold and silver were minted in the reign of Charles II.; some of the latter being far larger than to be of 20s. value.

SIEGEN, in Geography, a town of Germany, which gives name to a branch of the house of Naflau, in the vicinity of which are some considerable iron-mines and forges; 37 miles E. of Bonn, N. lat. 50° 48'. E. long. 8° 48'.

SIEGENBURG, a town of Bavaria, on the Ambs; 20 miles E. of Ingolstadt.

SIEGES, LES, a town of France, in the department of the Yonne; 24 miles W.S.W. of Troyes.

SIEGSTADT, a town of Norway, in the province of Agderhus; 58 miles N. of Christiana.

SIELE, a town of Lithuania, in the palatinate of Brzece; 56 miles N.E. of Brzece.

SIELUB, a town of Lithuania; 8 miles N. of Novogrodeek.

SIEIMIECZOW, a town of Lithuania; 15 miles W. of Luck.

SIEKAGE, a town of South America, in the province of Tucuman; 20 miles N. of St. Miguel de Tucuman.

SIELE', in Ancient Geography, a town of Egypt, situated, according to Pliny, in a peninsula, on the western bank of the Nile, in which was a Roman garrison. See SYN.

SIENITE, Granitella of Saussure, in Geology, a rock nearly resembling granite, but composed of felspar and hornblende, and occasionally containing quartz and mica. The name is derived from the city of Sienna, in Upper Egypt, where immense quantities of this stone were worked by the Romans, and large blocks and columns were brought from thence to Rome. The Egyptian sienite is in fact a granite,
granite, intermixed with a small quantity of hornblende. Some fienites are coarsely granular, containing large distinct crystals of red felspar; in other fienites the crystals are very minute, and the hornblende greatly predominates: in the latter case, fiente paffes into the rock which the Germans call grun-itein, or green-ite. When the fiente is finely granular, but contains large crystals of felspar imbedded, it is then denominated fiente porphyry. This rock frequently occurs in large continuous masses, lying over granite and flate rocks. It is sometimes divided into distinct layers, which, by the German geologists, have been called strata; in other instances, it affumes the prismatic or columnar form. Some mineralogists clas all those fienites with fiente, which contain a portion of hornblende; but this distinction appears ufelefs, for the fame mineralogists admit that hornblende is frequently a conftituent part of gneifs or flaty granite.

In the infancy of science, fubstances which are effentially distinct, are apt to be confounded together, if they poffefs certain points of reSEMBlance; and in a somewhat more advanced state of information, fubstances, that are effentially the fame, are often separated, by artificial classifications, into distinct orders or fpecies, by thofe who are accufomed to infpect the cabinets of collectors, and overlook the great features of nature. Thus much ufeles difcufion has arisen with refpect to certain rocks, whether they were to be clasled with granite or fiente, &c. The operations of nature, in the composition of the great rock formations, are not to be limited by the definitions of the mineralogist. Almost all rocks, with the exception of the calcareous, pafs by fuch infenfible gradations into each other, that the moft experienced eye would find it difficult to clas them, from the infpection of detached specimens. Nor will this appear surprizing, when we consider that flex generally comport half or more of the fubftance of all rocks not calcareous, whether fimple or compoud; and even the diftinct conceptions in compound rocks generally contain about the fame proportion of fexit, except quartz, which is almost entirely formed of it. Even in common clay, though the properties of flex are concealed by a portion of alumine, yet it is fill the predomiiating part of the mafs. Now whether rocks were confolidated from a solution, or from a flate of igneous fusion, the flex, or principal ingredient, as it became variously intermixed with the other earths, would, on confolidation, pafs into a vall variety of forms. Where the solution or fusion continued for a longer time undisturbed, tho' the laws of chemical affinity would have fecret action, and difpofe the different elementary parts in a certain manner, thefe diftinct cryflalline forms peculiar to certain combinations and proportions of the earths. Where from change of temperature, or other caufe, the play of chemical affinity was interrupted, the mafs would become confucedly cryflalline, and lofe all appearance of cryflallization; and between thefe extremes there might be every poffible variety of gradation, as we now find to exist.

Hornblende appears to be the fubflance which conneets granite with rocks that have a very different external appearance. When hornblende exifs in small quantities in granite, it does not change the character of the rock, where the three effential fubstances, quartz, felspar, and mica, form the prevailing part of the mafs; for chlorite, fletite, and other minerals, are intermixed in small quantities in the granite of the higher Alps. When the quantity of hornblende is increafed, and that of the mica and quartz defini, the rock is properly what mineralogists denominate fiente. When the hornblende and other minerals, except felspar, are fo intimately mixed as to form one homogeneous pate, in which the cryflals of felspar are imbedded, it then constitutes a porphyry. When the hornblende greatly predominates, and the felspar is in very small cryflals, it forms green-ite. When the cryflals are no longer difcernible, it forms rocks to which the name of trap have been given. (See Trap.) Green-ite may be confidered as a cryflalline variety, and basalt as an earthy variety, of trap. Thus by an intermixure of hornblende, we have an infenfible gradation from highly cryflalline granite and fiente to a compact earthy rock, in the internal structure of which scarcely any trace of cryflallization can be feen.

Sienna is found in Cornwall, and the western side of Wales, and at Chanwood forell in Leicesterfsire: from the latter place it is sent to London, and to Nottingham and Leicester, cut into blocks for paving-foles. A beautiful green and red fiente forms one of the hills called Markfield, which is described in Mr. Bakewell's Geography, as covered on its summit with pyramidal blocks of the fame flone, which he conceives might be employed for durable ornamental architecture. Sienna occurs in many of the mountainous parts of Scotland, but is not, we believe, a metalliferous rock in any part of Great Britain; nor has it, we believe, been applied to any other purpose than for paving-foles. Many of the ancient statues and columns in Egypt are formed of this folne; and it has been before observed, that it was brought in great quantities from that country by the Romans, on account of the varr columns, &c. which could be formed from fiente blocks. As a proof of its durability, it is flattered by travellers that columns which the Romans left unfinished in the quarries of Sienna, nearly two thousand years fince, preferve to the preient day the impreflion of the tools as sharp and diftinct as if they had been recently worked.

Sien-Ku, in Geography, a town of China, of the third rank, in Tche-kiang; 18 miles W.S.W. of Tai-tcheou.

SIENNA, or SIENA, a city of Italy, and capital of a district, in Tuscany. This district, called Sienne, or Tauriotus in the Romans, was once a free republic, conquered by the emperor Charles V. in the year 1554: whole fole, Philip II, king of Spain, ceded all parts, except the Stadt de gli Praedii, to Cosmo I. duke of Florence. The city is pleafantly built on three hills, in a healthy situation. The houses are of brick, and the streets paved with the fame. It is nearly five miles in circumference, but not peopled in proportion to its size; the inhabitants feem scarce exceeding 17,000. It is the fite of an archbishop, and the cathedral is a fine Gothic building, coated with white and black marble within and without. The great portal was begun in the year 1284, after the designs of Giovanni da Pisa, and finished in 1333, by Augultino and Agnolo, Siennefe architects. The front is prodigiously loaded with ornaments. All the work of the infide is most highly finished, as the carving in wood of the choir; the sculpture in marble of the pulpit; and especially the hisorical engraving of the pavement, repreffenting in chiaro-fumo the most remarkable stories of the Old and New Testament. From an aperture in the choir pavement may be feen St. John's church, which lies directly underneath. Its entrance is without, on the hill; and thus one church may be faid to f tand on another. Near the cathedral is the archbishop's palace, and oppofite to it a large and well-endowed hospital, founded by a shoe-maker. Here are also many other churches and convents. The church of the Dominicans is remarkable for an ancient picture of wood, repreffenting the Virgin with the infant Jesus in her arms, by Guido Sainfe: it is dated 1221, and is in the Venturini chapel: though fo ancient,
ancient, it is in good preservation. The university was founded by Charles V. The German students enjoy particular privileges, which they derive from the fame emperor. In the 15th century the academy of the Intronati was here founded. This city still retains some shadow of its former republican liberty, which may appear from the manner of electing its council, which consists of nine persons, styled Excellenzi; but whose power the great duke very much curtailed. The castle, built at one end of the city, in order to curb the inhabitants, is of no great strength. Near it is the university's academy for martial exercises. Many nobility reside here, who have a casino or assembly of both sexes; and it is generally allowed that the Italian language is in no part of Italy spoken with greater purity; 54 miles S. of Bologna. N. lat. 21°. E. long. 11° 16'.

SIENNE, a river of France, which runs into the sea, near Havre.

SIENNOI, a town of Russia, in the government of Mogilev; 60 miles N.N.W. of Mogilev. N. lat. 54° 30'. E. long. 29° 44'.

SIEN-TCHING, a town of Corea; 23 miles N.W. of Tong-kouang.

SIEU, a city of China, of the second rank, in Kiang-nan; 381 miles S. of Peking. N. lat. 33° 45'. E. long. 117° 32'.

SIEU-GIN, a town of China, of the third rank, in Quang-hi; 15 miles N.W. of Yung-ning.

SIEU-OU, a town of China, of the third rank, in Ho-nan; 36 miles S.W. of Vuc-kiun.

SIEU-YUEN-HOTUN, a town of Chinese Tartary; 330 miles E. of Peking. N. lat. 40° 18'. E. long. 122° 51'.

SIIPERNOI-PESOK, a small sandy island of Russia, in the Frozen ocean. N. lat. 71° 36'. E. long. 166° 14'.

SIER, a river of France, which rises about six miles S.E. of Thones, and runs into the Rhône, near Sefiel.

SIERAGE, a town of Hindoothan; 32 miles N.W. of Benares.

SIERCK, a town of France, in the department of the Mofelle. In 1792, this town was taken by the duke of Brunswick; 9 miles N.N.E. of Thionville.

SIERMAH, a town of Bengal; 24 miles S. of Paharn.

SIERNDORF, a town of Austria; 7 miles N.W. of Korn-Neuburg.

SIERNING, a town of Austria; 12 miles S.W. of Ebenfurth.

SIERO, a town of Spain, in Asturias; 9 miles N.E. of Oviedo.

SIEROCK, a town of the duchy of Warsaw; 15 miles N. of Warsaw.

SIERRA, the eastern part of New Castile, so called from its mountains. The word Sierra is a general name for mountain in Spain, and those distinctive appellations are often given from the neighbouring towns.

Sierra d'Adrian, a mountain of Spain, in Guipuzcoa, which took their name from the hermit Adrian. The road leading over it to Alaba and Old Castile is very difficult to travellers. At the very beginning of it is a dark space, between 40 and 50 paces in length, cut through a rock; after which we ascend up a hill, which is reckoned the highest among the Pyrenees. These mountains are but little inhabited, a few shepherds' huts only being to be seen; 18 miles S. of Tolosa.

Sierra de Bejar, a mountain of Spain, in the province of Leon; 20 miles N.N.E. of Placentia.

Sierra Cara, a small rocky island, near the east coast of Sardinia. N. lat. 39° 46'. E. long. 10°.

Sierra del Cid, a mountain of Spain, in Valencia; 14 miles N.W. of Alicant.

Sierra de Cobre, a mountain of the island of Cuba; 15 miles W. of St. Jago.

Sierra de Guadarama, a mountain of Spain, in the south part of Old Castile; 15 miles S. of Segovia.

Sierra di Gador, a mountain of Spain, in the kingdom of Grenada; composed of marble, of which they make excellent lime; 12 miles S. of Almeria.

Sierra de Greder, a mountain of Spain, in the province of Leon; 25 miles N.W. of Placentia.

Sierra Ialoma, a mountain of Spain, in Estremadura; 20 miles N.N.W. of Coria.

Sierra Leon, a country of Africa, in Upper Guinea; so called because it is mountainous, and the mountains abound in lions. It is composed of several states or kingdoms, and is well watered by a river of the same name, at the mouth of which an association of English gentlemen established a settlement, on land purchased of the prince of the country. This company was incorporated by act of parliament, in the year 1791. A considerable number of whites and free negroes were conveyed thither from Nova Scotia, besides many who went from England. At first the new settlers seem to have suffered from the want of proper habitations during the rainy season, but subsequent accounts were more favourable. In the month of December 1793, the natives continued perfectly friendly; the neighbouring chiefs shewed every desire of being connected with the company; some had sent their children to be educated at Sierra Leon, and many others proposed to send them in the ensuing dry season. The rainy season had passed over without any considerable mortality; and the Nova Scotia colonists had maintained their health, and appeared to have become well inured to the climate. The trade was much more brisk; the cultivation was advancing, both in the colony and parts adjacent; and there appears to have been no difficulty in procuring the native labourers. The rice, cotton, and other articles in the company's plantation, had thrived exceedingly, the sugar-cane excepted, which had been hurt by the white ants. The school of the company contained between 300 and 400 children, chiefly Nova Scottians, who appear to have made full as much improvement as is common in European schools, under similar circumstances. The colony had gradually improved in order, and appeared to be advancing in every respect; but neither these appearances, nor several parliamentary aids, could support it sufficiently against new difficulties which continually occurred; and the company was dissolved in 1807. Sierra Leon river abounds in fish, but is much infested with alligators. The country adjacent produces abundance of millet and rice; and the woods are filled with parrots of various kinds, and other beautiful birds; serpents are found, some of a very large size; and numerous wild beasts, such as lions, tigers, elephants, wild boars, and monkies.

The benevolent and laudable exertions of the African Institution, established since the abolition of the slave-trade, have very much contributed to the prosperity of the colony of Sierra Leon. The climate is much better for European constitutions than that of almost any other part of the coast. There are now 400 houses within the walls of Freetown, containing 1917 inhabitants, besides about 2500 Negroes, freed by sentences of the admiralty-court, and residing there under the protection of the government. There is a considerabl
The number of European forts on the coast, apparently very few, except for slave-trading purposes. From Apollonia to Aera, a distance of only 64 leagues, there are no fewer than 27; and the expense of the British forts is about 25,000 annually. Government, it is said, has in contemplation to dismantle all these, except one or two, which will be put in a respectable state of defense. See Slave-trade.

Amongst the labourers at Sierra Leona there are above 800 persons of the tribe of Kroomen; and they are to be found at every factory and town along the coast, for the space of 350 miles. They are employed as factors or intermediate merchants, boatmen, and laborers; and while the slave-trade was carried on upon this coast, they had their share of its occupation. After the age of 40, they return and settle at home. Their country, or Kroom country, extends along the Grain Coast, between Mount and Cape Palmas, from 4° 54' to 5° 7' N. lat. The chief town, Secutra Krea, is in W. long. 7° 48'. This district, though small, is populous, and the natives are of a migratory disposition. Their country produces grain, particularly rice, pepper, and cattle; but their staple article is their own labor, with which they purchase goods, and return to their home for the produce. Wars are rare among these people, and they never fell one another, nor kill their captives; nor do they punish any offence by slavery, though witchcraft is a capital crime, and the only one that is invariably fatal among them. While the slave-trade lasted, they used to kidnap the " Bulhmens," or natives of the interior, and sell them.

The Kroomen are indolent, but when task-work is assigned them, they exert themselves very much; as the reward, in this case, is proportioned to their labour. In their expenditure they are rigid economicals, the only luxury which they allow themselves being tobacco. Their whole subsistence is only from 1 lb. to 2 lb. of rice, clean and fit for use, per day; and of this they sell one half, when rice is dear. Though they are fond of rum, they never buy it; and some of them will not drink it, when offered to them. Their clothing does not cost them 10s. a year. The residue of their grain they lay out in goods; and in 18 months, or two years, the Krooman returns home with his wealth. This he distributes liberally; and what remains he gives to his father to buy him a wife. Having had a wife, after a few months of idleness and idleness, he sets off again for Sierra Leona. When his coffers are replenished, he returns home, and disposes of his riches as before; referring a part, which he gives to his father to buy him another wife. Thus he proceeds for twelve years or more, increasing the number of his wives, and establishing a great character among his countrymen.

The Kroomen are peculiarly distinguished by their extreme love of their own country, which they think superior to all others. All their exertions are to obtain a sufficiency, that they may return and live there. They have not the use of letters, and will not permit their children to learn; and as they live by daily labour, which is paid for in European goods, they have no occasion for manufactures of their own. They have few opportunities of displaying peculiar talents; however, they make their own canoes, several of their implements of agriculture, and some trifling musical instruments.

**Sierra Leona**, a river of Africa, called also "Ritomba," and "Tagrin," about eight miles broad at its mouth, which runs into the Atlantic Ocean, N. lat. 8° 20'. W. long. 12° 30'.

**Sierra Morena**, a mountain, or rather a chain of mountains, of Spain, between the provinces of Cordova and Jaen to the south, and Estremadura and La Mancha to the north. A few years ago, this district was the dread of travellers. M. le Maure, a Frenchman, who for a long time has been one of the corps of engineers of Spain, was chosen in the year 1779, by the count de Florida Blanca, to render practicable a road the most frequented of any in the kingdom; and he has made it one of the finest in Europe. Several new settlements have been formed, and new towns founded in this barbarous district.

**Sierra Madre**, a lofty chain of mountains of New Mexico, crossing the province of Cimbalos.

**Sierra de Malin**, a headland on the coast of Mexico. N. lat. 16° 52'. W. long. 104° 50'.

**Sierra Nevada**, mountains of Spain; 20 miles E. of Grenada.

**Sierra Nevada, or Ixtacihuatl**, a volcanic mountain of Mexico, whose summit is always covered with snow; 30 miles S.E. of Mexico.

**Sierra de Yufra Gomera**, a range of mountains in South America, forming the western boundary of the province of Tucuman.

**Sierra de St. Mamed**, a mountain of Spain, in Estremadura; 25 miles N. of Badajoz.

**Sierra de St. Pedro**, a mountain of Spain, in Estremadura; 30 miles S.W. of Truxillo.

**Sierra de Torquio**, a mountain of the island of Cuba; 25 miles N. of Bayamo.

**Sierra Vernon**, a range of hills in Spain, which run westward towards Malaga, and afford a singular curiosity; for though they run parallel, and so close that their bales join, yet one is red and the other is white; snow will not remain on the highest, whilst it constantly covers the other. The white hills produce the cork-tree, and the Encore oak; the red has no oak, but is covered with firs. The white has iron ore in little lumps; the red has several ores, but no iron. The waters of the white hills are marshy and vitriolic; those of the red sulfurous, alkaline, and with a strong smell like those of Cotterets, in France.

**Sierrasberg**, a town of France, in the department of the Meul, near the river Nied; 4 miles N.N.W. of Sar Louis.

**Sierrasagen**, a town of the duchy of Holstein; 2 miles N.W. of Neuchâtel.

**Siétamou**, a town of Spain, in Aragon; 5 miles E. of Huesca.

**Siétree**, a town of Bengal; 4 miles S. of Burwa.

**Siéve**, a river of Etruria, which runs into the Arno.

**Siéve, or Scarce**, an instrument serving to separate the fine from the coarse parts of powders, liquors, and the like; to cleanse pulse from dust, light grains, &c.

It is made of a rim of wood, the circle or space of which is filled with aplexus of filk, tiffany, hair, linen wire, or even thin slices of wood.

The sieve which have large holes, are sometimes also called riddles; such is the coal or lime-sieve, the garden-scive, &c.

When drugs are apt to evacuate are to be passed through the sieve, it is usual to have it covered with a lid.

**Siévernyagos**, or Rutheun Mountains, in Geography, mountains of Ruffia, extending between the Baltic and the White Sea.

**Siévernoipesok**, a small sandy island in the Frozen ocean, near the continent of Ruffia. N. lat. 76° 54'. E. long. 105° 14'.

**Siévercouóstochino**, a cape on the north coast of
of Russia, called Cape Taimura by captain King. N. lat. 58°. E. long. 101° 14'.

SIEVERO-ZAPADNOI, a cape on the north coast of Russia. N lat. 77°. E. long. 94° 14'.

SIEUGUR, a town of Hindoostan, in Malwa; 9 miles S. of Tandla.

SIEVI, a town of Sweden, in the government of Uleu; 45 miles S. of Braheind.

SIEUR, a title of honour, or quality among the French; chiefly used among the lawyers, and in public acts, and other writings of that kind.

The title sieur is also given by a superior to an inferior, in his letters and other private writings.

In this sense, authors sometimes use it, by way of modesty, in speaking of themselves: thus, at the heads of books, we see Traduction du fieur d'Abalance; Oeuvres du fieur d'Eprouet, &c.

Sieur is also a term expressive of singularity, or lordship; as ecuyer or fieur of such a place.

SIFACE, Giovan Francesco, Detto, in Biography, a celebrated opera singer in the service of the court of Modena, who obtained the title of Siface from his admirable performance of the part of Syphax, in the old opera of Mitridate, modernized by Metastasio, and set by Porpora for Venice in 1732. Algarotti highly praiseth the pathetic manner in which he sung. Though it is confidently asserted, in the work of a late historian, that Siface had been in England as a singer in the chapel of King James II., yet we can trace no proof of this assertion.

In travelling from Ferrara to Modena, he miserably lost his life in a quarrel with an insolent and brutal fellow.

SI-FANS, or TOU-FANS, in Geography, subjects of the Chinese empire, who inhabit the west of China, and the provinces of Chen-fi and Si-teheun. Their country is only a continued ridge of mountains, inclosed by the rivers Hoang-ho on the N., Ya-long on the W., and Yang-tsi-kiang on the E., between the 30th and 35th degrees of north latitude. The Si-fans are divided into two kinds of people; the one are called by the Chinese black Si-fans, the other yellow, distinctions arising from the different colours of their tents. The black are the most clownish and wretched; they live in small bodies, and are governed by petty chiefs, who all depend upon a greater.

The yellow Si-fans are subject to families, the oldest of which becomes a lama, and assumes the yellow drees. These lama-princes, who command in their respective districts, have the power of trying causes, and punishing criminals; but their government is by no means burdensome: provided certain honours are paid them, and they receive punctually the dues of the god Fo, which amount to very little, they molest none of their subjects. The greater part of the Si-fans live in tents; but some of them have houfes built of earth, and even brick. Their habitation is not contiguous; they form at most but small hamlets, consisting of five or six families. They feed a great number of flocks, and are in no want of any of the necessaries of life. The principal article of their trade is rhubarb, which their country produces in great abundance. Their horses are small; but they are well-shaped, lively, and robust.

These people are of a proud and independent spirit, and acknowledge with reluctance the superiority of the Chinese government, to which they had been subjected; when they are summoned by the mandarins, they rarely appear; but the government, for political reasons, winks at this contempt, and endeavours to keep these intractable subjects under by mildness and moderation: it would, besides, be difficult to employ rigorous means in order to reduce them to perfect obedience—their wild and frightful mountains (the tops of which are always covered with snow, even in the month of July) would afford them places of shelter, from which they could never be driven by force.

The customs of these mountaineers are totally different from those of the Chinese. It is, for example, an act of great politeness among them to present a white handkerchief of taffeta or linen, when they accord any person whom they are desirous of honouring. All their religion consists in their adoration of the god Fo, to whom they have a singular attachment; their superstitious veneration extends even to his ministers, on whom they have considered it as their duty to confer supreme power, and the government of the nation.

Some of their rivers walk down gold mixed with their sands: they are acquainted with the art of applying it to use, and form it into vases and small statues, of which they often make offerings to their idol; it even appears that the use of gold is very ancient among them; for Chinese books relate, that under one of the emperors of the dynasty of Han, an officer having been sent to the Si-fans to complain of the ravages committed by some of their chiefs, they endeavoured to appease him by making him a present of a piece of gold plate, which the officer refused, telling the Si-fans, that rice served up in golden dishes was to him an infipid food.

These people have lost much of their ancient splendour; for the Si-fans, who at present are confined in a wild country, where they have not a single city, enjoyed formerly an extensive dominion, and formed a powerful and formidable empire, the chiefs of which have often given great uneasiness to the emperors of China. They possessed towards the east several tracts of land, which at present make part of the provinces of Shchuen and Chen-fi; they even extended their conquests to China, so as to render themselves masters of several cities of the second class, of which they formed four principal governments; in the west, they seized upon all the countries which lie beyond the river Ya-long, and reach as far as the boundaries of Cachemir; but infallible divisions infensibly weakened this great monarchy, and at length brought it to ruin. The Chinese annals fix the epocha of its downfall about the year 1227; since that time, the Si-fans have retired to their native mountains, where, from being a conquering and polished people, they have again sunk into their original barbarity.

SIFEBAD, a town of Hindostan, in the province of Sirhind; 10 miles S. of Sirhind.

SIFEEROO, or White River, a river of Persia, so named from the foam occasioned by the rapidity of the current, that flows in a meandering course through Ghilan to the Caspian sea.

SIFFLET, Fr. 3 cat-calls. According to M. Laborde, it was during the reign of Augustus that clapping of hands and cat-calls were introduced in the Roman theatres. Effai fur la Musique.

SIFTE, in Geography, a pretty considerable village of Egypt, between Cairo and Damietta. It has three mosques, and a church belonging to the Copts, the congregation of which consists of 300 families. See SEDRE.

SIG, in Agriculture, a provincial term applied to urine, or chamber-levy, as employed by the farmer.

SIGS, in Geography, a lake of Russia, in the government of Olonetz, about forty miles in circumference; 40 miles W. of Povenetz.

SIGA, in Ancient Geography, a river of Africa, in Mauritania.
ritania Cæfarinensis. Ptolemy places the mouth of it between the town of Siga and the mouth of the river Afarath. —Alfo, a town of Africa, in Mauritania Cæfarinensis. It had the title of a colony, and was situated between the port of Apulia and the mouth of the river Siga. Ptolemy. Strabo says, that this town was destroyed by the Romans, and that the palace of Syphax was here.—Alfo, a royal town, situated in Africa, in Numidia, and on the western part of the river Mulucha. It was the capital of the kingdom of Syphax.

SIGAGIK, in Geography, a town of Asiatic Turkey, in Natalia, on the sea-coast; 14 miles S.W. of Smyrna. N. lat. 39° 18'. E. long. 16° 31'.

SIGAH-Gufb, or SIAH-Gufb, or Black-Ear, in Zoology, the name of a Peruvian animal, of the felis or cat-kind, and no way differing from the lynx, but in that it has no spots; it has a lengthened face, and small head; its ears have the fine velvety black pencil of hairs at the top, which are the distinguishing character of the lynx; the inside and bottom of the ears are white; the nose white, the eyes small, the upper part of the body of a very pale reddish-brown, the tail darker, and about half the length of the body; the belly and breast whitish; the limbs strong, and pretty long, the hind-part of each marked with black. This animal inhabits Peru, India, and Barbary; and is used in the chase of lefter quadrupeds, and the larger sort of birds, which it artfully surprize and seize; it is said to attend upon the lion, and to feed on the remains of its prey. It is fierce when provoked. Pennant's Hill. Quadr. vol. ii. p. 283. Phil. Trans. vol. ii. part ii. p. 648, &c.

SIGALA, in Ancient Geography, a town of India, on this side of the Ganges, according to Ptolemy, who assigns it to the Mandrakes.

SIGANA, a town of Arachosia. Ptolemy.

SIGARUM, in Geography, a town of Hindoostan, in Goleconda; 12 miles N. of Rachore.

SIGATHA, in Ancient Geography, a town of Libya. Strabo.

SIGEAN, in Geography, a town of France, in the department of the Aude, near which Charles Martel defeated the Saracens; 9 miles S. of Narbonne.

SIGEBERT I., in Biography, king of Austrasia, born about the year 535; was third son of Charles I., king of the Franks. At the death of that sovereign, in 562, his dominions were divided between his sons; and Austrasia, or the kingdom of Metz, fell to the lot of Sigebert. His territories were invaded, soon after his accession, by the Huns, whom he defeated and drove across the Elbe. During his absence, his brother Childeper made an irruption into Austrasia, and took several places; but Sigebert returning victorious, took Soissons, Childeper's capital, and defeated Childeper himself in battle. He was, however, induced to grant him favourable terms, and to restore the conquests made upon him. Sigebert's reputation was now so high, that he obtained for a wife the famous Brunehaut, daughter of the Spanish king of the Visigoths, with a rich portion. The dominions of his brother Carlert, at his death, were shared by the three survivors; but it was not possible for such a divided empire to continue long at peace. Childeper had married Guflwintha, sister of Brunehaut, who was afterwards murdered at the instigation of his mistress, Brunehaut. Brunehaut invited Sigebert, in conjunction with his brother Guntram, king of Burgundy, to revenge this crime, and they over-ran a great part of his dominions, and forced him to purchase peace by the cession of several places. The Avars, or Huns, soon after made a second irruption into Austrasia, when Sigebert's troops, terrified at their savage appearance, refused to act, and he was obliged to purchase a peace, and supply them with provisions to return to their own country. After this, Sigebert assembling a numerous army, after making himself master of the greatest part of Childeper's territories, invaded him in Tournaï, and refused to listen to terms of accommodation. When the ruin of that prince seemed to be inevitable, Fredegonde, hiring two affluents, who pretended to have some important secret to communicate to Sigebert, thrust their daggers into his body, in the midst of his army. This was in the year 575, after he had reigned 14 years, leaving behind him the character of the greatest and holl of the sons of Childeper.

SIGEBERT, SIGEBERTUS, a monk of Gemblours, in the diocese of Namur, in Brabant, who lived in his time for a man of wit, universal learning, and a good poet. In the younger part of his life he embraced the monastic state in the abbey of Gemblours, under the abbot Olbertus, who died in 1048. During his noviciate he was invited to Metz, where he studied in the school of the monastery of St. Vincent, and acquired great consideration by his learning, in which he was superior to most of the other writers who flourished at the same period. He was acquainted with the Greek and Hebrew languages, and in consequence of the progress he had made in the latter, was much esteemed by the Jews at Metz, where he refused a considerable time, and from which he was with difficulty prevailed to depart, in order to return to his former monastery. His celebrity accompanied him thither: he gained many scholars, who did honour to their instructor; and he was chosen by the clergy of Liege to manage their defence in a controversy which they had with the pope, and which he conducted with great talent and moderation. He took sides in the quarrel of Gregory VII., Urban II., and Paschal II., with the emperor Henry IV.; and he wrote against these pontiffs without the least ceremony. Sigebert is author of a Chronicle, the bell edition of which was published at Antwerp in 1608, in 400. It is carefully written, and in a vulgar style; but contains curious and well authenticated facts. And in endeavouring to ascertain to whom the fyltem of folimation by the hexachords belongs, Sigebert in his Chronicle, under the year 928, as well as in his account of ecclesiastical writers, says, that "he had excelled all his predecessors; as by his method children were taught to sing new melodies, with more facility than by the voice of the master, or the use of an instrument; for by only affixing five letters, or syllables, to fix sounds, all that music admits of, regularly, and differing these sounds by the joints of the fingers of the left hand, their distances ascending and descending through the whole diapason, are clearly presented both to the eye and the ear." Now as Sigebert was nearly contemporary with Guido, his testimony in favour of the discoveries attributed to him have more weight than any proofs that can be adduced from such of his own writings as are generally known. The Chronicle of Sigebert begins at 181, and is continued to 414; he died the year after

But what entitles Sigebert to an article in our department, besides his bearing testimony to the inventions of Guido, and his musical records in several other articles of his Chronicle, is the information which he himself gives us in his life, that he had set to muse the anthems and responsories of St. Guibert; that is, had composed all that was necess
fury to form an entire office to his honour. And this information is copied by Fabricius, De Script. Eccl. Arte Mufcae Antiphonae et responforia de fancü. SIGENBURG, in Geography. See Siegenburg.

SIGENUS PORTUS, in Ancient Geography, a port of Africa, on the coast of Mauritania Cæfarinensis, between Siga and Camarata, according to the Itinerary of Antonine.

SIGER, in Geography, a river of Silezia, which runs into the Oder, six miles below Beuthen.

Gen. Ch. Outer Common Calyx of five lineare, cylindrical, widely spreading, permanent leaves, longer than the flower; inner somewhat five-angled, of several ovate, concave, obtuse, equal leaves. Cor. compound, with a half radius. Florets of the disk united, several, funnel-shaped, exceeding the calyx in length, with either five or three teeth; of the radius five, or not fo many, all on one side of the flower, female, ligulate, broad, short, three-cleft. Stam. in the united florets, Filaments five or three, very short; anthers combined in a cylindrical tube. Pfl. in the united florets, German oblong, incurved, the fize of the calyx; fyle thread-shaped, the length of the flaments; stigma divided: in the females, German oblong, incurved, the fize of the calyx; fyle and stigma as in the united florets. Peric. none, the calyx remaining unchanged. Seeds in the united florets solitary, oblong, bluntly quadrangular, thickened upwards, obtufè, naked; down none; in the female ones the fame. Recept. chaffy; fcales very like the fcales of the calyx, concave, embracing the seeds at one side, deciduous.

Eff. Ch. Receptacle chaffy. Seed-down none. Outer common calyx of five leaves; inner spreading. Radius all on one fide.

Obf. S. flocculosa of L'Heritier offers a singular exception in this great natural clas, with regard to number, having the florets of the disk three-cleft, and triandrous.

1. S. orientalis. Oriental Siegenbeckia. Linn. Sp. Pl. 1269. Willd. n. 1. Ait. n. 1. (Sigebuckia; Linn. Hort. Cliff. 412. t. 23. S. triangularis; Cav. Ic. v. 3. 27. t. 253. Cichoreo affinis. Lampfana linearis, mentali folis, calyce fimbrati hispído, finice bi-him-fervi diâcta; Pluk. Amalth. 59. t. 380. f. 2.)—Leaves falked, ovate, unequally toothed; somewhat angular at the bafe. Outer calyx twice as long as the inner.—Native of China and the Eal Indies; also, according to Cavanielles, of Mexico. Thouin informed the younger Linnaeus that he had it from the Cape of Good Hope, and the fratts of Magellan. The plant has been known for near a century in the gardens of Holland and England, and is a tender annua, flowering in July and August, but with much more singularity than beauty to recommend it. The flem is bulbous, leafy, round, rough, three or four feet high. Leaves opposite, rough, two or three inches long, somewhat dilated and triangular at the bafe, tapering down into each ftofalk; the uppermost much smaller and more oblong. Flowers numerous, terminal, falked, brownish-yellow, chiefly conpicious for the spreading outer leaves of their glandular vifcid calyx, each three-quarters of an inch long. We cannot agree with Willdenow in discarding Plukener's fynonym, which furely agrees better with this than with the following.

2. S. ibérica. Georgian Siegenbeckia. Willd. n. 2. (Bidenti similis, folis latifimis ferratis; Buxb. Cent. 3. 29. t. 52.)—Leaves falked, ovate, bluntly toothed; rounded at the bafe. Outer calyx the length of the inner.—Obferved by Buxbaum about villages in Media, flowering in July. Willdenow, who had seen a dried fpecimen, afferts this to be a very distinct fpecies from the former, to which Linnaeus referred Buxbaum's fynonym. The leaves, it feems, are neither triangular, nor cut at the bafe, but shortlcy and bluntly toothed. The outer and inner calyces, being both of an equal length, feem to us a more certain distinction.

3. S. flocculosa. Small-flowered Siegenbeckia. L'Hérit. Stripa. 37. t. 19. Willd. n. 3. Ait. n. 2. Pursh n. 1. Ehrl. Exfl. f. 79.—Leaves nearly feftile, ovate, toothed. Florets of the disk three-cleft, triandrous.—Native of Peru, from whence we believe its feds were brought or fent by the unfortunate Domby. This has the habit of the firk fpecies, but the flem is loother. The leaves, though tapering at their bafe, are fcarcely falked, nor are they all dilated, or angular. The greatfe peculiarity is found, as we have already faid, in the flowers, which are fmaluer and paller than thole of S. orientalis, ufually, though we believe not always, delitute of a radius, but fingly remarkable for the florets of the disk having only three teeth and three flaments.

For S. occidentalis, Linn. Sp. Pl. 1269, see Phaethusa and Verbesina.

SIGET, in Geography, a town of Hungary, on the forwards of Poland, near the fource of the Theyfle; 50 miles E. of Munkacz. See als SIGET.

SIGEUM, in Ancient Geography, a town and port of Asia Minor, in the Troade, at the distance of 60 stadia from the town of Rhodeteum, and 100 stadia from Tenedos. Strabo reports that this town was ruined in his time. The Myli- nenians built it; but foon after the Athenians expelled them, which occasioned a long war between these two people; but at length, according to Herodotus (I. v.), having submitted it to the arbitration of Periander, the fon of Cyphieus, this prince adjudged it to the Athenians, in the year 564 B.C. or, according to the computation of Uther, in the year 589. The Athenians kept possession of it till the time of Alexander. Under his fuccelfors it was destroyed by neighbouring people. Pliny speaks of it as of a town which had long ago fubfitted: "quondam Sigem oppido." Sigem was re-established under the Chriflian emperors, and erected into a bifhopric dependent upon Cyzicus. A miserable village, which has been built upon its ruins, and which prefents a few veftiges of the ancient town, is called by the Turks "Yenitcher-Keui," or village of the janizaries, and "Disarg-Keu," or village of the infidels, as it is no longer occupied except by Greeks. The curious go thither to admire a block of marble, eight or nine feet long, placed by the fide of the door of a church: it bears a Greek infcription, almost entirely effaced, the words of which follow one another without interruption, i.e. that the firit runs, as among us, from left to right, and the fcond runs back from right to left, and so on to the end. (See Boustrophedon.) On the inner fide of the door is seen a bas relief in marble, tolerably well wrought: it repreffents a woman feated, to whom other women appear to offer children in swaddling clothes; behind there is feen another woman, holding a box in one hand and a vafe in the other.
SIGEUM Promontorium, a promontory of the Troade. It is near to and north of the mouth of the river called Scamander. Strabo calls it the port of the Achaeans, because the Greeks landed there in going to the siege of Troy. In the vicinity was a large lake, which was thought to communicate with the sea. This promontory is now called Yeni-Hifari.

SIGG, or Sikke, in Geography, a river of Algiers, which, united with the Habrah, forms the Muckda, or, as it is first called, Makerra.

SIGGU, a town of Japan, in the island of Niphon; 65 miles N.E. of Meaco.

SIGHING, an effort of nature, by which the lungs are put into greater motion, and more dilated, so that the blood pales more freely, and in greater quantity, to the left auricle, and thence to the ventricle. Hence we learn, says Dr. Hales, how sighing increases the force of the blood, and consequently proportionately cheers and relieves nature, when oppressed by its too slow motion, which is the case of those who are depressed and sad. Hales's Statistical Eff. vol. ii. p. 6. See LUNGS.

SIGHT, the exercise, or act of the senses of seeing. See EYE.

Our sight, the noblest and most useful of all our senses, father Malebranche shews, deceives us in abundance of instances; nay, almost in all: particularly with regard to the magnitude and extent of things; their figures, motions, &c. Our eyes do not show any thing less than a mote; half a mote is nothing, if we believe their report. A mote is only a mathematical point, with regard to it; and we cannot divide it, without annihilating it. In effect, our sight does not represent extension, such as it is in itself; but only the relation and proportion it has to our body. Hence, as half a mote has no relation to our bodies, and that it cannot either preserve or destroy us, our sight hides it entirely. Were our eyes made like microscopes, or were we ourselves as small as mites, we should judge very differently of the magnitude of bodies.

It may be added, that our own eyes are really no other than a kind of natural spectacles; that their humours do the same office as the lens in spectacles; and that, according to the figure of the crystalline, and its distance from the retina, objects are seen very differently by us; insomuch that we are not sure, that there are any two persons in the world who fee them equally big. It is ever very rare, that the same person sees the same object equally big with both eyes; as both eyes are very seldom perfectly alike; on the contrary, we generally see things bigger with the left than the right eye; of which we have some very good observations in the journal of the learned at Rome, for the year 1669. See VISION.

The Acta Leipfienfis give us an account of a man, who received a smart stroke on the pupil of one of his eyes from the end of a fiddle-string, which broke while he was tuning the instrument, and chance to fly that way. Some cooling things were applied to the eye, and a bandage used to shade it from the light; but at midnight the patient, thinking to wake in the dark, found that he could see with that eye, though not with the other: this continued a long time, and on trial he found that he could read a small print at midnight with this eye, but could scarcely distinguish any thing with it in a bright and clear day.

We have, in the same collections, an account of a man, who, after the cure of a confirmed pox, saw every object double for a long time. Act. Leip. 1690.

It is a very common, and a very just observation, that children do not see any thing clearly when new-born; and if their eye be then examined, they are found to want that brilliancy which they afterwards acquire; and finally, when any object is presented to their view, they at first turn their eyes about in such a manner, that it is evident they either do not see at all, or but very imperfectly and obscurely.

This imperfection may either be owing to a fault in some one of the humours, or in their capsules; or, finally, in the retina, or complexly in them all together. It is impossible to discover whether there be any imperfection in the retina in this rate of life, that membrane being ever, in new-born infants, tender and soft like a jelly: if it be in any of the other parts that the imperfection lies, it must be either in their nature or extent. M. Petit, of the Academy of Sciences at Paris, determining to enquire thoroughly into the cause of this, was at the pains of dissecting the eyes of several infants which had died soon after their birth, and in three-fourths of them he found the vitreous, the crystalline, and the capsule, all greatly deficient in their transparence. He uvea appeared also more opaque than in adults, and the pupil over-large; and that there was either none, or, at the utmost, very little of the aqueous humour; and in those eyes where the humours had not this opacity, they were all, as were also the membranes, of a reddish colour; and this was observed in fœtuses of seven and nine months old.

The cornea in these eyes was also remarkably thick, which, in general, found to be the case in the eyes of all fœtuses. The thicknes and opacity in these corneæ gradually diminish in time, and that soon; so that the eyes of children appear much brighter at two or three months old than when new-born. The aqueous humour seems also, in most fœtuses, to be wholly wanting; and where it is found, is ever greatly in under proportion to the other humours.

It therefore appears, that the dimness and imperfection of sight, in new-born infants, are owing to the over-thicknes of the cornea, and to the too small portion of the aqueous or watery humour. It appears plainly also, from experience, that the eye is not able, in infants, to bear the light, till the pupil is greatly contracted; as is the case also, though in a less degree, in adults; and it is very probable, that the extreme softnes of the retina in this state may make every ray of light affect it much more plainly than when grown more firm.

M. Petit having continued his examinations of the eyes of infants, up to the age of five or six weeks, found in all his dissections, that the cornea daily grew more and more convex and glossy; and this may be rationally concluded to be owing to the daily increase of the aqueous humour, which must, by that accretion, throw it out into a greater convexity, and make it daily more and more thin and transparent. The uvea also acquires a greater extension, and its fibres become more movable; whence the pupil acquires a power of enlarging or contracting itself, at the approach or absence of light, with much more ease and readiness than it could before. The humours thus all become capable of letting in a larger quantity of light; the retina is at the same time every day gaining a new firmness, and the pupil becomes capable of an easy dilatation, or restriction, for the letting in occasionally a greater or less number of rays, and the refractions are perfect by the augmentation of the aqueous humour. It is plain, therefore, that the clearness of vision must every day increse. All this change comes on in infants only by time; and it may be judged of, as to its state, by inspection, by the brilliancy and convexity of the cornea, and by the manner of their turning their eyes towards objects let before them; and this time is not cern.
tain, or limited, but differs greatly in different children, some being able to see clearly at the end of a month, others not till after many months.

At the time that this gentleman was detecting the eyes of human foetuses and infants, he also curiously observed the eyes of young quadrupeds. The puppy, when newly brought forth, has always its eyes opaque; the kitten, on the contrary, has them clear, and every way like those of adults of the same species. In features of other quadrupeds, the lamb has its cornea a little turbid and opaque; the calf and the pig have them more or less opaque, but the calf no more than all. Mem. de l'Acad. Par. 1777.

**SIGHT, Defects of.** See Cataract; Guuta Serena; Leucoma; Opithalmia; Pterygium; Trichiasis; Eye, Cancer and Excitiation of; Euphor; Fistula Lachrymalis; Staphylyoma; Hypopyion; Fusus Hematodes; &c.

**SIGHT, Short.** See Myopes and Short-sightedness.

**SIGHT, Second.** See Second Sight.

**SIGHT, Point of.** See Point of View.

**SIGHT, Line of.** See Collimation.

Sight. Singing or playing at sight, in Music, is the being prepared by long practice and experience for every difficulty, not only of execution, but also of expression: as a person allowed to read well in a book which he has never seen, must not only pronounce the words correctly and diligently, but observe the punctuation, and enter into the author's design. We do not always give credit to reports of dilettantes, or even every professor, performing à viva voce, or, as the French call it, à vue ouverte, all kinds of composition without study or practice. See GREETY.

**SIGHTS, in Mathematics,** denote two thin pieces of brass, raised perpendicularly on the two extremities of an alidade or index of a theodolite, circumferentor, or other like instrument; each of which has an aperture or slit up the middle, through which the visual rays pass to the eye, and distant objects are seen. Their use is, for the just direction of the index to the line of the object.

Sometimes the slits or apertures have glasses or lenses fitted into them; in which case, they are called telescopic sights, by way of distinction from the former; which, in respect of the others, are denominated plain sights.

Mr. Flamsteed and Dr. Hooker absolutely expounded the use of plain sights in astronomical observations. The errors in Tycho's latitudes of the stars Mr. Flamsteed ascribes wholly to his using plain sights; and suspects, that Hevelius, using the same kind of sights, must fall into the like errors. Hevelius, on the contrary, in a paper in the Philosophical Transactions, vindicates the use of plain sights, and prefers them to telescopic ones: the main objection he makes to the latter is, that no observation can be safely taken with them, without first examining and rectifying them; in which examination, many and gross mistakes are likely to be committed. To which he adds, that in sextants, octants, azimuth quadrants, &c., he does not see how such examination can be made, at all times, without much loss of time.

**SIGILLARIA,** a solemn feast held among the ancient Romans; thus called from a custom which obtained therein, of giving little presents from one to another, constituting of seals, little figures, and sculptures, made of gold, silver, brass, or even earthenware, and of devoting them to Saturn, as an atonement for themselves and their friends.

The Sigillaria followed immediately after the Saturnalia, and held two days; which, with the five days of the Saturnalia, made a solemnity of seven days.

Some derive the origin of sigils and figures, in this solemnity, from the argi, or rushen figures of men, thrown annually into the Tiber, from the Pons Sublicius, by the Veii-fly, on the ides of March. Vide Macrob. Saturn. lib. i. cap. 7. 19. and 11. See also AREEA.

**SIGILLATA TERRA,** a name given to several kinds of medicinal earths, marked with seals, to express their being genuine. The principal is the Lemnian earth: this is a kind of earth, or bole, dug in the ile of Lemnos, and also called Lemnian earth; of considerable use in medicine.

It was anciently found in a mountain, in the neighbourhood of the city Hephæstia, where Diana's prieiels went, at certain times, with great ceremony, to dig it up. After a little preparation, they made it up into troches, and sealed them with Diana's seal; whence the appellation of sigillata, sealed.

**SIGILLO,** in Geography, a town of Italy, in Umbria; 12 miles N. of Nocera.

**SIGILLUM, a seal, or signet.**

**SIGILLUM MARIS, Lady's Seal,** in Botany, a name by which some authors have called the Bryonia nigra, or black bryony, a climbing plant, common in hedges.

**SIGILMESSA,** in Geography. See SUGILMESSA.

**SIGINDUNUM,** in Ancient Geography, a town of Upper Moesia, on the banks of the Danube, according to Ptolemy. The Itinerary of Antoninus marks it on the route from Rimini to Byzantium, between Taurumnum and the mount of Gold.

**SIGINNI,** a people of Asia, who, according to Strabo, had the same manners with the Persians.

**SIGISA,** a town of Hifpania, upon the Tader, N.W. of Vergilia.

**SIGISMONDO,** in Biography. See INDIA.

**SIGISMUND,** emperor of Germany, and king of Hungary and Bohemia, was the son of the emperor Charles IV. of the house of Luxemburg. He was born in the year 1366, and at an early age was sent to the court of Lewis, king of Hungary, to one of whose daughters he was betrothed, with the intention of making him successor to the throne. During his minority, a party of nobles conferred the crown on Charles, king of Naples, on which event Sigismund retired to Bohemia. Charles being affililated by the contrivance of the queen-mother, who was put to death for the crime, Sigismund assembled an army, and entering Hungary, liberated his wife Mary, who had been imprisoned, and was crowned king when he was in the twentieth year of his age. He severely revenged the execution of his mother-in-law; and getting possession of the persons of the nobles who had invited Charles, he caused them all to be beheaded, to the number of thirty-two. The bloody act occasioned so much dissatisfaction, that the Turkish emperor Bajazet determined upon taking the opportunity of invading Hungary, which he did with complete success; and Sigismund was dethroned. He however escaped, and retiring to Bohemia, levied troops, with which he recovered his crown, and being brought to reason by adversity, he thenceforth conducted himself so as to obtain the goodwill of his people; and such was the reputation which he now acquired abroad, that he was elected emperor of Germany.

The first object of Sigismund in his new dignity, was to put an end to various disorders and dissensions which prevailed in Germany. He held a conference with pope John XXIII. for the convoking of a council; the principal object of which was that the termination of the feilism in the papacy which had long divided the church. He engaged with great zeal in this matter, and at length effected the assembling of a council at Constance, in 1414, at which he himself affiliated. As the opposition of the Hulfilites to the doctrines
of Rome was now making great progress, the emperor
granted a safe-conduct to John Hufz to come to the council,
and defend the articles of his faith; and it will be to his ever-
lasting disgrace, that he suffered the council to violate the
protection he had solemnly given, and to bring this re-
former to the stake. He now endeavoured to re-establish
peace among the Christian princes, that they might concur
in a plan for reforming the unity of the church, with this
view he visited both France and England, then at war with each
other, but with little success. The council, however, agreed in deposing the exiling popes, and electing a new one.
Upon the death of his brother Wenceslaus, in 1415,
Sigismund succeeded to the crown of Bohemia, which
country was in a flame, from the revolt of the perfected
Hussites, under their leader the famous Ziska. He marched
with an army into Bohemia, but was entirely defeated by
Ziska, and the fame fortune attended him a second time.
After the death of that hero, a long series of bloody wars
succeeded, which at last terminated in the submission of the
Thaborites, as the insurgents were afterwards called, and
Sigismund was crowned at Prague, in the year 1436, and
reduced the whole kingdom to obedience. He had some years
before this received the imperial crown both at Milan and at
Rome. His bigotry urged him to tyrannical proceedings
against his Bohemian subjects, which excited their animosity
to such a degree, that he determined to leave the country.
When he was just upon the point of putting this resolution
into execution, he was feized with a mortification in his
bones, which was the prelude to approaching dilution, and
having publicly declared his son-in-law, Albert, duke of
Austria, the heir to his dominions, he died in December
1437, in the 71st year of his age, and the 27th of his imperial
dignity. Sigismund is said to have had a fine person, and
to have possessed various accomplishments, especially an un-
common skill in the learned languages. He was, moreover, a
patron of learned men, was liberal, brave, and active; but,
on the other hand, he was cruel, vindictive, and superfi-
tiously devoted to the clergy. He was licentious in his
conduct, the confidencé of which made him indulgent to the
open and abandoned debauchery of his second wife,
Barbara de Cilley, denominated the Meisslina of Germany.

SIGISMUND I. king of Poland, furnamed the Great, was
the son of Casimir IV. He succeeded his brother Alex-
ander in 1507, and immediately applied himself to the re-
medying of abuses that had crept into the administration of
public affairs. In this arduous task he was assisted by the
able and faithful minister John Bonner, whose name is still
held in veneration by the Poles. A rebellion in Lithuania,
abated by the tsar of Muscovy, joined to an incursion of the
Walachians and Moldavians, obliged him to put him-
self at the head of the troops, and he completely succeeded
against his enemies. The next antagonist with whom he
had to contend, was the marquis of Brandenburgh, grand-
master of the Teutonic order, who had refused to acknow-
ledge the sovereignty of the king of Poland over the
province of Prussia: in this dispute he was also successful, and
obliged the marquis to grant him half the province of Prussia,
as a barrier against the Teutonic Knights. Sigismund now
fat down the peaceful sovereign of Poland, Lithuania, the
duchies of Smolensko and Severia, and considerable terri-
tories on the Euxine and Baltic, while his nephew Lewis
was king of Hungary and Bohemia. This accumulation of
power gave umbrage to the house of Austria; which, by its
intrigues, incited the Walachians, Tartars, and Musco-
vites, to make new inroads. These, however, were soon driven
back with great loss to their own countries, and Sigismund
left again in peace. He died, after a wife, fortunate, and
long reign, in the eighty-fourth year of his reign, and in the
year 1548.

SIGISMUND II. named Augustus, king of Poland, son of
the preceding, was elected to the crown before his father's
death. He offended the nobles by marrying the widow of an
obscure person; and it is asserted, that, in order to re-
cover their favour, he permitted them to lend their sons for
education to the Protestant universities of Germany, which
was the means of introducing their opinions into Poland.
He himself remained attached to the old religion, and by
his prudent and moderate conduct kept out of the king-
dom those disorders which disturbed the peace of so many
other European countries. He was extremely diligent
in promoting the improvement of his states by wise laws and
regulations, and the correction of abuses, which enabled
him to maintain a powerful standing army without the ad-
dition of new taxes. This force he had occasion to employ
as an auxiliary to his kinsman the archbishop of Riga, against
an invasion of the Russians. He made himself master of
great part of Livonia, and forced the grand-master of the
Teutonic order, who had called in the Russians, to renounce
their alliance, and put the order under the protection of Po-
land. From this period Livonia was annexed to Poland, and
the grand-master abdicating his dignity, received in com-
penation the duchies of Courland and Semigalia, which
long remained in his family. The tsar, John Balibowitz,
made an irruption into Lithuania, which occasioned much
bloodshed and devastation, and Sigismund was glad to pro-
pose an amicable; and while this measure was in discussion,
the king of Poland died in 1572, leaving only two daugh-
ters, and with him terminated the male line of the house of
Jagellon. He left a high character for courage, ability, and
evry princely quality, but he is said to have been too much
attached to the fair sex.

SIGISMUND III. king of Poland, furnamed De Vafa, was
the son of John III. king of Sweden, and Katharine, daugh-
ter of Sigismund I. king of Poland. He was born in 1566,
and in 1587 was elected to the crown of Poland, in compe-
tition with Maximilian of Austria. Through the exertions
of Zamoiski, the crown-general, after a civil war, in which
Maximilian was defeated and taken prisoner, Sigismund was
firmly seated on the throne. He governed successfully
with the assistance of Zamoiski, till the death of his father, in
1592, left him heir to the crown of Sweden. As he was
a zealous Catholic, and the Swedes were friendly to the
Reformation, they felt displeased to come under his author-
ity; besides, the duties of a king of Sweden, and of a
king of Poland, seemed to be quite incompatible. His uncle,
 duke Charles, who had been declared regent during Sigif-
mund's absence, inflamed those discontent. Sigismund
having obtained permission from the Polish diet to visit his
other kingdom, arrived in Sweden in 1593, accompanied by
the pope's nuncio, and his proceedings soon proved how
much the rupture of the Catholic religion was the object
of his wishes. Violent differences arose between him and the
states, and in 1595 he returned to Poland, leaving Sweden
in the greatest disorder. In 1598, Sigismund again entered
Sweden at the head of a foreign army, and a civil war en-
fused, which terminated in a pacification, and the king re-
turned to Poland. Peace did not last long, and in 1604 the
Swedes formally deposed him, and raised his uncle Charles
to the throne. War succeeded between Poland and Swe-
den, which ended in the conquest of Livonia by the Polish
general.

Russia, at this time, being thrown into confusion by a re-
volntion, Sigismund took part in its disorders, and entering
that country, in 1610, at the head of a numerous army,
gained
SIG

Sigs, the autumnal, are, Libra, Scorpio, and Sagittarius.

SIGNS, the brumal, or winter, are, Capricornus, Aquarius, and Pisces.

The vernal and summer signs are also called northern signs.

And the autumnal and brumal signs, southern signs.

Signs, Ascending. See Ascending.

Signs, Fixed. See Fixed.

Signs, Masculine. See Masculine.

Sign Manual, the letting one's hand and seal to a writing. See Signature.

The expirion is used when any bill or writing is signed under the hand of the king, &c. Counterfeiting the sign manual, privy signet, or privy seal, is treason. 1 Mar. rat. 2, cap. 6. See Patent.

Among the Saxons, before the invention of seals, a + was a common sign, or signum, prefixed to the names of most subscribing witnesles in charters, and other deeds: as + signum Roberti Episcopi, Lind. &c. See Seal.

Sign of Reference, in Music, signa repetitionis. See Signo.

Signs of Desease in Horos, the appearances which shew them to be out of order. The first sign of a horse's indifposition is, his loathing his food, especially when he has a wild and haggard look; as the eye of a horse is, as it were, a glass, through which may be discerned the inward disposition of his body: it should also be observed whether his ears be cold, his mouth hot or clammy, the hair of his flanks rough and fitting, and paler than usual about the ends; his dung hard, black, or greenish, and his urine clear like water. In this case his eyes are also subject to weep; his head is heavy and hanging down; he is apt to stumble as he walks; he is flow and dull, though he was vigorous before; he never moves other horses; contrary to his former custom, he rifes and lies down often in the stable, looking towards his flanks, which are doubled and folded in; his heart beats quick; and he is also indifferent and unconcerned at what is done to him. These and many other signs are met with in horses which are not in a state of perfect health, and should be immediately attended to; and suitable remedies be applied. This is of much consequence to be taken care of in teams and other work horses belonging to farms, &c.

SIGNA, Standards, among the Romans, were of different sorts; some of them the image of the emperor was represented, and they that carried them were called imaginiferi; others had a hand stretched out, as a symbol of concord; and these ensign-bearers were called signiferi; some had a silver eagle, the bearers of which were called aquiliferi; others had a dragon with a silver head, and the rest of his body of taffy, which was blown by the wind, as if it had been a real dragon, and the bearers of this ensign were called draconarii; lastly, the emperor's ensign was called labarum, and those that carried it labariferi, which they carried out when he went in person to the field; it was of a purple colour, befit with gold fringe, and adorned with precious stones.

All these ensigns were sustained with a half-pike, sharp at the end, that it might be the more easily fixed in the ground.

Signal, a certain sign agreed upon for the conveying of intelligence to places to which the voice cannot reach.

Signals are given for the beginning of a battle, or an attack; usuallly with drums and trumpets: at sea, they are given by cannon or musket-shot, by lights, sails, flags, &c.

All signals may be reduced into three different kinds: six those which are made by the sound of particular instruments, as the trumpet, horn, or sife; to which may be added, striking
SIGNALS.

Striking the bell, or beating the drum; those which are made by dislaying pendants, ensigns, and flags, of different colours; or by lowering or altering the position of the sails; and those which are executed by rockets of different kinds; by firing cannon or small arms; by artificial fire-works; and by lanthorns. See Telegraph.

The signals by the drum, made use of in military exercise, instead of the word of command, are as follow: a short roll, g. d. to caution; a drum, to perform any distinct operation; to arms, to form the line or battalion; the march, to advance, except when intended for a salute; the quick march, to advance quick; the point of war, to march and charge; the retreat, to retreat; drum ceasing, to halt; two short rolls, to perform the flank-firing; the dragoon march, to open the battalion; the grenadier march, to form the column; the troop, to double divisions; the long roll, to form the square; the grenadier march, to reduce the square to the column; the preparative, to make ready and fire; the general, to cease firing; two long rolls, to bring or lodge the colours.

Signals have been in use in all ages: the ancients, who had no regular couriers, or polls, made use of them to convey intelligence of what passed at a great distance; for which purpose, they placed sentinels on the eminences, from space to space; some mention of which we find made by Homer himself, Iliad o. v. 553, Sc. Odysse. q. v. 261. Tho' people, thus disposed, lighted fires, or flambeaux, in the night-time.

In the Agamemnon of Aeschylus, that prince, at his departure for Troy, promises Clytemnestra, that, the very day the city should be taken, he would apprize her of his victory by fires, lighted express. He keeps his word, and tidings are brought the princes, that Troy is taken, and that Agamemnon's signals are seen.

Frontinus observes they were in use among the Arabs; and Bonaventura Vulcainus, in his scholia on Arilottis book De Mundo, adds, that, while the Moors were masters of the greatest part of Spain, they built on the tops of the mountains an infinity of torrents, or watch-houses, called, in the Arabic, atalayas, a word the Spaniards still retain; whence, by fires, they could immediately alarm the whole kingdom. Indeed the custom was much more ancient than the Moors in Spain. Q. Curtius observes, it was very frequent among the Asiatics, in the time of Alexander: Livy and Cæsar also, both mention it as used among the Romans. Polydore Virgil shews it of great antiquity in England; and Boetius adds, that, in several places in England, there were the remains of huge poles that have served for this purpose.

Signals at Sea, are signs made by the admiral, or commander-in-chief of a squadron of ships, either in the day, or by night, whether for failing, for fighting, or for the better security of the merchant-ships under their convoy. See Engagement.

These signals are very numerous, and important; being all appointed and determined by order of the lord high admiral, and lords of the admiralty, and communicated in the instructions sent to the commander of every ship of the fleet, or squadron, before their putting out to sea. It is by the combination of signals, previously known, that the admiral conveys orders to his fleet; every squadron, every division, and every ship of which has its particular signal. The instruction may, therefore, occasionally be given to the whole fleet, or to any of its squadrons, to any division of those squadrons, or to any ship of those divisions. Hence the signal of command may at the same time be displayed for three divisions, and for three ships of each division; or for three ships in each squadron; and for only nine ships in the whole fleet. For, the general signal of the fleet being shewn, if a particular pendant be also thrown out from some remarkable place on the same mast with the general signal, it will communicate intelligence to nine ships that wear the same pendant.

The preparatory signal given by the admiral to the whole, or any part of his fleet, is immediately answered by those to whom it is directed; by shewing the same signal, to testify that they are ready to execute his orders. Having observed their answers, he will shew the signal which is to direct their operations: as, to chase, to form the line, to begin the engagement, to board, to double upon the enemy, to rally or return to action, to discontinue the fight, to retreat, and fave themselves. The dexterity of working the ships in a fleet depends on the precise moment of executing these orders, and on the general harmony of their movements; a circumstance which evinces the utility of a signal of preparation.

As the extent of the line of battle, and the fire and smoke of the action, or other circumstances in navigation, will often prevent the admiral's signals from being seen throughout the fleet, they are always repeated by the officers next in command; by ships appointed to repeat signals; and, finally, by the ship or ships for which they are intended. The ships that repeat the signal, besides the chiefs of squadrons or divisions, are usually frigates lying to windward or leeward of the line. These should be extremely vigilant to observe and repeat the signals, whether they are to transmit the orders of the commanders-in-chief, or his seconds, to any part of the fleet; or to report the fortunate or ditreeful situation of any part thereof. By this means, all the ships from the van to the rear will, unless disabled, be ready at a moment's warning to put the admiral's design in execution. To preserve order in the repetition of signals, and to favour their communication, without embarrassment, from the commander-in-chief to the ship for which they are designed, the commanders of the squadrons repeat after the admiral; the chiefs of the divisions, according to their order in the line, after the commanders of the squadrons; and the particular ships, after the chiefs of the divisions; and those, in return, after the particular ships, vice versa, when the object is to convey any intelligence from the latter to the admiral. Besides the signals above-mentioned, there are others for different ranks of officers; as for captains, lieutenants, mailers, &c. or for any of those officers of a peculiar ship. Falconer.

Signal-flags are hoisted at the mizen-peak, &c.; night-signals are made with lanthorns, and are hoisted by the same halliards as the flags. Since November 1805, the red flag at the main-mast has been the first in rank after the union flag. See Flag.

Signals by Day. When the commander-in-chief would have them prepare for failing, he first looses his fore-topmast, and then the whole fleet is to do the same. When he would have them unmoor, he looses his main-topmast, and fires a gun, which, in the royal navy, is to be answered by every flag-ship. When he would have them weigh, he looses his fore-topmast, and fires a gun, and sometimes hauls home his sheets; the gun is to be answered by every flag-ship, and every ship is to get to fail as soon as it can. If with the ketch-fove, the lertennent ship is to weigh first. When he would have the weather-mast and head-mast ships to tack first, he hoists the union-flag at the fore-topmast-head, and fires a gun, which each flag-ship answers; but if he would have the lertennent and leeward-mast ships to tack first, he hoists the union-flag at the mizen-topmast-head, and fires a gun; and when he would have all the whole fleet tack, he hoists an union both on the fore and mizen-topmast-heads, and fires a gun. When, in bad weather, he would
would have them wear, and bring to the other tack, he hoists a pendant on the ensign-staff, and fires a gun; and then the leeward-mast and main-mast ships are to wear first, and bring on the other tack, and lie by, or go on with an easy fail, till he comes a-head; every flag is to answer with the same signal. If they are lying by, or failing by a wind, and the admiral would have them bear up and fail before the wind, he hoists his ensign, and fires a gun, which the flags are to answer; and then the leeward-mast ships are to bear up first, and to give room for the weather-mast to wear, and fail before the wind, with an easy fail, till the admiral comes a-head. But if it should happen, when the admiral hath occasion to wear and fail before the wind, that both jack and ensign be abroad, he will haul down the jack, before he fires the gun to wear, and keep it down till the fleet is before the wind. When they are falling before the wind, and he would have them bring-to, with the starboard tacks aboard, he hoists a red flag at the flag-staff, on the main-top-mast-head, and fires a gun. But if they are to bring-to, with the larboard tack, he hoists a blue flag at the same place, and fires a gun, and every ship is to answer the gun. When any ship discovers land, he is to hoist his jack and ensign, and keep it abroad, till the admiral or commander-in-chief answer him, by hoisting his; on sight of which, he is to haul down his ensign. If any discovers danger, he is to tack and bear up from it, and to hang his jack abroad from the main-top-mast crosstrees, and to fire two guns; but if he should strike or stick fast, then, besides the same signal with his jack, he is to keep firing, till he sees all the fleet obverse him, and endeavour to avoid the danger. When any fires a ship or ships more than the fleet, he is to put abroad his ensign, and there keep it, till the admiral is out, and then to lower it, as often as he sees ships, and stand in with them, that so the admiral may know which way they are, and how many; but if he be at such a distance, that the ensign cannot well be discovered, he is then to lay his head toward the ship or ships so deferred, and to brace up his low fails, and continue hoisting and lowering his topsails, and making a waft with his top-gallant sails, till he is perceived by the admiral. When the admiral would have the vice-admiral, or him that commands in the second part of the fleet, to send out ships to chase, he hoists a flag, striped white and red on the flag-staff, at the fore-top-mast-head, and fires a gun. But if he would have the rear-admiral do so, he then hoists the same signal on the flag-staff at the mizen-top-mast-head, and fires a gun. When the admiral would have any ship to chase to windward, he makes a signal for speaking with the captain, and he hoists a red flag in the mizen yards, and fires a gun; but if to chase to leeward, a blue flag; and the same signal is made by the flag, in whose division that ship is. When he would have them give over chase, he hoists a white flag on his flag-staff at the fore-top-mast-head, and fires a gun; which signal is to be made also by that flag-ship which is nearest the ship that gives chase, till the chasing ship sees the signal. In case of springing a leak, or any other disater, that disables their ship from keeping company, they are to haul up their courses, and fire two guns. When any ship would speak with the admiral, he must spread an English ensign, from the head of his main or fore-top-mast, downwards on the throuds, lowering his main or fore-top-tail, and continue firing guns, till the admiral observe him; and if any ship perceive this, and judgeth the admiral doth not, that ship must make the same signal, and make the best of his way to acquaint the admiral therewith, who shall answer by firing one gun. When the admiral would have the fleet to prepare to anchor, he hoists an ensign, striped red, blue, and white, on the ensign-staff, and fires a gun; and every flag-ship makes the same signal. If he would have the fleet moor, he hoists his mizen-topstall, with the clew-lines hauled up, and fires a gun. If he would have the fleet cut or flip, he looses both his topstalls, and fires two guns; and then the leeward-mast ships are to cut or flip first, to give room to the weather-mast to come to fail. So if he would have any particular ship to cut or flip, and to chase to windward, he makes the signal for speaking with that ship, hoists a red flag in the mizen yards, and fires a gun; but if a ship is to chase to leeward, he hoists a blue flag as before. If he would have the fleet exercise their small arms, he hoists a red flag on the ensign-staff, and fires a gun; but if the great guns, then he puts up the pendant over the red flag.

Signals by Night; to be observed at an anchor, weighing anchor, and failing, are as follow. When the admiral would have the fleet to unmoor, and ride in port, he hangs out three lights, over one another in the main-top-mast-ends, over the constant light in the main-top, and fires two guns, which are to be answered by the flag-ships; and each private ship hangs out a light in the mizen-ends. Note, that all guns, fired for signals in the night, must be fired on the same side, that they may make no alteration in the found. When he would have them weigh, he hangs a light in the main-top-mast-ends, and fires a gun, which is to be answered by all the flags; and every private ship must hang out a light in his mizen-end. When he would have them tack, he hoists two flags on the ensign-staff, over one another, above the constant light in his poop, and fires a gun, which is to be answered by all the flags; and every private ship must answer, with one light at the mizen-peck. The main-mast and leeward-mast ships are to bear up fo soon as the signal is made. When he would have them, in blowing weather, to lie a-try, short, or a-hull, or with the head-fails braised to the mail, he will form lights of equal height, and fire five guns, which are to be answered by the flag-ships, and then every private ship must shew four lights; and after this, if he would have them to make fail, he then fires ten guns, which are to be answered by all the flags, and then the head-mast and weather-mast ships are to make fail. When the fleet is failing large, or before the wind, and the admiral would have them bring-to, and lie by, with their larboard tacks aboard, he puts out four lights in the fore-ends, and fires six guns; but if with the larboard tacks aboard, he fires eight guns, which are to be answered by the flag-ships; and every private ship must shew four lights. The wind-mast ships must bring-to first. Whenever the admiral alters his course, he fires one gun, without altering his lights, which is to be answered by all the flag-ships. If any ship hath occasion to lie short, or by, after the fleet hath made fail, he is to fire one gun, and shew three lights in his mizen-ends. When any one first discovers land, or danger, he is to shew as many lights as he can, to fire one gun, and to tack, or bear away from it; and if any one happen to spring a leak, or any be disabled from keeping company with the fleet, he shews out two lights of equal height, and fires guns till he is relieved by
by some ship of the fleet. If any one discovers a fleet, he is to fire guns, make false fires, put one light out on the main-top, three on the poop, to steer after them, and to continue firing of guns, unless the admiral call him off, by fleering another course, and fire two or three guns, for then he must follow the admiral. When the admiral anchors, he fires two guns, a small space of time one from the other, which are to be answered by the flag-ships, and every private ship must shew two lights. When the admiral would have the fleet to moor, he puts a light on each top-mast-head, and fires a gun, which is to be answered by the flag-ships, and every private ship must shew two lights. If he would have them lower their yards and topmasts, he hoists one light upon his ensign-flags, and fires one gun, which is to be answered by the flag-ships; and every private ship must shew one light. And when he would have them hoist their yards and topmasts, he puts out two lights, one under the other, in the mizen-topmast-flags, and fires one gun, which is to be answered by the flag-ships; and each private ship must shew one light in the mizen-flags. If any strange ship be discovered coming into the fleet, the next ship is to endeavor to speak with her, and bring her to an anchor, and not suffer her to pass through the fleet. And if any one discovers a fleet, and it blows so hard that he cannot come to give the admiral timely notice, he is to hang out a great number of lights, and to continue firing gun after gun, till the admiral answers him with one. When the admiral would have the fleet to cut or slip, he hangs out four lights, one at each main-yard-arm, and at each fore-yard-arm, and fires two guns, which are to be answered by the flag-ships; and every private ship is to shew one light.

Signals used when a Ship fails in a Fog. If the admiral would have them weigh, he fires ten guns; which every flag-ship is to answer. To make them tack, he fires four guns, which are to be answered by the flag-ships; and then the leeward-mast and hawn-mast ships must tack first, and after they are about, to go with the main sail they tacked with, and not to lie by, expecting the admiral to come a-head; and this is to avoid the danger of running through one another in thick weather.

When the admiral brings-to, and lies with his head-fails to the main; if with the starboard tack aboard, he fires fix guns; but if with the larboard tack, he fires eight guns, which the flag-ships are to answer. And after this, if he makes fail, he fires ten guns, which the flag-ships must answer, and then the headow-mast and weather-mast ships are to make fail first. If it grow thick and foggy weather, the admiral will continue failing, with the same fail felt that he had before it grew foggy, and will fire a gun every hour, which the flag-ships must answer; and the private ships must answer, by firing of masts, beating of drums, and ringing of bells. But if he be forced to make either more or less fail than he had, when the fog began, he will fire a gun every half-hour, that the fleet may discern whether they come up with the admiral, or fall a-tack of him; and the flags and private ships are to answer, as before. If any one discovers danger, which he can avoid, by tacking and standing from it, he is to make the signal for tacking in a fog; but if he should chance to strike, and lick fail, he is to fire gun after gun, till he thinks the risk has avoided the danger. When the admiral would have the fleet to anchor, he fires two guns, which the flags are to answer; and after he hath been half an hour at an anchor, he will fire two guns more, to be answered by the flags as before, that all the fleet may know it.

Signals for calling Officers on board the Admiral. When the admiral puts abroad an union-flag in the mizen-flags, and fires a gun, all the captains are to come aboard him; and if, with the same signal, there be also a waft made with the ensign, then the lieutenant of each ship is to come on board. If an ensign be put aboard in the same place, all the masters of the ships of war are to come on board the admiral. If a standard on the flag-staff be hoisted at the mizen-topmast-head, and a gun fired, then all the flag-officers are to come aboard the admiral. If the English flags only, then a standard in the mizen-flags, and fire a gun: if the flags, and land general officers, then the admiral puts aboard a standard at mizen-topmast-head, and a pendant at mizen-peak, and fires a gun. If a red flag be hoisted in the mizen-flags, and a gun fired, then the captains of his own squadron are to come aboard the admiral; and if, with the same signal, there be also a waft with the ensign, the lieutenant of each ship must come aboard. If he hoists a white flag, as before, then the vice-admiral, or he that commands in the second poll, and all the captains of his squadron, are to go on board the admiral; if a blue flag, &c. then the rear-admiral, and the captains of his squadron, must come aboard, and if with a waft, as before, the lieutenants. When a standard is hoisted on the ensign-flags, and a gun fired, the vice and rear-admirals must come aboard the admiral's ship. When the admiral would speak with the captains of his own division, he will hoist a pendant on the mizen-peak, and fire a gun; and if with the lieutenants, a waft is made with the ensign, and the same signal; for whenever he would speak with the lieutenants of any particular ship, he makes the signal for the captain, and a waft also with the ensign. When the admiral would have all the tenders in the fleet come under his lorn, and speak with him, he hoists a flag, yellow and white, at the mizen-peak, and fires a gun. But if he would speak with any particular ship's tender, he makes a signal for speaking with the captain and the ensign on the topmast of the vessel, and fires a gun. The signal for the long-boats to come on board him, manned and armed, is the pendant hoisted on the flag-staff, and a gun fired; and if he would have them chafe any ship, veslel, or boat in view, he hoists the pendant, and fires two guns. When the admiral would have all the boats in the fleet to come on board him, manned and armed, he hoists a pendant on the flag-staff, both on the fore-topmast and mizen-topmast-head, and a gun fired; and if he would have them chafe any ship, vessel, or boat, in open view, without coming on board him, he hoists the pendant, as aforesaid, and fires two guns. When the admiral would speak with the victualler, or his agent, he puts an English ensign in the mizen-topmast-flags; and when with him that hath the charge of the gunner's stores, he will spread a ensign at his main-topmast-yard-arm.

Signals for managing a Sea-fight. When the admiral would have the fleet form a line of battle, one ship a-head of another, he hoists an union flag on the mizen-peak, and fires a gun; and every flag-ship does the like. But when they are to form a line of battle, one a-head of another, he hoists a pendant with the union-flags, &c. When he would have the admiral of the white, or him that commands in the second poll, to tack, and endeavour to gain the wind of the enemy, he spreads a white flag under the flag at the main-topmast-head, and fires a gun; and when he would have the vice-admiral of the blue do so, he doth the same with the blue flag. If he would have the rear-admiral of the
the red do so, he spreds a red flag from the cap, on the fore-topmout-head, downward on the back-flag; if the vice-admiral of the blue, he spreds a blue flag, &c. and fires a gun. If he would have the rear-amarial of the red do so, he hoists a red flag at the flag-flaff, at the mizen-topmout-head, if the rear-admiral of the white, a white flag; if the rear-admiral of the blue, a blue flag, and under it a pendant of the fame colour, with a gun. If he be to leeward of the fleet, or any part of it, and he would have them bear down into his wake or grain, he hoists a blue flag at the mizen-peck, and fires a gun. If he would be to leeward of the enemy, and his fleet or any part of it be to leeward of him, in order to bring thes ships into the line, he bears down with a blue flag at the mizen-topmout-head; but a blue one, if he would have ships of the larboard quarter come to the larboard tack, with a gun. If the van are to tack fift, he spreds the union-flag at the flag-flaff, on the fore-topmout-head, and fires a gun, if the red flag be not on board; but if it be, then he lowers the fore-topsails a little, and the union-flag is spred from the cap of the fore-topmout downward; and every flag-flaff doth the fame. If the rear be to tack fift, he hoists the union-flag on the flag-flaff, at the mizen-topmout-head, and fires a gun; which all the flag-flaffes are to anfwer. If all the flag-flaffes are to come into his wake or grain, he hoists a red flag at his mizen-peck, and fires a gun; and all the flag-flaffes must do the fame. If he would have him that commands in the fectl polt of his squadron to make more fail, (though he himfelf shorten fail,) he hoists a white flag on the ensign-flaff. But if he that commands in the third polt be to do fo, he hoists a blue flag, and fires a gun, and all the flag-flaffes must make the fame fignall. Whenever he hoists a red flag on the flag-flaff at the fore-topmout-head, and fires a gun, every flag in the ffleet must ufe their utmost endeavour to engage the enemy, in the order preferred them. When he hoists a white flag at his mizen-peck, and fires a gun, then all the small frigates of his squadron, that are not of the line of battle, are to come under the flem. If the fleet be failing by a wind in the line of battle, and the admiral would have them brace their head-fails to the mift, he hoists a yellow flag on the flag-flaff, at the mizen-topmout-head, and fires a gun; which the flag-flaffes are to anfwer; and then the ships in the rear mift brace fift. After this, if he would have them fall their head-fails, and stand on, he hoists a yellow flag on the flag-flaff of the fore-topmout-head, and fires a gun, which the flag-flaffes must anfwer; and then the ships in the van mift fall fift, and stand on. If, when this fignall is made, the red flag at the fore-topmout-head be abroad, he spreds the yellow flag under the red. If the flets being near one another, the admiral would have all the fhips to tack together, the sooner to lie in a pofture to engage the enemy, he hoists an union-flag on the flag-flaffes at the fore and mizen-topmout-heads, and fires a gun; and all the flag-flaffes are to do the fame. The fleet being in a line of battle, if he would have the fhip that leads the van hoift, lower, fet, or haul up any of her falls, he spreds a yellow flag, under that at his main-topmout-head, and fires a gun, which fignall the flag-flaffes are to anfwer; and the admiral will hoift, lower, fet, or haul up the fail, which he would have the fhip that leads the van do; which is to be anfwered by the flag-flaffes of the fleet. When the enemies run, and he would have the whole flets follow them, he makes all the fail he can after them himfelf, takes down the fignall for the line of battle, and fires two guns out of his fore-chafe, which the flag-flaffes anfwer; and then evry fhip is to endeavour to come up with and board the enemy. When he would have the chafe given over, he hoists a white flag at the fore-topmout-head, and fires a gun. If he would have the red squadron draw into a line of battle, one abreath of another, he puts abroad a flag, if riplred red and white, on the flag-flaff at the main-topmout-head, with a pendant under it, and fires a gun; if the blue or fcond squadron is to do fo, the flag is riplred white, and blue; if the blue or third squadron is to do fo, the flag is a Genoefe enfign and pendant; but if they are to draw into a line of battle, one a-head of another, the fame fignalls are made with a pendant. If they are to draw into the line of battle one a-fern of another, with a large wind, and he would have the leaders go with the larboard tacks aboard, by the wind, he hoists a red and white flag at the mizen-peck, and fires a gun; but if they should go with the larboard tacks aboard, by the wind, he hoists a Genoefe flag at the fame place; which fignalls, like others, must be anfwered by the flag-flaffes.

SIGNATURES, among the Romans, witneffes who feal'd wills and marriage contracts.

SIGNATURE, Signatura, Signing, a subscription, or putting of one's name at the bottom of an act, or deed, in one's own hand-writing. Ancienfly, when very few people could write, they difpenfed with the ufe of signatures; and contenued themselves with the party's feal. See Deed.

SIGNATURE, of the Court of Rome, is a fupplication anfwered by the pope, by which he grants a favour, defpifation, or collation to a benefice, by putting the fiat at the bottom of it, in his own hand; or the exception eff written in his præfence. This fignature, at the bottom of the fupplication, gives name to the whole instrument.

The fignature contains the claufls, derogations, and defpifations, with which the pope grants the favour, or the benefice, with a commifjon for the execution of it, either in forma dignum, or in graciouf form.

A fignature of the pope's own hand, by which he anfwers, Fiat ut petitur, is preferred to another anfwered by the prefent, in his præfence, in these words, Concellum vti petitur in prefentia D. N. pope. Sometimes in fignatures, with the flat, the pope adds proprio motu; which clause gives them fìll farther force.

There are three kinds of fignatures: one in forma grata, difpatched on an affettation of the ordinary; another in forma dignum antiqua, difpatched for canonicates; the third in forma dignum novissima, which is a kind of fcond fignature, or executorial letter, granted where, upon the ordinary's failing to execute the ftrait, within thirty days, the nearest other ordinary is enjoined to execute it.

SIGNATURE, in Printing, denotes a mark at the bottom of each feet, to regulate the gathering and binding of the book; and to fwear the order and number of the feets, in collating, to fee if the book is perfect.

The fignatures conftit of the capital letters of the alphabet. If there be more feets than letters in the alphabet, to the capital letter they add a small one of the fame fort; i.e. a little a after a great A, &c. which they repeat as often as is neceffary.

SIGNATURE, Signatura, is also used, by some naturalists, for the refeemblance a vegetable or mineral bears to any part of the human body; this is, by fome fantafical people,
people, supposed to afford an indication of its virtues and use.

SIGNAU, in Geography, a town of Switzerland, and principal place of a district, in the canton of Berne; 12 miles S.E. of Berne.

SIGNES, a town of France, in the department of the Var; 12 miles S.W. of Brignoles.

SIGNET, one of the king's seals, used for sealing his private letters, and fixing all grants which pass his majesty's hand by bill. Forging it is treason. See Sign Manual.

The signet is always in the custody of the king's secretaries; on whom attend four clerks of the signet-office. See Secretary and Clerk.

SIGNIA, in Ancient Geography, a town of Italy, in Latium, at some distance to the right of the Latin way, and towards the S.W. of Anagnia. Livy says, that Tarquinius the Proud first hither a colony. Some remains of it are still visible. — Also, a mountain of Alia Minor, in the Great Phrygia. Pausanias says, that the town of Apamaea was built at the foot of this mountain.

SIGNIFICANT, among the Romans, an ensign-bearer, or the person who carried the standard, on which was represented a hand stretched out. See Sign.

SIGNIFICATION, the sense or meaning of a sign, word, phrase, emblem, device, or the like; that is, the thing denoted by such sign, word, figure, &c.

We are almost perfectly at a loss as to the signification of the hieroglyphic characters of the ancients.

SIGNIFICATION, in Law, is the notification of an act, &c. made to the opposite party, by a copy, &c. of it, given and attested by a proper officer.

Some significations are to be made to the perfon himself; or at least at his house; for others, it is enough that they be made to the party's attorney, or agent.

SIGNIFICATIV. See Excommunicato Capiendo.

SIGNING. See Signature, and Counter-signing.

SIGNINUM, among the Romans, a kind of pavement much esteemed: it was made of powdered shells mixed with lime.

SIGNORELLI, Luca, in Biography, was born at Cortona in 1439, and was a disciple of Pietro della Francesca. He was among the first of the Italian artists who deigned the naked figure with fidelity and accuracy; though still impeded by the flashes of stiffness and formalism, and too much adherence to common nature. His greatest work is his celebrated fresco in the chapel of the Virgin in the cathedral of Orvieto, representing the final dissolution and judgment of the world; a work of extraordinary quality, in which variety and originality of ideas are rendered with force and effect. Vafari, who was related to Signorelli, says that Michael Angelo adopted, in his Last Judgment, many of the ideas of this art; of which most probably he only took the characters of actions, and clothed them with his own emphatic style of design.

Though grace of form, and harmony of colouring, are not the most prominent features in the style of Signorelli, yet one of his works is extolled by Lanzi as poling the metaphysical qualities in a superior degree; viz. his Communione del Apostoli, in the church del Geta at Cortona. He was invited to Rome to assist in decorating the apartments of the Sifilina, where he painted the Journey of Moses and Zipporah, and the Promulgation of the Old Law; exhibiting a superior arrangement of composition. He painted at Urbino, Volterra, Arezzo, Sienna, and Florence, and established a name among the most eminent of the Florentine painters. He died in 1526, aged 52.

Vol. XXXII.

SIGNORELLI, Pietro Napoli, of Naples, author of an excellent critical history of the Ifage, "Storia Critica de' Teatri," 1783. This work is written with great spirit, and, in general, exactitude and genuine information, concerning other theatres, as well as those of Italy; particularly of Spain, where the author had resided twenty years, and with whose literature and dramatic productions he seems perfectly well acquainted. But having given the preference to the dramatic works and performance of the Italians, he provoked a controversy with a Spanish writer, which was not carried on with great patience or urbanity.

Signor Signorelli is likewise author of a work more voluminous and important, entitled "Vicende della Colutta nelle due Sicilie"; or, "Progress in the Culture of Legislation, Policy, Literature, Commerce, Fine Arts, and Theatrical Exhibitions, in the Two Sicilies," 5 vols. 8vo. Naples, 1786. This work contains much information of the progress of music at Naples during the two last centuries; but we were disappointed in finding no mention of the Conservatories, those famous musical seminaries which have produced so many great composers and singers, whose works and performance have not only delighted Naples and the rest of Italy, but all Europe.

SIGNORESSA, in Geography, a town of Italy, in the Trevifian; 6 miles N.W. of Trevigio.

SIGNUM PUGNÆ, the signal of battle among the Romans, was a coat of arms of a purple colour, set upon the general's pavilion.

SIGNY-le-Grand, in Geography, a town of France, in the department of the Ardennes, and chief place of a canton, in the district of Mezières; 6 miles S.W. of CHARLIEVE. The place contains 2380; and the canton 6699 inhabitants, on a territory of 210 kilometres, in 13 communes.

SIGNY-le-Petit, a town of France, in the department of the Ardennes, and chief place of a canton, in the district of Rocroy, 9 miles W.S.W. of Rocroy. The place contains 1723, and the canton 5790 inhabitants, on a territory of 142½ kilometres, in 10 communes.

SIGNONIO, Carlo, in Biography, was born of a good family at Modena, about the year 1534. At the age of seventeen he went to Bologna, where he palled three years in the study of philosophy and medicine, to which last profession he was directed by his father. But having no turn for physic, he spent a year at Pavia, and then entered into the service of cardinal Grimani. At the age of twenty-two he was taken by invitation from his native city to occupy the chair of Greek, vacant by the departure of Porta, the master under whom he had formerly studied. In 1550 he made himself advantageously known to the learned world by publishing the "Salii Confuores," with a commentary, which quickly went through several editions. In 1552 he was invited to the professorship of belles-lettres at Venice, and in that city he published several discourses on important topics of literature, and his valuable notes and conjectural emendations of Livy. In 1560 he was removed to the chair of eloquence at Padua, then the most celebrated of the Italian universities, but in 1563 he accepted an invitation to Bologna, which was from this time the usual place of his residence. In this situation he rendered himself so acceptable to the city, that he was presented with its freedom, together with a large inerit of salary. Here he employed himself in the composition of learned works, which have handed down his name to posterity with high honour, and he was so well satisfied with his condition, that he refused a very flattering proposal from Stephen, king of Poland, to occupy a professorship in that country.
country. He visited Rome in 1578, where he was honourably received by pope Gregory XIII., by whom he was engaged to compose an ecclesiastical history. Of this, however, he executed no more than some learned illustrations of Sulpicius Severus; for he died at Modena in the year 1584. He was a most able and successful elucidator of ancient history and antiquities. He was indefatigable in searching to the bottom all subjects which he undertook to examine, so that in many he left little to be added by later enquirers, and his works are all carefully composed in a pure, and even an elegant, Latin style. Besides the pieces already mentioned, he published many valuable tracts on the Roman laws and customs, also on the republics of the Hebrews, Athenians, and Lacedemonians. He composed twenty books of a history relating to the western empire, from the time of Diocletian to its final destruction, and he performed the more arduous task of framing from the rude and obfcuré chronicles of the times, a history of the kingdom of Italy, from the arrival of the Lombards to the year 1286. Sigonio was involved in several controversies, in one of which he is supposed to have disgraced himself. About twelve months before he died, an intimate friend of his edited a pretended treatise of Cicero, entitled "Confolatio." Its authenticity was immediately impugned by critics, and there is now no doubt that it was not genuine; but Sigonio wrote so warmly in defence of it, that he is generally supposed to be the author. The works of this learned man were published collectively in 1732-3, by Ardelati, at Milan, in fol. vol. with his Life, by Muratori, prefixed.

SIGORUM, in Ancient Geography, a mountain of Asia, in Melopotamia, in the vicinity of the town of Niltus, according to Sozomen. SIGOULES, Le, in Geography, a town of France, in the department of the Dordogne; 7 miles S. of Bergerac. SIGRI, a town on the N.W. part of the island of Metelin, in the Grecian Archipelago. SIGRIANA, in Ancient Geography, a country of Asia, in Media, according to Strabo. SIGRIANI, mountains of Asia Minor, on the coast of the Propontide. SIGRIUM, a promontory of the isle of Lebos, in the most westerly part of the island. SIGRUM, a part of the isle of Tenedos, in which was a statue of Diana. SIGTUNA, in Geography, a town of Sweden, in the province of Upland, situated on a creek of the Malar lake, anciently one of the chief cities of the kingdom. It is said to derive its name from the celebrated Odin, whose surname was Sigge; he came into the north before the Christian era, and had his residence, his temple, and his court of justice; others say the town was built by Odin. However that be, Sigtuna has undergone many changes; in the year 1068, it was plundered and burnt by Olaf the Pious, king of Norway; in 1188, it was destroyed by the Carelions, Etonians, and Ruffians. It recovered from these calamities, and flourished till the vast increase of Stockholm gave it a blow, which it is not likely to recover; 10 miles N. of Stockholm. SIGUA, in Ancient Geography, a town of Asia, in the Greater Armenia. Ptolemy. SIGUENC(A), in Geography, a city of Spain, in Old Calilfe, situated on the edge of a mountain, near the source of the river Henares; the fee of a bishop, suffragan of Toledo, with an university, founded in the year 1441, by cardinal Ximenes. It contains three churches, three convents, two hospitals, a strong castle, an arsenal, and between 700 and 800 houses. This town was anciently called Segontia. A battle was fought here between Pompey and Sertorius; and in the beginning of the seventh century, the Goths were defeated here by the Romans; 56 miles N.E. of Madrid. N. lat. 40° 58'. W. long. 2° 57'. SIGUETTE, in the Mange, is a caisson of iron, with teeth or tachys, that is, a semicircle of hollow and vaulted iron, with teeth like a saw, containing of two or three pieces joined with hinges, and mounted with a headflail and two ropes, as if they were the caissons that in former times were wont to be put upon the nose of a fiery stiff-headed horse, in order to keep him in subjection.

There is a fort of figuette, that is, a round iron all of one piece, fewed under the nose-band of the bridle, that it may not be in view. This figuette we employ with a martingale, when a horse beats upon the hand.

SIHASTRIA, in Geography, a town of Moldavia; 34 miles W. of Suceava. SIHAUL, a town on the W. coast of Sumatra. N. lat. 0° 25'. E. long. 119° 45'. SI-HIAM, a town of China, of the third rank, in Che-si; 37 miles E.S.E. of Han-tchong. SI-HO, a town of China, of the third rank, in Chen-si; 42 miles W. of Oei. SI-HOA, a town of China, of the third rank, in Ho-nan; 32 miles E.S.E. of Hiu. SIHON, or SION, or AMU. See JINON and AMU. SION, or Sharokah, a name given to the river Sier, in its course. SIHOR, a town of Hindostan, in Guzerat; 25 miles W. of Gogo. SIHUTLA, a town of Mexico, in the province of Mechoacan; 25 miles W. of Zacatula. N. lat. 18° 45'. W. long. 104° 26'. SIKAJOCKI, a town of Sweden, in Eait Bothnia; 8 miles N. of Brahehall. SIKE, in Rural Economy, a term provincially applied to a little rill, a water-furrow, and a gutter. SIEVI, in Geography, a town of Turkish Circassia, on the coast of the Black sea; 30 miles S.E. of Anapa. SIKFORD, a town of Sweden, in Well Bothnia; 18 miles N.W. of Pitea. SIKHS, or SEKS, an appellation formed of the Sanscrit term SIKH, or SIKHA, denoting a disciple or devoted follower, and in the Punjabi corrupted into SIKH, which is applicable to any person that follows a particular teacher; and hence used to denominate, in its primary use, a religious sect, which advanced, by successive gradations, from the humble condition of conditionists, to the rank of one of the most powerful states in Hindostan. The founder of this sect was Nanan Shah, a native of a small village called Talwandi, in the district of Bhatti, in the province of Lahore, where he was born A.D. 1459. It is now become a town, and denominated Rayapur, and is situated on the banks of the Beyah or Hyphasis. Nanak's father, whose name was Calo, and who belonged to the Chatriya cast and Vidi tribe of Hindostan, wished to bring him up to trade, but Nanak himself was from his childhood inclined to devotion, and manifested an indifference to all worldly concerns. This disposition was cherished by his intercourse with the Fakirs, among whom and the poor he distributed a great part of his substance. It is needful to recite his trances and visions, and converse with the prophet Elias, and the sages which he practised at the commencement and in the progress of his religious career. Nor can we accompany him in his travels which he undertook with a view of reforming the worship of the
the true God, that had been degraded by the idolatry of the Hindoos and the ignorance of the Mahometans. It will be sufficient for us to observe, that after he had visited all the cities of India, and explained to all ranks the great doctrines of the unity and omnipotence of God, he went to Mecca and Medina, where his actions, his miracles, and his long disputations with the Mahometan fainins and doctors, are most circumstantially recorded by his biographers. He is flated, on this occasion, to have defended his own principles without offending those of others; always professeing himself the enemy of discord, and as having no object but to reconcile the two faiths of the Mahometans and Hindoos in one religion; which he endeavoured to do by recalling them to that great and original text, which both of them believed, the unity of God; and by re-called them from the numerous errors into which they had fallen. During his travels, about the year 1526 or 1527, Nanac was introduced to the emperor Baber, before whom he is said to have maintained his doctrine with great firmness and eloquence. Baber treated him kindly, and offered him an ample maintenance, which the Sikh priest refused, alleging, that he trusted in him who provided for all men, and from whom alone a man of virtue and religion would content to receive favour or reward. The Hindoo zealots violently oppressed him, more especially after he had laid aside the habits of a Fakir; but he treated their opposition and reproaches with great contempt; and when they required him to exhibit some proof of his power, that might astonish them, he replied, "I have nothing to exhibit worthy of you to behold. A holy teacher has no defence but the purity of his doctrine; the world may change but the creator is unchangeable." Having migrated from Vatala to Multan, and from Multan to Kirtipur, on the banks of the Rave or Hydractis, he there performed many miracles, as it is reported, threw off his earthly shape, and was buried near the bank of the river Rave, which has since overflowed his tomb. Kirtipur continues to be a place of religious reformation and worship; and a small piece of Nanac's garment is exhibited to pilgrims, as a sacred relic, at his Dharamala, or temple. Nanac was unquestionably a man of more than common genius, which we may infer from the distinguished eminence to which he attained, and the successes with which he combated the opposition that encountered him; whilst he laboured without intermission to recall both the Mahometans and Hindoos to an exclusive attention to that sublimest of all principles, which invests devotions with God and peace towards men. Although he left two sons, he did not deem either of them worthy of a succession to his spiritual functions; but he devolved them upon a Chhatrinya of the Trehun tribe, called Lhana, whom he had initiated in the sacred mysteries of his sect, clothed in the holy mantle of a Fakir, and honoured with the name of Angad. Guru Angad was born at the village of Khundur, on the bank of the Bough or Hyphasis, in the province of Lahore. He taught the same doctrine as Nanac; and some of his writings, as well as those of Nanac, are contained in a book entitled "Grant'h." At his death, which happened A.D. 1532, he was succeeded by Amera Das, a Chhatrinya of the tribe of B'hal, who had been a mensal servant for twelve years. Amera Das was active in propagating the tenets of Nanac successful in gaining profelytes, by whose alliusion he established a degree of temporal power. He had two sons, and a daughter, named B'haini, who was married to a young lad, whose name was Ram Das, a Chhatrinya, of a respectable family, of the Sondi tribe, and an inhabitant of the village of Gondawal. Upon the death of Amera Das, A.D. 1574, he was succeeded by his son-in-law, whom he had initiated in the mysteries of his holy profession, and who became famous for his piety, and still more on account of the improvements he made at Amritfar, which was for some time called Rampur, or Ramdaspur, after him. Some writers have erroneously ascribed the foundation of this town, anciently and long before his time denominated Chak, to him; however, he added much to its population, and built a famous tank, or reservoar of water, which he called Amritfar, a name signifying the water of immortality, and which has become so sacred, that it has given its name, and imparted its sanctity, to the town of Ramdaspur; so that it has become the sacred city of the Sikh nation, and is now only known by the name of Amritfar. After a life passed in the undisturbed propagation of his tenets, in explanation of which he wrote several books, Ram Das died A.D. 1581, and left two sons, one of whom, viz. Arjunmal, succeeded him, and rendered himself famous by compiling the A'di-Grant'h, containing ninety-two sections, part of which was composed by Nanac and his immediate succedors, but arranged in its present form by Arjunmal, who blended his own additions with the compositions of his predecessors. Arjun, from this circumstance, is deemed the first who gave consistent form and order to the religion of the Sikhs. Arjun fell a sacrifice to the jealousy of the Mahometan government; and his death excited the indignation of the Sikhs, who, before this event, had been an inoffensive, peaceful sect; and they took up arms under Har Govind, the son of Arjunmal, and wreaked their vengeance upon all whom they thought concerned in the murder of their revered prict. From all the remaining accounts of Har Govind's life, it appears to have been his anxious wish to inspire his followers with the most irreconcileable hatred of their oppressors. Govind, with this view, introduced some change in their diet, allowing them to eat the flesh of animals, that of the cow excepted; and by other regulations converted a race of peaceable enthusiasts into an intransigent band of soldiers. Govind died A.D. 1644, and was succeeded by his grandson Har Ray, whose reign was upon the whole tranquil, which was probably owing to the vigour of the Mahometan power in the early part of the reign of Aurungzebe. At his death, A.D. 1664, a violent concil arose among the Sikhs, concerning the succession to the office of spiritual leader; for the temporal power of their ruler was, at this time, little more than nominal. The dispute was referred for decision to Delhi; and by an imperial decree of Aurungzebe, the Sikhs were allowed to elect their own prict. They chose Har Grin, son (or grandson) of Har Ray, who died at Delhi A.D. 1664, and was succeeded by his uncle, Tegh Behadur. During his life, which terminated prematurely, by the violence of his rival, A.D. 1675, and also from the period of Govind's death, the Mogul empire was in the zenith of its power under Aurungzebe; and the Sikhs, who had never attained any real strength, were rendered still weaker by their own divisions. However, after the death of Tegh Behadur, the history of the Sikhs assumed a new aspect. Under Har Govind the Sikhs had been initiated in arms, but they used them only in self-defence; but the plans of Govind's ambition were very different from those of his predecessor Nanac; and he wisely judged, that the only means by which he could ever hope to oppose the Mahometan government with success, were not only to admit converts from all tribes, but to break at once those rules by which the Hindoos had been so long chained;—to arm, in short, the whole population of the country, and to make worldly wealth and rank an object to which Hindoos, of every clafs, might aspire. It was the object of Govind to make all Sikhs equal, and that their advancement should solely depend upon their exertions; and well aware how necessary it was to inspire men of a low race, and
and of grovelling minds, with pride in themselves, he changed the name of his followers from Sikh to Sinh or lion; thus giving to all his followers that honourable title which had been before exclusively assumed by the Rajputs, the first military clans of Hindoos; and every Sikh felt himself at once elevated, by this proud appellation, to a footing with the first clays. The disciples of Govind were required to devote themselves to arms; always to have steel about them in one shape or other; to wear a blue dresa; to allow their hair to grow; and to exclaim, when they met each other, “Wa! Guruji ka khalfalt! Wa! Guruji ki futhee!” i.e. “Success to the state of the Guru! Victory attend the Guru!”

Govind inculcated his tenets upon his followers by his preaching, his actions, and his works. He is said to have first instituted the Guru-mata, or state council, among the Sikhs, which meet at Amritsar; by which institution he gave that form of a federative republic to the commonwealth of the Sikhs, which was most calculated to rove his followers from their indolent habits, and deep-rooted prejudices, by affixing to them a personal share in the government, and placing within the reach of every individual, the attainment of rank and influence in the state. The emperor Aurungzebe, aided by the rajas who were hostile to Govind, purfued him and his followers to Chamkour, and accompanied it on all sides. The siege was carried on with great vigour; and though Govind manifested an invincible spirit, and performed prodigies of valour, he was at last overpowered by numbers; and reduced to the necessity of making his escape from Chamkour in a dark night, covering his face, as it is said, from shame at his own disgrace. After his flight, a sene of his misfortunes, and the loss of his children, deprived him of his reason, and he wandered about for a considerable time in the most deplorable condition. At length, having obtained from the emperor Behadur Shah a small military command in the Deccan, he was flabbled by a Patan soldier’s son, and expired of his wounds, A.D. 1708, at Nared, a town situated on the Caveri river, about 100 miles from Hyderabad. Guru Govind was the last acknowledged religious ruler of the Sikhs. A prophecy had limited their spiritual guidance to the number of ten; and their superstition, aided, without doubt, by the action of that spirit of independence which its institutions had introduced, caused its fulfilment. Banda, a devoted follower and friend of Guru Govind, stabilized the union of the Sikhs under his banner; and his grief at the misfortune of his priest, is said to have fettled after the death of Govind into a gloomy and desperate desire to avenge his wrongs. The conflagration which took place on the death of Aurungzebe, which happened A.D. 1707, was favourable to his wishes. Having obtained a victory over the Mahometans in a bloody action, Banda, encouraging the Sikhs, and hardening them by his leonions to deeds of the most horrid atrocity, subdued all the country between the Setlej and the Jumna, and crossing that river, made inroads into the province of Sharanpur, which lies a few miles to the N.E. of Delhi, between the rivers Jumna and the Ganges. The march of the Sikhs was attended with the execrable of the most wanton barbarity; life was only granted to those who conformed to the religion, and adopted the habits and dress of the Sikhs; and if Behadur Shah had not quitted the Deccan, which he did A.D. 1710, the whole of Hindoostan would probably have been subdued by these merciless invaders. The first check which the Sikhs received was from an army under sultan Kuli Khan. They were afterwards defeated in a very desperate action by Abdal Samad Khan, an officer of the emperor Farakhfeir, after which the Sikhs were never able to make a stand, but were hunted like wild beasts from one strong hold to another, by the army of the emperor, by whom their leader, Banda, and his most devoted followers, were at last taken, after having suffered every extreme of hunger and fatigue. Great numbers of the Sikhs were put to death, after the surrender of Lohgad, a fortress 100 miles N.E. of Lahore; but Banda was sent, with the principal chiefs of the tribe, to Delhi, where, after having been treated with every kind of obloquy and insult, they were executed.

After the defeat and death of Banda, resentment prompted to every measure that could be devised, not only to destroy the power, but to extirpate the race of the Sikhs. From the Mahometans they met with no quarter; and after the execution of their chief, a royal edict was issued, ordering all who professed the religion of Nanak to be taken and put to death wherever found; and by way of giving greater effect to this mandate, a reward was offered for the head of every Sikh. During the interval that elapsed between the defeat and death of Banda, and the invasion of India by Nadir Shah, a period of nearly 30 years, we hear nothing of the Sikhs; but when that event occurred, they are said to have fallen upon the habitants of the Panjab, who sought shelter in the hills, and to have plundered them of that property which they were endeavouring to secure from the rapacity of the Persian invader. Enriched with these spoils, says the author whose account of them we are now citing, the Sikhs left the hills, and built the fort of Dalewal, on the Ravi, from whence they made predatory incursions, and are said to have added, both to their wealth and reputation, by harrying and plundering the rear of Nadir Shah’s army, which, when it returned to Persia, was encumbered with spoil, and marched, from a contempt of its enemies, with a disregard to all order.

The weak state to which the empire of Hindoostan was reduced, and the confusion into which the provinces of Lahore and Cabul were thrown, by the death of Nadir, were events of too favourable a nature to the Sikhs to be neglected by that race, who became daily more bold, from their numbers being greatly increased by the union of all those who had taken shelter in the mountains; the re-admission into the fold of those who, to save their lives, had abjured, for a period, their usages; and the conversion of a number of profelytes, who haintened to join a band which under robbery was made facred, and to plunder was to be pious.

Aided with these recruits, the Sikhs now extended their irruptions over most of the provinces of the Punjaib; and though it was some time before they reproached themselves of Amritsar, they began, immediately after they quitted their faithlessness, to flock to that holy city at the periods of their sacred feasts. Some performed this pilgrimage in secret, and in disguise; but in general, according to a contemporary Mahometan author, the Sikh horsemens were seen riding, at full gallop, towards “their favourite shrine of devotion.” They were often inlust in making this attempt, and sometimes taken prisoners; but they used, on such occasions, to feek, instead of avoiding, the crown of martyrdom; and the fame authority states, “that an infall was never known of a Sikh, taken in his way to Amritsar, concurring to abjure his faith.”

Encouraged by the confusion which took place on the first Afghan invasion, A.D. 1746, the Sikhs made themselves masters of a considerable part of the Doob of Ravi and Jandara, and the country between the rivers Ravi and Beyah, and that river and the Setlej, and extended their incursions to the neighbouring countries. But though they were frequently and repeatedly checked by Mir Manu, the governor of Lahore, yet, after his death, they availed themselves of all the advantages which the local distractions of a falling empire
pier afforded them of extending and establishing their power. Their bands, under their most active leaders, plundered in every direction, and were successful in obtaining possession of several countries, from which they have never since been expelled; and their successes, at this period, was promoted, instead of being checked, by the appointment of their old friend, Adina Beg Khan, to Lahore; as that brave chief, anxious to defend his own government against the Afghans, immediately entered into a confederacy with the Sikhs, whom he encouraged to plunder the territories of Ahmed Shah Abdali.

The Afghan monarch, resenting this predatory warfare, in which the governor of Lahore was supported by the court of Delhi, determined upon invading India. Adina Beg, unable to oppose him, fled; and the Sikhs could only venture to plunder the baggage, and cut off the stragglers of the Afghan army, by which they so irritated Ahmed Shah, that he threatened them with punishment on his return; and when he marched to Cabul, he left his son Taimur Khan, and his vizir, Jehan Khan, at Lahore, with orders to take vengeance on the Sikhs for all the exchequies which they had committed. The first expedition of Taimur Khan was again against their capital, Amritsar, which he destroyed, filling up their sacred tank, and polluting all their places of worship; by which action he provoked the whole race to such a degree, that they all assembled at Lahore, and not only attempted to cut off the communication between the fort and country, but collected and divided the revenues of the towns and villages around it. Taimur Khan, enraged at this presumption, made several attacks upon them, but was constantly defeated; and, being at last reduced to the necessity of evacuating Lahore, and retreating to Cabul, the Sikhs, under one of their celebrated leaders, called Jafa Sinh Calal, immediately took possession of the vacant fortress of Lahore, and ordered trophies to be coined, with an inscription to the following import: "Coin'd by the grace of Khaliuf ji, in the country of Ahmed, conquered by Jafa Sinh Calal." Although they were afterwards expelled, together with the Afghans, from Lahore, yet after the death of Adina Beg Khan, the governor of this province, they eagerly seized the opportunity that was thus afforded them, of making themselves again masters of Lahore. Their successes were, however, soon checked by Ahmed Shah Abdali, who, irritated by their unsubdued turbulence and obstinate intrepidity, made every effort (after he had gained the victory of Panipat', which established his supremacy at Delhi) to destroy their power; and, with this view, he entered the Punjab early in 1762, and over-ran the whole of that country with a numerous army, defeating and dispersing the Sikhs in every direction. That feat, unable to make any stand against the army of the Abdali, purloined their old plan of retreating near the mountains; and collected a large force in the northern districts of Sirhind, a distance of above one hundred miles from Lahore, where the army of Ahmed Shah was encamped. Here they conceived themselves to be in perfect safety; but that prince made one of those rapid movements for which he was so celebrated, and reaching the Sikh army on the second day, completely surprised and defeated it with great slaughter. In this action, which was fought in February 1762, the Sikhs are said to have lost upwards of twenty thousand men; and the remainder fled into the hills, abandoning all the lower countries to the Afghans, who committed every ravage that a barbarous and savage enemy could devise. Amritfar was razed to the ground, and the sacred reservoir again choked with its ruins. Pyramids were erected, and covered with the heads of slaughtered Sikhs; and it is mentioned that Ahmed Shah caused the walls of those mosques which the Sikhs had polluted to be washed with their blood, that the contamination might be removed, and the induct offered to the religion of Mohamet expiated.

This species of savage retaliation appears to have animated instead of depressing the courage of the Sikhs, who, though they could not venture to meet Ahmed Shah's army in action, harried it with an incessant predatory warfare; and when that sovereign was obliged, by the commotions of Afghanistan, to return to Cabul, they attacked and defeated the general he had left in Lahore, and made themselves masters of that city, in which they levelled with the ground those mosques which the Afghans had, a few months before, purified with the blood of their brethren.

When Ahmed Shah, after retaking Lahore, A.D. 1763, was obliged, in the ensuing year, to return to his own country, the Sikhs again expelled his garrison, and made themselves masters of the Punjab; and, from that period until his death, a constant war was maintained, in which the enterprize and courage of the Afghans gradually gave way before the almonishing activity, and invincible perseverance, of their enemies; who, if unable to stand a general action, retreated to impenetrable mountains, and the moment they saw an advantage, rushed again into the plains with renewed vigour and recruited numbers. Several Sikh authors, treating of the events of this period, mention a great action having been fought by their countrymen, near Amritfar, against the whole Afghan army, commanded by Ahmed Shah in person; but they differ with regard to the date of this battle, some fixing it in 1762, and others later. They pretend that the Sikh, inspired by the sacrficiency of the ground on which this action was fought, contended for victory against superior numbers with the most desperate fury, and that the battle terminated in both parties quitting the field, without either being able to claim the lead advantage. The historians of Ahmed Shah are, however, silent regarding this action, which, indeed, from all the events of his long contests with the Sikhs, appears unlikely to have occurred. It is possible the Sikhs fought at Amritfar with a division of the Afghan army, and that might have been commanded by the prince; but it is very improbable they had ever force to encounter the concentrated army of the Abdali, before which, while it remained in a body, they appear, from the first to the last of their contests with that prince, to have always retreated, or rather fled.

The Sikhs, when oppressed, became as formidable for their union, as for their determined courage and unconquerable spirit of refiiaence; but a state of persecution and distress was most favourable for a constitution like theirs, which required constant and great sacrifices of personal advantage to the public good; and such sacrifices can only be expected from men who act under the influence of that enthusiasm, which the fervour of a new religion, or a struggle for independence, only imparts, and which are almost readily made when it becomes obvious to all, that a complete union in the general cause is the only hope of individual safety.

The Sikhs may be reckoned the most western nation of Hindooostan: for the king of Candahar polishes but an inconsiderable extent of territory on the coast of the Indies. Since the complete downfall of the Mogul empire, they have acquired very extensive domains. But major Rennell observes, that their power ought not to be estimated in the exact proportion to the extent of their population, since they do not form one entire state; but a number of small ones, independent of each other in their internal government, and only connected by a federal union. They have extended their territories on the south-east, that is, into the province
of Delhi, very rapidly of late years; and perhaps, the Ze- 
mindars of that country may have found it convenient to 
place themselves under the protection of the Sikhs, in order 
to avoid the more oppressive government of their former 
masters. It is certain that the eastern boundary of the Sikhs' 
dominions has been advanced to the banks of the Jumnah river, 
above Delhi, and to the neighbourhood of that city; for the 
adjacent territory of Schaurunpore is subject to their depres-
sions, if not actually tributary to them; and they make 
incursions even to the side of the Ganges. On the south, 
they are bounded by the northern extreme of the sandy 
debris of Regilfan, and on the south-west their boundary 
meets that of Sindy, or Tatta, at the city of Behker or Bhek- 
r, on the Indus. On the west the Indus is their gen- 
eral boundary, as high up as the city of Attoc; near to 
which begin the territories of the king of Candahar; and 
their northern boundary is the chain of mountains that lies 
towards Thibet and Cashmere. As this is the caye, they 
will be found to possess the whole soufbah or province of 
Lahore, the principal part of Moultan, and the western part 
of Delhi; the dimensions of which tract are about 340 
British miles from N.W. to S.E., and from 150 to 200 
broad, in general; although in the part between Attoc and 
Behker (that is, along the Indus) the extent cannot be 
less than 320. Their capital city is Lahore.

According to the statement of brigadier-general Malcolm, 
the country now possessed by the Sikhs, which reaches from 
N. lat. 25° 30' to beyond N. lat. 32°, and includes all the 
Panjab, a small part of Moultan, and most of that tract of 
country which lies between the Jumnah and the Setlej, is 
bounded, to the northward and westward, by the territories 
of the king of Cabul; to the eastward, by the possessions 
of the mountainous rajas of Jumnu, Nadon, and Sinagar; and 
to the southward, by the territories of the English govern-
ment, and the sandy deserts of Jafalmer and Hanuya Hifar.
A general estimate of the value of the country possessed 
by the Sikhs may be formed, when it is flated, that it contains, 
besides other countries, the whole of the province of La-
here; which, according to Mr. Bernier, produced in the 
reign of Aurungzebe, 245 lacks and 95,000 rupees; or 
2,469,500, sterling. The Sikhs who inhabit the country 
between the Setlej and the Jumnah, are called Malawa 
Sinh, and were almost all converted from the Hindoo 
tribes of Jats and Gojars. The country of the Malwa 
Sinh is in some parts fruitful; but those districts which bor-
der on Hanuya and Carnal are very barren; being covered 
with low wood, and in many places almost destitute of water. 
Its former capital was Sibhind, but it is now a complete 
ruin. Patiala is now the largest and most flourishing town 
of this province, and next to it is T'hanefur, which is still 
held in high veneration by the Hindoos, who have also a 
high reverence for the river Serafoweti, which flows through 
this province. The country of Jalendra Doob, which reaches 
from the mountains to the junction of the Setlej and the 
Beah, is the most fruitful of all the possessions of the Sikhs, 
and is perhaps excelled, in climate and vegetation, by no 
province in India. The soil is light, but very productive; 
the country, which is open and level, abounds in every kind 
of grain. The towns of Jalendra and Sultanpore are the 
principal in the Doonab. The country between the Bayah 
and Ravi rivers is called Bari Doob, or Manjha; and the 
Sikhs inhabiting it are called Manjha Sinh. The cities 
of Lahore and Amritfar are both in this province, and conse-
quently it becomes the great centre of the power of this na-
tion. The country of Bari is said to be fertile, particular-
ly towards the mountains, than Jalendra, but lying on 
the same level, its climate and soil must be nearly the same.

The inhabitants of the country between Ravi and Chanhab 
are called D'harpal Sinh, from D'harpal, the name of the 
country; the D'hahugh Sinh are beyond the Chanhab, 
but within the Jeholam river. The Sind Sinh is the term by 
which the inhabitants of the district under the Sikhs bor-
dering on the Sind are known; and Nakai Sinh is the name 
given to the Sikhs who reside in Moultan.

The government of the Sikhs may be termed a theocracy. 
Although they obey a temporal chief, that chief preserves 
his power and authority by profiting himself the fervant of 
the khalfa, or government, which can only be paid to act, in 
times of great public emergency, through the means of a 
national council, of which every chief is a member, and 
which is supposed to deliberate and resolve under the imme-
diate inspiration and impulse of an invisible being; who, as 
they believe, always watches over the interests of the com-
monwealth. It is natural, however, to imagine that the 
power of this assembly should decline; and from Col. 
Malcolm's account, we may infer, that it is nearly de-
stroyed. The last Guru-mata was called in 1805, when the 
British army pursued Holkar into the Panjab. The 
government is mild; but in their mode of making war the 
Sikhs are unquestionably savage and cruel. Among the 
Sikhs there is a clasf of devotees, called Acals, or immortals, 
who, under the double charafter of fanatic priests and de-
ferateolders, have unfurled the false direction of all reli-
gious affairs at Amritfar; and who, of course, are leading 
men in a national council held at that sacred place, and which 
deliberates under all the influence of religious enthusiasm. 
This order of Sikhs was first founded by Guru Govind, and 
are distinguished by their drefs, as well as by their having al-
most the sole direction of the religious ceremonies at Amritfar. 
They have a place on the bank of the sacred rehervoir of 
Amritfar, where they generally refort, but are individually 
poffessed of property, though they affect poverty, and subfixt 
on charity. The principal chiefs of the Sikhs are all de-
cended from Hindoo tribes. The lower order of Sikhs, 
compared with the wretched Mahometans who are doomed 
to oppression and hard labour, are happy; they are pro-
tected from the tyranny and violence of the chiefs under whom 
they live by the precepts of their common religion, and by 
the condition of their country, which enables them to aban-
don, whenever they chuse, a leader whom they dislike. 
The civil officers, to whom the chiefs entrust their accounts, 
and the management of their property and revenue concerns, 
as well as the conduct of their negociations, were in general 
Sikhs of the Khalfa cast, who, being followers of Namae, 
and not of Guru Govind, are not devoted to arms, but edu-
cated for peaceful occupations, in which they often become 
very expert and intelligent. In the collection of the revenue 
of the Panjab, it is said to be a general rule, that the chiefs 
to whom the territories belong should receive the half of 
the produce, grain paying in kind, but sugar, melons, &c. 
in cash, and the farmer the other; but the chief never levies 
the whole of his share; and in no country, perhaps, is the 
ryat, or cultivator, treated with more indulgence. Com-
merce is rather restrained than encouraged by the heavy 
duties and the distracted state of the country. However, 
a great part of the shawl trade now flows through the cities 
of Lahore, Amritfar, and Patiala, to Hindooitam. The ad-
ministration of justice among the Sikhs is in a very rude and 
imperfect state.

Their law is all unwritten. Nothing is configned to any 
express form of words. There is no definition of any 
thing. The custom of the country, the custom of the 
court, (that is to say, as far as the judge is pleased to be 
governed by those customs), and the will of the judge,—are 
the
the circumstances which guide the decision. Among the Hindus some of the sacred books, among the Mahometans the Koran, are used as the books of law. Among the Sikhs there is no such reference to any sacred books; and their situation is, in all probability, much the better for the Koran or Hindu books afford scarcely any rules or principles of law, which are not so vague as to speak any language which the interpreter chooses to give them; and while their authority is sufficient to supercede that of the natural dictates of justice and equity, which are the only guides of the Sikh judges, the Hindu or Mahometan has only to find or to feign a principle of his book, which may enable him to decide as he pleases.

Trifling disputes about property are settled by the heads of the village, by arbitration, or by the chief. The court of arbitration is called *panchayat*, or a court of five, the general number of arbitrators chosen to adjudge differences and disputes. It is usual to assemble a panchayat, or a court of arbitration, in every part of India under a native government; and, as they are always chosen from men of the best reputation in the place where they meet, this court has a high character for justice. The decision obtained by either of these modes is final. If a theft occurs, the property is recovered, and the party punished, not with death, by the person from whom it was stolen, or by the inhabitants of the village, or his chief. Murder is sometimes punished by the chief, but more generally by the relatives of the deceased, who, in such cases, rigorously retaliate on the murderer, and sometimes on all who endeavour to protect him.

The character of the Sikhs, or rather Sinhs, which is the name by which the followers of Guru Govind, who are all devoted to arms, are distinguished, is very marked. They have, in general, the Hindu call of countenance, somewhat altered by their long beards, and are to the full as active as the Maharrats, and much more robust, from their living fuller, and enjoying a better and colder climate. Their courage is equal at all times to that of any natives of India; and when wronged upon by prejudice or religion, is quite desperate. They are all horsemens, and have no infantry in their own country, except for the defence of their forts and villages, though they generally serve as infantry in foreign armies. They are bold, and rather rough in their address, which appears more to a stranger from their invariably speaking in a loud tone of voice; but this is quite a habit, and is alike used by them to express the sentiments of regard and hatred.

The Sikhs have been reputed deceitful and cruel, but Sir John Malcolm knew no grounds upon which they could be considered more so than the other tribes of India; they seemed to him, from all the intercourse he had with them, to be more open and sincere than the Maharrats, and less rude and savage than the Afghans. They have, indeed, become, from national success, too proud of their own strength, and too irritable in their tempers, to have patience for the wiles of the former; and they retain, in spite of their change of manners and religion, too much of the original character of their Hindoo ancestors, (for the great majority are of the Hindon race,) to have the constitutional frolic of the latter. The Sikh soldier is, generally speaking, brave, active, and cheerful; without polith, but detest neither of fincerity nor attachment; and, if he often appears wanting in humanity, it is not so much to be attributed to his national character, as to the habits of a life, which, from the condition of the society in which he is born, is generally pait in scenes of violence and rapine.

The Sikh merchant, or cultivator of the soil, if he is a Sinh, differs little in character from the folder, except that his occupation renders him less preemining and boisterous.

He also wears arms, and is, from education, prompt to use them, whenever his individual interest, or that of the community in which he lives, requires him to do so. The general occupations of the Khalsa of Sikhs have been before mentioned. Their character differs widely from that of the Sikhs. Full of intrigue, plant, vertile, and infiniate, they have all the art of the lower classes of Hindoos, who are usually employed in transacting business; from whom, indeed, as they have no distinction of drees, it is very difficult to distinguish them.

The general character of the religious tribes of Acalis, Shabhid, and Nirmala, is formed from their habits of life. The Acalis are insolent, ignorant, and daring; presuming upon those rights which their numbers and fanatic courage have established, their deportment is hardly tolerant to the other Sikhs, and inoffensive to strangers, from whom they entertain a contempt which they take little pains to conceal. The Shabid and the Nirmala, particularly the latter, have more knowledge and more urbanity; they are almost all men of quiet, peaceable habits; and many of them are paid to public service.

There is another tribe among the Sikhs, called the Nanac Pautra, or descendants of Nanac, who have the character of being a mild, inoffensive race; and though they do not acknowledge the institutions of Guru Govind, they are greatly revered by his followers, who hold it sacrilege to injure the race of their founder; and under the advantage which this general veneration affords them, the Nanac Pautra pursue their occupations; which, if they are not mendicants, is generally that of travelling merchants. They do not carry arms; and profess, agreeably to the doctrine of Nanac, to be at peace with all mankind.

The Sikh converts continue, after they have quitted their original religion, all those civil usages and customs of the tribes to which they belonged, that they can practice, without infringement of the tenets of Nanac, or the institutions of Guru Govind. They are most particular with regard to their intermarriages; and on this point, Sikhs descended from Hindoos almost invariably conform to Hindoo customs, every tribe intermarrying within itself. The Hindoo usage regarding diet, is also held equally sacred; no Sikh descended from a Hindoo family ever violating it, except upon particular occasions, such as a Guru-mata, when they are obliged, by their tenets and institutions, to eat promiscuously. The strict observance of these usages has enabled many of the Sikhs, particularly of the Jat and Gujar tribes, which include almost all those settled to the north of the Sutlej, to preserve an intimate intercourse with their original tribes; who, considering the Sikhs not as having lost, but as Hindoos that have joined a political association, which obliges them to conform to general rules established for its preservation, neither refuse to intermarry, nor to eat with them.

We shall here add, that the "Jats" are Hindoos of a low tribe, who, taking advantage of the declining state of the Mogul empire, have, by their courage and enterprise, raised themselves to some consequence on the north-western parts of Hindoostan, and many of the strongholds of that part of India are still in their possession. The "Gujars" are also Hindoos, and have raised themselves to power by means not dissimilar to those used by the Jats. Almost all the thieves in Hindoostan are of this tribe.

The higher call of Hindoos, such as Brahmins and Chatriyas, who have become Sikhs, continue to intermarry with converts of their own tribes, but not with Hindoos of the call they have abandoned, as they are polluted by eating animal food, all kinds of which are lawful to Sikhs, except the cow, which it held sacrilege to slay.

The
The Mahometans, who become Sikhs, intermarry with each other, but are allowed to preserve none of their usages, being obliged to eat hog’s flesh, and abstain from circumcission.

The Sikhs are forbidden the use of tobacco, but allowed to indulge in spirituous liquors, which they almost all drink to excess; and it is rare to see a Sikh folder, after dinner, quite sober. Their drink is an ardent spirit, made in the Panjab; but they have no objection to either the wine or spirits of Europe, when they can obtain them.

The use of opium to intoxicate is very common with the Sikhs, as with most of the military tribes of India. They also take bhang (cannabis fativa), another intoxicating drug.

The conduct of the Sikhs to their women differs in no material respect from that of the tribes of Hindoos, or Mahometans, from whom they are descended: their moral character, with regard to women, and indeed in most other points, may, from the freedom of their habits, generally be considered as much more lax than that of their ancestors, who lived under the restraint of severe restrictions, and whose fear of excommunication from their cast, at least obliged them to cover their fins with the veil of decency. This, the emancipated Sikhs defy; and there is hardly an infamy which this debauched and dilolute race are not accursed, and with justice, as Sir John Malcolm believed, of committing in the most open and shameless manner.

The Sikhs are almost all horsemen, and they take great delight in riding. Their horses were formerly famous for their strength, temper, and activity; but they are now no better mounted than the Maharrattas.

Their horsemen use swords and spears, and most of them now carry matchlocks, though some still use the bow and arrow, a species of arms for excellence in the use of which their forefathers were celebrated, and which their descendants appear to abandon with great reluctance.

The education of the Sikhs renders them handy, and capable of great fatigue; and the condition of the society in which they live, affords constant exercize to that refined spirit of activity and enterprise which their religion has generated. Such a race cannot be epicures; they appear, indeed, generally to defpise luxury of diet, and pride themselves in their coarse fare. Their dress is also plain, not unlike the Hindoos, equally light, and diversified of ornament. Some of the chiefs wear gold bangles, but this is rare; and the general characteristics of their dress, and mode of living, is simplicity.

The principal leaders among the Sikhs affect to be familiar and easy of intercourse with their inferiors, and to despise the pomp and state of the Mahometan chiefs; but their pride often counteracts this disposition; and they appear to have, in proportion to their rank and consequence, more state, and to maintain equal, if not more reserve and dignity with their followers, than is usual with the Maharratta chiefs.

It would be difficult, if not impracticable, to ascertain the amount of the population of the Sikh territories, or even to compute the number of the armies which they could bring into action. They boast that they can raise more than a hundred thousand horse; and, if it were possible to assemble every Sikh horsemans, this statement might not be an exaggeration; but there is, perhaps, no chief among them, except Ranjit Sinh, of Lahore, that could bring an effective body of four thousand men into the field; and the force of Ranjit Sinh did not, in 1805, amount to eight thousand, and part of that was under chiefs who had been subdued from a state of independence, and whose turbulent minds ill-brooked an usurpation, which they deemed subversive of the constitution of their commonwealth. His army is now more numerous than it was, but it is composed of materials that have no natural cohesion, and the hirfierous check which it meets probably cause its disfission.

As for the religion of the Sikhs, it seems, say Sir John Malcolm, to have been a sort of pure deism, grounded on most sublime general truths, blended with the belief of all the absurdities of the Hindoo mythology, and the fables of Mahometanin; for Nanac professed to conciliate Hindoos and Mahometans to the belief of his doctrine, by persuading them to reject those parts of their respective belief and usages, which, he contended, were unworthy of that God whom they both adored. He endeavoured to impress both Hindoos and Mahometans with a love of toleration, and an abhorrence of war; and his life was as peaceable as his doctrine.

We cannot forbear remarking on the inconsistency and contradiction which are involved in the idea of “pure deism” blended with the belief of absurdities. As well might we call a fylem of philosophy perfect, the greater part of which is nonsense. Is it not evident, says an anonymous writer, that so far as absurdities are mixed with a religious creed, so far the purity of its deism is excluded.

—But to proceed; Guru Govind, as we have already goggled, gave a new character to the religion of his followers, by establishing institutions and usages, which not only lepated them from other Hindoos, but which, by a complete abolition of all distinctions of cast, destroyed a fylem of civil polity, which, from being interwoven with the religion of a weak and bigotted race, fixed the rule of its priests upon a basis that had withstood the shock of ages. For further particulars we must refer to the author, whose elaborate account of the Sikhs has furnished the principal materials of this article. Malcolm’s Sketch of the Sikhs in vol. xi. of his Asiatie Researches; or Sketch of the Sikhs, &c. London, 1812. Rennell’s Memoir, Introd. Edin. Rev. No. 42.

SIKI, in Geography, a town of Anatic Turkey, in Carmania, on the Dragant; 27 miles W. of Selaikhe.

SI-KIANG, or Weli River, a river of China, which rises near Fong-tceun, in Quang-tong, and runs into the sea, S. of Canton.

SIKIATZKOI, a town of Ruffia, on the Lena; 140 miles N. of Zigarfls. N. lat. 60° 20'. E. long. 121° 40'.

SIKINOS, an island in the Grecian Archipelago, which lies seven or eight miles to the W.S.W. of Nio. This island is lofty and mountainous, of small extent, being about twenty miles in circumference, and contains, according to Olivier, no more than 200 inhabitants. It has no harbour, and is now little frequented by Europeans. Its productions consist of wheat, barley, wine, cotton, and fruits. It pays about 2000 piastras to the captain-pacha. A town of the same name with the island is situated on a rock, which hangs over the sea. N. lat. 36° 43'. E. long. 25° 10'.

SIKKE. See Sikk.

SIKNA, a river of Moldavia, which runs into the Zita, 20 miles S.W. of Batyszani.

SIKOKO. See Xicoco.

SIKOVIT, a small island in the East Indian sea. S. lat. 7° 12'. E. long. 131° 51'.

SIL, a river of Switzerland, which runs into the Limat, one mile below Zurich.—Alfo, a river of Spain, in Galicia, which rises in the mountains to the west of Leon, where it receives the Beza and the Burvia in Galicia, flows to one to San-Estevan and to Torbe, where it receives the Lor, and in
I is Picentini preternatural small substance contains town. It alfo town mine-town the N. It on of multitude at dug. It town Geography, both nicely effervefence river the a member. There word 10 it. It much German town 40 was word 12 word 13 x143 nine.

—Alfo, a mountain of Italy, in Lucania.

SILAI, a town of Hungary; 32 miles S. of Zatmar. SILAMBOE, a town on the S. coast of the island of Java. S. lat. 7° 33'. E. long. 107° 15'.

SILANDAM, in Ancient Geography, a town of Asia Minor, in Lycaia.

SILARUS, a river of Italy, which commenced in the territory of the Hirpini, separated the Picentini from Lucania, and discharged itself into the sea near Puteum. Strabo says, that this river petrifed the plants that were thrown into it, without destroying their colour or their form.—Alfo, a mountain of Italy, in Lucania.

SILAS, a river of India, which fprung from a fountain of the fame name, and ran into the country of the Sileans, according to Arrian.

SILATUM, a word used by the ancient Romans to express a morning's draught of wine. This was usually of a wine medicated with the plant flil, or selefi, and thence had its name. It has always been the custom to medicate the morning draughts of any strong liquor; we do it with wormwood, or the common bitter tincture; the Indians with ginger.

SILAVENGO, in Geography, a town of Italy, in the Novarca; 10 miles N.W. of Novara.

SILAUNA, in Geography, a town of European Turkey, in Bulgaria; 40 miles W. of Nicopoli.

SILBERBACH, a village of Welfphalia, in which is found lead-ore mixed with filver; 12 miles S. of Brillon.

SILBE, a town of Africa, in the county of the Foolsaths, on the Senegal. N. lat. 17° 5'.

SILBERBACH, a town of Pruilia, in the province of Oberland; 6 miles W. of Liebigstadt.

SILBERBERG, a mine-town of Silelia, belonging to the principality of Brieg, but inluated in that of Munsterberg. N. lat. 50° 24'. E. long. 16° 26'.

SILBEREGG, a town of the duchy of Carnithia; 2 miles N.W. of Ebermühlen.

SILBERMANN, Johann Andreas, in Biography, the moft eminent and renowned organ-builder and maker of keyed-instruments in Germany. He was born at Strafburg in 1712, and the flil of a numerous and eminent family of that name, who have inherited his professional abilities and reputa
tion. There is, in Gerber's Continuation of Walther's Musical Lexicon, a fift of their feveral names and works; but old Silbermann was the Father Smith of Germany. His in
tuments are prized above all others for workmanship and tone. The Bach family have been always partial, not only to Silbermann's organs, but harpsichords and clavichords. When we heard Emanuel Bach perform at Hamburg, it was always on a favourite Silbermann clavichord; piano fortas were not then brought to great perfection anywhere; but since that time we find that John Henry Silbermann is much celebrated for his piano fortas.

SILBERSCHLAG, John Isaiah, a German mathematician and mechanift, was born in 1721. He fludied at the college Kloflcrberge, near Magdeburg, and afterwards went through a coufe of theology at Halle, from which place he returned to the college at which he had been before, where he taught natural philosophy and mathematics for nine years. After this he became pastor of one of the churches at Berlin, and rector of the royal school. He was a member of the Academy of Sciences in that city; and, besides writing various works on mechanical and mathematical subjects, constructed a great many machines, instruments, and models, for the ufe of the students in the feminary which had been placed under his care. He died

SILBERSTRASS, in Geography, a town of Saxony, in the circle of Erzgebirg; 4 miles S.E. of Zwicau.

SILBIDUM, in Ancient Geography, a town of Italy, in Italy.—Also, a town of Aet, in Greater Pityrga.

SILBODAL, in Geography, a town of Sweden, in the province of Warmeland; 35 miles W. of Carlslad.

SILBOJOCK, a town of Sweden, in the Lapland of Pitea; 12 miles N. of Niarg.

SILBURY HILL, one of the largest barrows or tumuli in England, and probably in the world, is situated on the Marlborough Downs, about six miles west of the town of Marlborough, in Wiltshire. The origin, appropriation, and history of this extraordinary mound of earth, are alike unknown to the topographer and antiquary. In the vicinity of the immense druidical temple at Avebury, (see Avebury,) it is reasonably supposed to have been originally connected with that structure; and as the most remote antiquities of this island, and of the civilized world, have given rise to much fabulous dilatation, and fanciful hypothesis, so the barrow now called Silbury Hill has been referred to various tribes of people, applied to different purposes, and attributed to the most remote origin. Dr. Stukeley was of opinion that its present name is of Saxon derivation, and signifies "the great or marvellous hill;" while others contend that it is either a corruption for Sil-barrow, which they translate "the peaceful grave;" or of Sel-barrow, meaning "the large or elevated barrow." The most common supposition respecting its nature ranks it among the sepulchral chiefs of monuments. Stukeley calls it the tomb of Cunedha, whom he characterizes as a celebrated Briton, who refided at Cunuo (then supposed to have been Marlborough), and gave his name to that town, and to the river Kennet, or Cruin. The Rev. Samuel Greathead, in a letter to Mr. Britton, printed in the account of Wiltshire, in the 17th volume of the " Beauties of England and Wales," regards Silbury as the burial-place of Prydain, a later king of the Britons, to whom he attributes the union of the British tribes under one monarchy, and the construction of Avebury, as a place of assembly for the chiefs and people on great national occasions. Another opinion respecting this tumulus is, that it was the mount on which the Druids lighted up fires, when they wished to give notice to the surrounding country of some intended religious ceremonial. This view of the subject is of course confined to those who consider Avebury as having been a druidical temple; among whom is the Rev. Edward Davies, author of "Celtic Researches," and of "The Mythology and Rites of the British Druids." To these opinions relative to Silbury Hill may be added a third, which may be regarded as equally probable with any of the conjectures above stated. It is that, like the Tinwald of the Isle of Man, and the Moote-hill of Scone, it was the mount of justice, the eminence from the summit of which the king promulgated the laws enacted in the national assemblies, and on which he and his judges sat to decide all important causes, whether of a civil or criminal nature.

Silbury Hill is situated directly south of Avebury, and nearly in the centre between the extremities of the two avenues, which extended from the temple to the distance of a mile each way. At the base the hill is about 560 feet in diameter, or 1680 feet in circumference; at the top, 105 feet diameter, or 315 feet in circumference; and it rises 170 feet in perpendicular height. Stukeley estimates its solid contents at 13,558,609 cubic feet, and highly praised the choice of the ground, and the symmetrical proportions of the structure itself. In digging here in 1723, a human skeleton, with the bit of a bridle, deer's horns, and an iron knife, were discovered, which Dr. Stukeley confidently considered to have belonged to the person for whom he supposed the mount was raised; but the pothole of the skeleton near the surface and on a declivity would render such a conclusion extremely improbable, even though it were undoubted that Silbury is of sepulchral origin. Stukeley's Abury, folio, 1743. Beauties of England and Wales, by J. Britton, F.S.A. 8vo. 1814.

SILCHESTER, a parish in Hampshire, England, at the northern extremity of that county, bordering on Berkshire, contains the site and ruins of an ancient Roman station. It appears also to have been a city of the Belgic Britons anterior to the Roman colonization of Great Britain, and was called Cacarenion, or Segont, as being the chief city of the Segontiaci. In the seventh Iter. of Antoninus it is named Vindomir, and marked 22 miles from Venta-Belgarum (Winchelster), and x from Callevam (probably Reading.) That this was a Roman station of importance, appears evident from the various roads, or vias, branching from it; from the magnitude and construction of the walls, valla, and amphitheatre; and from the numerous coins and other relics that have been found here at different periods. The whole city, or station, was surrounded by a fos, with a vallum on the infide, on which a wall was raised. This was constructed, in the usual Roman manner, with alternate layers, or rows of large flat stones, rubbish stones, and cement, also bricks and flints. In one place this wall was twenty-four feet thick, and the fos was above 100 feet across. The exterior form of this station is unlike any other Roman work in England, being an irregular octagon; whereas those of Camulodunum (Colchester), Venta-Belgarum (Winchelster), Lindum (Lincoln), Londonium (London), and almost all others, were constructed in the shape of a parallelogram, with the corners rounded off. The inclosed area of Silchester is about one mile and a half in circumference, and contains nearly one hundred acres, the whole of which is appropriated to the arable and pasture lands of a farm. In very dry seasons, it is easy to trace the situation and direction of the Roman streets, two of which intersected the town, and communicated with the four entrance gates, on the east, west, north, and south sides of the city. Near the centre of the area there have been traced the foundations of a large edifice, supposed to have been the forum. About 170 yards from the north-east corner of the walls, are the banks of an amphitheatre, which appears to have contained five rows, or terraces for spectators. A small church and a farm-house, with its offices, are all that now remain within the ancient walls; and thus present an amazing contrariety to the appearance and pursuits of former times. Now the humble and useful husbandman, with the humane Christian pastor, are the chief occupants of this peaceful spot, which, in the third century, was peopled with Roman soldiers, and was often the theatre of remoreless battles, savage sports, and nefeteful pagan ceremonies. A particular account of this place will be found in the 6th volume of "The Beauties of England," by J. Britton and E. W. Brayley.

SILCOLU, a town of Hindooftan, in Myfor; 8 miles S.E. of Seringapatam.

SILDA, in Ancient Geography, a town of Africa, in Mauritania Caflariensis, according to Ptolemy. The itinerary of Antonine places this town on the route from Toenofda to Tingis, between Aquax Dacie and Volfspace.

SILDE
SILDE REVEL, in Geography, a cluster of small islands belonging to Denmark, in the Cattegat; 6 miles S. of Lefoe.

SILE, in Ancient Geography, a town of Lower Egypt, on the route from Serapium to Pelphis, between Magdolun and Thaisaum, according to the Itinerary of Antonine.

SILE, in Geography, a river of Italy, which passes by Treviglio, and runs into the Adriatic, opposite to the island of Torcello.

SILE, in Rural Economy, provincially the name of a milk-pointer.

SILEBY, in Geography, a large and populous village and parish on the easterly bank of the river Soar, in the hundred of East-Golscote, and county of Leicester, England. The lordship contains about 2130 acres, the greater part of which was inclosed, with other contiguous lands, in conformity to an act of parliament passed in 1759. The manor belongs to Earl Ferrers. In the parish were formerly two ancient mausoleums, belonging to the Sherard and the Polcan families. In 1811 the parish contained 240 houses, and 1200 inhabitants, most of whom were employed in agriculture and farm-work, knitting. Here is one free-school, and three other large schools. The church, a handsome stone building, consists of a nave, aisle, and chancel, a porch, and a tower. The reversion of the church was formerly appropriated to the abbey of St. Ebrul, in Normandy, which was suppressed by king Henry V. Afterwards the living belonged to the prior of St. Mary, in the isle of Axholme, in the county of Lincoln. Nichols's History and Antiquities of the County of Leicester, folio, vol. iii.

SILEIN, a town of Hungary; 14 miles E.N.E. of Bolekdo.

SILENCE, Fr. in Music, equivalent to rest; which see.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, swelling, five-toothed, permanent. Cor. Petals five; claws narrow, the length of the calyx, bordered with a membrane; limb flat, horizontal, obtuse, often divided, and morelly furnished, more or less, with a crown, erect, toothlike crest at its base, constituting the crown of the flower. Stam. Filaments ten, awl-shaped, five alternate ones inserted into the claws of the petals, and later than the rest; anthers oblong. Fil. German superior, cylindrical; styles three, simple, longer than the flower; stigmas twisted contrary to the motion of the sun. Peric. Capsule cylindrical, ovate, or somewhat globule, covered by the calyx, more or less perfectly three-celled, bursting at the top into fix teeth. Seeds numerous, kidney-shaped, attached to a central receptacle.

Obi. The crown of the petals, on which Linnaeus depended for his character of Silene, in contradistinction to Cucubalus, being found not only to separate species most closely related, but even to vary in the same species, as Lamarck and many others have noticed; the authors which stand on our list of references above, have agreed to remove to Silene all the Linnaean Cucubalus, except C. baceta, on which Tournefort originally founded that genus, which has indeed a crown, but is distinguished by having for its fruit a real berry, not a capsule. See Cucubalus.

Silene, thus considered, is a vast genus, of which new species are still from time to time discovered, in the warmer and drier regions of the south of Europe, and north of Africa; countries abounding particularly with this tribe of plants. All the species in general are herbaceous, many of them annual, very few shrubby. Their stems are jointed, branched, leafy, frequently gluttonous, for a certain space, below each joint. The calyx and flower-flats are also, when downy, somewhat vilid. Leaves opposite, fimple, entire. Petals red or white, rarely greenish or yellowish; scarcely ever blue. Some of the flowers, especially the greenish ones, are deliciously fragrant at night; and if they have any scent, are sweetest at that time, like the Pink tribe in general. We shall select sufficient examples of the genus, particularly describing such as are new, or hitherto only mentioned in the Prodr. Fl. Grsec, as well as all those of British growth.

Sect. 1. Stem racemose; occasionally somewhat forked.

S. quinquerviulata. Variegated Catchfly. Linn. Sp. Pl. 595. Wildl. n. 3. Ait. n. 17. Pursh n. 1. Fl. Brit. n. 2. Eng. Bot. t. 86. (Lychins hirta minor, flore variegate; Tourn. Infl. 337. Dodart Mem. ed. Amst. 601. t. 23.)—Hairy. Petals roundish, entire. Flowers lateral, alternate, erect, as well as the fruit.—Native of dry or sandy fields in the fouth of Europe and the Levant. Mr. Hudson found it near Wrotham in Kent; and Mr. Pursh near Charlestown, Carolina, on the sea-coast. We presume this species to have been carried from Europe to America, being a common hardy annual in gardens, where it flowers in June and July. The plant is not viscous like the preceding, though hairy. The petals are remarkable for a brilliant crimson spot in the middle of each. The lowest calyctes are sometimes reflexed.

lui
Flowers spike, alternate, nearly sessile, directed one way. Petals deeply clawed. Leaves spatulate, hairy. — Native of Spain, the south of France, vineyards about Constantinople, and cultivated ground in Greece; also of Virginia; flowering in June and July. An annual, upright, slightly branched species; the leaves which accompany the flowers narrow, and much smaller than the leaf. Petals small, pale pink, or white with a green external tinge, minutely crowned. Capsules ovate, flattened. The flowers are said to expand at night only.

S. pendula. Pendulous Catchfly. Linn. Sp. Pl. 599. Willd. n. 27. Ait. n. 37. Curt. Mag. t. 114. (Vicagino hiera fucu. lychnidus aquaticus facie, fupina; Dill. E1th. 421. t. 312.) — Flowers racemose. Calyx of the fruit pendulous, inflated, with ten rough ribs. Stem decumbent. — Native of Italy, Sicily, Crete, and Cyprus, flowering in the spring. Every bank about Rome is decorated with this elegant plant in the spring. Nothing is better calculated for the decoration of rock-work, or dry parterres, than this hardy annual, whose purplish plumes spread in every direction, and are copiously adorned with large pink flowers, with a membranous, violet-ribbed, inflated calyx. The seeds scatter themselves without any trouble.

S. versicolor. Pink Evening Catchfly. Retz. Obl. fasc. 3. 31. Willd. n. 24. Ait. n. 35. Curt. Mag. t. 677. Sm. Fl. Græc. Sibth. t. 409, unpublished. (S. bipartita; Desfont. Atlant. v. 1. 352. t. 100. S. ciclata; Willd. n. 4, excluding the synonymy. Lychmis marina hirta purpurea, leucoj folio; Barred. Tc. 1010.) — Petals with two deep rounded lobes, and a sharp cloven crest. Calyx downy. Leaves spatulate. Stems diffuse. — Found on the sea-shores of Sicily, Barbary, Crete, Zante, and Greece, not uncommon. It has been known about twenty years in our gardens, as a hardy annual, flowering in summer. Linnaeus had specimens, but never determined the species. The stems bear numerous spatulate leaves. The flowering branches are naked below, each terminating in a simple cluster of eight or ten handiome bracteate pink flowers, all drooping one way, with a reddish club-shaped calyx. The pubescence, especially of the calyx, is more cold and soft than in S. pendula, though more long and flabby in some specimens than others. The stem is very rarely once forked, being usually altogether racemose.

S. dianthiflorus. Pale Spiked Catchfly. Prodr. Fl. Græc. n. 981. Fl. Græc. t. 410, unpublished. — Petals with two deep narrow segments, and a notched crest. Calyx villous. Leaves oblong. Stem diffuse. — Gathered by Dr. Sibthorpe, in the isle of Cyprus. The root is annual, long. Stems spreading, rarely a span in length, not forked, though morelly once divided, round, leafy, reddish, rough, like the leaf of the herbs, with long spreading hairs. Leaves thick and broad, rather more than an inch in length; the lower ones tapering at the base. Flowers six or eight in each spike, crested, on short, flat stalks. Calyx rather slender, hardly an inch long, with ten reddish hairs. Limbs of each with nearly as long as the claw; pale red on the upper side; light green, with darker veins, beneath; crest white, divaricated, double-toothed.

S. thyrsifolia. Thyme-leaved Catchfly. Prodr. Fl. Græc. n. 982. Fl. Græc. t. 411, unpublished. — Petals with two deep narrow segments, and a notched crest. Calyx hairy, glabrous. Stems procumbent, woody, much branched. Found by Dr. Sibthorpe on the sandy shores of Caria and the isle of Cyprus. Root perennial. Stems a foot or two in length, widely spreading, repeatedly branched, copiously jointed, round, hairy, sending up several terminal, ascending, simple, leafy, hairy, and rather vivid, flowering branches, from three to fix inches long. Leaves oblong, acute, rough, about half an inch long, with axillary tufts of still smaller ones. Flowers raceemose, three or four at the top of each branch, erect, white, but the back of the petals greenish. Calyx an inch long, hairy, pale green, with pink dots.

S. dichotoma. Forked Long-branched Catchfly. Ehrh. Beitr. v. 7. 143. Pl. Select. n. 65. Willd. n. 23. Fl. Græc. t. 413, unpublished. (S. trinervis; Soland. in Russell’s Aleppo, ed. 2. 252.) — Petals in two deep narrow segments, with scarcely any crenum. Stem forked, racemose, villous as well as the leaves. — Native of Hungary and the Levant. Dr. Sibthorpe met with it in Crete, and about the Bithynian Olympus. We believe this species was raised, about 25 years ago, in many gardens about London, from seeds sent by the late Mr. Davall, so that it is entitled to a place in the Hortus Kievini. Root biennial, tapering, as thick as a common radish. Stems several, ascending, from one to two feet high, round, flabby with long spreading hairs, once or twice forked, with an intermediate, nearly feathery, flower, and then extended into long, simple, spiked or racemose branches, each bearing five or six flat, round white flowers, whose petals are narrow, with only occasional rudiments of a cret. Calyx with ten green ribs. Anthers green. Seeds red-brown. The leaves are chiefly radical, and very numerous, composing a dense, flabby, hoary, and somewhat glaucous, tuft; each leaf two inches long, and nearly one broad, ovate, bluntly pointed, tapering down into a broad footstalk.

S. divaricata. Forked Spreading-branched Catchfly. Sm. Prodr. Fl. Græc. n. 983. Fl. Græc. t. 414, unpublished. — Petals in two deep rounded lobes, with a cloven crest. Stem forked, divaricat, racemose. Leaves all lanceolate, hairy, acute. Discovered by Dr. Sibthorpe on the coast of Asia Minor. In size and habit this bears some affinity to the last, but is more leafy, and the leaves are longer, tapering at each end, undivided, of a darker green, rough with shorter hairs, not flabby. The flowering branches spread at almost right angles. The flowers are white, but with much broader and rounder petals, each petal bearing a rounded cloven crest.

Seç. 2. Stem forked, with paniced branches.

chaux noticed it in Canada. The root is perennial, long, whitish, branching at the summit. Stems erect, a foot and a half or two feet high, branched, round, glaucous. Leaves ovato-lanceolate, acute, glaucous, usually very smooth, but occasionally roughish and fringed; the radical ones numerous, crowded, capitate. Peduncle forked, bearing numerous white drooping flowers. Calyx almost globose, membranous, white, elegantly reticulated with green or purplish veins and ribs. Limb of each petal almost as long as its claw, cut half way down into two spreading, oblong, somewhat rounded segments, generally delimitate of a cret, but we have sometimes detected the rudiments of one. Anters green, occasionally liable to a disease, by which they become enlarged, tending with ufeles purple dust, which stains the petals. The natives of Zante, who call this plant čokalaki, eat the boiled leaves, which are said to partake of the flavour of green peas.

S. maritima. Sea Campion or Catchfly. With. 414. Fl. Brit. n. 6. Engl. Bot. t. 957. Willd. n. 29. Ait. n. 23. (S. amena; Hudf. Angl. 188. Lightf. Scot. 227. Cucubalus bhenan B.; Linn. Sp. Pl. 591. Fl. Dan. t. 857. Lychnias marina anglica; Bauh. Hill. v. 3. p. z. 357. Ger. Em. 469. Lob. Lc. 337.)—Flowers nearly solitary, terminal. Petals cloven about half way down; the segments of their cret entire. Calyx smooth, reticulated with veins. Stem decumbent.—Native of the sandy or rocky sea-shores of Norway, Britain, Gotland, &c. as well as of the rocky beds of mountain torrents in Wales, flowering in August and September. The appearance of the leaves and flowers, at first sight, is so like S. inflata, that molot bo-nanths, for a long time, considered the plant as a mere variety of that species. They are indeed so nearly akin, as to be inseparable with respect to genus, though inflata is moist without a crown to the flower, and this is always furnished with one. The root of S. maritima is creeping, and the stems often quite prostrate, hardly a span high, bearing one flower, for the molt part, rarely two or three, fearcely constituting a panicule. The leaves are narrower, linear-lanceolate, or slightly flatulate, very smooth and glaucous, minutely toothed at the edges. Calyx much like the last. Capsule shorter, almost globular. Styles occasionally varying to four or five.

S. bimbrata. Fringed Campion or Catchfly. Sims in Curt. Mag. t. 908. Ait. n. 46.—Flowers panicked, drooping. Petals divided, many—eleft; the segments of their cret cloven. Calyx veined, down. Stem erect.—Native of mount Caucasus, from whence it was sent to Sir Joseph Banks and Mr. Lodgings. A hardy perennial, really increated by seeds, and flowering all summer long. The whole plant resembles a large rothgious variety of S. inflata, but the deeply fringed petals, and their evident cret, at once disting. With it.

S. fabaria. Thick-leaved Campion or Catchfly. Prodr. Fl. Græc. n. 685. Fl. Græc. t. 415, unpublished. Ait. n. 2. (Cucubalus fabarius; Linn. Sp. Pl. 591. Willd. Sp. Pl. v. 2. 685. Been album, feu Polemon masticale, fabaria folio, scabrum; Bosc. Mutt. 133. t. 92.)—Flowers clustered, crowded, drooping. Petals in two deep, rather narrow, lobes; the segments of their cret notched. Leaves ovate, with a small point.—Native of rocky places near the sea, in Sicily, Afa Minor, Mount Athos, and the Isle of Samos. Root perennial. Plant very glaucous and smooth, twice as tall as the inflata, with much thicker and broader leaves. The stem is once or twice forked, each of its long upright branches bearing several remote, short, tufted clusters of drooping white flowers, with a reticulated, purplish, timid, angular calyx; and flalks, with pointed bracteas, all of the same hue. The limb of each petal is half the length of its claw, in two narrow—ovata, spreading lobes; the cret deeply divided, with sharply crenate segments. Germin red in the lower half, green above. Calyp- fule nearly globose. The present species is evidently, according to the Linnean character itself, a Silene, and too clothly related to the three preceding, and the following, to be separable from any of them, even in a section of a genus.

S. beben. Oriental Bladder Campion or Catchfly. Linn. Sp. Pl. 599. Willd. n. 25. Ait. n. 36. Fl. Græc. t. 416, unpublished. (Cynoglossum orientale, parvum flore purpureo; Dill. Elth. 427. t. 317.)—Flowers in a corymbose panicle, nearly upright. Petals deeply divided, rounded; the segments of their cret notched. Calyx reticul- ated. Leaves ovato-lanceolate. —Native of Crete, Afa Minor, and Greece.—The root of this is annual. Herb less glaucous than the last, and more approaching in habit to our common S. inflata; but the flowers are smaller, and effenlly different. The limb of each petal is but a quarter the length of its claw, pale pink, in two elliptical, or almost orbicular, lobes, with a white cret, of two, quite separate, notched segment. Germin elevated on a stalk of its own length, along with the petals and stamens, within the calyx, as is more or less the case with most of this genus.

S. sestifolia. Sea-green Campion or Catchfly. Sm. Prodr. Fl. Græc. n. 689. Fl. Græc. t. 417, unpublished. (Lychnis recta montis Idae, folio subrotundo, cæli; Tourn. Cor. 24, by the character.)—Flowers in a corymbose panicule, erect. Petals in two deep linear divisions; the segments of their cret entire. Leaves roundish-ovate. —Native of mount Parnassus, and if we are right in Tournefort's synon- ym, of mount Ida. This delicate smooth species has a very deep perennial root, crowned with a dense tuft of nu- merous, branching, leafy, round, jointed stems, nearly a span high, each terminating in one or two naked flowering branches, about a finger's length, bearing a forked panicule, of from four to eight pale, but elegant, flowers. The leaves are full an inch long, and half as broad, of a deep glaucous green, tapering down into short broad footstalks, which clasp the stem. Bracteas under the partial flower-stalks small, ovate, acute. Calyx ovate, half an inch long, tipped with pink, and variegated with green and white, but hardly reticulated. Petals narrow, cream-coloured; green underneath; their lobes almost close, or parallel, three to half the length of the claw. Styles and stamens rose-coloured, with greenish anthers.

S. levigata. Smooth-cupped Catchfly. Sm. Prodr. Fl. Græc. n. 699. Fl. Græc. t. 418, unpublished.—Panicule spreading. Petals cloven half way down, narrow, without a cret. Leaves roundish-elliptical. Calyx very smooth and even, without veins.—Found by Dr. Sibthorp in hilly pastures of the island of Cyprus. The root is annual. Stems several, from three to eight inches high, leafy below, smooth like every other part of the plant. Leaves of a deep glaucous hue; the radical ones ovate, stalked; the rest ovate, long oblong, and nearly sessile. Panicules forked; the partial stalks much longer than the calyx, which is ovate, reddish, peculiarly even and polished. Petals small; their limb pink, in two oblong, obtuse lobes, separated but half way down, and deltate of it minute. Styles very downy, rather short.

way, Sweden, Switzerland, and Greece. The root is perennial, tufted, bearing several leafy flens, four or five inches high, with a somewhat corymbose panicle. Herbage smooth, green, glaucous at all glaucous. Leaves an inch long, acute, varying in length. Flowers small, white. Capsule splitting from top to bottom into six valves.

S. chloroferia. Armenian Catchfly. Sm. Plant. ex Herb. Limn. t. 13. Willd. n. 52. Ait, n. 52. Curt. Mag. t. 807. (Lycnis orientalis vifcofa, centarea lutea folio, flore longifimo; Tourn. Cor. 24.)—Panicle spreading. Petals cloven half way down, with a two-lobed crest. Leaves glaucous, elliptical, pointed. Calyx nearly cylindric, very smooth, without out veins.—Gathered by Tuinoufert in Armenia. Said to have been introduced at Kew in 1796, by Mr. John Hinnemann. A very hardy perennial, twelve or eighteen inches high, flowering in August, readily known by the general resemblance of its foliage to Chloba perfoliata, though the leaves are not perfolate. Flowers large, erect, in a wide panicle, without scent, white, turning reddish as they fade. Calyx above an inch long, tinged with purple, very smooth, without out ribs or veins, its form slender, cylindric, or slightly club-shaped.

S. longipetala. Long-petalled Catchfly. Vent. Jard. de Cels. t. 83. Sm. Prodr. Fl. Grac. Sibth. n. 902. Fl. Grac. t. 419. unpublished.—Petals pendulous. Petals in two deep linear segments; with a notched crest, and hairy claw. Leaves lanceolate, rough-edged.—Found by Bruguiera and Olivier, in the neighbourhood of Aleppo. Dr. Sibthorp met with the same in the Isle of Cyprus. The root is annual. Stem two feet high, leafy, panicled, spreading, and manyflowered. Herbage rather glaucous, smooth, except the edge of the leaves, which is rough to the touch. Leaves about three inches long, acute, strongly ribbed; the lower ones elongated and contracted at the base, clasping the stem at the very bottom. Flowers green, quite pendulous. Calyx obvate, ten-ribbed, smooth, half an inch long. Claws of the petals hairy below, as well as the flaments and styles; limb smooth, very long, involute. Stigmas club-shaped, red like the anthers.

S. inaperta. Small Greenish Catchfly. Linn. Sp. Pl. 600. Willd. n. 39. Ait, n. 44. Sm. Fl. Grac. Sibth. t. 420. unpublished. (Vicago levii, inaperto flore; Dill. Elth. 424. t. 315.)—Panicle spreading. Flower-sect. Petals in two deep narrow segments; with a double awl-shaped crest. Leaves linear-lanceolate, smooth.—Native of Madeira. Atten. Dr. Sibthorp found it on the mountains of Greece. The root in his specimens is creeping, and evidently perennial. Delphinus describes it as annual. Stem several, near a foot high, clothed in the lower part with numerous smooth green leaves, about an inch long; and branching at the top into a panicle of a few pale delicate flowers, which seem not to have expanded properly in Sherard's garden, whence originated the specific name. In our Greek specimens the calyx is slender, rather club-shaped, an inch long, smooth, with ten green ribs. Petals widely spreading, greenish-white above, light brown beneath; their crest small, in two simple awl-shaped lobes. Calyx ovate, its stalk, within the calyx, as long as itself.

S. juncea. Ruflhy Catchfly. Sm. Prodr. Fl. Grac. Sibth. n. 954. Fl. Grac. t. 421, unpublished.—Panicle elongated. Flower-sect. Petals in two deep narrow segments; each lobe of their crest three-toothed. Leaves spatulate, all over rough.—Gathered by Dr. Sibthorp in Asia Minor. This has a small, white, annual root. Stem solitary, erect, two or three feet high; leafy and rough below; terminating in a very long, slender, smooth, slightly spreading panicle, of numerous flowers, which are rather larger than the preceding, but with a shorter calyx. Petals white, with brown veins beneath. The leaves are crowded at the root, and bottom of the stem, green, an inch and a half long, somewhat pointed; those above the panicle are awl-shaped and smooth.

S. cretica. Cretan Catchfly. Linn. Sp. Pl. 601. Willd. n. 42. Ait. n. 47. Sm. Fl. Grac. Sibth. t. 432, unpublished. (Vicago folis inferioribus belliis, superioribus lineis, calice atrico, et turgidior; Dill. Elth. 422. t. 314. f. 404, 405.)—Panicle sparingly branched. Flowers erect. Petals in two deep dvaricated segment; the lobes of their crest acute, entire. Lower leaves obvate, undulated, roughish.—Found by Dr. Sibthorp on rocks near the sea, in Crete and Cyprus, as well as on the coast of Caramania. A hardy annual, springing up spontaneously year after year in Chelsea garden. The flens are two or three, one to two feet high, erect, slender, villose. Leaves green; the lower ones obvate, obtuse and rough; upper linear-lanceolate, acute, smooth. Flowers few, small, but not elegant, crimson, with a smooth, purplish, obvate, ten-ribbed calyx. There is an angular tooth at the claw of the petals, at each side, below the crest.

S. conica. Corn Catchfly. Linn. Sp. Pl. 598. Willd. n. 21. Fl. Brit, n. 8. Engl. Bot. t. 922. Auct. t. 253. Sm. Fl. Grac. Sibth. t. 243; unpubl. (Lycnis calicus friatis, sect. Sibth. Ger. Em. 470.)—Stem forked. Petals cloven half way down; with a rounded cloven crest. Leaves soft and downy. Calyx of the fruit conical, with thirty ribs.—Native of sandy corn-fields in the south of Europe and the Levant; rare in England, though it still occurs, as in the time of Dillenius, in the sandy parts of Kent, flowering about July. Root annual. Herb downy and villose, of a greyish-green. Stems solitary or numerous, spreading, various in height, forked and panicled. Leaves linear-lanceolate, acute. Flowers erect, pale rote-coloured, fragrant, especially at night, with the scent of a honey-fuckel. Calyx cylindrical, becoming conical as the capsule swells, and membranous, with thirty green ribs, and five long, slender teeth. Petals nearly obcordate, as is also the white crest of each.—The petals appear to be sometimes entire, so that we suspect S. conoidea of Linnaeus may be a variety of this, with finer, broader leaves.

S. nothoflora. Night-flowering Catchfly. Linn. Sp. Pl. 599. Willd. n. 31. Fl. Brit, n. 9. Engl. Bot. t. 291. (Oxycoites nothoflora; Camer. Hort. 109. t. 34.)—Stem forked. Petals rather deeply cloven; with a short blunt crest. Calyx with ten angles, connected by transverse ribs; its teeth as long as the tube.—Native of sandy or gravelly fields, in Sweden, Germany, England, Switzerland, Crete, and Asia Minor; not rare in Norfolk and Suffolk, flowering in July. Root annual. Herb dark green, softly hairy or downy, spreading, of a coarse rank habit. Leaves lanceolate, three-ribbed; the lowest obvate. Flowers the size of our common Lycnis chito, (their calyx and flaments very villose,) unrolling their pale bluish-coloured petals in an evening only, when they exhale, in warm weather, a powerful and delicious scent. The strong reticulated ribs of the calyx are remarkable.

S. leucophaea. White and Brown Catchfly. Sm. Prodr. Fl. Grac. Sibth. n. 1000. Fl. Grac. t. 424; unpubl. —Petals in two deep rather narrow segments; with a deeply cloven crest. Calyx with ten angles. Leaves linear-oblong, recurved, glabrous and hairy. Discovered by Dr. Sibthorp, in the isle of Cyprus. A hairy, glabrous, branching, annual species, about a span high. Leaves an inch or inch and half long, green, narrow, obtuse, channelled, somewhat...
what revolute, recurved. Flowers smaller than the leaf, especially their calyx, which is pale, reddish, defoliate of tracheal ribs. Petals cream-coloured above; of a cinnamon brown beneath; their crest in two rounded entire lobes. This is probably a night-scented flower, like the last.

S. ramphiflora. Bushy Red Catchfly. Sm. Prodr. Fl. Græc. Sibth. p. 1001. Fl. Græc. t. 425, unpublished. (S. fedoideæ; Desfont. Atlant. v. 2. 449? Bivon. Cent. 2. 58. Osynomides, flore rubro, minus, creticum; Buhl. Hill. v. 2. 355. cap. 59. Lycnis hirta angustifolia cretica; Tourn. Insert. 337.)—Petals deeply divided; with a four-cleft crest. Calyx club-shaped, with ten angles. Leaves spatulate, recurved. Stem very much branched.—Native of Crete and Sicily, on rocks near the sea. Root annual. Whole herb hairy and viscid, green with a brown tint, repeatedly high. Leaves about an inch long, obtuse, rather fleshy. Flowers very abundant, small, on long, red, hairy stalks, from the forks, sides, and summits of the branches, erect. Calyx somewhat obovate, hairy, red, with ten ribs. Petals rose-coloured; their limb divided nearly to the bottom; their crest white, in four deepawl-shaped segments. Capsule erect, cylindrical, opening with three spreading, obtuse, cloven teeth. Seeds black. That this is S. fedoideæ of figinier Bivona Bernardi, in his second Cent. Siculiac. Plantarum, we have ascertained by specimens from himself, since the publication of Prodr. Fl. Græc. But there is reason for hesitation respecting the plant of Desfontaines, which is probably Wildenow’s n. 36; the former describes it as procumbent, with only two appendages to each petal, and the latter cites Lycnis cretica maritima minimæ, postulata fynstis folio, Tourn. Cor. 4, a species unknown to us.

Seç. 3. Stem forked, corymbosæ.

S. rubella. Small-red-flowered Catchfly. Linn. Sp. Pl. 620. Wild. n. 38. Ait. n. 43. Sm. Fl. Græc. Sibth. t. 426, unpublished. (Vifcago lautanica, flore rubello viro conspicie; Dill Elth. 423. t. 314. f. 466.)—Smooth, corymbosæ. Calyx obovate. Petals emarginate; with a rounded two-lobed crest. Upper leaves ovato-lanceolate. Capsule threc as long as its partial flalk. Native of fields and waste ground, in Portugal, Rhodes, and Cyprus, flowering in spring. Root annual. Herb quite smooth, of a glaucous green. Stem a foot or more in height, branched from the bottom, leafy; all the branches erect. Leaves obovate, recurved, an inch and a half long; upper rather shorter, acute, lanceolate, slightly ovate, recurved at the point. Flowers mostly crowded into a level-topped panicle, with one or two below, in the forks of the branches, pale red, erect. Calyx scarcely more than half an inch long, ten-ribbed, smooth, pale, with purple teeth. Petals of a dull rose-colour, spreading, variously heart-shaped, but rather oblong; their crest of two oblong, rounded, entire lobes. Capsulae redish-ovate, on a short partial flalk.

S. orbicella. Orchis-flowered Catchfly. Linn. Suppl. 241. Wild. n. 46. Ait. n. 50. Sm. Fl. Græc. Sibth. t. 427, unpublished. (A. Atcoson; Jacq. Hort. Vind. v. 3. 19. t. 32. Lycnis graecæ, bellidio folio verna, flore parvo dilute purpureascens; Tourn. Cor. 24.)—Downy, corymbosæ. Calyx cylindrical-club-shaped. Petals four-lobed; with a sharp two-lobed crest. Upper leaves ovate. Partial flalk as long as the capsule.—Native of the Levant, flowering in May. Annual, of the size and habit of the last, but the herbage is of a grassy-green, and finely hairy or downy, particularly the stem, the upper part of which is also viscid. Leaves broader, sometimes smooth in the diff., though rough-edged. Flowers crowded and level-topped. Calyx an inch long, downy, often red. Petals rose-coloured, four-lobed like the lip of Orchis militaris, having two rounded central segments, and two narrower sharp lateral ones. The lobes of their crest are awl-shaped. The crest is not well distinguished in Jacquin’s figure from the lateral lobes.

S. Armeria. Common, or Lobel’s, Catchfly. Linn. Sp. Pl. 601. Wild. n. 46. Fl. Brit. n. 10. Eng. Bot. t. 1398. Fl. Dan. t. 559. (Mucropulpa Lobeli; Ger. Em. 601.)—Smooth, corymbosæ. Calyx cylindrical-club-shaped. Petals emarginate; with a sharp two-lobed crest. Upper leaves heart-shaped. Partial flalk as long as the capsule. Found in fields, and on banks, in various parts of Europe, but a doubtful native of England, though frequently cultivated as a hardy ornamental annual, flowering in summer. Dr. Sibthorpe met with this species in Greece, and on mount Athos. In habit it agrees very much with the last, but is smooth, more glaucous, with broader leaves, and the calyx is not downy. The petals are simply obcordate, without lateral lobes. There is a brown glaucescent ring under each joint of the flalk, by which flies are caught.

S. italicæ. Italian Naked Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1006. Fl. Græc. t. 429, unpublished. Ait. n. 6. (Cucubalus italicæ; Linn. Sp. Pl. 593. Wildl. Sp. Pl. v. 2. 688. Jacq. Offb. fæce; A. 12. t. 97, not 79, as in Hort. Kew. and Wildl. now.)—Panicle corymbosæ, spreading, somewhat three-forked. Petals in two deep narrow segments, without a crest. Leaves spatulate, rough.—Native of Italy and Greece. Cultivated by Miller. The root is biennial. Herb green, roughish with short rigid hairs. Stem solitary, herbaceous, erect, twelve or eighteen inches high, leafy, somewhat branched above, but chiefly at the base, from whence it tends out several, decumbent, leafy, purplish, shoots, three or four inches long. Lower leaves forked, spatulate or ovate; with lanceolate; all thin and small, not fleshy. Panicle erect, rather slender, dirrivated, more or less downy. Calyx an inch long, finely swelling upward, with ten rough reddish ribs. Petals quite naked; their limb cloven nearly to the base, narrow, obtuse; white above; veined with purple underneath. Capsule ovate, on a long flalk within the calyx.

S. catholica. Panicled Naked Catchfly. Ait. n. 10. (Cucubalus catholicae; Linn. Sp. Pl. 593. Wildl. Sp. Pl. v. 2. 688. Jacq. Hort. Vind. v. 1. 23. t. 59.)—Panicle forked, much branched, widely spreading. Petals in two deep narrow segments, without a crest. Calyx obovate. Smooth. Leaves ovato-lanceolate, nearly smooth.—Native of Italy and Sicily. Mentioned in Cupani’s Hortus Catholicus, or Garden of the Prince of la Catholica, whence came the specific name; and not, as many suppose, from the plant being a native of Roman Catholic countries. The plant is perennial, of a tall slender habit, green, smooth, or slightly rough, with a large dirrivated panicule, of numerous, small, white flowers, whose calyx is one-third of an inch long, often purplish, obscurely ribbed. Stamens usually longer than the petals. Capsulae nearly globose, on a long flalk.

We are not quite satisfied respecting Vifcago latifolia non viscosa, herbeceæ flore; Dill. Elth. 425. t. 316. considered by Linnaeus as a variety of this, but it seems to be S. fistulosa, Ait. n. 28. Curt. Mag. t. 689.

with foot down.—Native of the sea-coast of Italy. Gathered by Dr. Sibthorp in Alia Minor, between Smyrna and Paphos. We regret that he had not time to have a drawing taken of this rare and curious species, of which there is not, to our knowledge, any figure extant. Rand mentions the plant as cultivated at Chelsea, in 1739, and Linnæus had it at Upsal. The stem is branched, somewhat shrubby. Whole herbage clothed with velvety pubescence. Leaves crowded, spatulate, an inch and a half long, acute, slightly revolute. Panicle denser, level-topped. Calyx club-shaped, ten-ribbed. Petals white or reddish; their limb irregularly heart-shaped. We find this plant mentioned in Mr. Donn’s Cambridge catalogue, as introduced in 1804. If it exilis in any garden, a figure ought to be published.

S. fruticosus. Shrubby Catchfly. Linn. Sp. Pl. 597. Wildl. t. 14. Ait. t. 26. Sm. Fl. Græc. Sibth. t. 428, unpublished. (Saponaria frutescens, acutis foliis, ex Sicilia; Bocc. Sic. 58. t. 30. Ocydoides fruticosum; Cramer. Hort. 109. t. 33, excell. — Panicle corymbose, close, somewhat three-lobed. Calyx club-shaped, rough. Petals clavên; cleft of four teeth. Stem shrubby. Leaves round-edged.—Native of rocky situations, near the sea, in Sicily and Cyprus. It is supposed, on the authority of Parkinson’s Paradiso 254. t. 10, to have been cultivated here in his time. The stem is woody, half an inch in diameter, with numerous tufted leafy branches, whose erect flowering extremities, about an inch long, are more densely furnished with smaller leaves, and are downy, vilvíd, and coloured in the upper part, each bearing a dense level-topped panicle, of ten or fifteen large flowers. Leaves recurved, spatulate, pointed, about an inch long, long-ovate, smooth, and thick; the edges only being rough with minute, reflexed, rigid hairs. Calyx above an inch long, ten-ribbed. Limb of each petal of a long, inerely heart-shaped, form; pink above; veined with green beneath; their crest white, of two acute, somewhat notched, principal segments, and two sharp teeth at the base. In the Prodr. Fl. Græc., the figure of this plant is, by mistake, referred to S. paradoxus, which will be corrected in the Flora itself.

Sec. 4. Stem panicled, scarcely forked.

S. rigida. Slender Rigid Catchfly. Sm. Prodr. Fl. Græc. Sibth. t. 1009. Fl. Græc. t. 439, unpublished.—Stem alternately branched, spreading. Petals in two deep sharpish lobes; each segment of their crest four-toothed. Leaves lanceolate, smooth.—Discovered by Dr. Sibthorp, on mount Hympetnus, near Athens. The stem is annual. Stem erect, a foot high, copiously branched from the very bottom, spreading, flender, purplish, vilvíd, but, like every other plant, of a dérit of pubescence. Leaves green, narrow, few and remote, about an inch long; the lowermost longer and broader. Petals pale pink, veined with cr monuments. Calyx club-shaped, pale green, with ten red ribs, smooth, not an inch long. Capsule ovate, shorter than its flake. A very pretty species, whose copious and delicate flowers would be an acquisition to our gardens.

S. spinifex. Thorny-branched Catchfly. Sm. Prodr. Fl. Græc. Sibth. t. 1010. Fl. Græc. t. 431, unpublished.—Stem shrubby, branches opposite, horizontal, becoming thorns. Petals deeply divided. Leaves spatulate, downy all over.—Found by Dr. Sibthorp in Aia Minor. The stem is thick and woody, very densely branched, leafy, downy, remarkable for its numerous, long, divergated, lateral shoots, which finally harden into spines. The flowering branches are erect, a span high, each bearing a raceme, downy panicles, of pale-green flowers, veined underneath with brown, and, to judge by their aspect, doubtless fragrant at night. Calyx about an inch long, green, downy. The crest of each petal consists of two small, rounded, white lobes. Capsule ovate, twice the length of its flake.

S. gigantea. Gigantic Catchfly. Linn. Sp. Pl. 598. Wildl. n. 17. Ait. n. 29. Sm. Fl. Græc. Sibth. t. 432. (Lychnis graeca, fæci arboreceentric follio et facie; Walch. Hort. 32. t. 11.)—Stem erect, downy, and vilvíd. Flowers tufted. Leaves spatulate, villous. Petals in two rounded lobes. Capsule nearly globular.—Native of Crete and the islands of the Archipelago; Linnæus by mistake says of Africa. It has long been noted in our more curious green-houses; and is esteemed for its sweet nocturnal perfume of its pale green flowers. The plant, though only a yard high, and of a shrubby aspect, is only biennial. Radical leaves two inches long, copious, of a broad flatulate figure, more or less villous, light green, obtuse, with or without a small point. Stem straight, vilvíd, leafy, with a few short branches, below; slightly branched above, but beget with denfe, whorl-like, downy panicles, of numerous flowers. Calyx three-quarters of an inch long, club-shaped, downy. Limb of the petals divided more than half way, into two broad rounded lobes, veined beneath with purple; their crest claven, very short. Capsule twice as long as its flake.

S. congesta. Tufted Green Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1012.—Stem somewhat branched. Panicles terminal, dense, many-flowered. Petals deeply divided, without a crest. Leaves flatulate, downy.—Gathered by Dr. Sibthorp in Greece; we believe on hills near Athens. The stem is woody, evidently perennial, bearing many tufts of copious, flatulate, obtuse, green flowers, an inch and a half long, clothed, like the rest of the herbage, with dense, very short, pubescence. Stem erect, from nine inches to two feet high, scarcely leafy, bearing a few alternate branches, somewhat vilvíd at the top, where each terminates in a dense tufted panicle of greenish flowers, whose calyx is half an inch long, obovate, or club-shaped, and whose petals are claven into two rounded lobes, without any crest. This species, of which we have no figure, is in some points allied to the last, but more akin, on the whole, to the following.

S. viridiflora. Panièled Green Catchfly. Linn. Sp. Pl. 597. Wildl. n. 19. Ait. n. 31. (Lychnis ocymaltri folio, flore viridi; Herm. Parad 199, with a plate.)—Stem branched. Panicles elongated, leafy, drooping, many-flowered. Petals divided half way; their crest of two linear lobes. Leaves elliptic-lanceolate, acute, downy. Native of Portugal and Spain. The root is said in Hort. Kew, to be biennial, though Hermann calls it perennial. Stem one and a half or two feet high, ending in a long leafy panicle of drooping green flowers. Leaves two or three inches long, rough, like the rest of the herbage, with extremely minute tubercles, and more or less of short hoary hairs. Flowers like the last, but somewhat larger, and furnished with a crown, of which we can perceive no traces in S. congesta.

S. nutans. Nottingham Catchfly. Linn. Sp. Pl. 596. Wildl. N. 11. Fl. Brit. n. 3. Eng. Bot. t. 465. Fl. Dan. 3. 242. (Lychnis sylvatica alba nona Clutib; Ger. Em. 470.)—Flower-flakes panicked, drooping one way. Petals in two or three linear segments; their crest of two acute lobes. Leaves lanceolate, downy.—Native of dry lime-stone pastures or rocks, in various parts of Europe, flowering in June and July. It was first, in this kingdom, observed at Nottingham castle, but grows also at Dover, and various
various other places. The root is perennial, rather woody. 

Stems several, herbaceous, erect, a foot or more in height, downy; leafy below; racemose, in the first instance, above, the flower-branches florid, turned to one side, downy and viscid, panicked, or imperfectly forked, each of three or four drooping white flowers, which expand in an evening. Calyx obovate, near three-quarters of an inch wide; ten-ribbed, slightly downy. The lowest leaves are spatulate, on long stalks.

S. paradoxa. Soap-wort Catchfly. Linn. Sp. Pl. 1673. Willd. n. 13. Jacc. Hort. Vind. v. 3. 45. t. 84. (Lychnis viscosa peregrina noctiflora odorata; Zanoni. It. t. 126. t. 50.) — Panicle racemose. Petals inerally heart-shaped; their crest of two acute lobes. Calyx downy Leaves obovato-lanceolate, smooth.—Native of the south of Europe. Miller cultivated it for the Dover Catchfly, so that it requires a place in the Hortus Kewensis, though erroneously admitted into Fl. Brit. 467, as is explained at 1307 of the same work. What the older botanists found at Dover, and which may be seen in Petiver's and Badder's collections in the British Museum, is still an undetermined plant. We greatly suspect, after all the confusion that has attended it, that this Dover Catchfly may be, as Mr. Hudson made it, the true Cusubulus viscosus of Linnaeus, (see our next species but one,) a Swedish Silene, for which Tournefort's Lyciun us orientalis maxima, buglossi folio undulato, figured in his Voyage, v. 2. 148, is erroneously quoted. Botanists of late have found nothing of the true S. paradoxa; but Silene mutabilis, varying in fize and hairiness. The true S. paradoxa is a nearly smooth plant, not very unlike Saponaria officinalis in flowers, but more slender in habit. The lower leaves are inclining to spatulate; the upper are linear-lanceolate. Calyx above an inch long, downy. Petals large, pale red.

S. filiformis. Long-smooth-flowered Catchfly. Ehrh. Beitr. v. 7. 144. Pl. Select. n. 75. Willd. n. 16. Ait. n. 27. " Walld. et Kitab. Hung. v. 1. t. 8." (S. juncea; Roth Catal. v. 1. 54. Lychnis prolonisia folis et calyce; Barrel. le. 63. t. 382.) — Panicle flender, racemose. Petals in two deep, rounded, divericated segments; their crest of two acute lobes. Leaves linear-lanceolate, smooth, as well as the slightly ribbed calyx.—Barrelier says this plant grows in dry rocky situations in Tuscany. There can be no doubt as to his synonym, though entirely overlooked by the German writers, who mention Hungary as the country of their plant. This is a tall, flender, elegant, perennial species, quite smooth, with a purpel tinge on the stem and calyx. The latter is above an inch long, flender, nearly cylindrical, with ten obolote ribs; its surface even and polished, without any pubesence. Claws of the petals longer than the calyx; their limb white, tinged externally with red. Leaves three or four inches long, half an inch broad, slightly glaucous; the radical ones numerous, on long stalks. This species bears a considerable affinity to S. paradoxa, but the long racemose panicles, and smooth even calyx, afford clear marks of distinction.

S. viscosa. Clammy Hairyl Catchfly. Ait. n. 3. (Cnema
calus viscosa; Linn. Sp. Pl. 592. Fl. Suec. ed. 2. 148. Willd. Sp. Pl. v. 2. 685. Lychnis montana viscosa noliftera hirta latifolia alba, floribus albo appendicibus; Till. Pl. 105?) — Panicle simply racemose, hairy. Flowers opposite, longer than their stalks, drooping every way, without a crest. Stem simple, leafy. Lower leaves lanceolate, even, nearly smooth; upper downy, viscid; dilated and reflexed at the base.—Native of Scania and Finland, where it was gathered by Linneus; and perhaps of Tuscany; as well as of our cliffs at Dover; for the last species but one. The Finland specimen, in the Linnaean herbarium, is a foot high, with a rather stout, round, unbranched stem, leafy throughout, most downy and viscid in the upper part. Linneus says the root is biennial. The three or four pair of lower leaves are two or three inches long, pointed, quite even and entire at the margin, nearly smooth, half or three-quarters of an inch wide; as many pair above them are gradually shorter, taper-pointed, even, feebly wavy, both their surfaces viscid and denibly downy, their base greatly dilated, ovate, or almost heart-shaped, clasping the stem. The solitary simple panicles, or rather clayer, about five inches long, consists of eight or ten pair of opposite solitary flowers, on short simple stalks, accompanied by small heart-shaped bracteas, altogether very hairy, and apparently viscid, as Linneus describes them. He says the flowers are white, fragrant at night, and do not turn to one side, but droop in all directions. Calyx hardly an inch long, cylindrical, hairy, pale, with ten green ribs. Petals in two rather deep, somewhat rounded, segments, without a crest. Catchfly ovate, on a shortish stalk. We do not understand why Linneus describes the stalks as three-flowered. We have no means of knowing whether this plant was cultivated by Miller in 1739; but by his having sent S. paradoxa to Linneus for the Dover Catchfly, it is most probable that neither our visciosa, nor Tournefort's species next described, was ever in the English gardens.

S. buglossifolia. Bugloss-leaved Catchfly. (Lychnis orientalis maxima, buglossi folio undulato; Tourn. Cor. 23. Voy. v. 2. 148, with a figure.) — Panicle simply racemose, hairy. Flowers opposite, much longer than their stalks, erect, without a crest. Stem simple, leafy. Leaves undulated, hairy; the upper ones lanceolate.—Gathered by Tournefort at the foot of mount Ararat, flowering in the middle of August. By his description the root should seem perennial, as being divided at the crown into several parts. Stems several, a yard high, straight, firm, hollow, leafy, hairy and clammy, four lines in diameter. Lower leaves about five inches long, and one broad, ovato-lanceolate, acute, wavy and crisped at the edges, hairy, with a strong midrib and many veins; upper gradually smaller and narrower; the bracteas linear-lanceolate, mostly equal in length to the calyx, which is cylindrical, an inch long. Petals white, cut half way down, or more, into two rounded lobes, and apparently detitute of a crest; but Tournefort leaves that important circumstance unnoticed, while he minutely describes the green germen, and white stylos. His plant, though referred by all authors to the preceding, is unquestionably distinct. We have compared specimens.

S. amoenis. Tartarian Catchfly. Linn. Sp. Pl. 596, excluding all the synonyms, except Hort. Upl. 11. n. 11. Willd. n. 12. Ait. n. 25. (S. precumanens; Murray Comm. Gotting. v. 7. 81. t. 2.) — Panicle turned one way; the branches somewhat forked, hairy. Petals eleven half way down; their crests converging. Stem decumbent, alternately branched. Leaves lanceolate, nearly firm, simple. Native of Tartary and Siberia. We doubt whether this species has ever been cultivated in England, the plant of Mr. Blackburne's catalogue, in 1779, having doubtless been our S. maritima, then universally taken for amoenis. The latter is a spreading, branching, leafy, perennial species, with green leaves, an inch or two long, of which the upper ones are minutely downy. The panicle is two or three inches long, dense, with leafy lanceolate bracteas. Calyx pale green, with ten purplish ribs, obovate, finely hairy, rather more than half an inch long. Petals white.

SILENE.

downy. Leaves ovato-lanceolate.—Found by Mr. Nuttal, growing wild, in great abundance, in the neighbourhood of St. Louis, on the Mississippi, North America, from whence seeds were communicated to A. B. Lambert, Esq. who raised this fine plant in his garden at Boyton, Wiltshire. The stem is two or three feet high, somewhat angular. *Herbage green, finely downy and viscid; at least in the upper part. Panicled racemose, partly forked, composed of about a dozen large flowers, conspicuous for the vivid scarlet of their long lanceolate petals, filaments, and styles. The calyx is above an inch in length, angular, ten-ribbed, slightly swelling upwards. The petals are said to be sometimes emarginate. We guess at their craft from the figure cited, which is not sufficiently explicit on this important point.

S. Nuttallii. Spanish Catchfly. Fl. Brit. n. 7. Ait. n. 12. Prodr. Fl. Græc. n. 1014. (Cucubalus Nuttallii; Linn. Sp. Pl. 594. Willd. Sp. Pl. v. 2. 688. Eng. Bot. t. 85. Fl. Dan. t. 518. Scrophulariaceae falaminicæ magnum; Ger. Em. 493.-Panicled erect, much branched, tufted. Flowers dioecious. Petals linear, undivided, without a crest. Leaves pubescent, rough.-Native of dry gravelly open pastures throughout Europe, flowering in July and August. In England it chiefly occurs in the elevated chapagne county of Cambridgeshire, Suffolk, and some parts of Norfolk, where its green panicles may easily be confounded with those of the accompanying grasses. The root is woody and perennial. *Stems erect, two feet high, slightly leafy, very viscid in the middle part of their upper joints. Leaves copious about the root, about an inch in length, on very long falks; in British specimæns they are pubescent, clothed with minute pubescence; in Greek ones obovate, with longer hairs. The whole plant indeed varies greatly as to luxuriance, but we cannot discern a specific difference. *Flowers small, with narrow pale yellow petals, and a purplish calyx. The *filaments are usuallly imperfect, or obliterated, in all the flowers of one root, and the *sepals in those of another; but occasionally both are perfect in the same. *Calyx ovate, hardly bigger than a grain of wheat, splitting into six teeth.

S. linifolia. Sickle-leaved Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1015. Fl. Græc. t. 433, unpublished.—Stems panicled at the top. Flowers erect. Petals in two deep rounded lobes; their crests two-lobed, blunt. Leaves linear-lanceolate, rough.—Found by Dr. Sibthorp on mount Parrnissus. The root is perennial, thick, woolly, yellowish within, much divided at the summit. *Stems numerous, about a foot high, erect, clove, leafy, roughish, quite simple, except in the flowering part, very viscid between several of the upper joints. *Leaves numerous, narrow, acute, above an inch long, minutely rough, of a glaucous green. *Flowers erect, in clove, irregular, tender panicles. *Calyx green, smooth, not quite an inch in length, ten-ribbed. *Limb of the petals flesh-coloured above; greenish, with purple veins, beneath. *Calyx on a stalk as long as itself. These flowers, and those of the following, are probably fragrant at night.

S. flatifolia. Thrift-leaved Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1016. Fl. Græc. t. 434, unpublished.—Panicled racemose, simple, clove. Flowers erect. Petals in two deep rounded lobes; their crests two-lobed, blunt. Leaves linear-lanceolate, acute, very smooth. *Calyx shorter than its stalk. *Gathered by Dr. Sibthorp in Greece.—The root appears to be perennial, and somewhat creeping. *Stems foliary, a foot high, slightly leafy, smooth, like every other part of the plant; the middle of its upper joint, below the inflorescence, viscid. Radical *leaves numerous, filiform, narrow, glaucous, two inches long, including the stalks. *Flowers few. *Calyx club-shaped, an inch and a quarter long, smooth, with ten purple ribs. Limb of the petals inflexed; white above; cinnamon-coloured beneath. *The stalk supporting all the parts of the flower, within the calyx, is remarkable for its length, which nearly equals the petals, and exceeds the ripe calyx.

Sect. 5. Stems single-flowered.

S. auriculata. Auricled Mountain Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1017. Fl. Græc. t. 435, unpublished.—Stems single-flowered. Leaves lanceolate, fringed. Calyx bell-shaped, downy. Petals cloven, auricled on each side at the base. *Gathered by Dr. Sibthorp, on the precipices of mount Delphi, in Necropont. The perennial root runs deep into the earth, and is crowned by numerous, dense, rose-like tufts, of grey, ovato-lanceolate, sharply-pointed leaves, an inch long; smooth above; their cartilaginous edges fringed with white hairs. *Stems foliary, erect, simple, downy and viscid, a finger's length, bearing two or three distant pairs of smaller leaves. *Flowers erect, the size of S. maritima. *Calyx swelling upwards; its veins and segments purplish. *Limbs of the petals deflexed, in two rather deep, oblong, rounded segments, furnished at the base with two very peculiar lateral appendages; their crest of two spreading lobes; their upper white, tipped with pale purple; the under reticulated with purple veins. *Calyx ovate, nearly thrice the length of its stalk.

S. Pumilio. Dwarf Mountain Catchfly or Campion. Wulf. in Jacq. Coll. v. 2. 126. t. 10. Jacq. Aufl. appendix. 26. t. 2. Willd. n. 55. (Cucubalus Pumilus; Linn. Mant. 71. Caryophyllus sylvaticus octavus; Clus. Hist. v. 1. 285. C. montanus Chiff.; Ger. Em. 593. Betonica coronaria; Bœh. Hist. v. 3. 337.)—Stems single-flowered. Radical leaves linear-lanceolate, smooth. *Calyx nearly cylindric, hairy. *Petals undivided; their crest bristle-shaped. —Native of the mountains of Carinthia, Moravia, and Italy, in a miscaceous soil. A very handsome species. The root is perennial, crowned with dense tufts of greyish, or thistle-like, rather fuscous leaves, about an inch long; among which are several, foliary, partly decumbent, simple *leaves, about twice that length, bearing a pair or two of smaller filiform leaves. The *flowers are very large in proportion, rose-coloured, and, according to Arduinio, who sent specimens to Linnaeus, very fragrant, though Clausius and Wulfen describe them as without scent. The *calyx is an inch long, slightly bell-shaped, reddish, duskycoloured with soft whitish hairs. Limb of the petals rounded, wavy, but not lobed; their crest, overlooked by Arduinio, of two erect slender crimson teeth, growing pale as the flower fades. *Germen nearly or quite seolate.

They all afford ornament and variety in the clumps and borders of pleasure-grounds.

**Silenus**, in *Ancient Geography*, a people of India, placed by Pliny in the vicinity of the river Indus.

**Silenus**, in *Antiquity*, a fort of heathen divinities, the same with fathys, which were called Silenus when they came to be advanced in age.

Yet was there one principal Silenus, elder than any of the rest. Diod. Siculus says, he was the master or tutor of Bacchus, whom he discipled nobly, and followed him to the wars. He quotes an ancient poet, named Thymactas, who relates, that the Sileni afflicted Bacchus in the war he waged against the Titans; adding, that the first Silenus reigned in an island made by the river Triton, in Lybia.

He is represented as having a long tail hanging behind, which is likewise an attribute of all his posterity. The poets always mount him on an ass, always drunk, and hardly able to support himself; "titubantem annique mereoque," as Ovid (Met. i. v.) speaks. Upon all the antiques that represent him, he has the air of a drunken man dozing over his wine; and when Virgil, in one of his Eclogues, describes him, it is like a man gorged with wine as usual:

"Inflatum hefterno venas ut femper faccho."

Ancient authors, however, who are very worthy of credit, express more favourable sentiments of him. Silenus, according to their account, was a profound philosopher, whose wisdom was equal to his knowledge; and the drunkennes so often mentioned was merely mythical, signifying that he was profoundly imbered in Speculation. Cicero, Plutarch, and many others, had formed the fame idea of Silenus, and always regarded him as a very ingenious man, and a great philosopher. Accordingly Virgil, in his second eclogue, puts into his mouth the principles of the Epicurean philosophy, about the formation of the world, and the beings that compose it:

"Namque canebat uti, &c."

Midas, hearing of the extraordinary talents of Silenus, wished for an opportunity of conversing with him. Silenus, who rambled about the country upon his ass, frequently repose near a fountain, which Midas supplied with wine; and here Midas found him, and treated him with great respect. In consequence of this intercourse, Midas availed himself of the counsels of Silenus, in founding his laws and religious ceremonies. See *Midas*.

A passage in Diogenes Laerius is laid to explain the fable of Silenus's riding on an ass: for in comparing Arif- totipole to Silenus, he says, the first was always on horseback, and the second rode upon an ass: the meaning of which is, that he made only flow, but bare, advances in philosophy; whereas the other moved at a quick pace, and now and then made a trip. The fable of the ass's ears, according to Tertullian (l. ii. de Anima), informs us, that he was endowed with great intelligence. Vossius (de Idol. l. ii.) explains that of the fountain of wine, by saying that it dignified only the desir the desire that Midas had to get Silenus into his possession, who, according to him, was king of Crete, and actually became a great friend to Silenus. He is represented as distinguished for his skill in music. He is said, not only to have invented musical instruments, but to have had the courage, like Marsyas, to challenge even Apollo himself to a trial of skill. Herodotus, speaking of Marsyas, calls him Silenus, l. vii. c. 26.

Nonius makes Silenus a son of Tellus; and gives him
three forts, Aetraeus, Maron, and Lenzus. Servius, on Virgil’s Eclogue, makes Silenus the son of Mercury; others, the son of Pan and a nymph; others will have him born of the drops of the blood of Cæsus, the father of Saturn.

Aelian (Var. Hist. l. iii. c. 12.) alleges that Silenus was born of a nymph, and that though he was not of the number of the gods, he was, however, of a nature superior to that of man. Silenus is said to have been born at Malea, or at least brought up there, according to the testimony of Pindar, who thus speaks: “Silenus, that incomparable dancer, when a citizen of Malea, the happy spouse of fair Naïs had the good fortune to educate.” Lucian describes Silenus as of a middle size, fat and plump; and thus he is represented upon medals, and other monuments now remaining.

Bochart, in his “Canaan,” will have Silenus to take his name from יכדר, or ידרכ, Silo, the name of the Messiah, whence ידבר, Silan. He also adds, that all that is attributed to this imaginary deity is taken from what the prophets have foretold of Jesus Christ. Thus, whereas it is said, the Messiah shall be the instructor of the people; Silenus is made the preceptor of Bacchus. Because it was said, that our Saviour should bind his shaft to the vine, and his colt to the young vine; Silenus is made to ride on an as. Because our Saviour washed his garments in blood, as tho’ that trod the wine-press; Silenus was made to preside over those who presided over the vintage. Because it is added, his eyes were red by reason of wine; Silenus was made always fuddled. Bochart, however, advances all this with a great deal of difficulty, as he has reason, it having no warrant. He adds, that the devil invented the fable of Silenus, to turn the mysteries of our religion into ridicule. But the fable which he has given to the words, rubet oculi ex vino, &c. denite ex late abhincunt, is very forced and unnatural; as if the words signified anything more, in the propriety of the Hebrew tongue, than, his eyes are redder than wine, his teeth whiter than milk. We may add, that nobody, before Bochart, neither Christian nor idolator, ever knew any thing of Jesus Christ in the fable of Silenus.

Silenus was worshipped after his death as a demigod, and received the honours due to heroes, independently even of Bacchus. Thus Paufanias speaks (in Elac.), who, mentioning the temple which Silenus had in Elis, expresses himself in these words: “There you will likewise see a temple of Silenus, but a temple which is appropriated and peculiar to himself, while Bacchus has no share in the honour of it.”

SILENTIARIUS, SILENTIARIS, an officer among the ancient Roman flaves; being, according to some authors, a slave placed over the rest, to prevent any noise and uproar, and to keep them silent.

Seneca, in his Epistles, mentioning the great care taken to keep the flaves mute, has given occasion to Lipius, Pomps, and some others, to suppose, that the silentiary was established in his time: but others, as Pignorius, think no such conclusion can be drawn from Seneca’s words; nor any thing, but that they were, even then, very severe in preventing any noise among the flaves. As to the name and office of the silentiary, it was not established till about the time of Sallian, who is the first author that mentions it.

There were also silentarii established in the emperor’s court, called quiets minifiris, and silentarii palati; and honoured with the farther titles of clarisimi, spectabilis, de- votissimi, and in Greek συνωστικοι, q. d. most admirable. There were a great number of these; but only thirty ordinarily officiated, who were divided into three bands, each of which had its decurio. The council of Chalcedon call the body of silentarii, σχῆλα δεστομίσθιον σελεντιαρίων.

SILENUS, in Botany, a Latin name in Virgil, supposed to belong to some flender kind of willow, or other. It is used vaguely, by the earlier botanists, for different umbel- liferous plants, and retained by Gartzner, after Rivanus, for Laspiptium trilobum and aquilegifolium, which tho’ writers place in a genus by themselves. Linnaeus uses the above word, as the specific appellation of another Laspiptrium. See that article.

SILESIA, Duchy of; in Geography, a country of Europe, bounded on the N. by the marquisate of Brandenburg, on the E. by the duchy of Wawlaw and Austrian Poland, on the S. by Hungary, from which it is separated by a chain of mountains, and a wilderness or thicket, about four miles broad, and on the W. by Moravia, Lusatia, and Bohemia. To the W. and S. Silesia is environed by a chain of hills, being with respect to extent and height some of the most remarkable in all Europe. (See Sudetic Chain.) For other mountains of Silesia, and their productions, see Prus sia. In the mountains of this province, and in that part of it that lies towards Moravia and Hungary, the winter is earlier and of longer continuance, and much more severe, than in the more level territories. During those months, in which at the foot of the Rieengebirge and the Gefenck every thing is covered with ice and snow, the trees at Breflau are in full verdure even in winter. The sandy parts of the principal of Glogau, and beyond the Oder, towards Poland, with the mountainous tracts, which are of considerable extent, produce but little, nor is their grain sufficient for the consumption of the inhabitants. But this deficiency is compensated, in favourable seasons, by the fertility of the other and larger part of Silesia, which, besides wheat, rye, barley, and oats, yields likewise maize or Turkey-wheat, flpt, buck-wheat, millet, linseed, peas, and beans. The culinary vegetables about Breflau, Brieg, Neiel, Frankenstein, and Lignitz, are excellent; and the vicinity of Grunberg and Lower Befthen affords plenty of fine fruits. Tho’ spots that are not fit for tillage afford good pastur grounds, or are covered with wood. Of flax there is abundance, but hemp in less plenty, which is supplied by importation from Hungary and Poland. Hops principally abound near Munfterberg. Madder forms one of the principal articles of export. A yellow dye, called febrar, is plentiful; nor is this country deficient in tobacco plantations; but its faffron is of an indifferent quality. The wine of the country is good, more especially after it has been kept for some years in the cellar. In the mountains and Upper Silesia, tar, pitch, and resin, are made from the pine and fir, and the larch-tree produces turpentine. From these resinous trees, and the trunks of the coarser pines, the inhabitants of the mountains make a lamp-black. Terra sigillata is found in many places, and particularly near Strigau; but it is used not as an article of the materia medica, but principally in the manufacture of earthenware. Cattle are reared merely for the plough, and for the necessarty supply of milk, butter, and cheese; but the markets are furnished, particularly with oxen, from Poland and Hungary. The most noted markets are those of Brieg, Breflau, and Schweidnitz. Although the fluids in this country afford many fine and stout horses, the number is not sufficient; and therefore, besides those that are purchased at Frankfort fair, great numbers are brought hither from Lithuania. The inhabitants of the hilly districts keep goats, and cheese in great quantity is made from their milk. The breed of sheep is considerable and
and lucrative, on account of the excellent quality of their wool. The wild beasts of this country, whose skins are valuable, are lynxes, foxes, weasels, otters, and beavers. The Oder furnishes salmon and sturgeon, flake, lampreys, &c. The other rivers, as well as the lakes and ponds, abound in various kinds of fish, such as pike, carp, trout, mullets, &c. Bees are bred for a supply of wax and honey, but their commodities are not in sufficient quantity to supersede the necessity of importation from Poland. Silk is in a state of increasing cultivation. The principal manufactures of Silefia are those of thread, twine, linen, flax, and damask. The chief exports are madder, mill-stones, thread, yarn, linen, wool, and woollen cloth, together with ruffs and paper. Under the dominion of the king of Prussia the commerce of Silefia has been considerably improved.

The prevalent religion in Silefia, as well as in Prussia, is the Protestant; and the bishoprics here, as well as in Poland, retain their ancient limits, while the power of the prelates is much abridged.

The manners and customs of the inhabitants of this province resemble those of their neighbours the Bohemians; but those of both these races have been so much melted down into that of the Germans, that the peculiar features are minute and unimportant. Silefia has some pretensions to literary fame. The capital of Silefia is Breetlau; besides which there are only three towns which contain more than 600 inhabitants, viz., Glogau, Hircheberg, and Schweidnitz.

For other particulars, see Prussia.

Silefia affords few materials for history. Its ancient inhabitants were the Lygii and Quadi; but about the middle of the sixth century, the Slavi having overrun the country of the latter, a part of it was annexed to Poland, and called “Zlezia.” Under the Polish sovereigns, Silefia received the Polish language, manners, and usages, with the Christian religion. After having been a Slavonic province of the Polish dominion, it was feized, in the 14th century, by John of Luxemburg, king of Bohemia (February, 1339), and passed with that sovereignty to the house of Austria. On the death of the emperor Charles VI. in 1740, Frederick II. king of Prussia, laid claim to the principalities of Lignitz, Briet, and Wohlaus; and his claims were so effectually supported by the march of an army into Silefia, that Maria Theresa, daughter and heiress of the emperor Charles VI., and queen of Hungary and Bohemia, by a preliminary treaty at Breetlau, which was soon followed by a ratification of the same at the peace of Berlin, did, on behalf of herself, her heirs and successors, of both sexes, for ever cede to the king of Prussia, and his heirs and successors, of both sexes, with entire sovereignty and independency of the crown of Bohemia, the countries of Upper and Lower Silefia, together with the district of Kaffel, formerly belonging to Moravia, as also the county of Glatz; reserving, however, to herself the principality of Troppau and Jagerdorf, beyond the Opons, the part of the principality of Neisse bordering on Moravia, and a small district belonging to Moravia, with some frontier towns. Silefia was never immediately connected with the empire, having at no time been an imperial fief, nor obtained a fast or vote in the diet. Neither has it been ever subject to the supreme tribunals of the empire; so that here the imperial laws are of no force. This event happened in 1742. The king of Prussia having obtained the greater part of this country with entire sovereignty, and absolutely independent of the crown of Bohemia, governs it accordingly, as a state absolutely free and divested of the least connection with the empire; but in the year 1751, the empire becoming a guarantee to his Prussian majesty for the secure possession of the duchy of Silefia, a proviso was made for its rights confidcntial to such an engagement. Ever since the close of the twelfth century, Silefia has been divided into the Upper and Lower, and this division is still in use. Lower Silefia contains thirteen principalities, the names of which are as follow: viz., Breetlau, Briet, Glogau, Janos, Lignitz, Munsterberg, Glatz, Neffe, Oels, Sagan, Schweidnitz, Wohlaus, Trachenberg, and Carolaath; the free fandeherrschafs or lordships of Wartenberg, Militch, and Goschutz; and many minderherrschafs or inferior lordships. To Upper Silefia belong the fix principalities of Trench, Troppau, Jagerdorf, Oppeln, Ratibor, and Blitza, the free fandeherrschafs of Pfeff and Beuthen, and certain minderherrschafs. At present under two sovereignties, the capital divisions must necessarily be into that of Prussian and Bohemian. Breetlau is the capital of Silefian Silefia. The regency of Bohemian Silefia is erected at Troppau. The whole country is said to contain 180 cities and towns, 4,000 villages, and 1,890,000 inhabitants.

For other accounts of the population, see Prussia.

SILESIACA TERRA. See Terra.

SILEX, Kieselerde, German, in Mineralogy, a species of earth which is generally found in a stony slate, and from its forming nearly the whole composition of flint, it has acquired the name of flax, or sileceous earth. It is found in equal or perhaps greater purity in rock-crysal and quartz, and in white sand; and it is probably an earth that most abounds on the globe. Most of the stony combinations of flax are remarkable for their hardness, and will very readily strike fire with flint. Silex, when pure, is white, and perfectly void of taste and smell; it is insoluble in water, and incapable of artificial crystallization. For its other properties, see Flint and Silica.

SILHET, in Geography, a circar of Hindoosfan, in the N.E. part of Bengal, bounded on the N. by Bootan, and on the E. by Meckley, and elsewhere by a part of Bengal. Also, a town of Hindoosfan, and capital of a circar, to which it gives name; 106 miles N.E. of Dacca. N. lat. 24° 52'. E. long. 91° 57'.

SILI, in Botany, a name given by the old Greeks to a plant called allo feschi.

SILJAN, in Geography, a town of Sweden, in Dalecarlia, on a lake to which it gives name; 25 miles N.W. of Falhub.

SILICA, in Ancient Geography, a town of Africa, in Interior Libya, near the river Bagradas. Potlemey.

SILICA, in Mineralogy, a species of earth, in Chemistry. In the former it is an earthy sublimate, existing abundantly in the composition of the globe, and forms a distinct genus of minerals in such as it predominates. In chemistry it was formerly considered as a simple body, under the clas of earths. In the present state of chemistry it is regarded as a metal combined with oxygen, and belongs to one of the most extensive clas of compounds in chemistry.

The minerals in which it is principally found are rock-crysal, quartz, agates, and flints. The first of these almost wholly consists of silica. In order, however, to obtain it in perfect purity, let the rock-crysal, or quartz, be heated red-hot, and then plunged into cold water. This has the effect of lessening its aggregation. To facilitate its reduction into powder, let one part of this powder be fused in a silver crucible, with three parts of pure potash. The fused mass will be found soluble in pure water. To the clear solution add any acid sufficient to saturate the alkali, but not more. A gelatinous precipitate will be found, which, when well washed, dried, and heated to ignition, in a silver crucible, will be pure silica.
It is a fine white powder, harsh to the touch, and defitute of taste or smell. Its specific gravity is 2.6. 

Silica is not acted upon by the air, nor changed by moisture. When strictly pure, no ordinary heat will fuse it. It does however put on appearances of fusion, when heated by the aid of a blowpipe and oxygen gas. It does not combine with oxygen, sulphur, phosphorus, carbon, or azote.

The two fixed alcalies do not affect it in the cold, but when fused with it in a silver crucible they combine, forming compounds, which have all the appearance of glases. Indeed, when the two bodies are in one proportion, they form the purest and most perfect glases. When the alkali is to the silica as three to one, the compound is soluble in water. This solution has been called the liquor of flints. Any of the acids are capable of combining with the alkali, and precipitating the silica in a state of purity, as we have before observed in the process of obtaining silica.

If an excess of acid be added to the solution, part of the silica is dissolved. This is more especially the case with the muriatic acid. A very dilute solution of silica in potash, in a vessel covered with paper, was left at rest by professor Seigling for eight years. Crystals of silica were found in the fluid, and the surface had a transparent crust upon it, strong enough to allow the vessel to be inverted without spilling the liquid. Some of the crystals were found to be pure silica, in groups of tetrahedral pyramids. There were also crystals of sulphate and carbonate of potash. The former were so hard as to strike fire with iron.

When fluoric acid is diffused from a glases vessel, or from any other substance containing silica, this acid assumes a complete gaseous form. The moment it is absorbed by water, a proportion of silica is precipitated. In this case, the gas which comes over is a compound of silica and the acid, which may be called flus of silica. The liquid acid is also found to hold silica in solution. It was from this solution, after standing two years, that Bergman obtained crystals of pure silica. They were of a cubic form, with three angles truncated. They were not so hard as rock-crystal.

The boracic and phosphoric acids have no action upon silica in the cold, but unite with it by fusion, forming transparent vitreous substances. Silica does not combine with any of the metals, but it combines with many of their oxides, forming compounds, which are called glases, enamels, or porcelains, according to their appearance.

With the oyx of lead it forms the glazing of common pottery; with oyx of iron, a dark green or black glas.

We have already spoken of its combination with the alcalies which belong to this class of compounds. When a solution of lime or barytes in water is added to a solution of fucited potash, or liquor of flint, these earths become precipitated, forming a peculiar compound. A similar combination takes place when a solution of silica in potash is added to a solution of alumine in the same alkali. Although the fulibility of silica is impracticable at the heat of our hottest furnaces, yet its combination with other earths is fucile, though at a very high temperature. Equal parts of lime and silica fuse into a mass between porcelain and enamel at 150° of Wedgewood. We hence see the use of lime in melting iron ores which abound with silica.

Silica appears to be the most abundant of the earths, forming the greatest proportion of the primitive rocks, and the basis of the terrestrial globe.

Although it has not been directly proved to be a metallic oyx, there is the most presumptive reason for thinking it so. From the small action which acids have upon it, compared with the other earths, sir Humphrey Davy at first supposed it to be an earth already combined with an acid, and made some attempts, by the aid of Galvanism, to verify this idea, but without success. He fused silica with iron by the Galvanic battery, and obtained a mass which afforded silica when dissolved by an acid with water. He also heated silica to whiteness, and on bringing potash in contact, a compound was formed of silica and potash, but a number of black particles were diffused through the mass, which sir Humphrey Davy thought were conductors of electricity. They did not act upon water; but when an acid was added, an effervescence took place. They also burnt in a strong heat, affording a white fubstance, which had the characters of silica.

Little is known of the proportions in which silica combines with other bodies. Davy gives its atom as forty-five times heavier than hydrogen; and sir Humphrey Davy states the number for silica at sixty-one, which, reduced to Davy's standard, would be 30.5. But neither of these is to be depended upon.

SILICEOUS, in Mineralogy, denotes composed principally of fucile.

SILICEOUS Schistus, in Mineralogy and Geology, the horn-flet or flate of some geologists; flinty flate of Jæsnon; a rock of the nature of flate, but containing a great portion of fucileous earth. It frequently occurs in beds in clay-flete, and sometimes forms entire mountains, which are either homogeneous or porphyritic, containing crystals of felspar, and forming porphyritic flinty flate. The colour confils of various shades of grey, but it is sometimes red, approaching the nature and colour of Jasper. It is generally traversed by veins of quartz, but rarely, if ever, contains metallic veins. It is extremely hard, and breaks with difficulty; the fragments are sharp-edged, and more or less translucent in minute portions. The Lydian flate, which is used as a tell, or touch-flete, for determining the purity of metals, is nearly allied to fucileous fchiftus. This rock paffes, by gradation, into clay-flete; and when the fucile predominates, into hornfeline or chert.

SILICEOUS Earth, in Agriculture, such as is constifuted of fucileous materials.

SILICEOUS Marble, that which is of a fandy or fucileous nature. See MARL.

SILICERNIUM, among the Romans, a funeral supper, which is otherwise called exceipum.

SILICATE, in Mineralogy, a term lately introduced by professor Berzelius, to denote the combination of flic with other earths or oxides, in which the flic is suppos'd to act as an acid. These substances he denominates fublicates. As this view of the action of flic tends to throw considerable light on various processes in the mineral kingdom, it is but justice to our own countryman, Mr. Hume, a respectable scientific and practicable chemist in London, to state, that fo early as 1805, he had, in Mr. Park's Chemical Catechism, alluded the action of flic as an acidifying principle, and subsequently in the Philosophical Magazine for 1808, he distinctly and percuriously defin'd various processes, both natural and artificial, in which flic performed the part of a acid; this he attributed to the great proportion of oxygen contained in it. As flic is by far the most abundant fubstance in the composition of the globe, either pure or in combination with the other earths, its peculiar properties, and the part which it performs in the successive changes that take place in the mineral kingdom, are a sub-
ject of much interest both to the geologist and the chemical philosopher. The similarity of its effects with those of oxygen and acids, have been pointed out in a very striking manner by Mr. Hume in the paper before referred to.

There is a remarkable similarity in the effects of oxygen and filex on the metals, particularly in that process called vitrification, which is, in every meaning of the word, a complete saturation and oxidation. By means of filex, all the metals (perhaps without exception), from being the most opaque bodies in the universe, may be rendered quite transparent, allowing an endless variety of the most charming tints. It is chiefly from metallic substances that the most durable colours are obtained, particularly for staining glases, and making artificial gems. The belt opaque colours, such as are most suitable for enamel, water, oil, crayon, and all other descriptions of painting, are derived also from the metals combined either with filex or oxygen. Even the precious stones, and the best valuable crystals and pebbles, with an infinite number of mineral productions, seem to derive their beauty and value from the action of filex on the metals. Thus, the opacity of lead is effectually changed by the sand or filex used in the composition of flint-glases, and the compound is rendered not less diaphanous than when, by means of oxygen, the same metal is dissolved in dilute nitric acids.

The power which filex exerts over potash and soda, and a variety of other substances which enter into the composition of glases, is a striking and well-known instance (says Mr. Hume) of its neutralizing efficacy; for no acid more completely abounds the acrimony of alkaline bodies, and disarms them of their corrosive character. The effervescence which results when filex and the alkali enter into fusion and form this tafteless compound, is not observable till the materials are on the point of perfect combination; hence, as something is apparently evolved, neither oxygen nor any other aërisfom fluid can be suppos'd to enter; so that the acidifying power (if the term may be applied) which appears to excite the alkaline matter, is alone due to the fand which is usually employed to form glases. Indeed vitrification seems, in all instances, to be accomplished by filex, or by oxygen, and the glases of lead, of antimony, of phosphorus, borac, or any other body, is due to the one, as much as the glases in common use is to the other of these oxygenating agents.

The power of filex, as an oxydizing, saturating, and neutralizing agent, is by no means confined to rocks, minerals, and the inanimate parts of created matter; but it pervades also, as an essential element, the structure of organized beings, and occupies a distinguished place both in the animal and vegetable economy. "Nothing is more astonishing," says Dr. Smith, "than the secretion of flinty earth by plants, a fact which is well ascertained." According to modern experiments, human hair, and probably the hair of all animals whatever, also contains filex as a constituent element.

From numberless phenomena that admit of no other interpretation, it may justly be inferred, says Mr. Hume, that nature poffefles means of converting filex into other forms, and of so interweaving it into the constitution of her varied works, that it ceases entirely to appear in its original state. Every thing connected with the progress of animal and vegetable exisfence, with the infernal secrets of the assimilating powers, or with the physiology of all organized matter, seems that transmutation is an operation which we cannot disprove, though we may not be able to trace it through all its steps.

According to Berzelius, filex, or silica, considered as an acid, poifefles the property of giving fliciates of many different degrees of saturation. The most general is that in which filex contains the same quantity of oxygen as the base; these he denominates simply fliciates. The next most general are those in which filex contains three times the oxygen of the base; these he calls trifliciates: it not unfrequently contains twice the oxygen of the base; these combinations he calls bifliciates. Silex also produces a great number of combinations with excess of base of different degrees, which he denominates subliciates, to which again he applies the appellations bi, tri; for example, bithalluminous subliciate, tri-silicium, &c. all announcing that the base contains twice or three times the oxygen of the filex.

Silex, like other acids, gives also double fliciates, partly with and partly without water of crystallization. We most frequently find, that the bases which have a tendency to produce double fliciates with other acids, do the same thing here: in the fame manner, as in the double fliciates, we again find (although with many exceptions) the same proportion between the bases as in the other previously known fliciates with double bases. Hence, for example, if in common felspar we could exchange filex for sulphur, the combination would be alumb without water.

But Nature in her rich flores, says Berzelius, exhibits a number of combinations of filex still more various, for which we have few if any analogous combinations to produce from the experiments in our laboratories. Thus we find fliciates from three to four bases, which all form one common combination, whose pure crysllalline structure seems to render it evident that it must be considered as one chemical whole; unless it should hereafter be proved that such bodies belong to the classes of crystals that are formed of many different substances lying in juxtaposition, but not chemically combined.

It often happens, also, that these numerous fliciates are not of the same degree of saturation, but that one or more of the weaker bases are subliciates, or fliciates, while one or more of the stronger are bi or tri-fliciates. That similar combinations are not formed in our laboratories, arises evidently from the rapid and violent means by which these combinations are effected, which will not admit the action or influence of those weaker affinities which take place in the secret and undisturbed recesses of the mineral kingdom. As it is of importance to ascertain the quantity of oxygen in flicex, in order to determine its proportions in the different combinations of fliciates, Berzelius, from various experiments made by himself and others, estimates the proportion of oxygen to be 49.64. See Silex.

SILICULA, in Botany, the diminutives of Silica, (see that article,) is a Pouch, or pod of a short, or rounded, figure, along both the edges of whose partition the seeds are inserted; witness the Draba verna, or Whitlow-grafts, so common on walls in the spring, and the Thlaspi Burfordi, Shepherd's purée. The partition is always really parallel to the valve, though the latter are often so protruberant, as in the Thlaspi, that their depth is much greater than the real diameter of the fruit. Hence Linnaeus has fallen into an error, first detected by Mr. Brown, in the character of Subularia. See that article.

SILICULOSA, the first of the two orders of the 15th class in the Linnaean system, Tetradynamia, (see that article,) the character of which confines it in the short, or rounded, not oblong, form of the seed-velvet. See Stillicula.

SILIFREY, in Geography, a town of Africa, in the kingdom of Barra.

SILILICON, in Botany, a name given by some of the old
old Latin writers to the carob tree, *siliqua dulcis*. The Latins borrowed this name from the Greek *xyloglycon*, *ξυλογλυκον*, the sweet, or sweet-fruit tree.

Ibidore mispells the word *siliqua*, and making it only *sili-
con*, supposes it to be a barbarous way of spelling the word *siliqua*; but the evident derivation of the genuine word from the Greek, shews his error both as to the word itself, and the origin of it.

**SILIN** or **Abu Ait**, in Geography, a town of Egypt; 12 miles S.S.E. of Siut.

**SILINDIUM**, in Ancient Geography, a small town of Achaia Minor, in the Troadze, near mount Ida.

**SI-LING**, in Geography, a town of China, of the third rank, in Quang-ki; 20 miles S. of Si-long.

**SILINO**, a small island among the Philippines, near the north coast of Mindanao. N. lat. 9° 2'. E. long. 121° 40'.

**SILINUS**, in Ancient Geography, a river of the Peloponnesus, in the Elide, which watered the territory of the Scyllunte, according to Pausanias.

**SILIPICA**, in Geography, a town of South America, in the province of Cordova; 20 miles S. of St. Jago del Etero.

**SILIGUA, siliqua**, among the ancients, the third part of an obulus, or, what comes to the same, the fifth part of a drachm.

**SILIGUA Nabatea**. See Nabathæa Siligua.

**SILIGUA, siliga**, in Botany, a Pod, a foot of Pericarp.

(See that article.) The *Siliqua* is a solitary seed-velvel, of an elongated form, and dry substance, consisting of two parallel valves, separated by a parallel linear partition, or receptacle, along each of whose edges the seeds are ranged in alternate order. Examples are found in the Cruciferae, such as *Cicerarthus*, the Stock or Wall-flower; *as also in* Chelidonium, the Celandine; and Bignonia echinata, Gurt. t. 52. f. 1. This kind of seed-velvel differs from a Legume, (see that article,) in having the seeds inserted along each of its margins.

**SILIGUA.** See *Carob*.

**SILIGUASTRUM**, the appellation of the Judas-tree in Tourniére and preceding authors, alluding to its partial resemblance to the fruit of the Carob, which was called *Siliqua*, the Pod, by way of eminence. See Ceratonia and Ceris.

**SILIGUASTRUM**, in Natural History, the name given by Mr. Lluyd, and others, to the bony plate of fishes, when found fossil. See Ichthyopsia.

**SILIGUATICUM**, among the Romans, a custom or toll paid for merchandise. This the Greeks called *ceratifinos*.

**SILIGUOSA**, in Botany, the second order of the Linnaean 15th clafs, Tetradynamia; which is order is characterized by the oblong form of the seed-velvel. See Siliqua and Siliquia.

**SILIGUOSÆ**, the 39th natural order, among the fragments of Linnaeus, exactly analogous to the Cruciferae of Jussieu. See that article, as well as, hereafter, Tetradynamia.

**SILIS**, in Ancient Geography, a river of Italy, in Venetia, which had its source in mountains called Tanri-

**SILISTENI**, in Geography, a town of Moldavia; 10 miles S.W. of Huf.

**SILISTRIA.** See Dristra.

**SILIVRIA, or Killeeveh**, a large and populous town on the sea of Marmora, once well fortified, and still in part surrounded by a strong wall. Some of its houses and minarets are very handsome buildings. The lower part of the town is washed by the sea. Its bay is capable of accommodating a considerable number of vessels, and is so well sheltered by the high land on each side of it, that ships may, in any weather, ride in safety.

**SILLIUS ITALICUS, CAIUS**, in Biography, an Italian poet, was born about the year 15 of the Christian era. He has been supposed to have been a native of Latina in Spain; but his not being claimed as a fellow countryman by Martial, who has bestowed upon him the highest praises, renders the supposition improbable. It is certain that he lived chiefly in Italy, in which he pleased several emperors. The knowledge of him come down to these times is derived from a letter of Pliny the Younger to Caninius Rufus, announcing his death. From this it appears that he incurred some reproach in the reign of Nero, as having been forward in accusations, and that he was conful at the time of the tyrant's death; that he made a discreet and humane use of the friendship of Vitellius; and that having acquired much honour, from his conduct in the proconfulate of Afia, he thenceforth withdrew from public offices, and maintained the rank of the principal persons of the city without power, and without envy. It appears, likewise, that he passed his time chiefly in literary conversations, and in composing verses, which he sometimes recited in public. He had great taste for elegance, and purchased a number of villas, which, after enjoying a time, he deferted for new ones. He collected a number of statues, books, and curiosities, to some of the latter of which he paid a kind of religious veneration. This was particularly the case with respect to that of Virgil, whose birth-day he kept with much more ceremony than his own, and whose tomb was included in one of his villas. He is said also to have possessed a villa that had been Ci-
cero's. In his latter years he retired altogether to his seat in Campania, which he did not quit upon any account; and the general tide of his prosperity did not cease to flow, except in the infancy of the death of the younger of his two sons, which was in some degree compensated by the consular dignity of the elder. In his 75th year he was attacked with an incurable ulcer, and he is said to have put an end to his life, by abstaining from food.

The work of Silius, which has come down to the present time, is an epic poem on the second Punic war. In this he scarcely deviates from Livy, in the narration of transactions; but occasionally introduces a machinery, copied from Virgil, of whose style and manner he is an imitator. Pliny says, that "he writes with more diligence than genius." The best editions of this work are those of Drakenborch, 1717; and of Lefebvre de Villebrune, 4 vols. 12mo. 1782. 4

**SILK, SERICUM**, a very soft, fine, bright, delicate thread; the work of an insect, called *bombyx*, or the silk-
worm.

The ancients were but little acquainted with the use and manufacture of silk; they took it for the work of a fort of spider, or beetle, which spun it out of its entrails, and wound it with its feet about the little branches of trees. This in-
sect they called *ser*, from *seres*, a people in Scythia, whom we now call the Chinees, who, as they thought, bred it; whence the silk itself they called *sericum*. But this *ser* of theirs has very little affinity with our silk-worm, *bombyx*; the former living five years; but the latter dying annually, enveloped in a yellowish bag or ball, which, wound out into little threads, makes what we call silk.

It was in the isle of Cos that the art of manufacturing it was first invented; and Pamphila, daughter of Platis, is honoured as the inventor. The discovery was not long unknown.
unknown to the Romans. Silk was brought them from Serica, where the worm was a native. But so far were they from profiting by the discovery, that they could not be induced to believe so fine a thread should be the work of a worm; and thereupon formed a thousand chimerical conjectures of their own.

Silk was a very scarce commodity among them for many ages: it was even sold weight for weight with gold; info-much that Vopiscus tells us, the emperor Aurelian, who died A.D. 275, refused the empress, his wife, a suit of silk, which the solicited of him with much earnestness, merely on account of its dearness.

Others, however, with greater probability, assert that it was known at Rome so early as the reign of Tiberius, about A.D. 17.

Calen, who lived about the year of our Lord 173, speaks of the rarity of silk, being no where but at Rome, and only among the rich.

Heliodorus, the emperor, who died A.D. 229, is said by some to be the first person who wore a holofernicum, i.e., a garment of all silk.

The Greeks of Alexander the Great's army are said to have been the first who brought wrought silk from Perseus into Greece, about 323 years before Christ; but the manufacture of it was confined to Berytus and Tyre, in Phoenicia, whence it was dispersed over the West.

At length, two monks, coming from the Indies to Constantinople, in 555, under the encouragement of the emperor Julianus, brought with them great quantities of filk-worms, with instructions for the hatching of their eggs, rearing and feeding the worms, and drawing out the silk, and spinning and working it. Upon this, manufactures were set up at Athens, Thebais, and Corinth. The Venetians, soon after this time, commencing a commerce with the Greek empire, supplied all the western parts of Europe with silks for many centuries; though sundry kinds of modern silk manufactures were unknown in those times, such as damasks, velvets, lattins, &c.

About the year 1130, Roger II. king of Sicily, established a silk manufactory at Palermo, and another in Calabria; managed by workmen, who were a part of the plunder brought from Athens, Corinth, &c. of which that prince made a conquest in his expedition to the Holy Land. By degrees, Messeray adds, the rest of Italy and Spain learned, from the Sicilians and Calabrians, the management of the silk-worms, and the working of silk; and at length the French got it by right of neighbourhood, a little before the reign of Francis I., and began to imitate them. Thus was, indeed, in contradiction to most other writers, makes this manufacture of silk to be introduced into Sicily two hundred years later, by Robert the Wise, king of Sicily, and count of Provence.

It appears by 33 Hen. VI. cap. 5, that there was a company of silk-workers in England so early as the year 1455; but these were probably employed in needle-work of silk and thread: and we find that various sorts of small haberdashery of silk were manufactured here in 1482; but Italy supplied England, and all other parts, with the broad manufacture, till the year 1489. In Spain, indeed, the culture and manufacture of silk seem to have been introduced in an early period by the Moors, particularly in Murcia, Cordova, and Granada. The silk manufactures of this latter town were very flourishing, when it was taken by Ferdinand, &c. at the close of the fifteenth century.

In 1521, the French, being supplied with workmen from Milan, commenced a silk manufacture; but it was long after this time before they could obtain raw silk from the Vol. XXXII.

worns; and even in the year 1547, silk was scarce and dear in France; and Henry II. it is said to have been the first who wore a pair of silk knit stockings; though the first invention originally came from Spain, whence silk stockings were brought over to Henry VIII. and Edward VI. After the civil wars in France, the plantations of mulberry-trees were greatly encouraged by Henry IV. and his successors; and the produce of silk is at this day very considerable.

The great advantage which the new manufacture afforded, made our king James I. very earnest for its being introduced into England: accordingly it was recommended several times from the throne, and in the most earnest terms, particularly in the year 1618, to plant mulberry-trees, &c. for the propagation of silk-worms; but unhappily without effect; though from the various experiments we meet with in the Philosophical Transactions, and other places, it appears that the silk-worm thrives and works as well, in all respects, in England, as in any other part of Europe.

However, towards the latter end of this king's reign, i.e., about the year 1620, the broad silk manufacture was introduced into this country, and profecuted with great vigour and advantage. In 1629, the silk manufacture was become so considerable in London, that the silk-throwers of the city, and parts adjacent, were incorporated under the name of master, wardens, &c. of the silk-throwers; and in 1661, this company of silk-throwers employed above forty thousand persons. The revocation of the edict of Nantes, in 1685, contributed in a great degree to promote the silk manufacture in this kingdom; as did also the invention of the silk-throwing machine at Derby, in 1719; for an account of which, see SILK, Manufacture of.

So high in reputation was the English silk manufacture, that even in Italy, as Keyler (Travel, vol. i. p. 280.) informs us, in 1730, the English silks bore a higher price than the Italian.

The silk-worm is an insect not more remarkable for the precious matter it furnishes for divers fluffs, than for the many forms it affumes, before and after its being enveloped in the rich cod or ball which it weaves for itself. From a small egg, about the size of a pin's head, which is its first state, it becomes a pretty big worm, or caterpillar, of a whitish colour, inclining to yellow. In this state it feeds on mulberry-leaves, till, being come to maturity, it winds itself up in a silken bag, or case, about the size and shape of a pigeon's egg; and becomes metamorphosed into an aurelia: in this state it remains without any signs of life, or motion; till at length it awakes to become a butterfly, after making itself a paelage out of its silken pseulchre; and, at last, dying indeed, it prepares itself, by an egg which it calls, for a new life; which the warmth of the summer weather affilts it in refuming.

As soon as the silk-worm, or caterpillar, is arrived at the fize and strength necessary for beginning its cod, he makes his web; for it is thus they call that flight tissiz, which is the begining and ground of this admirable work. This is his first day's employment. On the second, he forms his folliculus, or ball, and covers himself almost over with silk. The third day, he is quite hid; and the following days he employs himself in thickening and strengthening his ball; always working from one single end, which he never breaks by his own fault; and which is to fine, and to long, that those who have examined it attentively, think they speak within compass, when they affirm that each ball contains silk enough to reach the length of six English miles.

In ten days' time, the ball is in its perfection; and it is now to be taken down from the branches of the mulberry-trees, where the worms have hung it. But this business requires
requires a great deal of attention; for there are some worms more lazy than others; and it is very dangerous waiting till they make themselves a passage, which usually happens about the fifteenth day.

The first, finest, and strongest balls are kept for the breed; the rest are carefully wound. If there be no more than can be well wound at once, they lay them for some time in an oven, moderately hot, or else expose them, for several days successively, to the greatest heats of the sun, in order to kill the insects; which, without this precaution, would not fail to open itself a way to go and use those new wings abroad, which it has acquired within. Ordinarily, they only wind the more perfect balls. Those that are double, or too weak, or too coarse, are laid aside; not as altogether useless, but that, being improper for winding, they are referred to be drawn out into fleins. The balls are of different colours; the most common are yellow, orange-colour, isabella, or flesh-colour. There are some also of a sea-green, others of a sulphur-colour, and others white; but there is no necessity for separating the colours and shades, to wind them apart, as all these colours are to be lost in the future scouring and preparing of the filk.

Silk. Manufacture of. In England, where filk is not produced in any quantities to be employed by the manufacturer, he must commence his operations upon the raw filk, with no other preparation than that of being wound off into fleins or hanks from the balls, or cocoons, which the filk-worms form.

In this state the filk is imported from those countries where it is produced, as Italy, Flanders, Spain, Portugal, Turkey, the East Indies, and China. A thread of this raw filk, drawn from the flein, is found to be composed of an assemblage of several of the fine fibres or threads produced by the worms; the fibres being united together by a natural gum, which is in the filk, and which is soluble in the hot water in which the cocoons are immerged when the filk is wound off.

To prepare this raw filk for use, it is wound from the fleins upon bobbins; the compound thread is then twilled, to unite the constituent fibres more firmly than they can be by the gum alone; and afterwards, being wound again upon fresh bobbins, two or three threads are twisted together to produce a stronger thread, fit for the weaver, who warps and finally weaves the filk into various articles of ornaments or utility, by processes very similar to the weaving of cotton or linen, but more delicately conducted.

In the countries where the filk is produced, the manufacturer is more properly said to commence with the operation of winding or reeling off the threads into fleins from the cocoons, or balls, in which the worms envelop themselves. These balls become an article of trade, as soon as the insects within them is killed by exposing them to heat, either of the fun, or in an oven, or by the steam of boiling water; and, in general, the breeders of filk-worms sell them, in this state, to persons who make a business of the operation of winding. In Piedmont, where capital filk is produced, it is conducted, as follows, by the aid of the filk reel represented in Plate Silk Manufactures, fig. 1.

The balls are thrown into hot water, contained in a copper basin or boiler, A, which is about eighteen inches in length and six deep, let in brick-work, so as to admit a small charcoal fire beneath it; or if a fire of wood is intended to be made, the fire-place must have a small flue or chimney of iron plate to carry off the smoke. At the side of the boiler is placed the reel, which is very simple. B B marks the wood-framing which fulfils its parts: there are, the reel D, upon which the filk is wound; the layer a, which directs the thread upon it; and the wheel-work c e, which gives motion to the layer. The reel, D, is nothing more than a wooden spindle, turned by a handle at the end; and within the frame, at each end, it has four arms mortised into it, to support the four battens or rails on which the filk is wound. The rails are parallel to the axis, and at such a distance, that they will form a proper-sized flein by the winding of the filk upon them. (It is usually a yard for each revolution.) One of each of the four arms is made to fold in the middle of its length with hinges, so as to cause the rail, which these two arms support, to fall in or approach the centre, and thus diminish the size of the reel, and admit the fleins of filk to be taken off at the end of the reel when the winding is finished.

Upon the end of the wooden spindle of the reel, and within the frame B, is a wheel of twenty-two teeth, to give motion to another wheel, c, which has about twice the number of teeth, and is fixed upon the end of an inclined axis, c b; this, at the opposite end, carries a wheel, b, of twenty-two teeth, which gives motion to an horizontal cog-wheel of thirty-five teeth. This wheel turns upon a pivot fixed in the frame, and has a pin fixed in it, at a distance from the centre, to form an eccentric pin or crank, and give a backward and forward motion to the flight wooden rail or layer a, which guides the threads upon the reel: for this purpose, the threads are passed through wire-loops or eyes, a, fixed into the layer, and the end thereof opposite the wheel and crank, b, is supported in a mortise or opening made in the frame, B, so that the revolution of the crank will cause the layer to move, and carry the threads alternately towards the right or left. There is likewise an iron bar, e, fixed over the centre of the boiler at e, and pierced with two holes, through which the threads pass to guide them.

To describe the operation of reeling, it should be understood, that if the thread of each ball or cocoon was reeled separately, it would be totally unfit for the purposes of the manufacturer; in the reeling, therefore, the ends or threads of several cocoons are joined, and reeled together out of warm water, which softens their natural gum, and makes the fibres stick together, so as to form one strong smooth thread; and as often as the thread of any single cocoon breaks or comes to an end, there is supplied by a new one, so that by continually keeping up the same number, the united thread may be wound to any length. The single threads of the newly added cocoons are not joined by any tie, but simply laid on the compound thread, to which they will adhere by their gum; and their ends are so fine, as to not occasion the least perceptible unevenness in the place on which they are laid.

The woman who conducts the reeling is seated before the basin A, and employs a boy or girl to turn the handle of the reel: a fire is lighted beneath the basin A; and when the water becomes nearly boiling hot, she throws into the basin two or three handfuls of cocoons, and leaves them some minutes, to soften that natural gum with which the filk is impregnated: then she flits up or brushes the cocoons with a wiff of birch or of rice-straw, about six inches long, cut flumpy, like a worn-out broom; the loofe threads of the cocoon stick to the wiff, and are drawn out: the then diverges these threads from the wiff, and, by drawing the ends through her fingers, cleans them from that loose filk which always surrouns the cocoon, till they come off entirely clean: this operation is called la battue: and when the threads are quite clean, she piles four or more of them, if she intends to wind fine filk, through each of the holes in the thin iron
iron bar, which is placed horizontally over the centre of the basin A; afterwards she twists the two compound threads (which consist of four cocoons each) twenty or twenty-five times round each other, that the four ends in each thread may the better join together by crossing each other, and that the thread of the filk may be round, which otherwise would be flat.

The threads, after passing through the holes in the iron bar, and being twisted together, are passed through the eyes of the loops, a, of the layer, and thence being conducted to the reel, are made fast to one of its rails. The child who turns the reel, gives it the most rapid movement possible, and thus draws off the threads from the cocoons in the basin A. The flow traversing motion of the layer prevents the threads lying over each other upon the reel, until it has made so many revolutions in the air as to dry the gum of the filk so far, that the threads will not adhere together. After the reel is covered for about the breadth of three inches, by the gradual propagation of the layer, it returns and directs a second course of threads over the first laid, and so on until the required length for the filks is obtained. The machine winds two filks at one time. As it is essential to the production of good filk, that the thread should have lost part of its heat and gumminess before it touches the bars of the reel, the Piedmontese are by law obliged to have a distance of thirty-eight French inches between the guides, a, and the centre of the reel; and the layer must also, under a penalty, be moved by cog-wheels instead of an endless cord, which is sometimes used in Italy, and which, if suffered to grow slack, will cause the layer to float and not lay the threads distinctly, and that part of the filk will be glued together, whereas the cog-wheels cannot fail.

When the filks are quite dry the reel is removed from the frame, and by the folding of two of its arms the filks are taken off. A tie is made with some of the refuse filk on that part of each filk where it bore upon the bars of the reel, and another tie on the opposite part of the filk; after which it is doubled into a hank, and usually tied round near each extremity, when it is laid by for use or sale.

This operation appears very simple, but to produce a good thread requires much attention. The reeler must not wait until the thread of a cocoon is entirely exhausted before he joins on another, because the threads near the end have not above a quarter of their full thickness. The cocoons produce a very unequal length; some may be with which yield 1200 ells, whilst others will scarcely afford 200 ells. In general, the production of a cocoon may be estimated from 500 to 600 ells in length. As often as the cocoons the winds are exhausted, or break, or only diminish, the joins fresh ones to keep up the requisite number, or the proportion; because, as the cocoons wind off, and the thread becomes finer, the must join two cocoons half wound to replace a new one. Thus she can wind three new ones and two half wound, and the filk will be equal to that produced from four to five cocoons. When she would join a fresh thread she must lay one end on her finger, throw it lightly on the other threads which are winding, and the gum will join it immediately, and it will continue to go up with the reel. She must not wind off her cocoons to the last, because when they are near at an end the bulk of the worm joins in with the other threads, and makes the filk foul and gouty. The filk may be wound of any size from one cocoon to 100, but it is difficult to wind more than thirty in a thread.

The nicety of the operation, and that part in which lies the greatest difficulty, is to wind an even thread, because as the cocoon winds off the end is finer, and other cocoons must be joined on to keep up the same size. This difficulty of keeping the filk always even is so great, that (excepting a thread of two cocoons, which is called such) they do not lay a filk of three, four, or six cocoons; but a filk of three to four, four to five, or six to seven cocoons. In a coarser filk it cannot be calculated even so nearly as to four cocoons more or less; they say, for example, from 12 to 15, from 15 to 20, and so on.

During the operation of winding, the woman must always have a bowl of cold water by her, to dip her fingers in, and to sprinkle frequently upon the iron bar, so that the heat of the basin may not burn the threads, also to cool her fingers every time she dips them in the hot water, and to pour into the basin when necessary, that is, when the water begins to boil. The water must be just in a proper degree of heat; for when it is too hot, the thread is dead, and has no body; and when too cold, which form the thread do not join well, and form a harsh filk. The heat of the water from which the cocoons are wound, causes that adhesion of the fibres which compose the filk: a thread can with difficulty be wound off when cold water is employed; but in this manner the adhesion is very slight, and the thread breaks with a flighty force, or the least moisture will separate the fibres; but the filk wound from hot water cannot be separated except by hot water.

The old cocoons require the water to be very hot: if the threads break very frequently, it may be concluded that the water is too cold; or, on the other hand, if the filk comes off entangled, and in the State of wool, the water is too hot. When the first parcel of cocoons is finished, the basin, A, is cleaned, taking out all the stripped worms, as well as the cocoons, on which there remains a little filk: these are thrown into a basket, into which the loose filk that comes off in making the battue is likewise put as waste filk, to be carded and spun into threads. The water in the basin must be changed four times a day for coarse filk, and twice only for good cocoons of fine filk; if the water is not changed, the filk will not be so bright and glossy, because the worms contained in the cocoons foul it very considerably. The reeler must endeavour to wind as much as possible with clear water, for if there are too many worms in it, the filk will be covered with a kind of dust, which afterwards attracts moths, which destroys the filk.

From the gummy or viscid material which filk gives out to water when the cocoons are infused in it, Chappe found that he was able to blow up the water into bubbles, or small balloons, far more permanent than those of soap or water, and offering all the colours of the rainbow. So close, indeed, is the texture of these filthy bladders, that even the most subtle gas does not penetrate them. Chappe filled many of them, the diameter of each not exceeding three inches, with hydrogen gas, and found several of them continued in a state of suspension, in an apartment, for considerably more than twenty-four hours. It is not all filk, however, that is sufficiently glutinous for this purpose; which that which is of a very deep yellow will not answer the same purpose. This filk, from its colour, is supposed to be produced by the worm in a peculiar diastase, yet this is a fact by no means uncommon.

All kind of filk which is simply drawn from the cocoons by the reeling, is called raw filk, but is denominated fine or coarse according to the number of fibres of which the thread is composed. In general, the raw filk requires dyeing; to prepare for which the thread is very slightly twisted, to render it strong, and more able to bear the action of the hot liquor, without separating the fibres or furring up. Silk-yarn, which is employed by the weavers for the woof or weft of the stuffs which they fabricate, is compos'd of

4 X 2

two
two or more threads of the raw silk, slightly twitted in a machine; and the thread employed by the flocking weaver is of the same quality, but composed of a greater number of threads, according to the thickness desired. Organzine silk is composed of two, three, or four threads of raw silk twitted, and so combined as to obtain the greatest strength: for this purpose, each thread of raw silk is twitted separately upon itself by a mill; the twit is given in a right-handed direction, and extremely tight. By a second operation of twitting, two of these threads are combined together, the twit being given in a contrary direction, and not above half as tight: this forms a thread similar to a rope. This description of silk, used for the warp of stuffs, is of the utmost importance to the manufacturer, for none of the principal articles can be fabricated without it. The Italians, from whom we formerly imported the silk in the flate of organzine, for a long time kept the art of throwing it a profound secret. It was introduced into this country by the enterprize and skill of Meffrs. Thomas and John Lombe, the latter having, at the risk of his life, and with wonderful ingenuity, taken a plan of one of these complicated machines in the king of Sardinia's dominions, from which, on his return, they established a flate of silk mills in the town of Derby. (See Derby.) In consideration of the great hazard and expense attending the undertaking, a patent was granted to Sir Thomas Lombe in 1718, for securing to him the privilege of working organzine for the term of fourteen years; but the construction of buildings and engines, and the instruction of the workmen, took up so much time, that the fourteen years were nearly expired before he could derive any advantage from it; in consequence of which, he petitioned parliament, in 1731, to grant him a further term; but parliament, considering it an object of national importance, granted him the sum of £1,000 on condition that he should allow a perfect model of the machinery to be taken, and deposited in the Tower of London for public inspection. Similar mills were, in course of time, erected in different parts of the country; but owing to the difficulties that were experienced in procuring raw Italian silk of the proper size for organzine (the exportation of which was prohibited by the Italians), and to the mills having subsequently found employment for other purposes, the quantities worked into organzine, for many years, bore scarcely any proportion to the imports from Italy; it has however been since revived and improved, in consequence of which it is now carried on to a very considerable extent, as well in other parts of England as at Derby.

The process which the silk undergoes to bring it into this flate, consists of six different operations. 1. The silk is wound from the feet upon bobbins in the winding machines. 2. It is then twitted into different qualities. 3. It is spun or twitted on a mill in the single thread, the twit being in the direction of from right to left, and very tight. 4. Two or more threads thus spun are doubled or drawn together through the fingers of a woman, who, at the same time, cleans them, by taking out the flubs which may have been left in the flake by the negligence of the foreign worker. 5. It is then thrown by a mill, that is, the two threads are twitted together, either flack or hard, as the manufacturer may require; but the twit is in an opposite direction to the first twit, and it is wound at the same time in feet upon a reel. 6. The feet are twitted according to their different degrees of finenesse, and then the process is complete.

The first operation which the raw silk undergoes is winding, that is, drawing it off from the feet in which it is imported, and winding it upon wooden bobbins, in which flate it can go to the other machines. The winding-frame is shown at fig. 2. of the plate, or rather a part of it, which will wind the threads at once, and by increasing the length it may be made to receive any number. Each of the feet is extended upon a couple reel A A, called a swit; it is composed of four small rods, fixed into an axis, and small bands of string are stretched between the arms to receive the feet, but at the same time the bands admit of winding to a greater or less distance from the centre, so as to increase the effective diameter of the reel, according to the size of the feet, because the feet, which come from different countries, vary in size, being generally an exact yard, or other similar measure, of the country where the silks are produced. The swifs are supported upon wire pivots, upon which they turn freely when the silk is drawn off from them; but in order to cause the thread to draw with a gentle force, a looped piece of string, or wire, is hung upon the axis, within the reel, and a small leaden weight, r, being attached to it, will cause a sufficient friction. B, B, are the bobbins which draw off the threads; they are received in the frame, and are turned by means of a wheel beneath each, the bobbin having a small roller upon the end of it, which bears the weight, upon the circumference of the wheel, and the bobbin is thereby put in motion to draw off the silk from the swit. D is the layer, a small light rod of wood, which has a wire-eye fixed into it, opposite to each bobbin, so as to conduct the thread thereupon; and as the layer moves constantly backwards and forwards, the thread is regularly spread upon the length of the bobbin. The motion of the layer is produced by a crank fixed upon the end of a cross-spindle, E, which is turned by means of a pair of bevelled wheels from the end of the horizontal axle, upon which the wheels for turning all the bobbins are fixed.

These winding-machines are usually situated in the top building of the mill, the frames being made of great length, and also double, to contain a row of bobbins and swifs at the back as well as in front. Two of these double frames are put in motion by cog-wheels from the vertical shaft, F, which ascends from the lower apartments of the mill, where the twitting-machines are placed. The winding-machines require a constant attendance of children to mend the ends or threads which are broken; or when they are exhausted, they replace them by putting new feet upon the swifs. When the bobbins are filled they are taken away, by only lifting them up out of their frame, and fresh ones are put in their places.

A patent has been lately taken out by Meffrs. Gent and Clarke, for a new construction of the swifs for winding-machines; they are made with fixed single arms instead of four double ones; and the arms are small flat tubes, made to contain the items of wire forks, which receive the feet instead of the bands of string in the common swifs. These forks admit of drawing out from the tubes until the swit is sufficiently enlarged to extend it; but as they extend the feet at fixed points instead of four, as in the common one, the motion is more regular. Instead of the weight which causes the friction, a spring is used to press upon the end pivot of the axis, and make the requisite resistance.

The twitting of the silk is always performed by a spindle and bobbin, with a flyer, but the construction of the machine which puts the spindle in motion is frequently varied. The limits of our plate do not admit a representation of the great machines, or throwing-mills, such as are used at Derby, and at almost all the great silk-mills in England. In fig. 3. we have given a drawing of a small machine, which is familiar in the parts which act upon the silk; and indeed many mills employ such machines constructed on a large scale.
SILK.

The one in our plate contains only thirteen spindles, and is intended to be turned by hand, a method which is too expensive for this country, but is common in the south of France, where many artisans purchase their silk in the raw flate, and employ their wives or children to prepare it by these machines, which they call ovales, because the spindles $b, b$ are arranged in an oval frame, $G H$. $B$ is the handle by which the motion is given; it is fixed on the end of a spindle, $R$, which carries a wheel, $D$, to give motion to a pinion upon the upper end of a vertical axle, $E$: this, at the lower end, has a drum or wheel $F$, to receive an endless flasper or band, $a a$, which encompass the oval frame $G$, and gives motion to all the spindles at once. The spindles $b, b$, are placed perpendicularly in the frame $G H$, their points resting in small holes in pieces of glass, which are let into the oval plank $G$; and the spindles are also received in collars affixed to an oval frame $H$, which is supported from the plank, $G$, by blocks of wood $d$ and $a$ are small rollers, supported in the frame $G H$, in a similar manner to the spindles; their use is to confine the flasper, $a$, to press against the rollers of the spindles with sufficient force to keep them all in motion.

The thread is taken up as fast as it is twilled by a reel, $K$, which is turned by a wheel, $b$, and a pinion, $i$, upon the end of the principal spindle $R$. The threads are guided by passing through wire-eyes, fixed in an oval frame, $L$, which is supported in the frame of the machine by a single bar or rail, $//$, and this has a regular traversing motion backwards and forwards, by means of a crank, or excentrical pin, $k$, fixed in a small cog-wheel, which is turned by a pinion upon the vertical axis $E$; the opposite end of the rail, $h$, is supported upon a roller, to make it move easily. By this means the guides are in constant motion, and lay the threads regularly upon the reel $K$, when it turns round, and gathers up the silk upon it, as shown in the figure.

One of the spindles is shown at $r$ without a bobbin, but all the others are represented as being mounted and in action. A bobbin, $e$, is fitted upon each spindle, by the hole through which it is adapted to the conical form of the spindle, but in such manner, that the bobbin is at liberty to turn freely round upon the spindle: a piece of hard wood is stuck fast upon each spindle, just above the bobbin, and has a small pin entering into a hole in the top of the spindle, so as to oblige it to revolve with the spindle: this piece of wood has the wire-flyer, $b$, fixed to it: the flyer is formed into eyes at the two extremities; one is turned down, so as to fall opposite the middle of the bobbin $e$; and the other arm, $b$, is bent upwards, so that the eye is exactly over the centre of the spindle, and at a height of some inches above the top of the spindle. The thread from the bobbin, $e$, is passed through both the eyes of this wire, and must evidently receive a twist when the spindle is turned; and at the same time, by drawing up the thread through the upper eye, $b$, of the flyer, it will turn the bobbin round and unwind therefrom. The rate at which the thread is drawn off from the bobbin, compared with the number of revolutions which the flyers make in the same time, determines the twist to be hard or soft; and this circumstance is regulated by the proportion of the wheel, $b$, to the pinion $i$, from which it receives motion; and these can be changed when it is required to spin different kinds of silk.

The operation of the machine is very simple; the bobbins filled with silk in the winding-machine, $F G$, are put loose upon the spindles at $e$, and the flyers are stuck fast upon the top of the spindles: the threads are conducted through the eyes of the flyers $b$, and of the layers $L$, and are then made fast to the reel $K$, upon which it will be seen that there are double the number of flyers to that of the spindles represented, because one half of the number of the spindles is on the opposite side of the oval frame, so that they are hidden. With this preparation the machine is put in motion, and continues to spin the threads by the motion of the flyers, and to draw them off gradually from the bobbins, until the skeins upon the reel are made up to the requisite lengths. This is known by a train of wheel-work at $n o p$, consisting of a pinion, $n$, fixed upon the principal spindle $K$, turning a wheel, $o$, which has a pinion fixed to it, and turning a larger wheel, $p$: this has another wheel upon its spindle, with a pin fixed in it, which at every revolution raises a hammer, and strikes upon a bell, $s$, to inform the attendant that the skeins are made up to a proper length.

When this machine is employed for the full operation of twilling the organzine, the wheel, $b$, must be larger, and the pinion, $i$, smaller than represented, in order that the reel, $K$, may be turned slowly, and the threads will therefore receive a stronger and closer twist. Also, the handle $B$ is turned in an opposite direction to that in which it must move for the final throwing off the two or three twilled threads together: and as it must also move for twilling the raw threads together for the warp of silk-fluffs, and for weaving flockings, this reverse movement makes no alteration in the machine, except that it will give twist in a contrary direction; for it is always necessary, when two or more twilled threads are combined by twilling, that the twists of the original threads shall be in the opposite direction to that which unites them into one thread, in the same manner as for making ropes, organzine silk being in fact small rope, and flocking-silk or warp being only yarn. The silk which is intended to be dyed, is previously twisted very slightly in this machine, and of course in that direction which will suit the purpose for which it is ultimately intended; viz. whether for yarn or organzine.

The great mills for twilling silk, originally introduced by Mellors, Lomb, though very complicated, are simple in their operation, because the complexity arises from the great number of spindles which are actuated by the same motion, every one of which produces its effect independent of the others, and in the same manner as the oval which we have described. A machine is contained in a circular frame, of which the diameter varies from 11 to 13, 15, and even 17 feet; but 15 feet is the general size of the original Piedmontese machines. In the centre of the frame is a perpendicular axis or spindle, coming up through the floor of the chamber, and riling to the cying; it is put in motion by a communication of wheel-work from a water-wheel, or otherwise from a horse-wheel. The axis has upon it two, three, or four horizontal wheels, according to the height of the machine, which revolve with it, and are of a sufficient size to fill nearly all the interior of the circular frame, and act upon the pulleys or rollers of the spindles, which are supported vertically in the frame, and arranged round the machine, at equal diameter, in a circle, the number being proportioned to the dimensions of the machine. The spindles are also arranged in as many different flages of height as there are wheels upon the vertical spindle; for the circumference of each wheel presses against the rollers of the spindles which are arranged round it; and thus, when the wheel revolves, it gives a very rapid motion to all the spindles at once, by the contact of the edge of the wheel, but without any flasper, as in the oval. Each spindle has a bobbin, filled with silk, fitted upon the top of it, and from this the silk is carried up to a horizontal reel, which is turned round slowly by the machine, and drawn off the thread gradually from the bobbin: the flyer, being all the while in rapid motion, twills the thread upon itself, or, if two or three threads are previously wound together upon the bobbin, they will be twisted
twisted round each other. Each reel serves to take up the thread from several spindles which are situated beneath it: thus, in a mill of fifteen feet diameter, there will be six spindles beneath each reel.

To explain this machine more clearly, we will give a description of one of thirteen feet diameter, which has four large wheels and stages of spindles, two of which are for giving the first preparation to the organzine: the spindles revolve in a direction from right to left. The spindles of the other two stages are for the finishing the twist, and also for twisting the single threads which are to be used for warp or for stocking-weaving: they revolve in a contrary direction to the former. The frame of the machine consists of two wooden circles of thirteen feet diameter, one placed upon the floor of the mill, and the other at a height of fifteen feet above, the two being united by fourteen upright pillars of wood, which altogether compose a large cylindric frame or lantern. Each stage contains eighty-four iron spindles, placed vertically, and supported in the stage, which is formed of two wooden circles, extended round between the fourteen uprights of the lantern, and fixed one above the other, at about a distance of four inches abunder, so as to support the spindles between them, in the same manner as the pieces, G, H, of the oval last described.

The circles of the stage are of a rather less diameter than the two circles which compose the top and bottom of the lantern; so that the spindles will be rather within the circle of the frame of the lantern, and admit the wheels of the central axis to act upon them. For this purpose, each of the stages of the frame is made up by fourteen segments fixed between the uprights, and each segment supports six spindles, making up the number of eighty-four in the whole circle. The spindles, like those of the oval, are sharpened at the lower end, and the points rest in small holes made in pieces of glass, which are set into the lower circle of the stage, whilst the upper circle supports the spindle at a height of four or five inches above the point, leaving one-third of the length of the spindle projecting above, for the purpose of fitting the bobbin upon it. The upper circle of the stage is rather smaller than the lower, because the spindles do not pass through it, but through holes in small pieces of hard wood, which project from it, so as to be exactly above the pieces of glass which sustain the points of the spindles. Each spindle has a small roller fixed upon it in the space between the two circles of the stage, and it is the contact of the rim of the great wheel, which, as before described, is placed upon a vertical & at right angles to the spindle, that causes the revolution of the spindles when the wheel revolves. In order to make the contact certain, the exterior rim of the great central wheel is made in several segments, and each segment has a constant tendency to recede from the central axis by the action of a weight, and thus press against the rollers of the spindles. In order to give the reverse movement of the spindles, which we have before spoken of in the description of the oval, the great wheels for two of the stages are made differently from those which we have just described, so that the segments of the rim will act upon the outside of the rollers of the spindles, instead of the inside: for this purpose the wheels are made larger than the stages in which the spindles are placed, and from the rim of the wheel small pillars rise up to support the segments, which act upon the rollers of the spindles in front or outside of the circles, instead of the inside, as is the case with the other stages, in consequence of which the spindles of these stages turn in opposite directions. The reels are placed over the bobbins, to take up the threads when twisted; and the rollers of the different spindles are made smaller or larger, as is required, to give more or less twist to the silk operated upon by them; for the velocity with which the spindles revolve, compared with the rate at which the reels take up the thread, determines the degree of twist which the thread will have; and to render this equal, the reels which draw off the silk from the bobbins of the spindles are turned regularly with the motion of the machine by means of wheel-work, which is more easily conceived than described: it is sufficient to state that it receives its motion from the central vertical axis. There is also a layer adapted to each reel, with a wire-eye to receive each thread; and the layers having a slowly reciprocating motion, distribute the threads regularly upon the reels, in a similar manner to that first described for the oval. One of these reels is placed between each of the uprights of the machine, so as to make fourteen reels in the whole circle of each stage, and every reel serves to take the silk from the bobbins of six spindles. The whole machine in the four stages contains 336 spindles.

A machine of four stages is so high, as to reach through two floors of the mill, and for this purpose the upper floor is made with a large round opening, to admit the machine: this floor serves the people who attend the machine, and change the bobbins when exhausted, and also remove the finished silk from the reels.

The spindles in the upper stages are usually devoted to the first twisting of the single threads for the organzine, and therefore turn the reverse way, as before mentioned; and as the silk is afterwards to be thrown, or re-twisted, they are drawn off from the bobbins by large bobbins of three inches diameter, and four inches long, instead of the reels. These bobbins are fluck in at once upon a long spindle, butted horizontally, and turned by similar wheel-work to that which actuated the reels; they have similar layers to conduct the silk regularly upon the bobbins from one end to the other, so that the operation is not at all different.

In many of the best silk-mills they have abandoned the original method of turning the spindles, for the preparation of organzine, the reverse way, by making the action of the wheels upon the outside, instead of the inside, of the circle of spindles. Instead of them they employ two different machines, one for the first operation on organzine, and the other for the second operation, both of them constructed with the wheels within: but the motion of the two machines is reversed to each other.

Fig. 5 represents a single spindle of a throwing machine, which, though the same in its action as the great mill, is different in its construction. G and H represent portions of the rails or circles of the stage which support the spindle, and a is a part of the rim of the great wheel of the central axis. This wheel is not made in segments, as before described, but is made very truly circular, and covered with leather on the edge, that it may act with more force to turn the roller, t, of the spindle. The point of the spindle rests in a glass cap, supported by the rail G, and the roller, t, is always made to press against the rim of the great wheel, a a, by a small lever, d, and a spring, which, after turning over a pulley, has the weight, e, made fall to it, to press the spindle always towards the wheel. In this machine, instead of the reel, the thread is taken up by a bobbin, K, is put into a frame, on which moves on pivots, and by a weight, n, is pulled down so as to make the bobbin bear upon the edge of a wheel, h, which is kept in constant and regular motion, by the same kind of movement which turns the wheels of the great machine. The intention of this is, that the action of the wheel, h, to turn the bobbin, being communicated by pressure against the part upon which the silk is to wind, will be constant,
silk.

ftant, and will not draw more when the bobbin is large and full, or less when it is empty, as must be the case when the motion is given to the axis of the bobbin.

After the filk is twisted in a right-hand direction, if it is intended for yarn, or for dyeing; or in a left-hand direction, if it is prepared for organza; it must be wound on fresh bobbins, with two or three threads together, preparatory to twisting them into one thread. In the original machines at Derby this was done by women, who, with hand-wheels, wound the threads from two or three of the large bobbins, upon which the filk is gathered instead of the ree, and assembled them two or three together upon another bobbin, of a proper size to be returned to the twisting mill. We have seen an attempt for a machine to perform the doubling, which is slightly represented in fig. 4.

The whole machine itself is very similar to the winding-machine, fig. 2, but instead of the twist, the bobbins from the throwing-mill are placed in front at A, fig. 4, two or three in a row. The threads from these are passed over the roll m, and beneath a piece of wood, n, both which, being covered with cloth, have the same effect to clean the filk by drawing through them, as the fingers of the washer. B is the bobbin upon which the two or three threads are to be wound together; it is turned by a wheel, E, upon which it rests, the same as the bobbins of the winding-machine; and D is the lever, which, for convenience, is in this case placed behind the bobbin, B; and the wire-eye, d, which receives the three threads, is made to reach over to the front. The additional apparatus consists of a small piece of wood, e, which slides freely up and down, in a hole, through a fixed board, f. On the top of the slider, e, is an eye of wire, through which one of the single threads of filk paves its passage from the pieces m, n, to the bobbin B; there are three of these sliders, e, to each of the three threads; a lever, g, is a lever moving on the centre c; the end e is immediately beneath the small slider e, and the end v is formed to a hook, to catch into the notches which are made in the end of the bobbin B. A small counter weight, r, always causes the hook, v, of this lever to recede from the bobbin; but if any one of the three threads breaks, it suffices the slider e, which belongs to it, to descend upon the end, v, of the lever, and depress the end of the lever, so as to bring the hook, v, in a situation to catch a tooth of the bobbin B, and stop its motion. By this means the winding of three threads together is rendered equally certain with the winding of one; for when any one breaks, the operation of winding on that bobbin stops, until the attendant repairs the broken thread and puts the machine again in motion. We have lately been informed, that a machine for winding two and three threads together is becoming common in the silk-mills, but we do not know if it is the same with this one, which however is not evidently impracticable.

The bobbins, being thus filled with double or triple threads, are carried back to the throwing-mill, and are there spun or twisted together, the manner of doing which does not differ from the operation which we have before described. In this second operation the filk is taken up by reeds instead of bobbins, and is thus made into skeins. The degree of twist varies with the purpose for which the filk is intended; and the wheels which give motion to the reeds are for this purpose adapted to the degree of twist which the filk is designed to have. The filk, being now spun, requires only the preparation of boiling to discharge the gum, and render the filk fit to receive the dye, and also to render it soft and glossy. The filk is boiled for about four hours, in a boiler filled with water, into which a small quantity of soap is put; this operation dissolves the gum, which before could be felt upon the filk, and renders it harsh. After the boiling, it is well washed in a current of clear water, and when dried, will be found to have lost about one-fourth of its weight: at the same time the volume of the filk is sensibly increased, and it has acquired that soft texture and glossiness, which are the principal beauties of filk. This change is produced by the dissolusion of the gum, which, in the first instance, was the only adhesion of the fibre to form a thread, but by the operation of the twisting the fibres are firmly united, and no longer require the gum. It is also necessary, in order to give a fine dye to the filk, that the gum should be removed, because it would prevent the entrance of the dyeing matter to the centre of the thread, and thus impair the beauty of the colour. If the filk was thus boiled before the twining, nothing but a fine entangled down or wool would be obtained, and it would require spinning, by a similar process to that of cotton, before a thread could be obtained. This, indeed, is necessary for that portion of waste filk which is drawn from the cocoons in the first operation of reeling; also for those cocoons which are reserved for breeding, and from which the moths eat their way out by holes, which render it impracticable to wind off the filk. This waste filk, when carefully spun by a spinning-wheel, is called spun filk, and the thread is not inferior to the regular filk which is wound off; indeed, the winding off the filk into a thread united by its gum, is of no advantage farther than as a preparation for spinning, from which proceeds the thread obtains its strength.

The filk is now in a state for use: if it is for flocking— weaving, or sewing, or if intended for weaving into fluff, it only requires warping to be put into the loom. The operation of warping is to put together all the threads which are to compose the warp of the intended piece of fluff, and lay them parallel, so that the warp, being put into the loom, will have no slack threads, nor any which are strained too tight. Formerly, this operation was performed by stretching the threads out at length in a field, or by extending them in a frame, and winding them backwards and forwards over pegs. The present machine now universally employed is shown in fig. 6, where A A is a trefoil or flock, which supports the small bobbins b, b, upon which the filk is wound. The number of these is equal to the number of threads which the warp of the intended piece of fluff is to have in its breadth. The threads from all these bobbins are drawn over wires d, d, which are in front of the bobbins, and are then all brought together, and passed through an opening in a piece of wood D; this conducts the threads all together upon a large reel E, which is supported in a frame FF, and turned round by means of a pulley at the lower end of its axle, from which an endless band is continued to a second wheel G, mounted on a spindle, and turned by a handle. This latter spindle is supported in a fort of fluff H, upon which a child sits down, and at the same time turns the handle and puts the reel in motion, so as to draw the warp or affilbage of threads off from the several bobbins, and lay it upon the reel E. The piece of wood D is fitted upon one of the upright pieces, F, of the frame, to slide freely up and down upon it, and is suspended by a cord, which, after passing over a pulley f, is wrapped round the spindle of the machine at c; by this means, the motion of the reel, E, draws the cord, and raises up the piece D, so as to lay the warp upon the circumference of the reel, in a regular spiral, from one end to the other, and prevent the coils lapping one upon another. When the required length of warp is wound upon the reel, the ends of all the threads are cut off, tied together, and thus drawn off from the reel and rolled up into a large ball,
in which the weaver takes it, and mounts it in his loom.

For the subsequent operations of weaving we shall refer to the article Weaving, because the weaving of silk goods is the same as for any other, except that finer and more beautiful articles are produced in this subsilence than in any other. Some information on the details of weaving mechanism will be found under our articles Drawn of Loom, Draw-Loom, Diaper, Dimity, and Dornock; and though these are rather the weaving of linen and cotton than silk, the same principles apply to silk, as will be more fully explained under Weaving; where a description of weaving ribbons and figured silks will be given.

Silk is distinguished by different names according to its different states. Thus,

Silk, Spun, is that taken from the ball, without fire, and spun into thread without any coating: such as is most, if not all, that is brought into England from the Levant; i.e. from Persia by the way of Turkey, from Bengal in India, and from China. The raw spun silk is commonly worked up into two forts, called organise and tram: the former is made by giving a throw or twist to each thread of raw spun silk singly, and then doubling two of these twisted threads together, and twisting them firmly together; this forms the warp or length of a piece when manufactured. The tram, or sheet, which makes the breadth of the piece, is formed by twisting two or more threads of raw silk. The waffe raw silk, or refuse in reeling, &c. is collected, carded, and spun, and called filo silk; this is doubled and thrown, and often made into a cheap sort of silk- stockings, which are very strong and durable.

In the French silks-works, the greatest part of this raw silk pales for little better than a kind of fine floretta; yet, when spun, it makes a bright thread, and serves for the manufacture of stuffs of moderate value and lustre. But the spun silks of the Levant, whence most of our come, are exceedingly fine and beautiful. The difference arises, however, that in France, the balls are reeled off in boiling water, and only the refuse made into spun silk; whereas, in the Levant, there is no such thing as reeling or winding on the fire, but the silks are all sent in bales, or packs, as they are drawn from off the balls; so that they are only distinguished by their quality of fine, middling, and coarse.

Silk, Boiled, is that which has been boiled in water, to facilitate the spinning and winding. This is the finest of all the sorts of silk manufactured in France, and is seldom used but in the richest stuffs; as velvets, taffeties, damasks, brocades, &c.

There is also another kind of boiled silk, which is prepared by boiling, to be milled; and which cannot receive that preparation, without being first penned through hot water. By the laws of France, it has been prohibited to mix raw with boiled silk; both as such a practice spoils the dyers, and as the raw silk corrupts and cuts the boiled.

Silks, thrown or twilled, are such as, besides their spinning and winding, have received their milling or throwing. This they receive in a different degree, as they are pulled oftener or seldomer over the mill; properly, however, thrown silks are those in which the threads are pretty thick-thowed, and twilled several times.

The thrown silk comes to us chiefly from Leghorn, Genoa, Naples, and Melfina. Silks, Stich, are such as are not twilded, but are prepared, and dyed for tapestry, and other works with the needle.

Silk, Eastern or East Indian. That popularly thus called is not the work of the silk-worm, but comes from a plant that produces it, in pods, much like those of the cotton-tree. The matter this pod contains is extremely white, fine, and moderately glossy; it spins easily, and is made into a kind of silk, that enters the manufacture of several Indian and Chinese stuffs.

Silks, French. It is only in the most southem provinces of France that silk is cultivated, mulberry-trees planted, and worms bred. The principal places are Languedoc, Dauphiné, Provence, Avignon, Savoy, and Lyons. This last place, indeed, furnishes very few silks of its own growth; but it is the great staple whence the merchants of Paris, and the other cities, are to fetch them. At least, they are obliged to have them pass through Lyons, if they bring them from other places, either by land or sea. There have been computed to be enter Lyons, communibus annis, fix thousand bales; the bale valued at one hundred and sixty pounds weight; of which fix thousand bales, there are one thousand four hundred from the Levant, one thousand fixed hundred from Sicily, one thousand five hundred from Italy, three hundred from Spain, and one thousand two hundred from Languedoc, Provence, and Dauphine.

At the time when the manufactures of Lyons were in their prosperity, there were reckoned to be eighteen thousand looms employed in the silk manufacture; but in 1698, there were not reckoned four thousand. However, this manufacture afterwards revived, and a great part of Europe has been supplied from hence with brocade and rich silks. The decay has not been less notable at Tours; they had formerly there eight hundred mills for winding and preparing the silks; eight thousand looms to weave them; and forty thousand persons employed in the preparation and manufacturing of them; but these have been reduced to seventy mills, twelve hundred looms, and about four thousand persons. The revolution has, however, made such an alteration in the manufactures and trade of France, and they are still (1816) in an unsettled state, that no correct estimate of them can be obtained.

Silks, Sicilian. The commerce of the silks of Sicily has been very considerable; and the Florentines, Genoese, and Luccefe, are the people who have chiefly availed themselves of it. Great quantities were yearly brought thence, especially from Melfina; part of which they used in their own manufactures, and fold the rest to their neighbours the French, &c. with profit. The Italians had this advantage, especially the Genoese, over other people, that, having large establishments in the island, they were reputed as natives, and paid no duty for the export.

Part of the Sicilian silks is raw, the rest are spun and milled; of which kind last, those of St. Lucia and Melfina are the most valued. The raw unwrought silks were always sold for ready money; the others, sometimes, in exchange for other goods. See Sicily.

Silks, Italian. The silks brought from Italy are partly wrought, and partly raw and unwrought. Milan, Parma, Lucca, and Modena, furnish none but the latter kind; Genoa most of the former; Bologna affords both kinds. The finest Italian wrought silk comes from Piedmont, Novi, Bergamo, and Bologna; and is imported into England from the ports of Nice, Genoa, and Leghorn.

The silk we have from Italy is generally thrown, and serves for warp for our manufactures.

Silks, Spanish, are all raw; and are spun, milled, &c. in England, according to the several works in which they are to be used.

Silks, Turkish, are all raw. One advantage we have in the commerce of the Levant, in silks, wanting in those of Sicily, is, that the latter are confined to a particular season of the year; whereas the former are bought at all times. They
They are brought from Aleppo, Tripoli, Sayda, and from the isle of Cyprus, Candia, &c. But the principal place of commerce, especially for the silks of Persia, is Smyrna. The silks are brought hither in caravans, from the month of January to September. The caravans in January are laden with the finest silks; those of February and March being indifferent ones; the rest, the coarsest. They all come from the several provinces of Persia, chiefly those of Ghilan and Shirvan, and the city of Schemachia, situated near the edge of the Caspian sea; from which three places, a Dutch author affirms, there have not come less than thirty thousand bales of silk in a year. Ghilan produces the best and greatest quantities of silk; next to this are Shirvan and Erivan, then Mazanderan, and lastly Altarabad; but the latter is much inferior, serving only for a manufacture mixed with cotton; that of Mazanderan and Altarabad is seldom or ever exported.

Ardeuil, or Ardebil, another city of Persia, not far distant from these silk countries, is the place where silks are laid up, and whence the caravans fet out for Smyrna, Aleppo, Scanderoon, and Constantinople; and it is this city, with Schamachia, that have always been esteemed the centre of the silk trade; which has been several times attempted to be removed from Smyrna, and the Mediterrenean, in favour of Archangel, and the White sea, by carrying them across Mesopotamia, by the Volga and Dwina, two rivers that traverse the principal provinces of that vast empire.

This new course of the Persian silks into Europe was first proposed by Paolo Centurio, a Genoese, to the tzar Bazil, under the pontificate of Leo X. The French had the same design in 1628. The duke of Holstein, in 1633, sent ambassadors to the court of Persia, purely with the same view. And in 1668, the tzar Alexis Michael attempted the thing himself; but he was disappointed by the rebellion of the Collacks, and the surpreme of Altarakan.

In 1688, the commerce of Persian silks had nearly been removed from Smyrna by an earthquake, which almost overturned the whole city; and, doubtless, the removal had been effected, but for the vigorous means used by the Turks to prevent it. Smyrna, however, still remains in her ancient possession; and the several nations of Europe continue every year to send their fleets, to fetch away the silks.

Silks, China, Japan, and Indian. Several provinces of China are so fertile in mulberry-trees, and their climate is so agreeable to the nature of silk-worms, that the quantity of silks there produced is incredible; the省份 province of Tcheliang might supply all China, and even a great part of Europe, with this commodity. The silks of this province are the most esteemed, though those of Nankin and China be excellent.

The silk-trade is the principal in China, and that which employs the most hands; but the European merchants who deal in it, especially in wrought silks, are to be careful of the spinning, &c. the wale being usually very great, as the French East India company have found to their cost.

Japan would not afford fewer silks than China; but that the Japanese, a barbarous and distrustful people, have interlarded all commerce with strangers, especially with Europeans, containing with the Dutch; who are to be admitted on certain imperious terms, related by Tavernier, but which, we must own, we cannot credit. The Dutch have endeavoured to vindicate themselves from these by the pens of several famous writers.

Great quantities of both raw and wrought silk are furnished by other parts of Bengal, and by several provinces of Hindoostan, which partly supply the natives, and afford a very considerable exportation to Europe. Several thousand bales of raw silk are annually imported from Bengal and China; some of which is, in this state, used for making princes' rubbish, but the greater part is prepared for the manufacturers by the silk-throws.

SILK, Linea relating to. The duties on silks and callicoses being under the same regulations with those on printed linens, the law respecting them is inserted under the article LINENS. By the 13 & 14 Car. II. c. 15. f. 2. no person shall exercise the trade of a silk-thrower, unless he hath served seven years' apprenticeship, on pain of 400. a month, half to the king, and half to him that shall sue in any court of record, or at the auzifes, or quarter-feelings of the peace. By 9 & 10 W. c. 43. no foreign silks, called callicoses or lutelfrings, shall be imported but in the port of London, on notice first given to the commissioners of the customs, and licence had from them, on pain of forfeiture, or the value; and they shall be sold, and exported again; and the owner so importing, and also the receiver and person offering to sell the same, shall forfeit 50l. Being marked and sealed by order of the commissioners, any person who shall counterfeit the customs-house seal, or that of the lutefring company, shall forfeit 50l., and be set in the pillory for two hours. And any person who shall buy and sell, and have in his custody, any callicoses or lutelfrings, sealed or marked with a counterfeit seal or mark, shall forfeit the same and 100l.

However, none but customs-house officers, or persons deputed by the lutefring company, and having writs of affiance under the seal of the exchequer, shall seize lutelfrings or alamodes within the bills of mortality. (5 Ann. c. 20.) The penalties shall be two-thirds to the king, and one-third to him that shall sue or sue in any court of record.

By 3 Geo. III. c. 21. and 5 Geo. III. c. 48. if any person shall import any ribbands, laces, or girdles, not made in Great Britain, whether the same shall be wrought of silks alone, or mixed with other materials, the said person shall be forfeited, and may be seized by any officer of the customs, in whatever importers', vendes', or retailers' hands they may be found; and the importers, and every person affilling therein, and the vendes and retailers in whose custody they shall be found, or who shall sell or expose the same to sale, or conceal with intent to prevent the forfeiture, shall forfeit respectively 200l., with costs. Half the said penalties to be to the king, and half to the officer who shall inform and prosecute.

But if any officer of the customs shall neglect or refuse, for one month after condemnation, to prosecute for effecting any person for any of the said pecuniary forfeitures, any other person may sue for and recover the same; half thereof to go to the king in like manner, and half to him who shall sue.

And when the goods seized (being out of the limits of the bills of mortality) shall not exceed the value of 20l., two juries, on information before them that such goods were seized, shall hear and determine the same, and proceed to condemnation or discharge.

After seizure, until condemnation or discharge, the said goods shall be deposited in one of the king's warehouses, if the seizure be within the bills of mortality; elsewhere, in the hands of the chief magistrate or constable; and the same shall be free to inspection, with leave of the court, judge, or juries, before whom the prosecution shall be.

And after condemnation, the said goods shall be publicly sold by the court for exportation; half of the produce by
SILK.

Spiders are usually distinguished, either with regard to their colour, as into black, brown, yellow, white, &c. or with regard to the number, or arrangement, of their eyes; some having fix, others eight, others ten. But with regard to the silk-spiders, M. Bon reduces them all to two kinds; those with long legs, and those with short; which last are those which furnish the finest raw silk. The silk-spider makes a silk every whit as beautiful, glossy, and strong, as the silk-worm: it spins it from the anus; around which are five papilles, or small nipples; and behind these, two others, all mucilaginous, and furnished with spiniceters. These nipples serve as so many wire-drawing irons, to form and mould a viscous liquor, which, when dried in the air, after being drawn through them, makes the silk. Each of these nipples, M. Reaumur observes, consists of a number of lefs and infulent ones; which one may be convinced of by preffing a spider's belly between the fingers, to oblige the liquor to flow into the nipples; for by this means, applying the finger against the anus, several distinct threads will be drawn out through the several perforations of each nipple. The threads are too fine to be counted with any certainty; but M. Reaumur reckons each larger nipple may lend forth a great many.

Hence we see how the spiders make their threads bigger or smaller: for as, before they begin to spin, they always apply more or fewer of these nipples against the body, whence the web is begun; or, as they apply each more or less strongly; so, as more or fewer of the minuter nipples come to take, the thread thus spun will be a compound of more or fewer of the fingle threads. Indeed, as the threads come from the anus all joined together, they appear to be fingle; but M. Bon has distinguished one of the fingle ones to consist of fifteen or twenty distinct threads.

The threads are of two kinds: the firlt is weak, and only serves for that kind of web with which they catch flies. The second is much stronger, and serves to wrap up their eggs in; which, by this means, are sheltered from the cold, as well as from insects, which might otherwise gnaw and defly them. These threads they wind very loosely round the eggs, resembling the balls or bags of silk-worms, which have been prepared and loosened for the distaff.

The spider-bags are of a grey colour, when new; but when turned blackish, when long exposed to the air: indeed, one might find other spiders' bags of other colours, and which would afford a better silk; but their scarcity would render the experiment difficult: for which reason, we confine ourselves to the bags of the most common spiders, which are the short-legged kind. These always find out some place, secure from the wind and rain, to make their bags; as hollow trees, the corners of windows, or vaults, or under the eaves of houses.

By collecting a quantity of these bags, a new silk is made, inferior in nothing to the common silk. It takes all kinds of dyes, and may be made into all kinds of stuffs. M. Bon had flocks and gloves made of it, which he presented to the Academy, and others to our Royal Society.

For the manner of preparing the bags to get the silk, it is thus: after having gathered twelve or thirteen ounces of thes bags, M. Bon had them well beaten for some time, with the hand, and a flick, to get out all the stuff; he then washed them in lukewarm water, till they left the water very clean; after this, he laid them to steep, in a large vessel, with soap, and salt petre, and gum arabic. The whole was left to boil, over a gentle fire, for three hours. The bags were next washed in warm water, to get out the soap; and after all, laid to dry some days, to fit them for

such fate to be to the king, and half to the officer who shall seize and secure the same; and the same goods shall not be delivered out of the warehouse, till security shall be given for exportation, and that the same shall not be landed again in any part of his majesty's dominions.

By 5 Geo. III. c. 48, if any foreign manufactured silk-flockings, silk-mitts, or silk-gloves, shall be imported into this kingdom, or any part of the British dominions, the same shall be forfeited, and liable to be searched for and seized as other uncustomed goods; and every person who shall import the same, or be affilling therein, the vendors and retailers in whose custody they shall be found, or who shall sell or expose the same to sale, or conceal with intent to prevent the forfeiture, shall, over and above the forfeiture of the goods, forfeit coacl, with costs; half to the king, and half to the officer who shall inform and procuce.

And when the goods seized (being out of the limits of the bills of mortality) shall not exceed the value of 20l., two justices may proceed to the condemnation thereof. The proceedings, in all other respects, shall be in like manner as in the case of ribbands and laces above mentioned.

SILK, in Chemistry, deserves notice on account of a peculiar fault, or crystalline subsance, obtained from it by the nitric acid. In its natural state, or before it is bleached, it contains a yellow refrinous matter, from which it derives its fine golden colour. When raw silk is infused in water, a portion of gummy matter is disolved, and a light amber-coloured liquor is produced. Pure alcohol extracts a much deeper yellow colour, and makes a tincture, that loses none of its colour by long exposure to the fun, which bleaches the silk itself. Nitrous acid acts powerfully on silk, in proportion to its concentration. If two draachs of this acid are mixed with a pint of alcohol, and silk, either raw or bleached, be immered in it, and kept in digestion, in a moderate warmth, for twenty-four hours, the silk becomes of a dull yellowish-brown, which, after rinsing and washing with soap, and drying, turns to a fine golden yellow, which is very permanent. But when concentrated nitric acid is distilled off silk, and the remaining liquor duly evaporated, much oxalic acid is obtained; and the refuse, if evaporated still further, yields, together with a little remaining oxalic acid, a quantity of yellow granular crystals, very bitter, not acid, and tainting the saliva and hands of all very deep yellow, not easily removed. If the liquor is previously saturated with potash, and evaporated, another yellow silky salt evaporates, which detones on coals like common nitre, and appears to be a triple combination of the former bitter substance with nitrate of potash. The first mentioned granular crystals, examined with a magnifier, appear to be composed of truncated oehedrons.

The above curious substance was discovered by Wolter, and called by him the "bitter principle." He supposes it to be generally produced by the action of nitric acid on animal matters; and it is perhaps the same substance which causes the bitterness of bile. Aikin.

The spirit of raw silk, rectified with some essentil oil, is the medicine commonly known by the name of Guite Anglische, or English Silk.

SILK, Spider. Within about a century the secret has been found in France, of procuring and preparing silk from the webs of spiders; and the using it in several manufacures has been attempted. This discovery is owing to M. Bon, in 1710, who published a dissertation on the subject, whence what follows is extracted.
for carding; which was performed by the common silk-carders, but with cards much finer than ordinary. By this means, he had a silk, of a very particular ash-colour, which was easily spun; and the thread spun from it was both stronger and finer than that of common silk; which, though all sorts of works may be made of it: nor is there any reason to fear, but it will stand any trials of the loom, after having passed that of the flocking-weavers.

The only difficulty, now, is in procuring a sufficient quantity of spider-bags to make any considerable work of it; which, M. Bon observes, would be no difficulty at all, had we but the art of breeding them, as we do silk-worms; for they multiply much more; every spider laying fix or seven hundred eggs, whereas the silk-worms do not live above one hundred: yet are these laid so tender, &c. that one half die without making any bags, or are hindered, by some little accident, from making them; whereas the spiders hatch of themselves, without any care, in the months of August and September, in fifteen or sixteen days after they are laid; the old spiders that lay them dying soon after. The young ones thus bred live ten or twelve months without eating, and continue in their bags without growing, till the hot weather, putting their viscous juices in motion, induces them to come forth, spin, and run about to seek food. Were a method, therefore, found of breeding young spiders in rooms, they would, doubtless, furnish a much greater quantity of bags than silk-worms do. For of seven or eight hundred young spiders, which M. Bon kept, hardly one died in a year; whereas of one hundred silk-worms, not forty lived to make their bags. M. Bon, having ordered all the short-legged spiders that could be found in the months of August and September to be brought to him, shut them up in paper coffins, and pots; covering the pots with papers, which he pricked full of pin-holes, as well as the coffins, to give them air. He fed them with flies, and found, some time afterwards, that the greatest part of them had made their bags. The fame ingenious person found, that spiders' bags, with regard to their weight, afford much more silk than those of the silk-worms: as a proof of which, he observes, that thirteen ounces yield near four ounces of clear silk, two ounces of which will make a pair of flockings; whereas flockings of common silk weigh seven or eight ounces.

Nor is there any venom in the silk, or even in the spider, as many have imagined. M. Bon has been bit by them several times, without any manner of harm; and as for the silk, it is used with very good success to stop bleeding, and cure wounds, the natural gluten of it acting as a kind of balsam. It likewise yields, by distillation, several specific medicines, particularly great quantities of spirit, and volatile farts, which being prepared after the same manner as that drawn from the bags of silk-worms, in making the guttae Anglicaee, or English drops, at one time so famous all over Europe, may serve to make other drops of greater efficacy, which M. Bon calls drops of Montpelier, and advises to be used in all febrile diseases.

M. Reaumur, being appointed by the Royal Academy to make a farther inquiry into this new silk work, has raised several objections and difficulties against it; which are found in the Memoirs of the Academy for the year 1710. The sum of what he has urged amounts to this. The natural fierceness of the spiders renders them unfit to be bred and kept together; four or five thousand being distributed into cells, fifty in one, or two hundred in others, the big ones soon killed and eat the less, so that, in a short time, there were feebly left one or two in each cell; and to this inclination of mutually eating one another, M. Reaumur attributes the scarcity of spiders, considering the vast number of eggs they lay.

But this is not all: he even affirms, that the spider's bag is inferior to that of the silk-worm, both in luster and strength; and that it produces less matter to be manufactured. The thread of the spider's web, he says, only bears a weight of two grains without breaking; and that of the bag bears thirty-fix. The latter, therefore, in all probability, is eighteen times thicker than the former; yet it is weaker than that of the silk-worm, which bears a weight of two drachms and a half; so that five threads of the spider's bag must be put together, to equal one thread of the silk-worm's bag.

Now it is impossible these should be applied so justly over one another, as not to leave little vacant spaces between them, whence the light will not be reflected; and of consequence, a thread, thus compounded, must fall short of the luster of a solid thread. To add to this, that the spider's thread cannot be wound off, as that of the silk-worm may, but must be collected; by which means, being torn in pieces, its evenness, which contributes much to its lustre, is destroyed. In effect, this want of lustre was taken notice of by M. de la Hire, when the flockings were presented to the Academy.

Again: spiders furnish much less silk than the worms: the largest bags of these latter weigh four grains; the smaller, three grains: so that 2304 worms produce a pound of silk. The spider-bags do not weigh above one grain; yet when cleared of their dust and filth, they lose two-thirds of their weight. The work of twelve spiders, therefore, only equals that of one silk-worm; and a pound of silk will require at least 27,648 spiders. But as the bags are wholly the work of the females, who spin them to deposit their eggs in, there must be kept 55,296 spiders to yield a pound of silk. Yet will this only hold of the best spiders; those large ones ordinarily seen in gardens, &c. fearfully yielding a twelfth part of the silk of the others: 280 of these, he shews, would not yield more than one silk-worm; 605,552 of them would fearcely yield a pound.

Silk-Grafs, in Botany, a name used for two very different genera of plants, the aloe, and dog's bane.

Silk-Tail, or Bohemian Chatterer, in Ornithology. See Roller.

Silk, Virginian, in Botany. See Periploca.

Silk-Worm, Bombyx. This insect, which is a species of the phalzena, (see Bombyx), consists of eleven rings, and each of these of a great number of other smaller ones, joined to each other; and the head, which terminates these rings, is furnished with two jaws, which work and cut the food, not by a perpendicular but a lateral action.

The humours found in the body of this creature all seem approaching to the nature of the silk which it spins; for on being rubbed in the hands, they leave a hard or solid crust behind them. Under the skin there is always found a mucous rosy-coloured membrane, enveloping the animal, and supposed to be the new skin in which it is to appear, on throwing off the old one. The heart of this creature reaches from the head to the tail, running the whole length of the body; it is, indeed, rather a series of many hearts connected together, than one: the motion of thet and sialole is very evident in this whole chain of hearts; and it is an elegant fight to observe the manner of the vital fluid's flowing from one of them to the other. The flan of this animal is as long as the heart, reaching, like it, from one end of the body to the other. This large receptacle for food, and the fud-
den palliage of it through the animal, are very good reasons for its great voracity.

In the sides of the belly, all about the ventricle, there is deposited a vast number of vesels, which contain the silky juice: these run with various windings and meanders to the mouth, and are so disposed, that the creatures can discharge their contents at pleasure at the mouth; and according to the nature of the juices that they are supplied with, furnish different sorts of silk from them, all the fluid contents of these vesels hardening in the air into that sort of thread, of which we find the web or balls of this creature consist.

These creatures never are offended at any touch, of whatever kind; but they always feel a souther wind, and an extremely hot air always makes them sick. Malpighi de Bombye.

SILKEBURG, in Geography, a town of Denmark, in North Jutland, with a castle, which was formerly very strong; 18 miles W. of Aarhus.

SILLA, in Ancient Geography, a river of India, which rife in a mountain of the same name, and lost itself in the ground, without receiving any other river.

SILLA, in Geography, a large town of Africa, in Bambara, on the right bank of the Niger, within two short days' journey of Jenné, which is situated on an island in the river. This place was the boundary of Mr. Park's journey, and from hence he began his return homeward; 75 miles N.E. of Sego. N. lat. 14° 48'. W. long. 10° 34'.

SILLA Point, a cape on the north-west coast of the island of Mindanoo. N lat. 9°. E. long. 123° 51'.

SILLABAR, or Cellebhar, a sea-port town on the west coast of the island of Sumatra, with a good and safe harbour; 30 miles S.S.E. of Bencoolen.

SILLAH-MEW, a handsome town of the Birman empire, situated on the Irawaddy. It is shaded by wide-spreading trees, and embellished with several temples. A smooth bank sloping to the river, and clothed with the finest verdure, adds much to its beauty. The soil around in general is but poor. Some fields are regularly fenced, and cattle in large herds graze in the neighbourhood.

SILLANGER, a town of Sweden, in Angermanland; 4 miles W. of Hernfoss.

SILLANO, a town of Etruria; 8 miles S.S.E. of Voiterra.

SILLEE, a circe of Bengal, bounded on the north by Rangpur, on the east by Pachete, on the south by Tomar, and on the west by Nagpore; its form is square, and each side is about 16 miles. Alto, the capital of the above circe; 25 miles S.E. of Rangpur. N. lat. 25° 22'. E. long. 85° 56'.

SILLESIS, in Ancient Geography, a river of the Troade.

Sille-le-Guillaume, in Geography, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Le Mans; 18 miles N. of Le Mans. The place contains 2121, and the canton 11,835 inhabitants, on a territory of 243/4 square miles, in 10 communes. N. lat. 48° 12'. W. long. 0° 31'.

Sillewood, a small island in the North sea, near the coast of Norway; 30 miles N.N.W. of Bergen.

Sillinga, a town of Bengal; 35 miles S. of Dofia.

Silllon, in Fortification, an elevation of earth, made in the middle of the moat, to fortify it, when too broad.

The sillon is more usually denominated an enceinte.

Sills, in Agriculture, a term signifying the shafts of a cart, waggon, &c.

Silly, in Geography, a rock on the south coast of the island of Jersey; 2 miles S. of Noirmont Point.

SILLYUS, in Ancient Geography, a town of Atha Minor, in Ionia, in the vicinity of Smyrna.

Silm, or Cilm Monou, in Geography, a country of Africa, near the river Schembro.

Silno, a town of Lithuania; 4 miles N.N.W. of Grodno.

Sil, in Ancient Geography. See Shiloh.

Siloe, Siloa, or Siloam, a fountain at the foot of the walls of Jerusalem, east, between the city and the brook Kidron, or Cedron. Joscphus (De Bell. 1. v. c. 26) says, that when Nebuchadnezzar besieged Jerusalem, the waters of this fountain increased; and that the cave was the same, when Titus besieged the city, so that, during the siege, it abundantly supplied the Roman army, and furnished also a sufficiency for watering the gardens; though, before this event, water could hardly be bought for money. The prophet Isaias (ch. vii. 6) infinuates, that its waters flowed gently and without noise. St. John speaks of the pool of Siloam. (John, ix. 7) The tower of Siloam, mentioned Luke, xiii. 4, is thought to have been near the fountain.

Sil-Long, in Geography, a city of China, of the second rank, in Kuang-ni. N. lat. 24° 34'. E. long. 105° 18'.

Siloar, a town on the north-coast of the island of Sumatra. S. lat. 1° 8'. E. long. 103° 51'.

Siloxerus, in Botany, so named by Labillardiere, from roco, the sky, and oxyces, dwelling, on account of the tumid base of that part. It would be difficult to trace this derivation, without authentic information from the author himself.—Labill. Nov. Holl. v. 2. 57. —Chalce and order, Syngnoscia Polymagia-segregata. Nat. Ord. Compositeae-accumulatae. Linn. Cornyphilus, Julli.

Gen. Ch. Common Calyx scarcely any, except the leaves surrounding the common compound receptacle; partial inferior, of from five to seven equal, obovate-oblong, concave, membranous leaves, containing several florets. Corolla uniform, dicyclic, of from two to five tubular, monopetalous, regular, pitcher-shaped, five-toothed, perfect florets. Stamens in each floret five, very short; anthers linear, united into a tube. Filaments in each floret inerely pyramidal, tuberculated; fyllve awl-shaped, swelling very much at the base; stigma two, obtuse, spreading. Pericarp none, except the permanent partial calyx. Seeds solitary to each floret, inerely pyramidal, befat with rows of tubercles, and crowned with about twelve little teeth; down of one leaf, membranous, pellucid, in five ovate, acute, fringed lobes. Common receptacle oblong, somewhat club-shaped, hairy, many-flowered; partial small, falcate. The scales membranous, oblong, scarcely longer than the florets.

E. Ch. Common receptacle hairy; partial clefty, partial calyx with from two to five perfect, equal, regular florets. Seed-down membranous, five-lobed, fringed.

1. S. humifusa, Labill. Nov. Holl. v. 2. 58. t. 299. — Native of Lewsen's land, on the south coast of New Holland. A small, diffuse, herbaceous plant, with a tapering, apparently annual, root. Stems several, spreading, simple, leafy, an inch or two long. Leaves mostly opposite, simple, linear, obtuse, smooth, near an inch in length; several of them crowded under the heads of flowers, which are terminal, solitary, ovate or nearly globular, scarcely an inch long. Nothing is mentioned concerning the colour, scent, or properties of this little inconspicuous, but singular, plant.

Silperry, in Geography, a town of Bengal; 2 miles S.S.E. of Ghidore.

Silpha,
SILPHA, in Entomology, a genus of insects of the order Coleoptera, of which the generic character is, Autenne clavate, the club perfoliate; shells margined; head prominent; thorax somewhat flattened and margined. This genus of insects, from its habits, is known by the trivial name of the Carvon-beetle. The several species are commonly found among decayed animal or vegetable substances, frequenting also dung-hills, carrion, and other offensive matter: they lay their eggs chiefly in the dead and putrid carcasses of animals. The larvae are of a lengthened shape, and of an unpleasant appearance, being generally roughened with minute spines and protuberances. There are about 120 species, in eight separate divisions or sections. The following are most worthy of notice.

Section A is characterized by a dilated and bifid Lip, and a one-toothed Jaw; in which, among others, are the following

Species.

SURINAMENSIS. Black; shells with a yellow band behind; hind-thighs toothed. It is found in South America.

* Littoralis. This is a black insect; the shells are naked, with three raised lines; thorax rounded and polished. This is an European insect, and found in our own country.

LIVIDA. This is brown; thorax, shells, and legs livid. It is found in Germany.

INDICA. This, as its name imports, is an Indian insect; it is black; the shells are marked with two ferrugious bands; thorax one-toothed before.

MICANS. Black, with a green polish; shells friate, truncate, one-toothed. This is an inhabitant of the Cape of Good Hope. Tail rufous; shells black, with three elevated flour, one-toothed at the future.

AMERICANA. This, as its name shews, is found in divers parts of America. It is depressid and black; thorax is yellow and black in the centre. The shells are ruged and immaculate.

* THORACICA. This is black; the shells are marked with a single elevated line; the thorax is tectaceous. This and the following are English insects. According to Mr. Donovan's figure and description, the shells of this species have three raised lines. It is distinguished by its red thorax, every other part being black.

* RUGOSA. Blackish; the shells are ridged with three raised lines, the thorax is ridged and minute behind. This insect consumes dead carcasses, fish, and flesh of all kinds; when caught it emits a very fetid smell.

* ANHATA. This is of a fize similar to the thoracica, but is totally black, and has the wing-features marked by three riling lines; its larva, which may be found in gardens, is of a lengthened shape, and of a black colour.

* LEVIAGA. Black; shells smooth and sub-punctured. The shells are without raised lines.

* OBSCURA. Black; the shells are punctured, with three raised lines; the thorax is truncate before. This species is figured by Donovan. The thorax has a bluefl glofs.

* OPACA. This is brown; the shells have three raised lines; the thorax is truncate before.

* SINAPATA. The thorax of this species is emarginate and rough; the shells have three raised lines, minute at the tip. This is a beautiful species; the thorax is brown, with a silvery glofs; it is rough, with raised dots.

* 4-PUNCTATA. The thorax is yellow, with a large black spot; the shells are yellow, with four black spots.

* GRISEA. Grey; the shells are smooth; the thorax is emarginate.

Section B is distinguished by an entirely rounded Lip, and a one-toothed Jaw.

4-MACULATA. Thorax and shells black, the latter with two rufous spots; the body is rufous: the antennae are ferruginous, brown before the tip, shells friate.

MULTIPUNCTATA. Rufous; shells subfriate, with numerous rufous dots. This is found chiefly in Sweden.

PICEA. Pitchy; shells friate, black, the base and band behind are ferruginous. This is a very small insect, and is found in Germany.

METALLICA. This is of a brassy colour; the legs are ferruginous. It is found in divers parts of Saxony.

C. Lip horny, entire; the Jaw is bifid.

4-NOTATA. Black; the shells are truncate, with two rufous spots. It is found in some parts of Germany. The antennae are long; the five last joints are perfoliate; the shells are a little shorter than the body; the abdomen is acute.

4-PUSTULACA. Black, polished; edge of the thorax and spots on the shells are fanguineous. It is found in New Holland; the shells are truncate, shorter than the abdomen.

AGARICA. This also is black and polished; the antennae and legs are yellow. It is found in many parts of Europe, but not in our own country. The shells are truncate, shorter than the abdomen; the body is black and immaculate; the abdomen pointed.

D. Lip emarginate, conic; Jaw bifid.

FASCIATA. Black; the shells are marked with two rufous bands, the fore one spotted with black. It inhabits North America, and is a rather large insect; though less than the

GRANDIS, which is an African insect, and so named on account of its fize. This is black, and the shells are marked with two rufous spots.

* 4-PUSTULATA. Black; the shells are marked with two ferrugious dots. This is found in England, and in many other parts of Europe. The larva is long, hairy, and grey.

* 6-PUSTULATA. Black; shells friate, with three rufous spots. This is found chiefly in the northern parts of Europe. It is reckoned a very beautiful species; the antennae are pitchy; the thorax is ferrugious at the edge; spot at the base of the shells finatee, the middle one is uniform; that at the tip is small and round; the body beneath is rufous.

* NICIPENNIS. Rufous; the antennae, shells, and breast are black. This is found chiefly on trees.

* RUFIPES. This is a black insect; the head, thorax, and legs are ferruginous. The abdomen is black.

* VENCEA. This is of a fine scarlet colour; the shells are brassy and immaculate.

* RUFIFRONIS. Black; but the front, two spots on the shells, and legs, are ferrugious. This is found in divers parts of England, and is reckoned a small insect.

E. The Insects of this Section are characterized by a heart-shaped Lip, emarginate and crested.

* GERMANICA. Black; front and edge of the shells are ferrugious. Sometimes the shells are marked with a ferrugious spot or two. It deposits its eggs in the carcasses of other insects, and buries them under ground. It is very like the

* VESPELO. This insect, which is not uncommon in our own
own country, is the most remarkable of the European species. It is distinguished by having the wing-heaths considerably shorter than the abdomen, or as if cut off at the tips; they are also marked by two waved, orange-coloured transverse bars, the cell of the insect being black; the general length of the animal is about three-quarters of an inch. The vespillo seeks out some decaying animal substance in which it may deposit its eggs, and in order to their greater security, contrives to bury it under ground. Three or four of these insects, working in concert, have been known to drag under the surface the body of a mole in the space of an hour, so that not a trace of it has appeared above ground. The eggs are white, and of an oval shape: from these are hatched the larvae, which, when fully grown, are about an inch long, of a yellowish-white colour, with a scaly orange-coloured shield, or bar, across the middle of each division of the body. Each of these larvae forms for itself an oval cell in the ground, in which it changes to a yellowish chrysalis, resembling that of a beetle; out of which, in the space of three weeks, proceeds the perfect insect. This species is reckoned very elegant in form, but it generally diffuses a very strong and unpleasant smell; it flies with strength and rapidity, and is usually seen on the wing during the hottest part of the day.

Mortarium. Black; shells marked with two ferruginous bands; the club of the antennae is black; the hind-thighs are unarmed. This is found in many parts of Germany; preying on careafes and fangi.

F. Lip square and emarginate.

* Scarabeoides. Oval, black; the shells are marked with two ferruginous spots. Lunata. Oval, black; shells with a lunate yellow spot at the tip. It is about the size of the leaf, and is found in Germany.

Colon. Yellow; the spots on the thorax, and marginal spot on the shell, black. It is found in Sweden. The head is black; the antennae are yellow; the club is black; the thorax is downy, with six spots disposed in a fteak; the abdomen is black, edged with yellow.

* Atoma. This insect is smooth and black; the shells have crenate frrc; the legs are pale.

* Melanocephala. This is black and smooth; the shells are grey, with a common black spot at the base.

* Unipuncta. This is black; shells yellowish, with a common black spot. The shells are sometimes immaculate.

* Fimicaria. Black, immaculate; the shells are very smooth. It is found chiefly in dung.

* Minuta. This is black and small; the shells are frr; the legs of the fame colour. It is found in many parts of England.

* Pulicaria. This is oblong and black; the shells are abbreviated; the abdomen pointed. This is found chiefly among flowers.

G. The Insects of this Section have a long and entire Lip; the Antennae are serrate.

* Saxicorin. Smooth, polished, and of a chestnut colour; the antennae are black.

Depressa. Smooth, ferruginous; the shells are frrate, and the body is depressed. It is found under the bark of oak-trees.

H. Lip and Jaw unknown.

Of this section there are no English species; it will be sufficient to mention the following.

Insignita. Black; shells oblongly frrate, with two large scarlet spots. Common at Berlin; as is the next.

Nigricans. Blackish; the shells are smooth, with four yellow spots.

Histeroides. Black; the antennae and legs are red; the shells are abbreviated with a red spot. It inhabits Upfal, and is the size of a fohne.

Gen. Ch. Common Calyx ovate, imbricated, squarrose; its scales ovate-oblong, reflexed for about half their length, projecting on all fides, permanent. Cor. compound, radiant. Perfect florets in the disk scervs, of one petal, funnel-shaped, five-toothed; their tube scarcely more slender than the limb; female ones, in the radius, fewer, lanceolate, very long, often three-toothed. Stam. in the florets of the disk only. Filaments five, capillary, very short; anthers united into a cylindrical tube. Pist. in the florets of the disk imperfect, German thread-shaped, very slender; style thread-shaped, very long, villous; stigma fimple; in the females, German inerfely heart-shaped; style fimple, short; stigma two, bristle-shaped, the length of the style. Peric. none, except the unaltered calyx. Seeds in the disk none; in the radius solitary to each floret, somewhat membranous, inerfely heart-shaped, with a membranous, two-armed, emarginate border. Recept. chaffy, with linear fcales.

Eiff. Ch. Receptacle chaffy. Seeds compressed, inerfely heart-shaped, bordered; their down bordered, with two horns. Calyx squarrose.

Fifteen species are defined by authors, hardy herbaceous perennial plants, generally rather large, with the atpec of Sunflowers; their leaves opposite, whorled, or alternate; the flowers yellow. The horns of the seed are wanting in some of the species.

1. S. laciniatum. Jagged-leaved Silphium. Linn. Sp. Pl. 1301. Ait. n. 1. Pursh n. 1. Linn. fil. facs. 15. t. 3.—Stem hispid. Radical as well as leaf-stems pinna-tid; their segments deeply toothed.—On the banks of rivers in the western territories of North America, particularly on the Missippf, flowering from August to October. Pursh. Collins sent the seeds to Linneus. The stem is from eight to twelve feet high, simple, leafy, round, an inch thick, rough in the upper part with brilfy hairs. Leaves alternate, stalked, two feet long, and one broad, with four or five remote lobes at each side; strongly ribbed, rough. Flowers four inches wide; the ten scales of their rough calyx armed with strong taper points.

The stem is about five feet high, panicked at the top, with bright yellow, rather drooping, flowers, three inches in diameter. The radical leaves are a foot long, and nearly as broad, coriaceous, rough, sharply toothed, with very long footstalks.

4. S. perfoliatum. Square-stalked Silphium. Linn. Sp. Br. 1501. Ait. n. 3. Pursh n. 5. — Leaves opposite, triangular, thick, perfoliated. Stem square, smooth. Native of the Allegheny mountains, from Pennsylvania to Carolina, flowering from July to October, according to Mr. Pursh, who considers as a variety of this the connatum. Wild. Enum. 193. The present is a robust plant, frequent in large gardens or plantations, taller than a man. Leaves rough like a file, with bordered rough-edged footstalks, clasping the stem with their compound bases.

Flowers about two inches wide, with a smooth calyx.

5. S. connatum. Round-stalked Perfoliate Silphium. Linn. Mant. 574. Willd. n. 5. Ait. n. 4. Pursh n. 5. — Stem round, hispid. Leaves opposite, finely serrated, rough; combined at the base. — Found on the high mountains of Virginia and Carolina, flowering in August and September. Pursh. as well as Willdenow, jully infits on this being a very distinct species from the last, of which Michaux thought it a variety. The stem is round, covered in the upper part with deflexed brightly hairy. Upper leaves nearly entire, broad and perfoliate at the base. The flowers resemble those of the preceding.  

11. S. tertia. Fringed Three-leaved Silphium. Willd. n. 10. Pursh n. 11. — Stem cylindrical, smooth. Leaves three in a whorl, falked, lanceolate, slightly and minutely toothed, roughish. — Gathered at the base; the upper ones scattered and febrile. Panicle forked. Calyx fringed. — Retzius communicated to Willdenow a description of this, as a new species from North America, and Pursh saw a specimen in Mr. Lambert’s possession. The stem is to be four feet high. Lowell, as well as the uppermost, leaves scattered; those of the panicle febrile, two together. Calyx-scales in four rows. Florets of the radius broader than in the last; but those of the disk are shorter. Retzius.

12. S. florid-choripipum. Violet-stalked Silphium. Willd. n. 11. Pursh n. 12. — Stem cylindrical, smooth. Leaves about four in a whorl, lanceolate, rough, nearly entire, almofit febrile; fringed at the base; the upper ones scattered. Panicle forked. — Willdenow was indebted to Retzius for this likewise, but Mr. Lyon is said to have met with it in Carolina and Georgia, flowering in August and September. Mr. Pursh, who had seen this plant alive, says it resembles the preceding, but is at first sight distinguished from the purple smooth stem. By the description of Retzius, the specimen of S. trifoliatum in the Linnaean herbarium should seem rather to belong to the present species. See its description above.

S. folidegmoide, Linn. Sp. Br. 1302, proves the same plant as Rudbeckia opipartifolia, Sp. Br. 1296, under each of which names it lies in the Linnaean herbarium. It is also Heliocneus levis, Sp. Br. 1278, adopted from Gronovius; and is Willdenow’s Buphthalmum bethanайдes, n. 19, to which last genus it had originally been referred by Linnaeus in his Horia Uphehena. Finally this plant is now called Heliope levis in Pursh. p. 563, after Peronon. See Rud- 

BECKIA.

Silphium, in Gardening, contains plants of the tall-growing, herbaceous, perennial kind, of which the species cultivated are, the jagged-leaved silphium (S. hecinatum); the broad-leaved silphium (S. teretinimum); the hairy-stalked silphium (S. afferens); and the three-leaved silphium (S. trifoliatum).
Method of Culture.—They are all readily increased by parting the roots, and planting them out in the autumn or spring, where they are to remain in the borders and clumps. They may also be raised by planting the slips in the same manner: they should be afterwards managed as the perennial sun-flower. They are durable in the root, but decay annually in the stalk.

They afford a good variety and effect among other perennial plants in the summer season, when put out in a proper manner.

Silphium, in Ancient Geography, a country of Libya, which took its name from the plant. It commenced eastward towards Aziris and the isle of Platea, and extended westward as far as the Syris.

Silnostadt, in Geography, a town of Germany, in the county of WermSaturday; 3 miles N.E. of WermSaturday.

Silva, a river of Ruflia, which runs into the Kama, near the town of Silva, in the government of Perm.—Allo, a river of Ruflia, which runs into the Tchufovata, 16 miles N.E. of Perm.—Allo, a town of Ruflia, in the government of Perm; 12 miles N.W. of Solkmik.

Silva Fisa, a town of Switzerland, in the bilingual of Coire; 16 miles W.N.W. of Bormio.

Silvanez, a town of France, in the department of the Aveiron; 9 miles S. of St. Afrique.

Silvella, a town of Italy, in the department of the Upper Po; 3 miles E.N.E. of Cremona.

Silver, a river of the King's county, Ireland, which rises on the north-west side of the Sibbah-Bloom mountains, and takes a northerly direction. It has this name in Beaufort's and Arrowsmith's maps, but is called the Frankford river by Mr. Longfield, in his report to the Bog commissioners, from the small town of Frankford, which it passes. Mr. Longfield represents it as capable of being easily made navigable for canal boats, and also of being made to contribute to the drainage of the said bogs between which it flows.

In one part of its course, a little before it joins the Briuna, the Macartney aqueduct, a part of the Grand Canal, paffes over it.

Silver, in the Arts, Manufactures and Commerce, and in Domestic Economy, is a white malleable metal, fusible of a fine polish. In Chemistry, it is a simple inflammable body.

It is sometimes found in the native state, but more frequently combined with antimony, arsenic, or sulphur; forming the varieties of silver-ores; with which we shall begin, and then proceed to the affay and analysis, physical properties, and chemical properties of silver.

Silver-ores contain that metal either native, or alloyed with other metals, or mineralized by sulphur, and sometimes with the muriatic acid, the sulphuric acid, and in one rare instance with the carbonic acid.

Silver-ores principally occur in the rocks which have been denominated primary and transition rocks, and rarely in secondary rocks; but many rich argentiferous lead-ores occur in alpine lime flone and secondary flarta. The ores of silver are accompanied by calcareous spar and sulphate of barytes, and sometimes with quartz, horn-flone, jasper, and fluorspar. It has been remarked, that the warmer regions of the globe afford the greatest quantity of gold, but the richest repositories of silver are situated either in high latitudes or in elevated regions. The most celebrated silver-mines of Europe are in Sweden and Norway, at no great distance from the polar regions; and those which are in warmer latitudes, are almost all situated near the summits of alpine mountains commonly covered with snow, as at Allemont in France, and the mines of Mexico and Peru, in the centre of the Cordilleras. Silver never occurs, like gold, in alluvial soil, or the sands of rivers. After the mineralogical description of the ores, we shall give a short account of the principal repositories of silver at present known.

Native silver, Argent natif of Haüy, possesses the characters of silver extracted from other silver-ores, but is generally less malleable. The colour is pure white, but the surface is commonly tarnished, and is of a yellowish-brown or greyish-black. Native silver occurs crystallized in cubes and octahedrons; the crystals are small, and are often aggregated, forming beautiful ramifications; the branches sometimes cross each other in a rectangular direction, and are reticulated. It is sometimes in leaves and sometimes capillary, and when the filaments are much entangled, it becomes nearly compact. Native silver is also found in flake-like malleable of considerable size. In the year 1750, there was found in the famous mine of Hemmels Furt, near Freyberg, in Saxony, a mass of native silver, which weighed one hundred weight and a quarter; in 1771 an equally large mass was found. It is also mentioned by Albini, in his "Meinichische Berg Arconicke," p. 30, "that at Schweibrice, in 1748, a rich silver vein was discovered; and so large a block of native silver cut out, that Duke Albert of Saxony defended into the mine, and used this large block as a table to dine upon. It was melted into four hundred centres of silver: a centner is 110 lbs."

(Jameison's Mineralogy.) Native silver is fusible into a globule, which is not altered by a continuation of the heat; it is scarcely ever pure: the metals with which it is alloyed are commonly gold, copper or arsenic, and iron. Native silver alloyed with gold is rare; its colour is intermediate between silver-white and brazi-yellow; it often contains a considerable proportion of gold. The flones which form the mass of native silver in the mine are very numerous; it sometimes appears to be infiltrated into the filaments, sometimes to vegetate on the surface, and in other instances to be intimately combined with the sublimate of the flone. It is found in almost all the silver-mines that are worked in Europe or America; but the mafles discovered in America are not so large as some which have been found in Europe. The pace, a most abundant ore in Peru and Mexico, confits of minute particles of native silver, intermixed with brown ody of iron; but the particles are too small to be seen without a lens, and bear but a very small proportion to the mass. Silver rarely occurs in detached grains, like gold or platina.

Antimonial silver-ore is composed of silver combined with antimony, without any other sublimate. Its colour is tarnished; it has a thinning metallic luster, which is often tarnished superficially reddish or yellowish. It is distinguished from native silver by its brittleness, being scarcely malleable; the structure is lamellar. It is commonly found crystallized in four-sided and six-sided prisms, having the sides deeply striated; its specific gravity is from 9.4 to 9.8. It melts easily before the blowpipe, giving a white smoke from the ody of antimony, and leaving a globule of silver. Its constituent parts are from 76 to 84 silver, and from 16 to 24 of antimony. Antimonial silver is rare, particularly the regular crystallizations of it. It occurs in veins with calcareous spar and sulphate of barytes, and is accompanied by galena and native silver. The foliated structure of antimonial silver differentiates it from white cobalt-ore, which has a granular structure; it differs also from arsenical pyrites, both by its structure and softness; the latter is extremely hard. Antimonial silver yields to the knife.

Arsenicel silver-ore is harder than the former species; its structure
structure is less perfectly lamellar, the fracture more even, and the lustre weaker. It occurs in small, globular, and kidney-shaped masses; before the blowpipe it yields the smell of garlic, peculiar to arsenic; a globule of silver more or less pure remains. The constituent parts of this ore are given by Klaproth as under:

| Silver   | - | - | 16 |
| Arsenic  | 35 |
| Iron     | 44 |
| Antimony | - | - | 4 |

Arsenic silver-ore usually occurs with native arsenic; dark red silver-ore, brittle silver-glance, lead-glance, and brown blende, in calcareous spar. It is a scarce mineral.

Corrosive silver-ore, or Horn-ore; Argent muriaticus, Fr. This mineral is distinguished by its translucency; it has a waxy or glistening lustre, is soft and tenacious, and yields to the nail. From these characters it is supposed to bear some resemblance to horn, whence its name. The most common colours of this mineral are pearl-grey, passing into greenish or reddish-blue or brown; it acquires a brownish tarnish. Horn-ore occurs crystallized in small cubes, and is sometimes, though rarely, angular and capillary; it is more common in laminae or small masses, or forms a coating on native silver. It is fusible in the flame of a candle. Under the blowpipe, on charcoal, it yields a globule of silver, and gives out a disagreeable odour, from the escape of the muriatic acid. Its specific gravity is from 4.75 to 4.80. Horn silver-ore is accompanied with native silver, black silver-ore, brown oxide of iron, quartz, and sulphate of barytes. It is supposed by some mineralogists to be the most recent formation of silver-ore. It occurs in veins in the silver-mines of Europe and America, and in Siberia, and is observed generally to occupy the upper part of the vein. According to Klaproth, it consists of 68 parts silver, 21 muriatic acid, a small quantity of sulphuric acid, with a portion of iron and earthy substances; but the latter may be considered as accidental. Horn-ore is rather a fœtida mine.

Vitreous silver-ore; Silver-glance, or sulphurified silver; Glafierus, Werner; Argent sulphureus, Haüy. Its colour is a dark lead-grey; it is malleable, and may be cut with a knife; the surface, when cut, is shining, and has a metallic lustre; in its natural state it has an iridescent tarnish. It occurs in a variety of forms, in branches, fibres, small irregular masses, and laminae, and is also frequently crystallized; the crystals are commonly the cube or octahedron, and the dodecahedron, with rhomboidal faces: the fracture is flatly conchoidal. The specific gravity of this ore is from 7.0 to 7.2: its constituent parts are from 73 to 85 silver, and from 15 to 25 of sulphur. When heated to a red heat, the sulphur is gradually sublimed, and the silver appears in filaments, dendritic or reticulated. Many mineralogists suppose that capillary native silver owes its formation very frequently to a similar kind of decomposition of vitreous silver-ore. This mineral occurs in veins, and is always accompanied with other ores of silver, and with galena, iron pyrites, brown blende, sulphate of barytes, calcarious spar, and quartz. It is found in almost all silver-mines in various parts of the globe.

Brittle vitreous silver-ore; Brod glafier, Werner; Argent noir, Haüy; differs from the former by its brittlenefs, splendour, and colour. The colour is intermediate between iron-black and dark lead-grey; it is brightly splendent externally; internally it alternates from shining to glistening; the lustre is metallic. It occurs massive and disseminated, and in thin small plates, and frequently crystallized in six-sided prisms, variously terminated, and in rectangular four-sided tables: the latter crystals frequently intersect each other, forming the cellular structure. The tabular crystals are generally minute. The fracture of the massive vitreous ore is uneven; that of the crystals imperfectly conchoidal. This ore is soft, brittle, and fusible by the blowpipe; the sulphur, arsenic, and antimony, are partly volatilized, and a globule of imperfectly malleable silver, accompanied with a brownish scoria, remains. According to Klaproth, the brittle vitreous silver-ore, from a mine near Freyberg, contained:

Black sulphurised silver-ore; Silber schwarz, Werner; differs from vitreous silver-ore by its want of lustre: it occurs massive, corroded, and in powder; the fracture of the former is uneven; the streak shining and metallic. It yields to the knife, and is fusible into a flag, containing globules of silver.

Red silver-ore, or Ruby silver; Roth gläser, Werner; Argent rouge, and Argent antimonious sulphure, Fr. The colours of this mineral are various shades of red, passing from a bright-red to dark-red, and reddish-grey or black. When scraped, the powder is of a crimson colour. The crystallized varieties are translucent, or semi-transparent, and the transmitted light is a carmine, light blood, or cochineal-red. It occurs massive, disseminated, and in thin plates, and crystallized in hexahedral prisms, variously terminated, and in dodecahedrons, with triangular faces, nearly similar to the crystallization of calcarious spar, called dog-tooth spar. The primitive form of the crystal, according to Haüy, is an obtuse rhomboid, whose plane angles are 104° 28' and 76° 22', and the inclination of the faces 109° 58' and 70° 32'. The fracture is usually uneven, and imperfectly conchoidal: its lustre externally is shining and metallic; internally glistening, sometimes metallic. It is brittle, soft, yielding easily to the knife. Before the blowpipe it gives out a copious smoke, with an arsentic smell, and leaves a globule of silver. Its specific gravity is about 6.6. There are several minerals which have a red colour, and may at first sight be confounded with red silver, as the fulphuret of arsenic, or realgar; but this mineral becomes yellow when powdered. Cinnabar has a greater refulbance, but the specific gravity is 7, and it is entirely volatilized by the blowpipe. Red oxyd of copper has a specific gravity of 3.9, and is usually accompanied with native copper, malachite, and brown iron ocelite; it also effervesces with nitric acid, and communicates to a solution of ammonia a blue colour. By these characters it may be known from red silver-ore. Werner has divided red silver-ore into two sub-species, the light and the dark. Klaproth analyzed this mineral, and found it to contain only silver, sulphur, antimony, and oxygen. Proust has shown that there are two kinds of red silver-ore, the one containing arsenic, and the other antimony. The constituent parts, as given by Klaproth and Vauquelin, are:

According to
According to the analysis of Proud, a variety of this ore contained nearly .75 parts of metallic silver, and .25 of metallic arsenic. Red silver-ore occurs in veins, but is always intermixed with other minerals, particularly with compact galena, cobalt, sulphuret of arsenic, native arsenic, grey copper-ore, and sparry iron-ore; and has a matrix of calcareous spar, sulphate of barytes, fluor spar, or quartz. It is a common ore in silver-mines, both in Europe and America; the dark-red ore is considerably more productive than the light-red.

Silver amalgam consists of pure silver combined with mercury. It has been found in the silver-mine of Salberg, in the province of Dalecarlia, in Sweden, in the mines of Deux-Ponts, in the Palatinate, and in some other places, either in thin plates or grains, or crystallized into octahedrons and dodecahedrons. It is sometimes semi-fluid. Its colour is silvery-white or grey, the fracture conchoidal, and the lustre metallic. It is soft, breaks when cut, and whitens the surface of gold or of copper; when rubbed upon them warm before the blowpipe the mercury evaporates, and leaves the silver pure. The constituent parts, given by Klaproth, are

White silver-ore has a near resemblance to compact galena. The colour is a light lead-grey, palling to steel-grey; it occurs massive and disseminated, and is generally intermixed with cubic galena. The fracture is mottled commonly even, but sometimes fine-grained and uneven, and also fibrous; the internal lustre is glinting and metallic; the streak shining. It is soft and brittle. The specific gravity is 5.3. Some mineralogists think this ore should be classed with the argentiferous ores of lead. According to Klaproth, different specimens from Hemmels Furil, near Freyberg, contain, of the

Carbonate of Silver.—This ore has hitherto been only discovered in the silver-mine of Wincellaus, in Swabia: it occurs sometimes in masses, and sometimes disseminated through other minerals. Its colour is a greyish-black; its fracture uneven, with a glinting metallic lustre; it is brittle and heavy, and effervesces with acids; it melts easily under the blowpipe. According to Mr. Selb, who first described this mineral, it contains

It contains also a slight trace of copper.

Besides the above ores of silver, there are ores of other metals which contain a portion of silver, and have been classed by some mineralogists with silver-ores. An argentiferous variety of grey copper-ore, of an iron-black or steel-grey colour, has received the name of black silver-ore. It occurs massive, disseminated and crystallized in tetrahedrons; the fracture is small conchoidal, with a shining metallic lustre; it is brittle and brittle. An ore which is a combination of lead, bismuth, and silver, has received the name of bismuthic silver. Its colour is a light lead-grey; it occurs disseminated, but rarely ever in masses; the fracture is fine-grained, uneven, with a glinting metallic lustre; it is soft and rather brittle; before the blowpipe metallic globules appear on the addition of borax, which unite; the bottom is brittle, and of a tin-white colour; the flux acquires an amber colour. According to Klaproth this ore contains

Argentiferous lead-ores are common in Great Britain and in various parts of Europe. Many of these ores are not sufficiently rich to repay the expense of extracting the silver. It is procured in considerable quantities in North Wales, the north-west parts of Yorkshire, and in the counties of Durham and Northumberland. Indeed, many lead-ores in these counties contain a much larger portion of silver than the average proportion of that metal in the ores of Mexico and Peru; but mineralogists do not class them with silver-ores.

Silver Mines in Great Britain.—Silver-ores, properly so called, are of rare occurrence in our island. A few years since, a vein of silver was worked with great profit in the parish of Alva, in the county of Stirling, in Scotland. The ores were native silver, and vitreous silver-ore. From forty to fifty thousands pounds sterling value was extracted before the ore was exhausted, after which the search to recover the vein proved fruitless, and since that time no silver-mines have been worked in that country. The silver-ores at Alva were accompanied with copper, lead, and cobalt-ores, with a matrix of calcareous spar, and sulphate of barytes. It is supposed by Dr. Millar that the veins traverse rocks of argillaceous porphyry.

Cornwall and Devonshire yield the richest argentiferous lead-ores of any part of Great Britain; but the quantity of these ores is small. In the former county a small quantity of native silver, with other silver-ores, have been occasionally found. We have been favoured with the following account of the present state of the silver-mines in those counties from Mr. Mawes, author of Travels in Brazil, who visited them in the summer of 1815.

From the lead-mines of Ben-Aliden, in Devonshire, a large quantity of silver has been extracted. The vein is situated in killas, (see Slate,) and is filled chiefly with fluor spar and galena. It has been worked to the depth of 110 fathoms: the silver extracted from the north and south vein averages about 70 ounces to the ton of lead. Another vein, running in a more easterly and westerly direction, situated in the same killas, produces 170 ounces of silver in the ton of lead. The vein is worked under the river Tamar. These mines are of considerable importance; during the last few weeks, the silver extracted from the lead procured here exceeded six thousand ounces. The works are extensive, and said to be well conducted.

About four miles to the south-east of Callington is a silver-mine of another description: the vein is situated in a similar rock of killas or chlorite slate. The vein was first worked for copper, but native silver and lead-ore were discovered in it. The mine is called Huel Jewel: the thickness of the vein rarely exceeds three or four inches. In many of the cavities were found a considerable quantity of capillary native silver, with galena, red silver-ore, and sulphuret of silver.
Silver.

The ores were exceedingly rich, and promised at one time an ample recompense to the adventurers.

The Hurland copper-mine, near Redruth, has produced a considerable quantity of native silver in a small vein, branching from the principal vein. Some of the fibres of silver were more than four inches long.

There is a lead-mine near Truro worked at this time, and a considerable quantity of silver is extracted from the lead, as it yields 100 ounces per ton.

Near Penzance, on the north coast of Cornwall, there was a mine formerly worked close to the sea, which produced lead-ores in various rates, and a portion of horn-silver, fine specimens of which are in various cabinets. Mr. Mawe found some specimens of this rare mineral among the refuse of the mine.

At Comb-Martin, in North Devon, are some lead-mines, which were formerly celebrated for the silver, but at present they are not productive.

Argentiferous lead-ores are the common lead-ores of the northern counties and of Wales; they vary in the quantity of silver they contain, from a few ounces to 45, 65, or 80 ounces of silver per ton. Some few rare instances have occurred in the north-west part of Yorkshire, of their exceeding the latter amount. On the average, the argentiferous lead that is calculated to extract the silver does not contain 20 ounces per ton; for some it has been calculated at 17 ounces.

According to Lehmann, there are no known lead-ores in the world but what contain silver, except that of Villoch, in Carinthia. (Lehmann fur Lesc Mines.) But according to Dr. Watton, the quantity of silver necessary to defray the expense of extracting, and the loss of lead, was nine ounces per ton, when lead was at the price of 15l. per ton. The price of lead is now 25l. per ton, and though silver be more advanced, yet the difference in the relative prices of each, taking the above as a standard, is such, that to repay the expense of extraction, the lead should contain about fifteen ounces of silver in every ton.

It is not to be expected that the proprietor of any lead-mines rich in silver should be forward in declaring to the world the quantity of silver they contain. The proprietor of the lead-mine containing silver may indeed work the same without any apprehension of its being taken from him under the pretence of its being a royal mine; yet the crown, and persons claiming under it, have the right of pre-emption of all the ore which may be raised. There was an act of parliament passed in the fifth year of William and Mary, entitled, An act to prevent disputes and controversies concerning royal mines. This act declared, that every proprietor of a mine of copper, tin, iron, or lead, should continue in possession of the same, notwithstanding its being claimed as a royal mine, from its containing silver or gold; but it is further enacted, that the crown, or persons claiming under it, should have the privilege of purchasing all the ore which should be raised out of such mine, at the following prices, when made clean and merchantable: for copper-ore, at the rate of 16l. per ton; for tin-ore, except that of Devonshire and Cornwall, 40l.; for iron-ore, 40l.; and for lead-ores, 9l. The standard price then fixed, particularly for lead, was much higher than the ordinary price of the ore in which there was no silver. Owing to the existence of this act, it is probable that we are not acquainted with the quantity of silver at present extracted annually. We are informed, that the value of silver produced by the lead-mines of colonel Beaumont, in Northumberland and Durham, is not less than 4000l. per annum; and other large proprietors also extract a considerable quantity of silver from the lead-ores in the northern counties. At present we believe that there is no silver extracted from the Derbyshire lead-ores.

It appears from Hollinghead's Chronicle, that silver was formerly extracted from lead in various parts of the island. In the reign of Edward I. 1600 pounds weight of silver was obtained in the course of three years, from a mine in Devonshire, which had been discovered towards the beginning of his reign: this mine is called a silver-mine by the old writers, but it appears to have been a mine of lead that contained silver. The lead-mines in Cardiganshire have at different periods afforded great quantities of silver; Sir Hugh Middleton is said to have cleared from his two thousand pounds per month, and to have been enabled thereby to undertake the great work of bringing the New River from Ware to London. The same mines yielded, in the time of Charles I. eighty ounces of silver in every ton of lead, and part of the king's army was paid with this silver, which was minted at Shrewsbury. Sir J. Pettie's Essay on Metal Works.

A mint for the coining of Welsh silver had been previously established at Aberystwith; the indenture was granted to Thomas Buful, for the coining of half-crowns, shillings, fixpence, two-pence, and pennies, and the money was to be flanked with the ottrich feathers on both sides. In 1671 nearly 3000 ounces of this Welsh bullion were minted at one time at the Tower. Weblin, in his History of Metals, published in 1671, makes mention, from his own knowledge, of two places in Craven, in the West Riding of Yorkshire, where formerly good argentiferous lead-ore had been procured. One of the places was Bronchithore Moor, in the parish of Skiddawh; the ore held about the value of 67 pounds of silver in 2 tons; the other was at Skelhornefield, in the parish of Giburn; it had formerly belonged to a person of the name of Pudsey, who is supposed to have coined it, as there were many shillings in that country which the common people called Pudsey shillings. There are several melting-houses at Holywell, in Flintshire, where silver is extracted from lead. According to Mr. Pennant, at one of the largest of these houses in the year 1754, more than 12,000 ounces of silver were produced, but in the subsequeut years the quantity of silver appears to have considerably diminished. The silver extracted from lead is sold principally to the manufacturers at Sheffield and Birmingham.

The silver is extracted from the lead by the oxidation of the latter metal in a reverberatory furnace of a particular construction, for the admission of air on the surface of the lead in a state of fusion. A shallow vessel or cupel is filled with prepared fern-ashes rammed down, and a concavity cut out for the reception of the lead, with an opening on one side for the mouth of the bellows, through which the air is forcibly driven during the process. The French smelters cover the surface of the ashes with hay, and arrange symmetrically the pieces of lead upon it. When the fire is lighted, and the lead is in a state of fusion from the reverberation of the flame, the blast from the bellows is made to play forcibly on the surface, and in a short time a crust of yellow oxide of lead, or litharge, is formed, and driven to the side of the cupel opposite to the mouth of the bellows, where a shallow flue or aperture is made for it to pass over; another crust of litharge is formed and driven off, and this is repeated in succession till nearly all the lead has been converted into litharge and driven off. The operation continues about forty hours, when the complete separation of the lead is indicated by a brilliant light on the convex surface of the melted mass in the cupel, which is occasioned by the removal of the last crust of litharge that covered the silver. The French introduce water through a tube into the cupel, to cool the silver rapidly and prevent
its spiritng out, which it does when the refrigeration is gradual, owing probably to its tendency to crystallize. In England the silver is left to cool in the cupel, and some inconvenience is caused by the spiritting, which might be avoided by the former mode.

The silver thus extractd is not sufficiently pure; it is again refined in a reverberatory furnace, being placed in a cupel lined with bone-ashes and exposed to a greater heat; the lead which had escaped oxydation by the first procefs is converted into litharge, and absorbed by the ashes of the cupel.

The last portions of litharge in the firft procefs are again refined for silver, of which it contains a part that was driven off with it. The litharge is converted into lead again, by heating it with charcoal; part is sometimes sold for a pigment, or converted into red lead. The loss of lead by this procefs differs considerably, according to the quality of the lead. The litharge commonly obtained from three tons of lead amounts to 58 hundred weight; but when it is again reduced to a metallic state it seldom contains more than 21 hundred weight of lead, the loss on three tons being about eight hundred weight. The Dutch are paid to extract the silver from the same quantum of lead, with a loss of only 51 hundred weight.

Silver Mines of France — The mine of Allemont, ten leagues from Grenoble, in the department of Iere, is situated near the summit of a mountain, composed of thin beds of mica-flake and hornblende, curiously contorted and broken. Its elevation is about 3000 yards above the level of the sea. The veins are numerous, and run in all directions; the mineral appears to have filled also numerous fissures in the rock. The ores are native silver, vitreous silver, red silver-ore, and horn-silver. Silver appears also disseminated in a kind of ferruginous clay, and is accompanied with various ores of cobalt, antimony, arsenic, and nickel. The matrix was ferruginous clay and carbonate of lime, mixed with albites, epidote, and calcareous fpar. The veins were much richer near the surface than at a great depth, and the working of this remarkable mine is at present nearly abandoned. Red silver-ore has also been found in the Voilges, in the department of the Upper Rhine, in a vein of argentiferous copper-ore. Indications of silver have been traced in other districts of France. The lead-ores of some parts of France are also sufficiently rich in silver to repay the expense of extraction.

The silver mines of Spain are the most ancient known in Europe. It appears, as well from the accounts of historians, as from the numerous vestiges of ancient workings, that the operations were continued on a considerable extent. The most remarkable mine was that at Guadalâlcar, in Andalusia, in the Sierra Morena, five leagues to the north of Seville; the ore which it contains is the red or ruby silver, in a matrix of compact galena. Since the discovery of South America no attention has been paid to the mines of Spain, though formerly fo productive both of silver and gold.

Germany.—The mining district of Freiberg, in Saxony, contains numerous veins that yield silver. The veins that traverse rocks of gneifs are generally composed of quartz, calcareous fpar, and fluor fpar; they inclde argentiferous lead, vitreous silver-ores, ruby silver, and grey argentiferous copper-ore. The mine at Annaberg, according to Klaproth, contains muriate of silver (horn-ore) mixed with much clay, which is imbedded in compact lime-stone. The mines of Schneeberg, in Misnia, and of Hartz, in Hanover, contain argentiferous lead, accompanied with proper silver-ores.

Hungary.—The mines of Schemnitz and Cremnitz, in Hungary, have been long celebrated, both for the richness of their productions and the immense extent of the opera-

tions. The rocks in which the mining operations are carried on, are described as being composed of an argillaceous clay, mixed with quartz or fhoil, or particles of calcareous fpar. "To this rock baron Born has given the name of the metalliferous rocks, fachum metalliferum; it is described by him as containing three principal veins, running from north to south, and parallel with the river Gran, following even the windings of the river. From this circumstance we should infer, that the river itself had originally taken the course of a fracture by another vein. The dip or inclination of all the veins is from west to east, varying from 30 to 70 degrees. In one part of the vein, called the foot-vein, it is joined with an argentiferous white vein, which runs along with it on the hanging side, and from the place of junction the vein is found to contain silver. In this white clay are occasionally found nodules of fpar and mafes of quartz, which yield from four to five ounces of silver in the hundred weight. The second great vein at Schenmiz has nearly the fame characters as the firl. The third great vein is more irregular in its inclination, and the ores are not so rich in silver, but in some parts it contains a considerable quantity of gold.

Some notion may be formed of the extent of the mining operations at Schenmiz, from the gallery or level called the Emperor Francis' Gallery, by which the whole of the royal mine is drained and cleared of water. This gallery, which forms a very considerable excavation, and is carried through hard rock, was a work of immense labour and difficulty; it is five English miles in length; it was begun in 1748, and finished in 1765.

The mountains round Kremnitz, according to baron Born, are composed of the fame metallic rock already described; but according to Patrin, they consist of primitive trap. At this place very extensive operations, which were begun at least a thousand years ago, have been established on a large and rich gold vein, and some of its branches. The rock is a white folid quartz, mixed with fine auriferous red and white silver-ore, and with auriferous pyrites. At the depth of 160 fathoms, the vein continued rich and productive.

Konigberg is another mining-town of Hungary, some miles to the north-west of Schenmiz. The valley in which this place is situated is bounded on one fide by the fame kind of metallic rock, and on the other, towards the north, by granite mountains. In the royal mine, at the time it was visited by baron Born, the vein was observed to run between the metallic rock, which formed its hanging fide, and the granite, which was its fiding or lower fide. The vein is grey quartz, mixed with auriferous pyrites. The firl fteam or fire-engine established in the Lower Hungarian mines was erected at Konigberg, in 1725, by Isaac Porter, an Eng-lish engineer, who was then in the imperial service.

Bohemia.—The circle of Sazis, in Bohemia, abound in various metallic ores, among which the ores of silver occasionally predominate. The prevailing rocks are gneifs and argillaceous fentus. The veins at Carkarineberg traverse gneifs, and generally run in a north and fouth direction, and parallel to the mountain in which they are situated. But there are also some powerful veins which cross the mountain. One of this nature is described, which seems to be infenibly blended with the mountain rock. The vein-stone is also of the fame kind of rock, but occasionally alluming the characters of a variety of granite. It is observed, that the vein, which seldom exceeds a foot in width, diminishes in thickfews when the containing rocks become harder; and when the fides are found incrusted with a ferruginous clay, it appears to be richer in ores. Fiffures from the fides of the vein are found to improve it: a fine white clay, with quartz.
quartz imbedded in it, indicates rich ore; but a coarse clay, destitute of quartz, especially when it increases in quantity, and occupies the whole vein, renders it unproductive, or entirely barren. The ores of the vein now described are rich silver and copper pyrites, with fluor spar, blende, various copper-ores, and sometimes native silver and copper.

Josachimihal, a place in the same circle, has been long celebrated on account of its valuable mines. The prevailing rocks are described as grey micaeous and quartzose clay-flate, which at a great depth became more of an argillaceous nature, soft, foliated, and of a black colour. The mountains around this place have a gentle declivity towards the south, but run in lofty ridges to the east, north, and west, and are intersected by deep valleys. This inequality of surface affords great accommodation to the miners to open numerous galleries, which converge to the south, and to the valley in which stands the town of Josachimihal. All the galleries and works of this district are divided into six different fields, belonging to the same number of companies, and they are drained by two deep drifts or levels; the one of which runs in a direct line 1,600 fathoms; but including its several branches, its whole length is 4,500 fathoms. The depth under the highest point of the mountain is 170 fathoms: the second great level, which runs through the space of 3,600 fathoms, and in a direct line 1,500 fathoms, is 20 fathoms deeper than the first; but the operations in the mines have been carried to a much greater depth; for at the time in which they were visited by Ferber, before 1774, the perpendicular depth under the surface was from 200 to 350 fathoms, and, excepting the mines in the Tyrol, were then considered as the deepest in the world.

The thickness of the veins varies from one inch to two feet; and the vein-planes are a whitish or blueish clay, argillaceous flate, and reddish horn-flate, or petro-filce, which is the matrix of the richest ores. The silver-ores which are found in this mining district are, native silver, which is attached to different vein-planes, and allures various forms; vitreous silver-ore, which is dug out sometimes in very large masses, and is considered as a very rich ore; one hundred weight being commonly valued at 180 marks of silver: red silver-ore, sometimes beautifully crystallized and transparent, is attached to red horn-flate or calcareous spar; and white silver-ore has sometimes but rarely appeared.

The silver-mines of Besslau, in the circle of Tabor, are in hills of a gentle declivity, and composed of grey or bluish clay-flate, in which appear figures of greenish limestone, or semi-indurated pot-flate. These mines were formerly rich in native silver, and other ores of that metal. A vein to the west of this place, which traversed a hard rock, contained reddish-coloured felspar, with galena, blende, and a little silver; but from the part where a vein containing white arsenical pyrites came into the hanging side, the vein produced native silver, vitreous, red, and white silver-ore. Another vein in the same place, which is from two inches to one foot in width, is observed to be richest where it is thickest. It is chiefly enriched by an undulating black clay fillure, which appears sometimes in the hanging side, and then it produces red and white silver-ore. When crofted by veins running from east to west, it appears to be cut off and barren, till beyond the place of junction it again becomes productive in its former course.

Sweden.—The silver-mines of Salberg, in Wettmania, are about 28 English miles from Upfal. The ore is an argen-
tiforous galena, yielding from one mark to a mark and a half of silver per quintal; it is in compact lime-flate, and has been worked to the depth of 150 fathoms. The average profits amount to about 400 cl. and one-eighth is paid to the king.

Porter's Travels.

Norway.—The silver-mines of Konigberg, in Norway, are situated in mountains of moderate height, composed of nearly vertical beds of mica-flate with garnets, and of grey quartz mixed with fine black mica, and a little lime-flate and red horn-flate. Other beds are composed of a ferruginous rock, which, in the upper part of the mine, is 33 feet thick, but in the lower not more than 6 feet thick.

The veins are from half an inch to two feet or more in thickness, and cut the strata transversely. The matrix of the ore is granular lime-flate, sometimes intermixed with flour spar. Enormous masses of native silver have sometimes been found in this mine; one is mentioned as weighing 2,200 lbs. The common ores are native silver and vitreous silver. The veins are most productive in the ferruginous rock. The annual produce is about 5,000 cl., weight of silver.

Asia.—The silver-mines of Zmeof are situated in that part of the Altanian chain of mountains which lies between the Oby and Irtysh, from 50° to 52° north latitude. The annual produce has been stated at 60,000 marks of silver, which is alloyed with about 3 per cent. of gold. The mines of Nerteflink in Daouria, near the river Anur, yield argentiferous galenas, producing about 30,000 marks of silver, and containing 14 per cent. of gold. The Russian merchants who trade to China bring back ingots of silver, from several ounces to a pound weight, in exchange for their commodities; hence it may be inferred, says Patrin, that there are silver-mines on the frontiers of China. Patrin, Hilt. des Mines.

America.—The most productive silver-mines in the world are those of South America and New Spain. Those of Peru, for many years after its conquest by the Spaniards, yielded the greatest quantity of silver; but at present the mines of Mexico are the richest. The mines of America furnish both silver and gold; and in making an estimate of their riches, we must take an account of each of these metals. The following table, given by M. Humboldt, will show the distribution of these mineral treasures in the different parts of the new world; the kilogramme being 2 lbs. 3 oz. 5 dr. avoirdupois, or rather more than 2 lbs. 8 oz. (troy).

The above was the annual produce of the different districts, at the beginning of the 19th century; from which it appears, that the total weight of the precious metals from all the mines in America, reduced to English pounds troy, is 45,780 lbs. of gold, and the enormous quantity of 145,000 lbs. of silver; equal in weight to one-third of the tin produced by the mines in Europe. Dr. Adam Smith, in his "Wealth of Nations," values the gold and silver annually exported into Cadiz and Lisbon at only six millions sterling, including not only the registered gold and silver, but that which may be suppressed to be smuggled. This estimate is only two-fifths of the real annual amount.

The mountain of Potosi has furnished, since its discovery in 1545, a mass of silver equal in value to 234,093,840 cl. sterling.
SILVER.

The mountain is 18 miles in circumference; it is composed of slate, but has a conical covering of porphyry, which gives it the form of a fugar-loaf, or basaltic hill; it rises 657 toises, or 480 yards, above the surrounding plain. The richness of the veins has diminished, as they have been worked to greater depths. At the surface of the earth, the veins of Rica, Centeno, and Mendicta, which traverse primitive slate, were filled with native silver, and silver-ores throughout their whole extent. The metallic mafes rose in ridges or crests above the surface, the sides of the vein having been destroyed either by water or by some other cause. In 1445, minerals containing from 80 to 90 marces of silver per quintal were common. In the year 1574, according to Acosta, the average richness of the ore was eight or nine marces per quintal. In 1607, the mean wealth of the ores was not more than an ounce and a half to the quintal. The ores are now extremely poor, and it is on account of their abundance alone that the works are still in a flourishing state: for from 1574 to the year 1789, the mean quantity of silver in the ores has diminished in the proportion of 170 to 1; while the absolute quantity of silver extracted from the mines of Potofo has only diminished in the proportion of 4 to 1.

About six miles from Pacho is the mountain Jauvichora: it is distinguished by the name of the Silver mountain. It is about half a mile in diameter, and only about 30 yards in depth: it is composed of brown iron-flone, which is intermixed with pure silver. This flone does not yield more than nine marces of silver in 500 lbs.; but there is a friable white clay met with in the middle of this mass of ore, which yields from 200 to 1000 marces of silver in every 50 cwt. The mountain is penetrated in all directions, without any attention to security; so that it is expected it may fall in, in the course of a few years. According to Helms, this mountain yields annually 200,000 marces of silver.

The veins of silver at Potofo are in slate, which Humboldt considered as primitive: this slate is covered with a clay porphyry, containing garnets. The mines of Gualgayoc, in Peru, are in the Alpine lime-flone. The veins which furnish nearly all the silver exported from Vera Cruz are in flate, porphyry, grauwacke, and Alpine lime-flone: the principal of these veins are those of Guanxato, Zacatecas, and Catore. The vein of Guanxato yields more than one-fourth of the silver of Mexico, and a fifth part of the total produce of America. This vein is, in some parts, from 147 to 150 feet in length, including the branches, and has been wrought from Santa Isabel to San Bruno to Buena-Vista, a length of 42,000 feet. The most celebrated mines in Mexico are elevated from 6000 to 9000 feet above the level of the sea. In the Andes, the mines of Potofo, Ocuro, Pas, Pacho, and Gualgayoc, are in regions higher than the loftiest summits of the Pyrenees. A mass of rich silver-ore has been discovered near the small town of Michiampa, at the absolute height of 13,450 feet. The great elevation of the Mexican mines is peculiarly advantageous to the working of them, as the climate is temperate, and favourable to vegetation and cultivation.

The part of the Mexican mountains which at present contains the greatest quantity of silver lies between the twenty-second and twenty-fourth degrees of latitude; and it is not a little remarkable, that the metallic wealth of Peru should be placed at an almost equal latitude, on the other side of the equator. In the vast extent which separates the mines of La Paz and Potofo from those of Mexico, there are no others which throw into circulation a great mass of the precious metals, but those of Pasco and Chota. The isthmus of Panama and the mountains of Guatemala contain, for a length of 600 leagues, vast tracts of ground, in which no vein has hitherto been worked with success.

The province of Quito, and the eastern part of the kingdom of New Granada, from the eighth degree of south latitude to the seventh degree of north, are equally poor in metallic wealth. It would not, however, say Humboldt, be correct to infer that these countries, which have been convulsed and torn by volcanoes, are destitute of the precious metals. Numerous metallic repositories may be concealed by beds of bafalt, and other rocks of supposed volcanic origin. It should, however, be remarked, that some of the rocks, which Humboldt enumerates as very metalliciferous, are by other geologists considered of volcanic origin, particularly clink-flone-porphyry, and other porphyries containing hornblende, but distinguished by the absence of quartz and common felspar.

The mines of Huantajaya are celebrated for the great quantities of native silver they formerly produced. They are situated in an arid desert, and surrounded by rock-fall, near the shores of the Pacific ocean, at no great distance from the small port of Yquique, in the vicinity of Lima. These mines are remarkable for the great elevation of silver-mines in Spanish America, being placed on a low and gentle declivity. Their produce is native silver, vitreous silver, and horn silver; the annual amount is about 30,000 lbs. of silver, or 80,000 marces.

The silver-mining operations of Chili, according to Humboldt, are in general not productive; but the vein at Uspallata contains pasos to rich, that the produce is from 2000 to 3000 marks in every 5000 lbs., or from 40 to 60 marces per quintal. Molina, in his History of Chili, describes the vein at Uspallata, on the Andes, as being nine feet in thickness. It has been traced 90 miles, and is supposed to extend 300 miles. From the main vein there are branches on each side, which extend to the neighbouring mountains: some of these branches are 30 miles in length. This is the largest metallic vein which is at present known in the world.

According to Humboldt, the greatest part of the silver extracted from the bowels of the earth in Peru is furnished by a species of ore called the pasos, of an earthy appearance, which M. Klaproth analysed, and was found to consist of almost imperceptible particles of native silver with the brown oxide of iron. In Mexico, on the contrary, the greatest quantity of silver annually brought into circulation is derived from vitreous silver-ore, grey silver-ore, horn-ore, and black and red silver-ores. Native silver is not extracted in sufficient quantity to form any considerable proportion of the total produce of the mines of New Spain. It is, says this traveller, a very common prejudice in Europe, that great masses of native silver are very common in the mines of Mexico and Peru, and that in general the mines of mineralized silver, destined to amalgamation, or to smelting, contain more ounces, or marces of silver, to the quintal, than the silver-ores of Saxony or Hungary; but he adds, I was surprised to find that the number of poor mines greatly exceeds those of the mines which, in Europe, would be esteemed rich. It is at first difficult to conceive how the famous mine of Valenciana, in Mexico, can regularly supply 30,000 marces of silver per month, as the vein consists of sulphuretted silver, disseminated in almost imperceptible particles through the matrix. In the formation of these veins, it should appear that the distribution of silver has been very unequal, being sometimes concentrated at one point, and at other times disseminated in the vein through the matrix or gangue; for, in the midst of the poorest ores are
are found considerable masses of native silver. Although the new continent has not hitherto produced single masses of native silver equal to what have been found in the old, the metal is more abundant in a state of perfect purity in Mexico and Peru than in any other quarter of the globe, not in masses, but in particles disseminated through the enormous quantity of the ore called pocos. The result of a general investigation of the richness of different mines is, that the mean richness of the different ores is not more than from three to four ounces of silver in every sixteen hundred pounds of ore. According to this result, the ore contains on the average, two ounces and two-fifths per quintal. It had formerly been ascertained, that no ores were worked in Mexico that did not contain one-third part of silver. The silver-ores of Peru are not richer on the average than those of Mexico. The district of Guanaxto has before been mentioned as furnishing more than one-fourth of the silver annually extracted in America, the riches of the mines here being superior to the celebrated repository at Potosí; they are all worked in one extensive vein. Among these mines, that of the count Valenciana is one of the richest; the average produce of silver is four ounces of silver from a quintal of ore.

The whole weight of silver from the vein of Guanaxto, on an annual average from 1786 to the year 1802, has been 556,000 mares, or 364,911 lbs. troy; and in thirty-eight years the weight of gold and silver, from the same vein, has been 12,700,000 pounds troy. In average years it yields from 500,000 to 600,000 mares of silver, and from 1500 to 1600 mares of gold. It has been doubted by some persons whether this be really a vein, or a metallic bed, as in some parts of its course it is parallel between the bed, or strata of the rock. It passes through both slate and porphyry, and is metalliciferous in both. Though it has been before stated that the extent of this vein is more than 42,000 feet; yet the enormous mass of silver which it has supplied for the last hundred years, sufficient alone to change the price of commodities in Europe, has been extracted from an extent of less than 2000 feet; for where this vein is not widened by branches, its general width may be stated at from 38 to 48 feet. It is for the most part separated into three masses, divided by banks of mineral matter, or by part of the matrix destitute of ore.

At Valenciana the vein continues undivided to the depth of 557 feet, and then divides into three branches; and its width, from the floor to the roof, is from 164 to 196 feet. Of these three branches of the vein, there is in general only one which is rich in metals. Sometimes, when these three branches unite, the mine is uncommonly rich. In this celebrated vein there is a certain middle region, which may be considered as a repository of greater riches, for above and below this region the ores are poor in silver.

At Valenciana the rich minerals have been in the greatest abundance, 300 and 1100 feet below the mouth of the gallery. The labour of the miner is entirely free throughout the whole kingdom of Spain, and no Indian or Mestizoe can be fined to work in the mines. The Mexican miner gains from 11. to 17. 42. troy per week of fixed days. The men employed in agriculture do not gain more than a third of that sum. The miners work nearly naked, and are searched in the most indecent manner on leaving the mine. They frequently conceal fragments of native silver and silver-ores in their hair, under their arm-pits, in their mouths, and even in the anus, into which they force cylinders of clay containing the metal. These cylinders are called longanas. A regifter is kept of the silver found in different parts of the body. In the mine of Valenciana, the value of these stolen minerals, a great part inclosed in the longanas, amounted, from the year 1774 to 1787, to 30,000l. sterling.

The silver is extracted from its ores in New Spain by amalgamation with mercury, and by smelting; the proportion of silver extracted by mercury is $3\frac{1}{2}$ to 1 of that extracted by smelting; and as fuel is becoming scarce, the quantity of silver extracted by amalgamation increases, the smelting being very imperfectly conducted.

The Mexican miners do not appear to follow any fixed principle in the selection of minerals destined to smelting or amalgamation; for in one district they smelt the same ores, which in another they believe can only be managed with mercury; and it is frequently the abundance or scarcity of mercury which determines the miner in the choice of his method. In general they smelt the argentiferous galena, and the mixed minerals of blende and vitreous copper. The pocos, the vitreous, red, and corneous silver-ores, the grey copper-ore rich in silver, and the meagre ores, differentiated in small quantities in the matrix, they find it more profitable to amalgamate.

All the metallic wealth of the Spanish colonies is in the hands of individuals. The government polities no other mine than that of Huancaya Velica in Peru, which has been long abandoned. The individual receivers from the king a grant of a certain number of metzures, on the direction of a vein or bed; and they are only held to pay very moderate duties on the minerals extracted. These duties have been valued on the average throughout all Spanish America at 11½ per cent. of the silver, and three per cent. for the gold.

In the space of a hundred years, the annual produce of the Mexican mines has increased from twenty-five to one hundred and ten millions of francs. The produce of the mines in Peru has of late years been rather decreasing, which Humboldt attributes to its being worse governed than Mexico. The proceeds of extraction seems also to be conducted upon worse principles than in New Spain, though in neither of these districts is smelting, or amalgamation, performed with much skill; for, according to M. Humboldt, the quantity of mercury annually consumed in New Spain exceeds two million one hundred thousand pounds troy. The mercury is separated from the amalgam by distillation; but in the whole process, the Mexicans waste eight times more than would be necessary, were the process conducted in the same manner as at Freyberg.

The following table will shew the annual produce of gold and silver in the mines of Europe, northern Asia, and America, as given by M. Humboldt, in killograrnmes. It may be regarded rather as an approximation to the real amount, than as a very accurate statement, the amount of English silver not being included; perhaps this may be estimated at 4000 lbs. troy.

The killogramme, it has been before stated, is rather more than 2 lb. 8 oz. troy. It is impossible to value the quantity of gold and silver annually extracted on the whole globe; for we are unacquainted with the amount of what is procured in the interior of Africa, and the central parts of Asia, Tonquin, China, and Japan. The quantity of gold and silver formerly brought by the Dutch from the latter country proves that it is rich in the precious metals. We may draw the same conclusion respecting the northern frontiers of China and other parts of Asia; and the quantity of gold-
gold-dust brought to the western coast of Africa, leads us to believe, that the countries south of the Niger contain large quantities of this metal, though we have little information respecting the silver of the African continent.

Affray and Analysis of Silver-Ores.—Pure native silver requires no other alloy than fuson, with a little potash to free it from its earthy matter. In the humid way the silver may be dissolved in nitric acid, and precipitated by common salt. The precipitate may then be fused with soda in a crucible, by which the silver is obtained pure, and the muriate of soda is precipitated and filtered. The so-called silver-ores may be treated with potash, by fuson in a crucible : the alloy of silver and gold is first obtained, and the two metals may be separated by the processes of parting. See Refining and Assaying.

Those ores which consist of silver combined with antimony or arsenic, or both, are first roasted, to drive off the arsenic and antimony, the silver remaining pure. The process is much facilitated by the use of nitre, for the purpose of oxidizing the metals to be disintegrated.

The humid analysis of this ore requires more particular treatment.

The ore commonly called arsenical is first to be coarsely powdered, and then distilled vinegar poured upon it, to dissolve the saline impurities adhering to it.

A given quantity of the ore so washed is now to be finely powdered, and nitric acid poured upon it: this oxidizes the metals, dissolving the greatest part, and leaving a yellowish residuum. To the part dissolved, muriate of soda is to be added, which precipitates the silver. This precipitate being washed and dried, will give \( \frac{77}{100} \) per cent. of pure silver. To the liquid from which the last was precipitated add a solution of potash: a light red precipitate is now formed, which, on drying, becomes of a deep brown, and by ignition assumes the form of powder of a whitish-grey colour: this is the arseniate of iron. This substance contains iron and arsenic, in the proportions of 50 to 45 or 44. This is shown by treating the arseniate of iron with charcoal exposed to a red heat; the arsenic is reduced, and sublimates, while the black oxyd of iron remains.

The yellowish residuum left in the first solution is to be digested with muriatic acid: if a white powder remains undissolved, it will be found to be muriate of silver, and must be added to that first obtained. To the muriatic solution add a solution of carbonate of potash, and a yellowish-green precipitate is formed: to this precipitate, when washed and dried, add muriatic acid by a little at once, till the powder is dissolved; add a large quantity of water to this solution, which will produce a white precipitate; this being separated and dried will be pure oxyd of antimony, affording \( \frac{77}{100} \) of pure antimony. What remains in solution, after the last substance is separated by the water, may be precipitated by pure potash, and will be found to be oxyd of iron, which, when treated with charcoal, like the first obtained, may be added to the fame to make the whole of the iron afforded by the mineral. In this way the arsenical silver-ore afforded, according to Klaproth, the following analysis:

<table>

The sulphurised ores in the large way sometimes merely require to be roasted to drive off the sulphur: the heat being urged affords a button of pure silver. This is the case with the variety called Silver-glance.

The brittle silver-ore contains a very small portion of antimony and copper. The metallic button obtained by heat will require to be cupelled with lead, in order to get the silver pure: it may, however, be made tolerably pure by treating the button with nitre, by which the base metals are separated.

To effect the humid analysis of brittle silver-ore, the powder is dissolved in dilute nitric acid with a gentle heat. By this treatment a rediduum is left equal to \( \frac{78}{80} \) of the whole. The solution is to be treated with muriate of soda, like the last.

If the presence of an alkaline sulphate does not form any precipitate with the remaining solution, the mineral does not contain lead; add to the solution an excess of ammonia, and a greyish-white precipitate will be left, which is the oxyd of iron, often containing a little arsenic. If copper be present, ammonia will give to the remaining solution a fine blue colour, and that metal may be separated by a rod of clean iron.

It now remains to examine the first residuum which was unaffected by the nitric acid; this is to be digested with nitro-muriatic acid: the residuum left after this treatment will be found to be pure sulphur. The nitro-muriatic solution is now to be diluted with a large quantity of water; a white precipitate falls down, which, when washed, dried, and ignited, will be found to be oxyd of antimony, of a brown colour.

Klaproth found 100 grains of this ore to yield as follows:

The white silver-ores afford nearly the same ingredients with the last; and the mode of analysis will be similar in the dry way.

The light-white and dark-white silver-ores contain lead and alumine, and require a different treatment. After the silver is precipitated by common salt, a quantity of muriate of lead is formed at the time, which, on concentration, affords the muriate of lead in bright silky crystals. When these are collected till the liquid will afford no more, a solution of sulphate of soda is to be added, which precipitates the remainder of the lead in the state of sulphate of lead. This powder, being washed and dried, contains \( \frac{4}{5} \) of metallic lead. The remaining liquid being supersaturated with ammonia, as in the analysis of the brittle silver-ore, a light-brown precipitate is formed: this precipitate is oxyd of iron and alumine. To separate the latter, dissolve the precipitate in nitric acid: separate the iron by prussian of potash, or prussiate of lime, and afterwards the alumine with soda. The prussian of iron, heated to a red heat, is decomposed, leaving the black oxyd of iron, which contains \( \frac{4}{5} \) of metallic iron.

The first residuum left by the nitric acid, besides antimony and sulphur, which constituted the residuum of the brittle silver-ore, also contains lead. By the frequent addition of muriatic acid with the application of heat, the lead is separated in crystals of muriate of lead; obtaining, by this means, a solution of the muriates of lead and antimony.
mony. The residuum is sulphur. The muriatic solution deposits crystals of muriate of lead on cooling. When no more crystals fall down, these crystals are to be added to those obtained before. These, being heated in an alys crucible with twice their weight of black flux, afford metallic lead. This lead, however, treated in the usual way on the cupel, affords a small portion of silver. The solution still contains a small portion of muriate of lead and the antimony. By adding a solution of Glauber's salt, the lead is precipitated in the state of sulphate, affording 1/10 of its weight of metallic lead. The antimony, which is the last, may be precipitated by affusion of water. The precipitate, being washed, dried, and ignited, is the pure oxide of antimony, yielding on its reduction 3/4 of the metal. The analysis of the light white silver-ore, by Klaproth, gives of

\[

The corneous silver-ore, which is muriate of silver, is easily reduced in the dry way by fusling it with soda, in a crucible capable of fusling the metallic silver. The soda takes the muriatic acid, forming muriate of soda, which escapes in white fumes, and the silver is left pure.

In the humid way, it is first fused in a glass retort with carbonate of potash. The mass is then dissolved in hot water, and the solution filtered. The residuum is then dissolved in nitric acid, leaving behind a red powder. This powder, being treated with nitromuriatic acid, leaves behind a small portion of muriate of silver, which must be accounted for in metallic silver, as before directed. Ammonia, being added to the nitromuriatic solution, precipitates a red powder, which is oxide of iron. To the nitric solution, from the mass first treated with carbonate of potash, muriate of soda is now to be added; which precipitates the silver in the form of muriate, from which the metallic silver may be either calculated, or obtained by fusion with soda. The aqueous solution from the fused mass is now to be saturated with acetic acid. If alumine be present, it will be precipitated. The liquid part is now to be evaporated to dryness. If alcohol be added to the dry mass, it dissolves the acetate of potash. The residuum is then dissolved in water. To this, muriate of barytes is to be added, which, if sulphuric acid be present, will cause a precipitation of sulphate of barytes, the sulphuric acid of which is to be considered as a product of the ore, and will be equal to one-third of the weight of this precipitate, when washed and dried. The remainder of the dark masses which was dissolved in water may be considered as muriate of potash, the acid of which is another ingredient of the analysis, and will be equal to 1/3 of the salt.

Physical and Chemical Properties of Silver.—Silver, when pure and newly polished, is of a splendid white colour, and becomes more white when the polish is deadened. Its hardness is nearly equal to that of gold. At a heat visibly red in the dark, it can be worked with great facility by the hammer into various articles, in the manner of working iron. After being rolled into very thin sheets, it can be beaten into leaves of 1/40th of an inch in thickness, and can be drawn into wire thinner than a human hair. A wire of 1/50th of an inch will require 336 lbs. to break it, when exerted in the direction of its length. At a temperature short of redness, these pieces can be united either by the hammer, or by pressing them together with friction by a steel burnisher.

It melts at the temperature of 28° of Wedgwood, or 471° of Fahrenheit. If the heat be raised the metal becomes more liquid, and boils. This is occasioned by its assuming the elastic form, in which it flares and air is condensed at the surface of bodies held over it, as has been observed with gold.

In purifying silver on the cupel, it is observed, that when it is removed from the furnace, and just at the point of congelation, a small explosion ensues, giving to the surface of the button an appearance as if some elastic fluid had been diffiguated from it. It has been discovered by Mr. Samuel Lucas, of Sheffield, that the elastic fluid which is separated, producing the phenomenon in question, is pure oxygen gas.

By keeping silver long in a state of fusion, at a very high temperature, it becomes oxidized.

Macquer converted silver into a vitreous oxyd by exposing it to the heat of a porcelain furnace.

Silver is readily inflamed by electricity, and converted into an oxyd of a greenish-yellow colour.

The most direct way to obtain the oxyd of silver is by dissolving the silver in nitric acid, and precipitating it with lime-water. The precipitate is at first white, in which state it may be considered a hydrate of the oxyd. When heated, the water escapes, and it assumes a greenish-yellow colour, inclining to grey. If the heat be raised, the air being excluded, the oxygen is drawn off, leaving the metal in a state of purity: 100 parts of silver have been found to contain 7.5 of oxygen; hence, if the atom of hydrogen be 1, that of silver will be 100. No combination of silver with azote or carbon has as yet been discovered.

It combines with sulphur with great facility: the mere contact of the metal with flour of sulphur is sufficient to give the surface a yellow colour. If the silver be in thin plates, and stratified in a crucible with the flame, at a red heat the combination soon takes place, and the mass fuses, forming a sulphuret of silver of a violet colour, sometimes in crystals of the shape of a needle.

This substance is brittle, but sufficiently soft to be cut with a knife. It is decomposable by heat. The sulphur escapes, leaving the metal in a state of purity. This compound is an atom of silver equal to 100, united to an atom of sulphur 15.

Sulphuret of silver is also formed by exposing the metal to sulphuretted hydrogen gas. The small quantity of the latter existing in the atmosphere is capable of foun communicating a yellow, and ultimately a purple colour to polished silver.

Vol. XXXII.
Mr. Proust found this tarnishing matter to be a phosphuret of silver. The thinneft coat of gum, or of varnish, completely defends the surface of silver from tarnifhing.

Silver combines with phofphorus, forming a phosphuret of silver. This combination is effected by heating in a crucible equal parts of silver and phofphoric glaft, with one-fourth their weight of charcoal powder, or, what is better, saw-dust. This compound is of a white colour. It is brittle, but may be cut with a knife. It is, like the fulphuret, decompofed by heat.

Silver combines with feveral metals, forming alloys. The alloy of silver with gold, when the former is in a very small quantity, is of a much paler colour than gold. These, like all other compounds, are doubtlefs definite, and hence we fhould expect, that when these metals combine in the ratio of the weights of their atoms, which will be 100 silver to 140 of gold, the alloy would be the most perfect. And the next perfect would be two atoms of one to one of the other. It is flated by Mufchenbroeck, that the hardreft alloy of these two metals is with two parts of gold to one of silver.

Silver, as well as rendering gold much paler, gives it a greenifh tinge. This alloy is more furfible than gold, and hence is employed as a folder for that metal.

Silver does not form any striking alloy with platinum. Indeed it rather appears to be a mixture than a combination. As is the cafe with lead and zinc, the two metals separate, when kept fome time in a flate of fusion. This fact is corroborated by the circumftance, that silver can fcarceely be made to unite two pieces of platinum together, when used as a folder, while gold can be employed for that purpofe with the greatest efccfes. For the other alloys of silver, see the refpective metals.

Salts of Silver. — These confift of the oxyd of silver combined with an acid, fome of which only are fufible in water. The prefence of the fufible falks of silver is easily detected by muriatic acid, or any fufible faine compound with that acid, by occafioning a fene white precipitate, which foon changes to a purple colour when expofed to the fun's light.

The infufible falks of silver have the property of coating bright copper with silver, when rubbed upon it with a little molifture. Salts of mercury would give the fame white appearance, but this would be diftinguifhed from silver by being capable of difpofition by heat. Salts of silver become black with the hydrofulphures of the alkalies. And gallic acid gives a brown precipitate.

Sulphate of Silver. — Sulphuric acid has no action upon silver at the common temperature. When, however, this metal is boiled with the acid, the silver becomes oxydated, fulphurous acid gas is difengaged, and sulphate of silver is formed, which is a white mass, sparingly fufible in water, except an excefs of sulphuric acid be prefent. The latter, on evaporation, affords fyllals of a brilliant fiverly white- nefs, in the form of needles or fine prifms.

This falt is fufible in nitric acid.

When heated, it firft fufes, and if the heat be raised, it is decomposed, fulphuric acid and oxygen efcapeing, leav- ing the silver in its metallic form.

This falt is decomposed by the alkalies and earths, and all thofe fufible falks, the acids of which form fufible compounds with silver. Bergman has flated, that 100 parts of metallic silver, precipitated from nitric acid by fulphuric acid, give 134 of the sulphate. Allowing the 100 of silver to have taken 7 of oxygen, there will remain 28 for the fulphuric acid. This, in 100, will give fulphuric acid 22, and 78 of oxyd of silver. If this falt be composed of one atom each of acid and bafe, then, by Dr. Wollaston's table, the proportions would be 25.5 acid, and 74.5 oxyd of silver. Dalton's numbers would give very nearly the fame refult.

Sulphate of Silver. — This falt, like the laft, is sparingly fufible in water. In other refpects, it is but little known.

Nitrate of Silver. — The nitric acid acts with considerable violence on silver, affording red fuffocating flames, occafioned by the copious difengagement of nitric oxyd. If the acid and the silver be pure, the folution becomes clear and co- lourles, without residuum: if the acid contains muriatic acid, which is often the cafe with the acid of the shops, then a dense white powder will fall down, which becomes purple in the funs-flone, and is the muriate of silver: if the silver contains gold, a purple powder will be left at the bottom of the vefsel: if it contains copper, the folution will be of a green colour, of greater or lefs intensity, depending upon the quantity of that metal.

The folution of silver affords crystals on evaporation: they are of a prismatic form, but differ in their number of fides; they do not change by expofure to the air, but are very fufible in water. These crystals, when heated, firft melt; the heat being raised, the water of cryftalization efcape, but the mass still remains liquid: in this flate it is frequently cast into moulds, in which it affumes a folid form on cooling. These flicks, which are employed in furgery under the name of lunar caftic, are of a grey colour, and when broken exhibit a cryftalline appearance.

A more violent heat than that required for its fusion decomposes it, nitrous gas and oxygen being difengaged.

This decomposition is much more rapid when it is heated in contact with inflammble matter. If thrown upon burning crals, it detonates.

If flk, cotton, leather, ivory, and many other bodies, be moistened with nitrate of silver, and the part be afterwards moifened, when a stream of hydrogen gas is applied to it the silver becomes reduced, and appears with its metallic lufure. A flick of phofphorus dipped in nitrate of silver foon becomes coated with metallic silver.

This falt has the property of detonating with fulphur or phofphorus, by being struck fharply with a hammer.

Nitrate of silver is decomposed by all the earths which form falks, and by the alkalies, by combining with the acid. Ammonia, however, does not only precipitate the oxyd, but afterwards combines with it, forming a compound having alarming fulminating properties. The following is the procefs recommended for its preparation.

From the nitrate of silver precipitate the oxyd by means of lime-water: separate the oxyd, and dry it upon blotting-paper: upon this oxyd pour pure caftic ammonia: let this remain for twelve hours. If a pellicle be formed upon the surface, add a little more ammonia, which will take it up. A black precipitate will be found at the bottom of the vefsel, which is the ammoniate of silver, and is the fulminating fubftance to be obtained. This precipitate is to be carefully collected, and laid in very small quantities upon feparate parts of blotting-paper, to dry. When dry, the lighteft touch or rubbing motion causes a violent explosion. Thofe unac- cuftomed to it should begin with the smalllefs poffible quantities, as ferior accidents have happened by exploding it in too large quantities. The liquid part from which the fubftance was separated will be found to be a folution of the fame: if it be heated in a glafs retort, a portion of it is de- composed, and the gaseous products difengaged: in a little time, small brilliant cryftals of the fame fubftance appear: thefe
these frequently detonate with such violence, as to break the vessel in which they are contained.

The theory of these appearances is obvious: the oxygen of the silver combines with the hydrogen of the ammonia, forming water, which, with the azotic gas of the flame, are in an instant rendered so highly clyclic by the caloric set free, as to produce the explosive effect so conspicuous in this substance. It is needless to say that the silver is left in the metallic form.

Nitrate of silver is decomposed by all those metals having a superior attraction for oxygen. The oxygen of the silver is given to the decomposing metal, which also combines with the acid. Copper, so employed, precipitates the silver in a white metallic powder, the result being nitrate of copper in the place of nitrate of silver. The precipitate is not pure silver, some copper will always be detected when the precipitate is re-decomposed.

Mercury has also the property of precipitating silver from the nitrate, producing the appearance which has been termed the arbor Diane. Lemery recommends one part of silver to be dissolved in nitric acid, and the solution to be then diluted with twenty parts of distilled water: to this add two parts of mercury. The mercury gradually occupies the place of the silver, and the latter is precipitated in the form of vegetation, from which the name has been derived.

The vegetable appearance is caused by the growth of the crystals being from the extreme points of that already formed, as is the case with the growth of vegetables. The mercury, and the smallest portion of precipitated silver, form a Galvanic combination. The silver now in solution is reduced upon that already formed, in consequence of its state of electricity being negative, that of the mercury being positively, by which it attracts the acid. This process would doubtless be facilitated by dropping a small bit of metallic silver upon the mercury, added to nitrate of silver. This would form a Galvanic combination, and the bit of silver would become an immediate rallying point for the silver in solution. If a little of a dilute solution of nitrate of silver be spread upon a pane of glass laid in an horizontal position, and a common pin be laid in the middle of the covered part, in a few hours, beautiful ramifications of silver extend from every side of the pin; sometimes to the distance of an inch. This is also to be explained by Galvanism.

Nitrate of Silver.—When nitric acid, or any soluble muriate, is added to nitrate of silver, a dense and blueish-white precipitate is thrown down, which is muriate of silver. Although white when it is just precipitated, it soon attains a purple tint by exposure to the light, and the change is quicker as the light is more intense: hence this substance has been employed to measure the degree of intensity of light, by the time in which the change of colour takes place.

It may be said to be insoluble in water: this property, and its conspicuous appearance in other respects, renders the nitrate or sulphate of silver so valuable as a test for nitric acid. The latter, on combining with the silver, forms the salt in question.

When this salt is exposed to heat, it easily melts: on cooling, it becomes solid. It is a semi-transparent mass, of a grey colour, and of a horn-like appearance, from which it has been called luna coerulea, or horn-silver. If fused with a great heat in a crucible, it becomes thin a fluid as to sink through the pores of the crucible. It is not decomposed by any of the acids nor the alkalis, but when heated with the carbonates of potash or soda, the acid is disengaged. It diffuses in caustic ammonia, forming a transparent solution: this, by exposure to the air, undergoes considerable change. A pellicle forms on the surface, which is frizz of a blueish colour, and ultimately black. This pellicle, on examination, is found to be muriate of ammonia and reduced silver. Those who with Sir Humphrey Davy hold oxyymuriatic acid to be a simple body under the name of chlorine, consider this substance as a compound of the latter substance with metallic silver. Sir Humphrey gives it the name of argentum, and Dr. Thomson, more confidently, chlorid of silver.

The composition of this salt, according to Proust, is

<table>

By the atomic theory it should be constituted by 102 + 7.5 = 107.5 of oxyd of silver, and 24 muriatic acid, which would give

<table>
<thead>
<tr>

</table>

Considering the 24.7 of chlorine as oxyymuriatic acid, which would be 18.8 muriatic acid, and 5.9 oxygen; then giving this oxygen to 75.3 of silver, would give 81.2 of oxyd of silver, and 18.8 of muriatic acid in the 100, which nearly agrees with the above. The property which this salt has of becoming black by the action of light, has rendered it useful for marking linen. Very improper ingredients have been used for this purpose. The nitrate of silver is employed to write with upon the linen, which is very proper; but the part is often prepared by a solution of iodin or potash, instead of a solution of muriate of iodin (common salt). The following will be a receipt which cannot fail of success: dissolve 30 grains of lunar caustic in one ounce of distilled water; this will be for the writing liquid. For the preparing liquor, dissolve half an ounce of common salt in four ounces of water; and in the same distil half an ounce of gum arabic. Moisten the part to be marked with the latter, and dry it till the writing will not run. The letters will first appear of a blueish-white, but become perfectly black by exposure to light.

The fluors, borate, phosphate, carbonate, and arseniate of silver, are insoluble powders, having no striking properties, or but little known. The arseniate is formed by adding arseniate of potash to any soluble salt of silver. It falls down in the form of powder of a yellow colour. Its insolubility, and its conspicuous appearance, have been taken advantage of by employing nitrate of silver as a test for arsenic.

The chromate of silver is an insoluble salt, of a red colour: it is formed by adding chromate of potash to nitrate of silver. It, however, becomes purple by exposure to air and light.

Acetate of silver is a soluble salt, formed by adding the acetic acid to oxyd of silver. The solution affords prismatic crystals.

The salt of the salts are but little known.

Silver, in Medicine, is called luna, the moon; and has been much extolled for its virtues by chemical writers. But
crude silver, however comminuted or attenuated, has not been observed to produce any medicinal effect. It is not soluble in any of the fluids of the animal or vegetable kingdom.

Several preparations have been made from silver; particularly a

Silver Pill, or Pilula Lunaris, which is a chemical preparation of silver, formerly highly commended as an anthelmintic, and as a purgative remedy for dropsies, and in many other invertebrate uncereus diseases.

The method of making this is: dissolve an ounce of pure nitre in distilled water; then dissolve an ounce of crystals of silver, made in the common way, with pure silver and aqua fortis, in three times the weight of water, so that the solution may be perfectly limpid; mix the two solutions together, they will become a clear homogeneous liquid; evaporate this to a pellicle, and crystals resembling nitre will float; pour off the remaining nitre as before, and the remaining nitre will float with the silver, in form of crystals, again, upon a second evaporation: let these crystals be dried upon a paper, and then placed in a glas vessel in a very gentle heat, enough to make them smoke, but not run; stir it with a piece of glass all the time, and keep it over the fire, till no more fumes arise; thus the acid spirits will be driven off, and the silver remain of a very bitter taste and purging quality. It must be kept in a dry close vessel.

This discovery has been made to serve to many other purposes, besides its use in medicine, and has furnished the dishonest practitioners to alchemy with one of their most cunning methods of deceit. They have been able, by this means, to conceal silver in nitre, and that in a very large proportion, as in one-tenth of the whole quantity; and this nitre being projected in an equal quantity on melted lead, gives an increase of one-tenth part in silver, which remaining upon the tell, will deceive the ignorant, as if a tenth part of the lead were converted into pure silver. People who are upon their guard, may, however, discover the cheat, by dissolving the pretended nitre in ten times its weight of water, and putting a polished plate of copper into the solution; for every particle of the silver will then be precipitated out of the liquor upon the copper, and to the bottom of the vessel.

The medicinal use is this: the dried mafs, consisting of the falls of silver and nitre, is to be reduced to a fine powder: this powder, applied to ulcers, acts in the manner of the lapis internalis, or silver-sulphate, only much milder; but for internal use, the quantity of two grains of it is to be ground to a fine powder, with fixed grains of loaf-sugar, in a glass mortar; this is then mixed with ten grains of the crumb of bread, and formed into nine pills: these are to be taken by a grown person upon an empty stomack, drinking after them four or five ounces of hot water, sweetened with honey. It purges gently, and brings away a liquid matter like water, often unperceived by the patient. It is said to kill worms, and perform great things in many obilinate uccerous disorders. It purges without griping, but it must not be used too freely, nor in too large a dose, for it always proves weakening, and in some degree corrosive on the stomack; but this inconvenience is greatly alleviated by rob of juniper. Boerh. Chem. part ii. p. 297.

However, with this affluence, it is at best a dangerous medicine, and as such is deferredly excluded from practice. Lewis.

Silver, Tincture of, is made by dissolving thin silver plates, or silver shot, in spirit of nitre; and pouring the solution into another vessel full of salt-water. By this means, the silver is immediately precipitated in a very white powder, which they wash several times in spring water. This powder they put into a matsraf; and pour rectified spirit of wine, and volatile falt of urine, upon it. The whole is left to digest in a moderate heat for fifteen days; during which, the spirit of wine assumes a beautiful sickly-blue colour, and becomes an ingredient in several medicines. This is also called potable silver, argentum potabile.

Silver is likewise converted into crystals, by means of the fame spirit of nitre; and this is called vitriol of silver.

The lapis internalis argentous is nothing but the crystals of silver melted with a gentle heat in a crucible; and then poured into iron moulds. See Caustic, Lunar.

Silver Aiz. See AlE.

Silver Bulbs, in Botany. See Anthyllis; which see. See also BARBIS Jovis.

Silver Coin. See Coin, and Money.

Silver Fir, the name of a tree of the pine kind. See Pine.

Silver, Green and Herring. See the adjectives.

Silver, Inflammable, a chemical preparation of the lapis internalis made by a small heat. The process is this: take an ignited piece of Dutch turf, after it ceases to smoke; place it with its upper flat surface parallel to the horizon; make a little cavity in the middle, and therein put a drachm of dry lapis internalis; it will immediately melt and glow, and finally it will take flame, and hiss and thine like nitre; after the flame ceases, pure silver will be found in the hollow, as much in quantity as was used in making so much lapis internalis.

This curious experiment shews the physical manner in which acids do but superficially adhere to silver; and the manner in which acids operate, when united to metals, while surrounding their metallic mass, they arm the ponderous principles of them with spicula: it shews also the immutability of silver dissolved in an acid, and the various ways in which it may be concealed, yet still have its action; it also shews the difference of potable silver, while existing in a saline form, by means of an adhering acid, from that potable silver of the adepts, where the principles of silver are suppos'd converted into a fluid, that will mix with the juices of the body, and cannot be reduced to silver again; but the great thing to be here observed is, that the acid spirit of nitre, adhering in a solid mass of silver, is, in this state, as inflammable, on coming in contact with an ignited combustible body, as crude nitre itself: this seems to happen with silver alone, which is unchangeable with spirit of nitre. Hence also we see one way, by which silver may be obtained pure from other adhering matters, by bare burning; the acid here acts neither upon the mercurial part of the silver, nor upon its forming sulphur. Boerh. Chem. part ii. p. 297.

Silver, King's. See King's Silver.

Silver-Leaf is that which the gold-beaters have reduced into thin leaves, to be used by gilders, &c. See Gold-Leaf.

Silver, Quick. See Mercury.

Silver, Rep. See REP Silver.

Silver, Salt. See SALT Silver.

Silver, Shell, is made of the shreds of silver leaves, or of the leaves themselves; and used in painting and gilding certain works. It is prepared after the same manner as shell-gold. See Gold.

Silver, Slough. See Slough Silver.

Silver, Smoke. See Smoke Silver.

Silver-Tree, in Botany. See Protea.

Silver-Weed, a species of Potentilla; which see.

Silver-Weed, in Agriculture, a term applied to wild tansey; a plant which grows naturally upon cold stiff land
in most parts, and is a sure mark of the feility of the soil. Its stalks spread upon the ground, and send out roots from their joints; by which means, and by frequent shedding of its seeds, as it flowers during the whole summer, it soon over-runs, and fills the land in a great distance. Its leaves are composed of several lobes or wings, which are generally placed along the mid-rib, and terminated by an odd one; they are jagged at their edges, and are of a silvery colour, especially on their under side. It has been noticed by Mr. Ray, that the root is somewhat of the tap-rooted or parsnip kind, and that hogs are very fond of feeding upon it.

**Silver.** See *White-hart Silver*.

**Silver Wire.** is silver drawn through the holes of a wire-drawing iron, and by this means reduced to the fineness of a thread or hair. The manner of drawing it, see under the article *Gold Wire*. See also *Wire*, and *Drawing*.

**Silver Bluff.** in Geography, a headland on the coast of South Carolina, at the mouth of the river Savannah.

**Silver Roses.** a cluster of rocks, 10 miles S. of Grand Cayes.

**Silver Creek.** a river of America, in Kentucky, which runs into the river Kentucky, N. lat. 35° 41'. W. long. 84° 40'.

**Silver-grain.** in Vegetable Physiology, is described by Mr. Knight, Phil. Trans. for 1801, 344. as consisting of numerous thin plates, "diverging in every direction from the medulla to the bark, having little adhesion to each other at any time, and less during spring and summer, than in autumn and winter; whence the greater brittleness of wood in the former seasons." The same writer remarks, that these plates are visible in every wood which he had examined, except some of the Palm tribe; but are of a different width in different kinds, lying between, and preying upon, the sap-vesseis of the *albicum*. It may be observed, that in the oak "every tube is touched by them at short distances, and slightly diverted from its course. If thefe," continues Mr. Knight, "are expansible under changes of temperature, or from any cause arising from the powers of vegetable life, I conceive that they are as well placed as is possible, to pro-
pel the sap to the extremities of the branches; and their resilient temper, after the tree has ceased to live, inclines me to believe, that they are not made to be idle whilst it con-
tinues alive." In support of this opinion, we would remark, that the plates in question are found where the spiral coats of the sap-vesseis either no longer exit, or have lost their direction. See *Circulation of the Sap*.

**Silvering.** the covering of any work with a thin coating of silver. This operation is recommended by two circumstances; viz. the superior beauty of silver to that of the cheaper metals, and also its superior wholesomeness to copper, brass, or lead, for culinary purposes, as it is not corroded by vinegar and other weak acids.

Silvering may be performed on the same substances, and by similar methods with gilding; which see. But as works of this kind are liable to tarnish and speckle, they are seldom used. But when this is the case, the coating of silver should be much thicker than that of gold, because otherwise the friction which is necessary for removing the tarnish, would soon wear off the silver from the most prominent parts, and expose to view the subjacent copper or brass. In order to avoid this inconvenience, some have recommended, when silvering is admitted, a strong varnish, formed of some of the compositions of mallic, sanguis, the gums animi or copalis, and white rosin; to be put over it.

The varnish recommended in silvering leather may be applied to other purpofes. See *Lacquer*.

The silver powder, called argentum muscum, may be either tempered, in the manner of the shell-gold, with gum-water, or rubbed over a ground properly sized; and it will take a very good polish from the dog's tooth or burnifher; and hold its colour much better with a flight coat of varnish over it, than any true silver powder or leaf.

The sizes for silvering, when they are used for this pur-
pofe, ought not to be mixed, as in the cafe of gold, with yellow, or box aramnicus, but with some white sublacune, whose effect may prevent any small failures in covering the ground with the silver from being seen. This may be done with flake-white, or white-lead, when the sizes formed of oil are used; but whiting, or tobacco-pipe clay, with a little lamp-black added to it, is the proper matter in the burnifh size for silvering, or wherever the glovers' or parchment size is used.

It is universal to silver metals, wood, paper, &c.

The only metals to which silvering is applied are copper and brass, and very rarely iron; and there are three modes of performing this operation, viz. by amalgamation, by nitrate of silver, and by silver in sublimate. The first mode is performed by adding plates of copper to a solution of nitrate of silver, which will precipitate the silver in its metallic flate, and very finely divided; scrape this from the copper, and let it be well washed and dried. With half an ounce of this powder, of common salt and sal ammoniac two ounces, and one drachm of corrosive sublimate, well rubbed together, make a paste by the addition of a little water, then clean the vessel to be silvered with a small quantity of diluted aqua fortis, or by scouring it with a mixture of common salt and tartar. Rub it, when perfectly clean, with the paste already mentioned, until it is entirely covered with a white metallic coating; which coating is an amalgam produced by the decomposition of the corrosive sublimate by means of the copper, to the surface of which it applies very closely and expedi-
tiously. The copper thus silvered over is then to be washed, dried, and heated nearly red, for the purpose of driving off the mercury; the silver remains behind and ad-
hers firmly to the copper, in a state capable of receiving a high polish. The second method of silvering is by lamina cornea. For this purpose, prepare the lamina cornea in the usual manner, by pouring a solution of common salt into nitrate of silver, as long as any precipitation occurs, and boil-
ing the mixture; then mix the white curdy matter thus obtained with three parts of good pearl-ash, one part of washed whiting, and a little more than one part of common salt. After the surface of the brass, cleared from scratches, has been rubbed with a piece of old hat and rotten flone, in order to remove any greafe, and then moistened with salt and water, a little of the composition, being now rubbed on with the finger, will presently cover the surface of the metal with silver. Then wash it well, rub it dry with soft rag, and then, as the coat of silver is very thin, cover it with transparent varnish to preserve it from tarnish. As this kind of silvering is very imperfect, it is only used for the faces of clocks, the scales of barometers, or similar objects. (See *Luna Cornea*.) The third mode of performing this operation is by means of silver in sublimate; and of doing this there are three different methods. The first is by mixing together 20 grains of silver precipitated by copper, two drachms of tartar, two drachms of common salt, and half a drachm of alum; and rubbing this composition on a perfectly clean surface of copper or brass will cover it with a thin coating of silver, which may be polished with a piece of soft leather. Another and better method, called French plating, consists in burnifhing down upon the surface of the copper succellutive layers of lead-silver to any required thick-
ness. Although the silver in this operation is more foodi
than
than in any of the former modes, the process is tedious, nor can the junctures of the leaves of silver be always entirely concealed. But the best method of all is the English plat- ing, for an account of which see Plated Manufacture. Aikin’s Dict.

Brafs may be silvered, by boiling it with filings of good pewter and white tartar, in equal quantities. There are several other methods of silvering, for which see Smith’s Laboratory, p. 37, &c.; also Handmaid to the Arts, vol. i. p. 471, &c. See Gilding of Metals.

The following is the recipe in practice with button-makers for covering the inferior kinds of plated buttons: 3 lbs. of sulphate of zinc; 3 lbs. of common salt; 1 oz. of corrosive sublimate; and 2 oz. of muriate of silver. This is made into a pulpy flake with water, and the buttons smeared over with it. They are then exposed to a certain degree of heat, which first causes the surface to be covered with an amalgam of silver and mercury, and then expelling the latter, which requires nearly a red heat, the copper retains a permanent coating of silver. This is afterwards to be cleaned and burnished, by which it acquires a silvery lustre, which, for a time, appears like durable plating. The salt and the sulphate of zinc appear to be of no other use than to dilute and give a pulpy consistence to the mass.

Silvering in the cold is performed by the following composition: 3 lbs. of cream of tartar; 3 lbs. of common salt; and 1 oz. of muriate of silver, which is the precipitate formed by adding common salt to nitrate of silver, till no more is precipitated. This composition is made into a similar pulp. The surface of the copper or brass to be silvered must first be cleaned with diluted acid, and then made dry, and kept free from grease. The surface, being now rubbed with the above paste, will assume a white colour, by the silver adhering to it. This process is generally employed for silvering clock-faces, and the scales of instruments. The surface should always be varnished to prevent its tarnishing, as the silver is too thin to bear cleaning. See Button.

Silvering of Leather. See Lacquer and Japanners’ Gilding.

The proceeding in silvering the leather is in all respects the same as when it is to have the appearance of gilding, except that, instead of the yellow varnish, a clear colourless one is to be used, where the appearance of silver is to be preferred.

The most common varnish for this purpose is only parchment size, made warm, and laid on with a sponge. However, the more hard and transparent the varnishes are, and the more they are of a refined nature, the more brilliant and white, and the more durable, will be the silver and polished appearance of the silvered leather. Some, instead of the parchment size, use that of finglas.

Silvering of Mirrors, is the application of a coating of quicksilver to their posterior surface, in the manner briefly described under the article Looking-Glafs. The management of the silvering is, in this case, extremely simple, and is thus detailed in Aikin’s Dictionary. A perfectly flat slab of free-base (or sometimes of thick wood), a little larger than the largest plate, is inclosed in a square wooden frame or box, open at the top, and with a ledge riving a few inches on three sides, and cut down even with the rim on the fourth. A small channel or gutter is cut at the bottom of the wooden frame, serving to convey the waste mercury down into a vessel below, let to catch it. The slab is also fixed on a centre pivot, so that one end may be raised by wedges (and of course the other depressed) at pleasure, when working freely in the box.

The slab being first laid quite horizontal, and covered with grey paper, stretched tight over it, a sheet of tin-foil, a little bigger than the plate to be silvered, is spread over it, and every crease smoothed down carefully; a little mercury is then laid upon it, and spread over with a tight roll of cloth, immediately after which much mercury is poured over it as will lie on the flat surface without spilling. That part of the slab which is opposite the cut-down side of the wooden frame is then covered with parchment, and the glass plate is lifted up with care and slid in (holding it quite horizontally) over the parchment, and lodged on the surface of the slab. The particular care required here is, that the surface of the glass should from the first just dip into the surface of the mercury (skimming it off as it were), but without touching the tin-leaf in its passage, which it might tear. By this means no bubbles of air can get between the glass and the metal, and also any little dust of oxide floating on the mercury is swept off before the plate without interfering. The plate being then let go, sinks on the tin-foil, squeezing out the superfluous mercury, which passes into the channel of the wooden frame above-mentioned. The plate is then covered with a thick flannel, and is loaded over the whole surface with lead or iron weights, and at the same time is tilted up a little, by which till more of the mercury is squeezed out. It remains in this situation for a day, the edge of the fome slab being gradually increased to favour the dripping of the mercury. The plate is then very cautiously removed, touching it only by the edges and upper side, and the under side is found uniformly covered with a soft pasty amalgam, confiding of the tin-leaf thoroughly soaked with the quicksilver, and about the thicken of parchment. It is then set up in a wooden frame, and allowed to remain there for several days, the edge of its position being gradually increased, till the amalgam is sufficiently hardened to adhere firmly as not to be removed by slight scratches, after which the plate is filched and fit for framing.

It is a considerable time before the amalgam has acquired its utmost degree of hardness, so that globules of mercury will often drip from new mirrors some time after they have been let up in rooms; and violent concussions of the air, such as from the firing of cannon, will often detach portions of the amalgam. These can never be perfectly replaced by any patching, as the lines of junction with the amal- gam will always be marked by white flaws, even when looking into the glass. See Foliating of Looking-Glafs.

SILVERIUS, pope, in Biography, the son of pope Hormifidas, was placed in the pontifical chair in the year 536, upon the death of Agapetus. Belifarius, the famous general of Julian, having soon after taken possession of Rome, the emperor Theodora resolved to take this opportunity of reëstablishing Athanarius, patriarch of Constantinople, and his party, who had been condemned for hereby by the council of Chalcedon. She wrote to Silverius, urging him to recognize Athanarius as lawful bishop, to which he gave a positive refusal. Upon this the emperor made an engagement with the deacon Vigilis, that he should be raised to the popedom on condition that he would anathematize the council of Chalcedon, and re-admit Athanarius and his party; and she at the same time sent orders to Belifarius to depose Silverius. To furnish a pretext for this act, an accusation of treason was brought against the pope, as having invited the Goths to repel themselves of Rome. This change was most probably invented for the purpose, and without the smallest foundation; and Belifarius, without acting upon it, sent for Silverius, and endeavoured by perfuasion
persuasion to get him to comply with the emperor's requisition, but he remained firm. Finding, however, that he had not strength to oppose his enemies, he took sanctuary in a church; but being artfully drawn from it, he was stript of the emblems of dignity, and exiled in the year after he had been elected pope. When arrived at Patara, a city in Lycia, the place of his exile, the bishop of the place met him, and, indignant at the treatment he had experienced, undertook to lay the case before the emperor, then at Constantinople, and from his representation, Julianus ordered the cause to be re-heard. Silverius, immediately on receiving this order, went to Rome, where his main conduct and personal appearance greatly disconcerted Vigilius, who had intruded into his chair. Through the intrigues, however, of Vigilius with Antonina, the wife of Dafianius, Silverius was put into his hands, and carried to the island of Palmaria, on the coast of Liguria, where he died, from want or hardship, in or about June, in the year 538; though Eoranius maintains that he held a synod of four bishops in the island, at which he excommunicated Vigilius, and that he did not die till June 540. In the church of Rome he is honoured as a martyr to orthodoxy.

SILVERMINES, in Geography, a small town of the county of Tipperary, Ireland, which obtained its name from productive lead-mines in the neighbourhood, from which much virgin silver was formerly obtained. These mines, the property of Lord Dunally, are no longer wrought, and are thought to be exhausted. Silvermines is north of the Keeper mountains, and gives name to a lower ridge of hills. It is 77 miles S.W. from Dublin, and about 5 miles S. from Nenagh.

SILVES, a town of Portugal, in the province of Algarve, situated on a river of the same name, containing 1000 inhabitants; formerly more considerable than at present, and from the year 1188 to 1580 a bishop's see, which was afterwards removed to Faro; 15 miles E.N.E. of Lagos. N. lat. 37° 10'. W. long. 8° 21'.—Alfo, a river of Portugal, which runs into the Atlantic, a little below Villa Nova de Portimao.

SILVester I., Pope, in Biography, was elected to the see of Rome in January 314. In that year was held the council of Arles, to which Silvester was invited, but he excused himself on account of his age, and sent two prelates and two deacons as his deputies. To the general council of Nice, in 325, he also sent deputies, which council was convened by the emperor, and not by the pope, nor did the latter preside at it. It was during this pontificate that the hierarchy of the Christian church, as it has ever since existed, formed upon the model of the civil government of the empire, took its origin. Silvester died in 335; after having held the papal see nearly twenty-one years.

SILVester II., Pope, previously named Gerbert, was born of an obscure family in Auvignon, in the 10th century. At an early age he entered himself as a monk in the monastery of St. Gerard, Aurillac. After laying a foundation of all the sciences cultivated in that ignorant age, he travelled for improvement, and visited Spain, in order to hear the Arabian doctors in its universities. At length he rendered himself so distinguished, that he was appointed by Hugh Capet preceptor to his son Robert. At Rome he became known to the emperor Otho I., who placed him at the head of the abbey of Bobbio, about the year 970. Having resided there some years, he returned to France, but visited occasionally Italy. In one of those visits he met with Otho II. at Pavia, who took him to Ravenna, where he held a solemn deputation on a mathematical question with a Saxon, very eminent for his learning. He was afterwards made preceptor to Otho III., who succeeded to the imperial crown while he was still a minor. In the year 991, Hugh Capet promoted him to the archbishopric of Rheims; but this elevation was a source of disquiet to him, and after much contention, he was obliged to resign the see to Arnulf, the natural son of Lothaire, king of France, who had been formerly deposed from it. This was in the year 997, and at the same time Otho III. conferred upon him the archbishopric of Ravenna; and on the death of pope Gregory V. in 999, he was elected to the papal dignity, when he assumed the name of Silvester. The acts of his pontificate were few, and not at all important. In the year 1000 he is said to have conferred on Stephen I., King of Hungary, the royal title, with the famous crown, the palladium of that kingdom, and to have constituted him perpetual legate of the holy see, with power to dispense all ecclesiastical benefices. An extraordinary influence of ecclesiastical vigour in this popedom is mentioned by Ademar, which, if it may be relied on, proves both the great power of the church at that period, and the disposition to abuse it. Guy, count of Limousin, having imprisoned Grimouald, bishop of that city, for taking part in a disputed monasticity, and afterwards released him, the bishop repaired to Rome, and complained to the pope, who cited Guy to his presence. The cause being heard, the count was condemned by the pope and senate to be bound to the tail of a wild horse, and dragged away till he was torn to pieces, the execution of which sentence he escaped by compromising the affair with the bishop, his accuser, and taking flight along with him. Silvester died in the year 1002. He was a very meritorious character, a promoter of learning, and a proficient in various branches of the sciences. He spent much time and large sums of money in the collection of books from various parts of Europe, composed himself a number of works, particularly in arithmetic and geometry, and with his own hands made globes, a clock, and an astrolabe. Living, as he did, in the very depths of the dark ages, he fell under the suspicion of magical practices, and several ridiculous stories are related to this purpose. There were, however, persons who knew how to appreciate his character: he is mentioned by Otho "as a most learned man, and eminent in the three branches of philosophy." He wrote a great number of letters on various topics, of which 150 of them were printed at Paris in 1611. One of these, written in the first year of his pontificate, is a call to the church universal, for delivering the Christians in Palestine; in other words, a project for a crusade.

SILVESTRE GRANUM, or Coccus Silvestris, a term used by some authors to express the coccus Polonicus; and by others, for a coarse or bad kind of cochineal, produced in the province of Guatemala, in New Spain; it is by some supposed to be the seed of a plant, but is, in reality, an insect, as the true cochineal is, only that the scarlet colour it yields is greatly inferior to the other. See COCHINEAL.

SILVIUM, in Ancient Geography, a place of Italy, in Puccetia, E. of Venula. The name is formed from Silva, a grove found in this place, and probably the "Saltus Banthii" mentioned by Horace.

SILUM, in Geography, a small island in the Adriatic. N. lat. 44° 59'. E. long. 14° 56'.

SILURES, or, according to the orthography of Poblény, Silvres, in Ancient Geography, a people of the isle of Albion, who policed, besides the two English counties of Hereford and Monmouth, Radnorshire, Brecknockshire, and Glamorganshire, in South Wales. The northern part
of Herefordshire has been supposed by some to belong to the Ordovices. The name of this ancient Britton nation is derived, by some of our antiquaries, from cael, a wood, and urs, men, because they inhabited a woody country; and by others, from the British words as heuil uir, which signify brave or fierce men. Tacitus has conjectured, with little probability, and no sufficient evidence, that the Silures had come originally from Spain, grounding the conjecture on a supposed, or perhaps fancied resemblance between them and the ancient Spaniards, in their persons and complexions. It is much more probable, that they, as well as the other ancient inhabitants of Britain, had come from some part or other of the neighbouring continent of Gaul. But from whencesoever they derived their origin, they reflected no dishonour upon it, as their posterity have not degenerated from them. The Silures were unquestionably one of the bravest of the ancient Britton nations, and defended their country and their liberty against the Romans with the most heroic fortitude. For though they had received a dreadful defeat from Oltorius Scapula, and had lost their renowned commander Caractacus, they still continued undaunted and implacable; and by their bold and frequent attacks, they at length broke the heart of the brave Oltorius. But all their efforts were at last in vain. They were repulsed by Aulus Didius, further weakened by Petilius Cerealis, and at last totally subdued by Julius Frontinus, in the reign of Vespasion. As the Romans had found great difficulty in subduing the Silures, so they took great pains to keep them in subjection, by building strong forts, and planting strong garrisons in their country. One of the most considerable of these fortifications, and the capital of the whole country, was Ica Silurum, now Caerleon, on the river Wlffk, in Monmouthshire. Here the second legion of the Romans, which had contributed greatly to the reduction of the Silures, was placed in garrison (as some antiquaries have imagined) by Julius Frontinus, to keep that people in obedience. It is however certain, that this legion was very early, and very long stationed at this place. Ica Silurum was, in the Roman times, a city not only of great splendour, but also of great beauty and magnificence. This is evident from the description which is given us of its ruins by Geraldus Cambrensis, in his topography of Wales, several ages after it had been destroyed and abandoned. "This (Caer Leon, or the city of the legion) was a very ancient city, enjoying honourable privileges, and was elegantly built by the Romans, with brick walls. Many vestiges of its ancient splendour are yet remaining; flately palaces, which formerly, with their gilded tiles, displayed the Roman grandeur. For it was first built by the Roman nobility, and adorned with sumptuous edifices; also an exceeding high tower, remarkable hot-baths, ruins of ancient temples, theatres encompassed with flately walls, partly yet standing. Subterraneous edifices are frequently met with, not only within the walls (which are about three miles in circumference) but also in the suburbs; as aqueducts, vaults, hypocausts, stoves, &c." This description of Caer-Leion was composed in the twelfth century, and therefore we have no reason to be surprised that its ruins are now so entirely destroyed, that they are hardly discernible. On the banks of the river Wlffk, besides Ica Silurum, there stood two other Roman towns; Burrium, now Ulftk, and Gobannium, now Abergavenny. Venta Silurum, now Caer-Gwent, near Chepflow, in Monmouthshire, was also a considerable Roman town, of which there are some faint vestiges still remaining. Blestum, in the thirteenth journey of Antoninus, is supposed to have been situated at Monmouth; and Magna, in the twelfth journey, at Kenchelter, or as others think, at Ledbury, in Herefordshire. When the Roman territories in Britain were divided into five provinces, the greatest part of the country of the Silures was in that province which was called Britannia Secunda. Henry's Hist. vol. i.

SILURUS, in Ichthyology, a genus of fishes of the order Abdominales, of which the generic character is as follows: The head is naked, large, broad, and compressed; the mouth is furnished with cirri, resembling the feelers of insects; the gape is very large, extending almost the whole length of the head; the lips are thick, jaws furnished with teeth; the tongue thick, smooth, and very short; the eyes are small; the gill-membrane is characterized with from four to eighteen rays; body elongated, compressed, without scales, mucous; lateral line near the back; the first ray of the dorsal or pectoral fins serrated, with recurved spines. There are twenty-eight species, divided into sections, according to the number of their cirri, as follows: The fishes in section A have two cirri; in section B, four; in section C, five; in section D, eight; and in section E, the fishes are without cirri.

The name is of Grecian origin, and is derived from the words ωρ, to move or fish, and ωπα, a tail. It is given to this fish, from its remarkable quality of being almost continually moving its tail in the water.

Section A. Two Cirri.

Species.

Militaris. The specific character of this is, that its second dorsal fin is flexible; cirri bony, toothed. It inhabits many rivers in Asia; feeds on smaller fishes, and grows to a large size. It is from twelve to eighteen inches long; the head and fore-parts are broad and depressed; the mouth is very wide; the teeth are small and numerous; the eyes are large; on each side of the head, near the nostrils, a very strong subcri, spine, or bony process; first ray of the dorsal fin excessively large, strong, and sharply serrated, both on the middle part and towards the tip; the tail slightly bilobate, with rounded lobes. It is a native of the Indian rivers.

Inermis. Second dorsal fin flexible; fins unarmed. It inhabits the rivers of Surinam. This is denominated by some naturalists the tabolivaceous silurus. It is transparently banded with brown spots, with unarmed fins, and flexuous lateral lines. It is about twelve inches in length; the head is bony, but smooth, and it is distillute of spiny processes. It is a native of the Indian and South American rivers.

Section B. Four Cirri.

Species.

Asotus. The back of this fish has only one fin; it inhabits Asia; there are two cirri above the mouth, and two beneath; the teeth are numerous; the dorsal fin is without spiny rays; the first ray of the pectoral is serrate; the anal fin is long, and connected with the caudal.

Chilenis. Second dorsal fin flexible; the tail is lanceolate; it inhabits the fresh waters of Chili; it is about ten inches long; the body is brown; beneath it is white. The flesh is said to be excellent.

Bagre. Second dorsal fin flexible; first ray of the dorsal and pectoral fins frotaceous. It inhabits South America.

Callichtys. Second dorsal fin one-rayed; a double row of scales on the sides. It inhabits the small running streams of Europe, and when these are dried up, it crawls across meadows in search of water: it is said to perforate the sides of referrors, for the purpose of making its escape.

Section
Section C. Six Cirri.

Species.

Silurus, or European Silurus. This is also called the great or common silurus, and may be considered as the largest of all European river-fish, growing in some cases, to the length of eight, ten, twelve, or even fifteen feet, and to the weight of 300 pounds. Its more general length, however, is from two to four feet. The head is broad and depressed; the body thick, and of a lengthened form, with the abdomen very thick and short. It is of a sluggish disposition, being rarely observed in motion, and comparatively lying half imbedded in the soft bottom of the rivers which it frequents, under the projecting roots of trees, rocks, logs, or other substan"
Cornutus. First ray of the first dorsal fin serrate; pectoral unarmed. It is not more than eight or nine inches long; the shape is oval; body carinated beneath; the snout is straight, compressed, a little recurved at the tip, and about half the length of the body; the first ray of the first dorsal fin extending as far as the middle of the tail, and serrated beneath for about half its length. It is a native of the Mediterranean.

Inberbis. The Gill-covers with two spines on the hind part. It inhabits Japan, and is about six inches long; the body is funnel-shaped, reddish, and coated with scales. It is a native of the Indian and South American rivers.

Silurus is also a name given by some authors to the sturgeon, called by others accipens, but by the generality of writers fluvius.

Silurus Mons, in Ancient Geography, a mountain of Hilpmania, in the vicinity of Bactica.

Silicum, or Cyama. In Architecture, a term used by Wolhus, and some other writers, for what we otherwise call cymatio, or finial of the cornices.

Sim, in Geography, a river of Ruffia, which runs into the Yenije; 6 miles N. of Balagovetshenki. N. lat. 60° 10'. E. long. 90° 40'.

Sima, or Cyama, in Architecture, a term used by Wolhus, and some other writers, for what we otherwise call cymatio, or finial of the cornices.

Simaba, in Botany, the name of a shrub in Guiana, described by Aublet. 400 t. 153; for which, being barbary, Schreber has substituted the more legitimate, if not more harmonious, one of Zwinglea; see that article hereafter.

Simæthus, or Simetus, now Giaretta, or St. Paul, in Ancient Geography, a river in the eastern part of Sicily, which passed through the territory of the city of Leonia, and which was celebrated by the poets. The nymph Thalia, after her amours with Jupiter, is said to have been converted into this stream, which, to avoid the rage of Juno, sunk under ground near mount Ætna, and continued this subterranean course to the sea. In the time of the Romans it was navigable. It takes its source on the N. side of Ætna, and surrounding the west skirts of the mountain, falls into the sea near the ruins of the ancient Morgantia. It does not now sink under ground; but0 throws up near its mouth great quantities of amber, which the peasants gather, and carry to Catanea, where it is manufactured in the form of croffles, beads, sants, &c. and is sold at very high prices to the superfluous people on the continent. There is a large sandy beach, that extends from the mouth of this river a great way to the S. of Catanea, and was, without doubt, continued the whole way to the foot of the mountain Tauromintus; but it was broke in upon, at a remote period, by the lavas of Ætna, which, from a low sandy shore, have now converted it into a high, bold, black iron coast. After piercing through the lava, beds of shells and sea-fand-have been discovered.

Simalischeva, in Geography, a town of Ruffia, in the government of Kolivan; 40 miles S.S.E. of Kolivan.

Simana, in Ancient Geography, a town of Asia, in Bithynia, situated between two rivers.

Simancas, in Geography, a small town of Spain, in the province of Leon, near the confluence of the rivers Pinfuera and Duero, celebrated for a white wine, that is very much esteemed. In the time of Philip II. it was a strong place, in which he ordered the archives of the kingdom to be kept. It was taken by the Moors in the year 967; 8 miles S.W. of Valladolid.

Simar, a town of Hindooftan, in the circuit of Gohud; 14 miles E. of Gohud.

Simara, one of the smaller Philippine isles; 24 miles E. of Mindanao. N. lat. 12° 5'. E. long. 121° 40'.

Simaria, a town of Naples, in Calabria Ultra; 4 miles E.N.E. of St. Severina.

Simarona, a name given by the Spaniards in America to a species of vanilla, called also baylard-vanilla. The pods of this kind are every way smaller than those of the true kind, and have very little liquor or pulp in them when broken, and contain very few seeds. They are greatly inferior to the true kind, having scarcely any smell. It is not yet certainly known whether this species be the fruit of a different kind of vanilla-plant from the common, or whether it be the fruit gathered at a different season, or from a plant growing in a different soil. See Vanilla.

Simarones, in Geography, a town of the island of Cuba; 105 miles E. of Havana.

Simarouba, or Simaruba, in Botany, is the bark of the roots of a tree, first imported into Europe in the year 1713, but not long ago botanically ascertained to be a species of the Quina; which i.e.

Simarouba, or Simaruba, in the Materia Medica. This bark, according to Dr. Wright's account of it, is rough, scaly, and wanted. The infuse, when fresh, is a full yellow, but when dry, paler; it has but little smell; the taste is bitter, but not disagreeable. Macerated in water, or in rectified spirit, it quickly impregnates both menhirs with its bitternes, and with a yellow tinture. It seems to give out its virtue more perfectly to cold, than to boiling water; the cold infusion being rather stronger in taste than the decoction, which has a transparent yellow colour whitties hot, grows turbid and of a reddish-brown as it cools. The milky appearance, which Jussieu finds it communicates to boiling water, Dr. Wright has not observed in the decoction of any of the specimens which he has examined.

The bark was first sent from Guiana to France, in 1713, to the count de Porchartrain, then secretary of state, as a remedy of great efficacy in dyentury. In the years 1718 and 1723, an epidemic flux prevailed very generally in France, which refilled all the medicines usually employed in such cases; small doses of ippecacuana, mild purgatives, and all astringents, were found to aggravate, rather than to relieve, the disease: under these circumstances, recoupe was had to the cortex simaruba, which proved remarkably successful, and first established its medical character in Europe. Dr. Wright says, "most authors who have written on the simaruba, agree, that in fluxes it restores the left tone of the intestines, allays their spasmodic motions, promotes the feconations by urine and perspiration, removes that lowness of spirits attending dyenteryes, and dispels the patient to sleep; the gripes and teneurums are taken off, and the fobs are changed to their natural colour and confections. In a moderate dose it occasions no disturbance or uneasiness, but in large does it produces sickness at the stomach and vomiting."
SIM

"Modern physicians have found from experience, that this medicine is only successful in the third stage of dysentery, where there is no fever, where too the stomach is no way hurt, and where the gripes and teneftums are only continued by a weakness of the bowels. In such cases, Dr. munro gave two or three ounces of the decoction every five or six hours, with four or five drops of laudanum; and found it a very useful remedy. The late sir J. Pringle, Dr. Hock Saunders, and many others, preferred the cortex Sinaruba in old and obstinate dysenteries and diarrhoeas, especially those brought on from warm climates. Fluxes of this sort, which were brought home from the siege of Martinico and the Havana, were completely and speedily cured by this bark. The urine, which in those cafes had been high-coloured and feanty, was now voided in great abundance, and perpiration reftored. Dr. James Lind, at Haslar Hospital, says, that the Sinaruba produced these effects sooner, and more certainly, when given in such quantity as to nauseate the stomach. Dr. Hock Saunders remarks, that if the Sinaruba did not give relief in three days, he expected little benefit from its farther use; but others have found it efficacious in fluxes, after a continued use for several weeks. My own experience, and that of many living friends, are convincing proofs to me of the efficacy of this medicine, and I hope the Sinaruba bark will soon be in more general use."

Dr. Wright recommends two drachms of the bark to be boiled in twenty-four ounces of water to twelve; the decoction is then to be strained and divided into three equal parts, the whole of which is to be taken in twenty-four hours, and when the stomach is reconciled to this medicine, the quantity of the bark may be increased to three drachms. To this decoction some join aromatics, others a few drops of laudanum to each dose.

Dr. Cullen says, that the virtues ascribed to Sinaruba have not been ascertained by his own experience, or that of the practitioners in Scotland. Woodv. Med. Bot.

SIMAROW, in Geography, a town of Hindooftan, in the province of Bengal. 13 miles S.S.W. of Arrah.

SIMARUM MUSCULUS, in Anatomy, a name given by some of the old writers to a muscle, called by the moderns the foreres magnus.

SIMAS, in Ancient Geography, a promontory in the Euxine sea, on which Venus had a statue.

SIMATIUM, or Simaex, in Architecture. See Cyrmatium.

Simatium and cymatium are generally confounded together, yet they ought to be distinguished; the latter being the genus, and the former the species.

Simatium, or fana, camous, according to Felibien, is the last and uppermost member of grand corniches, called particularly the great doucie, or gula velata; and by the Greeks, ephitheta.

In the antique buildings, the simatium, at the top of the Doric cornice, is generally in form of a cavetto, or femicocia; as we see particularly in the theatre of Marcellus. This some modern architects have imitated; but, in the Ionic order, the simatium is always a doucie.

The simatium, or doucie, then, is distinguished from the other kinds of cymatia, by its being camous or flat-squared.

SIMBALATH, in the Materia Medica, a name given by Avicenna and others to the pikkenard, or nardus Indica.

The exact interpretation of the word is spiigeras, and Avicenna, under this general name, distinguished it into several kinds; the first he calls albarlin, or nardin. It has been supposed by some that he means the Indian pikkenard by this word; but, on the contrary, it appears plainly that he means the Celtic nard: he calls it the nardus Romani orbis, and says that it is of European growth. After this he mentions the Asiatic nards of several kinds, which are only the Indian pikkenard, growing in different places, and such as used to be brought thence in different degrees of perfection.

SIMBANI, in Geography, a tract of country in Asia, abounding with woods, and uncultivated, lying between the kingdom of Woolli to the north-west, Fouta Torra to the north, Bondou to the north-east, and Tenda to the south-west.

SIMBING, a town of Africa, in Ludamar; 5 miles S.W. of Jarra.

SIMBIRSK, a town of Russia, and capital of a government, on the Volga; 380 miles E.S.E. of Moscov. N. lat. 54° 25'. E. long. 48° 30'.

SIMBIRSKOE, a government of Russia, bounded on the north by Kazanfko, on the west by Nizegorodfsko and Penzensko, on the south by the government of Saratov, and on the east by Uphemfko; about 180 miles from east to west, and 140 from north to south. N. lat. 52° 20' to 55° 30'. E. long. 45° to 51°.

SIMBOLAN, a town of South America, in the province of Tucuman; 85 miles S.E. of Rioja.

SIMBULETA, in Botany, altered by Forkall from the Arabic Symbola enunem.—Fork. Ägypt.-Arab. 115. Juff. 418.—Clais Didymia; Order probably Angioferna. Nat. Ord. uncertain.

Defer. "Stem annual, a foot high, simple, slender, erect, round, with some appearance of angles. Leaves scattered, near to each other, linear-thread-shaped; the upper ones simple, half an inch long; lower an inch long, in two deep, pointed, smooth divisions. Clavet terminal, four inches in length. Flowers solitary, drooping, on short stalks, with a short, linear, leafy bracteate under each. Calyx a perianth of one leaf, bell-shaped, permanent, in five linear equal segments. Corolla of one petal, ringed, white; tube bell-shaped, longer than the calyx; upper lip of the limb reflexed, cleft, lower long, three-lobed, bright, its middle lobe inflexed. Filaments four, inserted into the corolla, two of them long. Anthers four, black, united into a quadrangular compressed plate. Germen ovate. Style thread-shaped. Stigma capitit, ovate, nearly globose, oblique. Fruit not observed. The aspect of the plant is exactly that of a Refeda or Polygala; it moreover approaches the character of Columnea, so to the combined anthers, but differs in many other respects." Found on mount Kurna, and no where else, by Forkall, whose description has not enabled any learned botanist to guess at the plant; except that Jussieu thinks it may be akin to Vo roneja, or to Anellet's Pinpeca. We should rather suspect an affinity to Anthericum.

SIMCOE LAKE, in Geography, a lake of Upper Canada, formerly lake Aux Claires, situated between York and Glencoe, and communicating with Lake Huron. It has a few small islands; and several good harbours.

SIMELIUM, a Latin term, used by some to signify a table, with ranges of little cavities in it, for the dispensing of medals in chronological order.

The word is but ill written; it should rather be cimemum, as being formed of the Greek axiœnas, curiosities, or a cabinet of precious things.

We more usuallty say, a cabinet of medals, than a simeli-

SIMENAI, in Geography, a town of Phœlia, in the province of Oberland; 8 miles E. of Salfeld.

SIMEON, in Scripture Biography, a son of Jacob and Leah, born in the year 1757 B.C. (Gen. xxix. 37.) Simeon and Levi revenged the affront, sustained by the death of their half-brother Dinah, on the part of Shechem, the son of Hamor, by entering the town of Shechem, and killing all the men they found; after which they brought away Dinah, in the year 1759 B.C. (Gen. xxxiv. 25.) It has been supposed that Simeon was the most cruel to his brother Joseph, and that he advised his brethren to sell him. (Gen. xxxix. 20.) The conjecture is founded on the circumstance of his being detained prisoner in Egypt (Gen. xiii. 24.), and of his being treated with greater rigour by Joseph than the rest of his brethren. Jacob, on his deathbed, manifested peculiar indignation against Simeon and Levi. (See Gen. xix. 5.) Accordingly the tribes of Simeon and Levi were dispersed in Israel. Levi had no compact lot or portion; and Simeon received for his portion only a district dismembered from the tribe of Judah (John, xix. 1, 2, etc.), and some other lands which were over-run by those of this tribe on the mountains of Seir, and in the desert of Edom. (1 Chron. iv. 24, 39, 42.) The Tar-gum of Jerusalem, and the rabbins, who have been followed by some of the fathers, have affirmed, that the greater part of the feribes and men learned in the law were of this tribe; and as these were dispersed throughout Israel, we perceive the accomplishment of Jacob's prophecy, which foretold that Simeon and Levi should be scattered among their brethren. It has been suggested, however, that the dispersion of Simeon and Levi, which Jacob meant to be a degradation, was in the progress of events over-rude so as to be an occasion of honor; for Levi had the priesthood, and Simeon had the learning or writing-authority of Israel; in consequence of which both these tribes were honourably dispersed throughout Israel. According to the testament of the twelve patriarchs, a book indeed of no authority, Simeon died at the age of 120 years.

The sons of Simeon were six, and are enumerated Exod. vi. 15. Their descendants amounted to 59,300 men, at the Exodus (Num. i, 22.); but the number of those that entered the land of Promise amounted only to 22,200, the rest having died in the desert. (Num. xxi. 14.) The portion of Simeon was west and south of that of Judah; having the tribe of Dan and the Philistines north, the Mediterranean west, and Arabia Petrae south. Josh. xiv. 1-9. Calmet.

Simeon is also the name of that aged and pious person, mentioned Luke, ii. 25, 26, to whom Jesus Christ was presented by his parents in the temple, and who pronounced upon him his blessing. It is believed, with good reason, that he died soon after he had borne his testimony to Christ. Some, indeed, have pretended, that this Simeon was the same as Simeon the jilt, the son of Hillel, and master of Gamaliel, whose disciple St. Paul was.

Simeon, or Simeon, was also the name of our Lord's cousin-german, son of Cleophas and of Mary, the sister of Christ's mother, probably the same with him who is named Simon by St. Mark (ch. vi. 3.) He was probably one of our Lord's first disciples. According to Eusebius, he was unanimously elected bishop of Jerusalem, after the death of St. James, A.D. 62. When the emperor Trajan made strict inquiry for all who were of the race of David, Simon was accused before Atticus, the governor of Palestine; and having endured many sufferings with a fortitude which astonished obervers, at the age of 120 years, he was crucified about A.D. 107; so that he had superintended the church of Jerusalem about 43 years. The Latin place his feast February 18, the Greeks April 27.

Simeon, in Biography, the son of Jochai, a very celebrated man among the Jews, was a scholar of the rabbi Akiba, and flourished about the year 120. At the interruption excited by Barchochba, he fled, through fear of the Romans, and retired to a cave, where he concealed himself twelve years, in the course of which he is said to have composed his work, entitled "Sohar," which is an explication of the five books of Moses. This, from its abstract manner, and the matter being clothed, according to the Egyptian method, in hieroglyphical images and very florid language, is not easily understood. There are several editions of it, but its exact age is not known. It contains things that are very old; but it is not admitted by Christians, as well as Jews, who held it in esteem, to be the production of more authors than one, and to have been enlarged, from time to time, by various additions. Gen. Biog.

Simeon, furthmore, Metaphrastus, an ecclesiastical writer, lived in the tenth century, under Leo the philosopher and his son Constantine Porphyrogenitus. He was a native of Constantinople, and rose to high employments at court, having been secretary to the emperors, and the medium of communication between them and foreigners. His writings indicate a man conversant in ecclesiastical affairs. He derived his surname of Metaphrastes, or Translator, from his occupation of writing again, in a different style, not translating, the lives of the saints. In this business he evidently meant to give a panegyric, rather than a true history; whence he has made additions and alterations at pleasure, so that the subjects are represented not as they were, but as he imagined they ought to be. His "Lives of the Saints" have several times been translated into the Latin language. Simeon likewise composed sermons, hymns, and prayers, with various pieces of the religious kind, of which some have been printed, and others remain in manuscript.

Simeon, named Stylites, a distinguished person in the annals of fanaticism, was born about the year 352 at Sifon, a town on the borders between Syria and Cilicia. He was the son of a shepherd, and followed the same occupation to the age of thirteen, when he entered into a monastery. After some time he left it, in order to devote himself to a life of greater solitude and austerity, and he took up his abode on the tops of mountains, or in caverns of rocks, fasting sometimes, it is said, for weeks together, till he had worked himself up to a due degree of extravagance. He then, to avoid the concourse of devotees, but probably to excite still greater admiration, adopted the strange fancy of fixing his habitation on the tops of pillars, whence the Greek appellation; and with the notion of climbing higher and higher towards heaven, he successively migrated from a pillar of 6 cubits to one of 12, 20, 36, and 48. This feat was considered as a proof of extraordinary anxiety, and multitudes flocked from all parts to pay their veneration to the holy man, as he was denominated. Simeon passed 47 years upon his pillars, exposed to all the inclemency of the feasons. At length a horrible ulcer put an end to his life, at the age of 69. His body was taken down from his last pillar by the hands of bishops, and conveyed to Antioch, with an escort of 6000 soldiers; and he was interred with a pomp equal to any thing that had been displayed for the most potent monarchs. He has been enrolled among the saints, either in the Greek or Latin churches. These honours produced imitators, whose performances surpassed the original. One of them inhabited his pillar 68 years.
The madness remained in vogue till the twelfth century, when it was suppressed.

SIMON BEN JOCHAI. See CABALA.

SIMERCHÉT, in Geography, a town of Bohemia, in the circle of Bohlelaw; 4 miles N. of Michnik.

SIMEREN, a river of Syria, which runs into the Euphrates, at Romkala.

SIMERING, a town of Austria; 4 miles S.S.E. of Vienna.

SIMI, or SYMI, an island in the Mediterranean, between the island of Rhodes and the continent of Asia; 6 miles N. of Rhodes. N. lat. 36° 36'; E. long. 37° 34'.

SIMIA, in Natural History, a genus of the class and order of Mammalia Primates, of which the generic character is, that the individuals have four front teeth in each jaw, which are approximate; the tusks are solitary, longer, and more remote; the grinders obtuse. The animals of this genus greatly resemble man in the uvula, eye-lashes, hands, feet, fingers, toes, nails, and other parts of the body; they, however, differ widely in the total want of reason: they have retentive memories, are imitative, and full of gesticulations; chatter with their teeth, and grin; they macerate their food in the cheeks before they swallow it: they are filthy, lascivi- ous, thieving, gregarious, and the prey of leopards and serpents, the latter pursuing them to the fummits of trees and swallowing them entire.

This race of animals, which is very numerous, is almost confined to the torrid zone; they fill the woods of Africa, from Senegal to the Cape, and from thence to Ethiopia: a single species is found beyond that line, in the province of Barbary: they are found in all parts of Asia, and its islands; in Cochinchina, in the south of China, and in Japan; and one kind is met with in Arabia: they swarm in the forests of South America, from the Isthmus of Darien as far as Paraguay.

These animals, from the structure of their members, have many actions in common with the human kind; all of them are fierce and untameable; some are of a milder nature, and will shew a degree of attachment: they feed on fruits, leaves, and insects; inhabit woods, and live in trees: they go in large companies. The different species never mix with each other, but always keep apart: they leap with great activity from tree to tree, even when loaded with their young, which cling to them: they are not carnivorous, but, for the sake of mischief, will rob the nests of birds of the eggs and young; and it is observed, that in those countries where apes molt abroad, the feathered tribe discover singular fagacity in fixing their nests beyond the reach of these invaders.

Mr. Ray first distinguished the animals of this genus into three classes, viz. the Simi, or apes, such as wanted tails; the cercopithecus, or monkeys, such as had tails; and papionees, or baboons, those with short tails.

From Ray, Linnaeus formed his method, which was followed by M. de Buffon, who made a farther sub-division of the long-tailed apes, or true monkeys, into such as had prehensile tails, and such as had not.

The genus is divided into the following sections:

Section A. Apes without tail.

--- B. Baboons with short tails.

--- C. Monkeys. Tails long, not prehensile; checks pouched; haunches naked.

--- D. Satyrs. Tails prehensile; no cheek-pouches; their haunches are covered.

--- E. Sagons. Tails not prehensile; no cheek-pouches; haunches covered.

Of the whole genus, says Dr. Shaw, it may be observed that the baboons are commonly of a ferocious and follen disposition. The larger apes are also of a malignant temper, except the orang-outang and the gibbons. The monkeys, properly so called, are extremely various in their dispositions; some of the smaller species are lively, harmless, and entertaining; while others are as remarkable for the mischievous malignity of their temper, and the capricious uncertainty of their manners. It is no easy task to determine with exact precision the several species of this extensive genus; since, exclusive of the varieties in point of colour, they are often so nearly allied as to make it difficult to give real and distinctive characters. We shall, as usual, follow Gmelin's Systema Naturae of Linnaeus, in which there are sixty-four species delineated.

Section A. Apes without Tail.

Species.

THALLODYTES, or Angola brawny. The generic character is, that the head is conic, body brawny, back and shoulders hairy, the tail of the body smooth.

SATYRUS; Orang-outang. Rufty-brown, hair of the fore-arms revered, haunches covered. Besides this there are two varieties: 1. Without cheek-pouches, or callosities on the haunches. This variety always walks erect. Its trivial name is Pongo. It inhabits Java and Guinea, and is from five to six feet high. 2. The other variety resembles the former, but is above half as high: it is docile, gentle, and grave, and by some thought to differ from the other only in age.

Of these animals, the species which has most excited the attention of mankind is the orang-outang, or, as it is often denominated, the satyr, great ape, or wild man of the woods. It is a native of the warmer parts of Africa and Asia, and also of several of the Indian islands, where it resides principally in the woods, and is supposed to feed, like most other of this genus, on fruits. The orang-outang appears to admit of considerable variety in point of colour, size, and proportion; and there is reason to believe, that in reality there may be two or three kinds, which, though nearly approximated as to general similitude, are yet specifically distinct. The specimens imported into Europe have rarely exceeded the height of two or three feet, though full-grown ones are said to be six feet in height. The general colour seems to be of a dusky brown; the face is bare; the ears, hands, and feet nearly similar to the human; and the whole appearance is such as to exhibit the most striking approximation to the human figure. The likeness, however, is only general, and will not bear the test of examination; and the structure of the hands of the feet, when observed with anatomical correctness, seems to prove that the animal was principally designed by nature for walking on four legs, and not for an upright posture, which is only occasionally assumed, and which is thought to be the effects of instruction rather than truly natural.

The manners of the orang-outang, when in captivity, are gentle, and perfectly void of that disgalling ferocity which is often conspicuous in some of the larger baboons and monkeys. It is mild and docile, and may be taught to perform a variety of actions in domestic life. But, however docile and gentle when taken young, and instructed in its behaviour, it is peculiarly great ferocity in its native state, and is considered a very dangerous animal, capable of readily overpowering the strongest man. Its swiftness is equal to its strength; and hence it can rarely be obtained in its full-grown state.
M. Volfmaer's account of the manners of the orang-outang brought into Holland in 1776, and prefented to the prince of Orange, is nearly as follows. It was a female, about 2½ Rhenish feet. It shewed no symptoms of fercenefs and malignity, and was of rather a melancholy appearance. It was fond of company, and shewed a marked preference to thofe who took daily care of it, of which it seemed very fenfible. When the company retired, it would frequently throw itself on the ground, as if in defpair, uttering lamentable cries, and tearing in pieces the linen within its reach. Its keeper having fometimes been accustomed to fit near it on the ground, it took the hay off its bed and laid it by its fide, and feemed, by every demonstration, to invite him to be feated near. Its ufual manner of walking was on all fours, but it could walk on its two hinder feet only. One morning it got unchains, and was seen to ascend the beams and rafters of the building with wonderful agility, and it was with the utmoft diftinction retaken and secured. During its rate of liberty it had taken out the cork from a bottle of Malaga wine, which it drank to the faft drop. It would eat every thing that was offered, but was not obferved to hunt for insects like other monfies; it was fond of eggs, but fifth and roasted meat feemed its favourite food. It had been taught to eat with a fpoon and fork. Its common drink was water, but it would drink any kind of wine. At the approach of night it lay down to fleep, and prepared its bed by faking well the hay on which it fpt, and putting it in proper order, and lafly covering it with a coverlet. This animal lived five months in Holland. On its firft arrival, it had but little hair, except on its back and arms, but on the approach of winter it became well covered, and the hair on the back was full three inches long. The whole animal then appeared of a cheftnut-colour: the skin of the face, &c. was of a moufle-colour, but about the eyes and round the mouth it was of a dull fenfle-colour. It was imported from the ifland of Borneo. See Orang-outang.

In Dr. Gmelin's edition of the Syllena Naturæ, fays Dr. Shaw, the smaller variety, or the jockey, in its lefs fhaggy or more naked flate, is given as a distinct species under the name of S. troglodytes. The print publifhed many years paft, by the name of Chimpanzee, is of this kind. (See Chimpanzee.) The animal defcribed in the 59th volume of the Phil. Tranf, is by Gmelin referred to the orang-outang; but Mr. Pennant defcribes it under the title of GoIok. It has a pointed face; long and flenfer limbs; arms, when the animal is upright, not reaching lower than the knees; head round, and full of hair; grows to the height of a man. It inhabits the forests of Mavat, in the interior parts of Bengal. In its manners it is gentle and modest, diftinguifhed from the orang-outang by its flenfer form. In colour it is entirely black. In the Philofophical Tranfactions the defcription is as follows. "The animal is faid to be the height of a man, the teeth white as pearls; the arms in due proportion, and the body very gentle.""}

**SIMIA.**

**Sylvenus; Pigmy.** Haunches naked; head roundish; arms shorter. It inhabits Africa and the ifland of Ceylon. It is mild and easily tame: it uties threatening gestures when it is angry, chatters when pleased,举止 the manner of the Hottentots, and drinks from the palm of the hand. The face is fhort and flat; the forehead tranfverely projecting at the regions of the eye-brows; the fkin is rough; the hair on the head and fore-arms reverfed: it is about eighteen inches high.

**Inuus;** denominated by Buffon the Magot, and by Pen- nant the Barbary Ape. Its haunches are naked, and the head oblong. Inhabits Africa, is fond of the open air, deformed, dirty, and melancholy. It is a good deal remem- bles the S. sylvenus, but its fmit is longer, colour paler, nails rounded, and is about three feet and a half high. This is what is commonly feen in the exhibition of fuch kind of animals: it is not remarkable for docility or good temper: but, by force of difcipline, it is made to exhibit a greater degree of intelligence than many others. Its colour is an olivaceous-brown, paler or whiter beneath: the face is of a fwarthy fenfle-colour. The hands and feet have nails re- fembling the human. It is delitute of any real tail, but there is commonly a short skinny appendix in the place of one.

This animal inhabits many parts of India, Arabia, and all parts of Africa, except Egypt, and a small number is found on the hill of Gibraltar, which breed there. These apes are very ill-natured, mischievous, and fierce, agreeing with the character of the ancient Reynocephali: they are often exhibited to play tricks; assemble in great troops in India; and will attack women going to market, and rob them of their provifions. The females carry their young in their arms, and will leap from tree to tree with them.

**Sylla; or Hog-faced Ape.** Nefe blunt, truncate, re- fembling that of a hog.

**Section B. Baboons with short Tails.** See Baboon.

**Nemestrina.** Beard thin; colour grey; eyes hazel: haunches naked. It inhabits Sumatra and Japan: is lively, gentle, tractable, and impatient of cold. The face is naked and tawny; the nose is flat; lips thin, with hairs refeembling whiskers; hair on the body olive-black; belly reddish-yellow: it is about two feet high. This species is figured by Mr. Ed- wards, who was in poffefion of the living animal, and who, in order to compare his fpecimen with a much larger animal of the fame species, carried it to Bartholomew fair, and he faid they feemed highly delighted with each other's company, though it was the firft time of their meeting: the belt figure of this species is faid to be that given by Buffon.

**Apesia; Little Baboon.** Thumb clofe to the fingers; nails oblong, thumb-nails rounded; haunches covered. This is an inhabitant of India. The nails are oblong and com- preffed, except the thumb and great toe-nails, which refeemle of a man; the tail is scarcely an inch long; the face is brown, with a few fattered hairs.

**Sphinx; Great Baboon.** Mouth with whiskers; nails acuminate; haunches naked. This is found in the ifland of Borneo; it is lafievous, robust, and fierce; it feeds on fruits.
fruits and seeds; it makes great havoc in the produce of cultivated lands. The head is oblong, resembing that of a dog, but more obtuse; the neck is long; the tail is short and erect; the cheeks, red, edged with purple; it is from three to four feet high, in its sitting posture. It is extremely strong and muscular in its upper parts, and slender towards the middle. It is, says Dr. Shaw, ferocious in its manners, and its appearance is at once grotesque and formidable. The region surrounding the tail to a considerable distance on each side is bare and callous. It is a native of Borneo, and inhabits the hotter parts of Africa.

Mormon; Tufted Ape. Beard thin; cheeks tumid, naked, blue, obliquely-furrowed; haunches naked, red. It inhabits India. This, in an upright posture, is full five feet high. It is the most remarkable of the whole genus for brilliancy and variety of colour. The general tinge is a rich and very deep yellowish-brown; the hair, if viewed near, are speckled with yellow and black. The face is long, with the front end somewhat abruptly; the whole length of the nose, down the middle, is of a deep blood-red; but the parts on each side are of a fine violet-blue, marked by several oblique furrows. The remainder of the face is of a pale whithish-yellow. On the top of the front the hair rises, in a remarkable manner, into a pointed form, and beneath the chin is a pointed beard of a light orange-yellow. Round the back of the neck the hair is much longer than in other parts, and inclines downwards and forwards, somewhat in the manner of a wreath or tippet. The hands and feet are of a dusky colour, and are furnished with broad pointed claws. It is a native of the interior parts of Africa, but has been found in India.

Maimon; Ribbed-nose Ape. Beard thin; checks blue, friate; haunches naked. It inhabits Guinea; weeps and groans like men, when in trouble; it is libidinous, ugly, and disgusting. The general likeness which it bears to the former species is such as to give the idea of the same animal in a less advanced state of growth, with less brilliant colours. The chin is furnished with a small sharp-pointed beard of a pale orange-colour. The feet are armed with claws, and have no flattened nails. This baboon is not uncommon in exhibitions of animals.

Porcaria; Hog Baboon. The head of this species resembles that of a hog; the snout is naked; the body of an olive-brown; the haunches are covered, and the nails are acuminate. It is said to be three feet six inches in length; its colour is of a deep olive-brown; the face is large and black; the nose is truncated at the end, somewhat like that of a hog.

Sylvatica; Wood Baboon. Face, hands, and feet naked, black, smooth; nails white. It inhabits Guinea, and is about three feet high. It is of a robust frame. Its general colour is ferruginous, owing to the alternate blackish-brown rings with which every hair is marked, and which give a kind of speckled appearance to the whole. The nails on the hands are longish, but rounded at their extremities; those on the toes longer and acuminate. The face on each side the tail is large, bare and red: the tail is about three inches long.

Variegata; Yellow Baboon. This species is of a bright yellow colour mixed with black; the face is long, black, naked; the hands are covered on the back with hair. It very much resembles the sylvatica, and is found in Africa. Above the eyes are several long dusky hairs: it is about two feet high.

Cineræa; Cinereous Baboon. The face of this is dusky; the beard is of a pale brown; the crown is variegated with yellow; the body is cinereous. It is found in divers parts of Africa, and is about two feet high.

Cynosurus; Dog-tailed Monkey. It has no beard; the face is long; the forehead high; it has a whitish band over the eyes; male genitals coloured; the nails are convex. It is about two feet high, and is said to be faithless, ruffleged, and lascivious. The face of this animal appears uncommonly mild and placid. It was very fond of fruit, which it would occasionally rub over its body in a very ridiculous style.

Hamadryas; Tartarian Monkey. This is described as cinereous; the ears are hairy; the nails sharpish; the haunches red. It inhabits Africa, is fierce and very singular in its appearance. The face is prominent; the nose smooth and red; the ears are pointed, and almost hidden in fur; the hair on the sides of the head, as far as the waist, long and shaggy; the nails of the fingers are flat, those of the toes acute and narrow; it is about five feet high. There is a variety, of which above the fore-head is prominent, terminating in a ridge. It inhabits the Cape of Good Hope, is very gregarious, pillages gardens, and is watchful of fur-prize; the head is large; the nose is long and thick; the ears short; the crown is covered with long upright hairs; the body is rough and hairy; the tail is about half the length of the body, arched at the end; the nails are flat and rounded; the haunches are red, and the animal is from four to five feet high.

Vetter; Lowando. The beard is black; the body is white. There is a variety with a white beard. It is found in Ceylon, is wild, ferocious, and milchious. The tulks of this species are long and large; the head is surrounded with a broad mane; the body is long and tapering; it is between three and four feet high.

Silus; Wanderer. The beard of this animal is long and black; and the body is black. There are three other varieties of this species. The first has a bulky beard, is found in Ceylon, and other parts of India. The second is of a jet black colour; the beard is white, and very long; it inhabits Guinea, and is about two feet high. The third has a white beard, which is triangular, short, and pointed, extending on each side beyond the ears. It inhabits Ceylon, is harmless, and lives in the woods; it feeds on leaves and buds, and is easily tamed; the body is black; the face and hands...
hands are purple; the tail is long, ending in a dirty white tuft.

**Faunus; Malbrouck.** This species is bearded; the tail is bushy at the end; it is an inhabitant of Bengal; the face is grey; the eyes are large; the eye-lids are flesh-coloured; forehead with a grey band, instead of eye-brows; the ears are large, thin, flesh-coloured; body is blackish; the breast and belly are white; the beard is hoary and pointed; it is scarcely a foot high.

**Cynomolgus:** Long-tailed, bearded monkey, with callosities behind, ridged blind nostrils, and arched tail. This by Pennant is called the Hare-lipped monkey, who includes in the species the cynomolgus and cynomolgus of Linneus. It is of a thick clumsy form, resembling the Barbary ape, except in having a long tail. It varies in size very greatly; some specimens scarcely exceed the size of a cat, while others are full as large as a grey-hound. The colour also is various, being sometimes olive-brown, at other times grey-brown. The head is large; the eyes are small; the nose thick, flat, and wrinkled; on each side the tail is a hare space; the under sides of the body, and the infides of the limbs, of a light ash-colour. It is a native of Guinea and Angola. The nostrils are divided like those of a hare.

**Cynocephalus:** Dog Monkey. This has no beard; it is of a yellowish colour, has a projecting mouth, a straight tail, and bald haunches. It is found in divers parts of Africa, and resembles the S. inuus, except that it has a tail.

**Diana; Spotted Monkey.** This species is bearded; the forehead is projecting; the beard is pointed. This is described by Mr. Pennant as of a middling size, and of a reddish colour on the upper parts, as if fanged, and marked with white specks; the belly and chin are whitish; the tail is long. According to Linneus, it is of the size of a large cat, and is black, spotted with white; the hind part of the back is ferruginous; the face is black; from the top of the nose is a white line, passing over each eye to the ears in an arched direction.

**Sabea; Green Monkey.** This animal has no beard; it is of a yellowish-green colour; the face is black; the tail is grey; the haunches naked. It inhabits the Cape de Verde islands, the Cape of Good Hope, and other neighbouring countries. The body in the upper parts is a mixture of grey, green, and yellowish; throat, breast, belly, and thighs are white; the hair is long and reversed; the eye-brows are black and bristly; the tail is straight, as long as the body, and hoary; the feet are cinereous; the nails round, those of the hands ovate. It is about the size of a cat.

**Cephus; Mouflache.** Tailed; cheeks bearded; crown yellowish; feet black; tail rufy at the point. It inhabits Guinea. The body above is brown; beneath it is of a blueish-white; the head with white erect hairs; eye-brows with a white transverse arch; upper eye-lids white; hair on the cheeks standing out; the mouth is blueish; under the ears are two large tufts of yellow hairs, like maltachias.

**Æthiops; White eye-lidded Monkey.** This is without tail and beard; the fore-top is white, erect; the arch of the forehead is white. There is a variety, of which the neck and cheeks are surrounded with a broad collar of white hair. It is found in Madagascar. Its face is thick and broad; the eyes are surrounded by a prominent ring; the eye-lids are naked, very white; the ears are black, almost naked; the tail is arched, covered with long bushy hair; it is about eighteen inches high.

**Aegula; Egret.** This is tailed, the beard is scanty; the colour is grey; crown with an erect tuft of hair reveried

**Simia.**

It inhabits India and Java. The body is a good deal like that of a wolf; the throat, breast, and belly whitish; the tail is longer than the body, cinereous, and tapering; the face is flatish, whitish, naked; the nose is deprest, short, and dilatant from the mouth, with a double furrow on the upper lip; the cheeks are a little bearded; the hairs are turned back; the eye-brows are gibbous, bristly, prominent; the feet are black, semi-palmate; the nails of the thumbs and great toes are rounded, the rest oblong; the ears are pointed; an arched future from the ears towards the eyes and back to the base of the lower jaw, and a longitudinal seam on the fore-arm. There is a variety that has a rounder head; the face is less black; the body is of a paler brown.

**Nictitans.** Tailed, beardless, black, sprinkled with pale spots; the nose is white; the thumb very short; the haunches are covered. This is called the Nodding monkey. There is a variety of it having a long white beard. It inhabits Guinea, is playful, and continually nodding its head. The head is hairy; the mouth short; the orbits naked; the irides of a pale yellow; the hair is black, with a few pale rings; lips and chin whitish; the tail is straight, cylindrical, longer than the body; the thumb is not longer than the first joint of the fore-finger.

**Sinica; Chinese Monkey.** Tailed, bearded; fore-top horizontally placed, and sheding the whole head. There is a fore-top erect, having the appearance of a round black bonnet; the body is brown; the legs and arms black. The species is found in Bengal, and the variety in India. The tail is longer than the body; the nails of the thumbs and great toes are rounded, the rest oblong; the upper parts of the body are pale brown, mixed with yellow; the lower whitish. It is about the size of a cat.

**Nemeus; Cochinchina Monkey.** This is without tail and beard; the cheeks are bearded; and the tail white. It inhabits, as its trivial name imports, Cochinchina; also Madagascar, and other places. The face and ears are of a light red; the forehead is marked with a double brown band, covered with black hair; the hair surrounding the face is whitish, mixed with yellow; neck, on the upper part, with a wreath of the same colour as that of the forehead; the shoulders and upper parts of the arms black; hands and groin whitish; thighs on the upper part and toes black; feet to the knees brown; it is from two to four feet high. From this species is procured the bezor of the ape.

**Mona; Varied Monkey.** This species is tailed and bearded; it has a prominent whitish-grey semi-lunar arch over the eye-brows. It inhabits Morocco, and the warmer parts of Asia; is gentle, docile, and patient of cold. The head is small and round; the face is bright, and of a tawny brown; the hair on the crown is yellow, mixed with black; it has a dark band from the eyes to the ears, and to the shoulders and arms; tail is greyish-brown; the rump is marked with two white spots on each side. It is eighteen inches high.

**Rubra; Red Monkey.** This species is tailed and bearded; the cheeks are bearded; the crown, the back, and the tail, are of a deep blood-red. There are two other varieties; the first has a yellow beard; the band over the eyes is black; the second has a white beard; the band over the eyes is white. This is found in Senegal, Congo, and other hot parts of Africa. The crown is flat; the body and legs are long; the hair on the upper parts is of a bright red, beneath it is of a yellow-grey; over the eyes to the ears is a band. One variety is black; and another is white;
SIMIA.

Regalis. To this species there is no thumb; the head, cheeks, throat, and shoulders, are covered with long coarse flowing hairs. It inhabits the forests of Sierra Leona. The head is small; the face is short, black, naked; the toes are long and slender; the nails are narrow and pointed; the tail is long, covered with snow-white hairs, and a tuft at the end; the body and limbs are slender; it is three feet high. The skin of this animal, by the natives, made into pouches and gun-cases.

BODIA; Bay Monkey. This has no thumbs; the tail is long, slender, and black; the body and limbs are slender. It inhabits Sierra Leona. The crown is black; the back is of a deep bay; limbs on the outside black; checks, under parts of the body, and legs, of a bright bay.

Fusca; Brown Monkey. The tail shorter than the body, alternately annulate with dark and light-brown. The face is flat; the cheeks and forehead are covered with long hairs; the body above is of a tawny-brown, belly cinereous; hands black and naked.

Section D. Tails prehensile; no Cheek-pouches; Hands covered. These are denominated

SATIAGUS.

Beelzebul, or Bearded Black Monkey. By Pennant it is denominated the Preacher monkey. It is tailed, bearded, and black. The tail at the tip and feet are brown. It inhabits South America; wanders in herds at night, and howls hideously; it is exceedingly fierce; the beard is round and black; the hair long, black, and smooth. For the account given of this animal by Maregrave, see BEELZEBUL.

Senticulus; Old Man of the Woods. This is tailed and bearded; the colour is red. The body is uniformly of a dirty red; it has a mouth like that of the human subject, placed in the anterior part of the face; the chin is prominent, and is as large as a middling-sized calf. This, which by some has been regarded as a variety of the S. beelzebul, is denominated by Mr. Pennant the Royal monkey. There were formerly two in the Leverian museum, which were probably young, being of the size of a squirrel. They were entirely of a very bright ferruginous or reddish chestnut-colour, with the face naked and black, surrounded on the lower parts by a straggling beard of black hairs, and the tail was strongly prehensile. This species is common in Cayenne, but very rare in Brazil: on the contrary, the former species is very common in Brazil, but is not found in Guiana. Both species have the same voice and manners. The following is an interesting description given by an observer, who had seen and kept these animals at Cayenne.

"The Allouates, or Howlers, inhabit the moist forests, in the neighbourhood of waters or marshes. They are commonly found in the woody islets of large flooded savannahs, and never on the mountains of the interior of Guiana. They go in small numbers, often in pairs, and sometimes singly. The cry, or rather horrible rattling scream, which they make, may well inspire terror; and seems as if the forests contained the united howlings of all its savage inhabitants together. It is commonly in the morning and evening that they make this clamour: they also repeat it in the course of the day, and sometimes in the night. The sound is so strong and varied, that one often imagines it produced by several of the animals at once, and is surprised to find only two or three, and sometimes only one. The allouate seldom lives long in a state of captivity: in a manner loses its voice, or at least does not exert it in the same manner as when wild. The male is larger than the female, which latter always carries her young on her back.

Vol. XXXII.

5 C "Nothing
"Nothing is more difficult than to kill one of these animals. It is necessary to fire several times in order to succeed, and as long as the least life remains, and sometimes even after death, they remain clinging to the branches by the hands and tail. The sportman is often chastised at having lost his time and ammunition for such wretched game; for, in spite of the testimony of some travellers, the flesh is not at all good; it is almost always excessively tough, and is, therefore, excluded from all tables: it is merely the want of other food that can recommend it to needy inhabitants and travellers."

**PANISCUS.** This is the four-fingered monkey of Pennant; it is tailed, black, beardless, and without a thumb, hence its trivial name. This animal is distinguished by the graci- lity of its body and limbs; its uniform black colour, except on the face, which is of a dark flesh-colour; and by want of thumbs on the fore-feet, instead of which are very small projections or appendices. It is one of the most active and lively of animals, and is, besides, of a gentle and tractable disposition in a state of confinement. It inhabits the woods of South America; associating in great multitudes, affailing such travellers as pass through their haunts with an infinite number of sportive and mischievous gambols, chattering, and throwing down dry ficks, swinging by their tails from the boughs, and endeavouring to intimidate the passengers by a variety of menacing gestures. This is the Coatta of Buffon.

**EXQUINA.** Bearded; back variegated with black and yellow; throat and belly white. It inhabits South America. In size and disposition it resembles the S. paniscus.

**TREPIDA.** Tailed, but without a beard; the fore-top is erect; hands and feet are blue; the tail is hairy. A variety has the hair round the face grey; it is brownish-yellow on the body. It inhabits Surinam, is nimble, dextrous, and amusing, and about twelve inches high. The body is brown, beneath it is rufy; the hair of the head is formed into a black erect hemispherical tuft; the tail is hairy; the nails are rounded; the face and ears downy and flesh-coloured; the eyes are approximate chneft.

**FATUCELLUS.** The horned supajou is tailless and without beard; two tufts on the head resembling horns. It is found in several parts of South America, is harmless and gentle. The face, fides, belly, and front part of the thighs, are brown; the crown, the middle of the back, tail and feet, and hind part of the thighs, are black; the nails are long and blunt; the tail is spiral.

**APELLA.** Brown Supajou, or Sajou of Buffon. This also is without tail and beard; the body is brown; the feet are black.

**CAPUCINA;** Capuchin Monkey, or Saj of Buffon, and Weeper of Pennant. This has no beard; the skin is brown; the hair and limbs are black; the tail is flabby and the haunches are covered. There is a variety of this, of which the hair on the breast, throat, round the ears, and cheeks, is white. The face is sometimes black, sometimes flesh-coloured on the forehead; the tufts are approximate; the nose is carinate towards the eyes; a black varicose retractile wrinkle just under the hair of the forehead; the tail is long, always curved, and covered with long flabby hair; it is of the size of a cat. It inhabits divers parts of South America; it is mild, docile, timid; walks on its heels, and does not skip. It has a crying wailing voice, and repels its enemies by horrid howlings; it shrieks sometimes like a cricket. When made angry it will Yelp like a puppy; it carries the tail spirally rolled up, which is often coiled round the neck: it smells of mufk.

**SCUREA;** Orange Monkey, or Saimiri of Buffon. Beardless; the hind part of the head is prominent; the nails of the four smaller toes ungulate; the haunches are covered. The body is of a greenish-grey, under parts whitish; the legs and arms are rufy; the tail is flabby, black at the tip, and twice as long as the body; the nails of the thumbs and great toes are rounded; the face of a bluish-brown; the eye-brows are bristly; the ears are scantily covered with whitish hairs; it is of the size of a squirrel. It is found in South America; is pleasant in its disposition, beautiful, and graceful; it rides by lying on its belly. It looks full in the face of such as speak to it. It is impatient of European climates.

**MORTA.** Without beard, but it has a tail; it is of a cheenut colour; the face is brown; the tail is naked and fraly. It is found in different parts of America. It differs from the S. sciuereae only in being left, and on that account it has been supposed to be of the same species.

**VARIIGATA.** The hair on the fides and back is mixed with orange and black. It inhabits Antigua, is lively, docile, and full of amusing tricks.

Section E. **Monkeys with Tails that are not prehensile; that have no Cheek-pouches; the Haunches are covered. These are denominated**

**SAGONIS.**

**PITHECA;** Fox-tailed Monkey. Tailed, but without beard; the hairs of the body are long, and black at the tips; the tail is black, and very flabby. It inhabits South America; is very amusing, and easily tamed. It is entirely of a dusky brown colour, with a flight ferruginous cal, except on the head and face. This is the Saki of Buffon.

**JACCUUS;** Striated Monkey, or Ouilitt of Buffon, and Sanglin or Cagui minor of Edwards. This is tailed; its ears are hairy, broad; tail curved, very hairy; nails fubulate, throfe of the thumbs and great toes are rounded. There is a variety, which is of a yellowish colour, fimpling like mufk. It inhabits Brazil; is active, reffles, climbing like a squirrel; it feeds on infeets, fruits, milk, bread, and small birds; it gnaws the barks of trees, is untameable, biting, tormenting cats by fixing under their bellies, and eruis a hifing cry.

**OEDIPUS;** Red-tailed Monkey. This is tailed and beardless; locks hanging; the tail is red; nails fubulate. The body is grey, underneath it is white; the head has long white hanging locks; its face is black, and it has a few white hairs behind the ears; a wart on each cheek; the iris is rufy; the ears are roundish, black, and naked; nails fubulate, except the thumb; the tail is twice as long as the body; and is a little hairy, black, red at the base; the region of the anus is red. It inhabits South America, is active, bril, imitating the lion in its gestures. It is something less than the S. jaccus; it fmes of mufk, and the voice reffembles that of a mouse.

**ROSALIA;** Silky Monkey. Tailed; beardless; the head is hairy; circumference of the face and feet are red; the nails are fubulate. This fpecies derives its trivial name from the appearance of its hair, which is very fine, foft, long, and of a bright yellow colour, reffembling yellow filk. Round the face the hair is much longer than in other parts, fo as to form a large mane, like that of a lion; near the face this mane is of a red-diff colour, and it grows paler as it recedes from the cheeks; the face itself is of a dusky purple; the ears are round and naked; the hands and feet are also naked, and of the fame dull purple colour as the face; the claws are small and sharp; the tail is very long, and
and rather bushy at the extremity. It is a native of Guiana, and is a lively, active species, and gentle in a state of confinement. This is the Marikina of Buffon.

Midas; Tamarin. This species is tailless; beardless; the upper lip is cleft; the ears are square and naked; the nails are fimbriate. The tamarin, or great-eared monkey, is about the size of a squirrel; it is coal-black, except on the lower part of the back, which is of a reddish colour, and on the hands and feet, which are orange-coloured; the face is naked and flesh-coloured; the ears are very large, naked, of a squarish form, and of a dusky flesh-colour; the tail is very long and black. It inhabits the hotter parts of South America. The claws are small and sharp. It sometimes varies in having the face black, instead of flesh-coloured.

Sima Marina, the Sea-Ape, in Ichthyology, a name used by Bellonius, and some other authors, for the fish called vulpes marina, a kind of shark, remarkable for its long tail, from which probably it had both one and the other of these names. See Sea-Fox.

SIMICUS, in Biography, an ancient Greek musician, said to have been a great improver of music. He lived after Homer, and has the reputation of having invented the instrument above-mentioned; but Plutarch says, that the ancient Phrases attribute this instrument to Pythocleus. He also informs us, that the Argians fixed the first person that used it; but does not tell us how it was used, or whether there was a complete scale for every one of the genera: 35 notes in the diatonic scale would mount it above the additional compass of modern piano forte.

According to Pliny, Simicus added an eighth string to the lyre of Mercury. Boethius says that it was Lycanor of Samos; but Nichomachus gives it to Pythagoras. So many claimants to the fame inventions destroy all evidence to whom they belong.

SIMILAR, in Arithmetic and Geometry, the same with like.

Those things are said to be similar, or like, which cannot be distinguished but by their comprehension; that is, either by immediately applying the one to the other, or some other third to them both. So that there is nothing found in one of the similar things, but is equally found in the other.

Thus, if you note all the things in A, which may be discerned and conceived, without alluming any other; and, in like manner, note all the things in B, which may be thus conceived, and A be similar to B; all things in A will be the fame with those in B.

Since a quantity cannot be underounded otherwise, than by alluming some other quantity to which it may be referred; similar things, notwithstanding their similitude, may differ in quantity; and unless, in similar things, there is nothing in which they differ, beside the quantity; quantity itself is the internal difference of similar things.

In mathematics, similar parts, as A, a, have the same ratio to their wholes B, b; and if the wholes have the same ratio to the parts, the parts are similar. Similar parts a, a, are to each other as their wholes B, b. See PART.

SIMILAR ANgles are also equal angles. See Solid Angle.

SIMILAR Rectangles are those which have their sides about the angles proportional.

Hence, 1° all squares must be similar rectangles. 2°. All similar rectangles are to each other as the squares of their homologous sides.

SIMILAR Triangles are such as have all their three angles respectively equal to each other, and the sides about the equal angles proportional. See Triangle.

Hence, 1° since in all triangles mutually equiangular, the corresponding sides containing the equal angles are proportional, equiangular triangles are similar to each other. And if two triangles have their sides respectively proportional, those triangles are equiangular.

2°. All similar triangles are to each other, as the squares of their homologous sides.

In similar triangles, and parallelograms, the altitudes are proportional to the homologous sides, and the bases are cut proportionally by those sides.

SIMILAR Polygons are those whose angles are severally equal, and the sides about those angles proportional.

And the like of other similar rectilinear figures.

Hence, all similar polygons are, to each other, as the squares of the homologous sides.

In all similar figures, the homologous angles are equal, and the homologous sides proportional. All regular figures, and similar irregular ones, are in a duplicate ratio of their homologous sides. Circles, and similar figures, inscribed in them, are, to each other, as the squares of the diameters.

SIMILAR Archs. See Arch.

SIMILAR Curves, in Geometry. The similarity of curvilinear figures may be derived from that of rectilinear figures, that are always similarly described in them; or, we may comprehend all sorts of similar figures, planes, or solids, in this general definition. Figures are similar, when they may be supposed to be placed in such a manner, that any right line being drawn from any determined point to the terms that bound them, the parts of the right line, intercepted between that point and those terms, are always in one constant ratio to each other.

Thus the figures A S D, a S d (Plate XIII. Geometry, fig. 14.) are similar, when any line S P being drawn always from the same point S, meeting A D in P, and a d in p; the ratio of S P to S p is invariable. It is manifest, that the rectilinear inscribed figures, a p d s, A P D s, are similar in this case, according to the definition of such figures given in Euclid's Elements, book vi. See Mac-aulay's Fluxions, art. 122.

When the similar figures are in the situation here described, they are also similarly situated, and all their homologous lines are either placed upon one another, or parallel.

SIMILAR Segments of Circles are such as contain equal angles. See Segment.

SIMILAR Conic Sections are those where the ordinates to a diameter in one are proportional to the correspondent ordinates to the similar diameter in the other; and where the parts of similar diameters between the vertices and ordinates in each section are similar.

The same definition also agrees to similar segments of conic sections.

SIMILAR Diameters of two Conic Sections. When the diameters in two conic sections make the same angles with their ordinates, they are sometimes said to be similar.

SIMILAR Solids. See Like Solid Figures.

SIMILAR Bodies, in Natural Philosophy, such as have their particles of the same kind or nature one with another.

SIMILAR Plain Numbers are those which may be ranged into similar rectangles, i.e. into rectangles whose sides are proportional; as 6 multiplied by 2, and 12 by 4, the product of one of which is 12, and the other 48, are similar numbers.

SIMILAR Solid Numbers are those, whose little cubes may be
be so ranged, as to make similar and rectangular parallelepipeds.

Similar Animals. We have a treatise by Dr. Martin, wherein he treats of the laws and proportions of the motions and forces of the solids and fluids of animals, of however different magnitudes, which are supposed of similar make and constitution. See Tractat. de Similius Animalibus.

Similar Dishes, in Medicine, denotes a disease of some simple, solid part of the body; as of a fibre, with regard to its tension, or fluidity; of a membrane; a nervous canal, or the like. See Disease.

Similar Parts, in Anatomy, are those parts of the body, which, at first sight, appear to consist of like parts, or parts of the same nature, texture, and formation.

Of these we shall reckon ten, viz. the bones, cartilages, ligaments, membranes, fibres, nerves, arteries, veins, flesh, and skin; each of which we shall under its proper article.

Dr. Grew, in his Anatomy of Plants, observes, that these have likewise their similar and organic parts.

SIMILE, or SIMILITUDE, in Rhetoric, a comparison of two things, which, though different in other respects, yet agree in some one. As, He shall be like a tree planted by the water-folds, &c.; so that in every similitude three things are requisite; two things that are compared together; and a third, in which the likenesses or similarity between them consists.

The difference between a simile and a comparison consists in this, that simile properly belongs to what we call the quality of the thing, and the comparison to the quantity.

And the difference between a metaphor and similitude consists in this, that a metaphor has not those signs of comparifon which are expressed in a similitude. See Metaphor and Parable.

SIMILITUDE, in Arithmetick, Geometry, &c. denotes the relation of two things similar to each other, or which are only distinguishable by comprence.

The notion of similitude, which now makes some figure in geometry, &c. is owing to M. Leibnitz: it will be rendered easy by the following instance. Suppose two watches perfectly alike, the one belonging to Caus, the other to Gracchus. If now Caus pull out his watch in presence of Gracchus, the latter will be surprised, and fancy it his own; but he will perceive it different from his own, upon pulling out his own; that is, Gracchus distinguishes Caus’s watch from his own by their comprence; or, by applying the one immediately to the other.

Euclid, and after him most other authors, demonstrate every thing in geometry from the sole principle of congruity. Woldin, in lieu of it, substitutes that of similitude; which, he tells us, was communicated to him by M. Leibnitz, and which he finds of very considerable use in geometry, as serving to demonstrate many things directly, which are only demonstrable from the principle of congruity by ambagies.

SIMILOR is a name given to an alloy of red copper and zinc, made in the best proportions to imitate the colour of gold. See Gold-coloured Metal.

SIMIRA, in Botany, Aubl. Guiana. 1701, t. 65. Juss. 205, the Guiana name of a shrub, belonging to the natural order of Rubiaceae, and the Pentandria Monogynia of the Linnean system, but of whose generic characters nothing has yet been precisely settled. It seems very near akin to Psychotria, or to Stephanium; see those articles.

SIMITAR, or Scimitar, in War, a crooked or falcheted sword, with a convex edge; not now used.

SIMLEE, in Geography, a town of Hindoostan, in Guzerat; 17 miles N. of Champaner.

SIMLER, Josias, in Biography, was born at Cappel, in Switzerland, in the year 1530. He was minister at Zurich, and a professor in the school of that town. He wrote several controversial works against some of the heretical sects, as they were esteemed, and denominated by him. He taught mathematics with great reputation, illustrating his lefions by various machines of his own invention. Of his writings the principal were "De Helvetiorum Republica," which contained an account of the original constitution of the Swiss confederacy; "Valleviae Descriptio," being an account of the Valais, and the adjacent alps; and an abridge-ment of the Bibliotheca of Conrad Gexner, with the life of that distinguished perfon. In this last work he has not only given a good summary of the original, but has rendered it more complete, by the addition of a number of books. He died at Zurich in 1576, at the time when he was preparing a history of his native country.

SIMLY, in Geography, a town of Hindoostan, in Orissa; 15 miles N.W. of Boid.

SIMMEN, or Siben, a river of Switzerland, which rises in the mountains between the Valais and the canton of Berne, and runs into the lake of Thun; 4 miles N.N.W. of Spiez. The valley through which this lake runs, and which has on each side stupendous rocks, is called "Simmental," and is divided by it into the Upper and Lower. The inhabitants of some few parts of this valley grow rye, oats, or wheat; but they derive great profit from their grapes, which is very rich, and they also breed a great number of cattle, from which they make butter and cheese. The latter sort of cheese, called "Saan" cheese, is much esteemed abroad, being made wholly of cream; and of the common cheese, France and other countries purchase considerable quantities. Most of the inhabitants, instead of bread, eat the second sort of cheese, with thin barley cakes; and the principal food of the commonalty is potatoes, and their drink is milk or whey.

SIMMERN, a town of France, and principal place of a district, in the department of the Rhine and Morelle, late capital of a duchy of the same name, veiled in the electorat of the Rhine. The place contains 1460, and the canton 8611 inhabitants, in 31 communes. The territory of the district contains 10272½ kilometres; 26 miles S.S.W. of Coblenz,—Alto, a river of France, which falls by Simmern, Gemunden, &c. and runs into the Nahe; 3 miles E. of Kirn.

SIMMIA CHUMBA, a town of Bengal; 16 miles S. of Palamow.

SIMMONS’s ISLAND, a small island on the coast of South Carolina. N. lat. 32° 38'. W. long. 86° 10'.

SIMO, a town of Sweden, in East Bothnia, on a river of the same name, which runs into the gulf of Bothnia; 80 miles E. of Ulea.

SIMOGU, a town of Hindoostan, in Myfore, on the Tumbarada; 93 miles W. of Servingapatam. N. lat. 13° 21'. E. long. 75° 46'.

SIMOJOSIKI, one of the smaller Japanese islands, near the S.W. coast of Ximo. N. lat. 31° 50'. E. long. 132° 8'.

SIMOIS, in Ancient and Modern Geography, a river of Afta Minor, in the Lesser Phrygia, the source of which was in mount Idas, and which discharges itself into the Xanthus, or the Scamander, according to Pliny. The source of the Simois lies S.W. of Courtys; it flows nearly to the W., traverses a space of from twelve to fifteen leagues; receives the Andrias above Inchavi, and several other rivulets, and discharges
discharges itself into the Hellepont, half a league to the N.N.E. of cape Sigeum. This dream is not now sufficiently considerable to deserve the name of river; it is rather a torrent swelled by the rains, at the end of the autumn, in winter, and in the spring, or by the sudden melting of the snow, which falls on mount Ida and Cotylus. Its bed is tolerably wide, but its waters are seldom abundant, and in summer it is almost dry, since a pacha has turned aside the stream of the Seameander, and directed its waters into the Aegean sea. See Scamander.

SIMON, in Biography, a name that frequently occurs in ancient history: some of the principal persons who sustained this appellation are as follow; viz.

Simon the Just, high-priest of the Jews, was the son and successor of Onias I. and promoted to this dignity A.M. 3702, or 3703. He died A.M. 3711, before A.D. 293. — Also, Simon, son of Onias II., advanced to the high-priesthood A.M. 3805, B.C. 199. In his time, A.M. 3787, Ptolemy Philopater came to Jerusalem, and attempted to enter the interior parts of the temple, where no one but the high-priest ought to have entered. Simon opposed him, and prevented his design. He is supposed to have been the person to whom the book of Ecclesiasticus gives a high encomium. His successor was Onias III.

Simon Maccabaeus, surnamed Thaddæus, the son of Mattathias, and brother of Judas and Jonathan, was chief, prince, and pontiff of the Jews from A.M. 3860 to 3869, B.C. 135. He gave proofs of his valor in the battle between Judas Maccabæus and Nicæor (2 Macc. viii. 22, 23.), and on another occasion (2 Macc. xiv. 17.) In consequence of his judgment and valor, which were signalized in a variety of ways, he was made governor of the whole coast of the Mediterranean sea, from Tyre to the frontiers of Egypt, by the young king Antiochus Theos. He also took Bethbura and Joppa, and built Aïda, in the plain called Sephela. When Tryphon had slain Jonathan and his two sons, and having marched into Syria, put to death the young king Antiochus Theos, and usurped his kingdom, Simon supported his competitor, Demetrius Nicator, who, at his request, confirmed the ancient franchises of Judea, and granted freedom from tribute. After this he took Gaza, and the Syrians that were in the citadel of Jerusalem capitulated to him. His administration was singularly prudent, and it was his great object to render his nation prosperous and secure. With this view he made a harbour at Joppa, for the improvement of the trade of the Jews, and he extended the limits of his country. He also renewed the alliance of the Jews with the Romans and the Lacedæmonians; and the whole Jewish nation acknowledged their obligations to him by various tokens of respect, and particularly by recompensing him and his children as perpetual prince and pontiff of their nation. When Demetrius Nicator was taken by the Parthians, Antiochus Sidetes, king of Syria, the brother of Demetrius, applied to him for succours against Tryphon, and not only confirmed the grants of his brother, but allowed him the privilege of coining money, remitted to him all debts owing to the kings of Syria, and declared Jerusalem to be a free and an holy city. Simon sent him men and money to assist him in the reduction of Dora, in which Tryphon had flung himself up. But Antiochus would not receive them, nor would he confirm the articles of his treaty with Simon. He also demanded the surrender of several places, and a thousand talents of silver, threatening, in case of refusal, to enter Judea with troops, and to treat him as an enemy. Simon disregarded his threats; nevertheless he offered a hundred talents for the cities of Joppa and Gaza, of which he had made himself master, because they occasioned great calamities to his country. The army of Antiochus, which he had sent to the coasts of the Mediterranean, was defeated by John Hyrcanus, the son of Simon; and three years afterwards Simon visited the cities of Judea, and came to the castle of Doco or Dagon, where his son-in-law Ptolemy, son of Ambus, refuted. But Ptolemy, though he entertained him magnificently, caused him, in the midst of the entertainment, to be assassinated, together with his two sons Mattathias and Judas, hoping thus to become master of Jerusalem, and of the whole country. But John Hyrcanus arrived first at Jerusalem. Calmet.

Simon the Canaanite, or Simon Zelotes, was an apostle of Jesus Christ. Zelotes, the appellation given to him by St. Luke (vi. 15. Acts, i. 13.) seems to be a translation of the surname Canaanite, given to him by the other evangelists. (Matt. x. 4. Mark, iii. 18.) Some learned persons have supposed, that the term Zelotes denoted his zeal in embracing the gospel of Jesus Christ; but others think, that he was of a sect called Zealots, mentioned by Josephus, (De Bell. i. iv. c. 2. i. vi. c. 1.) It does not appear where he preached, or where he died. Some have asserted that he travelled through Egypt, Cyrenica, and Africa; that he preached in Mauritania and Libya, and that he propagated the gospel in Britain, closing his life by martyrdom, on the crux, which he endured with incredible courage. Others assert, that he suffered martyrdom in the city of Susin, in Persia, on the 28th of October, on which day the Latin church celebrates his festival. The Greeks honour him June 1, and say, that he was Nathanael, the bridesgroom at the marriage of Cana.

Simon Magus, or the Sorcerer, was a native, as it is said, of the village of Gitton, in the country of Samaria. His history is recited Acts, viii. 5—15. See also Acts, viii. 9, 10, 11. After having been discovered and refuted by the apostles, and particularly by Peter, he is said to have fallen into greater errors and abominations, applying himself more than ever to magic, and taking pride in opposing the apostles, and propagating his errors. It is laid by several of the ancient fathers, that at Rome, whither he arrived in the time of the emperor Claudius, about A.D. 41, he was honoured as a deity by the Romans, and by the senate itself, and that a statue was decreed to him in the vale of Tyber, with this inscription: "Simoni Deo Sanèto." This fact, however, is disputed by several able critics. It appears, that under the reign of Nero he acquired great reputation by his enchantments; and that he pretended to prove that he was the Christ, and that, as the son of God, he could ascend to heaven; and it has been said, that he really caused himself to be raised in the air, in a fiery chariot, by the assistance of two demons, but that by the prayers of St. Peter he was defeated by his demons, fell down and broke his legs, and afterwards, overcome by sorrow and shame, threw himself headlong from the top of the house where he lodged. But we shall not multiply these apocryphal stories, which are not worthy of recital. He died, probably, A.D. 65. Simon formed a sect of heretics, who were called Simoniæni; which see.

Simon, a disciple of Socrates, whose occupation was that of a leather-dresser at Athens, and whose shop was restored to by Socrates and his friends. He is said to have been the friend who published the Socratic Dialogues; but none are extant. Simon so much valued freedom of inquiry, that when Pericles invited him to make his house his residence, with the promise of an ample recompense, he refused, alleging, that he would not sell the liberty of speaking his mind at any price.

Simon, John Francis, an ingenious man of letters, was born at Paris in 1654. He was originally intended for the ecclesiastical profession, and took the degree of doctor
of laws. M. Pelletier de Souzy engaged him as preceptor to his son, and afterwards employed him as his own secretary, and as a remuneration for his services made him counsellor of the fortifications. He became very famous as a writer of inscriptions and legends of medals struck on public occasions, and on this account he was nominated a member of the Academy of Inscriptions and Belles-Lettres. He contributed several learned dissertations to the Memoirs of that body; and he read before it several parts of a medallion history of Lewis XIV. He was an excellent writer both in the Latin and French languages, and in verse as well as prose. In 1712 he was appointed keeper of the royal cabinet of medals. He died in 1719.

SIMON, RICHARD, a biblical critic, was born at Dieppe in 1648. He received his early education in the college of the Fathers of the Oratory in that place, and afterwards entered into that congregation. Quitting it in a very short time, he purveyed the study of theology, and of the Oriental languages, in which he made a great proficiency. He entered himself again a member of the Oratory in 1661, when his singular turn of thinking, and unaccommodating temper, involved him in differences, which had nearly caused him to abandon the society for that of the Jésuits. These were, after a time, compromised, and he was sent as professor of philosophy to one of their colleges. The house of the Oratory in Paris presiding a library rich in Oriental writings, Simon was engaged to draw up a catalogue of them, on which occasion he became known to M. de La Moignon, first president of the parliament of Paris. Having performed the task, he returned to his professorship, and there employed himself in literary labours. In the year 1670 he was ordained priest, and in the same year he gave a proof of the liberality of his mind, by undertaking the defence of the Jews at Metz, who had been accused of sacrificing the child of Christian parents. In 1674 he published, under the name Riccard Simeon, "A Treatise on the Ceremonies and Customs at present preferred among the Jews, translated from the Italian of Leo of Modena, with a Supplement respecting the Sects of the Caraites and Samaritans. It was reprinted in 1681, with a supplement, containing "A Comparison between the Ceremonies of the Jews and Discipline of the Church." In 1678 he published "A Critical History of the Old Testament," which, by the boldness of some of its opinions, gave a considerable degree of offence; and though it was protected by the approbation of a Doctor of the Sorbonne, and a royal privilege, an order was procured for prohibiting its sale, and the privilege was revoked. In the same year he quitted the Oratory, in order that he might enjoy that freedom which is natural to the mind, and of which he was enthusiasticly fond. He was accustomed to express his sense of the advantages of liberty by repeating the words "Alterius ne fit qui suus effe potest." For the purpose of enjoying still more liberty, he resigned his cure four years after this, and spent the remainder of his life in the composition of several works, of which a great part was controversial. He died at Dieppe in 1712, at the age of 74.

Simon was a man of extensive and very deep learning, and an acute critic, but fond of singularity. Few men of letters have engaged in more disputes, and among his adversaries are some of the most eminent men of his time, Catholic as well as Protestant. He has, however, been ever regarded as one of those, who have much contributed to the free and learned discussions which have improved scriptural theology, and though not avowedly a reformer, he was an effective promoter of the Reformation. He published a number of works, and in addition to those already noticed, we may mention "Histoire critique du Texte du Nouveau Testament"; "Histoire critique des Version du Nouveau Testament;" "Histoire critique des principaux Commentateurs du Nouveau Testament;" "Histoire critique de la Croyance et des Coutumes des Nations du Levant;" M. Simon left his MSS. and a number of printed books, with marginal notes written with his own hand, to the cathedral library of Rouen.

There was another Simon of some celebrity, a doctor of laws, the author of "A Dictionary of the Bible," explaining the geography of the Old and New Testament, and the ceremonies of the Jews, first printed at Lyons in 1693, and again in 1793, with considerable additions, forming two vols. folio.

Simon, a great musician among the ancients, who, rejecting former rules of his art, invented a new mode, which was called "Simodia," from his name, in the same manner as the genus invented by Lyfes, was called Lyfodia.

Simon, M., inventor of pedals for the harp, or harp à pedale. See Harp.

Simon, in Ichthyology, a name by which some authors have called the dolphin. It is affirmed, that this fish loves the name, and will come to a peron who calls him by it; but this, though recorded by authors of credit, meets with no faith among thejudicious readers.

SIMON'S BAY, in Geography, a bay on the coast of Africa, 11 miles on the W. side of the Cape of Good Hope; this is the only convenient station for ships to lie in; for although the road without it affords good anchorage, it is too open, and but ill-circumferenced for producing necessaries, the town being small, and supplied with provisions from Cape Town, which is about 24 miles distant. The anchoring place is situated in S. lat. 34° 20', or 34° 25'; E. long. 18° 29'. In April 1769, the day of the S. end of the magnetic needle was 46° 47', and variation of the compasses 22° 16' W. On the full and change days it was high water at 5 55' apparent time; the tide rose and fell 3 feet 3 inches; at the neat tides it rose 4 feet 1 inch. Cook's Third Voyage, vol. iii.

SIMONETTA, GIOVANNI, in Biography, an historian, was a native of Caslargo, in Sicily. In 1441 he entered into the service of Francesco Sforza, duke of Milan, of which prince his brother Cicco was the confidential minister. After the death of Francesco, he attached himself to his son Galeazzo Maria, to whom he, with his brother, continued so faithful, that when Ludovico Sforza unfurled the dukedom, they were arrested and sent prisoners to Pavia. Cicco, in the following year, was beheaded, and Giovanni was banished to Verceil. He, however, returned to Milan, where he was buried about the year 1491. Simonetta composed in Latin a history of the actions of Francesco Sforza from 1423 to 1466, which is accounted one of the best works of that time. It was several times printed. It is also found in Muratori's collection of Italian historians.

SIMONIACAL is applied to a peron guilty of simony; that is of purchasing a benefice, or other sacred matter, with money. See Simony.

SIMONIANS, or SIMONITES, in Ecclesiastical History, a sect
a feat of ancient heretics, the first that ever disturbed Christianiry; if they might be said to do so, who were little more than mere philosophers, and chiefly made profession of magic.

Simon Magnus, so often mentioned in the Acts, was their leader, and died under the emperor Nero; St. Peter still surviving; so that Clemens Alexandrinus is mistaken, when he makes Simon posterior to Marcion.

This impious man, says Moheim, is not to be ranked among the number of those who corrupted with their errors the purity or simplicity of the Christian doctrine, nor is he to be considered as the parent and chief of the heretical tribe; but he is rather to be placed in the number of those who were enemies to the progress and advancement of Christiarty. For it is manifest from all the records we have concerning him, that after his defection from the Christians, in consequence of the severe rebuke which he received from the apostle Peter, he retained not the least attachment to Christ; but opposed himself openly to the divine Saviour, and assumed to himself blaspemously the title of the supreme power of God. Orig. adv. Cellum. lib. v. p. 272. ed. Spenceri.

Simon was by birth a Samaritan, or a Jew; when he had studied philosophy at Alexandria, he made a public profession of magic, and perjured the Samaritans, by fictitious miracles, that he had received from God the power of commanding and restraining those evil beings by which mankind were tormented. As for his doctrines, Moheim adds, that he was, without doubt, in the class of those philosophers, who not only maintained the eternity of matter, but also the existence of an evil being, who prefixed, and thus shared the empire of the universe with the supreme and beneficent mind: and he, probably, embraced the opinion of those who held, that matter, moved from eternity by an intrinsic and necessary activity, had by its innate force produced, at a certain period of time, from its own substance, the evil principle which now exercises dominion over it, with his numerous train of attendants. From this pernicious doctrine, the other errors attributed to him concerning fate, the indifference of human actions, the impurity of the human body, the power of magic, and similar extravagancies, flow naturally, as from their true and genuine source.

He rejected the law of Moses, and said he was come to abolish it. He ascribed the Old Testament to the angels, and though he declared himself an enemy to them, he is said to have paid them an idolatrous worship.

This magician farther pretended, that in his person reclined the great and most powerful of the divine saints; that another saint of the female sex, the mother of all human souls, dwelt in the person of his mistresses Helena; and that he came, by the command of God, upon earth, to abolish the empire of those that had formed this material world, and to deliver Helena from their power and dominion. Moihn. Eccl. Hist. vol. i.

This fact is said to have continued to the fourth century. Justin, in his Apolog. 2, says that in his time, i.e. about A.D. 150, almost all the Samaritans, and some few others elsewhere, acknowledged Simon as the greatest of the gods. Clemens Alexandrinus (Shan. l. ii.) says that his followers worshipped him. About the year 249 this fact was reduced to about thirty persons, according to Origen (Cant. Cellum. l. i.); and elsewhere (l. v.), he says that they were quite extinct. But it appears from other testimonies, that some of them remained even at the beginning of the fifth century. Eusebius (Hist. Eccl. l. i. c. i.) speaks of Simonians, that mingled themselves among the Catholics, and received Catholic baptism; but who afterward spread in secret the venom of their doctrine. Several were discovered and expelled the church about the beginning of the fourth century. See Gnostics.

Simonides, in Biography, a celebrated Grecian poet, born in the isle of Chios, was the son of Leoprepes, and flourished in the fifth century before the Christian era. He excelled in various kinds of poetry, but especially in the elegiac, for which, as we learn from Horace and Quintilian, he was almost proverbially famous in antiquity. One of his most famous compositions was entitled "The Lamentations," of which the following fragment is all that remains, but this justifies his title to great excellence as a writer.

"Sweet child! what anguish does thy mother know,
Ere cruel grief has taught thy tears to flow!
Amidst the roaring wind's tremendous sound,
Which threatens destruction, as it howls around,
In balmy sleep thou liest, as at the breast,
Without one bitter thought to break thy rest.
While in pales, shimmering, interrupted light
The moon but shows the horrors of the night.
Didst thou but know, sweet innocent! our woer,
Not opiate's pow'r thy eyes lids now could close.
Sleep on, sweet babe! ye waves in silence roll,
And lull, O lull to rest! my tortur'd soul."

Simonides was endowed with a most extraordinary memory, and some have attributed to him the invention of the art of recollecting by localizing ideas, which has lately been brought into fashion in this country. The introduction of some of the compound letters of the Greek alphabet is also ascribed to him. He lived to an advanced age, and at the age of eighty gained a prize for poetry. According to Piny, Simonides added the eighth string to the lyre. In his old age, perhaps from seeing the respect which money procured to such as had lost the charms of youth, and power of attaching mankind by other means, he became somewhat mercenary and avaricious. He was frequently employed by the victors at the games to write panegyrics and odes in their praise, before his pupil Pindar had exercised his talents in their behalf; but Simonides would never gratify their vanity in this particular, till he had first tied them down to a stipulated sum for his trouble; and, upon being upbraided for his meanness, he said, that he had two coffers, in one of which he had, for many years, put his pecuniary rewards; the other was for honours, verbal thanks, and promises; that the first was pretty well filled, but the last remained always empty. And he made no scruple to confess, in his old age, that all the enjoyments of life, the love of money was the only one of which time had not deprived him. It is mentioned as a subject of displeasure, that Simonides was one of the first who wrote verses for money, and that he travelled through the cities of Asia, selling elegies on the victors in the public games. He paid a visit, in advanced life, to Hiero, king of Syracuse, to whom he gave the celebrated anfwer respecting the nature of God that has been handed down from generation to generation to the present time in the writings of Cicero. Hiero having asked his opinion on the subject, he requested a day to consider of it; when this was expired, he doubled the time, and thus he did repeatedly, till the monarch desired to know his reason for this proceeding: "It is," said he, "because the longer I reflect on the question, the more difficult it appears to be." He was reported to be extremely avaricious; he was, however, justly ranked among the philosophers and poets, and though sensible of the value of money, he knew what was more valuable. Undergoing shipwreck on a voyage, while the other passengers encumbered themselves with their most valuable effects, he left his behind him, saying, "I carry with me all that is mine;" and when he arrived safe at Cla-
zomene, his fellow sufferers being either drowned or pil-
laged, he met with a citizen acquainted with his poetry, who
liberally supplied all his wants. It was a witty reply which
this author made to Hero's queen, who demanded of him
whether knowledge or wealth was most to be preferred:
"Wealth," said he; "for I see every day learned men at
the doors of the rich." When he was accused of being
so fordid, as to sell part of the provisions with which his
table was furnished by Hero, he said he had done it, in order
to "display to the world the magnificence of that prince,
and his own frugality." In justification of his passion for
wealth, he said, "I choose rather to be useful to my enemies
after I am dead, than burdenfome to my friends while I am
living." He is said to have been sufficiently eloquent to re-
concile two princes extremely irritated against each other,
and actually at war. He was unquestionably one of the
most conspicuous characters of his time. Of his numerous
works only a few fragments remain, which are published in
the Corpus Poetarum Graecarum.

SIMONOR, in Geography, a small island in the Soolo
Archipelago. N. lat. 4° 59'. E. long. 119° 50'.

SIMONOKI. See XIMONOKI.

SIMONTORNY, or SIMON THORN, a town of Hun-
gary, situated on the Sarand, with a strong castle, taken by
the Imperialists in the year 1686; 32 miles S.S.W. of
Buda. N. lat. 46° 50'. E. long. 18° 25'.

SIMONY, SIMONIA, the crime of trafficking with sacred
things; particularly the corrupt presentation of any one to
an ecclesiastical benefice for money, gift, or reward.
The word is borrowed from Simon Magnus, who is men-
tioned in the Acts of the Apostles, as offering to buy the
power of working miracles with money; though the pur-
chasing of holy orders seems to approach nearer to his
offence.

By the English canons, anno 1229, simony is not only
committed by an agreement for money in hand, or to be
paid yearly; but by any other profit or emolument; any
reward, gift, or benefit, directly or indirectly; or by reason
of any promise, grant, bond, &c. and this either in the
acceptance of a living, or in an exchange or refignation.

Simony was by the canon law a very grievous crime
and it is so much the more odious, because, as Sir Edward
Coke observes, it is ever accompanied with perjury; for
the preference is sworn to have committed no simony.
However, it was not an offence punishable in a criminal way
at the common law; it being thought sufficient to leave
the clerk to ecclesiastical cenfures: but many acts of par-
liament have been made to restrain it by means of civil for-
feitures. Thus the statute of 31 Eliz. c. 6, enacts that,
if any patron, for money, or any other corrupt consideration
or promise, directly or indirectly given, shall prefer, admit,
impute, induce, induct, install, or collate any person to an eccle-
siastical benefice or dignity; such presentation shall be void,
and the patron be rendered incapable of ever enjoying the
same benefice, and the crown shall prefer to it for
that turn only; moreover, both the giver and taker shall
forfeit two years' value of the benefice or dignity; one
moity to the king, and the other to any one who will sue
for the same. If persons also corruptly resign or exchange
their benefices, both the giver and taker shall, in like
manner, forfeit double the value of the money, or other
corrupt consideration.

Further, by the statute 12 Ann. cl. 2. c. 12, if any
person, for money or profit, shall procure, in his own
name, or the name of any other, the next presentation to
any living ecclesiastical, and shall be preferred thereupon,
this is declared to be a simoniacal contract, and the party
is subjected to all the ecclesiastical penalties of simony, is
disabled from holding the benefice, and the presentation
devolves to the crown.

In the construction of these statutes, these points, says
judge Blackstone, seem to be clearly settled.
1. That to purchase a presentation, the living being ac-
tually vacant, is open and notorious simony.
2. That for a clerk to bargain for the next presentation,
the incumbent being sick and about to die, was simony,
even before the statute of queen Anne; and now, by that
statute, to purchase, either in his own name or another's,
the next presentation, and be thereupon preferred at any future
time to the living, is direct and palpable simony.

But, 3. It is held, that for a father to purchase such a
presentation, in order to provide for his son, is not simony;
the son not being concerned in the bargain, and the father
being by nature bound to make a provision for him.
4. That a simoniacal contract made with the patron,
the clerk not being privy thereto, the presentation for
that turn shall indeed devolve to the crown, as a punishment
of the guilty patron; but the clerk who is innocent, does
not incur any disability or forfeiture.

5. That bonds given to pay money to charitable uses, on
receiving a presentation to a living, are not simoniacal,
provided the patron or his relations be not benefited thereby;
for this is no corrupt consideration, moving to the patron.
6. That bonds of refignation in case of non-refidence, or
taking any other living, are not simoniacal, there being no cor-
crupt consideration therein, but such as is only for the good
of the public. So all bonds to refign, when the patron's son
comes to canonical age, are legal; upon the reason before
given, that the father is bound to provide for his son.

7. Lastly, general bonds to refign at the patron's request,
are held to be legal; for they may possibly be given for
one of the legal considerations before-mentioned, and where
there is a possibility that the transactio may be fair, the
law will not fuppose it iniquitous without proof; but if
the party can prove the contract to have been a corrupt one;
such proof will be admitted, in order to fow the bond
simoniacal, and therefore void. Neither will the patron be
suffered to make an ill use of such a general bond of refigna-
tion; as by extorting a composition for tithes, procuring
an annuity for his relations, or by demanding a refignation
wantonly, and without good cause, such as is approved
by the law, as for the benefit of his own son, or on account
of non-refidence, plurality of livings, or gross immorality
in the incumbent. Blackf. Comm. b. 3.

Simony is also committed by buying or selling the facra-
ment, baptism, ordination, or abolition; as well as by
the nomination and collation to a benefice, a place in
monastery, or the like.

By 31 Eliz. cap. 6, persons who shall corruptly ordain
or benefice any minister, or procure him to be ordained or
licensed, shall incur a forfeiture of 40l., and the minister
himself of 10l., besides an incapacity to hold any eccle-
siastical preferment for seven years afterwards. See Pre-
fentation.

Some have pretended it to be sufficient to avoid the
charge of simony, if only the ordination were gratuitous,
though the revenues were bought and sold as a temporal
thing. But the canons of several councils have condemned
this subtle distinction; since the revenues are attached to an
ecclesiastical office purely spiritual.

Cafellis distinguish three kinds of simony; viz.

Simony, Mental, is that which is refiricted to the mere
will and inclination, without ever breaking forth into act.
As when a precent is made to a collator, without taking
any notice, that we expect a benefit from him. This
kind of simony is only punifiable in foro conscientiae.

Simony,
SIMONY, Conventional, is where there is an express act, and a formal bargain, though it never come to an execution.

SIMONY, Real, is where the convention is executed on both sides; which last is the most criminal of all. The canonical penalty of simony is deposition in a cleric, and excommunication in a layman.

It is a maxim among the Romanist canonists, that there is no simony in the court of Rome; because the pope affixes there an absolute sovereign: they also say, that resignations in favor are not to be admitted but by the pope, as favouring a little of simony. On these occasions, however, the parties always swear, that there had been no deceit, collusion, simony, or other illegal covenant.

Peter Damian distinguishes three kinds of simony: that of money, that of the tongue, and that of services.

SIMONY of Money, or Per manus a manu, is where money is really paid down for a benefice: he adds, that the fame is likewise committed, by expending money to live at court to obtain a benefice.

SIMONY of the Tongue, or Per manus a lingua, confists in flattering the collaborator, or making one's self agreeable by complaisance and commendation.

SIMONY of Services, or Per manus ab obequo, confists in doing for them good offices to obtain a benefice.

It was agreed by all the jurists, Trin. oct. Jac. primi, that if the patron presigned any person to a benefice with care, for money; such pretention, &c. is void, though the preteniente were not privy to it; and the flatutae gives the preteniente to the king: but this is now repealed.

SIMORI, in Geography, a town of Naples, in Calabria Ultra; 13 miles N.E. of Squillace.

SIMORRE, a town of France, in the department of the Gers; 13 miles S.E. of Auch.

SIMPLA NOBLA, in Botany. See Phyllis.

SIMPLAR, Simplar, in Antiquity, a Roman folder, who had only single pay. Thus called, in opposition to the duplicae, or such as had double pay.

SIMPLE, Simplex, something not mixed, or compounded; in which sense it stands opposed to compound.

SIMPLE Bodies or Elements, in Chemistry, are those substances which have not yet been decomposed.

In every era of chemical science, something like a system or theory has prevail'd, which has held for its basis a certain number of bodies, called elements or simple bodies, of which all other bodies were formed. This has ever had the good effect of stimulating the minds of enquirers, and has tended much to the progress of this useful branch of philosophy. Theory has succeeded theory, varying widely from, and in some instances contradicting each other, till philosophers have become very cautious in the admission of the elementary nature of bodies; and hence have agreed in the above general definition of a simple body.

The limited proportions in which bodies combine, is sufficient to convince us, that simple bodies confitl of hard unchangeable particles or atoms, which are not practically divisible. And the general forms of the crystallas of compound matter go far to shew, that these atoms are spheres, a form the best calculated for motion, and under which they would be the least likely to change. How many varieties of these unchangeable spherical particles there exi%, it is difficult to say; and what ratio they bear to each other, in density or magnitude, we are equally at a loss to determine. One great Rep, however, has been made, which may lead us to more important conclusions. Although we are ignorant of the absolute dimensions and densities of these atoms, we are now in a way to acquire a knowledge of their relative weights, by which we shall be enabled to calculate the proportions of compound bodies, by smply knowing of what elements they are composed. The use of experiment will be to find out the elements of a compound, and rudely guess at its proportions; but the exact proportion will require to be determined by calculations, which will render chemistry as complete as astronomy.

There is the greatest reason to believe, that the atoms of simple matter attract each other by the same laws with gravitation. Sir Izaac Newton supposes, that in gold, which in his time was considered the densest body, the pores or interstices between its particles greatly exceed its material part. Of what density, therefore, must we consider the atoms of bodies. Our present idea of density is very vague, and varies with the temperature, and depends, therefore, upon the quantity of calorick they contain. If these atoms were to be finally defeated by the calorick, they would come in contact; and if they were spheres, the resulting sppecific gravity would be $\frac{4}{3}$ of the specific gravity of the atoms themselves. The calorick, on the contrary, if defeated by the atoms, would, from its repellent property, be dispersed to an unlimited extent. When, however, these two species of matter combine, they still retain their original properties; but the attraction of the atoms decreases, as they recede, by new additions of calorick in a less ratio than the repulsion of the calorick, and the two powers are kept in equilibrium by change of distance between them. If the attraction be as the square of the distance, and the repulsion as the cube; then, if the distances be successive intervals of 1, 2, 3, &c. the attractions at these points will be $\frac{1}{3}$, $\frac{2}{3}$, &c. and the repulsion $\frac{1}{3}$, $\frac{2}{3}$, $\frac{3}{3}$, &c. Therefore, the calorick at each point, to make the atoms stand in equilibrium at these respective distances, will be $1, 2, 3, &c.$ for $1 \times 1 = \frac{1}{3}$, $\frac{2}{3}$, $\frac{3}{3}$, &c. and so on. It is under this form that the specific gravity of a body is taken; but we know not what may be the density of the real atoms, although we know that it must be very considerable. In proportion as this is the case, we are to expect a greater attractive force agreeable to the laws of gravitation. If the earth were to be condened to half its diameter, the weight of bodies on its surface would be quadrupled. This circumstance, aided by the proximity of the atoms in chemical combination, and the state of aggregation, in which solids exist, will make us cease to wonder at the powers of chemical attraction, and at the same time gives a lively hope, that the same attraction is common both to gravity and chemical combination. However indeterminate this problem may appear, we understand that some experiments are soon to be instituted for settling this point.

The experiments will in the first place determine, whether these attractions are the same, or not; if they are the same, the experiments will determine, and point out the numbers which will express the strength of affinity between different bodies; the only facts which are now wanting to make chemistry a complete science.

In the present state of chemical science, those bodies considered as elements are divided into two classes; the one called combustible or inflammable, and the other supporters of composition; because in combining with the first class, much light and heat are developed.

The first class, which is by far the most numerous, consists chiefly of metals, with only a few exceptions. These are exhibited in the following table, which also contains the weights of their atoms and specific gravities; hydrogen, the lightest atom, being 1.

If the views of Gay Lussac, the French chemist, be correct, in a memoir on Jodine, or Jodine, which has been published in Dr. Thomson's Annals, we shall be hardly warranted in drawing this line between the combustible bodies, and those
SIMPLE BODIES.

The bodies of the first class, with the exception of sulphur, phosphorus, azote, hydrogen, and carbon, are known to be metals; and there is strong reason to believe that hydrogen is a metal in the elastic form. It is very remarkable, that those bodies, the metallic nature of which is doubtful, appear to possess the property of combining more strongly with inflammable bodies, than the metals with each other in forming alloys. Indeed, the combinations of most of the metals with those that are not metallic, are generally conspicuous, and always definite.

The first of the second class of bodies, viz. oxygen, has long been considered a simple body. The second has been lately, by the French chemists and by Sir Humphrey Davy, considered in the same light. It was till lately considered as a compound of muriatic acid and oxygen, from which it was called oxymuriatic acid. Its name is now changed to chlorine, from its green colour. Jodine is another substance of the same class, exhibiting striking properties with inflammable bodies. Its name has been derived from the violet colour of its vapour. It was discovered in kelp, a sublimate which consists of foda combined with certain impurities. The jodine is extracted from it by the following process. Infuse the kelp in hot water till all the soluble part is taken up; then evaporate the solution till the carbonate of foda crystallizes on cooling. In this way, by repeating the evaporation and cooling, separate as much as possible of this salt; then continue the evaporation to dryness. This residuum is now to be introduced into a gla's retort, or a long-necked matrafs, and a quantity of sulphuric acid poured upon it. This is then applied to, at first, a gentle heat. When the temperature reaches about 300°, a purple or violet-coloured vapour appears in the neck of the retort, which condenses into shining opaque crystals of the appearance of plumbeago. These crystals are pure jodine. Jodine, in the solid form, is of a greyish-black colour, its vapour being of a beautiful violet. Its crystals have a shining scaly appearance, like mica. Their form is that of rhomboid plates, and sometimes of elongated octahedrons. It is soft and friable, so as to rub to powder between the fingers. It stains the skin of a deep brown colour, but not permanently. It has the smell of chlorine or oxymuriatic gas. Its taste is acid, although it requires seven thousand parts of water for its solution. It destroys vegetable colours, like chlorine, but with less energy.

Its specific character is 4.948 at the common temperature, and water being 1. It fuses at 225° of Fahrenheit, and assumes the elastic form at 374° or 356°; but it will come over in distillation with the vapour of water. It is a non-conductor of electricity.

Jodine, like oxygen and chlorine, has the property of supporting combustion with combustible bodies. With some of these it forms compounds analogous to oxides, and with hydrogen it forms an acid resembling the muriatic acid, the compound formed by hydrogen with chlorine. It is that of these, jodine and chlorine have not only the property of supporters of combustion, but of forming acids with an inflammable base. They, however, in their turns, act the part of combustible bodies, by forming acids with oxygen. It appears also, from the views of Gay Lussac, that sulphur has also this double property, for by combining with hydrogen it forms the well-known compound called sulphurettdedt hydrogen, which possesses the properties of an acid, and is rendered so by acting the part of oxygen with the inflammable base. On the contrary, it forms sulphuric acid with oxygen by itself, acting the part of an inflammable base.

It also appears to this philosopher, that azote, carbon, and phosphorus, may have the power of producing acidity by...
by their combining with certain inflammable bases. He is of opinion, that most of the vegetable acids do not owe their acidity to oxygen combined with hydrogen and carbon, but to the carbon acting the part of oxygen with hydrogen, as sulphur, chlorine, and iodine do with the same.

According to this view, we shall give some of the facts attendant on chlorine, iodine, and sulfur, in their combinations with hydrogen and oxygen.

To the binary combinations of these bodies with others, in which they have no acidity, Gay Lussac has given the names of chlorures, iodures, and sulphures; as chloruret of potassium, ioduret of zinc, sulphuret of iron, and so on. When they form acids with hydrogen, they are termed hydrochloric, hydroiodic, and hydro sulphuric. The acids formed by their combinations with oxygen he terms chloric, jodic, and sulphuric acids. The chloric acid is the same with what has been called the hyperoxymuriatic acid, and forms with potash what has been termed hyperoxymuriate of potash. The jodic acid forms a compound with potash, having similar properties, and affording a large quantity of difposable oxygen.

The hydrochlorates are the salts which have been called muriates, and have some resemblance to the hydrates, a set of salts formed by the acid arising from the union of iodine with hydrogen, and the different saline bases.

The hydroacid is formed by first combining phosphorus with iodine, in the proportion of one of the former to nine of the latter. This compound being brought in contact with water, affords the hydroacid. The water is decomposed, the oxygen of which combines with the phosphorus to form phosphoric acid, and the hydrogen with the iodine, forming the hydroacid. If the iodine and phosphorus were 18 of iodine to 1 of phosphorus, then phosphoric acid would be formed in the water. On the other hand, if the iodine were 4 to 1 of phosphorus, then hydro acid would be formed, and a compound of phosphorus and oxygen, consisting of two atoms of the former to one of the latter. This is the red insoluble substance which has been called oxyd of phosphorus.

In all these, the hydric acid is evolved in fumes smelling like muriatic acid, and may be collected, like it, in the gaseous form. This gas is about 60 times heavier than hydrogen. Water absorbs a large quantity of it, so as to form a very strong acid, of the specific gravity of 1·7. This acid is decomposed in two ways, principally by such bodies as easily separate its hydrogen and yet free the iodine, such as the sulphuric and nitric acids, and many of the oxys, by which water and iodures are formed. It is also decomposed by the superior attraction of iodine for other bodies, letting the hydrogen free. Such is the case with most of the metals.

The compounds of the hydroacid with different saline bases form salts, resembling the hydrochlorates (muriates) and the hydro sulphates. The other binary compounds of iodine, and the different combustible bodies which are called iodures, are very conspicuous. Most of these are insoluble in water. Those metals which decompose water, form soluble iodures; as in these instances the ioduret becomes an hydro iodate.

Another set of compounds results from iodine, which we have already called iodates. Iodine combines with oxygen, in the proportion of 5 atoms of the latter to 1 of the former, which is 117 iodine to 5 x 7·5 = 37·5 of oxygen. This constitutes the jodic acid.

This acid cannot be directly formed by combining iodine with oxygen; but it is formed during the action of iodine upon potash, soda, barytes, flor- sial, lime, and magnesia, when water is present. The changes are precisely what take place, when chlorine is sublimated for iodine. Two salts are formed with the base employed; the one with chloric or jodic acid, and the other with hydrochloric or hydroiodic acid.

When iodine in vapour is passed through a solution of potash, four atoms of iodine decompose four atoms of water, by which four atoms of hydro iodic acid are produced. These unite with four atoms of potash, forming as many compound atoms of hydrates of potash. The four atoms of oxygen, separated from the water, now unite with a fifth atom of iodine, and a fifth atom of potash; the whole of which will amount to an atom of ioduret of potash, united to five atoms of oxygen, constituting an atom of jodurate of potash. It will appear, therefore, that during the formation of any of the iodates or the chlorates, that for every atom of such iodate or chlorate there will be formed, at the same time, four atoms of an hydrate or hydrochlorate.

In the example above illustrated, an atom of iodate of potash will be 1 atom of iodine (117) + 1 atom of potassium (37·5) + 5 atoms of oxygen (5 x 7·5) = 192. The 4 atoms of hydrate of potash will consist of 4 atoms of hydro iodate acid (4 x (117 + 1)) + 4 atoms of potash (4 x (37·5 + 1·5)) = 472 + 180 = 652. The ratio, therefore, of the iodate of potash to the hydrate will be 192 to 652, or 100 to 340 nearly. In the crystalline form, however, the hydrate of potash does not exist, but is converted into ioduret of potash, which will consist of an atom of iodine (117) added to an atom of potash (37·5) added to 187·5, and 187·5 x 4 = 750, the quantity of the crystallized ioduret to the iodate, which will be 100 to the latter to 322 of the former nearly.

It is rather out of place to enter into the particulars of bodies; but this last fact, from its recent discovery, has not been before mentioned in this work. There are also many interesting particulars respecting chlorine; but these are rather new explanations, under the idea of this being a simple body, than new facts.

We know little more of the body called fluorine, than that it is in all probability a body combining with hydrogen to form fluoric acid, in the manner that chlorine and iodine form hydrochloric and hydroiodic acids with that body. To the combinations of chlorine with the different bodies, in which no acidity prevails, Dr. Thomson has proposed the name of chlorides, as being more agreeable to the termination in the word oxyd; and we supposes would adopt, for similar combinations of iodine, jodides; and we should expect, from the sulphates being analogous, that they would be called phosphides, to keep up the same uniformity. The French chemists (see Gay Lussac’s Memoir on Jodine, Thomson’s Annals, vol. v.) have adopted for the same compounds the termination already used for the sulphates, viz. chlorures, jodures; and for the combinations of carbon and azote with the same bodies, they would use carbures, azoures, or, what is better, nitroesures. We see no objection to this termination for all the binary compounds not pollelling acidity, as in fact there would be no other change than that of altering oxyd into oxyduret. The acids would still retain their terminations, oxy and oxyet, distinguishing those which do not contain oxygen by the acidifying substance. The salts, as at present, would derive their names from the acids. See Nomenclature.

Simple, in Botany, is a general name given to all herbs and plants; as having each its particular virtue, by which it becomes a simple remedy.
The simples from the Levant, and the East Indies, were not known among us till about the year 1260.

Simple Leaves. See Leaf.

The term simple is also technically applied to some other parts of a plant. A simple calyx is used in the columnarous order, in opposition to the double one of Malvæ, Hibiscus, and many other genera of that order. A simple stigma means, that the part in question is of no elaborate or peculiar shape, or structure, but merely adequate to perform its requisite functions. This end is sufficiently answered by a rather obtuse, though not dilated, figure, jut enough to receive the pollen upon a moist surface, or point. If a stigma be acute, or taper-pointed, that character should be specified; as also if it be capitate, concave, lobed, fringed, &c. in all which latter cases it is no longer simple. See Stigma, and Fecundation of Plants.

A simple stem, or stalk, is destitute of branches, or subdivisions. Such also is simple pabulence, the hairs of which are unbranched and straight; not felated, entangled, or hooked.

Simple, in French Music, in an air with variations, implies the air itself; in opposition to the doubles or variations. See Air, and Double.

Simple Cadence, is that where the notes are all equal through all the parts.

Simple Concords, are those in which we hear at least two notes in consonance; as a third and a fifth; and, of consequence, at least three parts. This is either done immediately, and is called the harmonical triad, or in a more remote manner, that is, when the founds, that are not bals, are one or two octaves higher. This distance has no ill effect in the third, but in the fifth it has; and, generally speaking, the nearer, or more immediate, the concords are, the better. See Concord.

They also say C simple, or plain, in opposition to C accented.

Simple Counterpoint, Fugue, Interpol, Sounds, and Triple. See the substantives.

Simple Equation, Fraction, and Surd, in Algebra. See the substantives.

Simple Quantities, are those which consist of one term only; as $a + b$, $a - b$, or $a b c$; accordingly they are opposed to compound quantities.

Simple Glands, in Anatomy. See Glands.

Simple Anatomy and Excentricity, in Agriculture. See the substantives.

Simple Form, Modes, Necessity, Opposition, and Proposition, in Logic and Metaphysics. See the substantives.

Simple Average, Benefice, Church, Deposit, Exchange, Fee, Force, Larceny, Requisition, and Vandalism. See the substantives.

Simple Contract, Deeds by, are such, where the contract upon which the obligation arises is neither ascertained by matter of record, nor yet by deed or special instrument, but by mere oral evidence, or by notes unsealed, which are capable of a more easy proof, and (therefore only) better than a verbal promise.

Simple Diachylon, Diacodium, Diasorum, Diasprium, Dropus, Fomentation, Hydrocol, Mixture, Osmum, and Waters. See the substantives.

Simple Fencing. See Fencing.

Simple Flank and TENAILE, in Fortification. See the substantives.

In Geometry, we say, the most simple demonstrations are the best.

In Grammar, we have simple words, or primitives; and compounds, which have some particle added to them.

In Jurisprudence, they say a simple donation, in opposition to a mutual or reciprocal one; a simple sale, in opposition to that made with a reservation of the faculty of redemption; and simple homage, in opposition to liege homage.

Simple Fossils, in Natural History. See Fossils.

Simple Machines, Motion, Pendulum, and Wheel, in Mechanics. See the substantives.

The simplest machines are always the most esteemed.

Simple Vision, in Optics. See Vision.

In Pharmacology, there are simple remedies, and compounds; the former of which are usually preferable to the latter.

Simple Taste, in Physiology. See Taste.

Simple History and Style, in Rhetoric. See the substantives.

Simple Fracture and Ulcer, in Surgery. See the substantives.

SIMPLER'S Joy, in Botany. See Verena.

SIMPLEX Oculus, in Surgery, the name of a bandage for the eye.

Simplicity, in Ethics. See Sincerity.

Simplicity, in Music. There is much cast about simplicity in music, among the exclusive admirers of old things, and lamentation for the loss of our old melodies to the songs of Chancer, Gover, Lydgate, and others, of which the words are full extant. But if we may judge by what has escaped the ravages of time, of a later date, the loss of our musical compositions of this period may be supported without much affliction. We may perhaps heighten that affliction considerably by censoring modern refinements, and extolling the charms of ancient simplicity; but simplicity in melody, beyond a certain limit, is unworthy of the name that is bestowed upon it, and encourageth so much upon the rude and savage boundaries of uncouthness and vulgarity, as to be wholly separated from proportion and grace, which should alone characterise what is truly simple in all the arts: for though they may be enabled by the concealement of labour and pedantry, they are always degraded by an alliance with coarse and barbarous nature.

Old melodies, when we find them, and can ascertain their dates, are curious historical facts in the annals of the musical art; and afford us more satisfaction information concerning our ancient national tane, than all the verbal descriptions in prose and verse can do. And it must be owned, that though the natives of Scotland, Ireland, and Wales, can boast of national tunes, both plaintive and spirited, that are characteristic, pleasing, and distinct from each other, the English have not a melody which they can call their own, except the hornpipe and Cheshire-round. The hornpipe, indeed, was in all probability British, or Welsh, as the pip-corn, or pipe of Cornwall, was an armoric instrument and tune, brought thither by the Britons, driven to that part of the island, and into Britany and Wales, by the Saxons. The Cheshire-round is a melody of the same kind. See Hornpipe, and plate of National Tunes.

SIMPPLICIUS, Pope, in Biography, a native of Tivoli, was elected to the pontificate in September 457, on the death of Hilary. During the time of his pontificate the see of Rome, great commotions excited in the eastern and western empire. The latter terminated in the perfidy of Augustulus, who was dethroned by Odoacer, king of the Heruli, an Arian. In the East the emperor Zeno was dethroned by Bafilicinus, who declared against the council of Chalcedon. Simplicius does not appear to have been personally molested in these changes, but he was frequently called upon to exert himself in defence of the claims of his see, and of the orthodox faith. He moreover extended and strengthened
SIMPLIFIED, in Ecclesiastical Matters, is the taking away of a cure of souls from a benefice, and dispening the beneficiary from residence.

Several benefices, which have been simplified, now require residence; and many others, which required residence, have been simplified.

Some use the word in a more extensive signification, viz. for the shortening a relation, &c. or retrenching every thing not precisely necessary. When the matter of fact shall be simplified, and stripped of its vain circumstances, the court will see, &c.

SIMPLE, in Rhetoric, a figure which comprehends both the anaphora and epistrophe. In this figure the several members begin and end with the same word. Thus St. Paul: Are they Hebrews? So am I. Are they Israelites? So am I. Are they the seed of Abraham? So am I. 2 Cor. xi. 22.

SIMPLON, in Geography, a mountain of Switzerland, over which is a passage from the Valais to the duchy of Milan; 6597 feet above the level of the sea; 31 miles E. of Sion.

SIMPLUDIA RIA, in Antiquity, a kind of funeral honours paid to the deceased at their obsequies.

The word is formed from the Latin simplex, and ludus; whence simpliciaria, or simpliciaria, q. d. simple games. Some will have simpliciaria to be the funerals at which games were exhibited; such is the sentiment of Paulus Diaconus. Fellus says, they were those, in the games of which nothing was seen but dancers and leapers, called coritores, who, according to M. Dacier, were persons who run along the masts and yards of vessels or boats, called corbe.

In other respects, these two authors agree as to the kind of funerals called simpliciaria; viz. that they were opposite to those called indelica; in which, besides the dancers and leapers observed in the simpliciaria, there were defiltores, or people who vaulted on horses; or perhaps horse-races, in which the cavaliers leaped from horse to horse at full speed.

SIMPSON, Thomas, in Biography, a celebrated self-taught mathematician, was born at Market Bosworth in Leicestershire, in 1716. His father, who was a weaver in that town, intended to bring him up to his own trade, and took little heed of his education. Nature, however, had endowed him with fine talents, and an ardour of disposition, which excited him to nobler pursuits. At an early period he gave indications of his turn for study, by eagerly perusing every book that fell in his way, and omitting no opportunity to acquire instructions from others. His father, finding that he was thus led to neglect his work, endeavoured to restrain him from what he regarded as idle pursuits; but after some fruitless attempts, a difference was produced between them, which at length terminated in an open rupture, and Thomas left his father's house, and married the widow of a tailor, with whom he resided at Nuneaton, where he continued some time working at his trade, and improving his knowledge. Here he became acquainted with a traveling pedlar, who lodged in the same house, and who, to the profession of an itinerant merchant, had united the more profitable one of a fortune-teller. An intimacy was formed between them, and as the pedlar was going to Bristol, he lent, during his absence, Cocke's Arithmetic to Simpson, to which was subjoined a short appendix on Algebra; and a book on Genitures, by Partridge, the almanac-maker. These books he studied so closely, that on the pedlar's return, he was astonished to find that Simpson was little inferior to himself in the art of calculating nativities; and he predicted that he would shortly be his superior. Encouraged by this prophecy, he at first determined to embark in the trade of a fortune-teller; and by this occupation, and teaching a school, he found means to support himself without weaving, which he now entirely abandoned, and was soon regarded as the oracle of the neighbourhood. From this time he seems to have lived very comfortably, till an unfortunate event involved him in a deal of trouble. Having undertaken to raise the devil, in order to answer certain questions to a young woman, who consulted him respecting her sweetheart, then absent at sea, the credulous girl was so frightened on the appearance of a man from beneath some straw, who represented the devil, that she fell into violent fits, from which she was with difficulty recovered, and which for a considerable time threatened insanity or fatuity. In consequence of this exertion of his art, he was obliged to leave the place, and he removed to Derby, where he remained a few years, working at his trade by day, and instructing pupils in the evening. He became a writer in the Lady's Diary in the year 1736: his first questions were inserted in verse, and are of that kind as shew that at this period he had made some progress in mathematical knowledge. He from this period applied himself with great ardour to every branch of the analytic science, and acquired a deep insight into the doctrine of fluxions, upon which he afterwards published a work, which is even now regarded as among the best, if not the very best, existing in our language. After he had given up astrology, and its emoluments, he found himself reduced to great straits, notwithstanding his industry to provide a subsistence for his family at Derby; and on that account he determined to remove to London, which he did in the year 1736. When he arrived at the capital, unknown and without recommendation, he for some time followed his business in Spitalfields, and taught mathematics in the evening, and at other spare hours. His exertions were attended with such successes, that he returned to the country, and brought to town his wife, with her three children. The number of his scholars increased, and he was encouraged to make proposals for publishing by subscription.
subcription "A New Treatise of Fluxions." The book was printed in 1737. In the year 1740 he published "A Treatise on the Nature and Laws of Chance." This is a very thin and small quarto; and to this treatise are annexed full and clear investigations of two important problems, added to the second edition of De Moivre's Book of Chances, as also two new methods for the summation of series. Mr. Simpson's next publication was a volume, in quarto, of "Essays on several curious and interesting Subjects in speculative and mixed Mathematics," printed in 1740. Soon after the publication of this book, he was chosen member of the Royal Academy at Stockholm. This was followed by a smaller volume, on "The Doctrine of Annuities and Reversions, deduced from general and evident Principles, with useful Tables, shewing the Values of single and joint Lives." Next year came out an "Appendix, containing Remarks on De Moivre's Book on the fame Subject, with Answers to some personal and malignant Representations in the Preface to it." In 1743 he published his "Mathematical Diflertations on a variety of phicile and analytical Subjects." Shortly after this he published "A Treatise on Algebra," which in the year 1755 he enlarged and considerably improved. After this he gave the public his "Elements of Geometry," with their application to mensuration, to the determination of maxima and minima, and to the construction of a great variety of geometrical problems. This work has passed through many editions, and is still read in some places devoted to the education of the young; though we think it has been superceded by other treatises of more modern date. The first edition of this book occasioned some controversy between Mr. Thomas Simpson and Dr. Robert Simson, the author of a well-known edition of Euclid's Elements. See SIMSON.

In the year 1748, Mr. Simpson published "Trigonometry, plane and spherical, with the Construction and Application of Logarithms." In 1750 he published a new edition of his "Treatise on Fluxions," which, however, he wished to be considered rather as a new work than a new edition of an old one. In 1752 appeared in 8vo. a work, entitled "Select Exercises for young Proficients in Mathematics," and in 1755 he published his last work, entitled "Miscellaneous Tracts." "which," says Dr. Hutton, "was a valuable bequest, whether we consider the dignity and importance of the subjects, or the sublime and accurate manner in which they are treated." Such are the scientific works of Mr. Simpson. Through the interell of Mr. Jones, the father of the celebrated Sir William Jones, Mr. Simpson was, in 1743, appointed to the professorship of mathematics, then vacant, in the Royal Academy of Woolwich; and in 1745 he was admitted a fellow of the Royal Society. On this occasion, in consequence of his very moderate circumstances, he was excused his subscription fees, and from giving bond for the settled future annual payments. As a professor, he exerted all his talents in instructing the pupils committed to his care. He had, it has been said, a peculiar and happy method of teaching, which, united to a great degree of mildness, engaged the attention, and conciliated the esteem and friendship of his scholars. Mr. Simpson died in the year 1761, in the 51st year of his age. Besides the works already mentioned, he wrote several papers, which were read before the Royal Society, and printed in their Transactions. He was not only a contributor to, but for some years editor of, the Lady's Diary, during which, viz. from the year 1754 to 1760, he railed that work to a high degree of respectability. In 1760, when a plan was in agitation for erecting Blackfriars bridge, he was consulted by the committee in regard to the belt form for the arches. On this occasion he preferred the semicircular form; and besides his report to the committee, he wrote some letters on the subject, which were afterwards published in the Gentleman's Magazine.

SIMPSON, John, was born at Leiceter, in the month of March 1746. He was educated for the ministry among the Protestant dissenters, under the care of Mr. (afterwards Dr.) John Aikin, who kept a flourishing school at Kibworth, in Leicetershire, and afterwards an academy at Warrington, for the education of young men devoted to the ministry. From Warrington Mr. Simpson went, in 1765, to Glasgow, where he spent two years in this ancient seat of learning, and where he attended the lectures of the excellent Dr. Leechman. At Glasgow he remained two years, when he pursued his studies in a private manner among his relations, till the month of April 1772, when he settled at Nottingham, and from thence removed, in 1777, to Walthamstow, where he became pastor of the congregation of dissenters, which had previously enjoyed the joint services of Mr. Farmer and Mr. Radcliffe. Here he remained but two years, and after this it does not appear that he was settled any where as minister, but continued preaching occasionally to the end of his life. As a preacher he acquired considerable reputation, but he is chiefly known as a critic on the Holy Scriptures. His principal work is entitled "Essays on the Language of Scripture," two volumes octavo. Besides this he published many other works, among which are "An Essay to shew that Christianity is belit conveyed in the Historic Form."

SIMPSON, Christopher, an English musician of the seventeenth century, extremely admired for his performance on the viol da gamba, or six-stringed-baye, and general knowledge of music. The bafe-viol with six stringes, and a fretted finger-board, was in such general favour in his time, that almost all the first musicians of our country, whose names are come down to us, were performers upon it, and composed pieces purposely to shew its powers; but particularly Coperario, William Lawes, Jenkins, Dr. Colman, Lupo, Mico, and Loofemore.

Simpson, during the last years of the Ufurpation, published a treatise on this instrument, entitled "The Division Violit, or an Introduction to the playing upon a Ground." But this instrument, like the lute, without which no concert could subsist, was soon after so totally banished, that its form and construction were scarcely known, till the arrival of Abel in England, whose taste, knowledge, and expression upon it were so exquisite, that, instead of renovating its use, they seem to have kept lovers of music at an awful distance from the instrument, and in utter despair of ever approaching such excellence. The instrument itself, however, was so nafal, that this great musician, with all his science and power of hand, could not prevent his moit en-
thusiastic admirers from lamenting that he had not, early in life, applied himself to the violin cello.

But if its general use had continued, or were restored, this book of Simpson, from the universal change of taste and style of every species of music, would be of but little use to a student on that instrument now; when rapid divisions, of no other merit than the difficulty of executing them, have been totally supplanting by vocal expression, learned modulation, and that rich harmony to which the number of its strings is favourable. Rough, but warm encomiastic verses, are prefixed to Simpson's works by Dr. Colman, John Jenkins, Mathew Lock, and others, which only shew what with perishable materials musical fame is built!

A translation of this book into Latin, for the use of foreigners, with the original text on the opposite page, was published by the author in 1665, under the title of "Chelys Minutionum; Edition secunda," thin folio.

Besides these, Simpson published, in 1667, "A Compendium of practical Music, in five Parts, containing 1. The Rudiments of Song. 2. The Principles of Composition. 3. The Use of Figures. 4. The Form of Figurate Defects. 5. The Contrivance of Canon."

Whoever expects to learn the whole principles of an art by a single book, or, indeed, any number of books, without oral instruction, or great study, practice, and experience, must be disappointed. This compendium, like most others of the kind, more frequently generates new doubts and perplexities, than removes the old. However, something is to be learned from moff books; and what a student is unable to find in one, if out of the reach of a master, must be sought for in another.

Simpson, in his younger days, served in the royal army, raised for Charles I. by Cavendish, duke of Newcastle; he was a Roman Catholic, and patronized by Sir Robert Bolles, of Leicesters-Place, with whom he resided during the Interregnum. He seems to have been in close friendship with Jenkins and Lock, as, on all occasions, they reciprocally praise each other.

Simpson, Redmond, an eminent performer on the hautbois. He was a natural son of Dubourg, the famous performer on the violins, and served an apprenticeship to Low, the hautbois player and copyist. Simpson, when out of his time, improved in the performance on his instrument so much, as to be thought, till the arrival of Fischer, superior to all the hautbois players of his time, except T. Vincent, the disciple of Martini. On the death of Richard Vincent, in 1777, first hautbois, during more than thirty years, of Covent Garden playhouse, and of Vauxhall gardens, father of the first husband of Miss Burchell, Simpson was engaged as first hautbois at Covent Garden, and in a few years rendered himself so useful in bringing out musical performances at that theatre, that he was appointed joint manager; and was an active and important perfonage at the meetings of the musical fund; was one of the affiduous directors at the commemoration of Handel, in 1784; had a turn for bufinesses; and after ceasing to play in public, he was often useful in flats, calculating, and settling the accounts of the society, to the time of his death, in January 1787. He was buried in the cloister of Westminster Abbey, his funeral being attended by the principal professors in London.

Simpson, in Agriculture, a provincial term applied to groundsel, a troublesome weed in some soils.

SIMPSON'S Island, in Geography, a small island in the South Pacific ocean, discovered by captain Carteret in 1767; 4 miles W. from Carteret island. S. lat. 6° 20'. E. long. 15° 20'.

SIMPULUM, among the Romans, a vessel with a long handle, and made like a crust. It was used in sacrifices and libations, for taking a very little wine at a time.

SIMRAR, in Geography, a town of Hindostan, in Oude; 24 miles E.S.E. of Fyzabad.

SIMREE, a town of Bengal; 32 miles N.N.W. of Boghpiur.

SIMSAT, a town of Asiatic Turkey, in the government of Diarbekir; 54 miles W. of Diarbekir.

SIMSBURY, a post-town of America, in Hartford county, Connecticut; 14 miles N.W. of Hartford. Copper-ore has been found in this place. It contains 1966 inhabitants; 386 miles from Washington.

SIMSIA, in Botany, so called by Mr. Brown, is a just tribute to the botanical learning and skill of Dr. John Sims, F.R.S. and F.L.S. the continuator, since the fourteenth volume, of the popular and very useful Botanical Magazine, of the late Mr. William Curtis; see that article. - Brown Tr. of Linn. Soc. v. 10. 152. Prodr. Nov. Holl. v. 1. 367.

Gen. Ch. Cal. none, unless the corolla be taken for such. Cor. Petals four, inferior, linear-oblong, equal, deciduous; reflexed at the extremity. Nectary none. Stam. Filaments four, awl-shaped, prominent, inserted into the disk of each petal; anthers roundish, cohering, so that the adjoining lobes of each make one common cell, at length separating. Pjfl. German superior, obovate; style cylindrical; stigma dilated, concave. Peric. Nut inversly conical, of one cell, naked.

A New Holland genus of smooth shrubs, of humble growth. Leaves alternate, thread-shaped, forked; their foliage dilated at the base. Flowers small, yellow, smooth, compositing small, globoso, terminal heads, disposed either in clusters or panicles, with or without a short common involucrum, and with a minute bractea under each flower. Two species only are mentioned.

2. S. anethifolia. Fennel-leaved Simia. — Heads numerous in each panicle, and about as long as its partial branches, accompanied by imbricated involucral leaves. — Gathered by Mr. Brown, on the sandy sea-shores of the fame country.

SIMSKÅLÀ, Oster and Weijer, in Geography, two small islands in the Baltic, E. of Aland, about four miles apart. N. lat. 60° 21'. E. long. 20° 8'.

SIMSON, Ronard, in Biography, was born in the year 1687, of a very respectable family, in the county of Lanark. He was educated in the university of Glasgow, where he made great progress in his studies, and acquired in every branch of science a large flock of information, which, if it had never been greatly augmented afterwards, would have done great credit to any professional man. He became, at an early period, an adept in what was denominated the philosophy and theology of the schools, and was able to supply with great credit the place of a sick relation in the clafs of Oriental languages. While he was pursuing a course of theology, as preparatory to his entering into orders, mathematics took hold of his fancy, and he would, in after-life, say...
say that he amused himself in his favourite pursuit, while he was actually preparing his exercises for the divinity hall. When fatigued with speculations, in which he could not meet with certainty to reward his labours, he relieved his mind, ardent in the pursuit of truth, by turning to mathematics, with which he never failed to meet with what would satisfy and refresh him. For a long time he restricted himself to a very moderate use of the cordial, fearing that he should soon exhaust the stock which so limited and abstract a science was capable of yielding; at length, however, his views were diffipated on this head, for he found that the more he learned, and the farther he advanced, the more there was to learn, and a still wider field opened to his view. He accordingly determined to make the mathematics the profession of his life, and gave himself up to the study without reserve. It is said, that his original incitement to this science as a treat, as something to please and refresh the mind in the midst of feverish tasks, gave a particular turn to his mathematical pursuits, from which he could never deviate. He devoted himself chiefly to the ancient method of pure geometry, and felt a decided dislike to the Cartesian method of substituting symbols for the operations of the mind, and still less was he willing to admit symbols for the objects of discussion, for lines, surfaces, solids, and their affections. He was rather offixed in the solution of an algebraical problem, where quantity alone is to be considered, to substitute figure and its affections for the algebraical symbols, and to convert the algebraic formula into an analogous geometrical theorem. In fo little respect did he come at last to consider algebraic analysis, as to denominate it a mere mechanical knack, in which he would say we proceed without ideas of any kind, and retain a refult without meaning, and therefore without any conviction of its truth.

About the age of twenty-five Dr. Simson was chosen professor of mathematics in the university of Glasgow. He immediately went to London, and there formed an acquaintance with the most eminent men who at that time flourished in the metropolis. Among these was the celebrated Halley, of whom he always spake with the most marked respect, saying that he had more acute penetration, and the most just taste in that science, of any man he had ever known. Dr. Simson also admired the matterly steps which Sir Isaac Newton was accustomed to take in his investigations, and his manner of substituting geometrical figures for the quantities which are observed in the phenomena of nature. He was accustomed to say, that the 39th proposition of the first book of the Principia, was the most important proposition that had ever been exhibited to the physico-mathematical philosopher, and he used to illustrate to the higher classes of his pupils, the superior strength of the geometrical over the algebraic analysis, by comparing the solution given by Newton, of the inerter problem of centripetal forces, in the 423rd proposition of that book, with the one given by John Bernoulli, in the Memoirs of the Academy of Sciences at Paris, for the year 1743.

Returning to his mathematical chair, Dr. Simson discharged the duties of a professor, for more than half a century, with great honour to the university and to himself. It is scarcely necessary to add, that in his lectures he always made use of the geometry of Euclid, in preference to those works which he thought leaned too much to analysis. His method of teaching was simple and perspicuous, his elocution clear, and his manner easy and imperious. He uniformly engaged the respect and affection of his pupils.

It was owing to the advice of Dr. Halley that our author so early directed his efforts to the restoration of the ancient geometers. He had recommended this to him as the most certain means of acquiring a high reputation, as well as to improve his taste, and he presented him with a copy of Pappus's Mathematical Collections, enriched with his own notes. The periplicity of the ancient geometrical analysis, and the elegance of the solutions which it affords, induced him to engage in an arduous attempt, which was nothing less than the entire recovery of this method. His first task was the restitution of Euclid's Porisms, from the scanty and mutilated account of that work in a single passage of Pappus.

He, however, succeeded, and so early as 1718, feems to have been in possession of this method of investigation, which was confirmed by the eminent geometers of antiquity as their surest guide through the intricate labyrinths of the higher geometry. In 1723 Dr. Simson gave a specimen of this discovery in the Philosophical Transactions; and after that period he continued with unremitting industry to restore those choice porisms which Euclid had collected, as of the most general use in the solution of difficult problems. Having obtained the object of which he was in pursuit, he turned his thoughts to other works of the ancient geometers, and the Porisms of Euclid had now only an occasional share of his attention. The Loci Plani of Apollonius were the next task in which he engaged, and which he completed in the year 1738; but after it was printed he was far from being satisfied that he had given the identical propositions of that ancient geometry; he withheld the impress several years, and it was with extreme reluctance that he yielded to the entreaties of his mathematical friends in publishing the work in 1745, with some emendations, in those cases in which he thought he had deviated the most from the author. Anxious for his own reputation, and fearing that he had not done justice to Apollonius, he soon recalled all the copies that were in the hands of the booksellers, and the impression lay by him several years. He afterwards revised and corrected the work, and even then did not, without some degree of hesitation, allow it to come into the world as the restoration of Apollonius. The work was, however, received by the public with great approbation; the author's name became better known; and he was now considered as among the very first and most elegant geometers of the age. He had, previously to this, published his Conic Sections, a treatise of uncommon merit, whether considered as a complete restitution of the celebrated work of Apollonius Pergaeus, or as an excellent system of this useful branch of mathematics. This work was intended as an introduction, or preparatory piece, to the study of Apollonius, and he has accordingly accommodated it to this purpose. The intimate acquaintance which Dr. Simson had now acquired with all the original works of the ancient geometers, as well as with their commentators and critics, encouraged him to hope that he should be able to restore to its original state that most useful of them all, the Elements of Euclid, and under the impression of this idea, he began seriusly to make preparation for a new and more perfect edition. The errors which had crept into this celebrated work appeared to require the most careful efforts for their extirpation; and the data also, which were in like manner the introduction to the whole art of geometrical investigation, seemed to call for the noblest exertions of a real master in the science. The data of Euclid have fortunately been preserved, but the work was neglected, and the few ancient copies, which amount only to three or four, are said to be wretchedly mutilated and erroneous. It had, however, been restored, with some degree of success, by previous authors; but Dr. Simson's view of the whole analytical system pointed out to him many parts which still required amendment. He therefore made its restitution a joint task with that of the Elements, and all lovers
lovers of geometry are ready gratefully to acknowledge their obligations to him for his edition, which contains the Elements and the Data, and which has gone through many impressions in quarto and octavo, in the Latin and English languages.

Another work on which Dr. Simfon bestowed great labor and pains, was the Scenio Determinata of Apollonius, which, though begun early, was not given to the world till after his death, when it was printed with the work on Periems of Euclid, at the expense of the late earl Stanhope, who was himself deeply read in mathematics, and who for many years had kept up a constant correspondence with Dr. Simfon; and at the death of the professor, in 1768, the noble lord engaged Mr. Clow, professor of logic in the university of Glasgow, to whose care he had left all his papers, to make a selection of such as might serve to support and extend his well-earned reputation as the restorer of ancient geometry.

"The life of a literary man," says his biographer, "feldom marked with much variety; and a mathematician immersed in study, is more abstractive, perhaps, than any other person from the ordinary occurrences of life, and even the ordinary topics of conversation. Such was the case with Dr. Simfon. As he never entered into the marriage state, and had no occasion for the commodious house in the university, to which as professor he was entitled, he contented himself with chambers, spacious enough for his own accommodation, and for containing his large, but well-selected, collection of books, but without any decoration, or even convenient furniture. His official servant acted as valet, footman, and bed-maker; and as this retirement was entirely devoted to study, he entertained no company at his chambers, but on occasions, when he wished to see his friends, he repaired to a neighbouring house, where an apartment was kept sacred to him and his guests. He enjoyed a long course of uninterrupted health, but towards the close of life he suffered from acute disease, which obliged him to employ an assistant in his professional labours. He died in 1768, at the age of 81, leaving to the university his valuable library, which is now kept apart from the rest of the books. It is still regarded as the most complete collection of mathematical works and manuscripts in the kingdom, many of them being rendered doubly valuable by the addition of Dr. Simfon's notes. It is open for the public benefit, but the use of it is limited by particular rules and restrictions. Dr. Simfon was of a good nature, and he had a fine countenance, and even in his old age he retained much gracefulness and dignity of manner. He was naturally disposed to cheerfulness; and though he feldom made the first advances towards acquaintance, he always behaved with great affability to strangers." See Dr. William Trail's Account of the Life and Writings of Dr. Simfon.

SIMULACRUM, among the Romans. See IDOL and IDOLATRY.

SIMULATION, in Ethics, is making a thing appear which does not exist; and thus it is distinguished from dissimulation, which is keeping that which exists from appearing. See Dissimulation.

SIMULANDY, in Geography, a town of Bengal; 60 miles N.E. of Puckooe.

SIMULIYA, a town of Bengal; 25 miles N.N.E. of Dacca.

SIMUS, in Ichthyology, the name used by some authors for the nalu, or nate, a fish common in the large rivers in Germany, and somewhat resembling our chub, and in some respects our common rudd.

SIMYRA, SIMHAN, in Ancient Geography, a town of Vol. XXXII.
occasions; and our first parents, after their transgression, received such deep traces in the brain, by the impression of sensible objects, that it was very possible they might communicate them to their children.

Now, as it is necessary, according to the order established by nature, that the thoughts of the foul be conformable to the traces in the brain; it may be said, that as soon as we are formed in the womb, we are infected with the corruption of our parents: for having traces in the brain like those of the persons who gave us being, it is necessary we have the same thoughts, and the same inclinations, with regard to sensible objects. Thus, of course, we must be born with concupiscence and original sin. With concupiscence, if that be nothing but the natural effort the traces of the brain make on the mind to attach it to sensible things; and with original sin, if that be nothing but the prevalence of concupiscence; nothing, in reality, but these effects considered as victorious, and as matters of the mind and heart of the child.

Imputed original sin denotes that guilt or obligation to punishment, to which all the polterity of Adam are subject, by the imputation of his transgression. This is called the guilt of Adam's first sin, in which the finfulness of that state into which man fell is partly to consist; and it is denominated original sin, in order to distinguish it from actual sin, or personal guilt. This doctrine of imputed guilt has been explained and vindicated by supposing a covenant made with Adam, (called by divines the "covenant of works," see COVENANT,) as a public person, not for himself only, but for his posterity, in consequence of which he became the federal head, surety, or representative of all mankind; and they descending from him by ordinary generation, finned in him, and fell with him, in his first transgression. It has been debated, how far the imputation of Adam's sin reaches: some have maintained, that it extends to final condemnation, and eternal misery; others have suggested, that the sin of Adam has subjected his posterity to an utter extinction of being; so that all, who die in their infancy, fall into a state of annihilation, excepting those who are the seed of God's people, who, by virtue of the blessings of the covenant made with Abraham, and the promise to the seed of the rightous, shall, through the grace and power of Christ, obtain a part in a happy resurrection, in which other infants shall have no share.

It seems best to acknowledge, says Dr. Doddridge, that we know nothing certain concerning the state of infants, and therefore can assert nothing positively; but that they are in the hands of a merciful God, who, as he cannot consistently with justice and truth give them a sense of guilt for an action they never committed, so probably will not hold their souls in being merely to make them sensible of pain for the guilt of a remote ancestor, their existence in a state of everlasting insensibility (which was Dr. Ridgley's scheme) seems hardly intelligible; we must, therefore, either fall in with the above-mentioned hypothesis, or suppose them all to have a part in the resurrection to glory, which seems to put them all on a level, without a due distinction in favour of the seed of believers; or else must suppose they go through some new state of trial, concerning which the Scripture is wholly silent.

Such is the doctrine of original sin, both inherent and imputed, as some divines, eminent as scholars and theologians, have stated it. In proof of the degeneracy or depravity of human nature, they have appealed to observation and experience, and they have referred to a variety of texts of scripture, in which, according to their ideas of them, it is either implied or expressed. To those who object, that the phenomenon of universal corruption in adult persons may be accounted for by imitation, and to want of early instruction, restraint, and discipline, they reply, that the scriptures seem to trace it to a higher source, and that children often manifest propensities towards those vices of which they have seen no examples; to which it is added, that there are many examples of eminent virtue in the world, and yet they are not so frequently, or so easily imitated, as those of a vicious nature, which plainly shews a bias on the mind towards vice. Hence they say, Pagans themselves, who have been most distinguished by their study of human nature, have acknowledged, in strong terms, an inward depravation and corruption adding a disproportionate force to evil examples, and rendering the mind averse to good. Those who maintain, that the sin of Adam is imputed to all who descended from him in the way of ordinary generation, allege, in proof of this opinion, that we are all born with such constitutions as will produce some evil inclinations, which we probably should not have had in our original state; which evil inclinations are represented in scripture as derived from our parents, and therefore may be ultimately traced up to the first sinful parents from whom we descendent;—that infants are plainly liable to defea and death, though they have not committed any personal transgression, which, while they cannot know the law, it seems impossible they should be capable of, (Rom. v. 12-14;)—that the feats of defeas and death were undoubtedly derived to children from their immediate parents, and from them may be traced up to the first defeased and mortal parent, i.e. Adam,—that the scripture teaches us to consider Adam as having brought a sentence of death upon his whole race, and expressly says, that many were confutated criminals, i.e. on account of it are treated as such, (1 Cor. xv. 22, Rom. v. 12-19;)—that the sin of Adam brought upon himself depraved inclinations, an impaired constitution, and at length death:—and there is no reason to believe, that if man had continued in a state of innocence, his offspring would have been thus corrupt, and thus calamitous from their birth. Hence, it has been inferred, that the covenant was made with Adam, not only for himself, but in some measure for his posterity; so that he was to be considered as the great head and representative of all that were to descend from him.

On the other hand, many divines, no less eminent as scholars and theologians, than those whose sentiments we have already stated, have disputed the validity of the arguments alleged in proof of the doctrine of original sin; and whilst some of them have disfavored the doctrine in toto, as irrational and unscriptural, others have allowed that part of it which comprehends the depravity of the human species, but have rejected the imputation of Adam's sin to his posterity. Accordingly Limborch, rejecting and refuting the imputation of Adam's sin, acknowledges, that men are now born less pure than Adam was created, and with a certain inclination to sin; but this inclination cannot properly be called sin, or a habit of sin propagated to them from Adam; but merely an inclination to Rebel and pursue what is agreeable to the flesh, arising from the bodily constitution transmitted to them by their parent. Inclinations and appetites of this kind, being most agreeable to the flesh, are contrary to the divine will, as God by prohibiting them tries the readiness of our obedience, and of course these inclinations are inclinations to sin. But, if it be asked, says this author, whether there be in human nature a certain original corruption or habit of sin propagated from Adam to his posterity, which may truly and properly be called sin, by which the understanding, and will, and all the affections...
affections are so depraved, that they are inclined only to the evil, and that all mankind are by nature subject to the wrath of God, such kind of corruption is consistent neither with scripture nor with right reason. The scripture, he says, teaches no such doctrine, as that which charges infants with a moral corruption, that is truly and properly sin. (See Deut. i. 39. Jonah, iv. 11. Romans, i. 11.) Our Saviour recommends it to his disciples to be as little children. (See also 1 Cor. xiv. 20.) This notion, says Limborch, is contrary to the justice of God, who would not punish men with this moral corruption, from which all actual sins proceed, and which leads to future perdition and misery. God cannot be the author of sin. Besides, it cannot be conceived, how this fin can be propagated; it cannot belong to the mind, which proceeds immediately from God, nor can it exist in the body, which is incapable of sin. But as diseases may be propagated, so may a peculiar temperament or constitution, and together with this an inclination to certain objects, which, immediately indulged, may become sinful, but is not sinful in itself. Moreover, no sin is liable to punishment, which is involuntary; but original corruption is involuntary. Limborch explains many texts, and refutes many arguments urged by the advocates of original sin. Another writer, (Dr. Taylor,) who has taken a lead in this controversy, on the fame fide of the question, proceeds, in the examination of the doctrine of original sin, upon the same plan with Dr. Clarke, in his "Scripture Doctrine of the Trinity," by citing and explaining all those passages of scripture which expressly speak of the consequences of the first transgression. He observes, that the consequences of the first transgression are spoken of certainly and plainly but five times in the whole bible, twice in the Old, and thrice in the New Testament. The first passage is Gen. ii. 17. In this passage, he says, death is opposed to life, and must be no understand. But not one word occurs in this text relating to Adam's povertv. 2. The consequences of the transgression of Adam and Eve are related in Gen. iii. from the 7th verse to the end of the chapter. The natural consequences were shame and fear, the common effects of guilt, which was personal, and could belong only to them alone. The judicial consequences pertained either to the serpent, the woman, or the man. As far as they relate to the man, Adam became obnoxious to death, which, as our author conceives, was death in law, or eternal death; and if the law had been immediately executed, his povertv then included in his pains must have been extinct. But it is alleged, that there is not a word of a curse upon the souls of our first parents, i.e. upon the powers of their minds; nor does the least intimation occur with respect to any other death, besides that diflution which all mankind undergo, when they cease to live in this world. It is also observed, that we, their povertv, are in fact subject to the same afflictions and mortality here inflicted by sentence upon our first parents; but they are not inflicted as punishments for their sin, because punishment includes guilt; but we neither are, nor in the nature of things could be, guilty of their sin. We may suffer by their sin, and actually do suffer by it; but we are not punished for their sin, because we are not guilty of it; and this suffering is eventually a good. Accordingly it appears evident in our world, that the increase of natural evil (at least in some degree) is the lessening of moral evil.

3. The third text occurs in the New Testament, viz.: 1 Cor. xv. 21. 22. Here it is said, the death from which all mankind shall be released at the resurrection is the only death that came upon all men in consequence of Adam's sin: that as all men die, all men are mortal; all lose their life in Adam, and from him our mortality commences; and it is equally undeniable, that by Christ came the resurrection of the dead. From this place we cannot conclude, says our author, that any other evil or death came upon mankind in consequence of Adam's first transgression, besides that death from which all mankind shall be delivered at the resurrection, whatever that death be.

4. The most difficult passage is which occurs in Rom. v. 12—19. A popular advocate of the doctrine of original sin (Dr. Watts) thinks, that Adam's being a federal head, and our deriving a sinful nature from him, may be collected from this text. In this passage our author apprehends that the apostle is speaking of that death which takes place with regard to all mankind, when the present life is extinguished; and that by judgment to condemnation, or a judicial act of condemnation, the apostle means the being adjudged to the fore-mentioned death. The words "as by one man's disobedience many were made sinners," are (says Dr. Taylor) of the same signification with those in the foregoing verse, "as by the offence of one judgment came upon all men to condemnation;" and therefore they mean nothing more nor less than that by one man's disobedience, the many, that is, mankind, were made subject to death by the judicial act of God. The apostle, being a Jew, was well acquainted with the idiom of the Hebrew language; and according to that language, "being made sinners" very well signify being adjudged or condemned to death. (See Exod. xxii. 9. Deut. xxv. 1. 1 Kings, viii. 32. Job, x. 20. x. 22. xxxii. 5. xxxiv. 17. x1. 8. Phil. xxxvii. 33. xxiv. 21. Prov. xvii. 15. 1. 1. 9. 1v. 17.) In the Greek text it is not ευγνωστ, became sinners, but εικαισον, were sinners, viz. by the will and appointment of the judge. Befides, it is here expressly said, that the many, i.e. mankind, are made sinners, not by their own disobedience, but by the disobedience of another man; and therefore they can be sinners in no other way than as they are sufferers. Upon the whole our author thinks it plain, that "as by one man's disobedience many were made sinners," means that by Adam's offence, the many, i.e. mankind, were made subject to death by the judgment of God. In this passage there is an evident contrast or comparison between something which Adam did, and its consequences, and something which Christ did and the consequences of that; by the former the many, i.e. all men, are brought into condemnation; and by the latter, all men are justified unto life. The whole of the apostle's argument and affliction are supported by our author to rest upon two principles; viz. that it is by the one offence of Adam that death passed upon all men, and not by their own personal sins; and again, that it is by the obedience of one, or the one act of Christ's obedience, (in his sufferings and death upon the cross,) that all men are justified unto life, and not by their own personal righteousness. He adds, that throughout the whole paragraph, the apostle says nothing of any federal relations or transactions either on the part of Adam or Christ, nor of our deriving a sinful nature from Adam.

5. The text 1 Tim. ii. 14. declares a fact, with regard to Eve, which needs no explanation.

Dr. Taylor, in the second part of his book, proceeds to examine other passages of scripture, which some divines have applied to original sin. We shall here select two or three of the principal, that our readers may be able to form a judgment for themselves; one is Eph. ii. 3. "And were by nature the children of wrath even as others." The apostle, our author apprehends, cannot mean that they were liable to divine wrath or punishment by that nature which they brought into the world at their birth. For this nature, whatever
whatever infirmities belong to it, is no other than God's own work or gift; and he thinks, that to affect that the nature which God gives us is the hateful object of his wrath, is little less than blasphemy against our good and bountiful Creator.

In his address to the Ephesians, the apostle is not speaking of their nature, or the natural constitution of their souls and bodies as they came into the world, but evidently of the vicious course of life they had led among the Gentiles. Nature frequently signifies an appointed nature, which men bring upon themselves by contracting either good or bad habits. Besides, by nature may here signify really, properly, truly; for παιδία, children, strictly signify the genuine children of parents by natural generation; and figuratively the word denotes a relation to a person or thing by way of friendship, regard, imitation, obligation, &c.; so that "children of wrath" are those who are related to wrath, or liable to rejection or punishment. The Ephesians, as the apostle tells them, were παιδία σωτηρί, natural genuine children of wrath, not by natural birth, or the natural constitution of their bodies or souls, but they were related to wrath in the highest and strictest sense, with regard to sin and disobedience:—

Nature, in a metaphorical expression, signifying that they were really and truly children of wrath, i.e. ffood in the strictest and closest relation to suffering.

Another passage, sometimes referred to in connection with this subject, viz. Rom. vii. 7, 8, contains not so much as a single word that can carry our minds to Adam, or any confusions of his sin upon us.

Gen. vi. 5. expresses the universal wickedness of the old world, but does not so much as intimate that our nature is corrupted in Adam; for the historian doth not charge their sin in any way upon Adam, but upon themselves: and besides, Noah is exempted out of the number of the corrupt and prodigal; but this could not have been the case if the alleged text is a good proof that by Adam's transgression the nature of all mankind is corrupted.

Another text, which has been considered as of great importance in this controversy, is Pf. li. 5, 6. "I was flayed in iniquity, and in sin did my mother conceive me." The word יָלַד, which we translate fapen, signifies, says our author, to bring forth or bear. (If. li. 2. Prov. viii. 24, 25.) Again, the word יָלַד, conceived me, properly signifies warmed me; and the expression conveys the idea, not of his being conceived, but warmed, cherished, or nurtured by his mother, after he was born. Accordingly, the verse is thus translated, "Behold, I was born in iniquity, and in sin did my mother nurce me:" which has no reference to the original formation of his constitution, but is a periphrasis for his being a sinner from the womb, and as much as to say, in plain language, I am a great sinner; or I have contracted habits of sin. This, it is said, is a scriptural way of aggravating wickedness. (See Pf. lviii. 3. Iiaiah, xlvi. 8.) In the whole psalm there is not one word about Adam, or the effects of his transgression upon us. The psalmist is charging himself with his own sin. But if the words be taken in the literal sense of our version, then it is manifest that he chargeth not himself with his sin and wickedness, but some other person. But our limits will not allow of our enlarging farther in this way.

Dr. Taylor proceeds, in part iii. of his book, to examine and answer objections. It is asked, 1. Are we not in worse moral circumstances than Adam was? If by moral circumstances be meant the state of reason and virtue in the world, it is certain, that since Adam's first transgression, this has become very different from a state of innocence. But this is not the fault of human nature, no more than Adam's sin was the fault of his nature, but occasioned, as his transgression was, by the abuse of it. If by moral circumstances be meant the provision and means which God has furnished for our spiritual improvement, the apostle to the Romans expressly affirms, that in or by Jesus Christ, God hath given us an abundance of grace. But if by moral circumstances be meant moral abilities, or mental powers, our author suggests, that there is no ground in revelation for exalting the nature of Adam to such a degree of purity and strength as some divines have raised it, when they affirm, that all his faculties were perfect, and entirely devoted to the love and obedience of his creator. The sequel of his history seems to be inconfident with this notion.

It is said that man was made in the image of God; but can this be affirmed of his posterity? The image of God must be understood either of the rational faculties of his mind, or the dominion he had over the inferior creatures, by which he bore the nearest resemblance to God of any beings in this world; and not, as Dr. Taylor conceives, of holiness and righteousness, which is a right use of our spiritual faculties; because such an use of them could not be till after they were created; and this writer is of opinion, that original righteousness is as far from truth as original sin; and that to talk of our wanting that righteousness in which Adam was created, is to talk of nothing we want. Two texts, viz. Rom. ii. 14, 15, and Ecclef. vii. 29, are cited by the Assembly of Divines in their larger Catechism, to prove, that our first parents had the law of God written in their hearts, and power to fulfill it, in opposition to their posterity, who want that righteousness in which they are supposed to have been created, and whose nature is corrupted to a lamentable degree; but if these texts speak not of our first parents, but of their posterity, and of the most corrupt part of their posterity too, it must be true, and the truth is very important, "that by nature we have the law of God written in our hearts, and power to fulfill it," as well as they; and are equally bound to be thankful to God for our being, and to glorify him by it.

We have already spoken of that moral taint and infection, which we are said to have derived from Adam; and in consequence of which we have a natural propensity to sin. This taint or infection must exist either in the body or the soul. In the soul, which immediately proceeds from God, it cannot exist; nor in the body, which, in a state separate from the soul, is inactive matter, which in itself neither is nor can be the subject of moral good and evil. But such an infection, wherefoever it exists, or howsoever it is propagated, cannot be derived from Adam to every human being, independently of the will and operation of God; and to affect, that it is by his will and operation, is evidently to make him the author of the pollution. It is maintained, that by propagation it is not possible for parents to communicate vice; which is always the faulty choice of a person's own will, otherwise it is not vice. Children, it has been said, begin very soon to sin, and how can this fact be accounted for but upon the scheme of original sin; namely, that it is infused into their nature? To this objection it has been replied, that their early sin is owing to the early want of instruction and discipline. Another objection, which is strongly urged by the advocates of original sin, is this: Adam was a common or federal head and representative of all his posterity, and consequently all his offspring sinned in him, as their root; just as Levi is said to pay tithes in Abraham (Heb. vii. 9.) and as the branches must be morally corrupt, if the root be in that state. (Rom. xi. 16.) To the arguments deduced from the first of these passages it has been replied, that neither the cæfe of Abraham and Levi,
Levi, nor the apostle's argument grounded upon it, have any manner of relation to partaking in guilt, or contracting moral corruption: and it is alleged, that the inference deducible from the second passage would be very just, if the apostle were here speaking of moral holiness, of holiness, as it is a quality or principle in the mind: whereas the holiness here mentioned is said to be that external, relative holiness which is frequently attributed to the whole nation of the Jews, as they were God's peculiar church and people. The notion of a federal head or representative of moral conduct, a representative, the guilt of whose actions shall be imputed to us, and whose sin shall corrupt and debauch our minds, and this representative appointed by God himself, is, as its opponents maintain, not only without foundation in scripture, but in itself a great absurdity. Indeed, the external circumstances of holiness may be affected by the bad conduct of their ancestors. This is frequently affirmed in scripture, and certainly holds good in the case of Adam and his posterity; and may be a constitution, just, wise, and answerving very good purposes. But that any man should so represent me, that when he is guilty, I am to be reputed guilty, when he transgresseth, I shall be accountable and punishable for his transgression; and this before I am born, and consequently before I in any capacity of knowing, helping, or hindering what he doth; this, I say, every one who 1ses his understanding must clearly see is false, unreasonable, and altogether inconsistent with the truth and goodness of God. And, if you please, you may see him fully vindicated by the spirit of truth from all injustice of this kind in Ezekiel, xviii. 20, where he affirms, "that the soul that sinneth, it shall die. The fom, however he may come under disciplinary visitations, "shall not bear the iniquity of the father; neither shall the father bear the iniquity of the son; the righteous sones of the righteous shall be upon him, and the wickedness of the wicked shall be upon him." And v. 20, "that God will judge every one according to his ways." It is further alleged, that the imputation of sin, so far as to make the posterity guilty of and chargeable with the sin of the parent, is no scriptural notion. An action, indeed, is often said to be imputed, reckoned, or accounted to a person; but then it is no other than his own act and deed which is so accounted or imputed to him, either for righteouness or sin. See Gen. xvi. 6. Lev. xvi. 3, 4. Numb. xviii. 26, 27. Sam. xi. 2. 1 Sam. xxii. 15. 2 Sam. xix. 19. Prov. xxvii. 14. Psa. xxxii. 2. Psa. cxl. 31. Rom. ii. 26. Rom. iv. 3, &c. Rom. v. 13. 1 Cor. xi. 5. 2 Cor. v. 19. Gal. iii. 6. 2 Tim. iv. 16. James, ii. 23.

We might here introduce some arguments for, and some objections to, the doctrine of original sin, of a general nature, if our limits would allow. We can only suggest, on the part of its advocates, that original sin is necessary to account for the being of sin in the world. How comes it to pass, that there is so much wickedness in the world, if our nature be not sinful?—How is it consistent with the justice of God, that we suffer at all on account of Adam's sin? Besides, it has been generally received opinion, that the fall, corruption, and apostasy in Adam, have been the reason why Christ came into the world, and gave himself a ransom for us. To the question concerning regeneration, which is infallible upon in the New Testament, why must we be born again? it is replied, because we are born in sin. Our nature in Adam is corrupted, and utterly indigotised, disabled, and made opposite to all that is spiritually good, and wholly inclined to all evil, and that continually; therefore we must be born again, before we can do anything that is good and pleasing to God.

On the other hand, the opponents of this doctrine allege, that it is highly injurious to the God of our nature to believe that our nature is originally corrupted in the manner which this doctrine supposes. To disparage our nature, is, they say, to disparage the work and gifts of God. They also suggest, that the doctrine of original sin teaches men to transfer their sin to a wrong cause, to Adam rather than to themselves; and also that the doctrine, as it is commonly held, has a manifest tendency to propagate a notion that they must be necessarily vicious, and that it is thus destructive of virtue. They lay, that to reprent sin as natural, as altogether unavoidable, is to embolden men in sin, and to give not only an excuse, but a reason for sinning. They also intimate, that to charge Chritianity with teaching this doctrine, is to sink its credibility; and that it is injurious in another way, by perplexing the mind, and rendering all religious principles uncertain. We are made," as one of them expresses it, "sinners we know not how, and therefore must be sorry for, and repent of, we know not what. We are made sinners in an arbitrary way, and we are made fainis in an arbitrary way: but what is arbitrary can be brought under no rules." They think that it is not expedient or desirable to teach children, that they are born children of wrath, that they came into the world under God's curse, and that their being, as soon as given, is in the world and most deplorable state of corruption. Young people are exhorted to remember their creator; but how, it is said, can they remember him, without the utmost horror, who, it is supposed, hath given them life under such deplorable circumstances?

We shall close this article with a brief account of the "Fall of Man," and its consequences, as they have been flated by different divines. Adam was created, as the Assembly of Divines affirm, after God's own image, in knowledge, righteousness, and holiness, having the image of God written in his heart, and power to fulfill it; and for proof of this assertion, they refer to Gen. ii. 27. Col. iii. 10. Ephe. iv. 24. Rom. ii. 14, 15. Eccl. vii. 29. This state of moral rectitude, or original righteousness, in which he was created, is thus described by Dr. Watts. "His reason was clear, and sense, appetite, and passion were subject to it, his judgment uncorrupted, his will had an inward, constant, superior bias, bent, and propensity to holiness and virtue; he had an inward inclination to please and honour God, supreme love to his creator, a zeal and desire to serve him, a holy fear of offending him, with a readiness to do his will." When Adam sinned he lost this moral rectitude; and not only so, but his posterity became morally corrupt. We have already stated the opinion of the opponents to the doctrine of original sin, concerning the moral condition of Adam before his fall. By the advocates of this doctrine, it is further maintained, that a covenant was made with Adam, as a public perfon, not for himself only, but for his posterity; and therefore all mankind, descending from him by ordinary generation, sinned in him, and fell with him in that first transgression. (See Acts, xviii. 26. Gen. i. 6, 17. compared with Rom. v. 12—20. 1 Cor. xxv. 21, 22.) The Fall, it is said, brought mankind into a state of sin and misery. (Rom. v. 12. iii. 13.) And the sinfulness of that state into which man fell, consisteth in the guilt of Adam's first sin, the want of that righteousness in which he was created, and the corruption of his nature, &c. (See Rom. v. 12, 19. Rom. iii. 10, 20. Eph. ii. 1, 2, 3. Rom. v. 6. vii. 7, 9. Gen. vi. 5. James, i. 14, 15. Matt. xv. 19.) It is added, that the Fall brought upon mankind the loss of communion with God, his displeasure, and curse; so that we are by nature children of wrath, bond-slavcs to Satan, and justly liable to all punishments in this
this world, and in that which is to come. See Gen. iii. 8.  

On the other hand, it is alleged, that the language of  
man's sinfulness confiding in the guilt of Adam's first sin  
is unscriptural; nor, in the nature of things, can our  
sinfulness confide in the guilt of Adam's first sin: because,  
as we could not possibly commit that action in any sense,  
so we could not, upon account of it, become obnoxious  
to punishment. If the texts above cited prove that man's  
life by Adam's sin is so corrupted, that man, i.e. man, are  
utterly indisposed, disabled, and made opposite to  
all that is spiritually good; that is, to all moral actions,  
pleasing and acceptable to God, and wholly and continually  
inclined to all manner of wickedness; they would further  
prove, that men are no moral agents, and that sin must be  
agreed to be, as natural to us, and if natural, necessary;  
and if necessary, with regard to us, it is no sin, with regard  
to us, or so far as we are concerned in it. For a further account  
the state of this controversy, and of the arguments adduced for  
and against the doctrine of original sin, we refer to the  
Assembly's Catechism; Watts's Ruin and Recovery;  
lib. iii. c. 4. § 1. 2. Taylor's Scripture Doctrine of Original  
Sin, in Three Parts, with a Supplement, &c. ed. 4.  
Ben Mordecai's Letters, Letter V.  

The Romans distinguished actual sins from mortal  
which are such as make us lose the grace of God; and  
venial, which are a party, as being only sins of  
futility, not of malice. See PEPER.  

Divines are not yet agreed what the sin against the Holy  
Ghost is. See BLASPHEMY against the Holy Ghost.  

SIN, Philosophical, according to the doctrine of the Jesuits,  
is an action, or course of action, that is repugnant to the  
dictates of reason, and yet not offensive to the Deity.  

SINA, in Ancient Geography, a town of Aegina, in  
Margiana. Ptolemy.—Alfo, a town of Cappadocia, in the  
prefecture of Cilicia. 1d. Alfo, a place in the isle of Leblos,  
Strabo.  

Sina, or Juftiniopolis, a town of Aegina, in the Greater  
Armenia.  

SINAAB, in Geography, a town of Algiers, in the  
province of Transcen, on the E. side of the Shellif; 72 miles  
S.W. of Algiers.  

SINACA, in Ancient Geography, a town of Hyrcania.  

Ptolemy.  

SINADIZAVA, in Geography, a town of European  
Turkey, in Bulgaria, on the Ozma; 12 miles E. of  
Nicopolis.  

SINAE, in Ancient Geography, a people of India, according  
to Ptolemy. It appears that their country extended  
from Siam into a part of China.  

SINAI, Mount, in Geography, a famous mount of Arabia  
Petra, on which God gave the law to Mois. (Exod.  
xix. 1. xxiv. 16. xxxi. 18. xxxiv. 2. 4. &c. Levit.  
xxvi. 1. xxxvi. 46.) It is situate in a kind of peninsula,  
formed by the two arms of the Red sea, one extending  
N. called the gulf of Kollun; the other extending E. called  
the gulf of Elas. The Arabs call mount Sinai by the  
name of " Tor," i.e. the mountain, by way of  
excellence; or " Jebbel Mufa," the mountain of Mois;  
comprehending a range of mountains which rises at the  
interior extremity of the valley of Fazan, rechristing  
the name of Tor Sinai to that part of the range on which  
the convent of St. Catharine stands; and distant about 260  
miles from Cairo. The wildernefs of Sinai, where the  

Israelites continued encamped almost a year, and where  
Moses erected the tabernacle of the covenant, is considerably  
elevated above the rest of the country; the ascent to it is  
very craggy, the greater part being cut out of the rock;  
and then you arrive at a large space of ground, which is  
plain surrounded on all sides by rocks and eminences,  
whose length is nearly twelve miles. Towards the extremity  
of this plain, on the north, two high mountains appear,  
the highest of which is called Sinai, the other Horeb.  
They are both of a very steep ascent, and the ground  
on which they stand is inaccessible, when compared with  
their height. Sinai is one-third part higher than the other,  
and its ascent more upright and difficult. The Greeks  
have cut a flight of steps up the rock. Pococke reckons  
3000 of these steps to the top of the mountain, or rather bare,  
pointed rock. Two German miles and a half up the mountain  
stands the convent of St. Catherine. The body of this  
monastery is a building 120 feet in length, and almost  
as many in breadth. Before it stands another small building,  
in which is the only gate of the convent, and which  
remains always shut, except when the bishop is there. At  
other times, whatever is introduced within the convent,  
whether men or provisions, is drawn up by the roof in a basket,  
and with a cord and pulley. The whole building is of  
hewn stone, which, in such a desert, must have been  
constructed with great labour and expense. Within the  
walls is a small mosque for the convenience of the Arabs.  
This monastery belongs to Greek monks, who had in former  
times only a tower erected near the burning bush of Moses.  
But being molested by the infults and depredations of  
the Arabs, they petitioned the emperor Justinian to build  
for them a strong monastery for their future security; and  
the emperor is said to have complied with their request.  
Before the convent is a large garden, planted with  
excellent fruits. According to the account of the Arabs,  
the monks enter it by a subterraneous passage. These Greek  
edificates are not allowed to receive an European visitor,  
without an order from the bishop of mount Sinai, who refides  
or did not ordinarly at Cairo. When the bishop happens to be  
present, the gate is opened, and the convent muft entertain  
all the Arabs who come in there; and this is a grievous  
charge on the poor monks, who live merely on alms, and  
whose provisions, which they are obliged to bring from  
Cairo, are often stolen by the way. The Arabs are, in  
general, very dangerous neighbours, as they often fire on  
the convent from the adjacent rocks; and seize the monks  
whenever they find them without the walls of the monastery,  
and refuse to release them without a considerable ransom.  

Five hundred steps above the convent is found an  
excellent spring, which superfluous perfons have counted  
marvellous, as the mountain is to high and so barren. A thousand  
steps higher stands a chapel dedicated to the Bleffed Virgin;  
and 500 above this, are two other chapels, built in a plain,  
which the traveller enters by two small gates of mafon-work.  
Upon this plain are two trees, under which, at high festivals,  
the Arabs are regaled at the expence of the Greeks. Sinai  
is held in great veneration, on account of the law which  
God gave on this mountain. The whole mountain is a very  
remarkable rock of red granite, interperfed with spots,  
which foil has been brought by human labour, or washed  
down by the rain, and in which grow almond-trees, figs, and  
vines. Mount Horeb stands W. of Sinai, so that at fun-  
rise the shadow of Sinai covers Horeb. Befide the little  
fountain at the top of Sinai, there is another at the foot  
of Horeb, which supplies the monastery of St. Catharine.  
At a small distance is thrown a fcone, four or five feet high,  
and three broad, from which, it is pretended, Moses caufed the  
water
SIN

SIN

water to gush out; in this stone are twelve holes or channels, about a foot wide, from which, it is said, the water issued which the Israelites drank.

SINAI, Knights of. See Catharine.

SINALOA, in Geography. See CINALOA.

SI-NAN, a river of Algiers, which joins the Wed-el-Mailah, about five miles before it runs into the sea. It glides in a variety of beautiful windings, and is known by several names, according to the remarkable places which they water. Near the banks of this river, Barbaroflo the Elder scattered his treasures when pursued by the victorious Spaniards, and here he made his last ineffectual effort to retard their progress.

SINANELLY, a town of Hindooftan, in Myfore; 22 miles S.W. of Bangalore.

SINAPATINGA, in Ancient Geography, a town of India, on this side of the Ganges, in the vicinity of the river Indus, and one of those which belonged to the Cathedi, according to Ptolemy.

Gen. Ch. Cat. Perianth inferior, spreading, divided into four, linear, concave, channelled leaves, forming a cros, deciduous. Cor. cruciform; of four, rounded, flat, spreading, undivided petals, with erect, linear claws scarcely the length of the calyx. Nectary composed of four ovate glands, one on each side between the shorter flamen and the pillif; and one on each side between the longer flamen and the calyx. Stam. Filaments six, awl-shaped, erect; the two shorter ones opposite; anthers erect, spreading, pointed. PIff. German superior, cylindrical; style the length of the germen, and height of the flamen; stigma capitate, undivided. Pet. Pod oblong, indated unequally at the lower part, rough, of two cells and two valves; partition generally twice as long as the valves, large, compressed. Seeds numerous, globular.

Obs. Sinapis differs principally from Brassica in having a spreading calyx, and the claws of the petals erect. Crantz unites this genus with Raphanus.

Eff. Ch. Calyx widely spreading. Claws of the petals straight. Nectariferous glands four. Pod more or less cylindrical, the partition longer than the valves.

1. S. arvensis. Wild Mustard or Charlock. Linn. Sp. Pl. 933. Fl. Brit. n. 1. Eng. Bot. t. 1748. Curt. Lond. fasc. 5. t. 47. Fl. Dan. t. 752.—Pods with many angles, rugged, longer than their own two-edged beak. Leaves ovate, somewhat lyrate.—One of the most common and most troublesome European weeds in heavy moist corn lands, as well as about wattle ground and hedges. It flowers most commonly in May and June, but occasionally in all open weather. Root annual, spindle-shaped, small, rigid. Stem round, stiffened, hispid with slightly deflexed bristles, tinged with red. Leaves alternate, trilobate, ovate, rough, unequally toothed; lower ones somewhat lyrate; upper feathery. Flowers in a terminal, clustered corymbs, of a bright yellow colour. Seeds extremely pungent, well known under the name of Durham-Mustard.

2. S. orientalis. Oriental Mustard. Linn. Sp. Pl. 933. Amen. Acad. v. 2. 820. Ait. n. 2. "Schkuhr. Handb. v. 1. 264. t. 186." (Sinapi orientalis maxima, rapi foliis; Tourn. Cor. 17.)—Pods rough with reflexed bristles, and four blunt angles, compressed at the tip.—Native of the Levant, and introduced at Kew by M. Thouin in 1758, where it flowers in June and July. This annual is extremely like the last, from which indeed it differs merely in having the pods rough with reflexed bristles, the peak only being smooth.

3. S. brasiieta. Cabbage Mustard. Wild. n. 3. Loureir. Cochinch. 399.—Leaves ovate, smooth, toothed in a diminutive manner.—Native of China, where it is much cultivated. This plant, we are informed by Loureiro, has the habit of Cabbage or Lettuce, but in the structure of its calyx it resembles Mustard. Stem a foot and half high, very smooth. Radical-leaves oblong, obtuse, white-veined, on channelled stalks; stem-leaves oblong, mottled with two auricled appendages at the base of the leaf, upper ones feathery, lanceolate, embracing the stem. Flowers like those of the Common Cabbage, bright yellow. Pod also resembling that of Brassica alere.

7. S. pubescens. Downy Mustard. Linn. Mutt. 95. Prodr. Fl. Grce. n. 1580. Arian Spec. v. 2. 21. t. 9—Pods downy, erect, with a compressed beak. Leaves lyrate, villous.—Native of Sicily, flowering in June and July. Stem perennial, shrubby. Leaves obtuse. Flowers yellow, with undivided petals. Pods erect, hairy, or very downy, as indeed are all the parts of the plant.

8. S.

16. S. fruticosa. Shrubby Mustard. Willd. n. 17. Alt. Hort. Kew. n. 11. — Pods linear, smooth. Lower-leaves oblong; toothed; upper lanceolate, undivided. Stem smooth, shrubby.—Native of Madeira, whence it was intro- duced at Kew by Mr. P. Maffon in 1777. It flowers from December to June. Figure and description wanting.

The Linnean S. hispida, a rare and little-known plant, Ait. n. 15, is removed to Desfontaines' new genus Cardi- lecarpus, in Prodr. Fl. Græc. v. 2. 33.

Mr. Brown, in Hort. Kew, has, after Tournfort's ex- ample, confedered Sisymbrium torvifolium and murale of Linneus as species of Sinapis. See Sisymbrium.

Sinapis, in Gardening, contains plants of the hardy, herbaceous, annual kind, of which the species cultivated are, the white mustard (S. alba); and the common or black mustard (S. nigra).

The first fort is generally cultivated in gardens as a fallad herb, with creoles, radishes, rape, &c. for winter and spring use; in which intention it is a highly valuable plant.

In the second fort, it is the flour of the seed that affords the common mustard for the table.

Method of Culture.—The first fort is sown along with other small fallad herbs, at all times of the year, sometimes every week or fortnight, in a bed or border of light earth, fown generally in shallow drills very thick, covering it very thinly with earth; and in winter, and early in spring, during cold weather, in hot-beds. The herbs are always cut for use whilst in the seed-leaf, and but a few days old; other- wise they become too strong and rank-tafted for use. See Sallad Herbs, and Small Sallad Herbs.

But in order to have seed of this fort for garden use, it should be fown on an open spot of ground, in March or April, either thinly in drills a foot asunder, or broad-cast all over the surface, and the plants be left to run up to it, when they will furnish ripe seeds in August. And in order to raise the plants for the seed for mustard, the seeds should be fown in the spring, any time in March, in some open situation, either in the kitchen-garden, or in open fields. In either case, having dug or ploughed the ground, the seed should be fown broad-cast all over the surface, and raked or harrowed in lightly; or it may be fown in shallow drills a foot asunder, and be lightly covered in. The plants soon come up; and when they have four or more leaves an inch or two broad, if they stand very thick, those fown in the broad-cast way particularly should be hoed and thinned, leaving them six or eight inches asunder, cutting up all weeds; repeating the operation once or more, if nec- essary. After this the plants will soon spread and cover the ground, and shoot up to stalks for flowers and seed, which ripens in July or August, when the stalks should be cut or pulled up, and the feed, being properly hardened,
and dried in the pod, should either be thrashed out directly, or stacked up dry, and thrashed at occasional opportunities afterwards; but the first is the best method.

**Sinapis Nigra**, Common Black Mustard, in the *Materia Medica, &c.* is common in corn-fields and banks of ditches, but is cultivated for use, and flowers in June. (See **Sinapis** and **Mustard**). The feeds of this species of mustard, which are directed by the London College, and those of the *S. alba*, which are preferred by that of Edinburgh, are not different in taste or their general effects, and answer equally well for the table and for medical purposes. Their taste is acrid and pungent, and when bruised this pungency becomes volatile and affects the smell: they readily impart these qualities to aqueous liquors, and by distillation with water yield an essential oil of great acrimony; but to refined spirits they give out very little either of their smell or taste. When subjected to the press, they yield a considerable quantity of mild insipid oil, which is as free from acrimony as that of almonds. By writers on the materia medica, mustard is considered as promoting appetite, affording digestion, attenuating vitious juices, and by stimulating the fibres, proving a general remedy in paralytic and rheumatic affections. In considerable quantity, it opens the body and increases the urinary discharge, and hence has been found useful in tropical complaints. In these affections, perhaps, the best mode of exhibiting mustard, is in the form of whey, which is made by boiling 5½ of the bruised feeds in a quart of milk, and straining to separate the curd. A fourth part of this quantity may be taken for a dose three times a day. It has also been recommended as an antiscorbutic; though Haller says that the use of mustard pulls the humours to putrefy, to which opinion he was probably inclined by the supposition that it contained volatile alkali; but it has been found that vegetables reckoned among the alkali plants may be so directed by fermentation as to be of the acifcent kind, and the alkali obtained from them seems not to have existed in the vegetable in a separable state. The great pungency of these plants is therefore not to be ascribed to the volatile alkali, but to the essential oil which they contain. Bergius informs us, that he found mustard of great efficacy in curing venal intermitten; for which purpose he directed a spoonful of the whole seeds to be taken three or four times a day, during the apoplexy; and when the discharge is obstinate, he added flour of mustard to the bark. Externally these seeds are frequently used as a stimulant or rubefacient. The flour rubbed on the skin, or applied, in the form of a cataplasm, made into a paste with crumbs of bread and vinegar, soon excites a burning pain, considerable inflammation, and sometimes vesication. In these forms it has been found serviceable in paralysis, and applied to the soles of the feet in the delirium of typhus, and in cutaneous affections. It is observed by Cullen that the fresh powder of mustard shews little pungency and much bitterness; but when it has been moistened with vinegar, and kept for a day, the essential oil is evolved, and it becomes considerably more acrid, as is well known to those who prepare mustard for the table; a circumstance which should be attended to when designed for external use. Mustard-feed may be most conveniently given entire or unbruised, and to the quantity of a spoonful or half an ounce for a dose. The constituents of mustard-feed appear to be flax, mucus, a gland fixed oil, an acrid volatile oil, and an ammoniacal salt. The officinal preparations of mustard are "cataplasmum sinapis," L. D. and "emulsionem meloe compostum," E. See **Plaster**.

The cataplasm of mustard of the London Ph. is prepared by mixing mustard-feed and lint-feed, of each in powder half a pound, with a sufficient quantity of hot vinegar, to the thickness of a cataplasm. The mustard cataplasm of the Dub. Ph. is formed of mustard-feed in powder and crumbs of bread, of each half a pound, and a sufficient quantity of vinegar. This preparation may be rendered more acrid by adding two ounces of horse-radish finely scraped. These cataplasms are powerful local stimulants and rubefacient. They are to be spread on cloth to the thickness of about half an inch, and applied to the soles of the feet, in the low state of typhus fever, particularly when stupor or delirium is present, and in apoplexy, coma, and other cases in which there is a great determination to the head. Their rubefacient effects are very quickly produced, and often so powerfully as to raise blisters on the part. Cullen's Mat. Med. Woody. Med. Bot. Thompson's Lond. Disp.

**Sinapici Persicum**, Persian Mustard, a name by which some botanical authors have called the thalphi, or treacle mustard.

**Sinapis**, or **Sinapum**, formed from **Sinapi**, or **Sinapum**, mustard-feed, in Pharmacy, an external medicine, in form of a cataplasm. See **Sinapi**.

**Sinapistrum**, in Botany, Tourn. Inst. 231. t. 116, a name of Hermann's, alluding to the resemblance of the plant, or at least of its pods, to **Sinapis**, or Mustard. See **Cleome**.

**Sinarca**, the name of the male dancers, who, according to the mythology of the Hindoos, amuse their god Indra, regent of the firmament. (See **Indra**). These are perhaps the same beings whose name is sometimes written Cinnara, and described as human figures with the head of a horse, but we never saw them so represented. See **Sitanta** and **Sura**.

**Sinarum Regio**, in Ancient Geography, a country of Asia, and the land on the eastern coast, according to Ptolemy.

**Sinarus**, a river of India, which discharges itself into the Hydaspes, according to Arrian.

**Sinasbarium**, in Botany, a name given by some authors to the *Hydnium*; or water-mint, common in all our ditches and watery places.

**Sinasse**, in Geography, a town of Abysinia; 40 miles N. E. of Addis Ababa.

**Sinay**, a small island near the W. coast of the island of Lucan. N. lat. 18° 11'. E. long. 120° 36'.

**Sibnach**, or Simpach, a town of Bavaria; 5 miles S. of Landau.

**Sinaeipura**, or Sincapura, an island, with a town of the same name, near the S. coast of Malacca, which gives name to the narrow sea, called the "Strait of Sinaeipura." N. lat. 1° 10'. E. long. 103° 36'.

**Sin-Caripou**, a town of Chineef Tartary; 555 miles E. N. E. of Peking. N. lat. 41° 21'. E. long. 126° 46'.

**Sincerity**, in Ethics, is that excellent habit and temper of mind, which gives to virtue its reality, and makes it to be what it appears. Simplicity, called by the Greeks *aphrēstos*, is included in this virtue, but does not express the whole of it; so that it is necessary to add *aphrēstos*, truth; of which two the first stands in opposition to what is mixed and adulterated; the other to what is counterfeit. Sincerity has respect to two sorts of objects; persons and things. Of the first kind are God; other men, and every man's self. Sincerity, with regard to God, signifies, that the form of religion is accompanied with the power of it, and that piety and obedience are substantial and unaffected; proceeding from principles, right in themselves, and uniform in their influence. Sincerity, as it regards men, implies an honestly
and opennefs in our dealings with them, extending to the springs and motions of our actions, as well as the actions themselves; to our words and our thoughts. Sincerity, with relation to a man's self, is opposed to self-deception. As to things, truth and goodnefs are the principal objects of sacrefty. The extremes of this virtue are over-franknefs and hypocrisy. Grove's Syftem of Moral Philofophy, vol. ii. ch. 2.

SINCHO, or CHINCO, in Geography, a town of Africa, in the kingdom of Ningo, on the Gold Coast, the inhabitants of which are chiefly employed in fishing.

SINCIPUT, in Anatomy, the fore-part of the head, in opposition to occiput.

SINCKEL, in Geography, a river of Bavaria, which joins the Wertha; 2 miles S.S.W. of Augsburg.

SINCLAIR. See St. Clair.

SIND, in Agriculture, provincially to rifle or wash out, as a milking pail, dish, &c.

SINDA, in Ancient Geography, a town of India, on the other side of the Ganges, placed by Steph. Byz. on the coast of the great gulf between Corgatha and Pagrafa.—Alfo, a town of Afa, in Phidia, on the confines of Caria. Strabo.—Alfo, a town of Afiatic Sarmatia, upon the Cimmerian Bofphorus, between the ports Sindicus and Bara, according to Ptolemy.

SINDA, in Geography, a town of Hindooftan, in Baghla; 20 miles N.W. of Nafnuck.

SINDAE, in Ancient Geography, the name of three iflands in the Indian sea, S. of the Baruffa, according to Ptolemy.

SINDAGUA, in Geography, a ridge of mountains in South America, between Popayán and the Pacific ocean.

SINDANGAN BAY, a bay on the N.W. coast of Mindanao, extending from N. to S. about 100 miles. N. lat. 8° 15'. E. long. 123° 5'.

SINDE. See ISDE.—Alfo, a river of Hindooftan, which rifes about 20 miles W. of Bilfah, and runs into the Jumnah, at Putterahee.

SINDEJUA, a town of Napaul; 40 miles W. of Mo- caumpur.

SINDELFINGEN, a town of Wurtemberg; 6 miles S.W. of Stuttgart. N. lat. 48° 41'. E. long. 8° 52'.

SINDER, a town of Hindooftan, in Baghla; 15 miles S.E. of Nafnuck.

SINDERINGEN, a town of Germany, in the county of Hohezlohe, on the Kocher; 12 miles N.E. of Heilbron. N. lat. 45° 16'. E. long. 9° 33'.

SINDI, a people of Afiatic Sarmatia, in the number of thofe who inhabited the Cimmerian Bofphorus. Strabo.

SINDIANI, a Scythian people who inhabited the vicinity of the Palus Mæotis, according to Lucian.

SINDICUS PORTUS, a port of Afiatic Sarmatia, on the coast of the Cimmerian Bofphorus, according to the Periplus of Scylax.

SINDINICES, a people of Germany, who formed a part of the nation of the Vandals.
