LONDON:

1819.
SCOTLAND.

SCOTLAND, in Geography, an ancient, and formerly an independent kingdom, but now constituting an integral part of the united kingdom of Great Britain and Ireland; is situated, exclusive of its islands, between 54° 37' and 58° 42' north latitude, and between 1° 47' and 6° 7' west longitude, from London. It is bounded on the south by the Solway frith, and the rivers Elk, Lark, Liddel, and Tweed, which divide it from England; on the east and north by the Northern ocean; and on the west by the waters of the Atlantic. Its greatest length, in a direction due north and south, is 275 miles, and its greatest breadth 147 miles; but its breadth is extremely various, and in one place does not exceed 36 miles. According to calculation, the superficial contents of the mainland amount to 25,520 square miles of land, 494 square miles of fresh-water lakes, and 5000 square miles of salt-water lochs, or lakes. The islands, which are usually classed under two divisions, the Hebrides on the west, and the Orkney and Zetland islands towards the north, comprehend an area of 4224 square miles, so that Scotland, with its lakes and islands, exclusive of its bays, presents a surface of 30,238 square miles. Politically speaking, it comprises 33 counties, which are named in the sequel under the head Parliamentary representation, and contains, according to the population census of 1811, 317,763 houses, and 1,865,688 inhabitants.

Historical Events.—The history of Scotland, previous to the union of the two crowns, has been divided by Dr. Robertson into four periods; the first reaching from the most remote ages to the reign of Kenneth II.; the second, from Kenneth's conquest of the Picts to the death of Alexander III.; the third, from that event to the death of James V.; and the last, thence to the advancement of James VI. to the throne of England. The first of these periods, observes the same author, is the region of pure fable; truth begins to dawn in the second period with a light, feeple at first, but gradually increasing; the events which then happened may be slightly touched, but merit no laborious inquiry. In the third period, Scottish history, chiefly by means of records preferved in England, becomes more authentic; not only are events related, but their causes and effects explained; the characters of the actors are displayed; the manners of the age described; and the revolutions in the constitution pointed out. During the fourth period, the affairs of Scotland were so much mingled with those of other nations; its situation in the political state of Europe was so important; its influence on the operations of neighbouring kingdoms was so visible; that its history becomes an object of attention, not merely to Scotsmen but to foreigners; as, without some knowledge of the various and extraordinary revolutions which happened there, it would be impossible for them to form a just notion with respect either to the great transactions, or the distinguished characters, of the sixteenth century.

After a minute examination of nearly all the works which have been written respecting the early history of Scotland, it is impracticable to unravel the mystery in which it is involved, and to separate authenticated facts from ingenious conjecture. In the present article, therefore, we shall advert to the first periods only in a general way, and shall dilute our narrative, in proportion as events become more certain, important, and interesting.

History of the First Period.—It is agreed by Pinkerton and Chalmers, though on most other points they materially differ, that the aboriginal inhabitants of Scotland were a colony of the Celtes, who are generally allowed to have been the first colonizers of western Europe. Respecting the era of their arrival in North Britain, and the route by which they reached the country, nothing is known; nor has record,
or tradition, preferred to us the smallest trace of their history, till the period of Agricola's invasion, when their descendents appear to have been divided into twenty-one distinct clans, called by the Romans the Cattani, Genani, Selgoziz, Novantii, Darnii, Holleii, Venricous, Thaixuli, Vaecomi, Albani, Attacotti, Caledonii, Cantze, Logi, Carnabii, Catini, Merze, Carmannacce, Creones, Cersones, and Epidii.

These various tribes, who are usually mentioned in the Latin writers by the generic name of Caledonians, on the advance of the Romans into their country, united under the authority of Galgacus, one of their most powerful chiefains, to resist their progress. The utmost efforts of valour, however, proved vain against the military skill of the great Agricola, and the discipline of the legionary troops. In his first campaign in North Britain, A.D. 80, that celebrated general penetrated, according to Tacitus, as far as the river Tay; and in the year following he constructed a chain of forts between the friths of Clyde and Forth, within which he had retired for the protection of the southern country against the inroads of the free tribes of the North. The summer of 82 was employed in subduing and securing the district which extends from the Solway to the Clyde. Thus freed from the danger of a flank attack, he again paused the Forth, and advanced, without opposition, as far as Loch Leven, establishing, as he proceeded, military polts to keep the inhabitants in subjection. These polts the Caledonians had the hardihood to attack; and by this display of daring intrepidity, seem to have struck great terror into the Roman soldiery. In this dilemma, Agricola divided his army into three bodies, and pushed forward the weakest to Lochore, where he ordered it to encamp, while he stationed the other two at short distances on the right and left. The Caledonians, perceiving the Romans thus separated, made a vigorous attack during the night on the intrenchments at Lochore, and had already entered the camp, when Agricola arrived with the light troops of the other divisions, and, after a furious combat, repulsed the assailants, and forced them to a disorderly and precipitate flight. This victory, though dearly bought, inspired the Romans with renewed ardour; but it did not intimidate the Caledonians, who magnanimously resolved to dispute every foot of ground with the invaders. Agricola consequently found sufficient employment during the remainder of the year in subduing the Horelli, the inhabitants of the straits between the Tay and the Forth. The following year he advanced to the base of the Grampian mountains, where the Caledonian warriors lay encamped and prepared to receive him. The battle which ensued was contested with the most obstinate valour, but at length terminated in the complete overthrow of the latter. Agricola, however, seems to have derived little advantage from his victory, for after a few days spent in ascertaining the condition of the enemy, he led his troops back to the country of the Horelli, and terminated the campaign. The Caledonians immediately advanced, and demolished all the forts in the territories which the Romans had abandoned. Agricola, in the interim, ordered the commander of the Roman navy to sail round Britain, on a voyage of discovery, and with the design of intimidation. This voyage was happily accomplished, by the return of the fleet to the Forth, before the commencement of winter. With these remarkable exploits the campaigns of Agricola terminated; for, having excited the jealousy of the emperor Domitian, by the splendour of his achievements, he was soon afterwards recalled to Rome.

From this period to A.D. 120, the Roman authors are entirely silent respecting the affairs of Britain; but from an incidental expression in Tacitus, some later writers have supposed that, during that interval, the Caledonians succeeded in recovering the country conquered by Agricola, as far as the Solway on the west, and Tynemouth on the east. This opinion seems to receive some confirmation from the fact, that when the emperor Adrian visited our island in the year 117, mentioned, he caused a rampart to be constructed between these two citadels, "which has in every age been a monument of his power, and a memorial of his circumspection." Chalmers, however, contends that this measure was merely precautionary, and that the Roman legion still held all the country south of the Forth and Clyde. The emperor, on his departure, left Julius Severus as his lieutenant in Britain, who does not appear to have attempted any military exploit. Antoninus, who assumed the purple on the death of Adrian, named Lollius Urbicus to the chief government of the island, an officer who equally possessed talents for peace, and a genius for war. Having tranquillized some insurrectionary movements in the south, he carried his arms from the Forth to the Varar, and settled flations in the intermediate country; throwing the whole of that extensive district into the form of a Roman province. Under his directions was constructed the rampart of Antoninus (now called Grimes' dyke), which extends from Caer-riden on the Forth, to Aulcluid on the Clyde, a distance of thirty-six miles, fixed hundred and twenty paces. Several military roads, and numerous flations and encampments, were likewise formed in all the provinces, both of North and South Britain. Lollius was succeeded in his government by Calphurnius Agricola, during whose time the Romans abandoned all the country north of Grimes' dyke. Chalmers affirms that this retreat was not the consequence of weakness, but simply of choice. It nevertheless inspired the unconquered tribes with fresh vigour. Breaking through the barriers of Antoninus, they pillaged a large tract within that boundary, and put numbers of the Romans to the sword; but Ulfixus Marcellus soon drove them back again into their own territories. They renewed their inroads again in the year 200, with better success; and for some years afterwards seem to have made such progress, as to induce the emperor Severus to assume the government of Britain in person. On his arrival at the head of a larger army than had ever before visited this island, the Caledonian tribes fled for peace, but Severus rejected their proposals. The particulars of his expedition into Caledonia are very imperfectly narrated. It is clear, however, that he penetrated as far to the northward as the frith of Cromarty, though, as Dion affirms us, with the loss of no less than 50,000 men. Before he set out, he constructed a wall from the Solway to the Tyne, parallel with the rampart of Adrian, in order to facilitate his retreat in the event of disaster.

On the return of Severus to York, he left his son Caracalla in the government of North Britain; whose conduct is said to have incited the Caledonians to acts of aggression. Irritated at this, the aged emperor issued orders to renew the war, and to spare neither age nor sex; but his death, and the contest for the empire between his sons, seem to have prevented their execution. At all events, it is certain that Caracalla made peace with the Caledonians, and gave up to them all the country northward of the Forth and Clyde. From this period, for nearly a century, we hear nothing respecting the Caledonians, who may therefore be presumed to have made no serious attempts to molest the Romanized Britons. At length, however, about the year 350, we are informed that the emperor Constans found it necessary to come into Britain to repel "the Caledonians and other Picts." This statement affirms, is the first time the Picts are mentioned in history, and contends that the Caledonians were on this occasion called Picts, "owing to their peculiar seclusion from the
the Roman provincials on the south of the walls." Pinkerton, on the other hand, maintains, that they were a Scythian colony, who had posseffed themselves of the eastern coast of Scotland before the Christian era; but his opinion is not supported by evidence or probability.

Conflantius having driven back the Caledonians, and other Picts, within their own territories, retired to York, where he died July 25, A.D. 526. Almost forty years elapsed before they were again able to infilt the territories of the romanized Britons, though the empire was harassed by civil wars.

In 343, however, they made some inroads, but were soon repelled, and the provincials again enjoyed peace for seventeen years. At the close of that period, when Conflantine and Julian were contending for the imperial sway, the Scots and Picts made a formidable attack upon the provinces.

Lupicinus, an able officer, was sent to oppose them, but does not seem to have effected the object of his mission.

This is the first time the Scots are mentioned in the pages of Roman history. Ammianus, in whose work they are noticed, joins them with the Picts, as if they formed one army, though they had no connection whatever by neighbourhood, lineage, or interests: they were, in fact, an erratic people of Ireland, who were much accustom'd to naval predatory excursions against the Roman provincials during the fourth and fifth centuries, but they had no territories in North Britain till about the year 503, as will be more particularly noticed in the sequel.

The next attack upon the Roman provinces by the Picts and Scots happened in the year 504, and seems to have been more general and destructive than any former incursion by either of these people. For three years they continued gradually advancing towards the south, spreading death and desolation wherever they came. At length Theodinus, the most distinguished general of his age, was sent into Britain by the emperor Valentinian, to put a stop to their ravages and to restore tranquility. In two campaigns he drove the Scots from the island, and the Picts beyond the wall of Antonine, which he repaired, and strengthened with additional forts, and conftituted the territories within it into a province, by the name of Valantia. Such, indeed, was the energy of his operations, and the wisdom of his precautionary measures for the maintenance of peace, that the Scots and Picts did not dare to renew their aggressions till the year 598, and even then they were easily repelled. The Roman empire, however, was now rapidly on the decline. In 407, the revolt of the troops in Britain transferred the government to Gratian, and after his death to Conflantine, who conveyed the army with him into Gaul. The British provincials, thus left in a manner to themselves, assumed a fort of independence, which was sanctioned by the emperor Honorius, who, confiding of his inability to protect this distant part of the empire, directed the British cities to rule and defend themselves. "But," to quote the words of Chalmers, "their inexperience soon occasioned them to feel their own weaknecfs. And in A.D. 422, though the walls were then garrisoned by Roman troops, the provincials again applied for additional protection against the defultory attacks of a predatory people, who could be more easily repelled than tranquillized. A legion is said to have been sent, who chastiffed the invaders, and, for the last time, repaired the fortifications that had long overawed the Pictish tribes. From this epoch the provincials enjoyed twenty years' repose. The year 446, when Atius was conful for the third time, is the memorable epoch, when the British provincials acknowledged themselves to be Roman citizens, by their supplication to that able supporter of a degenerate state for Irish affilliance; but he was unable to gratify their desire, owing to the preflure of the barbarians upon Gaul. The provincials were again told, in a more deponding tone, that they must rely on their own efforts for their future government and effectual defence. The abdication which Honorius seemed willing to make in A.D. 409, Atius thus more completely effected in A.D. 446."

Caledonia, vol. i.

After the final departure of the Romans, North Britain was occupied by two races of men, the Picts, and the romanized Britons of the province of Valentia. The latter, some authors contend, united themselves under one ruler to refit the inroads of the Picts, and thus formed the kingdom of Cumbria, or Strathclyde. Of the existence of such a monarchy, however, within the limits of proper Scotland, there is much room to doubt. At all events, it is very improbable that this new nation was able to confine the Picts within their ancient boundaries. On the contrary, it is most likely that the Picts, in conjunction with the Scots from Ireland, conquered and occupied the greater part of Valentia. At a later date, the Anglo-Saxons of Northumberland posseffed themselves of the eastern coast of that province; but it does not appear certain that the Lothians ever were integral portions of the Northumbrian or Bernician monarchy; though they might be for a time annexed to it by temporary conquest from the Picts. See STRATHCLYDE.

Several ancient Scotch writers, upon the authority of monkish legends, contend that their ancestors first settled in Argyle 320 years before the Christian era; and they give a list of kings, and a narrative of their actions, from that remote period. Later investigations, however, have shown that these details are most probably fictitious, and that the Scots did not colonize any part of present Scotland till the year A.D. 503, when a body of them passed over from the north of Ireland, their proper country, and fixed themselves in the district of the British Epidii, which they denominated Caerint. These colonists were led by Loarn, Fergus, and Angus, the three sons of Ere, a chiefman or petty king of Dalriada, viz. the portion of Rhinda in Ullter, whence the Scots were sometimes called Dalriads. The derivation of the name Scot is uncertain, but the most plausible opinion is, that it was a corruption of the word *Seite*, which signifies in Irish dispersed or scattered, and was therefore applied generally to denote the roving tribes who had habituated themselves to maritime excursions against the western shores of romanized Britain.

Chalmers judiciously observes, that there scarcely occurs a period of history so perplexed and obscured as the annals of the Scotia-Irish, from the date of their settlement in Argyle, till their ascendency over the Picts in 843. This confusion and obscurity originated in the want of contemporaneous writings, and were afterwards greatly increased, by the contest of the Irish and Scotch antiquaries for pre-eminence in antiquity as well as in fame. In the sifter island, however, there have happily been preserved various documents, particularly the annals of Tyrconnell and Ullter, which throw many lights of light on the transactions of that dark era. Several brief chronicles and historical documents, calculated to elucidate the fame fuhi cé, have likewise been brought into notice by Innes; and Pinkerton first published a Gaelic poem, which professes to give a genealogical account of the Scotia-Irish kings. From an attentive examination of all these, and from an accurate examination of other documents, Chalmers compiled his genealogical and chronological table of the Scotch monarchs, to Kenneth inclusive, from which it appears that they were twenty-nine in number, and occupied by their united reigns a period of 340 years. The first was Fergus, who became sole chiefman, or king of the new colonists, soon after their arrival. He died in 506, leaving his power and pretensions
to his son Domangart, who reigned five years, and then transmitted his dominion to his eldest son, Comgal. This prince enjoyed his sovereignty twenty-four years, during which time he had leisure to extend his dominions and consolidate his authority. Dying in 535, he was succeeded by his brother Gawran, to the exclusion of his own son, Conal. Gawran reigned twenty-two years, and engaged in a war against the Picts, which terminated in his defeat and death. Conal then obtained the sceptre, and held it for fourteen years. Aidan, the son of Gawran, next claimed it; but Duncha, the son of Conal, opposed his pretensions. The bloody body of Loro, in which Duncha fell, put an end to the dispute, and gave Aidan possession of the crown. He was inaugurated by St. Columba in 574, on the holy island of Jona; and proved himself, throughout a reign of thirty-five years, to be a prince of great enterprise. He extended his dominions along the western coast of Valentia, which had been feized upon and colonized by various tribes of "Scetes" from Ireland, by consolidating the whole of them under his superior sway. In 577, having advanced into Cumberland, he engaged Rydderch, king of Cumbria, but the battle seems to have been indecisive. He afterwards entered into a league offensive and defensive with the Cumbrian monarch against the Saxons, who were defeated with great slaughter at Stanmore, in Westmorland. Buchanan affirms this was a league as well against the Picts as the Saxons, and further intimates, that Aidan was monarch of the district, now included in the counties of Renfrew, Ayr, Wigton, Kirkcudbright, and Dumfries; and this view of the subject certainly bears the stamp of greater probability than the opinion which confines his territories to the illusory of Cantire and the neighbouring islands. Aidan, according to all the writers who treat of his reign, fought several battles against the Saxons, in most of which he was victorious; but in the year 603, he was completely defeated by Ethelfrid, king of Northumbria, at the battle of Dawftane, in Roxburghshire. This disaster, joined to the death of St. Columba, his kinsman and friend, so much affected him, that he died in the second year thereafter, at the advanced age of eighty, and was buried in the chapel of Claran at Campbeltown. The succecor of Aidan was Eoche-bui, called by Buchanan Eugeneus, who, according to Chalmers, carried on a successful warfare against the Cruithine of Ireland; but the Scottish historian mentions only that he horified the Picts and Saxons by continued incursions. Eoche died in 621, and had for his successor Kenneth the Aukward, his son. This prince is said to have prosecuted the Irifh war begun by his father with great vigour, till it happened in the unfortunate contest of Fidhhevin, when he had scarcely reigned three months. Ferchard, the son of Eogan, of the race of Loarn, next obtained the throne. Chalmers lays he reigned sixteen years, but left no events for history to recount. Buchanan, however, affirms that he was a great tyrant, and that the nobility, irritated at his oppressions, and at the circumstance of his embracing the Pelagian herefly, conspired against him, and threw him into prison, where he laid violent hands on himself. His successor was Donald, who, as Chalmers informs us, invaded Ireland with an army composed of Scots, Picts, Britons, and Saxons, but was totally defeated on the plain of Moyrath in 637, and compelled to seek shelter in Cantire. Donald, however, continues our author, derived no wisdom from this disaster, for in the following year he attacked the Picts, and was again overthrown with great slaughter. He was ultimately slain at Strath-Carmac, by Hoan, one of the regal of Strathclyd, in the year 642. Such is the history of Donald, as given by Chalmers, but not a word on the subject either of Irifh or Pictifh wars occurs in Buchanan. By that historian, on the contrary, he is represented as an excellent man, the protector of Oswold, afterwards king of Northumberland, during the misfortunes of his early life, and his affluent in more fortunate times, in the propagation of the Christian religion among his heathen subjects.

From this period to the year 736, the events of Scottish history are so involved and so important, that we shall pass them over in silence, remarking only, that nine kings reigned in the interval, whose names are thus recorded by Chalmers: Conal II., Donal-duin his son, Mal-duin, Ferchar-pada, Eocha-rineval, Anlbheallach, Selwec, Eocha Ill., and Murdach. The last monarch had been unwillingly drawn into holllities with the Picts, and transmitted their enmity to his succcecor, Eoghan, or Ewan, a feeble prince, who died in 739, when Aodhfin feized the sceptre, and soon evinced himself equal to the arduous talk of government, even in the most troublesome times. In 740 he boldly encountered the mighty Ugus, king of the Picts, and forced him to quit his territories. Aodhfin died soon after, having reigned with greater glory than any of his predecessors, for the long period of thirty years. He left his kingdom, but not his talents, to his son Fergus, who reigned about three years, whilst that of his succcecor, Selvach II., lasted twenty-four years. The government of Eocha IV., or as he is called by Buchanan, Achauns, the next king, was marked by several important transactions. Some authors assert, that he formed an alliance with Charlemagne, and instituted the most ancient order of the Thistle, but both these statements are erroneous. It is true, however, that he entered into a treaty of great importance to himself, his children, and his country, for he made peace with the Picts, and received the hand of Urgula, daughter of Urgus, and filler of Con Tinata and Ungus, all of which in feuencefhy swayed the Pictifh sceptre.

Eocha died in 826, after a reign of thirty years. Buchanan lays, that the succcecor of Eocha was Congallus, but Chalmers makes no mention of this monarch, afferting that Dungal, the son of Selvach II., obtained the throne on the death of Eocha. He died in 833, when Alpin, the son of Eocha and Urgus, was acknowledged king. Chalmers, who does not admit the Scottish monarchs to have possessed, even in this reign, any territories beyond the district of Cantire, and the disputed tracts of Argyle and Lorn, states that Alpin, ambitious of reining over richer people and more extensive domains, landed on the coast of Ayr in 836, and penetrated a confiderable way into the country, but was at length defeated and slain near the seat of Lachit castle, on the confines of Galloway. Buchanan, on the other hand, afferts that Alpin fell in a battle fought near Dundee against the Picts. Kenneth, the son of Alpin, next succeeded to the throne, and waging war against the Picts, after several obstinate battles overthrew their government, and united the two rival monarchies into one kingdom, under the name of Scotland, an event which brings us to the close of the first period of Scottish history.

History of the Second Period.—Kenneth, having thus accomplished the union of the two kingdoms, endeavoured by every means in his power to render that union permanent. He enacted many excellent laws for the better administration of the government, and removed the flone chair in which the kings of Scotland were wont to be crowned from Argyle to Scone. After a reign of twenty-three years, sixteen of which he ruled over his new monarchy, he died in 854, when Donald, his brother, was proclaimed king. This prince relaxed the public discipline established by his predecessor, and gave himself up to the most shameful excesses. The Picts rose in open rebellion against his authority,
thority, and formed alliances with Òbreth and Ælla, monarchs of two of the Anglo-Saxon kingdoms adjoining Scotland. These princes entered Merch with a powerful army; and from thence dispatched heralds to Donald, requiring him to re-establish the Pictish monarchy. Donald, routed by a sense of his danger, marched against them, and totally defeated their united forces on the Jed, a river of Teviotdale. This victory enabled him to recover Berwick and all the territory to the north of the Tweed; but his successes was of very short duration, for having indulged too far the natural licentiousness of his troops, the English took advantage of their carelessness, fell upon them in the night, routed them with great slaughter, and made Donald prisoner. The enemy afterwards advanced to the Forth, which they attempted to cross in ships, when a violent storm arose, and occasioned the wreck of half of their fleet. This event so weakened their forces, that they were induced to conclude a peace with the Scots, upon the condition of their abandoning all the country southward of the Forth and Clyde. Of the Picts nothing was said in the treaty, and hence molt of them, deceived in their hopes, passed over into Denmark and Norway. Donald, having returned from captivity, still continued his voluptuous conduct, which so exasperated the nobles, that they committed him to prison, where he laid violent hands upon himself in the year 893. Such is the account of Buchanan; but Chalmers speaks of him with praise, and says that he died at the palace of Balacho in the year 896, and was buried at Icolmkill.

Constatintine, son of the great Kenneth, now mounted the throne. Being a prince of great valour and lofty spirit, says Buchanan, he was anxious to eradicate the ignominy which Donald had brought upon the kingdom, and to recover the territories he had lost, but his nobles dissuaded him from the attempt. He therefore directed his attention to the reformation of the public morals, particularly those of the military and priesthood. In this reign the Danes invaded Scotland, by landing a large army in two divisions in the firths of Fife. Constatinentine hastened to oppose them, and fortunately overthrew one division before the other could arrive to his assistance. Upon this, the rest of the Danes retreated to an entrenched camp, which they had constructed near their landing place. The Scots, flushed with victory, too rashly assaulted the Danish works, and were defeated with the loss of their king and half their army. The Danes, however, had suffered so much, that notwithstanding this success, they immediately reembarked for their own country.

Othus, or Aodth, brother to Constatinentine, succeeded him in the regal dignity. His reign was short and disturbed by rebellion; and terminated, according to Chalmers, in consequence of a wound received in the battle of Strathal. Buchanan, on the other hand, affirms that he was thrown into prison by the nobles for his tyrannical and licentious conduct, and that he died there before he completed the first year of his reign. Gregory, or Grig, who next reigned, emulated the virtues and achievements of the great Kenneth. While his internal policy was mild and just, he rendered himself feared and respected by foreigners. The Danes having seized from the English the greater part of the country south of the Forth, they drove them out of it, and once more established the Solway and the Tyne at the northern boundary of Scotland. He afterwards defeated the English, who had entered the western district of the kingdom, and compelled them to give up Cumberland and Westmoreland to the Scots. Gregory afterwards landed in Ireland, and having defeated the Irish in a battle fought on the river Bann, advanced to Dublin, which surrendered without resistance. Here he found King Duncan, then a minor, with whom he concluded a peace, and immediately returned to his own dominions, where he died in 902, greatly regretted by his own subjects. Such was the life of Gregory, as represented by the Scotish historians; but the researches of Chalmers have discovered that instead of being a hero and a conqueror, he was a man of unprincipled morals, an usurer, and a hypocrite; and was driven from his throne by the indignation of his people.

Gregory was succeeded by Donald, the son of Constatinentine, during whose reign the Danes made several incursions upon Scotland, but were, in every instance, repulsed. Chalmers informs us that the king fell, gallantly fighting in defense of his kingdom against a body of these invaders, who had penetrated almost to the Scottish capital. Buchanan, on the other hand, states that he died during an expedition to quell a feud between the Rossians and the Merchmen; and Boethius affirms that he expired in Northumberland in 903. His successor was Constatinentine, the son of Aodth, the early part of whose reign was equally disturbed by the incursions of the Danes. He afterwards engaged in a war with Athelstan, king of England, who ravaged all the country as far as the Forth and Clyde, and forced Constatinentine to sue for peace. Constatinentine, however, only offered it till an opportunity for revenge occurred, and then, joining with Anlaf, one of the most powerful of the Anglo-Danish princes, their united forces failed for the Humber, and disembarked without opposition. Athelstan, who had foreseen and prepared for this event, soon came up with the invaders, and after a battle, till then unexampled in the English or Scots annals, gained a complete victory, and Constatinentine and Anlaf only faved the remains of their army by a speedy re-embarkation. In this action Constatinentine having lost his son, and most of his nobility, resigned the kingdom in favour of Malcolm, the son of Donald, and retired to a monastery at St. Andrews, where he ended his days. Soon after the accession of Malcolm, the conquered provinces of Cumberland and Westmoreland revolted from the English monarch, who, fearful of his ability to retain them, agreed to surrender both to the king of Scotland, on condition, as Buchanan states, that Malcolm and his successors would acknowledge they held them of the crown of England, in fealty; the condition was accepted, and Malcolm passed the remainder of his reign in reforming the administration of justice, and the licentious character of his subjects. With this view he made a tour through the whole of his dominions every two years, and is said to have been paying his last biennial visit to the north, when he was assassinated in Moray, in the fifteenth year of his reign. His successor was Indulfus, who formed an alliance with the English, and enjoyed peace during the first seven years of his rule. At length the Danes unexpectedly disembarked in Lothian; the Scottish king marched and gave them battle, overthrew them with great slaughter, but unfortunately perished himself in the ardour of pursuit.

Duffus, the son of Malcolm, next sware the sceptre, and appointed Culenus, the son of Indulfus, governor of Cumberland. This monarch having held the reins of government with a firm hand, many of his nobles rose in open rebellion against the royal authority. By his vigorous measures, however, he was enabled to crush the insurrection, and to bring the leading offenders to punishment. He afterwards directed his endeavours to crush the banditti who infested the counties of Moray, Ross, and Caithness. Many of these were slain in various skirmishes, but the principal of them were secured and brought to the town of Forres, in order
order to render their fate more exemplary. Here the king was affiliated by the governor and his wife, who had vainly interceded to save some of the criminals, their relations. Culemus, the son of Indulfus, now mounted the throne; and immediately instituted an inquiry into the murder of his predecessor, and visited with condign punishment all who were concerned in that tragic event. But with these acts the merits of his reign cease, for scarcely had the executioner performed his duty, before the king abandoned himself to every species of vice, and gave equal licence to the younger nobility. Having been, in consequence, summoned to answer for his conduct in an assembly of the estates convened at Scone, he was affiliated on his journey thither by the thane of Methven, whose daughter he had injured. Culemus was succeeded by Kenneth, the brother of Duffus, a man in every respect the reverse of him in character and conduct. His first object was to put an end to the abusiveness of the former reign; which he had scarcely accomplished, when the Danes, made a descent on Aberdeenshire, and pillaged the country as far as the town of Perth, to which they laid siege. The king hastened to give them battle, and after an obstinate and bloody contest, was defeated and put to flight. This disaster being perceived by the chief of the clan, Hay, he, and his sons and vassals, placed themselves in a narrow pass, through which the main body of the Scots fled, and by their exhortations and courageous conduct, succeeded in changing the fortune of the day. The Scots turned upon their conquerors, and after a second encounter, still more furious than the first, gained a complete victory. The gallant Hay was rewarded with extensive estates, and raised to the dignity of nobility, which is still enjoyed by his descendants. From that time peace continued for several years, during which period Kenneth attempted to regulate the succession to the royal dignity, so as to render it hereditary in his own family. In the pursuit of this object he committed the only crime with which his reign is tainted, the murder of Malcolm, the son of King Duffus, who was considered by the nobility as the next successor to the throne. All his efforts, however, proved unsuccessful; for though he obtained a vote of the estates in favour of his views, yet when the throne became vacant by his death, which happened in the year 994, Constantine the Bald was proclaimed king. Malcolm, Kenneth's son, collected a large body of troops to assert the preference of his rights, but on the approach of the royal troops he disdained his army, and retired into Cumberland. Kenneth, his natural brother, regarding this conduct as dishonourable, prevailed on most of the soldiers to join his standard and continue the war. A battle soon afterwards ensued, in which both Constantine and Kenneth fell, each by the hand of the other, at the very moment when victory had declared for the latter.

In this critical emergency, the nobles elected Grimus, the son of Duffus, to the sovereign authority. This prince seems to have polled greater popularity than his predecessor, for he was no sooner declared king than most of his opponent's partizans deserted to his cause. Malcolm's party therefore deemed it advisable to negotiate for peace, and accordingly a treaty was concluded, by which it was agreed that Grimus should retain the kingdom till his death, when it should revert to Malcolm and his heirs, according to the intentions of Kenneth. This peace was scrupulously observed during eight years; but after that period, Grimus having begun to evince a most tyrannical disposition, Malcolm thought himself justified in again taking up arms. He accordingly marched into Scotland, and as the tide of popularity was now decidedly in his favour, he soon acquired a large army. Grimus marched to oppose him, but being betrayed by his soldiers, he was severely wounded in the first battle, and soon after terminated his existence.

Malcolm, on assuming the sceptre, laboured to compose the various factions which agitated the state, and to destroy the numerous banditti of robbers who had taken advantage of the laxity of the old government, to infest almost every district of the kingdom. He renewed, in his capacity of king of Scotland, the league which he had formed with the English, as governor of Cumberland, and in virtue of its conditions sent a corps of troops to assist in opposing the Danes. This measure so routed the indignation of the Danish monarch, that he dispatched a large fleet and army to invade the Scottish territories, under the command of two of his best generals, Olave and Euceus. A landing was effected in the province of Moray, which was subdued, the invaders laid siege to the fortresses of Nairn. Malcolm, who, during these operations, had been busily engaged in levying forces, arrived while the garrison yet continued a gallant defence; but being defeated, they were compelled to surrender; and the fortresses of Elgin and Moray were evacuated without resistance.

Upon these successes the Danes resolved to fix their habitation in Moray, and with this view sent home their ships to bring over their wives and children. In the mean time Malcolm re-organized his army, and made head against the enemy again at Mortlach, in the district of Marr. At first the Scots, discouraged by the fall of three of their commanders, retreated to their camp, where they made a vigorous stand, and changed their flight into a glorious victory. Malcolm, however, did not deem it prudent to advance far in pursuit, nor to attempt the expulsion of the whole Danish colony before he had recruited his forces with new levies. This cautious policy afforded time to king Swein to dispatch a second body of troops to the assistance of his countrymen. They were commanded by Camus, a general of tried courage and abilities, and disembarked near Aberbrothick, in Angus, whence they marched forward to the village of St. Bride, near which the Scots lay encamped, and ready to receive them. The action that followed terminated in the total rout of the Danes, who, finding their retreat to their ships cut off, dispersed in different directions. Camus and the most considerable party fled towards the mountains, with the intention of penetrating to Moray; but before they had proceeded far from the field of battle, they were overtaken, and either slain or made prisoners. A similar fate attended all the other fugitive bands.

This second discomfiture, though more signal than the first, did not yet discourage the Danish king. Immediately on being apprized of it, he sent a third armament under his own son, Caute, which landed in Buchan without opposition, and plundered the surrounding country. Malcolm, who had scarcely recovered the losses sustained in former battles, nevertheless hastened to oppose this new invasion. At first he declined risking a general engagement, but when he had ascertained that his opponents were less strong than was originally supposed, he seized a favourable opportunity to fall upon them with his whole forces. The battle was the most dreadful which fought against the Danes; the Scots remained masters of the field, but were unable to pursue the enemy, who retreated without molestation. Next day both parties, equally afraid to hazard another contest, eagerly litten to the interposition of the clergy, and concluded a peace, in which it was stipulated that all the Danes should leave Scotland, and that neither Swein nor Malcolm should, in future, wage war against one another.

Malcolm
Malcolm having seen the first article of the above treaty performed, disbanded his army, and reigned for some years in greater splendour and glory than any preceding monarch of Scotland. As old age approached, however, he acquired an exorbitant love for money, a passion which led him to commit many acts of oppression and injustice. This conduct excited the hatred of the nobility, and eventually occasioned his assassination, though authors are not agreed as to the perpetrators of the bloody deed.

Duncan, the grandson of Malcolm, by his daughter Beatrice, succeeded to the vacant throne. He was a prince of great popularity, which he had justly acquired; but while his virtues endeared him to the wife and good, they awakened feelings of enmity in the breasts of the turbulent and seductive Macduagald, a chieftain of the west, first raised the standard of rebellion, and attracted to it many of the invaders, and a body of Iriwh, who joined him in the hope of plunder. The king dispatched one Malcolm, a thane of high rank, to quell this insurrection, but he was unfortunately defeated and taken prisoner. Alarmed at that event, Malcolm summoned a council, in which Macbeth, one of his relatives, declared, that if he were made general of an expedition, in conjunction with Bancho, thane of Loch Abyr, they would soon bring the traitors to punishment. Macbeth obtained the wished-for command, and performed his task almost without resistance; for such was the terror infused into the rebels by his known character for severity, that on his approach they endeavoured to save themselves by flight, but the main body was overtaken, and most of them put to the sword.

Thus was Duncan freed from domestic sedition, but he did not long enjoy peace. The Norwegians, under Swen, king of Denmark, soon after landed in Fife-shire, and again aroused him from his natural inactivity. Having entrusted to Macbeth the charge of levying a new army, he himself advanced, with such troops as he could collect, to oppose the invaders, whom he met at Culrofs, where a battle ensued, which terminated to the disadvantage of the Scots. Duncan retired to the town of Perth, which was immediately beleaguered by the Danes. In the mean time Macbeth advanced with the new levies, upon whose arrival the king made a sudden attack upon the enemy's camp, while they were totally unprepared, and routed them with such slaughter, that only Swen, and a few attendants, were enabled to reach their ships.

But no sooner was Duncan relieved from this second danger, than he was alarmed by the news of the landing of the Danes in Fife-shire. Bancho marched to oppose their progress, and beat them back to their ships. About the same time, Macbeth, whose ambition led him to aspire to the throne, was encouraged in his daring views by a dream, in which he imagined that three women, naked, and of uncommon beauty, appeared to him and saluted him, one as thane of Angus, another as thane of Murray, and the third as king of Scotland. Henceforth he determined to accomplish his purpose at all hazards; and accordingly, having brought over many of the nobles to his side, he waylaid and murdered the king at Inverness. Macbeth then hasted to Scone, where he was invested with the royal authority. The sons of Duncan, affonihed at these events, fled, one into Cumberland, and the other to the Hebrides. Shakespeare has dramatized some of these events in his admirable tragedy of "Macbeth."

The first act of Macbeth's reign was to suppress the feuds which disturbed the lives of the thanes of Caithness, Rox, Sutherland, and Nairn. He afterwards defeated and slew Macgill, lord of Galloway, who refused to acknowledge his authority; and quiet having been thus restored to the kingdom, he applied his attention to the enactment of many salutary laws, and to the correction of abuses in their administration. Thus he reigned ten years with so much justice, that the manner of his obtaining the throne was totally overlooked. At the close of that period, however, he began to give way to the natural cruelty of his temper, and to convert his hitherto laudable government into an oppressive and cruel tyranny. The first shock of his inhumanity was vented against Bancho, whom he invited to a feast, and caused to be slain on his return home, giving out that the deed was perpetrated in an accidental fray or tumult. Upon this, most of the nobles departed to their own castles, and only a few of them occasionally repaired to court. Hence mutual distrust and jealousy sprang up between them and the king, who upon the slightest pretences seized their property, and put them to death. The confiscated estates he employed to maintain a band of plunderers, whom he kept as a guard about his person. But even with their protection he did not consider himself in safety, and therefore resolved to erect a castle for his residence on the summit of Dunfurnan hill. In the accomplishment of this work, he ordered all the thanes of the kingdom to assist; but Macduff, thane of Fife, sent only workmen on his part: this disobedience exasperated Macbeth so much, that he swore vengeance against Macduff, who, fearful of the consequences, immediately fled to England, where he found Malcolm, the son of Duncan, royally treated by king Edward the Confessor. After several interviews with the Scottish prince, he encouraged him to assert his rights to the throne of Scotland. Malcolm, assured of Macduff's integrity, hesitated not a moment to adopt his views, and being assisted by king Edward with 15,000 men, marched directly into Scotland, where he was joined by all ranks of the people. Macbeth, not daring to hazard a battle, endeavoured to escape, but was arrested and put to death.

Malcolm, having thus recovered his father's dominions, was declared king in the year 1057. This prince is said to have introduced into Scotland the titles of earl, baron, and knight. Macduff, to whose encouragement and exertions he owed the crown, is mentioned by Buchanan as having been the first who held the dignity of earl. At the same time, the privilege of placing the king in the chair of state at the ceremony of coronation was granted to him and his posterity.

But though Malcolm thus easily obtained the crown, he was not allowed to enjoy it long in peace. The faction of Macbeth proclaimed his son, Luthive, king, and for three months contended openly for the maintenance of his pretensions. At length his followers were defeated and himself slain in Strathbogie. Malcolm now reigned for several years, undisturbed either by foreign or domestic enemies. In the interim Edgar Aetheling, who with his mother and sisters had fled from England to avoid the furiences of William the Conqueror, was driven by divers of weather into Scotland, where they were courteously received by Malcolm, who married Margaret, the sister of Edgar. The Scottish prince further protected all Edgar's banished friends, and supplied them funds for their maintenance. This conduct excited king William to declare war against Scotland; but after several unsuccessful attempts at invasion, he concluded a peace favourable both to Edgar and Malcolm.

The danger of foreign troubles being removed, several of the clans raised the standard of rebellion against the government, and for a time threatened its subversion; but the valour of Macduff, and of Walter, grandson of Bancho,
eventually restored quiet; for which service the latter was constituted lord steward of Scotland, and from him the royal family of Stewart were descended. Malcolm now applied himself to the reformation of the public morals, and established the two new bishoprics of Caithness and Moray. In 1579 he took advantage of the civil war in Normandy, between king William and his son, Robert, to devastate the county of Northumberland: to revenge this aggression, the English monarch sent an army into Scotland, but Malcolm's cautious policy prevented it from effecting any important exploit, and a treaty was soon afterwards negotiated between the two kingdoms. The accession of William Rufus, however, again proved the signal for hostilities, Malcolm advanced into England as far as Cheltenham-street, whence he retreated, as soon as he understood that the English army was in march to oppose him. William, in his turn, prepared for the invasion of Scotland both by land and sea, and had actually passed the borders, when the destruction of his fleet, and the interception of Robert, duke of Normandy, and Edgar Atheling, induced him to conclude a peace with his antagonist. Malcolm promised the same homage which he had yielded to the conqueror; and William engaged to surrender to the Scotch king twelve manors, which Duncan had held in England, and to pay him twelve marks of gold annually: but peace did not continue long; William fortified Carlisle in the subsequent year, a measure which Malcolm pointedly refented: a personal interview was proposed in the hope of accommodating matters, but it had an opposite result. The Scottish king, therefore, led his army into Northumberland and besieged Alnwick; where he was surprized and slain, as was also his eldest son Edward, earl Mowbray, on the 13th of November, 1103.

Donaldbane, the brother of Malcolm, succeeded, but he was soon driven from the throne by his nephew, Duncan, who was aslaged in recovering his dominions by king William Rufus; Duncan, however, had not enjoyed his dignity above six months, before he was affalinated at the instigation of his uncle, who once more usurped the crown, and reigned about two years, when he was a second time deposed, and Edgar, the son of Malcolm, set up in his stead. This prince cultivated peace with king William Rufus, and his successor Henry I., to whom he gave his sister Matilda in marriage. Edgar died at Edinburgh on the 8th of January, 1106—7, and was succeeded by his brother Alexander I., who likewise preferred peace with his southern neighbours; but his reign was disturbed by an alarming rebellion at home, and by the ecclesiastical pretensions of the archbishops of York and Canterbury. His promptitude and valour, however, soon quelled the former, and his steady opposition to the latter enabled him to maintain the rights of his country and the independence of his government. Alexander died in April 1124, and was succeeded by David, the younger son of Malcolm and Margaret. This prince, having been educated at the court of Henry I., had acquired a knowledge of the English laws, and gained considerable experience in the art of government. Like his predecessor, he refilled with success the efforts of the court of Rome to destroy the independence of the Scottish church. His attention was afterwards drawn to an insurrection raised by Angus, earl of Moray, who was defeated and slain at Stracathrow, one of the parishes of Forfarshire. During these transactions David maintained the strictest amity with England, till the civil dissensions which ensued upon the death of Henry, when he took up arms in support of the empress Matilda; but he afterwards concluded a treaty with the usurper, Stephen.

This lasted about two years, when David again passed the borders, and sought the battle of the "Standard" on the 22d of August, 1138. In that action the Scots were overtaken with great slaughter, and the king himself, with the remains of his army, found great difficulty in securing a retreat to Carlisle. David nevertheless soon recruited his troops, and shewed himself to be still formidable, by reducing the castle of Werk; but his further progress was arrested by the conclusion of peace. After this David applied himself chiefly to the laudable task of civilizing his yet semi-barbarous subjects. He founded several towns, and enacted the "Leges Burgorum," which still continue in force. He likewise introduced into the kingdom many Anglo-Saxon, Anglo-Norman, and Anglo-Belgic inhabitants, a measure that met with great opposition, but which nevertheless was eventually advantageous to Scotland. David died at Carlisle in May 1153, and was succeeded by the grandson of Malcolm, who had fearlessly seated himself on the throne, before Somerled, a Hebridean chief, invaded the Mainland, and forced him to take the field. After various conflicts, Somerled was repulsed, but not subdued; and Malcolm was forced to conclude a peace with him, upon terms degrading to the dignity of the Scottish monarch.

About this time, the demise of Stephen placed the crown of England on the head of Henry II., who not only disregarded his solemn engagements to cede to Scotland the country lying between the Tyne and the Tweed, but demanded restitution of those territories which Malcolm held in England. The latter, conscious of his inability to wage war with so powerful a monarch, complied with this unjustifiable demand, and in return, Henry conferred on him the honour of Huntington, for which he did homage in 1157, retaining all his dignities. Malcolm on that occasion was invested with the honour of knighthood; after which he accompanied Henry to France. These circumstances excited great discontent among the barons, and Somerled took advantage of the distracted state of the country to renew his inroads. Malcolm, however, on his return triumphed over all his adversaries; but did not long enjoy his good fortune, having died at Jedburgh on the 9th of December, 1155.

William, the brother of Malcolm, now ascended the throne, and almost immediately repaired to the English court to demand the restitution of Northumberland. Henry amused him with fair promises for twelve months, when William began to perceive the futility of further solicitation: and therefore entered into a league with France, in 1168, though it does not appear that war was the immediate result. William, however, waited the borders in 1173; and in the subsequent year engaged in a similar expedition, during which he was surprized in his camp at Alnwick, and taken prisoner; an event which cost him the ancient independency of his crown: for, in order to gain his liberty, he stipulated to do homage to Henry for Scotland, and all his other possessions; engaged that all the barons and nobility of his kingdom should also do homage; that the bishops should take an oath of fealty; that both should swear to adhere to the king of England against their native prince, if the latter should break his engagements: and that the castles of Edinburgh, Stirling, Berwick, Roxburgh, and Jedburgh, should be delivered up to Henry till the performance of all these articles. "This severe and humiliating treaty," says Hume, "was executed in its full rigour. William, being released, brought up all his barons, prelates, and abbots, and they did homage to Henry in the cathedral of York, and acknowledged him
and his successors for their superior lord. The English monarch stretched still further the rigour of the conditions which he exacted. He engaged the king and states to make a perpetual cession of the fortresses of Berwick and Roxburgh, and to allow the castle of Edinburgh to remain in his possession for a limited time." This is the first great accendant which England obtained over Scotland.

These disgraceful measures, and the feeble conduct of William, rendered him extremely unpopular. The lords of Galloway and Ros successfully displayed the standard of rebellion, and though eventually compelled to submit, kept the kingdom in a state of disquietude for some years. In 1188, Henry II. sent Hugh, bishop of Durham, and several priests, into Scotland, to collect a dîme for the Holy Land; but this met with the warmest opposition. He next offered to restore the castles of Roxburgh and Berwick to William, if he would give the tenth of the kingdom for the holy war; and his consent was only withheld, in consequence of the barons and clergy indignantly declaring, that "they would not pay, although both kings should have sworn to levy them." This was the last proposal of Henry affecting the independence of Scotland; as he died soon afterwards, leaving his crown to his son Richard, who restored to William all the rights and territories which had been wrested from him during the government of his father: thus Scotland again regained her independence, though her monarch became the baronial vassal of England, as earl of Huntington. In the latter capacity William did homage to king John A.D. 1200, and after the ceremony demanded restitution of the three northern counties of England, a demand which was tacitly refused. In 1209, both monarchs assembled their troops on the borders, but the interference of their respective barons effected a reconciliation without bloodshed. From this period William lived in peace till his death, which occurred on the 4th of December, 1214.

Alexander II., the son of William, succeeded to the throne, and almost immediately engaged in hostilities against king John, in support of the barons. John lost no time in making a signal retaliation. In 1216 he passed the Tweed, and burnt the towns of Dunbar and Haddington. Alexander next year entered England to join Lewis, the French prince; but the death of John, and the subsequent disasters of Lewis, prevented the accomplishment of his designs, and a treaty was soon after concluded with Henry III. This pacification lasted till the year 1233, when the English king thought proper to call in question the validity of Alexander's coronation, and even intrigued to deprive him of his crown. In an interview between the two kings at Newcastle, they endeavoured in vain to accommodate their differences. They adjourned them not only from York, in September, 1237; but as the terms of their agreement were unequal, it was not of long duration.

Jealousies arose between them in 1244; Henry collected a large force at Newcastle, and Alexander marched to the borders, a highly disciplined army, amounting, as some writers state, to the number of 100,000 men, all animated with the most determined resolution to defend their country. The appearance of so formidable a force induced the English barons to mediate a peace, which was accordingly agreed to. Alexander was next routed from repose by an insurrection in Galloway, which he had feebly quelled, before Angus, lord of Argyile, assumed independence, and refused to acknowledge the sovereignty of the Scottish crown.

The king marched against him, but died in Kerraray, an island on the coast of Argyile, on the 8th of July, 1249.

Chalmers remarks concerning this prince, that he is properly characterized by Fordun, "as a king, pious, just, and brave; as the shield of the church, the safeguard of the people, and the friend of the miserable."

Alexander III. was crowned at Scone July 13, 1249, after having been knighted by David de Berneham, bishop of St. Andrews. In 1251 he celebrated his nuptials with Margaret, daughter of Henry III., and on that occasion did homage for his English lands. The felicitous of Henry led him to demand homage for the kingdom of Scotland also, but the young king, with equal fortitude and prudence, replied, that he had come to England to be married, not to treat of affairs of state; and that he could not comply with his desire without the approbation of the great council of the Scottish nation. With this prince commenced that series of regal minorities which caused so much distraction to Scotland for several centuries, through the intrigues of the nobles, and of the court of England, to secure the chief influence in the state. Henry began to forward his views, by diffusing all the leading men attached to the late king, and elevating a more servile faction to power; but this arrangement was quickly overthrown by a coalition of the nobles, headed by the Cumyns, who fizeled the persons of the king and queen, and ruled in their names. As this party confided of the most powerful persons in the kingdom, Henry found it necessary to accommodate himself to the state of affairs, and a new regency was formed, including the chiefs of all the factions. Thus domestic peace was restored; but foreign invasion almost immediately succeeded. In the year 1263, Haco, king of Norway, came into the Clyde with a fleet of 160 sail, and landed a numerous army near Largs, in Ayrshire. The Scottish forces, commanded by Alexander, hastened to oppose him, and in a decisive battle fought on the second of October, in that same year, completely routed the Norwegians.

Haco with difficulty escaped to his ships, attended only by a few followers, and soon after expired in Orkney. Magnus, his successor, made over to Alexander all the islands of the Hebrides in full sovereignty, but he still retained the islands of Orkney and Zetland. From this period the Scottish king was chiefly occupied, for several years, in affecting the independence of the Scottish church against the pretensions of the pope, and in curbing the ambition of his own clergy. In 1278 he went to London, to attend the coronation of Edward I., and to do homage for the lands held by him in England. The events which ensued were at once afflicting to the king, and ultimately disastrous to the nation. Within one year, viz. in 1283, Alexander, the young prince of Scotland, and his sister Margaret, who had married Eric, king of Norway, died. The former had no issue, but the latter left an only daughter, Margaret, commonly called the Maid of Norway. The Scottish king, anticipating the dangers of a disputed succession, resolved, if possible, to avert them. He assembled the great council of the nation at Scone, in which it was declared that the princes of Norway should succeed to the throne, "failing any children Alexander might have, and failing the issue of the late prince," whose widow it was supposed might be pregnant. To add strength to these prudent measures, Alexander himself married, for his second wife, Jolerta, daughter of the count de Dreux; but the felicitous for that event had feebly ceased, when he was killed by a fall from his horse, near Kinghorn, on the 16th of March 1285—6.

History of the Third Period.—On this fatal accident, Margaret was unanimously declared queen, and a regency, consisting of six principal prelates and barons, was appointed to govern the kingdom during her absence and minority. Through their exertions, and protected by her father Eric, and her grand uncle, C.

Vol. XXXII.
uncle, king Edward of England, the seemed firmly seated on the throne; a circumstance from which the English monarch was led to anticipate great advantages. Having lately subjugated Wales, he formed the plan of marrying his eldest son, Edward, to the Scottish queen, hoping thereby to consolidate the whole island into one monarchy. With this view he drew closer the ties of amity between England and Norway, and did all in his power to attach the Scottish regency and nobles to his interest. The friendship which had of late prevailed between the two nations greatly facilitated the execution of this design, so favourable to the happiness and grandeur of both kingdoms. The alloys of Scotland not only gave a ready assent to the marriage, but agreed that their young sovereign should be educated in the court of Edward. Anxious, at the same time, to ensure the independence of their country, they took care to stipulate very equitable conditions before they entrusted themselves into the hands of so ambitious a monarch. It was formally agreed that they should enjoy all their ancient laws, liberties, and customs; that in case their queen should die without issue, the crown of Scotland should revert to the next heir, and should be inherited by him free and independent; that the military tenants of the crown should never be obliged to leave Scotland, in order to do homage to the sovereign of the united kingdoms, nor the chapters of cathedrals, collegiate or conventual churches, in order to make elections; that the parliaments summoned for Scottish affairs should always be held within the bounds of that kingdom; and that Edward should bind himself, under the penalty of 100,000 marks, payable to the pope, to observe all these articles.

It is not easy to conceive that two nations could have treated upon terms of greater equality than Scotland and England maintained during the whole course of this transaction; and though Edward gave his assent to the article concerning the future independence of the Scottish crown, with a fawning of his former rights, this refusal gave no alarm to the nobility of Scotland. The marriage treaty was therefore signed at Brigham, on the 18th of July 1290, with the cordial concurrence of all parties.

But this project, so happily planned, and so amicably conducted, failed of success by the sudden demise of the Norwegian princes, who expired in Orkney, while on her passage to Scotland, and left a very dismal prospect to the kingdom. Though for the present disorders were prevented by the authority of the regency, the succession of the crown was now become an object of dispute, and the regents could not expect that a controversy, which is not usually decided by reason and argument, would be peaceably settled by them, or even by the states of the kingdom, amidst so many powerful competitors. As the poison of King William became extinct by the death of the Maid of Norway, the right to the throne devolved on the issue of David, earl of Huntingdon, brother of William, whose male line being also extinct, left the succession open to the poetry of his daughters.

The earl had three daughters, Margaret, married to Allen, lord of Galloway; Isabella, wife of Robert Bruce, lord of Annandale; and Ada, who espoused Henry, lord Haiftings. Margaret, the eldest of the sisters, left one daughter, Deverilga, married to John Baliol, by whom she had a son of the same name, one of the present claimants. Isabella, the second, bore a son, Robert Bruce, who was now alive, and also urged his pretensions; Ada, the third, left a son, John Haiftings, who contended that the kingdom of Scotland, like other inheritances, ought to be divided equally among the three daughters of the earl of Huntingdon, and that he had a right to a third of it, as representing his mother. Baliol and Bruce united against Haiftings in maintaining the indivisibility of the kingdom, but each of them supported by plausible arguments the preference of his own title. This occasioned a long and complicated investigation and dispute. Edward of England was appointed umpire, and he pronounced in favour of Baliol; but as he treated him in many respects as a vassal, impelling upon him the most degrading services, Baliol was soon incited to relitigate his pretensions, and the two kingdoms were thus involved in a war, which terminated in the conquest of Scotland. Edward, having fetted the government, and, as he thought, secured tranquillity, returned to the south, carrying with him the throne in which the Scottish kings were seated during the ceremony of coronation. Baliol was sent a prisoner to the Tower of London, where he remained two years, and was only liberated upon the condition of refunding upon the continent during the remainder of his life. At this period William Wallace, one of the greatest heroes of which the annals of history can boast, appeared as the vindicator of his country's freedom. Beginning with small attempts, in which he was always successful, he gradually proceeded to more momentous enterprises, and discovered equal caution in securing his followers, and valour in annoying the enemy. His intimate knowledge of the country enabled him, when purfued, to ensure a retreat among the morasses, in the forests, or the mountains. At times he defecled his associates in one place, and collecting them again in some distant quarter, surprized and routed the English before they had any idea of his approach. Every day was marked by some daring exploit, which increased his influence and renown. At length he resolved to strike a decisive blow, by attacking Ormefby at Scone. The judiciary, apprized of his intentions, fled hastily into England, and was followed by all his colleagues in office, an event which gave a new character to the efforts of Wallace. Many of the principal barons, and particularly Sir William Douglas, now openly countenanced his party, and the nation at large prepared to defend, by an united effort, that liberty, which they had so unexpectedly recovered.

In the mean time, the earl of Surrey having mustered an army of 40,000 men, hastened to suppress an insurrection, which had become formidable in a great measure from his own negligence. After traversing Annandale, he marched along the western coast to Irvine, where he found the Scots encamped, and sufficiently formidable by their numbers to have punished his temerity, if distrust and dilution had not weakened their ranks. Fortunately for him, however, the jealousies of the nobles were still stronger than their patriotism, and many of them auguring no advantage from resistance, submitted to the English, and received pardon. Others, who had not so unequivocally declared themselves, likewise joined the oppressors of their country. Wallace alone remained inexcusable to bribe or threat; but thus deterred, he was unable to give battle to the governor, and therefore marched to the northward, with the intention of prolonging the war, and of turning to his advantage the mountainous districts of the Highlands. When Warrene arrived at Stirling, the Scottish hero lay encamped at Cambuskenneth, on the opposite side of the Forth; the English commander again endeavoured to negotiate, but Wallace replied, that his object was not to treat, but to set Scotland free. This bold language being construed by the English as a defiance, they demanded to be led against the enemy. Warrene hesitated, but Creflingham urged an immediate attack, and his counsels prevailed. The English began to pafs the bridge that separated the two armies, but before half of them had reached the opposite side, they were attacked
tackled by Wallace, and either pulled into the river, or destroyed by the sword. Among the slain was Creffingham himself, whose memory was so hateful to the Scots, that they flayed his dead body, and made garths of his skin. The remainder of the English army precipitately retreated into England. Wallace pursued, and reduced the fortresses of Berwick and Roxburgh; Dundee and the other strong holds also capitulated, and thus was Scotland a second time freed by the valour and constancy of her patriotic champion.

Wallace was now declared guardian of the kingdom by the unanimous voice of his followers, and with the general consent of the people, and under this title he directed affairs in the name of the captive Baliol. As the misfortunes of war and an unfavourable season had produced a famine, he marched into England, laid waste the northern counties, and returned loaded with spoils, and crowned with glory.

Edward, who during these transactions was prosecuting the war in Flanders, having concluded a truce with France, hastened over to England, in the confident hope of recovering, by his activity and vigour, the important conquest of Scotland, which he always regarded as the chief advantage of his reign. For this purpose he assembled an immense army, with which he laid siege to the castle of Dirleton. Wallace in the mean time, sensible of the jealousy of the Scottish nobles, voluntarily resigned his authority as guardian to the Stewart of Scotland, and Cumyn of Badenoch, men of eminent birth, under whom he hoped the great chieftains would be more willing to fight in the defence of their country. These two commanders took post at Falkirk, and determined there to await the assault of the English. Wallace also brought his troops hither, and placed them at the disposal of the regents. The resolution of the Scottish chiefs to risk a general battle was highly agreeable to Edward, whose army was already much strained for provisions, and was in a state of mutiny. He advanced therefore with great rapidity to Falkirk, and immediately on his arrival led his troops to the attack. Cumyn, with his division, fled on the first onset, and left that of the Stewart to be cut to pieces. This cowardly conduct decided the fate of the day; but in the general rout, Wallace's military skill enabled him to preserve his patriot bands entire. After a gallant resistance he retreated leisurely along the banks of the Carron, followed by a corps of the English army under the orders of Bruce, who demanded a conference with the Scottish hero, in which the latter fully convinced him of his want of patriotism, in expounding the canons of the oppressor of his country.

Soon after this victory, Edward returned to England, and the Scots once more rallied, and obtained many advantages over the forces left behind by the English monarch. Three victories were gained in one day, and the renown of these great exploits, echoed by the favourable disposition of the people, soon made the regent master of all the fortresses in the south, and it became necessary for Edward to begin anew the conquest of the kingdom.

The English king accordingly prepared for that event with his usual activity and prudence. He assembled both a great fleet and army, and entering the kingdom, proceeded almost to its utmost extremities, without encountering any opposition. All the nobles, and even the regent himself, made their submission to the conqueror. The only fortresses which did not immediately yield were those of Brechin and Stirling. So gallantly, indeed, did the garrison of the latter defend their tracts, that it was nearly demolished before Edward, after a siege of four months, was enabled to take it by assault, an event which again placed the whole of Scotland under his power. Still, however, he disfruited the permanency of his successes, for Wallace was yet alive, unfilled in his character, and unsubdued in his spirit. Edward employed every art to discover his retreat, and to obtain possession of his person; and he at length succeeded, through the treachery of Sir John Monteith, whom Wallace had always regarded as one of his bosom friends. By him he was arrested, and sent in fetters to London, where he was tried as a traitor, though he never made submissions or sworn fealty to England, and was executed on Tower-hill, on the 23rd of August, 1305. Such was the unworthy fate of the greatest hero and most disinterested patriot of his own or perhaps of any other age.

By this unjust and barbarous treatment of the gallant Wallace, Edward hoped to strike terror into the Scots, and enure their submission. Thrice calculations, however, were soon shown to be erroneous. The execution of Wallace, and the exposure of his mangled limbs in different towns of the kingdom, served only to inflame the resentment of his countrymen. Even the nobles, whose jealousy of his influence had prevented his final successes against the tyranny which oppressed them, bewailed his fate, and vowed vengeance against his murderer. Bruce, in particular, became more confirmed in his purpose of asserting his rights, and vindicating the liberties of his country. Flying to different parts of the kingdom, he incited the people to rise against their oppressors, attacked and defeated the detached parties of the English, secured the possession of many fortresses, and having established his authority in most places of the south, proceeded to Scote, where he was solemnly crowned on the 27th of March 1306.

Bruce having by repeated successes driven all the English from Scotland, except such as fled to the few fortresses still in their hands, Edward dispatched Alexander de Valence to enure this new and formidable revolt. That nobleman advanced without opposition to Methven, in Perthshire, where he found the Scottish forces encamped, attacked them before they were aware of his approach, and gained a complete victory. The Scottish king fought with great courage, but was at last obliged to quit the field, and to seek security for himself and a few followers in the Waternish islands. All the prisoners of note were executed as rebels, and many acts of outrageous oppression were exercised against those of inferior rank. On the death of Edward, which happened in 1308, Bruce resolved again to try the fortune of war. He attacked and brought under his dominion the territories of Argyle, and thereafter took the fortresses of Inverness, Forfar, and Brechin. By these exploits he gradually increased his influence, and reconciled the barons to his cause. Indeed, such was the acquirer with which the people in general seconded his operations, that in three months the whole of Scotland, except one or two fortified places, were wrested from the tyranny of the English. Edward, harassed by dilations at home, now found it necessary to agree to a truce, which, though it was only of short duration, enabled Bruce to consolidate his power, and organize his government. At its conclusion he entered England, and gratified the revenge and cupidity of his followers by laying waste and plundering the northern counties. Edward, in his turn, became the plaintiff during the same year, and advanced beyond Edinburgh. But the want of provisions soon obliged him to retire, without having gained any material advantage. Though, however, he abandoned Scotland for the present, he resolved to undertake its conquest again at no distant period. With this view he summoned the most warlike of his vassals from Galway, enlisted numerous foreign troops into his service, and assembling the whole military force of England, marched towards the borders with an army composed of 100,000 men.
The Scots at this time were besieging the castle of Stirling, and had compelled the governor to a capitulation, unless relieved by a certain day. Bruce, judging that Edward would endeavour to save this fortress, poited his army at Bannockburn, about two miles to the southward, where his right flank was protected by a precipitous hill, and his left by deep moras. This gallant band consisted only of 30,000 combatants, but all of them men of tried courage, determined to perish or to ensure the liberties of their country. The English arrived in fight on the 24th of June, and on the fame evening dispatched a body of horse to penetrate to the castle. Bruce ordered his nephew, Randolph, earl of Murray, to intercept their march, and a furious engagement ensued, which terminated in the total discomfiture of the invaders, and contributed greatly to the confidence of the Scots. Early on the following day the English king led his army to a general attack. The earl of Gloucester, who commanded the cavalry, rushed forward to the charge with the utmost impetuosity, and fell into the covered pits which Bruce had formed in front of his line. The Scottish cavalry, commanded by sir James Douglas, advanced upon them, and after a prodigious slaughter, chased them from the field. Returning, they threw themselves upon the rear of the infantry, who were engaged by the Scottish foot. At this critical moment, the waggoners and limpter boys of the army, whom Bruce had supplied with military standards, appeared on the summit of a neighbouring hill, and decided the fortune of the day. The English, supposing them to be another army, were panic-struck, threw down their arms, and fled in the utmost confusion. They were pursued by the victors as far as Berwick with immense loss; and the king himself escaped only by the fleetness of his horse. The Scots, besides an inestimable booty, took many persons of quality prisoners, and above 400 gentlemen, all of whom Robert treated with great humanity. Barton, a monk of Scarborough, who had accompanied Edward to celebrate his triumph, composed a poem in honour of the victory of the Scots, as the price of his liberty; and the ransom of the other prisoners brought a great accession of wealth to the victorious army. Such, says an eminent historian, "was the great and decisive battle of Bannockburn, which secured the independence of Scotland, fixed Bruce on the throne of that kingdom, and may be deemed the greatest overthrow that the English nation, since the conquest, has ever received. The number of slain on those occasions is always uncertain, and is commonly much magnified by the victors. But this defeat made a deep impression on the minds of the English, and it was remarked, that for some years no superiority of numbers could induce them to keep the field against the Scots."

After this victory the castle of Stirling surrendered according to agreement, and that of Berwick was taken by assault. Bruce likewise attempted to make himself master of the town of Carlisle, but his efforts were baffled by the bravery of its garrison. In April 1315, he assembled a parliament at Ayr, to settle the succession to the crown, which was declared to devolve to Sir Edward Bruce, his brother, in preference to the king's own daughter Margery, who gave up her rights for the benefit of her country. Sir Edward immediately passed over into Ireland, to aid the Irish against the English, and he was soon after followed by the king himself, but the latter returned to Scotland in the same year. His brother, however, continued to pursue his projects of conquest, till his defeat and death in the battle at Dunick, which was fought in 1318. This event rendered a new settlement of the regal succession necessary, and accordingly a parliament met at Scone in December, and acknowledged as heir, Robert, the infant son of Margery, who had married the Stewart, and died in 1316. But this declaration of the crown was also rendered nugatory in the first instance, by the birth of a son to the king himself, in 1323. In the mean time the war continued to rage with various successes, and Robert dispatched Randolph as ambafador to France, to conclude a treaty offensive and defensive with Charles IV. In March 1327, the English government agreed to acknowledge the kingship of Bruce and the independence of Scotland, and paid a solemn act of parliament to that effect. The treaty of Northampton was the immediate confluence, and settled the peace between the contending kingdoms as independent sovereignties. One of its stipulations was, that David, the infant son of Robert, should marry Jane, the sister of the English king. Bruce, having thus obtained the confirmation of his magnanimous efforts, died in the year following, at the age of fifty-five. David I. now ascended the throne, which the abilities and vigour of his father had established, apparently on a firm foundation. Randolph, earl of Murray, was declared guardian to the young king; but, unfortunately for the prince and for Scotland, he died in 1332, the very year in which a new competitor for the crown arose in the person of Edward Baliol, son of that John who had so meanly surrendered his kingdom to Edward I. This pretender, with the secret support of the English monarch, collected a considerable body of troops, and landed in Fife. The new regent, Donald, earl of Mar, hesitated to oppose this invasion, and for that purpose is said to have marched an army of 40,000 men. His imprudence and want of skill, however, destroyed the advantages which superiority of numbers gave him over his antagonist. Both armies encamped opposite to each other, separated only by the river Earn; and the regent, confiding in that security, and the small force of the enemy, neglected all order and precaution. Baliol, apprized of this, crossed the river in the night, penetrated into the camp of the Scots, threw them into confusion, and pursued them from the field with great slaughter. Baliol, on this unexpected success, marched for Perth, and made himself master of that important station. Here he was besieged by the earl of March and sir Archibald Douglas, but their efforts were defeated, and Baliol was proclaimed king. David and his betrothed queen were sent over to France, and the leaders of his party fled for and obtained a truce from his competitor, whose power they were unable to refit. Thus did Baliol, by a display of the most chivalrous valor, seat himself on the throne of Scotland. His reign, however, was of short duration, for having disfigured the greater part of his English followers, he was attacked and defeated near Annan, by sir Archibald Douglas, and other chief lieutenants of the Bruce faction. By this disaster Baliol lost his kingdom more rapidly than he had gained it. But in the interval he had induced the English king openly to support his cause, by offering to acknowledge his superiority, to renew the homage for his crown, and to espouse the prince's Jane, whose marriage with David was not yet consummated. Edward had eagerly embraced these offers; and as the dethronement of Baliol now rendered them ineffective, he resolved to reinstat him in the possession of the crown, an enterprise which he flattered himself would be easy. Accordingly, he besieged Berwick, which the governor, after a gallant defence, agreed to surrender, unlees relieved by a certain day. The regent being informed of this capitulation, was forced, contrary to his wishes, to risk the fate of the kingdom on the issue of one battle. He attacked the English at Halydon Hill, north of Berwick, and as he himself was slain at the first onset, his army was totally routed. The English
The English king about this time was led to advance pretensions to the throne of France, which soon provoked him to war with that kingdom. This event elated the hopes of the Scots, who gradually reduced all the fortified places held by the English within their territories; and in order that they might have the countenance of sovereignty authority, they invited David and his queen to return to Scotland. The royal pair accordingly landed at Innerberry, in the Mearns, in June 1342. Indignant at the defolation that everywhere met his eyes, David immediately entered England, and ravaged the country as far as Newcastle, to which he laid siege; but after several disfartious affairs, he was obliged to abandon the enterprise. David again invaded England in 1347, and advanced to the vicinity of Durham, where he was encountered by an English force, raised by the energetic conduct of queen Philippa. The contest was warmly maintained for some time on both sides, but the Scots were in the end defeated, and the king himself, and many of the nobility, made prisoners. Baliol, who commanded the English army in this action, professed his victory with great vigour. Before the conclusion of the year he had reduced the castles of Hermitage and Roxburgh, and extended his conquests ever Annandale, Teviotdale, and Tweedale. In the next year success continued to attend his march; but in 1348 he was forced to retreat into England, and a truce was agreed to. On its expiration, in 1355, the Bruce once more took the field, which they were better enabled to do by means of a considerable assistance, both in men and money, furnished to them by the French king. One party, commanded by lord Douglas, completely defeated the English mariners at Nisbet Moor, and afterwards assaulted and took the town of Berwick, but the approach of Edward prevented the reduction of the castle. At this period Baliol, tired of attempting to regain a crown, determined to retire into private life, and to resign to the English king all his rights to the throne, in exchange for a subsistence adequate to his rank. The bargain was agreed to, and Edward marched into Scotland with a powerful army, to secure his newly acquired possessions. The Scots adopted the wife policy of harrying their enemy by frequent skirmishes, in which they were so successful, that Edward was soon compelled to a precipitate retreat. During these events David remained a prisoner in England, but in May 1357, a truce was concluded, wherein he was virtually acknowledged king, and was ransomed for the sum of 100,000 marks, to be paid by instalments within ten years.

David having, by this treaty, regained his liberty, paid the two first instalments of his ransom; but he found it impracticable to raise money for the third payment. After various unsuccessful expeditions, therefore, he was obliged to appeal to Edward himself, and to conclude a treaty with him in 1365, in which it was stipulated that the latter should succeed to the throne of Scotland, and that a federal union of that kingdom with England should take place, provided David died without issue. But the Scottish nobles having rendered this treaty nugatory and unavailing, another was agreed to in May 1365, by which Scotland became bound to pay to England the sum of 100,000 pounds within the space of 25 years. From this period no event occurred worthy of notice in the history of Scotland, till the death of David, which happened in Feb. 22, 1370—71; when Robert II. succeeded to the throne, and was crowned at Scone on the 26th of March 1371, at the advanced age of 55. Among the first acts of his government, was the dispatch of ambassadors to France, by whom was negotiated a treaty, which stipulated that neither the king of Scotland nor the king of France should be obliged to make war upon England; not even the dispensation of the pope should relieve either party from their engagement to each other; that, in the event of a competition for the crown of Scotland, the king of France should take care that no English influence was used; that he should acknowledge the king elected conformably to the laws; and that no Frenchman should serve against Scotland, nor any Scot against France.

Robert and Edward continued to keep up a friendly correspondence, notwithstanding their respective borderers were engaged in perpetual hostility, and the former was punctual in discharging the instalments of his uncle's ransom.

Robert, who had a numerous progeny, and seems to have feared some disputes might arise relative to the succession after his death, convoked a parliament at Scone, in April 1373, in order that their declaration might guard the kingdom from a repetition of its past misfortunes. This parliament recognized, in the first instance, the title of John, earl of Carrick, and the Stewart of Scotland, his eldest son by Elizabeth More, his first wife, thereafter his other sons by the same lady, according to their seniority; his sons by Euphemia Rois, his second wife; and lastly, "the true and lawful heirs of the blood and stock royal." Buchanan erroneously calls Euphemia Rois the first wife, and Elizabeth the second wife, alleging that the children of the latter were born during an illegitimate connection in early life; but sufficient evidence has been adduced from papal archives to show that the king married Elizabeth More at a time prior to his marriage with queen Euphemia, and that she died long before he ascended the throne.

In 1377 the border wars began to rage with signal fury. The lord Percy, now earl of Northumberland, ravaged the counties of the earl of March, and a party of Scots, commanded by one Ramfay, surprised the castle of Berwick, and declared that they held it for the king of France. It was re-taken, however, by assault, after a siege of nine days, when all the garrison, except Ramfay, were put to the sword. The English army then marched into Scotland, but their advanced guard having been entirely cut off, they defiled from their expedition. In 1379, the Scottish borderers again invaded England, and laid waste the country. The earl of Northumberland, in retaliation, fitted out privateers, and captured some Scotch ships; but the English government restrained these proceedings, and ordered the borderers not to provoke the Scots, but to observe the truce. These commands, however, not being attended to, the earl of Douglas built into Cumberland with 20,000 men,
men, plundered the town of Penrith during its fair, and returned with an immense booty in merchandise, besides 40,000 head of cattle.

The duke of Lancaster, about this time, was sent to redress the borderers, and also to obtain some satisfaction from the Scottish king for the many infractions of the existing truce, which had been committed by his subjects. Before he entered upon hostilities, however, he invited the Scots to a treaty, and a truce was agreed to for ten months, which was afterwards prolonged for seven months more. But this convention seems to have related only to the borders, as the Scottish monarch does not appear as a party to it. This pacific conduct of the duke created him many enemies in England. Hence, when the people rebelled against his nephew’s government, he found it necessary to seek safety for a short time in Scotland, where he was hospitably received. On his return, the Scots having assaulted the castle of Werk, he was again dispatched to demand reparations, and to treat of a general peace. Conferences were accordingly held with the earl of Carrick, but nothing definite was agreed to. Indeed the continuance of peace appears not to have been the wish of the Scottish monarch, for he soon after renewed the ancient league with France, and commenced hostilities by taking the castle of Lochmaben. On this the duke advanced as far as Edinburgh, whence he was obliged to return to Berwick, without having gained any advantage. The Scots again became the aggressors, and had laid waste the country as far as Newcastle, when the conclusion of a new truce put an end, for a time, to regular hostilities. The border wars, however, still raged, and the town of Berwick was taken by the Scots, but was given up again on payment of 2000 marks.

On the expiration of the truce, Robert, who had received considerable supplies from France, prepared to invade England, and create a diversion in the north, while a French army should land in the south. But in the interim the French king was obliged to abandon the intended descent upon England, and hence Robert was left to contend, single-handed, against the undivided force of that powerful monarchy. Richard marched into Scotland at the head of 50,000 men.

The Scottish king wisely refused to risk a general action, though strongly urged to do so by the officer commanding the French auxiliaries,contenting himself by harrying the enemy by frequent attacks, till they were forced to retreat within their own territories. After this, the earl of Douglas invaded Ireland and the Isle of Man, whence he returned with immense booty. Robert, elated by these successes, resolved to attempt an invasion of England on a grand scale. Accordingly a powerful army entered Northumberland, and laid siege to Newcastle, which was defended by Henry Percy, surnamed Hotspur. This nobleman challenged Douglas, the Scottish general, to meet him in single combat, and the challenge having been accepted, a contest took place in fight of both armies, and terminated in the overthrow of Hotspur. Next day Douglas ordered a general assault, but was unsuccessful; and as the English had received reinforcements during the night, he deemed it prudent to retire towards Scotland. Percy, eager to wipe off the disgrace of his personal defeat, pursued, and came up with the Scots at Otterburn, where a battle was fought by the light of the moon, and is represented by historians as the most obstinately contended of any that occurred in that age. Earl Percy, and above a hundred pursuivants, were made prisoners, and contributed, by their ransoms, to enrich their conquerors. Scarce was this battle finished, when another English army appeared in view, under the orders of the bishop of Durham.

The Scots, notwithstanding their fatigued state, resolved to venture a second contest, and nobly disdaining the customary barbarity of putting their prisoners to death, (though nearly as numerous as their whole army,) drew up in martial array, having simply required them to give their word of honour that they would not interfere in the action. The bishop, who imagined the Scots would fly at his approach, perceiving their bold attitude, thought it more advisable to retreat than to hazard the destruction of his army. The Scots henceforth continued their march un molested; and, in testimony of the honourable conduct of their prisoners, they dismembered all those of inferior rank without ransom, and accepted obligations from their superiors, all of which were punctually fulfilled; examples of honour and generosity worthy of the most enlightened period of society.

In the year 1389 a treaty was concluded between the kings of England and France, to which the Scots were invited to accede; but as the earl of March and the lord of the Isles were admitted as parties, great opposition was manifested to it by the nobles, who considered both these noblemen as subjects of the Scottish monarchy, and therefore not entitled to treat as independent persons. The king, however, inclining to peace, and after some explanations on the part of the French and English ambassadors, the nobles were induced to give a reluctant consent to the termination of hostilities for three years. Robert died soon afterwards, oppressed with grief and age, April 19th, 1392, and was succeeded by his eldest son, John, earl of Carrick, who assumed the title of Robert III. In earlier life he had commanded armies, and negotiated treaties, with ability and success; but he had lived for some time in retirement. Now that he was called to the throne, he committed the direction of public affairs to his brother, the earl of Fife, by whose advice he confirmed the late truce, and renewed the ancient league with France. In this reign a violent feud broke out between the clans Chattan and Kay, which raged for nearly three years with the most ruthless fury. The earl of Crawford was sent to restore peace; but fearing that the employment of force might cause an union against the government, he had recourse to the following expedient, which serves to illustrate the character of the Highlanders, and the general state of society in that age. He proposed that their quarrel should be decided by thirty champions from each clan, who should fight with the sword only, in presence of the king and his court. The proposal, being perfectly agreeable to the spirit of the feudal laws, was sanctioned by both parties. A level spot near Perth was fixed upon for the scene of action, but when the combatants were mustered, it was found that one of them, belonging to clan Chattan, had failed to appear. In this difficulty it was suggested that one of clan Kay should be withdrawn, but all of them refused to relinquish the honour and danger of the combat. Various other expedients were started with no better success. At length Henry Wynd, a smith, no ways connected with either clan, offered to supply the place of the absentee, and his offer was accepted. The champions on both sides now joined battle, and after a contest probably unparalleled for its fury, victory declared for clan Chattan, principally owing to the superior heroism of Wynd, who, with ten of his comrades, all desperately wounded, alone survived the contest. Of clan Kay one only was left alive, who, being unhurt, threw himself into the Tay and escaped. This singular combat happened in the year 1396; and in 1398, as the truce with England had nearly expired, it was prolonged. and several regulations were made tending to preserve the peace of the borders. In the same year the title of duke was first introduced into Scotland, by the elevation of the king’s eldest son David to the dukedom of Rothesay; and of his own brother,
brother, the earl of Fife, to the dukedom of Albany. A custom also began to prevail in the border treaties, of naming cautioners, who acted as conservators of the peace, and were a kind of attorneys for their fellow subjects, in all matters cognizable in the border courts, which had been lately established on both sides. These regulations are justly considered as important steps in the progressive civilization of the two kingdoms.

The events of the year 1401 were the most disTurbing in themselves, and in their consequences, which ever occurred to Scotland. The death of earl Douglas was followed by the death of William Trail, archbishop of St. Andrews, a prelate of great weight; and Queen Annabella, a woman of exemplary virtue and prudence. This princess, by her influence, had conciliated the jealousies of several branches of the royal family, and in particular had restrained the tempestuous temper of the duke of Rothesay, the heir apparent to the throne, who was barbarously murdered soon after by the duke of Albany. The truce with England being now expired, war was renewed on the borders, and a severe action was fought at Watern-Nibet, in which the Scots were defeated. Strongly contended was this battle, that it is affirmed that few of either army escaped unhurt. It was succeeded in the year following by another combat, fought between the troops of Henry Hotspur and Douglas, at Homeldon, where the English were again victorious, and numbered among their prisoners the earls of Douglas, Fife, Angus, Murray, lords Montgomery, Erkleine, Graham, and Orkney, eighties knights, and about 10,000 gentlemen and private soldiers. This battle, so immediately disastrous to Scotland, proved in its results no less to England. King Henry having ordered earl Percy and the other barons not to ransom their prisoners, they regarded that mandate as such a tyrannical infringement of their feudal rights, that they raised the standard of revolt against the government, and for a time defied all its efforts. The victory of Shrewsbury, and the fall of Percy, terminated this formidable insurrection. Douglas, the rival of Percy, was present in this battle, and was taken prisoner, but his conduct had so greatly excited the admiration of the English king, that he gave him his liberty without ransom.

Henry, notwithstanding this victory, was extremely desirous of concluding a peace with Scotland, in order that he might employ the whole force of his government in overawing his discontented subjects. He first attempted to open a negotiation through the medium of the French ambassadors at the Scottish court, but finding that measure unavailing, he dispatched special commissioners with the same view. The result was unfavourable, and hostilities continued, though without any remarkable transaction on either side. All this time Robert remained ignorant of the fate of the duke of Rothesay, but it soon became necessary to make him acquainted with it. The king, unable to punish his murderers, adopted the prudent resolution of sending his second son James to France; he did not reach his destination, having been captured by an English privateer, and sent as a prisoner to London. The news of this second disaster so affected Robert, that he died three days afterwards, in March 1405.

On this event the estates of the kingdom nominated the duke of Albany regent. This prince was a man of consummate abilities, but ambitious, and hence appears to have been lukewarm in his endeavours to obtain the liberty of his sovereign. The spirit of the people, however, forced him to declare war against England, but it was soon terminated by a truce, during which it was proposed to enter into negotiations for a permanent peace. Conferences were, in consequence, held for that purpose, but they ended only in a prolongation of the truce, at the close of which the war was renewed, and Henry prepared to strike a decisive blow against Scotland; but these preparations were never carried into effect, as a treaty was agreed to which lasted till 1415. This period of Scottish history is distinguished by the foundation of the university of St. Andrews, the first institution of the kind of which Scotland can boast. (See St. Andrews.) It may therefore be regarded as an era of peculiar interest, as from it may be dated the rise of learning in that kingdom; which, though confinedly among the laik to devote itself to science, has contributed as much to its progress as any other nation of modern Europe.

The truce last-mentioned being ended, the Scots besieged Berwick, but that enterprise was unsuccessful, and all that was done during the campaign was the burning of Penrith by the Scots, and of Dumfries by the English. Next year negotiations were entered into for the liberation of James, but these were as fruitless as the former, and the war continued. No action worthy of record, however, occurred during five years, and hence it has been, with some probability, affirmed that there existed an understanding between the regent and the English general; though this would not seem to have been the opinion of his contemporaries, for we are told that, on his death, which happened in 1420, the Scots held his memory in such veneration that they conferred the regency on his son Murdoch, solely from respect for the father.

In 1421, king Henry being informed that the earl of Douglas was meditating an invasion of the northern counties, invited him to a conference at York, when the earl, with the consent of James, agreed to receive the English king during life. At the same time some fluctuations were made relative to the release of the Scottish monarch, but that event did not take place till the year 1424. Henry V. was then dead, and the tide of fortune in France had so completely changed, that the English regent found it necessary to conciliate the Scots, and if possible to detach them from the French interest. He therefore treated James with the greatest attention, and proposed a negotiation for his liberty. Commissioners were, in consequence, named on both sides, who agreed that the Scottish king should be ransomed for 60,000 pounds, and should marry some lady of the first quality in England. James, it is probable, had already fixed his choice upon the lady Joan, daughter to the late earl of Somerset, son to John of Gaunt, duke of Lancaster, by his second marriage; but he made his people the compliment, not only of consulting their opinion, but of concluding the match. The royal nuptials were celebrated in the beginning of February 1424, when the young king of England presented James with a suit of cloth of gold for the ceremony, and the next day gave him a legal discharge for 10,000 pounds, to be deducted from the amount of his ransom, as the marriage portion of the lady.

Hitherto the history of Scotland consists of little else but a detail of battles and predatory excursions; of feuds between lawless clans, and rebellions against the sovereign authority. Neither the government nor the people were sufficiently enlightened to recognize fixed principles of foreign or domestic policy. The great barons, though bound to render homage to the king, and to perform several feudal services, assumed all the importance, and exercised most of the functions, of independent princes. On the accession of James I., however, the actual power, the annals of the kingdom begin to assume a new aspect. The reiterated theme of defeats and victories, of negotiations and truces, may henceforth be diversified with more interlacing intelligence, and
and the arts of peace may afford a pleasing contrast to the
devastations of war.

James, shortly after his arrival in Scotland, was solemnly
crowned, with his queen, and Murdoch, duke of Albany, as
crown prince. He performed the ceremony of placing his sovereign
on the throne. His first public act was to convene a parlia-
ment, and to direct their deliberations to the enactment of
futural laws. Among other enactments it was declared,
that the ancient privileges of the church be confirmed; that
the king's peace be firmly held, and no private wars allowed;
that no man should travel with more followers than he
could maintain; that efficient administrators of the law be
appointed through the realm; that no extortions, from
churchmen or farmers in particular, be admitted; that the
customs and borough rates be assigned to the king, also
mines of gold and silver, under certain restrictions; that
the clergy should not pass the sea without the king's per-
mission, nor have pensions out of benefices in Scotland;
that gold and silver should not be exported, but upon paying
a high custom; that all persons under twelve years of age
should be taught archery; that agriculture be protected;
that certain customs be raised on horses, cattle, sheep, her-
rings and firs; that rents be kept in every borough; and that
no beggars be allowed, except permitted by the sheriff in the
county, and in towns by the alderman or bailie. The two other
enactments were made by the same parliament, which merit
separate consideration: the first granted the king a large
liberty, by taxation, for defraying his ransom, which occasion-
ated so much dissatisfaction, that he was obliged to avert
the danger of a general insurrection, by giving up the idea
of levying the imposed taxes. Unaccustomed to pay direct
contributions toward the support of the government,
the people considered this ordinance as an act of oppro-
was agreed, that the king should remain in the custody of the latter.

In the interim, the earl of Douglas continued to brave the power of the government in a manner amounting to open rebellion, which highly exasperated the chancellor in particular; and as he knew the earl was above the reach of the law, he resolved to get rid of him by summary means. With this view he invited him to attend a parliament then about to be held at Edinburgh, and having inveigled him and his brother into the castle, on the pretence of dining with the king, ordered both to be executed on the Castle-hill. The young monarch endeavoured to save them; but the chancellor was fixed in his purpose, and had already ventured too far to recede with safety.

James, as soon as he attained his 14th year, declared himself of age, and took the reins of government into his own hands. The numerous friends of the young earl of Douglas now strive to reconcile him to the prince; and an accident happened which led to the fulfilment of their wishes. That was the murder of Sir Robert Semple, of Fullwood, by one of the earl's partizans, who was in consequence arrested.

Douglas, anxious to save his life, repaired to Stirling, threw himself at the king's feet, and implored his pardon, solemnly promising that he would ever afterwards conduct himself as a dutiful and loyal subject. His submition was joyfully received by James, and he was immediately admitted into the royal councils.

Alarmed at this event, the chancellor resigned the great seal, and took possession of the castle of Edinburgh, the custody of which he pretended had been committed to him by the late king, till his son should arrive at the age of 21 years. Livingston also resigned all his posts, except the command of Stirling castle, which he retained upon the same pretence.

James demanded the immediate surrender of both fortresses, and the demand being refused, the estates of the offenders were confiscated. The result was a civil war, during which almost every corner of the country presented a scene of desolation and bloodshed. It terminated by the reconciliation of Crichton to the king, and the sacrifice of Livingston to the vengeance of Douglas.

The king, now in his 18th year, was married to Mary, the daughter of Arnold, duke of Gueldres; but this event provoked the hosility of England, and a war immediately ensued. An English army advanced into Scotland, as far as the river Sark in Annandale, where it was totally defeated by Douglas, earl of Ormond. Next year a truce was concluded for an indefinite period, bore which this singular chafe, that either party might violate it upon giving 180 days' notice. The royal bride having arrived in Scotland about this time, her marriage was solemnized with great pomp at Holyrood House, an event which put an end to the influence of Douglas, who retired to his estates. James, being thereby emancipated from thraldom, summoned a parliament, in which many salutary enactments were made, tending to curb the power of the aristocracy, and to ensure the tranquillity of the kingdom. One act of this parliament deserves particular attention. It ordained, that if any man should "commit or do treason against the king's person or his majesty, or rise in war against him, or lay hands upon his person violently, of whatever age the king be, young or old; or receive any that have committed treason, or that supply them with help or advice, or garrison the houses of them that are convicted of treason, and hold their houses against the king; or garrison houses of their own in affiance of the king's rebels, or that assault castles or places where the king's person shall happen to be, without the consent of the three estates, shall be punished as traitors." This statute has occasioned altercations between the favourers of monarchy, and those who attach ideas of freedom to a parliament of the middle ages; though, in fact, the only dispute lay between monarchy and aristocracy. Many other statutes were passed to increase the power of the sovereign.

Douglas, chagrined at the loss of his power, and wishing to display his pomp to the continental princes, went to the jubilee at Rome with a train of six knights, fourteen gentlemen, and eighty inferior attendants. In his absence many complaints were made against his dependants, which so enraged James, that he seized upon the castle of Lochmaben, and demolished that of Douglas. The earl, on his return home, sent a submissive message to the king; and as he could not in equity be reputed guilty of events which happened without his knowledge, he was graciously received; but he soon proved himself unworthy of confidence, by engaging in treacherous practices, and soliciting the protection of England. Douglas having been prevailed upon to visit the court of Stirling, was conducted into a secret chamber, where James mildly told him that he knew of the league he had made, and advised him to break off all such illegitimate engagements. The earl treated the proposal with his usual arrogance, whereupon the king, routed to momentary fury, exclaimed, "If you will not break this league, by God I shall," and drawing a dagger, instantly stabbed Douglas.

The brother and successor of the late Douglas was reconciled to the king, and entered into a solemn engagement; viz., not to pretend any title to the earldom of Wigton, except with the queen's consent; 2dly, to the lands of Stewarton, a part of the patrimony of the dukes of Stourton, his mother; 3dly, to abandon in future all hatred or enmity against all persons; 4thly, to prefer the public peace, and make compensation to persons already injured; 5thly, to observe the strictest duty and respect to the king. This instrument, which was signed by Douglas and lord Hamilton for themselves and their adherents, affords a curious picture of the state of government and manners in the age.

The interval of domestic quiet which succeeded this reconciliation was only of short duration; but it was marked by an event of some interest in the history of Scottish learning, viz., the foundation of the university of Glasgow, through the munificence of bishop Turnbull. The standard of rebellion was again raised by Douglas, aided by the Yorkist party in England. The king, aware of this conspiracies, summoned Douglas to appear before the privy-council; and upon his refusal ravaged his estates, and besieged his castle of Abercorn. The earl of Crawford advanced with an army to its relief, determined to force his sovereign to fight or fly the kingdom. James, distrusting the loyalty of the southern counties, hastened to St. Andrews, whence, by the advice of Kennedy, bishop of that see, he illused a proclamation, summoning the army of the north, and offering an annuity to all who should join his service. In a few days he found himself at the head of a numerous body of troops, with whom he marched against Douglas, whose army was encamped on the banks of the Carron. The effect produced was almost miraculous, for in less than twenty-four hours, Douglas was defeated by his whole army, excepting the persons who formed his household. Upon this unexpected change, he fled to Annandale, and afterwards to England.

James next proceeded to crush the remaining partisans of the insurrection, and to reduce the castles of Abercorn and Strathaven, which still resisted his authority. He afterwards assembled a parliament at Edinburgh, in which he
the forfeiture of the earl of Douglas, with his mother and brothers, was solemnly decreed. In another parliament held in the same year, several important and interfering enactments were made, tending to confirm the paramount power of the king, and to sap the foundation of the feudal system.

He next turned his attention to the subjects of foreign policy: enraged at the conduct of England for supporting the Douglas, he invaded that kingdom, and spread deploitation throughout the northern counties. Meanwhile Douglas was admitted to the titles of an English subject, and continued in that allegiance till his death.

Not long after this invasion, Truce was negotiated with England, and James returned to his favourite occupation, the enactment of laws for the improvement and tranquillity of the country. In the several parliaments held at Edinburgh, measures were taken to reform the coinage, and to regulate the internal commerce of the kingdom; a regular militia was established for the national defence; and several laws were made to promote agriculture, and to fix the constitution of parliament. But the most important act passed in this reign relates to the establishment of a supreme court of judges, independent of the king's council. This court consisted of three eminent clergy, three barons, and three commissioners of burgesses, to be changed each month. It was, in fact, a committee of parliament, the members having been taken in rotation from that assembly; and no appeal lay from its decisions.

While these matters were under consideration in Scotland, England was distracted by the rivalry of the houses of York and Lancaster. James seems to have inclined to favour the former, but took no active part on either side till the captivity of Henry VI., when he commenced hostilities, by laying siege to the castles of Berwick and Roxburgh. The latter enterprise he conducted in person; and here he unfortunately met his death, by the accidental bursting of a cannon, on the 3d of August, 1460. The nobility who were present concealed his death, from the fear of discouraging the soldiers; but the spirited conduct of the queen soon rendered this precaution unnecessary. Her young son, James, having arrived in the camp a few hours after, the prefentled him to the army as their king, and declared she would act the part of their general herself.

Accordingly she assumed the reins of government, and pushed the siege of Roxburgh castle with much vigour, that the garrison was obliged to capitulate in a few days; after which the army took and dismantled the castle of Werk. In 1466, negotiations were begun for a marriage between the young king and Margaret, princess of Denmark; and in 1468, the following conditions were stipulated: 1st, that the annual rent hitherto paid for the northern isles of Orkney and Zetland should be for ever remitted and extinguished; 2dly, that Chrisliorn, then king of Denmark, should give 65,000 florins of gold for his daughter's portion, whereof 10,000 should be paid before his departure from Denmark; and that the isles of Orkney should be made over to the crown of Scotland, by way of pledge for the remainder; with this proviso, that they should return to that of Norway after complete payment of the whole sum: 3dly, that king James should, in case of his dying before the said Margaret his spouse, leave her in possession of the palace of Linlithgow and castle of Doun in Menteith, with all their appurtenances, and the third part of the ordinary revenues of the crown, to be enjoyed by her during life, in case she should choose to reside in Scotland: 4thly, but if she rather chose to return to Denmark, that in lieu of the said life-rent, palace, and castle, she should accept of 120,000 florins of the Rhine; from which sum the 50,000 dols for the remainder of her portion being deducted and allowed, the isles of Orkney should be re-annexed to the crown of Norway as before. When the completion of these articles became necessary, Chrisliorn found himself unable to fulfill his part of them. Engaged in an unsuccessful war with Sweden, he could not advance the 10,000 florins, as agreed to. He therefore applied to the plenipotentiaries to accept of 2000, and to take a mortgage of the isles of Zetland for the other 8000. This treaty led to the final annexation of Orkney and Zetland to the Scottish crown.

In 1476 these misfortunes brought to an end James, which afterwards terminated in his ruin. He had made his brother, the duke of Albany, governor of Berwick; and had entrusted him with very extensive powers upon the borders, where a violent propensity for the feudal habits still continued. The Humes and the Hepburns could not brook the duke of Albany's greatnes, especially after he forced them, by virtue of a late act, to part with some of the estates which had been granted them in the preceding reign. The pretended science of judicial astrology, by which James happened to be infatuated, was the evil, as well as the most effectual engine that could work their purposes. One Andrew, an infamous impertinent in that art, had been brought over from Flanders by James; and he and Scoues, then archbishop of St. Andrews, concurred in perilling James that the Scotch lion was to be devoured by his own whelps.

In 1482, the king began to feel the bad consequences of taking into his councils men of worthless character. His great favourite at this time was Cochran, whom he had raised to the dignity of the earl of Mar. All historians agree that this man made a most infamous use of his power. The other minions of the king were James Honsill, a taylor; Leonard, a blacksmith; and Torffaw, a dancing-mank, who were professedly rendered them wholly unworthy of the royal countenance. The favour shown to these men gave such offence to the nobility, that they resolved to remove the king, with some of his head exceptional domesties, to the castle of Edinburgh, and to hang all his favourites over Lawer bridge, both which measures were accomplished with the most spirited resolution. During his confinement, James conducted himself with great firmness, refusing all terms of compromise with those who had feized his person, or were engaged in the execution of his favourite. Having been liberated by his brother, the duke of Albany, he immediately repaired to Holyrood House, whither most of his nobles came to pay their respects to him; but so much was he exasperated by their conduct, that he imprisoned no fewer than sixteen. Albany was appointed chief minister, and became a great favourite; but this cordiality did not last long; for in less than three years we find Scotland solemnly denounced a traitor by act of parliament. During all this period, hostilities were carried on with the English government; but a truce was agreed to in 1484; and James, finding himself in tranquillity both at home and abroad, infenibly relapsed into his former impolitic system. The result was, an association of several of the most powerful barons, who seized the person of the heir apparent, and induced him to put himself at their head. James at this period was making progress and holding courts in the North; but immediately on hearing of the insurrection he hurried to Perth, which he appointed as the place of rendezvous for his army. When the whole were assembled, he marched to Stirling, where he first learned that his son commanded the rebel forces who were advancing from the east. Both armies drew up in battle array, nearly on the same ground.
ground which had been already consecrated by the victory of Bannockburn. At first the rebels gave way; but being supported by their second and third lines, the royalists were in vain forced to retreat. This event, and the cowardly flight of the king, terminated the action with little effusion of blood. James, in passing through the village of Bannockburn, was thrown from his horse, and carried into a mill, where he was stabbed by one of the rebels, who, pretending to be a priest, was conducted to him by the miller's wife. Thus perished a prince, whose natural goodness deferred a better fate, than to fall the victim of a lawless arbitrariness, more inimical to public order than the feeble deputation of their sovereign.

The duke of Rothsay, apprised of his father's fate, assembled a parliament at Edinburgh, in which several of the friends of the late king were arraigned for high treason. He afterwards made a progress throughout the kingdom, and endeavoured to acquire popularity. In that object, however, he was not immediately successful, as we find the early part of his reign was disturbed by a formidable rebellion. The leader of this insurrection was the earl of Lenox, who was defeated and taken prisoner at Tilly-Moor. James, however, afterwards became a great favourite with the nation, on account of his zeal for the improvement of the kingdom. The arts of ship-building and of architecture were particularly the objects of his patronage; and indeed to so high a pitch did he carry his anxiety to establish a navy, that he brought himself into serious financial difficulties. This distinguished monarch closed his reign and his life in the celebrated field of Flodden, where most of his nobility perished with him.

James V. now ascended the throne, though only a year and a half old. The long minority which ensued was remarkable for internal intrigue, and particularly for the fixed establishment of the French and English factions in Scotland, which continued to distract the kingdom, more or less, till the close of its existence as a separate and independent state. From this circumstance the history of Scottish affairs becomes more interesting, as becoming more intimately connected with the general history of Europe; but as the limits of this article will not permit of their being detailed at length, their bearings cannot be pointed out in a satisfactory manner.

The parliament, which met immediately after the fatal battle of Flodden to deliberate on the critical situation of the kingdom, elected the queen-mother to the regency. This prince conducted the government with great wisdom and energy; but having unhappily married the earl of Arran, that scep conquered occasion to violent intestine combinations. By the constitution of Scotland, a marriage under the circumstances of the queen regent was a virtual renunciation of her authority; and as Arran was not a favourite with the nobility or the nation at large, parliament refused to continue him in power. The duke of Albany was therefore appointed regent; and a deputation was immediately sent to France to request his acceptance of that station. On his arrival in Scotland, he was received with every mark of respect; but as he attached himself closely to the French interest, the English party, headed by the queen and lord Hume, opposed him in all his measures, and excited combinations in different parts of the country. Henry VIII. of England declared war against him; and though it does not appear that the regent feared the issue of a contest, he nevertheless soon found it necessary to make peace, on account of the discontents that prevailed in the army, which he had led to the borders with the view of invading England. Shortly afterwards, the increasing opposition manifested against his authority induced him to resign the regency; when the sovereign power was again assumed by the queen. Arran, by feizing on the peron of the king, and pretending to rule in his name, soon overthrew the party of the queen; but his own elevation was not of much longer continuance; for the king, having escaped from his custody, feized the reins of government himself, and not only deprived Arran of all his dignities, but had him denounced in parliament as a traitor.

Thus freed from the control of all parties, James displayed an excellent capacity for government. He called frequent parliaments, and directed their attention principally to the improvement of his kingdom. In 1532 he instituted the court of seisin, on the model of the parliament of Paris. This court originally consisted of fifteen members, half clergy and half laity, and was empowered to give decisions in all civil suits.

The years immediately succeeding that last-mentioned, were marked by the most horrid atrocities, committed in the name of religion. Many persons of distinguished rank suffered at the stake for their opinions. A court of inquisition was established, of which Sir James Hamilton was appointed president; and certainly no man ever shewed himself more worthy of his meritorious station. During the same period the Scots had to deplore the miseries of a war with England, which raged for two years with various successes. But notwithstanding these misfortunes, Scotland continued to rise in power and importance. The friendship of James was anxiously sought by all the great European sovereigns. Even the pope sent an ambassador to the Scottish court, and conferred upon James the title of "Defender of the Faith."

In the year 1536, the king negotiated a treaty of marriage with Marie de Bourbon, which was solemnly ratified by the French king; but it was afterwards annulled by the visit of James himself to the continent, where he espoused Magdalen, the daughter of Francis, who died in less than two months after her arrival in Scotland. The Scottish king, however, did not long remain a widower; for in 1538 he espoused Mary of Guise, dowager duchess of Longueville.

In 1540 a parliament was held at Edinburgh, in which an act of indemnity was passed for all offences committed during the king's minority. Shortly after war broke out with England, and the duke of Norfolk invaded Scotland; but was compelled to retreat by the skilful movements of the earl of Huntley. James resolved to pursue this advantage by penetrating into England; and the expedition would most probably have been successful but for the appointment of an unworthy favourite to the chief command in the moment of attack, which so much disgraced the nobles, that they chose rather to surrender to the English, than submit to his orders. This disgraceful occurrence happened at Solway Moss; and produced such an effect upon the mind of the king, that it brought him to his grave, in the 31st year of his age.

Mary, his infant daughter by Mary of Guise, succeeded to the throne, and cardinal Beaton, who had been for many years prime minister, assumed the regency; in virtue of a pretended testament which he himself had forged in the name of the late king. The earl of Arran, the next heir to the crown, was however elected to the regency by the nobles; and thus new jealousies were excited. The English monarch proposed his son Edward as a match for the young queen, but this was opposed by the regent. A war was the consequence; but it was soon terminated by a peace negociated with the French king, in which Scot-
land was included. Shortly after this, cardinal Beaton fell a sacrifice to the hatred of the reformers, who were particularly incensed against him for the barbarous execution of one of his champions, named Wilhart. This event proved fatal to the Catholic religion, and to the French interest in Scotland; for though a large party in the nation still continued zealously attached to both, the loss of so bold and skilful a leader rendered their influence and exertions much less effective.

In September 1547, Henry VIII. being deceased, the protector, Someret, in pursuance of the intentions of his late master, entered Scotland with a large army, and having engaged the Scots, commanded by the regent in person, at Pinkie, near Musselburgh, gained a complete victory. Above ten thousand men fell on this day, which was fearfully felt disfavour to Scotland than the fatal one of Flodden. The victory, however, was of little advantage to the protector, whose cruel ravages only increased the aversion of the Scots to unite with England; and induced them to form a close alliance with France. The queen dowager, who, after the death of Beaton, took a considerable share in the direction of affairs, seized every opportunity to promote this object. By her advice ambassadors were sent to the court of Henry II. to offer the young queen in marriage to the dauphin; and accordingly a treaty was concluded, by which the parties were betrothed, and the Scots became bound to send Mary to receive her education in France. In vain did a few patriots remonstrate against such extravagant concessions, by which Scotland was made a French province; and Henry, from an ally, raised to be master of the kingdom.

While Mary was enjoying the pleasures of the court of France, the only scene in which she ever experienced the smiles of fortune, Scotland, first under the regency of the earl of Arran, who had been dignified with the title of duke de Châtellerault, and afterwards of the queen dowager, Mary de Guise, was rent by factions, and experienced all the direful effects of religious and feudal divisions. The whole time which had elapsed from the death of James V. had been a season of anarchy, during which parties had riven and fallen in rapid succession. To the commotions so common in every country, while the feudal system was in its vigour, and in none more than in Scotland, may be added those caused by the collision of the principles of the reformation, with the interests of a powerful hierarchy. Throughout Europe the wealth of the church was exorbitant; but in Scotland it far exceeded the just proportion, that not less than half of the national property was possessed by ecclesiastics. The mode of its disposal like- wise considerably increased their influence. Church lands being let on lease, at an easy rate, and possessed by the younger branches of the great families, many estates in all parts of the kingdom were held of the church. This extraordinary share in the national property was accompanied by a proportionable weight in the national councils. The number of temporal peers being small, and the lesser barons and representatives of boroughs seldom attending, the ecclesiastical members formed a very considerable body in the Scottish parliaments, in which they possessed all the influence that exorbitant wealth and superior talents could give.

A hierarchy established on so firm a basis, with so many pillars for its support, it was difficult to overturn. The progres of the reformation, however, gave a serious alarm to the clergy, and the sword of persecution was effectually drawn in defence of the privileges and emoluments of the Catholic church.

In spite of all these difficulties, however, the reformed religion was established in Scotland, by act of parliament, in 1560, and the exercise of religious worship, according to the rites of the Popish church, was prohibited, under the penalty of forfeiture of goods for the first, banishment for the second, and death for the third offence. "Such stragglers," says Dr. Robertson, "were men at that time to the spirit of toleration, and to the laws of humanity; and with such indecent haste did the very perfons who had just escaped the rigour of ecclesiastical tyranny proceed to imitate those examples of severity, of which they themselves had so justly complained." The new system of church government, however, was yet to be modelled; and in this business Knox, a popular preacher, of a rude but energetic eloquence, of rigid morals, and republican ferocity, had a principal share. This reformer had long resided at Geneva, and considered the system of church government established by Calvin in that city, as the most perfect model for imitation. He, therefore, recommended it to his countrymen, and succeeded in accomplishing its establishment.

When Mary returned to Scotland, she was received by her subjects with every demonstration of joy. Never did a prince ascend a throne under circumstances of greater difficulty, or conduct herself at first with more prudence. Finding the Protestant religion completely established over the whole kingdom, the very properly took into power the most eminent men of that party; and, to remove all dread of molestation from the minds of their followers, she formally declared, "that until the should take final orders concerning religion, with advice of parliament, any attempt to alter or subvert the religion which she had universally professed in the realm, should be deemed a capital crime." The division of the property of the church, and the settlement of the Protestant revenues, however, soon gave rise to animosities; and the queen, in her anxiety to please both partizans, lost the confidence of the Papists by her concessions to the Protestants, while the latter were offended at the small share of spoil which was declared to accrue to them. Difcontents broke out among the nobility; and particularly between the earls of Marr and Huntley. The latter, who was a zealous Catholic, professed the queen to reprove poverty; and finding his counsels neglected by the influence of Marr, in a proper manner to affaimage him, and therafter raised the standard of rebellion against his sovereign. The earl of Murray marched to oppose him, and after a bloody contest put his forces to rout.

The year following these transactions, Mary, who was desirous of entering into a more intimate correspondence with Elizabeth, employed Maitland to defend a personal interview with her, but the English queen declined the meeting. In 1563, the Scotch sovereign avowed her determination to contract a second marriage, an event for which the nation in general was extremely anxious, in order that the crown might be continued in the right line of its ancient posterity. Many suitors of great eminence, among the princes of Europe, professed themselves; but these were all rejected in favour of Henry Stuart, Lord Darnley, eldest son of the earl of Lenox, who had been forced to seek refuge in England in the reign of James V. The royal nuptials were celebrated in July 1565, in conformity to the rites of the church of Rome; and not content with elevating this undeserving man to her bed, the queen issued proclamations at the same time, conferring upon him the title of king of the Scots. All those who had opposed the marriage were treated with great severity; particularly the earl of Murray, who, having taken up arms, was defeated, and compelled to fly the kingdom.
With this rash step began the misfortunes of Mary. Henceforth her life was one continued scene of political folly, and personal imbecility. Inflicted by hatred to all those who manifested an aversion to Darnley, she denounced that prudent conduct which had hitherto enabled her to maintain the dignity of her crown in the midst of conflicting factions. Her Protestant counsellors were now disdained; she joined the league of Catholic princes against the reformers; and evinced her full determination to restore the Roman religion in Scotland. The effects of this new system of policy soon became visible. The time of the prorogation of parliament was shortened; and by a new proclamation, the 17th of March was fixed for its meeting. Mary resolved, without further delay, to proceed to the attendance of the malcontent nobles, and at the same time to take some measures towards the re-establishment of her favourite worship. The ruin of Murray and his party seemed now inevitable, and the danger of the reformed church imminent, when an event unexpectedly happened which saved both. This was the murder of Rizzio, the queen's favourite, by her husband, and several of the nobility, in her own presence, which roused her indignation to the highest pitch, and completely alienated her affections from Darnley, who had already disdained her by his inconstancy and licentiousness. Having been confined, however, by the conspirators, she was obliged to dissemble, in order to detach the king from their party, a project in which she completely succeeded, and thus was enabled to regain her liberty. Murray and the exiled nobles were immediately received into favour; and Morton, and the rest of the murderers, were compelled to seek safety in England.

The charm, which had at first attached the queen to Darnley, and held them in a happy union, was now entirely dissipated; and love no longer covering his follies and his vices with its friendly veil, they appeared to Mary in their full dimensions and deformity. Though the king published a proclamation disclaiming all knowledge of the conspiracy against Rizzio, the queen was fully convinced that he was not only accessory to the contrivance, but to the commission of that odious crime. That very power, which, with liberal and uninfamous fondness, she had conferred upon him, he had employed to infilt her authority, to limit her prerogative, and to endanger her person. Such an outrage it was impossible any woman could bear or forgive. Cold civilities, secret distress, frequent quarrels, succeeded to their former transports of affection and confidence. About this time a new favourite grew into credit with the queen, and soon gained an ascendency over her heart, which encouraged him to form designs which proved fatal to himself and to Mary. This was James Hepburn, earl of Bothwell, the head of one of the most ancient and powerful families in the kingdom. When the conspirators against Rizzio obtained her in custody, he became the chief instrument in recovering her liberty, and served her with so much fidelity and success, as made the deepest impression upon her mind. Her gratitude loaded him with marks of her bounty; she raised him to offices of dignity and trust; and invested him with importance without his advice.

The hour of the queen's delivery now approached; and she was advised, for the sake of perfect security, to take up her residence in the castle of Edinburgh, where she was accordingly delivered of her only son, James, whose birth was happy for the whole island, and unfortunate only for her. His accession to the throne of England, united the two divided kingdoms in one mighty monarchy, and established the power of Great Britain on a firm foundation; while she, torn early from her son by the cruelty of her fate, was never allowed to indulge those tender passions, nor to taste those joys, which fill the heart of a mother.

The queen, when recovered, did not evince any change of sentiment towards her husband. On the contrary, the breach between them became every day wider, notwithstanding the attempts of the French ambassador to effect a reconciliation. Her attachment moreover to Bothwell increased, in proportion as her love for Darnley declined. At length the latter was murdered by the explosion of some barrels of gunpowder, placed under the house he had been induced to retire in at Edinburgh, and Bothwell was accused of and prosecuted for the murder, but was acquitted on a trial by his peers. Of his guilt, however, not the slightest doubt can be entertained; and it is much to be feared that Mary herself was accessory to the crime.

Bothwell now redoubled his affections to fix the affections of the queen, and having succeeded in that object to his utmost will, he carried her to the castle of Dunbar, where she remained many days before their nuptials, when she removed to Holyrood House, and was soon afterwards united to Bothwell, whom she created duke of Orkney. This step, the most unjustifiable of all her actions, was the prelude to her ruin. The nobles almost immediately conferred against her and Bothwell, who was obliged to seek refuge in England, while she herself fell into the hands of her unenlightened subjects. By them she was conducted first to Edinburgh, and subsequently to Lochleven castle. The confederate leaders assumed the title of lords of the secret council, and arrogated to themselves the whole regal authority. Deliberations were held to fix the destiny of the nation, and to determine respecting the person of the queen. The result was, that she was compelled to resign the crown in favour of her son, who was instantly proclaimed, and the earl of Murray was invested with the dignity of regent.

Matters being thus arranged, the first act of the regent was to call a parliament, in which all the measures of the confederates were confirmed. But notwithstanding this, Mary still had many friends who were ready to support her cause, if she could regain her liberty. Apprized of these favourable sentiments, she used every effort to effect her escape, and at length succeeded in her object, in a manner so laudable as to excite the admiration which could not be expected from her enemies. By the influence of her charms, the captivated young Douglas, the brother of the owner of the castle, and prevailed upon him to join in a plot for her liberation. Accordingly, on the appointed night, having stolen the keys from his brother's room, he allowed Mary to pass out, and then locking the doors again, threw the keys into the lake. The queen entered a boat prepared for her, and landed safely on the shore, where she was received by lord Seaton, sir James Hamilton, and some other of her friends, who had been apprized of the plot. Instantly mounting on horseback she fled to Hamilton, where she was joined by a number of the nobility, and in a few days found herself surrounded by a formidable army. In this critical situation, the genius and prudence of the regent were eminently displayed. While he annulled the queen for some days by negotiations, he employed himself with the utmost industry in drawing together his adherents from different parts of the kingdom. As soon as he was in a condition to take the field, he broke off the negotiation, and determined to hazard a battle. Mary, whose interest it was to delay the decision of her fate, imprudently favoured his wishes. She attacked his army in an advantageous position at Langside, and being completely defeated, fled to England, and threw herself upon the generosity of queen Elizabeth, by whom she was detained a prisoner for
the period of nearly twenty years, and was at last tried and executed upon an accusation of high treason. See Mary.

In the meantime the regent Murray, by his vigorous administration, soon restored Scotland to tranquility; and continued to govern without any serious molestation till his death in 1573, by the hand of Hamilton of Bothwellhaugh. He was succeeded in his high office by the earl of Lenox, during whose rule, and that of his successors Marr and Morton, the kingdom was distracted by civil war. "Fellow citizens, friends, brothers, took different sides, and ranged themselves under the standards of the contending factions. In every county, and almo in every town and village, king's men and queen's men were names of distinction. Political hatred destroyed all natural ties, and extinguished the reciprocal good will and confidence which held mankind together in society. Religious zeal mingled itself with these civil distinctions, and contributed not a little to heighten and inflame them."

Morton, the last regent, during the minority of James, having excited the enmity of several of the nobility, was accused of being accessory to the murder of Darnley, and suffered for that crime in 1581, though the proofs of his guilt were far from being satisfactory. After this event, James himself began to exercise the sovereign authority; but his love for favouritism proved prejudicial to his own peace and that of his kingdom, by fomenting jealousy among his nobles. One of these favourites, the earl of Arran, conducted himself so arrogant and tyrannical a manner, that a confederacy was formed against him; and the king was forced to deprive him of all his offices and honours, and to declare him an enemy to the country.

James having been bred in the principles of the Protestant faith, exerted himself on every occasion to secure the reformed church from the danger of being overthrown by the Catholic party, which was fynonymous with the queen's party, and continued to be very formidable so long as she lived. When his mother was put to death by queen Elizabeth, however, he renounced strongly against her conduct, and even declared war; but that wily prince found mean to soothe his anger, and regain his friendship. During the whole of his reign, James was constantly in danger of his life from the plots of the Popish lords, towards whom he flewed more lenity than was probably politic or prudent. On one occasion his person was feized by Bothwell, but he happily contrived to escape from his power, before any of the ulterior objects of that bold measure could be effected. Several attempts to murder him were likewise made, by various persons; but the most dangerous, though unsuccessful, conspiracy formed against his life, was that usually denominated the Gowrie conspiracy, from the title of the principal actor, John Ruthven, earl of Gowrie. From the mystery in which all its circumstances are involved, it has greatly excited the attention of historians; some even questioning the existence of any plot, and maintaining that the king murdered the Ruthvens without any reasonable cause. This opinion, however, is justly confided by Dr. Robertson as extremely improbable; though it must be confessed that the conduct of James, and the impression on the public mind against him at the time, cast an air of great suspicion over the whole transaction.

From this period no event of material interest in the history of Scotland occurred till the year 1603, when the death of queen Elizabeth opened the way for the accession of James to the throne of England, and laid the basis of that more intimate union, which has since consolidated the power and resources, and raised to an unparalleled height the happiness, prosperity, and glory of our island. The annals of the two kingdoms are henceforth so much identified, that it is scarcely possible to treat them separately. The reader is, therefore, referred for the continuation of the history of Scotland to the article England. He will also find some details of portions of the subject under the words Union, Stuart, Prince Charles, and others, designating leading events or characters.

General Aspects of the Country, the Soil, and Climate.—The most prominent features in the general aspect of Scotland are its barren hills and mountains, and the numerous and extensive lakes which fill the intervening valleys. In some districts the hills are covered with herbage, but in general they exhibit only heath vegetating above peat, rock, or gravel; hence, whether the eye ascends the mountains, or glances over the vales, the scenery is presented to the view, though often grand and picturesque, is seldom naturally rich. On the former, the signs of fertility are always apparent; and as the soil of the latter is usually mixed with the substanices composing the hills, no high degree of fertility can be expected. These remarks apply to almost every part of the Highlands, which comprehend about three-fifths of the whole extent of Scotland. South of the Forth, however, and even in a few of the eastern counties farther to the northward, the character of the scenery is more improved, and the soil, though extremely various, is frequently as fertile as in any district of England. As to the climate of this kingdom, it is such as a knowledge of its latitude, and of its peculiar situation with regard to the Northern and Atlantic oceans, would point it out to be. Both on the eastern and western coasts, but particularly on the latter, rains are extremely prevalent throughout the whole year. Snow in general lies only for a short time, even in the central districts; for though it often falls in considerable quantities, it is seldom attended, as in some more southern counties, by intense and long continued frosts. The lowest average heat is 41°.11 of Fahrenheit, and the highest 50°.326; so that the annual average temperature of the whole kingdom may be computed to be from 45° to 47° of the same scale. It is remarkable that, in some of the vales of Moray, the influence of the sun's rays is so allayed by circumstances, that corn ripens there as soon as in Yorkshire or Northumberland.

Rivers.—Scotland abounds with streams of various magnitude, most of which fall into the Northern or German ocean. The principal of them are the Tweed, Forth, and Tay, on the east coast; and the Clyde on the west coast. Tweed is a beautiful and pastoral river, which discharges its waters into the sea at Berwick. It is noted for its salmon fisheries, and for the circumstance of its forming the boundary for several miles between England and Scotland. The Forth and Tay both form large estuaries, called the Firths of Forth and Tay, which serve important purposes in commerce. On the former are situated the town and port of Leith, and on the latter the towns of Dundee and Perth. The salmon fisheries of the Tay are the most valuable in Great Britain, and afford a constant supply to the markets of London and Edinburgh. But Clyde claims a pre-eminence over all these rivers in commercial utility, and perhaps also in picturesque beauty. Taking its rise from a hill in Tweeddale, it flows first in a northerly, and afterwards in a westerly direction, exhibiting in its progress much interesting scenery. On its banks are situated the towns of Lanark, Hamilton, Glasgow, Rutherglen, Dumfartoon, Port-Glasgow, and Greenock.

The other rivers of Scotland, which deserve notice, are the Annan and Nith in Dumfriesshire, the Eden in Fifeshire, the Dee and Don in Aberdeenshire, the Spey in Banffshire,
SCOTLAND.

Banffshire, the Nefs and Beany, which form the Moray Frith, and the Grady and Conan, which form the Frith of Cromarty.

Lakes and Lochs.—The numerous and beautiful lakes interposed throughout Scotland, and especially throughout its mountainous tracts, constitute a very striking and interesting feature in its scenery. The chief in extent and beauty is that of Lomond, fringed with islets, and adorned with shores of the greatest diversity. Extremes of this lake are those of Kettering, Chroin, Achray, Vanachor, and Luihnag; all of them distinguished by singular and picturesque scenes. The lake of Menteith is also in this vicinity. In Galloway are many fine lakes, on the banks of one of which stands the village of New Galloway. Lochleven, in Fifeshire, derives fame at once from its beauty, and from its historical interest, as the residence of queen Mary, when a prisoner in the hands of the confederate nobles. The lakes formed by the Tay are both numerous and extensive; the principal of them are Rannock, Lyddock, Ernich, and Loch Tay. The last, in particular, is a grand and beautiful expanse of water, of such length as to resemble a noble river. Loch Nef, in Inverness-shire, is equally noted for its extent and the charms of its scenery. Its usual depth is from 60 to 135 fathoms; and hence it is to be explained the phenomenon of its never freezing, even in the coldest winters. This lake forms part of the chain of lakes which intersect the kingdom, from the Moray Frith to the Atlantic ocean, which we trust, are defined shortly to become of high importance in forwarding the commercial prosperity of the kingdom. The other chief lakes of Scotland are Loch Lom, Loch Naver, and Loch Shin, in Sutherland and Caithness; Loch Fannich, in Ross-shire; the Lochy and Laggen, in Inverness-shire; and Loch Awe, in Argyllshire.

Friths and Inlets of the Sea.—Scotland is much indented with arms of the sea, which enter deep into the land. This indentation is highly beneficial; it facilitates commerce, as each of these branches so far serves the purposes of a canal; it promotes the fisheries, as it brings them more within reach; and it renders the climate more temperate, from the influence of sea-breazes. Even the shortest description of these friths and inlets separately would extend this article beyond its prescribed limits, we shall content ourselves with the bare mention of their names. Those on the eastern coast, beginning from the south, are the Frith of Forth, the Frith of Tay, the Moray Frith, the Frith of Beauty, Cromarty Frith, the Frith of Dornach, Thurflo and Dunnet bays, Kyle of Tongue, Loch Eribol, and the bay of Durness. Those on the west coast, beginning from the north, are Loch Inchard, Loch Laxford, Loch Affint, Loch Enard, Loch Broom, Loch Ew, Garloch, Loch Torridon, Loch Carron, Lochalsh, Loch Duich, Loch Hourn, Loch Nevis, Loch Aylort, Loch Moydart, Loch Sunart, Linhe Loch, Lochichel, Loch Leven, Loch Crenan, Loch Etive, Loch Melfort, Craigint. Loch Swam, Loch Killilport, Loch Tarbat, the Frith of Clyde, Loch Fyne, Loch Long, Loch Gair, Loch Streven, Loch Ryan, the bay of Glenhace, Wigtom bay, Kircudbright bay, bay of Nith, and the Solway Frith. Most of the above rivers, lakes, friths, and inlets of the sea, are noticed under their respective names, or under those of the counties to which they more immediately belong.

Mountains.—The mountains of Scotland, as already mentioned, occupy a large proportion of its surface, and constitute a prominent and distinctive feature in its geographical character. The principal chains are the Grampian hills, the Pentland hills, and the Lammar Muir. The first extends almost entirely across the kingdom, from the vicinity of Aberdeen to the Cowal in Argyllshire. In their western range, they form the southern boundary of the Highlands; and are celebrated in history for the stand made upon their altitudes, by the Caledonians under Galgacus, against the Roman general Agricola. The second chain commences near Edinburgh, and running southwards through Lothian, joins Tweeddale hills; and the third, beginning near the eastern coast of Berwickshire, stretches to the westward through the Merse. In the province of Galloway is a fourth extensive assemblage of hills, which do not, however, form an uniform chain. With respect to the other mountains of Scotland, they do not admit of arrangement into distinct groups; and, therefore, it will be sufficient to notice some of the more remarkable among them for size and elevation. Ben Nevis is the highest mountain in Britain, its summit being 4350 feet above the level of the sea. On its north-east side it presents a most prodigious precipice, nearly perpendicular, which is said to be 1700 feet in height. The precipice on this hill is truly sublime, and extends on all sides a distance of 80 miles. The next mountain in point of elevation is Cairngorm, or the Blue mountain, which is constantly covered with snow, and is remarkable for quartz of different colours, well known to lapidaries under the name of Cairngorms. The other chief mountains in this district are those of Braemaron, Scarich, and Ben Aun. To the Grampian ridge belong Ben Lomond, 3262 feet high; Ben Ledhi, 3309; Ben More, 3503; Ben Lawres, 4015; Shihallion, 3564; and Ben Verliech, 3300; besides some scarcely less important elevations on the east. Mount Batoock, in Kincardineshire, is 3465 feet high; and Ben Cruachan, a solitary hill in Argyllshire, 3300. In the more northern division of the Highlands, the mountains are yet more numerous, but not so memorable. The chief of them are Ben Nevis, Ben Chat, Ben Chalker, Ben Golich, Ben Folklaig, Ben Nore, and the hills of Cunnak, all in Ross-shire; and BenOrmord, Ben Cliberg, Ben Grim, the Paps of Caithness, Ben Hop, and Ben Lugal, in Caithness and Sutherland. Along the whole of the western coast, the scenery is bold and precipitous in its character. One part of it, extending from Loch Richard 24 miles to the south, presents a most singular appearance, as if mountains had been broken in pieces, and small lakes interposed among the fragments.

Mineral Products.—The mineral products of Scotland are numerous, and are, in many instances, supplied in such abundance, as to form important objects of traffic. Gold was formerly procured in the lands of Elvan, a rivulet which joins the Clyde; and a place still exists, called Gold-foun, where the Germans used to wash the sands; but scarcely any has been found recently. The silver discovered in Scotland has hitherto been of little account; the chief mine was that at Alva, which has latterly only afforded cobalt. Nor can Scotland boast of copper, though a small quantity was found in the Ochils, near Alva; and it is said that the islands of Zetland offer some indications of that metal. It has also been found at Cowden, in Galloway; at Curry, in Lothian; at Oldswich, in Caithness; and Kippern, in Rossshire. The lead-mines in the south of Lanarkshire have long been known. Those of Wanlock head are in the immediate neighbourhood, but in the county of Dumfries, and belong to another proprietor. These mines yield yearly above 2000 tons. The Swanmore vein, Leadhills, has been worked for sixty years, and produced vast wealth. Some fine veins of lead have also been found in the western Highlands, particularly in Arran. Iron is found in various parts of Scotland; the Carron ore is the most
molt known, which Mr. Kirkman describes as being an argillaceous iron-oxide of a blueish-grey, internally of a dark ochre-yellow. It is found in flatly mafles, and in nodules, in an adjacent coal-nape, of which it sometimes forms the roof. At the Carron-works this oxide is often melted with the red greasy iron ore from Utterton, in Lancashire, which imparts easier fusion, and superior value. Calamine and zinc are also found at Wanlock-head; and it is said that plumbago and antimony may be traced in the Highlands. Coal has been worked for a succession of ages. Popen Pins II., in his description of Europe, written about 1450, maintains that he beheld, with wonder, black stones given as alms to the poor of Scotland. But the use of this mineral may be traced to the twelfth century. The earliest account given of the Scottish coal is contained in a book published by one George Sinclair, who calls himself professor of philosophy at Glasgow, but his name cannot be traced in the university lists. He explains with some exactness the manner of working coal, and mentions the subterraneous walls of which intersect the frata, particularly a remarkable one, visible from the river Tyne, where it forms a cave, and passing by Pratton-Pans to the shore of Fife. Mr. Williams has recently given his observations on this subject with much practical skill. The Lothians, and Fifeshire particularly, abound with this useful mineral, which also extends into Ayrshire; and near Irvine is found a curious variety, called ribbon coal. A fingular coal, in veins of mineral, has been found at Castle-Leod, in the eastern division of Ross-shire. Among the least important minerals of Scotland, is the new earth found at Strontian, in the district of Sunart, and parish of Arnamurchan, Argyllshire, which is now introduced into numerous systems of mineralogy and chemistry. Den Nevis affords beautiful granites. Fine flinty marble is found in Ayrshire, and at Blair Gowrie, in Perthshire. A black marble, fretted with white, like face-work, occurs near Fort William; dark brown with white at Cambuslang, Clydeford. Jasper is found in various parts; Arthur's seat offers a curious variety; and on the western shore of Incomkill, are many curious pebbles of various descriptions. Fuller's-earth is found near Campbeltown, in Caintre; and it is supposed that there must be a vast mass of slate, equal to that of Muckgowy, in the mountains which give rise to the river Findon, as large pebbles of it are sometimes found in that stream.

Natural Curiosities. — Scotland, like other mountainous countries, abounds with singular scenes and natural curiosities. The caves on the shore near Colvend, in Galway, are well worthy of notice; and the beautiful falls of the Clyde, near Lanark, have deservedly excited much attention. On the east of this part of Scotland, are the pastoral vales of the Tweed and Teviot, celebrated in song; the deep pafs of the Peaths; and the romantic rock of Bals, the haunt of the folan goose. The basaltic columns of Arthur's seat, near Edinburgh, deserve inspection. On the northern shore of the Forth, near Dyfart, a coal-mine has, for ages, been on fire, probably from decomposed pyrites, and has supplied Buchanan with a curious description. The beauties of Loch Lomond have been often defcribed; but the trophes, or singular hills around lake Kettering, form a new acquisition to the traveller. The hills of Kinnow, near Perth, constitute a great curiosity, prefenting a mass of uncommon minerals. The numerous lakes and mountains need not be again mentioned. Many of the rocks off the coast of Aberdeen come allusive fingular forms of arches, pillars, &c.; and the space from Trouphead to Portfoy abounds in uncommon rocks, and singular marine productions. The caves of Nigg, in Ross-shire, are worth visiting, and the more northern fhores prefent innumerabfe wild scenes of savage nature. Near Lathron, in Caithness, is a large cave, into which the inhabitants fail to kill seals. Nob Head presents a singular quarry of slate, marked with various metallic figures. The isles Stroma, near the northern shore, preferve dead bodies for a long time without corruption. Near Torg is the cave Fagraill, about fifty feet high and twenty wide, variegated with a thouland colours, which are lost in each other with a delicacy and softnefs that no art can imitate. On the exit of Durness is the cave of Smo, within which is the resemblance of a gate, succeeded by a small lake of fresh water, containing trout; the extent of this subterraneous lake has never been explored. The singularity of the coast of Edrachills, south of Loch Inchard, may likewife be mentioned as a natural curiosity, as also the grand cataraft of Kinem river, and the cave of Gandeman, near A'ffy Point. The cascade of Glanna, in the heights of Glen Echaig, is truly sublime, amidst the confant darknefs of hills and woods. Ben Nevis will, of coucre, attract notice from its singular form and elevation. According to Mr. Williams, it consists of one solid mafs of red granite, which he traced at the base for four miles along the coure of a rivulet on the east; the height of this mafs he computes at 3000 feet, and above it are stratiied rocks, the nature of which he does not explain, but he fays that thofe on the summit are fo hard and tough, that wrought iron is inferior to them in these qualities. The tremendous precipice on the north-east fide exhibits almost an entire fection of the mountain. In Argylshire the marine cataraft of Loch Etif, the beautiful lake of Awe, and the environs of Inverary, prefent the chief objects of curiosity.

Sketch of the Agriculture. — Scotland, with respect to agriculture, exhibits great variations, from caules partly of a moral, but chiefly of a physical nature. To give his readers just ideas on this subject, Sir John Sinclair, in his "General Report," has divided the country into nine districts, each distinguished by some peculiarities of surface, or relative circumstances, from the reft. The first district includes the counties of Roxburgh, Berwick, and the three Lothians, and may be justly termed, by way of eminence, the agricultural district, as the art of husbandry is carried on there in as great perfection as in any country in Europe. The proportion of land in cultivation is very considerable, and its farmers are, in general, remarkable for their intelligence, industry, and capital. In this district is situated the metropolis of Scotland, which unites to signal advantages of situation, a degree of art and elegance in its buildings, unknown in any other town in Great Britain. As it is the seat of the courts of law, the public offices, and a celebrated university, the population within its bounds is much greater than its agriculture or commerce would otherwise require. The several counties which compose this district may be thus discriminated. Roxburghshire, the most fouterly, has a great extent of hills of confiderable elevation, and only adapted for the paffuring of sheep; but it also includes the rich vale of Teviot, which is one of the most improved tracts in the kingdom. Berwickshire, though a large share of its surface is likewise best fitted for paffure, contains in the Merse, soil at once fertile and well cultivated. East Lothian, throughout the greater part of its extent, is a rich and highly improved plain, diversified by a few gentle eminences; and yields to no county in Great Britain the palm of superiority in agriculture. Mid-Lothian, though inferior in soil to East Lothian, nevertheless raises excellent corn and green crops, and likewise derives wealth from horticulture in the vicinity of Edinburgh. West Lothian, besides being noted for the carefulness of its agriculture, in the more cultivated parts, is ornamented with many extensive plantations, while
its peculiar situation on the southern bank of the Forth adds much to the beauty of the scenery, and to the advantages which the country possesses within itself.

The second district includes the counties of Peebles, or Tweedale, Selkirk, Dumfries, Kirkcudbright, and Wigton. Here are the highest mountains south of the Forth; and from the greatest proportion of hills, and the small extent of arable land, more of the surface is appropriated to the feeding of live flock than to the growth of corn. Yet the vales, particularly in Dumfriesshire, are of considerable extent and fertility, and exhibit much diversity of appearance. The green hills of Tweedale, and the intervening vales, are prolific of corn. Only a small proportion of the territory, however, is arable, and late harvests occasionally blast the prospects of the farmer. In the county of Selkirk, formerly called the Forreit, a hill less proportion of the land is cultivated; but new plantations begin to rise, and will in time supply the place of those natural woods, with which, several centuries ago, this county abounded. The hills, both in this county and in that of Peebles, are covered by numerous flocks of sheep, partly of the Tweedale, but chiefly by the Cheviot race. Great numbers of cattle also are found in these districts. In Galloway, its excellent breed of cattle, and hardy race of sheep, are supported much better than formerly; and not only oats and barley, but wheat of good quality are raised in every part of the arable tracts. The valley of the southern Dee, in Kirkcudbright, has likewise been much improved; and though on the banks of that river there are neither coal-pits nor lime-quantities, yet imported coal forms the chief article of fuel, and imported lime the principal manure.

The third district is washed by the Atlantic ocean, and by means of a navigable canal communicates with the German sea. It includes the counties of Ayr, Renfrew, Lanark, and Dunbarton. Notwithstanding the humidity of the climate, from its exposure to the sea, and the extent and elevation of its hills, agriculture is much attended to, and in many parts is carried on with great success, as the exertions of the farmers are stimulated by commerce and manufactures. Still, however, this district is more adapted to the rearing or fattening of live-flock, than to the reaping of corn; and the best breeds of horses and of dairy cows are to be found in it. From the concurring causes of commerce, manufactures, and minerals, agriculture has flourished in an ungenial climate; and nearly one-half, or, more accurately, seven-fifteenths of the whole surface are under cultivation. With only one-thirteenth part of the extent, nearly one-fourth part of the population of Scotland is included in this division.

In the fourth district are included the counties of Fife, Kinross, Clackmannan, Stirling, Perth, and Forfar or Angus. This district exhibits every variety of soil and surface, from the level and rich carse of Stirling, Falkirk, and Gowrie, and the great valleys of Strathmore, Athol, and Kethnfs, to the lofty Grampians, which shelter a considerable proportion of the division from the northern blasts. In the rich carse, and along the cliffs and sea-coast, it produces the best wheat, beans, barley, and broad clover. And in some of the inland districts are raised excellent crops of turnips, bear, and oats. Its live-flock in general is of an excellent description. The towns of Dundee, Perth, Alloa, Dunfermline, Stirling, St. Andrews, Clackmannan, Kinross, Forfar, Montrose, Brechin, and a number of inferior villages, contain two-fifths of its whole population. In this extensive district, Fifeshire is distinguished by its great variety of productions, and by its fisheries, its flax and linen manufactures, its coal-mines, lime-works, and iron-works, by its improved agriculture, and its breeds of cattle and horses. The small county of Kinrofs, ornamented by its lake, and abounding in coal and lime-stone, is considerably elevated above the level of the sea. Formerly it was not attractive to a stranger, but its aspect is now much improved. Clackmannan, of still more limited extent, but of greater fertility, is distinguished by a correct cultivation of the soil, and by the abundance of lime and coal. The half of its population resides in towns of very moderate extent. The county of Stirling includes every variety of soil, from the rich carse on the southerly bank of the Forth, to the barren rocks of Ben Lomond. In the parishes of Enrick and Strathblane, there are rich fields, cultivated by intelligent and enterprising farmers; and the scenery is much diversified in all parts of the country. Two very extensive counties of Perth is equally remarkable for the most fertile, and the moat barren soils, each of them, and exhibits the two extremes of correct and defective agriculture. In the carse of Gowrie, and the valley of Strathearn, there are many opulent and enterprising farmers, who cultivate successfully the moat fertile soil in the kingdom. In several of the smaller vales an improved cultivation is also general. But in the more remote highland glens, where the land is naturally good, improvements in agriculture are little known and less practised. In Forfarshire, along the sea-coast, and in the rich valley of Strathmores, the farmers have been long distinguished for their exertions; and in the inland parts of the county, shell-marsh, obtained in abundance from the fresh-water lakes, has contributed very much to the improvement of the soil.

Scotlan.

The fifth district includes the counties of Kincardine, Aberdeen, Banff, Moray, and Nairn, and contains a greater extent of sea-coast than any of the preceding divisions. Yet on the south-west, where it extends to the middle of the island, it is extremely mountainous; the Grampians stretching from its boundary with Perthshire nearly to the sea at Aberdeen. By far the greatest part of the arable land is either in the maritime or midland parts, there being very little near the mountains. It is remarkable, that the maritime parts of Moray enjoy perhaps the best climate in Scotland, and that for many centuries wheat has been cultivated there to great advantage. Wheat is also raised successfully in the maritime parts of Kincardine and Banffshire, and its cultivation is spreading rapidly in Aberdeen. The turnip husbandry and artificial gristles are to be met with over the principal part of this division in very great perfection. But the most striking feature in its cultivation is the great expense at which barren land is improved, by trenching with the spade and mattock, which has been known to exceed a hundred pounds for a single acre. This district in general raises food for the support of its inhabitants, and in good seasons exports a considerable quantity of grain; but it is chiefly distinguished for the rearing of excellent cattle, of which it feeds yearly great numbers to England. Owing to the large proportion covered by mountains, only four eleventh parts of this district are yet under cultivation. It is, however, much adorned by plantations, particularly near the hovels of its proprietors, and its natural woods in Braemar are extensive and valuable. Kincardinshire, except that part of it which lies in Mar, is sheltered on the north by the Grampian mountains. This small county was early induced to attend to the cultivation of its soil, by the examples of the late Robert Barclay, esq. of Ury, and a few others of its landed proprietors. Aberdeenshire, which fifty years ago brought most of its work oxen from Fife and the Lothians, has now taken the lead in the rearing of black cattle, and cultivates for that purpose fowm grass and turnips in great perfection.

Wheat
Wheat and beans also are raised successfully in the heavy loams of Formater, and on the still heavier clays of Buchan. Banffshire owed much to a distinguished character, the earl of Findlater and Seafield, who introduced an improved system of cultivation in that county, and encouraged his farmers to imitate his example. Not only near the sea-coast of the Bogue and the Erse, where that improved system began, but in the more inland parts, a spirit of improvement has now become general, and has greatly altered the face of the country. Though nature has done much for Moray, yet the culture of turnips and of fowl griddles was not, till within the last thirty years, so general, as in the favour ed counties; but of late, both these and corn, with the rearing of live flock, have been attended to with ardour and perseverance.

In the sixth district are included the two extensive counties of Argyle and Inverness, comprehending nearly one-fifth part of the whole surface of Scotland. About two-nineteenth parts of this district are cultivated, and productive. Near Inverness, at Campbeltown, in Argyllshire, and in some other spots, wheat and turnips are successfully cultivated, but in general the country is unfit for tillage, except on a small scale; its grazings, however, are extensive, and well adapted for the rearing of live-flock. It likewise contains a great extent of plantations, and the remnant of the Cocillmore, or great forest of Scotland. The black cattle of this district are in high estimation as excellent feeders. The hardy breed of Tweedale sheep, and in some instances those of Cheviot, occupy the hills. This division extends across the island; and the Caledonian canal is now carrying on directly through it, from the German sea to the Atlantic ocean, which it is to be hoped will carry industry and wealth into this remote district, and furnish the means of facilitating and enlarging the commerce of the other parts of the kingdom.

The seventh district includes the counties of Cromarty, Ross, Sutherland, and Caithness. It is in some respects superior to the former, though more northerly. East Ross, with a part of Cromarty, contains a considerable proportion of excellent soil; and both the wheat and turnip husbandry are carried on successfully. The eastern coast of Sutherland, and the plains of Caithness, are also good corn counties. West Ross, and by far the greatest part of Sutherland, of Cromarty, and of that portion of Caithness which bounds with Sutherland, are rugged and unproductive. Not a tenth part of this district is capable of being cultivated, and only a twelfth part of the people resides in towns or villages; yet, by the introduction of sheep-farming, by encouraging manufactures, and, above all, by the extensive fisheries of herring and cod, now successfully established along the coast of Caithness; this district must soon greatly increase in value, and the inhabitants become richer and happier. The breeds of cattle have been much improved of late years; the Tweedale breed of sheep is now spreading over the western parts of this district; and there are already about 4000 of the Cheviot breed in various parts of it, more especially in Sutherland and Caithness. The Merino breed, and croffes of them, have been successfully introduced into Ross-shire, and other parts of this district. East Ross and Cromarty are ornamented with the seats of the proprietors, and extensive plantations. Wood also thrives in Sutherland, and in the more hilly parts of Caithness; but in the plains of Caithness, and near the sea-coast, it cannot be raised to advantage, from the nature of the subsoil, in general a gritty close gravel of little depth, incumbent on a horizontal flaggy rock, which keeps the water near the surface.

The islands which are included in the eighth district, were formerly denominated Ebude, but are now better known by the name of the Hebrides, or the Western Islands. They contain about one-tenth part of the total extent of Scotland, with about one-eightheenth part of its population. Of the whole surface, nearly one-seventeenth part is under culture. Wheat has been raised in some of the islands, more especially Butie, Ilay, and Coll; and turnips have also been cultivated successfully in Skye, and some of the smaller islands. In all these islands the breed of black cattle is excellent, though in general small. The fisheries and help manufacture are valuable; and by proper attention to them, these islands may furnish a great addition both to the wealth and strength of the empire.

In the ninth or east district are the northern islands of Orkney, and Zetland or Shetland. The former contain about 440, and the latter nearly 880 square miles, and form one county. Only about one-seventeenth part of the whole surface of these islands is in cultivation. Wheat and turnips have both been tried, and not without success. The pure Merino breed of sheep has been introduced into Orkney recently, and a zeal for improvement has lately appeared in these islands, which may be attended with the best effects; for they enjoy a very temperate climate, though in a high northern latitude. The islands being situated low, snow seldom lies many days, and ice is never more than two or three inches thick.

Forset and Woods.—That Scotland was anciently clothed with extensive and luxuriant forests, is abundantly proved by the concurring evidence of tradition, of history, and of the actual remains of their spoils. Innumerable places, where scarcely a tree is now to be seen, derive their names from the circumstance of their having been covered with wood, or from the particular kinds of timber with which they abounded; as Woodhead, Woodside, Aikhenhead, Asbyhurst. The great forest of Selkirk, of which scarcely a trace remains, existed, as appears from ancient documents, as late as the 12th or 13th century; extending over the upper parts of Ayrshire, Lanarkshire, and Peeblesshire. The forest of Pailley seems to have communicated with that of Selkirk, extending, without much interruption, through the higher parts of Renfrewshire, the marches of Ayr and Lanarkshire by Loudon-hill, to the shores of Galloway. The Caledonian forest, of which the Roman historians speak, appears to have extended in a southerly direction to the English borders; and in a western, from the boundary of Stirlingshire, by Falkirk and Stirling, (including the higher grounds of St. Ninian, once the royal forest of Dunaff,) as far as Gartmore in Perthshire, covering the great moors, called Moors Flanders, through a tract of about twenty miles. Of this no trace remains, except Callendar Wood, and Tor Wood, unless we trace it, as we may, in the deep moors, from six to nine feet under the surface, incumbent on the clay, its original soil. Many other instances of ancient forests, long since lost, might be given from authentic records. In all our moors, from 20 feet above the level of the sea, to 500, and even 1000 feet above that elevation, the remains of trees of a much larger size than any which now exist in a growing state, are found in abundance. In the northern moors these are principally of the pine tribe. To the south of the Forth it does not appear that the fir ever grew spontaneously. The oak is, in that district, to be found every where imbedded in the moors. In Dalferr parish, in Lanarkshire, an oak was lately dug up 65 feet long, which is so straight, and so equal in girth, that it is difficult to determine which is its root end. In Moors Flanders, innumerable trees of the
the same kind occur. Even the Hebrides, exposed as they are to the sea, present venerable remains of ancient forests. A yew tree, which grew on a ledge cliff in the Storny island of Bernera, when cut into logs, loaded a large boat. The island has annually been filled with woods. Though Lewis, adds Dr. Walker, is now entirely desolate of timber, there are large trunks of alder, birch, and especially of Scots fir, found in its extensive moorlands. Of the destruction of these magnificent forests, we are furnished with a satisfactory account both by history and observation. Herodian and Dion Cassius inform us, that the emperor Severus, about A.D. 207, employed the Roman legions, with the auxiliary troops, and such of the natives as were under his control, in cutting down the forests of Scotland, an undertaking, in which (the historian tells us) he lost no less than 50,000 men. The forest that once covered Moors Flanders, to the west of Stirling, appears evidently to have been thus cut down; the prostrate trees lie under the mists in every direction, which demonstrate that they have not been overthrown by storms, which would have laid them down uniformly. At a later period, John, duke of Lancaster, set 24,000 axes to work at a time to cut down all the woods of Scotland. In the northern parts of Scotland, the Danes cut down and burnt many woods, as did King Robert Bruce in his expedition against Cumyn. Mr. Graham of Gartmore has in his possession an original document, relating to the woods of Aberfoyle, now the property of the Duke of Montrose, formerly of the earl of Menteith and Airth. It is an order from General Monk to cut down the woods of Milton and Gles, on account of the shelters they afforded to the rebels.

Government.—The political constitution of Scotland, since the Union, has been blended with that of England. Previous to that event, the parliament of Scotland was, like England, composed of peers and representatives of counties and burghs, with this distinction, that they sat in one house. That wise prince, James I. of Scotland, as has been mentioned, attempted to establish a house of commons, in imitation of that of England, but his subjects maintained the most firm resistance to that enlightened measure. The most distinguishing feature of the ancient government is the general assembly. The high courts of justice, and particularly the court of sessions, may be classed in the next place. The lords of council and session are fourteen in number, besides a president; and on their appointment assume a title, generally derived from the name of an estate, by which they are addressed, as if peers by creation. The only appeal from this court is to the house of lords. It has long been a subject of regret, that the causes were not determined by jury, as in England. But this ground of complaint has been very recently removed, and three judges have been appointed to prefix in a court where the civil suits are to be determined by a majority of jurors. These judges have been named lords commissioners. The court of judicature consists of five judges, all lords of seions, with a president, styled the lord justice clerk, as representing the lord's justice general. This is the supreme court of all criminal cases of importance, which are determined by the majority of a jury, and not by their unanimity, as in England. The court of exchequer consists of a lord chief baron, and four barons; in the court of admiralty there is only one judge.

The law of Scotland differs essentially from that of England, being founded, in a great degree, upon the civil law. It partly consists of statute law, but many of the ancient enactments never having been enforced, reference is made to the decisions of the court of seison, which are carefully preserved and published, and which afford precedents generally reckoned unexceptionable. There is fearcely a vestige of common law, so that the civil and canon laws may be denominated the basis of Scottish jurisprudence. The inferior courts are those of the shires of counties, the magistrates of boroughs, the commissaries, and the justices of the peace. While the feudal system prevailed, the hereditary jurisdictions were nearly absolute, and every chief maintained an unlimited control over the lives and property of his vassals and followers; but this system is now happily abolished.

Parliamentary Representation.—Scotland is represented in the British parliament by sixteen peers and forty-five commoners, in conformity to the treaty of union between the two kingdoms. The sixteen peers are elected for every new parliament by the whole body of the peers duly qualified to vote: at the period when the election takes place, and are not, when once elected, continued for life, as is the case in regard to Irish peers, by the recent union with Ireland.

The following table will give an idea of the diminution that has taken place in the members of the Scottish peers since the Union, and their amount at present:

Of these, 23 (including the duke of Rothsay) are British peers, but who still retain the privilege of voting at elections, and even continue eligible; though it can hardly be supposed that these hereditary peers would permit their brethren not enjoying the same privilege to elect them. At the last election, on the 13th of November 1812, there were three minor, three peerages, and two Roman Catholics, consequently eight disqualified from voting. The peers who actually voted were fifty-two, and twenty-two were out of the kingdom, or did not vote.

Of the forty-five commoners, thirty represent counties, and fifteen boroughs.

The county members are elected by freeholders possessing £40 of Scotch of valued rent, in land held of the crown. The only exception to this rule is found in the county of Sutherland: where, as the greater part of the land is held of the earl of Sutherland, it became necessary to give the vassals of that earldom a right to vote as well as the vassals of the crown; and in consequence of the inconsiderable number of small proprietors in the county, the qualification of the freeholder was reduced to £20 of Scotch of valued rent.

The following table shews the amount of the valued rent in each county, as it stood in 1674; also the number of qualified freeholders returned in the last drawn up for the year 1811, since which there has been very little variation.

Glafgo, Rutherian, Renfrew, and Dumbarton; Stirling, Cullins, Dumferline, Inverkeithing, and Queensferry; Burntihland, Kinghorn, Kirkaldy, and Dyaff; Anfruther, East and West Pittenweem, Kilrenny, and Crail; St. Andrew's, C&M, Fife, Dundee, Perth, and Forfar; Brechin, Abroath, Montrose, Berrie, and Aberdeen; Kinmore, Inverary, Banff, Cullen, and Elgin; Forres, Nairn, Inverness, and Fortrose; Dingwall, Tain, Dornock, Urick, and Kirkwall.

State of Religion.—According to the present establishment of the church, Scotland is divided into 15 synods, comprehending 78 presbyteries, and 933 parishes, which are represented in the general assembly of the church, which meets annually at Edinburgh. In its deliberative and judicial capacity this ecclesiastical court is justly accounted among the most enlightened and respectable in the Christian world.

In the division of the country into synods and parishes, convenience has been principally attended to; but the limits of counties being no further observed than they are consistent with the respective synodical and presbyterial acts, but in the arrangement of the whole into parishes, the limits of the counties have not been so much observed. Hence, in many instances, remote parts are conjoined into one parish, to the great inconvenience of the parishioners, as well as of the officiating clergyman. With respect to extent and population also, there is a great disparity; the first was settled in remote times; the second has been determined, in a great degree, by the effects of manufactures and commerce.

The names of the fifteen synods are as follows: 1. The synod of Lothian and Tweedale. 2. The synod of Moray and Teviotdale. 3. The synod of Dumbries. 4. The synod of Galloway. 5. The synod of Glasgow and Ayr. 6. The synod of Perth and Stirling. 7. The synod of Fife. 8. The synod of Angus and Mearns. 9. The synod of Aberdeen. 10. The synod of Moray. 11. The synod of Rofs. 12. The synod of Sutherland. 13. The synod of Argyle. 14. Glendal, or synod of Lochaber and the Isles. And, 15. The synod of Orkney. These synods come in the place of the bishopric, and have jurisdiction in ecclesiastical questions; in regard to which there is an appeal from the presbytery to the synod, and thence to the general assembly.

In former times, particularly before the revolution in 1688, Scotland, with respect to ecclesiastical government, was divided into two archbishoprics, St. Andrews and Glasgow, and twelve bishoprics, Edinburgh, Dunkeld, Aberdeen, Moray, Brechin, Dumbarton, Ross, Caithness, Orkney, Galloway, Argyll, and the Isles. The country in general was parcelled out among the respective sees, in an arrangement having some regard to population, but not always so; for several parishes were attached to bishoprics, and many to the archbishoprics, that were very remote from the provinces in which they were locally placed. This still remains the case with the jurisdictions of the different commissaries, which have been substituted from these bishoprics, which is called confessional courts. At present, the Scots Episcopalians have only eight bishoprics, viz. 1. Edinburgh and Fife; 2. Glasgow; 3. Aberdeen; 4. Moray; 5. Rofs; 6. Dunkeld; 7. Brechin, and 8. Dumbarton: comprehending seventy-six sees, served by sixty clergymen.
of their adherents is supposed to be about 19,000, which, perhaps, with the children, may amount to 28,000. The Roman Catholics divide Scotland into two districts only, the Lowland and the Highland, in order chiefly to make a separation between the two languages, the English and the Gaelic. Over in each they have a vicar apostolical, and a bishop coadjutor. In the low counties they have about thirty officiating priests, and in the Highlands eighteen; hearers about 27,000 in number. The Seesd from the Scotch Presbyterian ecclesiastical church divide the country among them thus.

The Burgher Associate Synod lay it out in ten prebyteries. They have in all 150 congregations in Scotland, with about 66,000 hearers.

The Anti-Burgher Seesd from divide it among three synods, containing eleven prebyteries. They have 134 congregations, with about 60,000 hearers. The church of Relief divides the country into six prebyteries, including 76 congregations, with about 50,000 hearers. The other presbyterian Scots, as the Cameronians, &c., may amount to about 14,000. The separatists of various descriptions, as Babilities, Bearer, Glissets, may amount to nearly 50,000.

The Methodists, of whom there are supposed to be about 6000 members, or, including children, about 9000 souls, divide the country into circuits, eleven in all, served by eighteen preachers.

The Friends, or Quakers, are so few in number, that they have only five places of meeting, viz. Glasgows, Hawick, Edinburgh, Aberdeen, and Kilmarnock, near Old Meldrum; their whole number does not exceed 2000.

Chief Cities and Towns.—The most important towns in Scotland, both as to extent and population, are Edinburgh and Glasgow; the former the metropolis of the kingdom, and the latter the emporium of its manufactures and commerce. They both contain nearly the same number of inhabitants, viz. about 100,000 persons, and are royal burghs, governed each by a lord provost and town council. The next towns to these in importance are Perth, Aberdeen, Dundee, and Paisley, each containing about 30,000 souls. The other towns of note are Berwick, Dunbar, Haddington, Musselburgh, Aberbrothick, Montrose, Portfoyt, Elgin, Inverness, and Dingwall, situated on the eastern side of the kingdom; Ayr, Greenock, Paisley, Inverary, and Cambell-town, situated on its western side; and Dunfries, Lanark, Stirling, Dunfermline, Dunkeld, Falkirk, Linlithgow, Hamilton, Selkirk, and many others little inferior to these, which are situated in inland counties. Many of the above towns enjoy the advantage of separate jurisdiction, but others are under the authority of the county magistrates, and of these last is Paisley, the greatest manufacturing town in Scotland next to Glasgow.

Manufactures and Commerce.—Previous to the Union, Scotland could boast little as to the extent either of its manufacturing or commercial property. It is true, indeed, that tradition, as well as history, point out Perth as a great trading mart some centuries ago, but the accounts are most probably exaggerated. At all events, it is certain that the commerce of the kingdom was at a very low ebb during the seventeenth century, and that it has only risen into importance within the last fifty years. Formerly the staple manufacture of the kingdom was linen; but that has now given way, comparatively speaking, to the weaving of cotton goods. The chief seats of the former manufacture are Perth and its vicinity, and the county of Fife; and of the latter the counties of Lanark and Renfrew, including the towns of Glasgow and Paisley, and others of inferior note. Woollen cloths are only made for home consumption, and in trifling quantity, excepting carpets, the manufacture of which is very considerable. Several other kinds of manufacture are carried on in Scotland, but that of iron is the only one which deserves to be specified in this article. The works of the Carron are probably the most celebrated in Europe for the founding of cannon, cast-iron wheels, &c.

With respect to the commerce of Scotland, it may be remarked, that though on a smaller scale, it is much affiliated to that of England. The chief exports are linen, grain, iron, glafs, lead, soap, cotton goods of every description, also earthenware, cordage, leather, candles, and innumerable other articles, which it is unnecessary to mention. The imports are wines, brandy, and all kinds of colonial produce, likewise butter, linen, fil, wood, oil, and tallow. The principal ports are those of port Glasgow and Greenock, on the west coast, and Leith, Dundee, Perth, and Aberdeen, on the east coast.

To the above foures of Scottish commerce, may be very properly added the fisheries, which, if placed under appropriate regulations, would prove a fund of great wealth, not merely to Scotland, but to the British empire at large. To effect this object several enactments have been made, but their beneficial operation has hitherto been much restricted. A bill, however, is now in progress, which it is hoped will produce a more favourable result.

Roads and Canals.—In the Lowlands of Scotland the great roads are not inferior in formation to those of England; but they are not yet sufficiently numerous, nor are they always planned in the most judicious manner. Rapid improvements, however, are making in this branch of political economy, so indispensable to commercial prosperity, and the advancement of national civilization. From the mountainous character of the Highland, the construction of good roads is perhaps impossible; but even in that wild district, efforts are daily making to render communication more easy.

The principal canal in Scotland is that which connects the navigation of the Clyde and Forth. It was begun in 1769, and constructed according to a survey furnished by Mr. Smeeon. The depth of this canal is seven feet, and its width at the surface fifty-six feet. In some places it is carried through mossy ground, and in others through solid rock, and appears evidently, throughout its whole extent, to have been planned and executed with great ability. Another canal has been proposed between Edinburgh and Glasgow, and is believed to be in progress of execution. There is also a canal forming across the isthmus of Cantire, to connect the Frith of Clyde with the Atlantic ocean, to the north of Jura. But the chief work of this description now going on, is the grand canal from the Moray Firth, through Loch Nefs and Loch Loyal, to the inlet of the sea called Loch Linhe, on the western coast. Parliament has already voted a large sum towards this undertaking, which it is computed will require upwards of 400,000l. to complete it. See CANAL, INVERNEYS.

Literature.—The literature of Scotland, though it cannot boast of great antiquity, has acquired a distinguished place in the annals of fame, by the rapidity of progress and brilliancy of its fields in later times. The Caids, indeed, the venerable hermits of Jona, are represented by ancient historians as having been men of extensive learning and great erudition; but their claims to this cologue are probably overrated. The earliest genuine work relative to Scotland is the Chronicon Picorum, written by an Irish clergyman, supposed, with considerable probability, to have been a dialect of the church of Abertuth, in the commencement of the eleventh century. In the twelfth century the chronicles published by Linnis, and those of Melrose and Holyrood, deserve to be noticed. About the year 1320 flourished Thomas of Er-}

eceldon,
caldon, commonly called Thomas the Rhymer, who wrote a metrical romance, called Sir Tritrim, lately republished by Mr. Scott. The next writer of confluence is John Barbour, archdeacon of Aberdeen, who wrote a poem in commemoration of the heroic actions of Robert Bruce, in the year 1375, not less celebrated for its historical fidelity than for its poetical merit. About this time flourished John Fordun, designated the father of Scottish history. In the fifteenth century, James I of Scotland wrote some poems of great merit, and he was succeeded by Holland, and Henry the Rhymer. Next arose Dunbar, whose merit has entitled him to be placed at the head of the ancient Scottish poets. In the beginning of the sixteenth century flourished Gavin Douglas, and Sir David Lindsay. These were followed by many others of various merit, till the middle of the nineteenth century, when the unhappy events of that turbulent period checked the career of the arts and sciences. Before this, however, the illustrious Drummond had confounded to the world his exquisite poems. In modern times, the field of poetical merit has been more luxuriant. The names of Thomson, Ramsay, Blair, Armstrrong, Beattie, Burns, Campbell, and Scott, with many others, are held in universal estimation.

In the other departments of science, though of later cultivation, the Scots have made rapid progress. In history, the names of Boethius and Buchanan are everywhere revered. The classic elegance and purity of the style of the latter, has entitled him to rank with the first authors of antiquity. In our own age, among other historians of great merit, have arisen Hume and Robertson, whose works will ever be read with enthusiastic delight by the admirers of taste and genius. In the mathematical department, lord Napier, the celebrated inventor of the logarithms; Maclaurin, no less celebrated for his astronomical works; and Dr. Simpson, noted for his knowledge of ancient geometry, have acquired a lasting reputation. In medicine, the names of Pitcairn, Monro, and Cullen, may be mentioned as holding the highest rank; and in the department of metaphysical and moral sciences, the perils stands unrivalled. The labours of Hume, Hutchinson, Reid, Campbell, Beattie, Monboddo, Kames, Smith, and Ferguson, will be regarded with admiration, so long as the philosophy of the mind continues to be a subject of interest, and the English language is understood. Scotland has also attained the praise of superior excellence in other departments of science, particularly in political economy and in chemistry.

Universities.—The universities in Scotland are four in number; St. Andrews, Glasgow, Aberdeen, and Edinburgh. The first was founded by bishop Wardlaw, in 1412; the second by bishop Turnbull, in 1453; the third by bishop Elphinston, in 1500; and the last by James VI. in 1582. A; the reader will find each of them derived under their respective names, we shall only observe farther concerning them in this place, that the university of Edinburgh is the most celebrated medical school in Europe, and is annually attended by from 1200 to 1500 students.

Education.—The mode of education adopted in this country is highly laudable, and is probably the best practicable system established in any kingdom. The plan followed in the cities and large towns is nearly similar to that of England; that is, by private feminaries and great public schools, of which the High School of Edinburgh is the most eminent. But the chief advantage of the Scottish education arises from the circumstance of every country parish having a schoolmaster, regularly appointed by the heritors, in the same way as the clergyman, who receives a small salary, which enables him to educate the children of the parishioners at a rate easy and convenient even to the most indigent parents. In the Highlands, the children of the poor are occupied as herds during summer, and in winter attend schools. To be unable to read and write is considered so disgraceful in Scotland, that such persons are scarcely ever to be met with.

Manners and Customs.—In every part of the kingdom, but more especially throughout the Lowlands, the higher orders in Scotland are characterized by much the same features as in England. Their dree, their mode of living, and their amusements, both public and private, are nearly alike. The inferior orders in the Lowlands are likewise much attainted to their southern neighbours in their style of dree, but their food and diversions materially differ. The ordinary diet of the Scottish peasant is parish, a composition of oatmeal and water, boiled together till it amuses a thick consistence. It is eaten with milk twice and sometimes thrice a day, and is seldom varied, except by broast, which differs from parish only in having the addition of butter, and not being boiled. Butcher's meat is rarely eaten, except on Sunday; but vegetable broasts made with butter are not unfrequently used for dinner. Pork and eels were formerly held in great abhorrence, and even yet are regarded as impure articles of food, on account of superstitious opinions respecting them. In the Highlands these sentiments are particularly strong; and hence the rearing of swine is very little attended to in that district. In the same division of the kingdom, the national dree is still prevalent; but the tartan kilt has very generally given place to pantaloons of the same material. From the influence of education, and the well-directed exertions of the clergy, the peastantry have long been distinguished for sobriety, industry, and moral rectitude; and, in point of intelligence, are indubitably the first in the world. Even the artisans are entitled to share in this eulogy, though it must be confessed that exceptions to the rule are too numerous, especially in the great trading towns. The existence of witches, fairies, and ghosts, is still part of the creed of the Scottish peasant; and the Highlander confidently believes in the power of second sight, or the capability of perceiving future events. Some relics of the idolatrous worship of his remote ancestors are yet discernible, both in his amusements and his more serious occupations; but they are gradually becoming fainted, and will, no doubt, disappear in the progress of refinement and civilization. For information on the amusements, superstitions, and manners of the Scottish peasantry, the reader cannot consult any works with greater advantage than those two exquisite poems, the "Hallowen," and "Cottar's Saturday Night," of the celebrated Burns. Referring, therefore, to them, we shall only further remark under this head, that in their religious ceremonies, considerable variations exist from the forms in England. Thus, for instance, in baptism, godfathers, and godmothers are inadmissible, the parents alone being made anwserable for the education of their children in the path of morality and religion.

Antiquities.—Monuments of antiquity of every age, from the Celtic colonization of the kingdom, are yet visible in various districts. Those of the first epoch are all of the tumular kind, and are only to be discovered by nice investigation in the more wild and uncultivated tracts. Of the Roman period, the remains are numerous, confining of vestiges of roads, flintations, encampments, foundations of walls, and other minor antiquities. The celebrated wall of Antoninus may yet be traced, with perfect accuracy, nearly the whole of its extent from the Forth to the Clyde; and many interesting inscriptions are frequently dug up from its ruins. Near it was formerly a small edifice called Arthur's Oven, which the most intelligent antiquaries suppose to have been a temple.
a temple dedicated to the god Terminus. The most northerly Roman camp yet discovered is situated on the river Ythan, in Aberdeenshire; and there are some roads extending into the county of Angus; but the chief remains of them are but a foot of the walls. The monuments of the Pictish era consist of those circles of stones, cromlechs, &c., usually, but erroneously, denominated Druidical temples; and of those artificial mounds, or hills, whence the Picts and Dalriadic kings were wont to promulgate their laws. The most remarkable stone circles in the kingdom are those in the Isle of Lewis, and on the Mainland of Orkney. The structures commonly called "Picts' houses," and the heaps of stones called "cairns," or "kaross," have also been supposed to belong to this age; but Pinkerton refers the latter entirely to the Dalriads, or Scots, and thinks the former may be Danifh, as it is certain similar edifices have been traced in Scandinavia. They seem to have consisted of a vast hall, open to the sky in the centre, and having cellars for beds, &c., in the wall. "These buildings," 1757, the author last mentioned, "are remarkable, as displaying the first elements of the Gothic style; and the castle of Coningburgh, in Yorkshire, forms an easy transition." The remains of later ages are the sculptured obelisks at Forres, and other places; which are probably monuments of signal events, such as battles and treaties of peace; the noted vitrified forts, and churches, abbeys, and caisles almost innumerable. Among the more remarkable buildings which owe their origin to religion, are the abbeys of Melrose, Jedburgh, and Aberbrothick; the cathedrals of Dunkeld, Glasgow, and Brechin; and the chapel of Koflyn, near Edinburgh. The last is one of the most singular and interesting remains of ancient architecture in Great Britain; and Melrose abbey may vie with many in England, both as to the extent and magnificence of its buildings.

Scotland Neve, a town or rather village of America, in Halifax county, North Carolina, in which is a post-office; 250 miles s. of Washington.

Scotland, New. See Nova Scotia.

Scotland River, a river, or rather rivulet, in the island of Barbadoes, which rises in St. Andrew's parish, and falls into Long bay, on the e. side of the island, 4 miles S.S.E. of Cuckold's point, or 24 miles N.W. of St. Joseph's river, the only other small brook of the island.

Scotodinos, a term used by medical writers to express a vertigo, or dizziness of the head, attended with a dinnings of light.

Scots, in Geography, the name of one of the two great tribes,
tribes, into which the inhabitants of the northern region of Caledonia was divided, as early as the reign of Constantine; Pict's being the denomination of the other. The name and almost the memory of the Picts have been extinguiished by their successful rivals; and the Scots, after maintaining for ages the dignity of an independent kingdom, have multiplied, by an equal and voluntary union, as Gibson expresses it, the honours of the English name. The hand of nature hath contributed to mark the ancient distinction of the Scots and Picts: the former were the men of the hills, and the latter those of the plain. The eastern coast of Caledonia was a level and fertile country, and produced, in a rude state of tillage, a considerable quantity of corn; so that the epithet of cruthnoch, or wheat-eaters, expressed the contempt or envy of the carnivorous highlanders. Nevertheless, the love of arms and rapine was still the universal passion of the Picts; and their warriors, stripped for a day of battle, were distinguished, in the eyes of the Romans, by the strange fashion of painting their naked bodies with gaudy colours and fantastic figures. (See Picts.) The western part of Caledonia irregularly rises into wild and barren hills, which fearfully repel the soil of the husbandmen, and are most profitably used for the pasturage of cattle. Accordingly the highlanders were condemned to the occupations of shep- herds and hunters; and as they were seldom fixed to any permanent habitation, they acquired the expressive name of Scots, which, in the Celtic tongue, is said to be equivalent to that of foragers. That the Irish descent of the Scots, though lately revived by Mr. Whitaker, is a fable, has been satisfactorily evinced by Mr. Gibbon; and he has traced the foundation upon which this fabulous super- structure has been gradually reared by the bardic and the monks, two orders of men, who equally abused the privilege of fiction. It is probable, says this sagacious and elegant historian, that in some remote period of antiquity, the fertile plains of Ulster received a colony of hungry Scots; and that the strangers of the North, who had dared to encounter the arms of the legions, spread their conquests over the savage and unwarlike natives of a solitary island. It is certain, that in the declining age of the Roman empire, Caledonia, Ireland, and the Isle of Man, were inhabited by the Scots; and that the kindred tribes, who were often associated in military enterprizes, were deeply affected by the various accidents of their mutual fortunes. They long cherished the lively tradition of their common name and origin; and the missionaries of the Isle of Saints, who diffused the light of Christianity over North Britain, established the vain opinion, that their Irish countrymen were the natural, as well as spiritual, fathers of the Scottish race. The Scottish nation, with mistaken pride, adopted their Irish genealogy; and the annals of a long line of imaginary kings have been adorned by the fancy of Boethius, and the chaste elegance of Buchanan. Gibbon's Hift. vol. iv. See Scotland.

Scots Tunes. In February 1722, the newspapers of the times inform us, that there was a concert for the benefit of Mr. Thomson, the first collector and publisher of Scots tunes in England. To this collection, for which there was a very large subscription, may be ascribed the subsequent favour of these national melodies south of the Tweed.

After this comfort, at the desire of several persons of quality, was performed a Scotch fong.

In 1744, in the opera of "Rofelinda," fet by Veracini, at that time the leader of the opera band, the first air that presents itself, in the printed copy of the favourite songs, is "The Lads of Patie's Mill," which Monticelli confounded to sing, and to which Veracini added parts and ritornelli, in order, as they imagined, to flatter the British nation. But as few of the North Britons, or admirers of this national and natural music, frequent the opera, or mean to give half a guinea to hear a Scots tune, which perhaps their cook-maid, Peggy, can sing better than any foreigner, this expedition failed of its intended effect. See Palma.

Scott's Bay, a bay on the S.W. coast of the island of Dominica, towards the S. extremity of the island; 4 miles S. of Charlotte-town.—Allo, a bay on the North Pacific coast, on the W. coast of America; 10 miles S. of Queen Charlotte's found.

Scott's Cere, a cape on the S.W. coast of Jamaica.

Scott's Head, a cape at the southern extremity of Dominica. N. lat. 15° 20'. W. long. 61° 24'.

Scott's Islands, a cluster of islands in the North Pacific ocean, near the N.W. coast of the island of Quadra and Vancouver. N. lat. 50° 57'. E. long. 231° 2'.

SCOTT, John, in Biography, a clergyman of the church of England, was born in 1638, at Chippenham, in Wiltshire. He was first apprenticed to a trade in London, which not being congenial to his taste, he quitted, and entered himself as a commoner of New Inn, Oxford. After receiving orders, he obtained a rectory in London, and a prebend in St. Paul's cathedral. In 1685 he took his degree of D.D.; and in 1691 he was appointed to the rectory of St. Giles-in-the-Fields, and was made canon of Windfor. "The Christian Life," which was published at different times, and finished in 1686, acquired for him a high reputation, that, after the revolution, he was offered the bishopric of Chester; which, however, he refused, because he could not conscientiously take the oaths required.

He was afterwards offered the bishopric of Worcester, and a prebend of Windfor, which he likewise declined, because they were the places of persons who had been deprived for an adherence to those principles, which he himself secretly cherished. Nevertheless he had strenuously opposed the progress of Popery in the reigns of Charles II. and James II., and published some works in controversy with the Papists, while the latter prince was still on the throne. Dr. Scott died in 1694, leaving the character of an excellent man and worthy parish-priest. Besides the work already mentioned, he wrote "Cales of Conscience resolved, concerning the Lawfulnefs of joining in Forms of Prayer in public Worship;" and "Thirteen Sermons," preached on different occasions. His "Christian Life" is a book very generally read in the religious world.

SCOTT, Michael, a celebrated Scot of the 13th century, was born at Balcarres, in Fife, about the beginning of the reign of Alexander II. At a very early period he made great progress in language, as well as in mathematics; and having finished his studies at home, he went over into France, where he remained some years; but hearing that the emperor Frederick II. was a great patron of learning and learned men, he repaired to the court of that prince, and applied himself closely to all the branches of philosophy then studied. After residing some time in Germany, he proceeded to England, and was highly in the favour of Edward II.; but it is not at all known how long he continued here. Upon his return to Scotland he received the honour of knighthood from Alexander III., and was afterwards sent, with Michael de Wemys, to bring to Scotland the Maid of Norway, who, being taken ill at sea, was landed on one of the Orkney islands, where she died in the year 1290. At this time Sir Michael was probably far advanced in life; he died in 1291. He was esteemed a man of
of great learning, though so much addicted to the occult sciences, that he paffed among his contemporaries as a skillful magician. Boccaceio and Folengo both exhibit him as such; the former in one of his novels, and the latter in his macaronic poem; and he is introduced under the name character by Dante. It is not known where he was interred, but it seems generally admitted that his books of magic were either buried with him in his grave, or preferred in the convent where he died. A Latin translation of Ariflotle's works is ascribed to Sir Michael Scott, but probably upon insufficient evidence. There is a translation of that philosopher's works, partsly from the Greek and partly from the Arabic, by various hands, undertaken at the command of the emperor Frederic II., at whose court Sir Michael resided some time; and as he is reported to have translated Ariflotle's Natural History of Animals from the Arabic version of Avicenna, it has been assumed that this is the only part of the work which should be ascribed to him.

The title of the work is "Ariflotelis Opera, Latinae verae, partim e Graeco partim Arabico, per viros leitos et in utriusque Linguae prolacione peritos, juxta Imperatoris Frederici II. Venet. 1496." The works of Sir Michael Scott are numerous, among which the following may be mentioned: "Phylognomenia et de Hominis Procreatione," "De Secretis Nature," "Quello curioso de Natura Solis et Lunae." The subject of this last work is the pretended transmutation of metals, gold and silver being reckoned among alchemists the sun and moon. According to the opinion of Riccioli, Scott was a diligent observer of the stars, and, at the request of the emperor Frederic II., he wrote a treatise on the sphere of Sacrobosco. Gen. Biog.

Scott, George Lewis. This learned and accomplished man was not only an able mathematician, but an excellent musician. He was an intimate friend of Dr. Pepusch, and assisted him in drawing up his paper for the Royal Society, on the genera and styles of the ancient Greek music; and whatever articles he furnished to the Supplement of Chamber's Dictionary, concerning harmonics or the ratio of sounds, may be depended on. Mr. Scott was a performer on the harpsichord, and very fond of music; but always calculating, during his own performance and that of others, as to the legality of modulation. And we well remember his being much disturbed at the unregular succession of chords, in the opening of Pergolesi's "Stabat Mater," at the second bar, where that most pleasing author surmounts the car, as well as the eye and intellect, in modulating from F minor to Eb major. De Moivre, who had no taste or feeling for music, used to calculate ratios for the ingenious and worthy organist of the Charter-houfe, and laugh at him for his Greek and mathematical pretensions; but Scott, the sub-preceptor of his present majesty, was in earnest, and wished to make discoveries in Greek music, as much as Pepusch. For though attatched to old masters of eminence, as well as the Carthusian maestro di cappella, he enjoyed the productions of the moderns extremely, when he could discover in them either genius or science.

As we had the honour to be personally acquainted with him, we are sure that the elaborate article Temperament in music, in the additional volume to Chamber's Dictionary, was drawn up by the late learned and scientific Mr. Scott, who was one of the very few theorists that ever paid the least regard to practice, or who seemed to recollect that the ear had anything to do with harmonics.

Scottia, or Scottus. See Scot.

Scotti, Teresa, in Biography, the first woman in the operas of 1764 and 1765, in which Manfoni sung.

The Scotti, with an elegant figure, a beautiful face, and a feeble voice, sung in a very good taste; and though in want of power, she possessed great flexibility and expression.

Scottia, in Botany, bears that name, as we presume, in memory of Robert Scott, M.D., late professor of Botany at Dublin, commemorated by Mr. Davison Turner in the preface, as well as the dedication, of his "Mycologete Hibernico Spicilegium."—Brown in Ait. Hort. Kew. v. 4. 268.—Classification, Diasphilia Decandria. Nat. Ord. Papilionaceae, Linn. Leguminose, Jull.

Ed. Ch. Calyce with five rather unequal teeth; its base clothed with imbricated appendages. Standard folded, shorter than the wings, which are the length of the keel. Stamens all connected. Legume stalked, compressed; thickened at each margin. Seeds few, crested. I. S. dentata. Tooth-leaved Scottia. — Found by Mr. Brown on the south-west coast of New Holland. A burr, sent to Kew garden, in 1803, by Mr. Peter Good. It is kept in the greenhouse, and flowers from June to September.

Scottsburg, in Geography, a post-town of Virginia; 256 miles W. of Washington.

Scotus, in Ancient Geography, a town of Macedonia, on the banks of the river Strymon, in the Odontania, near Berga. — Alto, a town of Greece, in Thessaly, Ptolomey.

Scour, among Cattle, a disease of the flux kind, which frequently affects cows, calves, sheep, and other animals. See Scouring in Cows, and in Calves.

This is a disease in sheep, which is common in the winter season, being believed to originate from the severity of the frosts, especially when they let in suddenly, or alternate frequently with thaws. The chief dependence for a cure, in these cases, is upon an expeditious change to dry keep; as, in the practice of some good sheep-farmers, the use of hay, on the mornings when hoar-frosts are prevalent, has been found a good preventative. It is sometimes called the "gall" by sheep-farmers. Early, soft, tawny, luxuriant pastures, is also liable to produce this complaint, especially in previously worn-down sheep. It arises frequently, too, from sudden changes from dry, warm, poor pastures, to such as are rich, cold, and damp; or the contrary. It is sometimes likewise the consequence of other affections, as well as of the local weakneds and relaxation of the bowels. In all these instances, the above changes of food will be highly useful and necessary. The disease may be stopped, except where it is critical, after clearing the intestines of any irritating matters, by mild purgatives, by the following means, particularly where there is great weakneds of the affected parts.

Boil four ounces of the shavings of logwood in two pints of water, until it be reduced to one pint; then add one ounce of cinnamon water, and give one half at a time. Where this is not strong enough to check the disorder, half a dram of the extract of catechu may be dissolved in it, with fifty or more drops of the tincture of opium. These will molly leaffen the over-action of the bowels, and speedily remove the complaint. In mild cases of this nature, it will seldom be necessary to have recourse to the above remedy, as they will easily be removed by the use of water, in which a little calcined chalk and hartshorn shavings have been boiled. In high states of the disease, the strength of the medicine must be increased.
The black scour is, however, seldom capable of being restrained by any means that have yet been had recourse to; it therefore, for the most part, terminates fatally.

Scour, White, a disease in sheep of the more violent flux kind, supposed to originate in confluence of their feeding upon putrefactive vegetable food, especially that of the shells of such turnips as have been left upon the feeding grounds. In these cases, it has been advised to give two or three large spoonfuls of the following mixture, every two or three days; the diseased sheep being separated from the rest of the flock. Take of finely powdered and sifted bay-fall, half a pound, and dissolve it in good old verjuice, one pint; to which add of good common gin half a pint; mixing the whole of them well together.

And in order to facilitate the removal of the disease, the sheep should be put upon good dry food, in an upland pasture. See Sheep.

Scouring in Cows, a disease in these animals of the flux kind, in which there are frequent liquid dejections from the intestines, proceeding from irritation, the excrements, according to Downing, being slimy, bilious, or black; sometimes they are limpid and fluid, like water cast out; at other times they are frothy, greasy, and mixed with a fat clayish coloured substance. This disorder is generally attended with a bad appetite, a weak depressed pulse, harsh dry skin, dull countenance, and something of a low fever. This disease is so obvious, that it needs no further description; for the copious evacuation of the excrements, and many other signs, make it evident to the knowledge of every person. And he supposes, that the first stage of it is a companion of the joint yellowish, and may be traced out to the satisfaction of any one who will take the trouble to open any animal that dies of this disorder.

According to others it affects oxen as well as cows, and arises from want of sufficient food, both in quality and proportion; from being overheated or overworked; by feeding on wet unwholsome fog or after-grafs; by not being lodged in dry situations; sometimes from giving them too large a quantity of cut hay and straw, hotter than their natural temperature; though it is sometimes a constitutional taint, and in cows is caused by their taking cold while calving. But whatever be the cause, as soon as it begins to appear it will be necessary to hose the beast, and put it to dry food, which, in early stages of the disease, often effects a cure. But in this case Mr. Downing advises the following:

Take of mutton suet, one pound; oil of turpentine, four ounces; boil these together in three quarts of milk till the suet is dissolved, and give it at night milk-warm; and the next morning give the following medicine:

Take pomegranate powder, eight ounces; logwood in powder, two ounces; new pipes pounded, two ounces; Peruvian bark in powder, two ounces; rock alum in powder, fix ounces: mix these together, to be given in two quarts of old ale or urine, and repeated every other day. The beast should fall two hours before and two after taking the medicine. He afterwards has recourse to crab verjuice, in the quantity of a pint, for several mornings. And also the following: Take calcined oil-flax shells in powder, four ounces; ditto pipe-clay, one ounce; oak-bark powder, two ounces; grains of paradise, one ounce; rock alum, one ounce. Mix these together for one dose, to be given in a quart of old beer and a pint of red wine, or in three pints of oak-dip from the tan-pits.

But others advise half a pound of grosly pulverized tormentil root, to be boiled in two quarts of water till reduced to one quart, then straining it off, and adding a quart of red wine, a quarter of a pound of finely powdered chalk or whiting, and two ounces of diceordium, without honey. The mixture should be preferved in a bottle, and occasionally well shaken together, making it lukewarm before it is given. The dose is half a pint, given three times in the day, at equidistant periods. Or half a pound of pulverized common chalk may be boiled in two quarts of water, till diminished to three pints, then adding four ounces of hartshorn flavings, and one ounce of calsia, stirring the whole carefully. When cold, two drachms of tincture of opium, and one pint of lime-water, may be added; the whole being kept closely flopped in a bottle, and well shaken before it is used; the dose is one or two hornsful in the day.

Scouring in Calfs, a disease to which they are very subject at an early period, being often caused by improper management in putting them too soon to the teas, or letting them remain too long at it. It is also sometimes caused by too frequently changing the milk.

But in order to effect a cure, it has been advised to restrict the calf in the quantity of its food, giving a hard boiled egg, made fine by chopping, in a trench, the first thing in the morning. Chalk powdered and mixed up with flour into balls with gin has also been recommended as useful and safe in these cases, by a writer in the Annals of Agriculture.

In Essex, some farmers have found the following remedy almost infallible. Two tea-spoonfuls of rhubarb in fine powder, and a table-spoonful of peppermint water, kneaded well together. If once giving of this does not stop the complaint, a second dose is given, with a little red port wine added to it, which mollify completes the cure. In one case an apparently dying calf was restored by the use of this medicine.

Powdered chalk given in their troughs, with the barley meal for fattening them, is found to have a good effect in this intention, as well as in other ways.

And a decoction of calcined chalk, hartshorn flavings, and a little courlessly pounded calisia, with a very small quantity of the tincture of opium, will mostly be found of great benefit in cases of this nature, when given to the extent of from two or three to five or fix table-spoonfuls once or twice in the course of the day.

Scouring in Lambs, &c. a disease which is common to them in many places, but especially to those which have been sent to winter on the hills from the Romney-marsh lands in the southern part of the kingdom. These also which continue in the Marsh during the same feaon, are liable to be attacked with the complaint on the approach of spring. Sheep which are weakened in their constitution, and have experienced a quick transition from poor, low, to rich, full keep, are the most subject to be affected. Likewise when they are first brought upon the marsh-lands in the early spring, particularly when moist warm weather succeeds to keen frosts, though it often shews itself at other times of the year, as already noticed. The writer of the Romney-marsh sheep-grazing system remarks, that the farmers there consider it fatualy, and believe that the sheep fatten more quickly after it: but he regrets, that when it is long continued, the powers of their systems must be greatly injuried and reduced. In such cases, the disorder ought moly to be restrained and removed by having recourse to dry food, and the use of suitable remedies. The above writer has had twenty lambs attacked with it in a feaon, and not being able to learn them to eat hay, succeeded in saving most of them, by means of giving them an altringent cordial drink, with a small portion of opium, and
turning them upon dry, found, old, artificial pasture-land. But three of the number, to which fue boiling in milk had been given, all died. Tar mixed with the finely powdered lime of an old wall, and formed into suitable balls, is said, in some instances, to prove an effectual remedy for this complaint.

On the whole it is thought, that as the disorder evidently arises either from cold, moisture, and poor food, or from weakly sheep being suddenly put upon too rich keep, the most proper and rational method of removing the affection is, in the first circumstances, to turn the sheep immediately into a new warm pasture, and supply them well with fresh good hay, &c. and in the latter case, to put them upon found old ward land. In support of this practice, a sheep farmer in the same neighbourhood affords, that he constantly keeps his wether lambs on or near to the above March, and that he never has any of his flock affected with the disease; which he imputes to the allowing of them old grass upon the land. The grounds are warm, and well sheltered by trees and fences.

SCOURING, Preventative Remedies, for Horses, such as are given to work and other horses, as well as occasionally to other forts of live-flock, for the purpose of preventing the occurrence of disease in them. The incautious and indiscriminate use of remedies of this nature among horses and other cattle has been the cause of much loss and mischief. Animals by no means stand so frequently in need of medicines of this fort as has been supposed, though they may sometimes have occasion for them. The state and circumstances of the animals, with a full knowledge of the manner in which they have been kept, and the labour or exercise which they have had, will, with due discrimination and judgment in the person who has the care of them, mostly lead point out when they may be necessary and useful; and when, on the contrary, improper and hurtful. Calomel and aloes are probably the most proper substances to be generally employed in this way, though others of the purging kinds may sometimes be joined with them to promote their operation with much advantage and effect. However, from the natural motion of the bowels of horses being slow, and the length of the intestinal canals great, unless the stimulant purgative power of the substance continues for some time after it has passed from the stomach, no effect will be produced upon them. This accounts for the failure of such remedies in many cases. Yet on the same grounds, it may naturally be supposed, that a powerful dose of such medicines may increase this action in such a manner, and propel the contents of the bowels in so forcible a degree, as to produce great pain, inflammation, or other mischief, which may either kill the animal or greatly injure it, as is frequently exemplified.

Consequently, in every case where the strength and the state of the animal are not well known, the best method may be to begin with giving not too large doses of remedies of this nature, but increasing them afterwards, where found necessary. In this way there will be every advantage secured, without the danger of injury being done.

Such horses as are newly taken up into warm stables from cold exposed situations, will often stand in need of one or two gentle doses of this kind. But horses employed in team labour, or hard work of other forts, will very seldom require such assistance. It may, however, be occasionally useful. Swellings of the legs, inflammations of the eyes, coughs, and colds, arising from the sudden change of temperature may in many cases be prevented, by rendering the stables more open and airy on the horses being first taken up into them, especially if they be close and warm.

Strong young horses mostly require a few dozes on their first coming into the stables, but by no means so many as are usually given. Horses too, after being long foiled on green food, sometimes are the better for such remedies. Also such as have swelled and cracked heels from high feeding and too much inaction. There may be some other cases in which such remedies are beneficial, but they are only few, as it is not at all necessary to have recourse to them in that general way which is commonly imagined.

The most usual, and perhaps the best mode of giving such remedies, is that of letting the animal have the calomel balls in the evening, and those of the aloe kind in the morning, so as to work them off in some measure.

From one drachm to two drachms, in proportion to the strength of the animal, of the first or calomel, with half an ounce of some aromatic powder, made up with treacle or honey, will form a proper ball for the evening dose. And from half an ounce to one ounce, according to the state of the animal, of finely powdered Barbados aloes, with two drachms of powdered ginger, made up in the same way, will form a suitable morning ball in this intention.

Proper measures and feeds, with suitable work or exercise, and grooming, are to be had recourse to at the same time. The space of eight or ten days should always elapse before the doses are repeated.

SCOURINGS, among Farriers, such gentle purges as preferve horses from noxious humours. SCOUTS, in Military Language, are generally horsemen sent out before, and on the wings of an army, to discover the enemy, and give the general an account of what they observe.

SCOUZIE HEAD, in Geography, a cape of Scotland, on the E. coast of the county of Caithness; 3 miles S. of Duncanby Head. N. lat. 58° 31'. W. long. 2° 25'.

SCOW, in Agriculture, a term used by farmers to signify the sheath of a horse.

SCOWBEGAN FALLS, in Geography, falls which boats cannot pass, in the Kennebec river, in the state of Maine, North America, near the town of Canaan.

SCRABY, or Scraba, a small port and sea-town of the county of Cavan, Ireland, near Lough Gawnah; 60 miles N.W. from Dublin, and 7 N.W. by W. from Granard.

SCRAPER, an instrument used in mezzotinto engraving, formed much in the manner of a knife, except that the edge is straight till near the point, and there slopes off at an angle from both sides; the lines of which slopes meeting form another angle of the point; but the slope on one side is much longer than that of the other.

SCRAPING in Mezzotinto. See MEZZOTINTO.

SCRAPING, in Naval Language, is the act of shaving off the dirty surface of the planks, in a ship's side or decks, particularly after a voyage, or when the seams have been covered with a new composition of melted pitch or rosin. The instrument with which this is performed is called a scraper.

SCRATCH, in the language of the falt-workers of our country, the name of a calcareous, earthy, or fatty sub stance, which separates from sea-water in boiling it for salt.

This forms a thick crust in a few days on the sides and bottoms of the pans, which they are forced to be at the pains of taking off once in a week or ten days, otherwise the pans burn away and are destroyed. (See Salts.)

This is no other than the same substance which crusts over the infides of our tea-kettles, and is truly a spar, fultained more or less in all water, and separable from it by boiling.
boiling. The shells of sea-fish have great affinity in their
substance and nature with this, both being powerful alkalies,
and both easily calcining into lime.

The magnesia alba, so celebrated in Germany for its
mild purgative and alkaline virtues, seems very nearly allied
to this; and it is probable, according to Hoffmann,
that the purgative virtues of many springs are owing to the
quantity they contain of this substance.

SCRATCHES, among Farriers, a distemper incident
to horses, consisting of dry scabs, chaps, or rifts,
that breed between the heel and the pattern joint.

There are various kinds of scratches, distinguished by var-
ious names, as crepanes, rat-tails, mules, kites, pains, &c.,
which are all of many species of the same malady, engen-
dered from some hot humour falling on the legs, or from
the fumes of the beast’s own dung lying under his heels,
or near them, or for want of rubbing his heels, especially
after a journey from over-hard riding, &c.

The disorder begins first with dry scabs in the pattern
joint, in several forms. It is known by the flaring, dividing,
curling of the hair on the part. For the cure of this
disorder, see Grease.

In order to prevent it, the heels should be kept supple
with carriers’ dubbing, which is made of oil and tallow:
by using this precaution before exercise, and washing the
heels with warm water when the horse comes in, the scratches
will be prevented.

SCRATCH-PANS, in the English Salt-Works, a name
given to certain leaden-pan’s, which are usually made about
a foot and a half long, a foot broad, and three inches deep,
and have a bow, or circular angle of iron, by which they
may be drawn out with a hook, when the liquor in the pan
is boiling. See SALT.

The use of these pans is to receive the scratch; and these
pans being placed at the corners of the salt-pan, where the
heat is least violent, catch it as it subdyes there.

SCRATCH-WORK, Soraffiata, a way of painting
in tin-co, by preparing a black ground, on which is
laid a white plaster; which white being taken off with an
iron bodkin, the black appears through the holes, and serves
for shadows.

This kind of work is laffing; but being very rough, it
is unpleasing to the light. It is chiefly used to embellish
the fronts of palaces, and other magnificent buildings.

SCRAPYLY, in Agriculture, a term provincially signifi-
ying thin and ravelled as grain.

SCREAMER, in Ornithology. See PalaMADEA.

SCREEN, an instrument for keeping off the wind, or
the heat of the fire.

SCREEN is also used for a frame of laths to sift earth,
fand, gravel, &c.

SCREEN, or Screen-Machine, in Agriculture, a simple con-
trivance, invented for the purpose of clearing grain of dif-
frent kinds, of various injurious sorts of feeds, by paffing
it through it. It consists of a wooden frame, which has
ledges on the sides, with a foot of hopper in the upper part
of it, to which is attached a kind of valve, that moves to
suitable distances by means of a screw, for letting proper
quantities of grain pass down upon a square wire sieve,
which is fixed below in the frame, and communicates with
the hopper in some measure. The screen stands up in a
sloping position by means of a leg, that draws out behind
it, and is commonly regulated by a cord, while the
operation of screening or clearing the grain is going on.
It is a very useful and convenient machine on small arable
farms, but on large ones the work is now usually done
by a somewhat similar contrivance in the threshing ma-
chine, while that is going on with it. See Threshing
Machine.

SCREEN-Fence, such fences as are raised for the pur-
pose of affording shelter from winds, storms, &c. The writer
of the tract on improving landed estates suggests, that for
the purpose of shelter to paffuring stock, a tall impenetrable
fence is nearly equal to a depth of coppice-wood, and in-
finity preferable to an open grove of timber-trees; besides
its additional use as a fence, or means of inclosure. And
that there appears to him to be only one kind of fence
which is properly adapted to this purpose, which is that
of the coppice mound hedge of Devonshire and South
Wales, and which consists in a high wide bank or mound
of earth, planted with coppice-woods. This becomes,
immediately on its erection, a shelter, and a guard to-parlure-
grounds round which it is formed.

And in respect to the method of forming fences with this
intention, it is that of carrying up long piles of earth, be-
tween two foot-fences, battering, or leaning somewhat in-
ward, to the required height; and planting on the top the
roots and lower stems of coppice-plants, gathered in woods
or on waste grounds, or with nursery plants adapted to the
given situation. If the mound be carried to a full height,
three or four feet, and about that width at the top, and this
be planted with strong plants, with stems cut off about two
feet above the roots (in the usual practice of Devonshire),
a sufficient fence is thus immediately formed against ordinary
stock; but if the bank be lower, or if nursery plants be put
in, a flight guard run along the outer brink, on either side,
and leaning outward over the face of the mound, is, he ob-
erves, required (especially against sheep), until the plants
grow up. But where a hedge of this kind is raised as a plant-
ation-fence, (especially on the lower side of a slope,) the
outer side only requires to be faced with sods; the hedge-
plants being let in a rough shelving bank, on the inner side
of the fence.

Further, with respect to the species of hedge-woods pro-
per for mound fences, they depend entirely, he thinks, on
the soil and situation. On mounds of bad foil, in a bleak
situation, he has seen the furze alone affordmg much shelter,
and a good fence. The fides being kept pruned, so as to
shew a close firm face rising above the top of the bank, it
was a secure barrier, even against the wilder breed of Welsh
sheep. The beech is commonly planted in high exposed
situations, and in places more genial to the growth of wood,
the hazel, the ash, and the oak are the ordinary plants of
hedge mounds. The willow tribe have a quality which
contributes them in situations where they will flourish; they
grow freely from cuttings, or truncheons set in the ground;
whereas to secure the growth of ordinary coppice-woods,
rooted plants are required. The fallow (Selix cuprea) will
grow in high and dry situations, in a matter so as to be
useful in this fort of business. And it may be further no-
ticed in regard to this description of fences, that on thin
folded stony surfaces, tall mounds are difficult to raise; and,
there, stone walls are not only built at a small expence,
but are convenient receptacles for the stones with which the
soil is encumbered. But a stone wall, unless it is carried up
to an inordinate height, at a great expence, is, he conceives,
useless as a screen-fence, and is laid to be dangerous as such
in a bleak, exposed situation; for as soon as the drifting
snow has reached the top of the wall, on the windward side,
it pours over it, and inevitably buries the sheep which may
be seeking for shelter, on the leeward side. It is therefore
conceived, that it is necessary that a stone fence should be
backed with a screen-plantation, in order to render it more
safe and effectual for the purpose.
It may be remarked, that these sorts of screen-fences should be more attended to by the proprietors of land in all exposed situations, as they have much effect in promoting the improvement of different sorts of live-flock in such exposures.

Screen-Plantations, and Planting, a term sometimes applied to such belts, clumps, or hedges, as are planted with a view of affording shelter in exposed situations. And Mr. Marshall, in his work on "Landed Property," considers the effect of such plantations, not merely that of giving shelter to the animals lodging immediately beneath them; but likewise in breaking the uniform current of the wind; shattering the cutting blasts, and throwing them into eddies; thus meiorating the air to some distance from them. And, moreover, he is of opinion, that living trees communicate a degree of actual warmth to the air which envelopes them. It is at least, he thinks, a probable truth, that where there is life there is warmth, not only in animal but in vegetable nature. The feverel frost rarely affects the sap of trees; it conseqently appears to him, that trees and shrubs, properly disposed in a bleak situation, tend to improve the lands so situated in a threefold manner for the purposes of agriculture: namely, by giving shelter to flocks, by breaking the currents of winds, and by communicating a degree of warmth or softness to the air in calmer weather, or when the seasons are more mild.

Besides, it is suggested that the proper disposal of screens in this intention, is in lines across the most offensive winds, and in situations bel calculated to break their force. Placed across valleys, dips, or more open plains in bleak exposures, they may, he supposes, be of singular use; and also on the ridges, as well as on the points and hags of hills, and other elevated places.

And in regard to the width of such screens, they ought generally, he thinks, to be regulated by the value of the land for agricultural uses, and the advantages of the situation for the sale and delivery of timber. In ordinary cases, it is conceived that from two to four stature poles may safely be considered as an eligible width for such purposes. With regard to the nature or species of plants which are most suitable, they must constantly be adapted to the given soil and situation. Mr. Marshall thinks, that in bleak and barren situations the larch will generally be found the most profitable as timber. But being deciduous, it does not in winter afford so much shelter as the common fir. A screen to shelter live-flock should be close at the bottom: it is otherwise injurious rather than beneficial. Not only the blast acquires additional current, but snow is liable to be blown through, and to be lodged in drifts on the leeward side, to the annoyance and danger of sheep that have reared it for shelter. A larch plantation margined with firs, and thofe headed at twelve or fifteen feet high, would, he supposes, afford the required shelter for a length of years. The firs, thus treated, would be induced to throw out lateral branches and feather to the ground; while the larches, in their more advanced state of growth, would, by permitting the winter's winds to pass through the upper part of the screen, break the current and mellow the blast, and in this way a complete shelter be provided; but in other more genial situations, the beech, by retaining its leaves in winter, especially while it is young, forms a valuable screen. And that, if the outer margins were kept in a state of coppice-wood, and cut alternately, and the middle ranks suffered to rise as timber-trees, the triple purpose of screen-plantations might, he imagines, be had in an eminent degree, and almost in perpetuity, with but little trouble. And in deep-foiled, vale districts, which not unfrequently want shelter, screens of oak might, he conceives, be managed in a similar way: and hollies, or other hardy evergreens, planted as underwood in groves of either of the above descriptions, would, if suitable situations were assigned to them, he supposes, affit much in this intention, especially where proper care was taken in planting and protecting them.

This sort of plantation, when first formed, should always be well suited to the nature of the exposure, both in respect to the kinds of the trees and plants which are made use of for the purpose, and the space or extent of the planting which will be necessary for effecting the business. In common, narrow slips never answer the intention in any perfect manner, as the trees neither rise well, nor afford the shelter which is wanted in such cases. See Shelter.

Screen-Bulkhead, in Ship-Building, the after-bulkhead under the round-house, when the ship has a walk, or balcony.

Screw, or Screw, Coehcle, in Mechanics, one of the six mechanical powers; chiefly used in rolling or squeezing bodies close, though sometimes also in raising weights. See Mechanical Powers.

The screw is a right cylinder, as A B (Plate XXXVIII. Mechanics, fig. 1.) furrowed spiral-wise; it is generated by the equable motion of a right line F G (fig. 2.) around the surface of a cylinder; while, at the same time, the point I descends equably from F towards G. Or, it may be conceived to be made by cutting a piece of paper into the form of an inclined plane, or half-wedge, and then coiling it round a cylinder; so that its action depends on the same principles as that of an inclined plane. The force tending to turn the screw round its axis may be considered as applied horizontally to the base of the wedge, and the weight which is to be raised as acting vertically on its inclined surface: the circumference of the cylinder will represent the horizontal length of the wedge; and the distance between the threads, measured in the direction of the axis, will be its height, provided that the threads be single; consequently, the forces required for the equilibrium are to each other, as the height of one spire to the circumference of the screw. But besides these forces, it is necessary that some obstacle be present, which may prevent the body, on which the screw acts, from following it in its motion round its axis; otherwise there can be no equilibrium. If the furrowed surface be convex, the screw is said to be male; if concave, it is female.

Where motion is to be generated, the male and female screw are always joined; that is, whenever the screw is to be used as a simple engine, or mechanical power; and when thus fitted together, they are sometimes called a screw and a nut. The nut acts on the screw with the same mechanical power as a single point would do, since it only divides the pressure among the different parts of the spire. When joined with an axis in peritrochial, there is no occasion for a female; but in that case it becomes part of a compound engine.

The screw cannot properly be called a simple machine, because it is never used without the application of a lever, or which, to assist in turning it. Sometimes the spires of the screw are made to act on the teeth of a wheel, when a very slow motion of the wheel, or a very rapid motion of the screw, is required for the purposes of the machine.

Screw, Doctrine of the. 1. If, as the compass, described by the power in one turn of the screw, is to the interval or distance between any two threads, or spiral windings, as B I (measured according to the length of the screw), so is the weight or resistance to the power; then the power and the resistance will be equivalent one to the other; and, consequently, the power being increased, so as to counteract the friction of the screw, which is very considerable, will overcome the resistance. For it is evident, that in one turn of
of the screw, the weight is so much lifted up, or the resistance so much moved, or the thing to be pressed is squeezed so much closer together, as is the distance between two immediate spirals; and in the same time, the power is so much moved, as is the compass described by the said power in one turn of the screw. Wherefore the velocity of the weight (or whatsoever answers thereto) will be to the velocity of the power, as is the said distance between the spirals to the compass described by the power, in one revolution or turning round of the screw; so that the gaining in power is here commended by the losses in time.

2. As the distance between two threads, BI, is less; the power required to overcome the said resistance is less; therefore the finer the thread, the easier the motion.

3. If the male screw be turned in the female, at right, a less power will be required to overcome the resistance, as the lever or feynta CD (fig. 3) is the longer.

4. The distance of the power from the centre of the screw, C D, the distance of the two threads I K, and the power to be applied in D, being given, to determine the resistance it will overcome: or, the resistance being given, to find the power necessary to overcome it.

Find the periphery of a circle described by the radius CD; then to the distance between the two threads, the periphery just found, and the given power; or, to the periphery found, the distance of the two threads I K, and the given resistance, find a fourth proportional. This, in the former case, will be the resistance that will be overcome by the given power; and, in the latter, the power necessary to overcome the resistance.

E. gr. Suppose the distance between the two threads, 3, the distance of the power from the centre of the screw CD, 25, and the power 30 pounds; the periphery of the circle to be described by the power, will be found 157. Therefore, as 3 : 157 :: 30 : 1570, the weight to which the resistance is equal.

5. The resistance to be overcome by a given power being given; to determine the diameter of the screw, the distance of the two threads I K, and the length of the feynta, or handle: the distance of the threads, and the diameter of the screw, may be assumed at pleasure, if the male be to be turned in the female by a handle. Then, as the given power is to the resistance it is to overcome, so is the distance of the threads to a fourth number, which will be the periphery to be described by the handle CD, in a turn of the screw. The femidiameter of this periphery, therefore, being sought, we have the length of the handle CD. But if the female screw be to be turned about the male, without any handle, then the periphery and femidiameter found will be very nearly that of the screw required.

E. gr. Suppose the weight 6000, the power 100, and the distance of the threads 2 lines; for the periphery to be passed over by the power, say 100 : 6000 :: 2 : 120; the femidiameter of which periphery being 3d of 120 = 40 lines, will be the length of the handle, if any be used; otherwise the side of the female screw must be 40 lines.

Mr. Hunter has described a new method of applying the screw with advantage in particular cases. Phil. Trans. vol. lxxi. part. i. p. 58, &c.

A cylindrical screw is bored, and made at the same time a tubular screw, with a little difference in the distances of the threads, so that when it is turned within a fixed nut, it rises or sinks a little more or less than the internal screw, which perforates it, would rise or sink by the action of its own threads; and a weight attached to this internal screw ascends, in each revolution, only through a space equal to the difference of the height of the two coils. Here the machine is analogous to a very thin wedge, of which the thicknes is only equal to the difference of the distances of the threads, and which of course acts with a great mechanical advantage. It might, in some cases, be more convenient to make two cylindrical screws of different kinds, at different parts of the flame axis, rather than to perforate it. The friction of such machines is, however, a great impediment to their operation.

Screw, Endless. If a screw be so fitted as to turn a dented wheel DF (fig. 4) it is called an endless, or perpetual screw, because it may be turned for ever, without coming at an end. From the scheme, it is evident enough, that while the screw turns once round, the wheel only advances the distance of one tooth.

Screw, Doctrine of the Endless. 1. If the power applied to the lever, or handle of an endless screw AB, be to the weight, in a ratio compounded of the periphery of the axis of the wheel EH, to the periphery described by the power in turning the handle, and of the revolutions of the wheel DF, to the revolutions of the screw CB, the power will be equivalent to the weight.

Hence, 1. As the motion of the wheel is exceedingly slow, a small power may raise a vast weight, by means of an endless screw; for this reason, the great use of the endless screw is, either where a great weight is to be raised through a little space; or, where a very slow gentle motion is required. On which account it is very useful in clocks and watches.

2. The number of teeth, the distance of the power from the centre of the screw AB, the radius of the axis HE, and the power, being given; to find the weight it will raise.

Multiply the distance of the power from the centre of the screw AB, into the number of teeth; the product is the space of the power passed through, in the time the weight passes through a space equal to the periphery of the axis. Find a fourth proportional to the radius of the axis, the space of the power now found, and the power. This will be the weight which the power is able to sustain. Thus, if AB = 3, the radius of the axis HE = 1; the power 100 pounds, number of teeth of the wheel DF 48; the weight will be found 14400; whence it appears, that the endless screw exceeds all others in increasing the force of a power.

A machine for shewing the power of the screw, may be contrived in the following manner. Let the wheel C (fig. 5) have a screw a b on its axis, working in the teeth of the wheel D, which we may suppose to be forty-eight in number. It is plain, that for every revolution of the wheel C, and screw a b, by the winch A, the wheel D will be moved one tooth by the screw; and, therefore, in forty-eight revolutions of the winch, the wheel D will be once turned round. Then, if the circumference of a circle, described by the handle of the winch, be equal to the circumference of a groove round the wheel D, the velocity of the handle will be forty-eight times as great as the velocity of any given point in the groove. Consequentially, if a line G goes round the groove a, and has a weight of forty-eight pounds hanging to it below the pedestal EF, a power equal to one pound at the handle will balance and support the weight. To prove this by experiment, let the circumferences of the grooves of the wheels C and D be equal to one another; and then, if a weight H of one pound be suspended by a line going round the groove of the wheel C, it will balance a weight of forty-eight pounds hanging by the line G; and a small addition to the weight H will cause it to descend, and so raise up the other weight. If the line G, instead of going round the groove...
groove $e$ of the wheel $D$, goes round its axle $I$, the power of the machine will be as much increased, as the circumference of the groove $e$ exceeds the circumference of the axle; and if we suppose it to be fix times, then one pound at $H$ will balance fix times $48$, or 288 pounds hung to the line on the axle; and hence the power or advantage of this machine will be as 288 to 1; i. e., a man, who by his natural strength could lift a hundred weight, will be able to raise 288 hundred, or $14.5^p$ ton weight by this engine.

Ferguson's Mech. edit. 4to p. 44.

SCREW. Archimedes', or the spiral pump, or as it is called in Germany, the water sail, is a machine for the raising of water, first invented by Archimedes.

Its structure and use will be understood by the following description of it. A B C D (Plate XIV. Hydraulics, fig. 11.) is a wheel, which is turned round, according to the order of the letters, by the fall of water $E F$, which need not be more than three feet. The axle $G$ of the wheel is elevated so as to make an angle of about $45^g$, or between $45^g$ and $60^g$, with the horizon; and on the top of that axle is a wheel $H$, which turns such another wheel $I$ of the fame number of teeth; the axle $K$ of this last wheel being parallel to the axle $G$ of the two former wheels. The axle $G$ is cut into a double-threaded screw (as in fig. 12.), and mustly resembling the screw on the axis of the fly of a common jack, which must be what is called a right-handed screw, like the wood screws, if the first wheel turns in the direction $A B C D$; but it must be a left-handed screw, if the screw turns the wheel contrary way; and the screw on the axle $G$ must be cut in a contrary way to that on the axle $K$, because these axes turn in contrary directions. Thence screws must be covered close over with boards, like those of a cylindrical cask; and then they will be spiral tubes. Or, they may be made of tubes of flax leather, and wrapped round the axles in shallow grooves cut therein, as in fig. 13. The lower end of the axle $K$ turns constantly in the screw that turns the wheel, and the lower ends of the spiral tubes are open into the water. So that, as the wheel and axle are turned round, the water rages in the spiral tubes, and runs out at $L$ through the holes $M$, $N$, as they come below the axle. These holes, of which there may be any number, as four or fix, are in a broad close ring on the top of the axle, into which ring the water is delivered from the upper open ends of the screw tubes, and falls into the open box $N$. The lower end of the axle $K$ turns on a gudgeon, in the water in $N$; and the spiral tubes in that axle take up the water from $N$, and deliver it into another such box under the top of $K$; on which there may be such another wheel as $I$, to turn a third axle by such a wheel upon it. And in this manner water may be raised to any given height, where there is a stream sufficient for that purpose to act on the broad float-boards of the first wheel. Ferguson's Mechanics, Supplement, p. 23.

An instrument of a similar nature is called by the Germans a water screw; it consists of a cylinder with its spiral projections detached from the external cylinder or coating, within which it revolves. This machine might not improperly be considered as a pump, but its operation is precisely similar to that of the screw of Archimedes. It is evident that some losses must here be occasioned by the want of perfect contact between the screw and its cover; in general, at least one-third of the water runs back, and the machine cannot be placed at a greater elevation than $50^g$; it is also very easily clogged by accidental impurities of the water; yet it has been found to raise more water than the screw of Archimedes, when the lower ends of both are imibed to a considerable depth; so that if the height of the surface of the water to be raised were liable to any great variations, the water screw might be preferable to the screw of Archimedes. Plate XIV. Hydraulics, fig. 14.

When a spiral pipe, consisting of many convolutions, arranged either in a single plane, or in a cylindrical or conical surface, and revolving round a horizontal axis, is connected at one end by a water-tight joint with an ascending pipe, while the other end receives during each revolution nearly equal quantities of air and water, the machine is called a spiral pump. It was invented about 1746, by Andrew Writz, a Pewterer at Zurich, and it is said to have been used with great success in Florence and in Russia; it has also been employed in this country by Lord Stanhope; and I have made trial of it (says Dr. Young) for raising water to a height of forty feet. The end of the pipe is furnished with a spoon, containing as much water as will fill half a coil, which enters the pipe a little before the spoon has arrived at its highest situation; the other half remaining full of air, which communicates the pressure of the column of water to the preceding portion, and in this manner the effect of nearly all the water in the wheel is united, and becomes equivalent to that of the column of water, or of water mixed with air, in the ascending pipe. The air near the joint is compressed into a space much smaller than that which it occupied at its entrance, so that where the height is considerable, it becomes advisable to admit a larger portion of air than would naturally fill half the coil, and this lessens the quantity of water raised, but it lessens also the force required to turn the machine. The joint ought to be conical, in order that it may be tightened when it becomes loose, and the pressure ought to be removed from it as much as possible. The loss of power, supposing the machine well constructed, arises only from the friction of the water on the pipe, and the friction of the wheel on its axis, and where a large quantity of water is to be raised to a moderate height, both of these resistances may be rendered inconsiderable. But when the height is very great, the length of the spiral must be much increased, so that the weight of the pipe becomes extremely cumbersome, and causes a great friction on the axis, as well as a strain on the machinery; thus, for a height of 40 feet, Dr. Young found that the wheel required above 100 feet of a pipe which was three quarters of an inch in diameter; and more than one-half of the pipe being always full of water, we have to overcome the friction of about 80 feet of such a pipe, which will require 24 times as much excess of pressure to produce a given velocity, as if there were no friction. The centrifugal force of the water in the wheel would also materially impede its ascent if the velocity were considerable, since it would be always possible to turn it so rapidly as to throw the whole water back into the spoon. The machine which Dr. Young had erected being out of repair, he thought it more eligible to substitute for it a common forcing pump, than to attempt to make any further improvement in it, under circumstances so unfavourable. But if the wheel with its pipes were entirely made of wood, it might in many cases succeed better; or the pipes might be made of tinned copper, or even of earthenware, which might be cheaper and lighter than lead. See fig. 15.

The centrifugal force, which is an impediment to the operation of Writz's machines, has sometimes been employed together with the prelure of the atmosphere, as an immediate agent in raising water, by means of the rotary pump. This machine consists of a vertical pipe, caused to revolve round its axis, and connected above with a horizontal pipe, which is open at one or at both ends, the whole being furnished with proper valves to prevent the escape of the water when the machine is at rest. As soon as the rotate
tion becomes sufficiently rapid, the centrifugal force of the water in the horizontal pipe causes it to be discharged at the end, its place being supplied by means of the press of the atmosphere on the reservoir below, which forces the water to ascend through the vertical pipe. It has also been propounded to turn a machine of this kind by the counter-pref- 

ture of another portion of water, in the manner of Parent's mill, where there is fall enough to carry it off. This machine may be so arranged, that, according to theory, little of the force applied may be lost; but it has failed of producing in practice a very advantageous effect. Young's Phil. vol. i.  

See Centrifugal Machine, and Wheel.

Screw, Bed or Barrel, a powerful machine for lifting heavy bodies; and, when placed against the grate of a ship to be launched, for slanting her. It consists of two large 
poppets, or male screws, having holes in their heads to admit levers to turn therewith, a bed formed of a large oblong piece of elm, with female screws near each end to admit the poppets, and a sole of elm plank for the heels of the poppet to work on. When used for launching of ships, the grate of the sole is inclined so as to stand square to the item or grate.

Hand-screws, or jacks, double or single, are used by hand to lift weighty bodies. It consists of an elm box, contain- 
ing cogged iron wheels, of increasing powers. The outer one, which moves the others, is put in motion by a winch or handle on the outside. They are called single or double, according to their increasing force.

SCRIBE, Scriba, 

f o p h er, derived from 

d f o p h er, ox, number, whence 

d f o p h er, letter, a principal officer in the Jewish law, whose business it was to write and interpret Scripture.

The Scribes, according to the etymological meaning of the term, were persons employed about books, writings, numbers, or accounts; in transcribing, reading, explaining, &c.

We find no mention of Scribes, in the Old Testament, 

before Ezra, chap. vii. 6, whence some learned men have con- 

dealed, that the office was brought from Chaldaea and 

Alyria, and first established by the Jews after their return from the Babylonish captivity. However, Ezra's being called a Scribe, which was a general title given to men of literature, will not prove the office of ecclesiastical Scribes, as it occurs in our Saviour's time, to have been so ancient. It probably grew up by degrees, after the spirit of prophecy ceased among the Jews; for when they had no prophet to resolve their doubts about doctrine or worship, they fell into disputes, and split into sects and parties; which made an order of men necessary, whole proper business it should be to study the law, that they might explain and teach it to the people.

The Scribes were in great credit and esteem among the Jews, and had even the precedence of the priests and sacrificers.

The Scribes are referred by most authors to two general classes: viz. civil, and ecclesiastical Scribes; the former were employed about any kind of civil writings or records, and the latter were such as addicted themselves to studying, tran-

scribing, and explaining the holy scriptures. Of the civil Scribes there were various ranks and degrees, from the com-

mon scrivener, or public notary or schoolmaster, to the prin-

cipal secretary of state. As for the ecclesiastical Scribes,

they were the learned of the nation, who expounded the law, and taught it to the people; and they are, therefore, sometimes called 

d o t o r o f t h e l a w , o r 

t r y m a n , 

d ayers. Compare Matt. xxii. 35, with Mark, xii. 28. 

These Scribes, who were generally Pharisees, were the preaching clergy among the Jews; and whilst the priests at tended the sacrifices, they instructed the people. But though the greatest part of the Scribes took part with the 

Pharisees, and adhered to their opinions and tenets, as we learn from the gospel-history, yet it is probably, from several passages of the New Testament, that some of them were of the sect of the Sadducees. Some of the Scribes made it their business to explain the traditions, which they called the oral law, that is, the law delivered by word of mouth, which, as they pretended, had been conveyed from Moses down to them, from generation to generation, by the tradition of the elders. They much respected these traditions, conferring them as the key of the law, and giving them the preference to the law itself. Hence this blasphemous maxim: "the words of the Scribes are more lovely than the words of the law of God." But it is evident, from the frequent reproaches pronounced by our Saviour on the Scribes and Pharisees in reference to this point, that under pretense of explaining the law by their traditions, they had actually made it of no effect. Matt. xv. 2, 3, 6. Mark, vii. 7, 8, 9. The Talmud will amply justify these reproaches. 

Jof. Scaliger endeavours to establish a distinction between the Scribes of the people, referred to by Herod, Matt. ii. 4, and the Scribes of the law. The former he considers as a sort of public notaries, who were employed in secular business; the latter as preachers and expounders of the law. But the phrase, Scribes of the law, no where occurs in scripture; and the Scribes of the people, whom Herod consulted, were applied to, on account of their skill in explaining scripture prophecies. (Matt. xvii. 10.) And they were probably called Scribes of the people, because they were the flated and ordinary teachers of the people. (Mark, i. 22. ) Camero observes, that a key was delivered to each Scribe, as a badge of his office, when he first entered upon it, to which our Saviour may be supposed to allude, Luke vii. 52.

Scribe, Scriba, was also the title of an officer among the Romans, who wrote decrees or acts, and made out authentic copies of them.

Their magistracy had his s trading, editor, or secretary; so that they were 

Scribes antiquity, proctor, quoctor, &c.

The Scribes were not admitted to the management of the principal offices of the republic, unless they relinquished their profession.

In the time of the emperors, they were also called notarii; because they made use of abbreviations, and short notes, in writing.

SCRIBERING, in Joinery, &c., a term used, when one side of a piece of fluff being to be fitted to the side of some other piece, which last is not regular; to make the two joint close together all the way, then scribe it.

That is, they lay the piece of fluff to be scribed close to the other piece they intend to scribe to, and open their com-

piles to the greatest distance the two pieces any where stand from each other; then, bearing one of the legs against the side to be scribed to, with the other point they draw a line on the fluff to be scribed. Thus have they a line on the irre-

gular piece parallel to the edge of the regular one; and if the fluff be wrought away exactly to the line, when the two pieces are put together they will seem a joint.

SCRIBONIUS LAREUS, in Biography, a Roman phy-

sician, who lived in the reign of Claudius, and is said to have accompanied this emperor in his campaign in Britain. He 

wrote
wrote a treatise "De Compositione Medicamentorum," which is very often quoted by Galen, and was "most impudently pilfegd and tranffcribed" by Marcellus the empiric, according to Dr. Freind. This work Scribonius dedicated to Julius Calliius, the most favoured of all the freed-men of the emperor; and he speaks of Mellafina and Claudius in a way which evinces that they were living at that time. After giving the formula of a dentifrice, he adds, "Mellafina Dei nostri Caferis hoc utitur." Great faith was, in that age, imputed in particular formulæ, or combinations of drugs, which were suppos'd to poffefs peculiar powers of healing; and it was the practice of many physicians to keep their compositions secret. Scribonius, however, published his collection, and expressed great confidence in their efficacy; but many of them are trifling and founded in superstition, and his practice seems to have been purely empirical. His language, too, is so much inferior in point of elegance to that of Celsus, who had written but a short time before him, and to the general character which the language still maintained in the reign of Claudius, that some learned men have suppos'd that Scribonius wrote his work in Greek, and that it was translated into the Latin drefs, in which it has descended to us, by some later hand. Rhodius, however, and some others, have shewn that his language has the air of originality; and it is remarked, that in his dedication to Calliius, he thanks the favourite for having forced the opportunity of serving him by presenting his medical works, written in Latin, to the emperor: "Scripta mea Latina medicinalia." It is remarkable, indeed, that two men, living about the same time, should write their native language so differently as Celsus and Scribonius; but the latter was probably a man of inferior education. The farceur of Freind is, however, not far from the truth. "Scribonius Largus, who cannot," he says, "well be reckoned any more than a mere empiric, though he wrote in the tone of the first Claudius, when the Roman language was in some tolerable degree of purity, ought, as I may lay, to be translated into Latin, in order to be understood by those who are conversant only with the classics of that age." The treatise of Scribonius has been several times rejected, and flands among the "Medice Aristo- principals" of Henry Stephens, 1567. See Freind's History of Medicine, vol. i. Sprengel, Geschichte der Arzneikunde, ii. Theil. Le Clerc, Hist. de la Medicine, p. 3.

SCRINIA, in Geography, a river of France, which runs into the Po, five miles N. of Tortona.

SCRIPTORIUM, a particular apartment in monasteries, where writers were employed in transcribing copies of works intended for preservation; and to their labour the cause of literature has been much indebted.

SCRIPTORIUS CALAMUS. See CALAMUS.

SCRIPTORIUM CALAMUS. See CALAMUS.

SCRIPTORIUM, among the Jews. See Caraites.

SCRIPTORIUM, among the Romans, the twenty-fourth part of an ounce, and equal to two oboli. See OBOLUS.

SCRIPTORIUS, a word used by some instead of ser- lupus, a scraping, or weight of twenty grains.

SCRIPTORIA, in Antiquity, the name of the revenue which the Roman people raised upon the paffure-lands, of which the property was in the commonwealth, and which was farmed to particular persons. It was so called, because the number of cattle, which individuals were to put into these paturages, was registered; and it was by that number the yearly sums which they engaged to pay were regulated.

SCRIPTORIA, or Scriptures. See BIble.

The collection of tracts, says the learned and judicious Vol. XXXII.
many ancient authors, which he illustrated by comments of his own: among these works were those of Vegetus, Fronto-
tinus, Hyginus, Apuleius, Martial, and Seneca the trag-
edian. Scriverius wrote a work in the Dutch language on
the "History of Printing," in which he maintained the
claim of Laurence Cotter to the invention of that invaluable
art. He published a collection of Batavian antiquities, and
other pieces relative to the early history of the united pro-
vinces. Scriverius, at the age of 74, lost the use of his
eyes, but he continued to solace himself with literature till
his death in 1666. His funeral was attended by the uni-
versity of Leyden in a body, and an oration was pronounced
over him by Frederic Gronovius. A collection of philo-
logical and poetical pieces from his MSS. was published
at Utrecht in 1737. Morei.

SCROBICULUS Cord., in Anatomy, the small
depression in the middle of the upper part of the abdomen,
just over the eniform cartilage. In common language it is
called the pit of the stomach.

SCROBILUM, in Ancient Geography, a promontory of
the Arabian gulf, which is supposed to have been the
Hercopolis and Elan-
nitic gulfs.

SCROFA, in Zoology, See Sus.

SCROFA, in Ichthyology, See Scorpaena.

SCROFA, in Entomology, See Scarabaeus.

SCROFANELLO, in Ichthyology, a name by which
some have called a small fish of the Mediterranean, more
usually known by the name of the scorpaena.

SCROFULA, or Scorophula, from scrofa, scrova,
called also fruma, or the king's evil, in Surgery. The name
of scorfula was derived from an opinion that swine were par-
ticularly subject to this disease. The scorfulous constitution
is observed to be, in many instances, denoted by partial
symptoms. The complexion is often fair, and the colour
of the hair either reddish, or of some other light tint;
people with dark complexions and black hair being much
less subject to scorfulous complaints. The skin is remarkably
soft and white, and the face often has a shining polished
smoothness. The cheeks are in general florid; and the
unica albuginea is frequently of a dead white colour, and
more pale than usual. The edges of the eye-brows are some-
times affected with a degree of tenderness which easily dege-
erates into a troublesome inflammation, that distresses the
patient by its continuance, and produces a disagreeable
degree of deformity. There is likewise frequently a swelling
of the upper lip, with some thickening of the hoqfris and
point of the nose. Rufell on Scorfula, p. 8.

One of the most frequent symptoms of scorfula is a swell-
ing in the superficial lymphatic glands, especially in the
neck. Such glands swell without any previous com-
plaint, and often attain a large size before the swelling at-
tracts notice. The swellings are frequently accompanied
with pain or discoloration; a circumstance which favours the
conclusion that the inflammation attendant on scorfulous
disease is flow, and the complaint of an indolent nature.

The frequency and great number of such tumours of the
lymphatic glands have led many surgeons to suppose scorfula
to be altogether a disease of the lymphatic system. Mr.
Rufell, however, entertains doubts respecting the accuracy
of the doctrine; for he observes that many other parts of
the body, which are not very glandular, are often the
primitive seat of scorfula. It is very frequently attacks
the joints of the extremities, the bones, and the mucous mem-
branes, without any previous or concomitant affection of
the lymphatic system. Besides, it is to be recollected that
the absorbent system is not only liable to idiopathic attacks
of scorfula, in common with the rest of the body, but is
likewise exposed to suffer symptomatically, in conquene-
ence of the disposition of the glands to swell and inflame from
any cause of irritation propagated along the course of the ab-
 sorbents; and from this source of error the commencement
of scorfula in the lymphatic system may be supposed more
frequent than what the natural proportion of idiopathic
cases warrant.

Scrofulous swellings of the glands are often stationairy, or
at least very slow in their progress of increase or diminution.
The same indolence and absence of inflammatory symptoms,
which characterize scorfulous swellings of the lymphatic
glands, likewise distinguish similar affections in other parts of
the body. The commencement of the attack is, in general,
unperceived, and the progress slow; though the tumefaction
which follows is frequently very considerable.

The greater number of scorfulous affections are accom-
panied with a preternatural swelling of the parts attacked.
The tumour is of two kinds, one remarkable for its softness,
the other of a more firm consistence. Soft scorfulous
tumours are always formed by the effusion of a fluid, and it
may be remarked that they are somewhat variable in their
size, being one day more prominent and tense, the next more
fleshy and flaccid. When they are opened in the early state,
they are found to contain nothing but a serous fluid, which
lies in the cells of the cellular membrane. As the fluid is
not contained in one common cavity, the tumour has a soft
flabby feel, and imparts to the fingers of a surgical examiner
no distinct sensation, either of elasticity or fluctuation.
But when the fluid has been for some time effused, a striking
difference occurs, a fluid lodged in a particular cavity now
being evidently perceptible. This change seems to proceed
from the diffusion of the partitions which are between the
cells of the cellular substance. As these collections, how-
ever, are not accompanied with any sensible degree of
inflammation, they are not surrounded with a firm, solid, cir-
cumferibed bafe; and they do not betray any great tendency
or ulcerate the skin, and burst of their own accord. Hence
they sometimes become very prominent, and the skin is gra-
dually dilated to a tumefying degree.

The matter contained in such tumours also undergoes a
change. After a time, the more solid parts are deposited
in the form of little masses, resembling congealed milk.
The remaining portion of the fluid is rendered thinner, and
resembles whey. A quantity of purulent matter is also formed
on the internal surface of the cavity, which seems to be
attacked with a flow kind of inflammation. The admixture of
this purulent matter greatly changes the appearance of the
contents of the tumour, and they now bear more resemblance
to those of a common abscess.

They never acquire, however, exactly the properties of
healthy purulent matter, being always thinner, more
transparent, and more of a greenish color.

Although the tendency to ulceration is not confiderable,
the skin at length gives way, and allows the matter to
escape through a narrow opening. After the contents are
evacuated, the tumour hardens; but there being in general
little disposition in the parts to heal, a scorfulous sore is
usually formed, which discharges a watery matter, and con-
tinues open for an indefinite length of time.

The other more firm kind of scorfulous swelling always
increases slowly, and is felt commonly attacks the neighbour-
hood of joints. The affected part enlarges, without ac-
quiring any circumferibed determinate form. By degrees,
the tumour becomes softer, and at last particular portions
near the surface become more prominent, inflame, suppurate,
burst, and discharge matter. But as the suppuration is
only partial, and the discharge inconsiderable, they have little
effect
SCROFULA.

In diminishing the size of the swelling, or in producing any other change of importance. The only difference occasioned is the addition of little ulcerations, which lead to sinuses, and emit matter.

A common abscess is in the presence of a scrofulous constitution often exhibits appearances, which betray the diseased state of the system. The matter first secreted is formed with extraordinary rapidity; the swelling is somewhat more transparent; the surface more shining, and the color of the tumour more blue, than is observable in a case of healthy abscesses. Scrofulous abscesses also contain, before they burst, a larger quantity of purulent matter, in relation to their size, than common phlegmonic abscesses. When abscesses in scrofulous patients burst, an empty cavity is not left; but there is seen a mass of cellular membrane apparently deprived of life. It resembles wet cotton, and often separates in the form of a solid mass. The separation is effected without pain. This state of the cellular membrane bears some remote analogy to the death of the central parts in a carbuncle; but it differs from the latter disease by there being no malignancy, pain, nor danger.

The bones of scrofulous people partake of the general disease in the constitution; they seem to contain a smaller proportion of the phosphate of lime, and a larger one of gelatinous matter, than what exists in the composition of a healthy bone. They are also exceedingly susceptible of morbid action. The particular changes, however, induced in the bones by scrofula, will be noticed in the articles Spine, Curvature of, and White Swelling.

With regard to scrofulous ulcers, their margin is commonly of a pale red or purplish cast, with a shining surface; the edges in general thin; and the surface of the sore sunk somewhat below the level of the surrounding parts. These fores are mostly attended but with a small degree of inflammation, and little pain; they are not very feable, and have no great disposition to spread. The matter discharged from them is white, having very little colour, and often an offensive smell. In consequence of its viscidity, it adheres to the surface of the sore, and covers the granulations. It is to be observed, however, that scrofulous ulcers sometimes assume a more malignant aspect, having elevated indurated edges, and fungous central granulations, accompanied with pain and an ichorous discharge. In these cases, they may counterfeit the appearance of cancerous ulcers; but though the resemblance may be very imposing, we are in general able to ascertain the real nature of the case, by tracing its history from the commencement, and by inspecting the rest of the patient's body with accuracy; when the veltiges of former scrofulous ulcers, or other proofs of a scrofulous constitution, often manifest themselves.

Scrofulous ulcers often continue to discharge for a long while, with very little change of appearance. In time, however, they begin to heal, and, for the most part, dry up altogether at last, leaving a very ugly red irregular cicatrix, upon which the skin seldom recovers its natural look.

In general, scrofulous complaints are most troublesome in the springs, and get better towards the end of the summer. Ruffell on Scrofula.

Scrofula has always been considered as an hereditary disease. Many well-informed men have thought the application of the term, hereditary, to scrofula, and indeed to diseased in general, exceedingly wrong, because the affections in question do not regularly descend from parents to children, and sometimes attack persons, none of whose relations are known to have had such diseases. That there is truth in these arguments must not be disputed. But it is at the same time certain, that the children of scrofulous parents are much more likely to be affected with scrofula, than the offspring of persons who never have had any symptoms of this disease. The children of scrofulous parents may, however, remain during life free from every mark of the disease. This fact is not at all questioned by such writers as employ the term hereditary; for the whole of their meaning is, that scrofulous parents more frequently have scrofulous children, than is the case with perfectly healthy parents. The offspring of the former, however, are not certain of being diseased in this manner; nor are the children of the latter sure of not being so.

Scrofula is undoubtedly not a contagious disease, nor can it be communicated by contact, or even inoculation. Ruffell tried to transfer scrofula from one person to another by inoculation; but although he took great pains to infest the matter completely, and repeated the experiment frequently, yet all his attempts failed, as no disease was communicated to the person inoculated, nor even any very evident irritation excited at the place where the matter was infested. De Vito Scrofulofo, p. 218.

The proximate cause of scrofula is a subject, concerning which many conjectures have been started; but none that appear to carry with them much probability. It is indeed a question, that is at present not at all understood.

Of all occasional causes, says Mr. Ruffell, climate is the most powerful. The extremes of heat and cold are equally free from scrofula. It prevails most in those climates, where the atmosphere is perpetually loaded with cold vapours; where the fea is variable, and no weather steady. From latitude 45° or 50°, to latitude 60°, is the principal climate of scrofula. The climate of Scotland, which is within this range, is remarkable for the frequent occurrence of scrofulous complaints. When the temperature of the air is just above the freezing point, the cold is the most difficult to bear, on account of the great quantity of watery vapours which float in the atmosphere. A greater degree of cold condenses the aqueous vapours, and renders the air clear: a greater degree of heat disperses them. Accordingly, it is an universal observation, both in the torrid and frigid zone, that perfectly dry air, whether produced by great heat, or great cold, always brings the most healthy weather. Mr. Dobson, in his account of the bar-mattan wind, which blows on the coast of Africa, and is so warm and dry as to accomplish the crystallization of pure alkali, observes, that all endemical diseases get well during the blowing of this wind. Mr. Graham, likewise, who was long governor of the Hudson's Bay factory, situated on the salt coast of America, about the 60th degree of north latitude, makes nearly a similar observation with respect to intense cold; as he invariably found, that the raw, cold, damp weather, when the mercury in Fahrenheit's thermometer stands between 30 and 40 degrees, was the most intolerable to bear, and the most unfriendly to health. Now this (continues Mr. Ruffell) is very nearly the winter weather of Scotland. Upon the whole, therefore, we may lay it down as a general maxim, that the greatest degree of cold, which can be conjoined with moisture, is the most which tends to favour the appearance of scrofula.

The long continuance of inclement weather increases the predilection to scrofula; and in persons already sufficiently predisposed to the disease, any uncommon, though temporary exposure to cold and wet, is often an exciting cause of an immediate attack.

Every thing which weakens the constitution, predisposes to scrofula. Thus, breathing impure air, and living upon a scanty allowance of unwholesome indigestible food, promote the accesse of scrofula. The fame may be laid of uncleanliness.
uncleanliness; neglect of salutary exercise; confinement in cold damp situations; and the want of sufficiently warm clothing.

But, one of the most frequent occasional causes of scrofula is external violence. Many accidents, which would not be followed by any serious consequence to a person in health, produce severe scrofulous affections in persons predisposed to these diseases.

It is almost unnecessary to mention, that all those circumstances which have been specified as occasional causes, must be avoided.

There is no medicine which, internally administered, has the power of completely correcting the peculiarity of constitution implied by the expression *scrofulosis habit.* But there are many medicines which seem to improve this state of the system, and to promote the spontaneous amendments, which flourish affections frequently undergo. Scrofulous patients, for the most part, have constitutions in which the natural actions do not proceed with vigour, and perhaps it is on this account, that every thing tonic is more or less useful in cases of scrofulous disease. This observation is not meant, however, to forbid the judicious employment of evacuations, which, when the habit is disposed to plethora and colletive, are indispensably necessary.

The medicines which are given for the cure, or prevention of scrofula, are either such as are supposed to act upon some general principle, or such as are supposed to affect a specific virtue in the cure of this distressful disease.

A draught of salt-water is recommended almost indiscriminately to every patient who is advised to use sea-bathing. It acts as a purgative, and proves a serviceable medicine, so far as purging is indicated. The water of the sea, however, is not nearly so palatable, as the solutions of many of the neutral salts, and its medicinal virtues do not appear to be superior. Hence Mr. Ruffell believes, that it is preferred rather from accidental convenience, than from its being in reality a better medicine than several others.

In some cases of hereditary predisposition, scrofula seems engraven on a constitution, otherwise healthy and vigorous, where the patient feels no weakness, has no disorder of the stomach, and at the same time has tendency to fulness and corpulency. In cases of this kind, a continued course of purgative medicines often proves highly beneficial by procuring a frequent and copious evacuation of the bowels, and thereby reducing that disposition to fulness, which very much promotes the formation of glandular swellings. But, in general, scrofula is not combined with the foregoing fort of constitution, and purgatives are then only useful for the purpose of obviating colletive.

Several mineral springs, besides saline ingredients, contain sulphurous impregnations, which are supposed to increase the medicinal virtues of the waters. The reputation of the waters of Harrowgate and Moffat is universally known. Mr. Ruffell acknowledges that their efficacy may have been over-rated; but he still thinks favourably of their effects in cases of scrofula.

Calomel, or, as it is now called, the hydrargryi submuras, is the most celebrated of all the purgative medicines, which have ever been employed in the treatment of scrofula. In order to derive the greatest benefit from it, however, it should not be given in so large a quantity as to produce the specific effects of mercury in their full extent; for, as Mr. Ruffell observes, a deep and lasting impression on the system aggravates every symptom of scrofula. Calomel, taken in moderation, contributes more than any other medicine to diffuse tumours, and resolve scrofulous indurations. An alternative course with this medicine, however, must be main-
SCROFULA.

eacy in changing the condition and forwarding the cure of certain malignant scrofulous ulcers, which counteract the appearance of cancer. He has likewise found it of service in promoting the cure of certain scrofulous affections of the tongue, which bore a near resemblance to some rare venereal ca\(c\)es. In a few cases, Mr. Ruffell has had reason to ascribe to it a share of efficacy in promoting the resolution of scrofulous swellings of the breast. The medicine must be given in as large doses as the constitution can bear. The head being affected with a degree of giddiness, and the stomach with a little nausea, is the criterion of the dose being sufficiently powerful.

The triturated barytes has been recommended by Dr. Crawford; but though it has been frequently exhibited, its reputation is far from being increased; a sure proof that its virtues were originally exaggerated.

The muratic of lime is another remedy that has been of late much talked of, for its good effects as a specific in cases of scrofula. In order to derive the utmost benefit from it, Mr. Ruffell is of opinion that it is necessary to prefer it in much larger doses than those which have usually been directed. One of the most successful instances of its efficacy was the confluence of an ounce of the saturated solution having been taken, for many weeks, three times a day. It well deserves attention, however, that professor Thomson employed muratic of lime in various cases of scrofula, without a single example of its having any efficacy. He admits that some patients got well, while under a course of muratic of lime; but then he had no reason to ascribe the cure to the effect of the medicine. In other cases, on the contrary, he found that the muratic of lime produced severe sickness and oppression of the head, and that the patients got worse, till the medicine was left off, and other remedies employed. The relief, experienced from the discontinuance of the muratic of lime, left no doubt with regard to the injurious effects which the use of it had produced; and from extensive experience and accurate observation, professor Thomson is satisfied that, in many cases of scrofula, the muratic of lime is attended with prejudicial effects.

With respect to the local treatment, stimulant applications are found not to be in general advantageous for scrofulous complaints. For ulcers, the mild saltpetre and mild dressings are the resort. When the patients are using a course of sea-bathing, it is usual to wash the sores with sea-water frequently every day. Cold spring water is likewise a favourite application; and experience seems to prove that the operation of cold is well suited to counteract the state of inflammation which accompanies scrofulous sores. Preparations of lead are employed, upon the whole, very convenient and useful applications, provided the solutions be used in a state of sufficient dilution to prevent irritation. Liquid applications are made by means of wet linen, which is renewed whenever it dries, so that the surface of the sore is kept constantly moist.

Upon the same principle, simple ointment and Gouland’s cerate are, in ordinary cases, the best dressings. The employment of simple applications and of cold, however, is more properly adapted to the mild and pure forms of scrofulous sores; for when they are more malignant, or combined with any other disease, a different mode of dressing becomes necessary. Venereal sores, for instance, breaking out in a person of a scrofulous constitution, partake of the nature of both disorders, and require correspondent treatment. Even a pure scrofulous sore, attended with more meviteracy than usual, may demand particular sorts of dressings, different from such as are found to be most proper for common cases. When the ulcer is extremely indolent, gentle stimulants may be necessary; and when there are fungous granulations, they must be destroyed by efficacies.

Those scrofulous swellings which contain a fluid, when they are superficial, and not connected with any parts of importance, are in general better left untouched. They are very slow in their progress, but they slowly burst at last by a superficial ulceration, which forms a small aperture. They do not often admit of resolution. The most likely applications for promoting this desirable object, are solutions of the acetate of lead, and of the muratic of ammonia.

The progress of the cure, after the tumour has discharged its contents, is very variable; though, upon the whole, it is slow, and the cure often incomplete. The sides of the cavity seldom adhere uniformly, or granulate from their whole surface; so that little partial separate cavities remain, which form sinuses, and continue to discharge matter, accompanied with some degree of pain and inflammation. At last, however, often indeed after a considerable time, the discharge ceases altogether, and the sore completely heals. When the sinuses continue for a long time, without any tendency to get well, it is sometimes proper to open them to the bottom with proper incisions; but in the generality of scrofulous cases, such practice is, upon the whole, feverish, disadvantageous, and even dangerous.

Scrofulous abscesses, when not large, need not to be opened; but deep-seated collections of matter, which increase gradually in size, without showing any disposition to make their way to the surface of the body, ought to be opened: for if this be not done, the matter spreads, and the disease acquires by degrees a dangerous extent. The opening should not be larger than what is sufficient for the complete evacuation of the matter; because a large opening excites great irritation, and is often the cause of violent inflammation of the whole wall of the abscess, attended with alarming, and often with fatal, consequences. The fever that occurs is accompanied with a rapid train of symptoms, which speedily end in death. In other instances, the fever is hectic, being more flow in its progress, though not less certainly fatal. According to Mr. Ruffell, sulphuric acid and saline draughts, in a state of effervescence, are the medicines which agree best with both forms of fever; and he observes, that neither of them seems to be much relieved by the use of cinchona. (P. 116.) This author recommends opening the tumour with a trocar, letting out the whole of the contents, withdrawing the cannula, and bringing the sides of the puncture together with flossing plaster. For our part, we prefer making the opening with a lancet, and then closing the wound with adhesive plaster, as advised by Mr. Abernethy in cases of phæo abscesses. See Phæo Abscess.

With respect to the treatment of swelled glands, it is to be remarked, that it is always desirable to prevent suppuration. When the glands are superficial, their progress may be influenced by topical applications; but when they are deep, they are scarcely capable of being affected by such remedies. In ordinary cases, Mr. Ruffell recommends the use of fomentations two or three times a day. Sea-water, vinegar, and water, dilute solutions of the acetate, or muratic of ammonia, and a decoction of chamomile, are eligible for remissions. Friction with camphorated and ammoniated oils, and with marine plants, has also been well spoken of.

In such cases, Mr. Ruffell, however, does not place much confidence in external applications, as he considers that the cure chiefly depends upon the state of the constitution, upon regimen, and the effect of internal remedies.
When enlarged glands, which lie superficially, are attacked with inflammation, and in danger of suppurating, Mr. Russell strongly recommends the frequent use of topical bleeding. This author is also an advocate for blisters, both at the commencement of the inflammation, and on its decline.

When the swelled glands suppurate, and healthy inflammation predominates, the case must be treated nearly in the same way as a common abcess. An artificial opening is hardly ever necessary, as the abscess in a short time bursts of itself. The only influence, in which the surgeon is called upon to open the swelling, is when the matter flows a tendency to spread over a large space. When the suppuration is completely suppurative, a small opening is at length spontaneously formed, through which all the matter is discharged. The aperture, though always small at first, sometimes becomes larger, and frequently it remains for a long while nearly in the same state, shewing little disposition to heal, acquiring a gloomy appearance, and becoming thick and callous at its edges. In the end, however, a cicatrix is mostly produced.

In cases of indolent, stationary, scrofulous swellings of glands, where there is no hope of resolution, it has been proposed to remove or destroy the diseased glands by excision, or by the application of cautery. Such practice has been particularly suggested for glandular swellings of the neck. The superficial situation of the glands of this part of the body rendering them very apt to be affected by cold, the vicissitudes of the weather, and other external circumstances, they must be subject to temporary impressions. The frequency with which they swell, and the facility and facility with which they sometimes subsist, afford strong arguments against an operation in recent cases. In other examples, where the affection has existed long, it often happens that other more deeply seated glands are also diseased, so that the removal of an enlarged superficial cervical gland would prove a very partial and useless operation, and would do nothing towards the total extirpation of the disease.

As for the mere removal of deformity, this is not an adequate reason for the operation, which would itself be followed by a fear, that must disfigure the part quite as much as the swelled gland could possibly do. We will say nothing of the danger and difficulty with which, in many cases, such an operation would be attended.

The attempt to destroy a scrofulous gland in the neck with cautery would be liable to objections, fully as strong as those which are applicable to the use of the knife. The action of cautery can never be regulated with much precision, and the cicatrix, produced in this manner, is always a considerable deformity.

Firm scrofulous tumours in the more external parts of the body do not usually require local bleeding, unless attended with symptoms of inflammation. It is chiefly in the early stage of such cases that the practice is advantageous. In general, warm fomentation, stimulants, infusions, and blisters repeated, or kept open with the favour ointment, are the most eligible remedies. Here also the employment of friction as a sufficient deferves particular recommendation. Its safety, simplicity, and efficacy, are now well acknowledged. There is no substance interposed between the surface of the swelling, and the hand of the person who is employed in rubbing it, except a little flour to prevent the skin from becoming chafed. The friction is to be applied two or three hours a day, and the plan continued for some months.

Permanent compression by means of tight bandages, or long strips of adhesive plaster, is another means of reducing the indolent scrofulous induration and thickening of parts. But of this practice, and of dry rubbing, or friction, by the hand, we shall have occasion to speak in a future volume. See White Swelling.

When a scrofulous disease is circumscribed and incurable, and attended with so much pain and irritation, as to injure the health in a feverish and dangerous degree, the removal of the part by an operation becomes indispensabile. The symptomatic enlargement of the lymphatic glands, which are nearer than the diseased to the heart, presents no solid objection to such practice; for this enlargement proceeds from irritation, and not from absorption; and the glands often subside, as soon as the original cause of their swelling is removed. Russell on Scrofula, p. 137.

SCROGS, in Rural Economy, a term provisionally applied to such thunted thrubs as have been browsed upon by cattle, as hazel, &c. They are mostly met with on commons and waffle lands.

SCROLL, in Heraldry, is the ornament placed under the escutcheon, containing a motto or short sentence, alluding sometimes to the bearings, or the bearer's name; sometimes expressing somewhat divine or heroic; sometimes enigmatical, &c. It is often placed by the French and Scotch above the achievement; which, according to Sir J. Mackenzie, is right, when the motto relates to the crest; otherwise it should be annexed to the escutcheon. Those of the order of knighthood are generally placed round shields. See Escrol.

SCROLL, in Ship-Building, is a spiral moulding of the volute kind, used sometimes at the druffs, and the upper part of the hair-bracket. A scroll-head signifies that there is no carved or ornamental figure at the head, but that the termination is formed and finished off by a volute, or scroll turning outwards. If the scroll is turned off, or inwards, it is then called a fiddle-head.

SCROON, in Geography. See SCAROON.

SCROPHULARIA, in Botany, an old name, supposed by some to have been given to the herbs of this genus, because swine, scrof, were fond of them. But the most probable derivation is from scrophula, the king's evil, for which disease some of them have been recommended as a cure; especially Scrophularia nodosa, whose knobby roots, compared to scrofulous tumours, are thought to have given rise to that opinion. Yet there can be no doubt that one of this genus is the real genus of Dioscorides, as Fuchsius, and some other old botanists, have maintained, which original Greek writer on the materia medica celebrates for its virtues in the above-mentioned complaints, and even in cancerous ulcers. Yet his identical species, our Scrophularia peregrina, has no knobby roots. It is probable therefore that the above explanation is of more modern date, and it may account for the etymology of Scrophularia, if not for the application of the herb to medical use. The Gelenchus of Fuchsius is indeed Scrophularia nodosa; Anguillara being, as far as we can find, the first writer on drugs who fixed upon the precise plant of Dioscorides, Scrophularia peregrina, and whose opinion is confirmed by the recent enquiries of Dr. Sibthorp. — Linn. Gen. 212. Schreb. 408. Willd. Sp. Pl. v. 3. 269. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 662. Prod. Fl. Græc. Sibth. v. 1. 435. Ait. Hort. Kew. v. 4. 22. Pursh v. 2. 419. Juff. 119. Tourn. t. 74. Lamarck Dict. v. 7. 27. Illrus. t. 533. Gerani. t. 53. Clas. and order, Didynamia Augitofermia. Nat. Ord. Proftanae, or rather Lr. Linn. MSS. Scrophularia, Juff.

Gen. Ch. Cal. Perianth of one leaf, inferior, with five rounded segments shorter than the corolla. Car. of one petal, unequal, revered; tube globoso, large, inflated; limb very small, five-cleft; its two lower segments (turned uppermost)
SCROPHULARIA.

uppermost) largest, erect; two lateral ones spreading; the odd one (turned downwards) reflexed. Stam. Filaments four, linear, the length of the corolla, declining towards its lower segment, two of them later than the others; anthers two-lobed. Pith. German ovate; style simple, agreeing in length and position with the filaments; stigma simple. Peric. Capsule roundish, pointed, of two cells and two valves, bursting at the top; partition double, formed of the inflated edges of the valves. Seeds numerous, small. Capsule roundish, protruding into each cell.

1. S. marilandica. Maryland Fig-wort. Linn. Sp. Pl. 863. Willd. n. 1. Ait. n. 1. Pursh n. 1. (S. nodosa, americana; Michaux Borell-Amer. v. 2. 21.)—Leaves heart-shaped, doubly ferrated, acute, smooth; decurrent at the base. Stem with blunt angles. Footstalks connected by a hairy line.—In low grounds, from Pennsylvania to Carolina, flowering from June to August, perennial. Flowers greenish-brown. Plant often more than four feet high. Pursh. Mr. Miller is said to have cultivated this herb, but it is scarcely to be met with in gardens, nor could it be expected to engage much attention, being to like other common species, carefully weeded out of all gardens. What we have been shown for it, in collections of primary authority, was S. peregrina. Michaux unites it with the following, but Linnaeus appears correct in distinguishing it. Besides the greater size of marilandica, its leaves are doubly, and far more coarsely, ferrated; their base, though heart-shaped, not cut away to the lateral ribs, but decurrent along the footstalk. An elevated hairy line runs across the stem, from the insertion of one footstalk to the other.

2. S. nodosa. Knotty-rooted Fig-wort. Linn. Sp. Pl. 863. Willd. n. 2. Fl. Brit. n. 1. Engl. Bot. t. 1544. (S. major; Ger. Em. 716. Scrophularia; Riv. Monop. Illr. t. 107. f. 1; also S. minor; ibid. suppl.)—Leaves heart-shaped, acute, nearly equally ferrated, smooth; three-ribbed at the base. Angles of the stem acute.—Native of woods and hedges, in dry, rather fertile, places, throughout Europe, flowering in July and August. The root is perennial, tuberous, whitish. Stem two or three feet high, erect,imple, leafy, smooth. Leaves opposite, falcate, nearly and acutely ferrated; of a shining dark green above; paler beneath. Flower-flats axillary and terminal, forked, angular and glandular, purplish, with lanceolate bracteas, and all together composing a compound, terminal, upright clusfer, or panicle, interspersed with a few leaves. Calyx smooth. Corolla dull green, with a livid purple, or brownish, lip, bearing a small internal appendage. The whole herb, when bruised, has a fetid scent, something like Elder, which is common, under various modificatians, to the whole genus.

This species is mentioned, by several authors, as varying occasionally with green flowers, of which we have seen an instance; as well as with three leaves together, instead of two.

3. S. aquatica. Water Fig-wort, or Water Betony. Linn. Sp. Pl. 864. Willd. n. 3. Fl. Brit. n. 2. Engl. Bot. t. 854. Curt. Lond. fac. 5. t. 44. Fl. Dan. t. 507. (Betonica aquatica; Ger. Em. 715.)—Leaves heart-shaped, falcate, deciduous, obtuse. Stem winged.—Native of watery places; about the banks of lakes and rivers, from England to Greece; very rare in Scotland, and the northern parts of Europe; flowering in July. The root is fibrous, and, we believe, perennial, though Linnaeus says biennial. Whole plant larger than the last, and distinguished by the membranous edges of its stem, as well as blunt leaves.

Cluster terminal, compound, bracteate, without leaves. Calyx bordered with a white membrane. Lips of the corolla of a deep blood-colour, with the fane small intermediate lobe as in the former. Herb fettid, smooth.

4. S. auriculata. Ear-leaved Fig-wort. Linn. Sp. Pl. 864. Willd. n. 4. Ait. n. 4.—Leaves oblong-heart-shaped, doubly ferrated; downy beneath; with a pair of leaflets at their base. Cluster terminal.—Native of Spain, from whence it seems Loebligent feeds, which produced the specimen in the Linnaean herbarium. This specimen appears to us a mere variety of S. Scrodonia, with accidentally auricled leaves; whereas the synonym of Lobel represents a precisely parallel variety of S. aquatica. The figure we have cited above, from Ger. Em. 715, is the flower of Lobel's. Barrether's t. 274 has not the character of the auricled leaves, and the foliage is all too long for the Scrodonia; see betonicae foliis hereafter, n. 6. S. auriculata may therefore, if we mistake not, be reduced to a variety of the following species. We have not examined Mr. Aiton's plant, sent to Kew by Richard, in 1772. Scopoli's auriculata, Fl. Carn. t. 32, is most assuredly very different.

5. S. Scrodonia. Balm-leaved Fig-wort. Linn. Sp. Pl. 884. Willd. n. 6. Fl. Brit. n. 3. Engl. Bot. t. 2209. (S. Scrodonia foliis; Morif. sect. 5. t. 35. Plk. Phyt. t. 59. no. 5.)—Leaves heart-shaped, doubly ferrated; downy beneath. Cluster leafy.—Native of watery swampy places in Jersey and Cornwall, as well as in Portugal and Italy, and near Constantinople, flowering towards autumn. Root perennial, fibrous. Stems two to four feet high, square, leafy, clothed, like the backs of the leaves, with soft spreading hairs. Leaves opposite, falcate, acute, various in size, veiny; three-ribbed at the base, like S. nodosa. Flower-flats axillary and terminal, doubly forked, confluent at a terminal leafy clusfer, clothed with capitulate glandular hairs. Flowers rather small, of a paler more vivid hue than in our more common species, their intermediate, or acceller, lobe green. Calyx downy, obtuse. Capsule smooth.

6. S. betonicae. Betony-leaved Fig-wort. Linn. Mant. 87. Willd. n. 8. Ait. n. 7. (S. betonicae folio; Tourn. Infl. 166. S. aquatica montana mollior; Barrel. Ev. t. 274.)—Leaves heart-shaped, oblone, somewhat downy, doubly toothed; veins radiating from the base. Panicle leafy. Calyx downy.—Native of Portugal. Cultivated by Linnaeus at Upsal. Root perennial. Stem two feet high, square, slightly downy, purplish, especially at the bottom. Leaves all simple, rather large, acute, broad at the base, strongly and sharply toothed, each tooth again notched or ferrated, even in the original specimen; nor do we comprehend the description of Linnaeus, where he says "the teeth are quite entire, and therefore very like F. foliis. Flower-flats branched and forked, rough with glandular hairs, and accompanied by toothed leaves. Corolla dull purple; its little lip, or acceller, lobe, greenish.—This is nearly akin to the last, but we have little doubt of their being distinct species. Barrether's figure is as good as most of his, and tolerably expressive. What he represents as leaves on the stalk of his separate leaf, and which originally perhaps led Linnaeus to quote this plate for his own auriculata, are probably small axillary leaves only.

7. S. nupetris. Catmint-leaved Fig-wort. (S. auriculata; Scop. Carn. v. 1. 446. t. 32.)—Leaves heart-shaped, obtuse, nearly smooth, simply ferrated, on short broad foot-flats. Clusfer leafless. Bracteas lanceolate. Calyx smooth. Gathered by Scopoli on the mountains of Carniola. We have a specimen, found by the late Dr. Brouillon at Tangier, flowering in June, which answers exactly to Scopoli's description, and seems not referrible to any of the species in Linnaeus.
Linnaeus or Willdenow. In this the leaves are about an inch long, on broad, flat, smooth stalks, a quarter of that length, along which the two lateral ribs are continued, by the side of the midrib; the margin of the leaf is neatly, regularly, and acutely serrated. Clusters erect, long, quite naked, except the lanceolate bracteas; its pedicels forked, rough, with glandular hairs. Segments of the calyx ovate, obtuse, smooth, bordered with a broad white membrane, within which the margin is of a brown or rusty hue, as Scopoli describes it. He says the corolla is yellow.

9. S. petraea. Flat-leaved Fig-wort. Linn. Sp. 866. Wildl. n. 26. Alt. n. 18. Camer. Hort. 157. t. 43. Sm. Fl. Græc. Sibth. t. 597, unpublished. (S. folio urtic.; Baum. Pin. 233. S. eretica altera; Haff. Hilt. v. 2. 210.)—Leaves heart-shaped, acute, finely serrated, smooth and shining. Stalks axillary, two or three-flowered. Bracteas lanceolate. Calyx acute.—Native of Italy and Crete. Very common about hedges, paths, and courtyards throughout Greece, as Dioscorides describes his Græcicus to be. We cannot but accord to the opinion of Anguillara, Fuchsius, and Sitnorph, that this, and not our Galeopsis, was the plant. The root is fibrous, annual, or biennial. Stem two or three feet high, not much branched, occasionally with five or six angles. Leaves of a dark shining green, an inch or more in length; we cannot agree with Willdenow that the upper ones are generally entire, though such an accident may occur; as the upper part of the stem, now and then, in gardens, becomes elongated, and the foliage in that part diminished in size; but this is rarely the case. The natural state of the plant is to have axillary flowers in stalks from near the bottom of the stem to the top; each bearing two, three, rarely more flowers, whole tube, as well as the limb, is of a blood colour, and the segments of the calyx are ovato-lanceolate, with sharp points, and without membranous edges. The flowers, stalks, like the leaves which they accompany, are more or less distinctly alternate, rarely opposite. We have taken the liberty to remove this species from the end of the genus, to place it near thence to which, both on account of its simple leaves and general habit, it is most closely allied. In doing this we shall here notice three others, which conclude the genus in Willdenow. Two of these, at least, require to be totally expunged, and the third, if it has any right to remain, must stand next to peregrina.

S. chinesis. Linn. Mant. 250, consists of an imperfect specimen of what seems to be an Ocyum, accompanied by a still more imperfect branch of what may be a Céfia, or Verbæcum; but neither of them has any thing to do with Scrophularia, nor was Linnaeus, when he originally described these specimens, at all satisfied about them.

S. meridionalis. Linn. Suppl. 280, sent by Mutis, is indubitably the same genus, and very nearly the same species, as Hemimeris urticifolia, Wildl. Sp. Pl. v. 3. 282, Alnifia incisifolia, Alt. Hort. Kew. v. 4. 27. The capitate only forms a little more elongated, and the leaves less deeply cut, than in our garden plant; see Hemimeris. The shape of the calyx is indeed important in distinguishing the species of this genus. We are at a loss to distinguish Alnifia from Hemimeris.

10. S. coccine. Scarlet Fig-wort. Linn. Sp. Pl. 866. Willd. n. 25.—Leaves ovate, four in a whorl. Flowers whored, fuscous.‘—Native of Vera Cruz. Houttoun lent an account of this plant to Miller, by the name of S. flori coccine, folis urtic. quaterni cautum undulatis. Hence probably this definition reached Linnaeus, and it was all lie ever knew of the plant, for he had no specimen. We should not be surprised if it proved another Hemimeris, which Houttoun might very excusably take for a Scrophularia. We now return to more certain species.

11. S. orientalis. Hemp-leaved Fig-wort. Linn. Sp. Pl. 864. Wildl. n. 9. Alt. n. 8. “S. Scholzii Handb. v. 2. 196. t. 173.” (S. orientalis, folis cannabinis; Tourne. Cor. 9.)—Leaves lanceolate, harshly serrated, opposite or whorled; auricled at the base. Clusters, leafy, with hoarded, coriaceous, downy, vivid branches. Flowers drooping. Calyx smooth, obtuse.—Native of the Levant; sometimes seen in botanic gardens. The root is perennial. Stem with four, or more, acute angles, leafy. Leaves often five or four in a whorl, widely spreading, forked, or four or five inches long and one broad, smooth, copiously deeply, and rather unequal, serrated, either sharply lobed, or furnished with a pair of lanceolate serrated leaflets, at the base. Clusters terminal, long, erect, its branches either opposite, or more usually three or four in a whorl, forked, many-flowered, rough with glandular hairs, and furnished with linear bracteas, but no leaves. Flowers greenish.

12. S. lanceolata. Lanceolate American Fig-wort. Pursh n. 2.—Leaves lanceolate, pointed, unequally serrated; acute at the base. Footstalks without appendages. Branches of the panicle coriaceous.‘—In wet meadows and woods of Pennsylvania, flowering in August and September. Perennial. Flowers greenish—yellow. Pursh. This seems nearly related to the last, to which the author has not adverted. We have seen no specimen.

13. S. altaica. White-flowered Fig-wort. Murr. in Comm. Gott. v. 4. 35. t. 2. Wildl. n. 13. Alt. n. 10.—Leaves heart-shaped, nearly smooth, doubly toothed, somewhat lobed; the lower teeth turned towards the base. Clusters terminal, compound. Bracteas lanceolate, Calyx acute.—Native of the Altai mountains of Siberia. Introduce into our gardens by Mr. Hunnemann in 1786, where it proves a hardy perennial, flowering in May and June. The stem is furred, one or one and a half feet high, obscurely angular, scarcely branched. Leaves on long stalks, of a broad roundish—heart-shaped figure, with strong branching ribs, plant, nearly smooth, somewhat siniuted, harshly toothed. Flowers pale yellow, or white, larger than the following, from which they are essentially distinguished by the lanceolate acut segments of their calyx.

hairy beneath. Flower-flats all axillary, about as long as the leaves, bearing some small opposite serrated leaves, and a few lanceolate entire bracteas. Flowers numerous, pale yellow, with a large globose tube, contracted at the mouth, and a very minute limb, the length of whose segments is not nearly equal to the diameter of the tube. Segments of the calyx deep, elliptical, obtuse, downy, without any membranous border. A striking resemblance between the habit and flowers of this plant, and the Peruvian genus Calceolaria, is pointed out by English Botanists.

15. S. arguta. Slender Upright Fig-wort. Ait. n. 12. Willd. n. 15.—Leaves heart-shaped, doubly serrated, smooth. Flowers isolated, axillary, forked, leafy. Bracteas linear. Calyx obtuse. Limb of the corolla nearly equal to the tube.—Gathered by Mr. Maffon in Madeira and Teneriffe. An annual greenhouse plant at Kew, flowering in May and June. Root fibrous. Stem two feet high, erect, angular, smooth in the lower part. Leaves an inch or less and half long, sharply and deeply serrated. Flowers, few, in the upper part of the stem, downy and rather villose. Flowers small, red, their limb bearing its usual proportion to the tube. Caulis ovate, pointed, as in the last, but febrilis half fo large.

16. S. trifoliata. Three-leaved Axillary Fig-wort. Linn. Sp. Pl. 865. Willd. n. 16. Ait. n. 13. (S. fimbriolata, flore rubro luteo vario paluro; Grill. Virid. Lufit. 75. Pluk. Alm. 73. Pl. t. 313. f. 6.)—Leaves serrate, roundish, coarsely serrated; the lower ones ternate. Stems axillary, about three-flowered. Segments of the calyx orbicular, with a wavy membranous margin.—Native of Barbary, Corsica, and Portugal. A hardy biennial, sometimes met with in curacious gardens, flowering in summer. Stem about a foot high, febrilis branched, leafy, nearly smooth, thick, with four blunt angles. Leaves opposite, enlarged, flexible and glabrous, about two inches long, and nearly as broad, bluntish, veiny; many of the upper ones quite simple; the root accompanied by a pair of smaller leaflets, more or less distinct or remote, at the top of the footstalk, which is about an inch long. Flowers all axillary, large, two or three on each stalk, which is shorter than the footstalk, rough, with glandular hairs, and bears several linear-lanceolate bracteas. Calyx glabrous, smooth, with peculiarly round, deep, broad-bordered segments. Corolla half an inch long, pale yellow, with an orange or rose-coloured limb.

17. S. appendiculata. Three-leaved Clustered Fig-wort. Jacq. Hort. Schonbr. v. 3. 19. t. 286. Willd. n. 6. (S. lavigata; Vahl. Symb. v. 2. 67. S. trifoliata; Desfont. Atlant. v. 2. 54.)—Leaves smooth, heart-shaped, doubly serrated and bluntly serrated; the lower ones ternate. Clusters terminal, leafy, compound. Segments of the calyx orbicular, with a wavy membranous margin.—Native of the borders of fields, and the neighbourhood of the sea-shore, in Barbary. We gathered it in August 1866, in the royal garden at Paris, where it was raised from seeds brought by professor Desfontaines, but have not seen the plant in England. The root is said to be perennial. Plant entirely smooth, of a light glaucous green, larger than the leaf, to which it is most nearly akin, though essentially different; particularly in its racemose compound inflorescence, and heart-shaped, doubly toothed or serrated, leaves, with longer footstalks. The flowers are very similar.

verbenaefolius; Tourn. Infl. 167. S. peregrina frutecens, folis tenuei crassifolius; Herm. Lugd. Bat. 545. t. 547.)

19. S. rapelris. Rock Fig-wort. Willd. n. 11. "Leaves oblong, falcated, toothed, nearly smooth. Clusters terminal. Stalks three-flowered."—Gathered by the celebrated botanical traveller Marshall of Beverley, on the rocks of Taormina. Wildenow, to whom specimens were sent, says this plant is very nearly related to S. frutescens, of which it is perhaps only a variety; but it differs in having a stem only half a foot high, and very finely downy; leaves all falcated, more rigid, and of a smaller size; a terminal cluster, composed of three-clf three-flowered stalks; and small, obtuse, not acute, bracteas.

20. S. caesia. Sea-green Dwarf Fig-wort. Sm. Prod. Fl. Grac. Sib. n. 1460. Fl. Grac. t. 624, unpublished. (S. orientalis minor, melastema folio; Tourn. Cor. 9.) Buxb. Cont. 5. 16. t. 17. f. 2.)—Leaves smooth, rather glaucous, lyrate, finely serrated, cut. Stems numerous. Clusters short; branches two or three-flowered. Gathered by Dr. Sibthorpe on rocks about Athens and Melissa; as well as in Laconia. The root is perennial, thick and woody. Stems very numerous, somewhat fuscous at the base, spreading in all directions, a span high, leafy, febrilis branched but at the bottom, bluntly quadrangular, smooth. Leaves opposite, falcated, an inch and half long, sharply cut and toothed, of three principal lobes, one of them very large and pinnatifid, the others smaller, besides one or two very small ones below, mostly entire. Clusters or panicules two or three inches long, with entire oblong bracteas; its branches opposite, simply forked, their lateral branches single-flowered, and one of them often deficient. Segments of the calyx orbicular, smooth, with a white membranous edge. Tube of the corolla inflated, greenish, brown on the upper side, two longer segments of the limb chocolate-coloured, the rest greenish-white. We can but guess at the synonyms. The leaves are not much like basil, Melissa. Buxbaum's rude figure is not unfitted to our plant.

Lower leaves interruptedly pinnate; upper ternate; leaffets...
leaflets heart-shaped, ferrated, smooth; unequal at the base. Flower-flanks axillary, slightly branched.—Native of the south of Europe, Barbary, and the Levant, in sandy ground. The roots are tuberous, according to Alpinus, perennial, but subject to rot in a garden soil. Herb thick, smooth, succulent, of a light glaucous green. Leaves opposite, or somewhat alternate, irregularly, more or less sharply, ferrated, varying much in size and bluntness. Flowers very large, axillary, drooping; their flasks usually shorter than the flower-flanks, simple, divided, or forked; sometimes elongated towards the upper part of the branch, and the leaves being occasionally contracted, or wanting, there, the inflorescence becomes racemose. Calyx smooth, or slightly downy; segments orbicular, with a membranous edge. Corolla of a pale purplish tawny hue, with a greenish limb. Capitate as big as a small forbid, with a conical point.

We can find no decisive character between the two plants of authors, which we have here combined. The leaflets of \( \theta \) are commonly more rounded or obtuse, but a comparison of the figures of Miller and Desfontaines will show that there is no difference in their inflorescence. A specimen from Barbary, given us by the botanist left mentioned, is \( \textit{Sambucus} \), which not being mentioned in his work, he plainly did not distinguish from his \( \textit{mollifera} \). Those who have mentioned these two supposed species, have not contradicted them with each other, nor have we had an opportunity of comparing them in a living state; but it is to be presumed the fame honey-bearing glands are to be found in the bottom of the corolla of each, they being in every other respect so much alike.

22. \( \textit{S. hipida} \). Hipid Fig-wort. Desfont. Atlant. v. 2. 55. Wildl. n. 19. "Stem square, erect, hipid. Leaves villous, pinnate, doubly crenate; the terminal lobe heart-shaped, very large. Cluster compound, leaflets."—Native of the cliffs of rocks on mount Atlas, near Tlemcen. Root perennial. Stem erect, firm, slightly branched, about two feet high, hipid with very abundant short hairs. Leaves opposite, on short flanks, two to three inches long, and above half as broad, villous, soft and hoary, of a few small ovate leaflets, often cut away at the upper edge, besides the large, sometimes lobed, terminal one. Cluster terminal, six or eight inches long; its branches opposite or alternate, subdivided, hairy. Bracteas linear. Calyx smooth, with rounded membranous-edged segments. Corolla the size of \( \textit{S. nodosa} \). Desfontaines.

23. \( \textit{S. canina} \). Wing-leaved Fig-wort, or Dog's Rue. Linn. Sp. Pl. 865. Wildl. n. 20. Ait. n. 16. Sm. Fl. Græc. Sibth. t. 598, unpublished. (S. saxatilis lucida, laceritvel magniflens folius; Tourn. Infl. 167. Bocc. Muf. 166. t. 117. S. indica; Ger. Em. 716? S. glauco folio, in amphis lacinias divo; Tourn. Cor. 9. Voy. t. 1. 84, with a plate.)—Leaves pinnate, fleshy, smooth; leaflets pinnatifid, recurrent, cut. Stem round. Cluster leaflets; its branches forked, cymose. Flowers flaked; without an intermediate lobe.—Native of Italy and the Levant; common in the islands of the Archipelago. The root is woody, and said to be perennial. It is not safe to disinguish this species, by description, from the \( \textit{canina} \), except that the leaves appear to be more glaucous, and the cluster of flowers altogether more cylindrical, with shorter compact branches, of a cymose habit, the flowers all flaked. The four uppermost segments of the corolla are all of one nearly uniform blood-red, (without any intermediate lobe,) the odd one green. Capitule nearly twice the size of canina. Linnaeus quotes the plant of Tournefort's Voyage as the fame with that which writer had previously mentioned, by another name, in his \textit{Institutions}. Dr. Sibthorp's exactly answers to the plate of Tournefort, and is drawn with leaves more glaucous than \textit{canina}.

24. \( \textit{S. variiseta} \). Spotted-flowered Fig-wort. Marf. von Biebr. in Sims and Kon. Ann. of Bot. v. 2. 445. Wildl. n. 22.—"Stems shrubby at the base. Leaves bipinnatifid, downy. Clusters elongated; flower-flanks short, rough, with hooked hairs."—Native of the flanks of rivers, and barren hills, between the rivers Terek and Kur, in the neighbourhood of the Caffian sea, flowering in June and July. The root is perennial. Stem woody at the base, with numerous long slender branches, clothed, like all the rest of the herbage, with rough hairs. Flowers rather less than in \( \textit{S. canina} \). Corolla purplish; its two upper segments short, obtuse, incumbent, one of them marked with a white spot; three lower ones white, very small, obtuse. Akin to the last, but, according to this description, sufficiently distinct.

25. \( \textit{S. lucida} \). Shining-leaved Fig-wort. Linn. Sp. Pl. 365. Wildl. n. 21. "Hort. Berolin. t. 57." Ait. n. 17. Sm. Fl. Græc. Sibth. t. 599, unpublished. (S. saxatilis lucida, laceritvel magniflens folius; Tourn. Infl. 167. Bocc. Muf. 166. t. 117. S. indica; Ger. Em. 716? S. glauco folio, in amphis lacinias divo; Tourn. Cor. 9. Voy. t. 1. 84, with a plate.)—Leaves pinnate, fleshy, smooth; leaflets pinnatifid, recurrent, cut. Stem round. Cluster leaflets; its branches forked, cymose. Flowers flaked; without an intermediate lobe.—Native of Italy and the Levant; common in the islands of the Archipelago. The root is woody, and said to be perennial. It is not safe to disinguish this species, by description, from the \( \textit{canina} \), except that the leaves appear to be more glaucous, and the cluster of flowers altogether more cylindrical, with shorter compact branches, of a cymose habit, the flowers all flaked. The four uppermost segments of the corolla are all of one nearly uniform blood-red, (without any intermediate lobe,) the odd one green. Capitule nearly twice the size of canina. Linnaeus quotes the plant of Tournefort's Voyage as the fame with that which writer had previously mentioned, by another name, in his \textit{Institutions}. Dr. Sibthorp's exactly answers to the plate of Tournefort, and is drawn with leaves more glaucous than \textit{canina}.

26. \( \textit{S. filicifolia} \). Fern-leaved Fig-wort. Mill. Dict. ed. 8. n. 10. Sm. Profl. Fl. Græc. Sibth. n. 1456. Fl. Græc. t. 600, unpublished. (S. folius filicis modo lacinias, vel ruta canina latifolia; Tourn. Infl. 167.)—Leaves pinnate; leaflets pinnatifid, recurrent, cut; in the lowest leaves obovate. Stem square. Cluster leaflets; its branches forked, divaricated, with from five to nine flowers. Corolla with an intermediate lobe.—Native of Crete. A large tall species, with dark-green leaves, of which the lowermost are a foot long, with broad, obovate, lobed, cut, recurrent leaflets. It is readily distinguished from \( \textit{S. canina} \); lucida, and their allies, by the squareness of its stem, to the very top of the clifer, and the presence of an intermediate lobe to the corolla; the two upper segments of whole limb are of a peculiarly dark red, or chocolate colour; the lateral segments, like the lobe just mentioned, of a pale red; the lower one green.
green, and very small. The flowers are all nearly sessile: nine on the lowest branches of the cluster, even on those about the middle; five or three on the uppermost. *Calyx* with a white membranous edge, as in all this tribe.

27. S. livida. Vivid Fig-wort. Sm. Prodr. Fl. Græc. Sibth. n. 1457. Fl. Græc. t. 601, unpublished.—Leaves pinnate; leaflets pinnatifid, deciduous, angunt and cut, all uniform. Stem square. Cluster leaflets, straight; its branches forked, with three to seven flowers. Corolla with an intermediate lobe.—Gathered by Dr. Sibthorp in Asia Minor, probably near Smyrna. This appears to be annual, and differs from the lath in the uniformity, lighter colour, and smaller size, of its leaves, whose segments are small, wedge-shaped, slender, and channelled. The *inflor-efcence* is similar, but more slender and condensed. Two upper segments, and intermediate lobe, of the *corolla* pale purple, or lilac-coloured; lateral and lower ones, like the tube, of a light green.

28. S. bicolor. Striped-flowered Fig-wort. Sm. Prodr. Fl. Græc. Sibth. n. 1458. Fl. Græc. t. 602, unpublished. (S. chrysanthesfolia; March. von Bieberit. in Sims and Kon. Ann. of Bot. v. 2. 446) S. orientalis, chrysanthes folio, flos minimo variegato; Tourn. Cor. 9.)—Leaves bipinnate, bipinnatifid, narrow, sharply cut. Stem round. Cluster leaflets; its branches simply forked, their divisions racemose. Flowers infert, without an intermediate lobe.—Native of Sicily and the Levant. A tall, branching, panicled species, with very narrow, smooth, shining leaves, whose segments are sharply cut and pointed. The **inflor-efcence** forms a large compound panicle, with numerous lanceolate *bracteas*. *Calyx* elegantly bordered with a purple line, within its white marginal membrane. The two upper, as well as the lower, lobes of the *corolla* are of a blood-red, edged with white, the two lateral ones pure white; tube blood-red, pale at the base. We have little doubt of Tournefort's synonym, which is fo very apposite in character; respecting that of Von Bieberstein, we are more doubtful. The present elegant species is left naturally allied to the tall, than to those of thence immediately preceding them; but its leaves are more finely divided than in any other known *Sporhularia*.

The whole genus is more or less fuscus when bruised, and of a noxious quality to most of the larger animals.

*Sporhularia*, in *Gardening*, comprises plants of the fibrous-rooted, herbaceous, and shrubby kinds, of which the species cultivated are, the shrubby fig-wort (S. fruticosa); the three-leaved fig-wort (S. trifoliata); the elder-leaved fig-wort (S. fumicifolia); and the flax-leaved fig-wort (S. lucida).

Method of Culture.—These plants may be increased by seeds, which should be sown in autumn in the borders or other places where the plants are to remain. The plants should be kept free from weeds; when the roots continue several years, unless destroyed by fever frolts. It is therefore a good practice to have some in pots protected by a frame and glasses; and as the young plants flower the *froglings*, a proper succession should be begun annually. They may also be sometimes raised from the *parted roots*; and the shrubby sorts by cuttings or slips in the summer or spring months.

They afford ornament and variety in the clumps and borders, as well as other parts, of pleasure grounds: *silo* when set out among collections, in pots.

*Sporhularia*, in *Botany*, a natural order of plants, named from one of the most remarkable and bell-known genera, *see Sporo-ularia*; making the fortieh order in Jussieu's system, or the seventh of his eighth clafs; see *Labiatae* and *Gentianae.* See also *Peronizate*, a Linnean order, to which that under consideration is, in a great part, parallel. The character of the *Sporhulariae* is thus given by Jussieu.

*Calyx* divided; often permanent. *Corolla* often irregular; divided in the limb. *Stamens* often four, two longer than the others; rarely only two in all. *Style* one; *stigma* simple or two-lobed. *Fruit* capsular, of two cells, split at the summit, if not completely separated, into two valves, which are in some few instances divided again into two parts; their inside is naked and concave, with a central receptacle, bordered vertically all round, and bearing seeds at each side, supplying the place of a partition, being parallel to the valves, and often connected, in its whole circumference, with their margins. *Seeds* often numerous and minute. Stem herbaceous, rarely shrubby. *Leaves* opposite or alternate. *Flowers* bracteate.

Section 1. *Stamens* four, two longer and two shorter.

**Buddleia**: *Scoparia*; *Rafflesia* of Jacquin; *Capsaria*; *Stemodia*; *Halberia*; *Galvezia* of Dombey; *Abelmoschus* of Browne; *Scrophularia*; *Maturea* of Auleit, suspected by Schreber to be a *Vandella*; *Dedaria*; *Gerardia*; *Cymbaria*; *Linaria* of Tournefort; *Antirrhinum*, comprehending *Ajarina* of Tournefort; *Hemiscellis*; and *Digitalis*.

Section 2. *Stamens* two.

**Pederota**: *Calcolotria*; and *Bea* of Commeron.

Section 3. *Genus* akin to *Sporhularia*, with opposite leaves.

**Columnnea**: *Beffleria*; *Cyrtaandra* of Forlter; *Gratiola*; *Torenia*; *Vandella*; *Lindernia*; *Mimuscius*; *Polyspermum*; and *Mentira* of Auleit.

Section 4. *Genus* akin to *Sporhularia*, with alternate leaves.

**Schwarzella**: *Schawiola*; and *Brownella*.

**SCROPHULOUS TUMOURS**, in *Hoes*, swellings of the glands about the necks and other parts of the body, arising from colds and obstructions caused in other ways. They may most safely be removed by mild camphorated mercurial ointments, used two or three times in the day to the diseased parts.

See *Hog* and *Swine*.

**SCROTOCELE**, in *Surgery*, a hernia, or rupture, which has descended into the scrotum.

**SCROTUM**, in *Anatomy*, the bag of skin which contains the testicles. See *Generation*.

**SCROLLS**, or *Scroils*, in *Architecture*. See *Volute*.

**SCRUB**, in *Geography*, one of the smaller Virgin islands, in the West Indies.

**SCRUPI**, in *Natural History*, the name of a class of silli, formed in detached mallets, without any crust; of no determinate figure, or regular structure; and composed of a crystalline or sparay matter, debased by an admixture of earth, in various proportions.

Under this class are comprehended, 1. The *teleghia*. 2. The *petridia*. 3. The *thozoua*. 4. The *jafipides*, or *japlers*.

All these genera strike fire with ease, only some more readily than others.

**SCRUPLE**, *Scrupillus*, *Scrupalum*, or *Scrupulum*, the lead of the weights used by the ancients, which, amongst the Romans, was the twenty-fourth part of a ounce, or the third part of a drachm.

**Scruple** is still a weight among us, containing the third part of a drachm, or twenty grains.

Among goldsmiths the scruple is twenty-four grains.

**Scruple**, in *Chronology*. The Chaldean scruple is the part
part of an hour, called by the Hebrews helakia. These
ferpents are much used by the Jews, Arabs, and other
eastern people, in computations of time.

SCURRILUS, in Astronomy. Scurrilus eclipsed, that part of
the moon’s diameter which enters the shadow, expressed in
the same measure in which the diameter of the moon is
expressed. See Digit.

SCURRILUS of Half Duration, an arc of the moon’s orbit,
which the moon’s centre describes from the beginning of an
eclipse to its middle.

SCURRILUS of Immersion, or Incidence, an arc of the moon’s
orbit, which her centre describes from the beginning of the
eclipse, to the time when its centre falls into the shadow.
See Immersion.

SCURRILUS of Emission, an arc of the moon’s orbit, which
her centre describes in the time from the first emersion of
the moon’s limb, to the end of the eclipse.

SCRUTAIN, SCRUTAINM, in Antiquity, an examination,
or probation, practiced in the last week of Lent, on the cate-
chumens, who were to receive baptism on the Easter-day.

The scrutiny was performed with a great many cere-
nomies: exorcisms and prayers were made over the heads
of the catechumens. On Palm Sunday, the Lord’s prayer
and Creed were given them, which they were afterwards
made to rehearse.

The process was called feretinum, scrutiny; because here-
by the hearts of the catechumens were scrutinized, or
searched, that the priests might understand who were fit
to be admitted to baptism.

This custom was more in use in the church of Rome than
any where else; though it appears, by some mislaid, to have
been likewise used, though much later, in the Gallican
church. It is supposed to have ceased about the year 650.
Some traces of this practice still remain at Vienne, in
Dauphine, and at Liege.

SCRUTINY is also used, in the Canon Law, for a ticket,
or little paper billet, wherein, at elections, the electors write
their votes privately, so as it may not be known for whom
they vote.

SCRUTINY, among us, is chiefly used for a strict perusal
and examination of the several votes hastily taken at an
election; in order to find out any irregularities committed
therein, by unqualified voters, &c.

SCRUTORE, or Scrutoir (from the French escrioire)
a kind of cabinet, with a door or lid opening downwards, for
convenience of writing on, &c.

SCRI, in Falconry, denotes a large flock of fowl.

SCUD, in Agriculture, a term used provincially to signify
to clear with a spade or spittle.

SCUD, in Sea Language, a name given by seamen to the
lowest and lightest clouds, which are most swiftly wafted
along the atmosphere by the wind.

SCUDDING, the movement by which a ship is carried
with great velocity before a tempell.

As a ship moves through the water with so great a ve-
cocity whenever this expeditious is put in practice, it is never
attempted in a contrary wind, unless when her condition
renders her incapable of fulfilling the mutual efforts of the
wind and waves any longer on her side, without being ex-
pended to the most imminent danger. See Drining.

A ship either foods with a sail extended on her fore-mast,
SCUBERI, in Geography, a mountain of Sicily, in the valley of Demona, 10 miles S.W. of Messina. Next to Etna, this is the highest mountain in Sicily, and retains snow all the year.

SCUDO, in Commerce, a money of account, and also a silver coin, in different parts of Italy, in Sicily, and also at Malta. At Rome, accounts are kept in crowns or scudi, called feudi romani, and scudi monetari; each scudo being divided into 10 paoli or grani, and each paolo into 10 bajocchi. The scudo is likewise divided into 3½ telti, 500 quattrini, or 1000 mezzi quattrini; so that 5 quattrini make 1 paolo, and 3 paoli 1 teltino. The scudo di fompa d'oro, by which many of the foreign exchanges are regulated, is reckoned at 1525 or 1525 mezzi quattrini; that is, when a bill is drawn from Rome on a foreign place, the scudo di fompa d'oro is reckoned at 1523 mezzi quattrini; but when drawn from another place on Rome, it is reckoned at 1525 ditto: this scudo is divided into 20 foldi, or 2½ denarii. Among the silver coins are scudi romani, and half ditto. The scudo weighs 22 denari 10½ grai, Roman weight, or 409.99 English grains; and the silver is 1012½ ounces fine in the lb.; it therefore contains 403 grains of English standard silver, and is worth 4s. 4d. sterling. The scudo di fompa d'oro, of 1525 mezzi quattrini, is worth 6s. 7½d. sterling; and the paolo, 5½d. sterling nearly; or 1d. sterling = 4 scudi 6 bajocchi, all valued in silver. All payments above 5 scudi are made in cedole, or schedules, a forti of bank notes, which cannot be refused in payment, and which are constantly at a discount. At Malta, accounts are kept in scudi of 12 tari, each tari being subdivided into 2 carini, 20 grani, or 120 picciosi. These monies of account are valued in silver and copper money, silver money being to copper money as 3 to 2. At Mantua, a scudo of account is 6 lire, or 120 foldi. At Milan, a scudo di cambio, or imperiale, is reckoned at 5 lire 17 foldi, or 117 foldi imperiali; a scudo corrente at 5 lire 15 foldi, or 115 foldi correnti: 1219 scudi imperiali are equivalent to 1755 scudi correnti. Among the silver coins are scudi of 18 denari 21½ grani, at 6 lire, and halves in proportion. In copper the scudi are about 10 denari 18 grani (or 10 oz. 15 dwt.) fine; but the lire are only 6 denari 14 grani (or 6 oz. 11½ dwt.) fine. The scudo imperiale is worth 5½. 2½d., and the scudo corrente 3½d. If valued in gold, the scudo corrente is worth 3½. 6½d. sterling. According to the mint price of gold and silver in England, viz. 3l. 17½. 10d. per ounce for gold, and 51. 2d. per ounce for silver, the scudo of 7 lire at Bergamo is 35. 6½d. in silver, and 36. 5½d. in gold:—At Florence the scudo d'oro, or gold crown, is 63. 9½d. in gold:—at Geneva, the scudo di cambio, or crown of exchange, is worth 54. 75½d. in silver, and 56. 0½d. in gold; and the scudo d'oro marche 83. 8½d. in silver, and 84. 7½d. in gold:—at Lucca, the scudo d'oro is 55. 50½d. in silver, and 58. 27½d. in gold; the scudo corrente 51. 80½d. in silver, and 54. 30½d. in gold:—at Malta, the scudo, or crown, is 21. 32½d. in silver, and 23. 34½d. in gold:—at Milan, the scudo imperiale is 60. 90d. in silver, and 61. 60d. in gold; and the scudo corrente 42. 32d. in silver, and 42. 78d. in gold:—at Novi, the scudo d'oro marche is 85. 49½d. in silver, and 84. 77½d. in gold:—at Rome, the scudo, or crown, is 52. 05½d. in silver, and 51. 63½d. in gold; and the scudo di fompa d'oro 79. 37½d. in silver, and 78. 73d. in gold:—at Sicily, the scudo, or crown, is 49. 02½d. in silver, and 49. 02½d. in gold. For the aßay, value, &c. of the scudo, see the table under Coin. For the Impressions on the scudo, and other particulars, we refer to Kelly's Universal Cambitt.

SCUFFLE, or SCUFPELL, in Agriculture, an implement of somewhat the same kind as the furrower, but which is moystly lighter, and employed in working after it. There is a great variety of these sorts of implements described in works on agriculture. The following have been found to perform the work well in actual practice. It is noticed, that a tool of this sort, invented in Norfolk, has been found highly useful in that district. It is described in the Agricultural Survey of the above country, as being formed from a double-breasted foot-plough, by taking off the beams, and having a share larger and flatter than the original one made. To the end of the beam of the plough, a cros-beam of wood, three feet long, four inches broad, and four inches thick, is fastened; and at the distance of twelve inches and a half each way from the centre of this cros-beam, are inserted two coulters, each twelve inches long, three inches broad, and a quarter of an inch thick on the back, but reduced to three-eighths in the front; and into these coulters, at the bottom, are riveted two shares, of nearly the same size as the first share, which was nine inches broad, but these two only eight inches. The cros-beam is strengthened by two iron reins fixed to the cros-beam, and also to the beam of the plough, in the belt manner for the purpose.

It may also be noticed, that the coulters which are fixed to the cros-beam do not stand perpendicularly; but inclining, as the couler at the head of the plough: thus they are fixed into a cros-beam by means of a screw and a nut, so as to keep them quite fast and steady.

The advantage of this scuffle above any that the inventor has seen is, that it is used with two horses only. It does the work of more than two ploughs, as the three shares cut nearly the width of thirty inches, whereas two ploughs would cut only twenty-four inches. It is used on farms which confit of heavy land, as well as land of a mixed soil. But a scuffle recommended by Mr. Amos is occasionally in use, which has wheels on which it is carried from one field to another, and by which the depth of working is regulated. These wheels turn round upon their axles, and also upon the under end of the upright share, in imitation of bed-callers. The middle beams are the parts to which the horses are fixed; but there are likewise side-beams; and the flanks of the shares are fixed in the beams by nuts and screws. They are fifteen inches long below the beams, and made of iron, one inch and a half by an inch square; they are riveted on their flanks. The handles for managing the machine are about four feet three inches long.

This tool is said to be of great utility in cleaning bean and pea stubbles, in order to their being sown with wheat. And it is very advantageous in destroying weeds and grasses, which usually grow among the shoots of young wheat. It is likewise admirably adapted to the cleaning of land that has been sown with the garden pea, in order to its being ploughed, harrowed, rolled, and drilled with turnips or rape-seed in the latter end of summer, at the beginning of August.

And with this tool it is asserted that one man and two horses are capable of scuffling fix or eight acres per day. It is advised, that after the land is scuffled over, it should be harrowed twice or three times in a space of time, and the weeds collected and destroyed. But it has been made an objection to these sorts of tools with some, that they cannot be made to operate in a beneficial manner, except where the land has been previously brought into a fine condition, and rendered clear from weeds. These, as well as furrowing implements, are likewise liable to objection from their being subjected to clog much when the land are wet. A tool of this sort has however been employed in the midland districts, which is said to be in a great measure free from the
the half objection. It has been recommended by Mr. Bower. In this tool, by the teeth being only twelve inches from each other, and their interjecting, that distance is reduced to fix inches, where the breadth of the shares, from being full three inches, afford another reduction, which brings them so near together, that the land is almost wholly broken and reduced, and the intention of a ploughing as well as a harrowing accomplished at once, without cutting the roots of the couch-grass in two, which is a great superiority that it possesed over the plough. And from the teeth bending forward, and having that kind of position, the roots are brought to the top more perfectly, which is another superiority over the plough. It has also much superiority in the dispatch of work; four horses and a man being able to finish six acres or more of land of a handy quality in the course of a day. And the following are the dimensions of this tool. The length of the hilt bull is four feet and a half; and the length of the second bull three feet nine inches. The teeth are two feet in length, and bent near the bottom, in order that they may lie flat on the earth. The length of the beam is fix feet. And the length of the iron that shifts through the beam, and fastens with a screw, is two feet.

Many other light tools of the same description have been lately provided by different implement-makers in different parts of the country, which are well fitted for particular uses in the cultivation of land, and which, by their convenience and modes of working, save much labour and expense. They are some of them made with two rows of shares, five and four in each, about six inches in breadth; the front ones cutting the interstices of the hinder ones, by which means the work is done in an excellent manner. The depth of working is regulated by small wheels that let up and down. They prepare bean and other stubbles admirably for wheat or any other crops. They are a sort of tool which is fast getting into general use by the farmer.

SCUFFLING in Crops, the practice of putting them into the soil or ground by means of the tool called the scuffle. It is a practice which has lately been much had recourse to in some heavy, moist, land districts with great utility and advantage, and it may probably be employed in almost every part with considerable benefit, as much time and labour, in the busy period of the spring, may thereby be saved; as the ploughing being performed in the leisure season of the autumn, the feed can readily be put into the ground by the operation of scuffling in the early spring months. In all cafes where the flate of the weather, and the lands that have been ploughed for a barley fallow, or other purpose, will not let that grain be put into the ground early in the spring, this may be a good method of proceeding, as further ploughing, in such circumstances, would be highly dangerous and improper. Such fallows, or other ploughings, having had the full effect of the frosts, and the influence of the atmosphere during the whole of the winter season, cannot but be well fitted for the operation of scuffling at this period, and by that means being made fit for putting in the feed. The farm will frequently be the cafe with all other lands which have been ploughed before the commencement of the winter season; such as those of the taro, bean, and pea stubble kinds, as well as those turnip-lands which have been cleared and ploughed at an early period, and this method of preparing them for, and putting in, the feed, may be had recourse to with great safety and advantage. There is no danger in this way of destroying the fine surface pulverization and tilth which is so essentially necessary for the reception of the feed, as is often done by the use of the plough under such wet and unfavourable circumstances of tillage lands. See SCARIFYING, and TILLAGE.

The working of the surface soil in this manner, and the relinquishing of the use of the plough in some measure, is a great modern improvement in the tillage system, which is most fully practiced in Suffolk; but it is fall coming into use in other districts. In Essex, some farmers find it a more effectual and cheaper method of cleaning falls than that of trudging wholly to the plough. It is also found useful in cleaning land for turnips, as well as in lightening the ground in fly-eaten crops of that fort.

SCULCOATS, See Geography. See HULL.

SCULION, in leksyology, a name given by Aristotle, and many others of the ancient writers, to the fifth called by later authors catulus, and catulus major, and in England the bouse.

SCULK, among Hunters, denotes a company; as, a feul of foxes.

SCULL. See SKULL.

SCULL-CUP, in Gardening, the common name of a curious garden plant. See SCUTELLARIA.

SCULPONE, among the Romans, a kind of shoes worn by slaves of both sexes. These shoes were only blocks of wood made hollow, like the French sabot.

SCULPTURE, English, is from the Latin, sculptura; and the verb sculpto, I carve or engrave, which is the same as the Greek ἱαυτόν: therefore basso-relievo was called analaphobic in that language; which word was also understood for carved representations in general. The Greeks had other words by which they signified particular works of sculpture; as Engravers, images; and types, or representations in relief.

Sculpture is the art of imitating visible form by means of solid substances, either modelled, as clay or wax, or carved, as marble. The principles of sculpture and of painting are both the same; till painting divides itself into a distinct branch by the imitation of colour; while sculpture is expressed by form alone.

Of Hebrew Sculpture.—As the bible is the most ancient history we possess, these instances of the arts of design which are mentioned in that sacred volume ought to be noticed, and particularly of sculpture.

The first mention of images is in Genesis; where Rachel stole her father's gods, which are called Teraphim, or images. Mention is made also in Genesis of Judah's signet.

In Exodus, Moses receives commands and injunctions concerning the tabernacle; that he should cause it to be made according to the pattern which was shewed him on the Mount. And in order to this, Bezaleel and Aholibah are inspired with the spirit of God to devise cunning works in gold, and in silver, and in brass, and in cutting of stones, and in carving of timber to work all manner of workmanship.

The importance of the arts of design is here particularly demonstrated by the manner in which Bezaleel and Aholibah are called, even in the service of religion; and filled with the divine spirit for their employment in the Tabernacle and the Ark of the Covenant, as described in the following passage by Moles.

"And Moses said unto the children of Israel, see, the Lord hath called by name Bezaleel, the son of Uri, the son of Hur, of the tribe of Judah. And he hath filled him with the spirit of God in wisdom, in understanding, and in knowledge, and in all manner of workmanship. And to devise curious works in gold, and in silver, and in brass. And in the cutting of stones, to let them, and in carving of wood, to make any manner of cunning work."
SCULPTURE.

It on his heart, that he may teach, both he and Ahohiah, the son of Ahifamach, of the tribe of Dan. Thus hath he filled with wisdom of heart, to work all manner of work of the engraver, and of the cunning workman, and of the embroiderer in blue, and in purple, and in scarlet, and in fine linen; and of the weaver, even of them that do any work, and of those that devise cunning work."

Such inspired works being ordained, and Moses coming down from the Mount to cause all to be performed according to the divine will; he finds that the people have made a golden calf, crying out, "These are thy gods, O Israel, who brought thee out of the land of Egypt." The golden calf is evidently the Egyptian Osiris or Apis.

The manner of making the golden calf is thus described by Aaron: "I said unto them, whoever hath any gold let them break it off; so they gave it me; then I called it into the fire, and out came this calf." It is also said, "He received the earrings and gold at their hand, and fashioned it with a graving tool after he had made a molten calf."

This dreadful attempt to annihilate inspired art at its birth, is visited by a grievous judgment, but no more grievous than is necessary to its security: for this deliverance from Egypt was the deliverance of man, both as to his bodily and mental faculties, from slavery.

When the tables of stone are renewed, that they may be deposited in the ark, Moses, Bezaleel, and Ahohiah, and every wise-hearted man, in whom the Lord had put wisdom and understanding, sat about their inspired work.

The tabernacle and its curtains and cherubim; the veil and its cherubim; the ark and mercy-seat and their cherubim; the table of show-bread and the golden candlestick; the altar of burnt-offerings, and the altar of incense; the laver; the garments of Aaron, and his breast-plate and mitre and holy crown, and the garments of the sons of Aaron.

Whether the cherubims which were woven in the curtains and the veil are to be considered simply as mentioned in Exodus; or, according to the more extended and poetical representations in Ezekiel, accompanied by their dreadful wheels, containing Orion and Pleiades, Mazzaroth and his sons, Arkurus and the chambers of the south, as mentioned in Job, Isaiah, and Amos; like the representations on our celestial globe; the difference will be only in their more or less splendid design and embroidery. But the description is more positive concerning those sculptured cherubims which covered the ark of the testimony.

"And he made the mercy-seat of pure gold. Two cubits and a half was the length thereof, and one cubit and a half the breadth thereof. And he made two cherubims of gold; beaten out of one piece, made he them on the two ends of the mercy-seat. One cherub on the end on this side; and another cherub on the other end on that side: out of the mercy-seat made he the cherubims on the two ends thereof. And the cherubims spread out their wings on high, and covered with their wings the mercy-seat; with their faces one to another; even to the mercy-seatward were the faces of the cherubims,"

These figures, as also the candlestick and table, and all other works of sculpture contained in the tabernacle; together with Aaron's breast-plate, a span each way, foursquare; containing twelve precious stones, each engraved with the engraving of a figure, with the names of the children of Israel; must have been worthy of their divine author.

And the necessity of such inspired sculptures and other inspired works of art is explained sufficiently in the deliverance of Israel from the idolatry of Egypt; where no one dared to practice any art or science, but that of his fathers; who, like him, were kept from every indication of individual character. And the Hebrew being born a slave, continued so while under the Egyptian yoke; let his inspiration be what it would, he was compelled to work in making bricks, and in iron-furnaces. Such then was the deliverance of art and science from destruction, and the earth from returning to its primeval chaos.

All idolatrous sublitudes for fine art, wood and stone deformities, God, by the mouth of Moses, repeatedly commands the children of Israel to destroy, in thee and the like words. "And destroy all their pictures and defile all their molten images."

After the establishment of Israel in Canaan, there are continual indications of fine art. So early as the song of Deborah, we hear of those who delineate with the pen or pencil of the writer. Gideon destroys the altar of Baal, but afterwards himself makes an idol. Micaiah's mother dedicates gold and silver to the Lord, to make a graven image and a molten image; but Micah makes them a house of gods, which he worships and causes others to worship, not using them as works of art, but as idols.

We next hear of the image of Dagon, when the ark of God is taken by the Philistines; and of the golden emerods and golden mice, which were put into a coffer by the side of the ark, for a trespass-offering.

The image which Micah placed in David's bed, to deceive Saul's messengers, some supposing to have been a statue of David; it is called a teraphim.

But the most magnificent production of Hebrew art was the temple of Solomon. It contained the same cherubim that Moses had seen on the Mount; and they adorned and covered the whole temple within and without. Two in particular were placed in the holy of holies, of colossal dimensions: they covered the place of the ark with their wings; the height of each was ten cubits, and the breadth each spread his wings was ten cubits. A figure five yards high is capable of the greatest effects at perfection in art, and this no doubt they had, being done by divine command, for purpooses whose importance reaches to the end of time.

The brazen sea of Solomon's temple, and its twelve oxen; the two pillars, Jachin and Boaz; the candlesticks of pure gold, twelve in number; the ten lavers, and their bases and wheels, and ornaments of lions and oxen, and cherubim, works inspired by God and wrought by his holy Spirit, with the other sublime ornaments of Solomon's temple, as also Solomon's throne and its twelve lions. The excellence of the work must be considered as equal to the purpose of containing the covenant between God and man, and other dispensations relating thereto.

Thus, the art of sculpture was not only allowed, but encouraged and employed in the service of religion, in the representation of divine attributes or the symbols of divine Providence; and the abstinence only of this art was forbidden when perverted to idolatrous and impious purpooses.

But Solomon became an idolater: and it is said, "then did Solomon build a high place for Chemosh, the abomination of Moab, in the hill that is before Jerusalem; and for Moloch, the abomination of the children of Ammon." From this time fine art and inspiration were successively removed.

It has been thought necessary to be particular in giving quotations from the Bible concerning the sculpture of the Hebrews, as it is the earliest of which we have any authentic account.

There are found in Syria, in the present time, ruins of monuments called the sepulchres of the prophets. These remains have nothing like the Egyptian or the Persian style of construction,
constructions, but are of Roman or Grecian origin, and must have been erected in an age greatly posterior to the prophets. This seems to be allowed in the words of our Saviour to the Pharisees: “Your fathers killed the prophets and ye build their sepulchres.” It should seem that the Pharisees added Roman ornaments to the simple forms of ancient Hebrew veneration, as is signified in these words. “Ye build the tombs of the prophets and garnish the sepulchres of the righteous.”

There are engravings of these sepulchral monuments, published by Mr. Cafa in Paris.

Of Babylonian and Persian Sculpture, also of Asiatic Sculpture in general.—It may be proper to take only some general notice of the most ancient sculpture of other nations of the East, of which our accounts are very imperfect, previous to the description of Egyptian sculpture, for two reasons: 1st, that the sculptures of these nations will have considerable light thrown upon them by the Egyptian remains; and, 2dly, because, as the history and examples of Egyptian sculpture are abundant and succellent; they lead us more naturally and accurately to the great object of our present enquiry, Grecian sculpture.

In the very ruined state of some, and the utter devastation of most of those countries in Asia which were once the seats of art and science, the traveller in vain seeks for memorials of Noah, or of Abraham, or of Moses, or even of Solomon: all historical record of these early times is without corroborative evidence from remaining monuments.

The first method of transmitting ideas to posterity is supposed to have been by hieroglyphics or ideal writings, whether painted or sculptured. Such also was used in Mexico when first discovered. All the most ancient writings approach to the figurative or ideal writing, every word being as much as possible a picture or image. Some of the learned have thought that the first chapters of Genesis were originally transmitted in this way.

How such figurative words could have occurred, previous to the art of ideal writing, cannot be easily conceived. The author of a figurative expression must have a figurative idea in his mind, and that is a hieroglyphic, which might as well be painted or sculptured as written, and with infinitely greater effect on the reader.

The descriptions of the creation and fall of man, of the flood of Noah, of the building of Babel, and of the departure of Abraham from Chaldea, are each of them a sublime series of ideal writing.

After the flood, when men began again to multiply upon the earth, Nimrod’s followers are said to have “built a city and a tower, whose top should reach unto heaven.” The sacred writings do not mention any thing of sculpture in this building. But Berosus says, that representations of the terrible forms that inhabited chaos previous to the creation, were to be seen on the walls of the temple of Belus in Babylon; and that these consisted of human figures with wings, of human figures with two heads, of others with legs of goats and with horns; and that they were executed both in painting and sculpture.

There are no works of sculpture discovered in any country at all to be compared with Greek art. All the great empires, previous to the age of Pericles, are vanished; not any thing of Nebuchadnezzar, nor of Semiramis, nor of Belus; their names remain in history but not in sculpture, and it cannot be certified whether the golden image of Nebuchadnezzar was merely a colossal or a work of fine art.

Much less can we speak of Belus, from any thing that remains. Herodotus, in describing the temple of Jupiter Belus in Babylon, says it is a “square building, two stades in length on every side, having gates of brass, as may be seen in our time. In the midst of this temple stands a solid tower of one stade in height, and in length and breadth the same measure. On this tower another is built, and a third upon that, till they make up the number of eight. The ascent to these is by a way carried round the outside of the building to the highest part. In the midst of the ascent is a place, where those who go up may rest themselves. Within the uppermost tower a spacious dome is built, in which a table of gold stands, at the side of a magnificent bed. No image is seen in this place, but in a chapel which stands below within the temple, a large image of gold, representing Jupiter Belus, is placed on a throne of gold, by a table of the same metal, all together weighing eight hundred talents, as the Chaldeans affirm. Without this chapel is an altar of gold, and another of a greater size, which is used when cattle of full age are sacrificed; for on the golden altar no other than sacrificing victims may be offered. On the great altar the Chaldeans consume yearly a thousand talents in incense, when they celebrate the festival of this god. Besides these things, a statue of gold, twelve cubits high, stood formerly in this temple, which, because I did not see, I shall only relate what I heard from the Chaldeans. Darius, the son of Hystaspes, had designed to take away this, but had not courage for this purpose; but Xerxes, the son of Darius, not only took away the statue, but killed the priest who had forbidden him to remove it. In this manner the temple of Jupiter Belus is built and adorned, not to mention divers other donations consecrated there by private persons.”

Diodorus Siculus has given a description of the works of queen Semiramis in Babylon. “She built two palaces, at the end of the bridge upon the banks of the Euphrates. That on the west had a high and flatly wall, built circular, upon which were portrayed, before they were burnt, the forms of all sorts of living creatures, laid with great art in curious colors. This wall was in circuit forty furlongs, in height a hundred yards, upon which were turrets a hundred and forty yards high. The third and most inward wall immediately surrounded the palace, thirty furlongs in compass, and far surrounded the middle wall both in height and thickness; and on this wall and the towers were represented the shapes of all sorts of living creatures, artifically expressed in the most lively colors: especially was represented a general history of all sorts of wild beasts, each four cubits high and upwards. Among these was to be seen Semiramis on horseback, striking a leopard through with a dart; and next to her, her husband Nimus, in close fight with a lion, piercing him with a lance. This palace far excelled that on the other side of the river, both in greatness and adornments, for the outermost wall of that made of well burnt brick, was but thirty furlongs in circumference. Instead of the curious portraiture of beasts, there were the brazen statues of Nimus and Semiramis, the great officers, and of Jupiter, whom the Babylonians call Belus, and likewise of armies drawn up in battle; and divers sorts of hunting were there represented, to the great diversion and pleasure of the beholders. In the middle of the city the built a temple to Jupiter, whom the Babylonians call Belus. Upon the top the placed three statues of beaten gold, of Jupiter, Juno, and Rhea. That of Jupiter stood upright, in the posture as if he were walking. He was forty feet in height, and weighed a thousand Babylonian talents. The statue of Rhea was of the same weight, sitting on a golden throne, having two lions at her knees, standing one on either side, and near to them two exceeding great serpents of silver, weighing thirty talents a piece.” Here likewise the
SCULPTURE.

The image of Juno stood upright, and weighed eight hundred talents, grasping a serpent by the head in her right hand, and holding a cæptre, adorned with precious stones, in her left.

But Babylon is now a ruin, nor are the caverns of the earth found to yield any fragments of her ancient sculptures. Among the ruins of the Persian monarchy, which display themselves in melancholy state amid the deferts, is Persepolis. The fragments of sculpture that here remain are very rude, and give an idea of the mere infancy of art, though of gigantic dimensions. Such are those colossal monuments carved on high in the rock mentioned by Isaiah in these words. "He that hewneth himself out a temple on high, that graven an habitation for himself in a rock."

The ruins of Persepolis present examples of Persian sculpture on the wall, and in the portals of its ruined palace, and also on the tombs of its kings. Their antiquity may be about the time when Ahæruæus removed the feast of government from Babylon to Shushan. We hear that Alexander took possession of Babylon, Shushan, and Persepolis, the chief cities of the Persian empire, and burnt down the palace of Persepolis, of which the ruins now remain. They are hardly more ancient than that removal of the Persian government by Ahæruæus, who isarius Hylæas.

This palace of Persepolis has its walls still remaining on three of its sides. The extent of the front comprehends six hundred paces, from north to south; it is three hundred and ninety feet from east to west. On the west front are two magnificent flaire-cafes, consisting of each of two flights of steps. On the top of these flaire-cafes are seen two grand portals, one fronting the west, the other eastward; between them are two magnificent columns, each fourteen feet in circumference and fifty-four in height: within the portals are carved, in fline, the heads and breasts, and front feet projecting beyond the portals, of two animals somewhat like sphynxes, twenty-two feet from the fore to the hinder legs, and in height fourteen feet and a half; they have the body of a horse, with the legs thick and short, like those of a lion: there is some appearance of their having had human heads, one of them having a crowned bonnet like a turret. The other of these grand portals eastward has two somewhat similar animals, but these have wings on their shoulders, their dimensions being nearly the same with the former. And at the distance of a hundred and seventy feet from this portal are two flaire-cafes like the former. The walls which belong to these flaire-cafes are six feet seven inches high, of which the lower stories make it evident that they were adorned with figures in low relief. The upper part of the flight is embellished with foliage, and the representation of a lion rearing a bull, much larger than life, and likewise in low relief. The flaire are seventeen feet in length, three inches high, and fourteen inches and a half in breadth.

What remain of this palace are chiefly pillars and porticoes, the pillars being fluted, having bases and capitals of uncouth ornament, of sometimes an animal's head and neck, and sometimes ornaments like Gothic arches. All the upper part of the building is entirely destroyed, and what remain of that below are only separate members, which have little connection with each other. Some of the columns are 70 feet high, and have been as numerous as 76 in a range, though but comparatively few remain, and these terribly mutilated.

The other ruined portals are ornamented with figures carved in the inides of the jambs, of rude grandeur; one portal is a man fighting with a lion; on another, a man fighting with a griffon or horned lion; and on a third, a figure like a king, with two figures behind him, one with a parapet, the other with a sea-horse's tail, which being set in a gold handle, is used in Persia at the present time to drive away flies. Over his head, in the air, is a little figure on eagle's wings, perhaps a god or a genius. Another portal has a great many figures in different compartments, one above the other: in the top compartment is a figure sitting on a throne: on another ruined pilaffect, which was once the side of a door: way, is a figure sitting on a throne, and behind him an attendant; beneath, in three compartments, are many little figures much defaced. Other pilaffects have had other ornaments, and unknown characters of letters shaped like the heads of arrows, disposed in different directions and in different combinations. The windows of these ruins, some of which remain, were ornamented also with sculptures in the same manner as the doors. One that remains has a man holding an animal by the horn, which is single and very long, and bending backwards; before them walks a figure of a man with something in his hand, like a sacrificing instrument: other windows have also the same unknown characters of letters engraved on their sides.

The flaire-cafes are half buried in the earth, and toward the top very much broken; they have each two flights of steps with landing places between, the walls of which, and of the flaire-cafes, have been ornamented with sculpture, in two ranges, one above the other. The first six figures at the entrance are smaller than the rest, and have large vestments with plaïed sleeves, and a round bonnet rising in plaits, and larger in the upper than in the lower part; they have hair and long beards; each holds a lance, and a quiver of arrows is fastened at their back with a strap carried over the shoulder. The figure which is next in order, precedes a train of others; he holds the next by the left hand, and grasps a fork with the right. It seems to represent an ecclesiastic at the head of a procession of others; he is likewise arrayed in a large robe, with a girdle hanging down very low. The three figures by which these are succeeded have shorter robes and sleeves, with upper and under veils, and pointed bonnets formed into five plaits; these are properly the tiaras, called also reflexa, sloped into a curve backwards, contrary to the tiara Phrygiana, which are bent forwards. Two of these figures hold a basin in each hand; a figure following them has two hoops or circles in his hands. This is followed by two horses drawing a chariot, and by two other figures that place their left hands on the back, the other on the neck of the horses. They are all represented with hair and beards; the two last bare-headed, the other has a bandage or diadem.

Between each compartment of six or seven figures, is a kind of vase, and the two first figures always hold each other by the hand. A horse, led by a bridle, follows the two first figures in the second compartment; three figures following this, one of which bears something that resembles a vegetal. In the third compartment are five figures with little basins or buckets, and two others with balls or globes. These in the fourth compartment are not habitated as the others, having only a very straight veil, with a cinature, and long drawers, which are straight and plaited: three of these figures have also basins or little buckets in their hands, and are followed by a camel, having two hunches on its back, with a little bell hung round its neck, after the manner of the eastern caravans, that the sound may be heard at a distance, especially when they pass through narrow defiles; to give notice also to the inhabitants of the caravan's arrival: it is a signal like wise to those who have lost their way, and enables them to join their companions. The last compartment is distinguished by a figure bearing a pole, with a pot suspended at each extremity; and in each of these pots are seen...
Sculpture.

There are forty-eight figures of men and beasts in this range, and as many in that above it, which consists of the following figures. The first six of these are meanly habit ed; each of them has some veiment in his hand. Those that follow carry the same, but are better arrayed. Most of them are greatly impaired by time. These are followed by an ox led with a halter. The only difference between this and the third compartment is, that in the latter, two rams are led, and each has a large crooked deflected horn. After these appears a figure armed with a buckler, and another leading a horse by the bridle, followed by a third with two hoops: the other three are habited like the preceding figures. Next comes a led ox, followed by a man armed with a lance and shield, behind whom appears two other figures, each with three lances, and their sleeves longer than their veils. The last figures that follow have very short veils, with drawers that are long and straight, which come down to their feet; they are armed with long bucklers hanging at the girdles of their waists; two of them have hoops in their hands, and a third a fork; they are followed by a horse led by the bridle.

Such are the figures on this altar-case. Toward the west side, and toward the east side, are as follow. Twenty-eight figures, each grasping a lance with both hands; their veils are long and wide, and they are represented with hair and beards, and seem to be bare-headed, unless we may suppose them to wear a plaited bandage, or kind of diadem. These are succeeded by a number of other figures, armed with long bucklers, which are pointed and bent at one end, with a short broad dagger hung at their girdles: their veils are of unequal lengths; they are like the last figures in the drefs of their heads; they have also some ornament in one hand, and the other is placed upon their beard. This range consisted of sixty figures, the last of which are defaced. All these figures seem to represent some triumph, or procession of people bearing presents to the king, which was customary under the ancient monarchs of Persia, and is practiced at this day.

A traveller counted 1300 figures of men and animals remaining in this great ruin.

There is another immense ruin in the deserts of the ancient empire, called Palmury or Tadmor, said, in the Book of Kings, to be built by Solomon. The present ruins of this great city are very different from those of Persepolis, and indicate a much more modern construction; and that if Solomon originally built this city, the Roman emperors, and particularly Adrian, so far re-edified it as to leave no traces of greater antiquity.

As the remains of Palmyra, though vast and stately, are more properly architectural than sculptural, we shall refer the reader, to satisfy further curiosity concerning them, to the admirable work of Wood and Dawkins; for whatever remarks might be requisite on the sculptures of Palmyra, would more properly belong to observations on the subject in the section of Roman sculpture. See Palmyra.

Balbec, near the site of the ancient Damascus, is another ruin of the same description. (See BALEB.) As for those many great cities mentioned by the Hebrew prophets as flourishing in their time in magnificence and riches, the places of some of them cannot be found, such as Teman, the capital of Edom, and the cities of Moab and Ammon, of Abur and Aram; some are dwindled into little villages, and most have left no traces in the desert where they might be found.

With regard to Heshbon and Rabbath, and Bozra and Hamath, all the mighty cities described by Isaiah and Ezekiel, as filled with multitudes in power, riches, and magnificence; the cormorant and the bittern poffefs them, the wolf howls there, and the wild beasts inhabit those forlorn places, where ancient kings and their counsellors, and warriors, thought they had built an everlasting habitation; even Ni neveh and Damascus are now indeed no more; they are, as the prophets said, “gone down into the nether parts of the earth,” nor does history design to tell their tale.

And of the ancient Tyre, and its Hercules of ancient Tyrian art, there are no remains. Herodotus says, “I failed to Tyre, in Phoenicia, because I heard there was a temple dedicated to Hercules. That temple I saw, enriched with many magnificent donations, and, among others, with two pillars, one of fine gold, the other made of a timagnosticus, which shone by night in a surpining manner.”

The Tyrian Hercules, or god of Tyre, is thus described by the prophet Ezekiel. “Every precious stone was thy covering, the sardius, the topaz, and diamond, the beryl, onyx, and jasper, the fapphire, the emerald, the carbuncle, and gold. The workmanship of thy tabrets and pipes was prepared in thee in the day that thou wert created. Thou art the anointed cherub that coverest, and I have set thee in a most holy temple, in the presence of the Lord; and thou hast walked up and down among the filones of fire.”

It looks as if there was some omission in the account Herodotus gives of this temple of Hercules, in Tyre. Herodotus, indeed, saw this temple after the ruin of Tyre by Nebuchadnezzar, consequently not in its glory, as Ezekiel had seen it; he has described the pillars as filones of fire, but he has not said any thing of the god; perhaps, in his time, the statue of Hercules had been taken away by mercenary cupiditv, as the statue of gold in Babylon had been removed by Xerxes. Such is the melancholy picture of ancient times, the fulfilment of the denunciations against those ancient empires; “they utter a faint murmur out of the dust.”

As there is a general resemblance in the early attempts at fine art in different nations; so there may be a likeness traced between the productions of Hindoo sculpture and the early productions of art in Egypt, Greece, and Etruria; however, we must always remember that the accurate observations made by the Greeks on beautiful nature, affiled by the regular progres in science, soon gave their productions a decided superiority over those of every other people.

The caverns of Ellora are vast halls excavated in the rocks, equal in dimensions to the large temples of other nations.

That of Ellora is architecturally divided, by rows of columns, into aisles; the friezes, and pannels in the walls, are filled with sculpture, detached, or in feryes, of the mythological personages, and acts of the Brahmin religion.

The sculpture of Elephanta is of the same kind, with the addition, at one end of the temple, of a colossal built of the triple-faced Brahah.

The columns of these temples offer a continual variety of ornaments in their capitals, shafts, and bases; redundant and extraordinary for the application of the lotus, canes, and other vegetable and animal productions of the country, in which the human figure is occasionally introduced.

On the banks of the Ganges are continually seen such ancient works of sculpture in the living rock, of inferior dimensons, but of the same sacred character, obelisks magnificently adorned, the figures of oxen, horses, tygers, elephants, 

The necessity of halting to the great object of our present
SCULPTURE.

Of Egyptian Art.—Egypt, the land of science, was visited by the most distinguished of the Greeks in arts and letters, among whom we find more especially the names of Orpheus, Dædalus, Linus, Homer, Thales, Pythagoras, Plato, and others of distinguished wisdom; all went to Egypt, as to the wise-felt nation of antiquity, for instruction. The earliest historian, Herodotus, went also, and has given an account of this extraordinary country. He says, that in the time of their king Amais, Egypt contained 20,000 populous cities. The remains, at this present time, as described by the latest travellers, are more stupendous than those of any other, with their attendant sculptures and paintings: though devastated by the tempest of war deluge after deluge, still the colossal power of Egypt has a remnant left to testify what it once was.

Herodotus says, on the authority of the Egyptian priests in his own time, from Egyptian records, that Mene was the first king of Egypt, the posterity of whom reigned three hundred and thirty kings; and after those were twenty, named Nitocris. Of the actions of these kings, he was told, no record remained, except of Nitocris, and of Memnon, the last of these kings. He says, I shall, therefore, pass them by, to relate the memorable actions of a succeeding king, whose name was Sesostris. That he conquered all nations, and caused his image to be carved on stones in the countries that he subdued, which he describes thus. His figure is five palms in height, holding a bow in one hand, and an arrow in the other, and armed after the Egyptian and Ethiopian manner.

On a line, drawn from one shoulder to the other, these words are engraved in the sacred letters of Egypt: “I obtained this region by the strength of these arms.”

After Sesostris reigned six kings. Statues made in the time of the last of these were in ruins in the time of Herodotus, which was about the year of the world 3500. When Herodotus saw them, the hands had dropt off through age, and were lying on the floor of the temple. Afterwards reigned in succession four kings, who were succeeded by twelve kings, all reigning at one time over Egypt, who built the magnificent labyrinth which Herodotus describes. These were succeeded by four more kings in succession; but no work of importance is ascribed to any of them. They were succeeded by a king named Amais.

The works of Amais, as described by Herodotus, are exactly like those whose ruins remain to this day. Herodotus says, that Amais was a great lover of the Grecians, and permitted them to establish themselves in Egypt, and erect temples and altars to the gods. He also took a Grecian wife, and sent consecrated donations to Greece, particularly a gilded statue of Minerva to the city of Cyrene, a colony of the Greeks, with his own resemblance taken from the life. To Lindus he gave two statues of stone, representing the same goddef, together with a linen pectoral or admirable workmanship. He sent two statues of himself, carved in wood, to the city of Samos; where, our author says, this day they are seen standing in the great temple of Juno, behind the gates.

His works in Egypt Herodotus thus describes: “He caused a colossal, lying with a face upwards, 74 feet in length, to be placed before the temple of Vulcan at Memphis; and on the same basis erected two statues, of 20 feet each, wrought out of the same stone, and standing on each side of the great colossal. Like this, another is seen in Sais, lying in the same posture, cut in stone, of equal dimensions. He likewise built the great temple of Isis, in the city of Memphis, which well deserves to be admired.

“He built the admirable portico, which stands before the temple of Minerva in Sais; far surpassing all others in circumference and elevation, as well as in the dimensions of the stones; and adorned the building with colossal statues, and the monstrous figures of androcephali. One part of the stones employed in this work were cut in the quarries of Memphis; but those of the greatest magnitude were conveyed by water from the city of Elephantis, distant from Sais as far as a vessel can make in twenty days. But that which I beheld with the greatest admiration was a house he brought from Elephantis, made of one stone. Two thousand men, all pilots, were employed during three whole years in the transportation of this house, which is in front twenty-one cubits, in depth fourteen, and eight in height. This is the dimension of the outside.”

Such works are ascribed to Amais, who was conquered by Cambyses, the son of Cyrus the Persian, about the year of the world 3400, a hundred years before Herodotus; so that 500 years will remain to be occupied in Egyptian history, from Sesostris to Amais; and within this time, the Egyptian buildings and works of sculpture, which the priests represented to Herodotus as so very ancient, might easily have been produced.

Thus a division is made between the fabulous and the historic ages, both in Egypt and Greece; and a decided era produced, which will not infringe on the truth of sacred scripture, nor on the credibility of authentic Gentile history; and by a comparison of the remaining monuments, it may give some date to the early works of Egypt and Greece.

The moderns have been no less zealous to examine the remaining ruins of Egypt, than the ancients were to contemplate its ancient glories.

Of these wrecks, these ruins of ancient knowledge, the late publications of Egyptian antiquities give majestic and awful ideas. Some of the drawings made by the French Institute in Egypt have been published, and they display what Egypt once was.

The ruins of Egypt are contained in a compass of about 550 miles along the banks of the Nile, among pyramids, and pillars, and porticoes, and subterraneous palaces hewn out for the dead.

The first objects of Egyptian sculpture that seize hold on the imagination are the colossal statues: among these are the sphynx, and the statues called Menmon or Olomandu. The sphynx is situated to near the pyramids of Giza, as to make it apparent that these maules of solid bulk were accompanied by other maules of ornamental sculpture; and being divested of their gigantic accompaniments of intellectual labour, the pyramids are left alone, inexplicable monuments of loft wisdom as well as departed power.

The sphynx is thus described by Ripaud: the length of the rock, to which the form of this chimerical animal has been given, is about 95 feet; its height from the knees to the top of the head is 38 feet. The ancients very generally believed that there was a passage in the body of the sphynx, which led by subterraneous channels to the interior of the pyramid. It is still conjectured that, beneath these enormous maules, cavens have been dug, which some suppose to have been employed in the mysteries of initiation. On the head of the sphynx there is a hole five feet in depth; and it may even extend further. There are also appearances of another opening of the same kind on the back of the figure.
The head of the sphynx bears the lineaments of a Negro. It is deprived of the nose.

Of this monument Denon says: although the proportions of the sphynx are colossal, the contours are free and pure; the expression of the head is sweet, graceful, and tranquil. It is the character of an African: the mouth and lips thick, with a softness in its movements, and a fineness in its execution, truly admirable: it is the flesh and the life. At whatever time this was produced, art was without doubt in a high degree of perfection. If there is wanting in this head that which we call style, that is to say, those forms, just and exalted, which the Greeks have given to their divinities; it is but justice to acknowledge, that there is no great and sweet character of nature which we cannot admire in this figure: if we are surprised at the dimensions of this monument, no less are we astonished at its execution.

The temples of Karnac and Luxor, on the right bank of the Nile, together with those of Medinet Abou and the Memnonium on the left bank, are fupposed to occupy the situation of the ancient city of Thebes. The ruins of these temples are of vast extent. The palace of Karnac was in front 240 feet, and its depth near three-quarters of a mile. It consisted of four great courts of nearly equal dimensions, comprehended within a long figure; the first court was occupied by four rows of columns; the second court had 130 columns, the largest 11 feet in diameter, the smallest 7 feet; the third court was adorned with obelisks 90 feet high, and colossal statues, surrounded by various royal apartments. On each side of the entrance to the fourth court was a saloon of granite: the rest of the space was occupied by porticoes, colonnades, and numerous chambers for officers and attendants. This palace, with four dependent structures of similar magnificence, but inferior proportions, was approached by four paved roads, bordered on each side with figures of animals, each 15 feet long. In one avenue were 50 lions; in another avenue, sphynxes; in another, rams; and in the fourth, lions with hawks' heads. From the ruined state of these avenues, we have no computation of the number of animals by which they were bordered; though it is almost certain that they were not fewer than 300, and it is possible they might be many more. In this palace 22 colossal statues still remain, and a great many statues of granite, and fragments of the size of nature; besides which, the walls were nearly covered within and without with bafio relieves and pictures. The lesser structures in this group of buildings were adorned in the same manner, and communicated with the other palaces of Luxor and Medinet Abou, as well as the Memnonium, which was the magnificent tomb of Ozymandus or Memnon.

The Memnonium looks to the east: it is a palace of the most ancient construction, and its dimensions also colossal. In one of its courts are seen the remains of the celebrated statue of red granite, which may be considered as that of Memnon. Its height was 64 feet, and its remains are scattered 40 feet around it. One of its feet subsists almost entire, whose breadth is 46 feet; and one of its ears measured 39 inches in length. The excavations are still visible, where the wedges were placed which divided the monument, when it was thrown down by Cambyses.

Between the Memnonium and Medinet Abou, and distant about half a league from each of them, are the remains of a great number of colossal statues and traces of buildings, which indicate that these two places were communicated with each other by structures which filled up the whole space between them. This mass of edifices appears to have composed, according to Diodorus Siculus, the tomb of Memnon or Ozymandus. We are confirmed in this conjecture, by the conformity which exists between the monuments in their present state, and the extensive as well as precise descriptions which that writer has left of pictures which are found in both palaces. They reprent the sieges of fortified towns, hostile invasions, and victories obtained by the Egyptians.

The Memnonium has not been finished, as well as the greater part of Egyptian works, where, by the tide of objects but roughly hewn, are seen examples of exquisite finishing. Between the Memnonium and the palace of Medinet Abou are the largest colossal statues which now remain in Egypt: these are the figures now called Memnon. They are both fitting, with their heads looking straight forwards; both their hands lying equally on their knees; their feet straight forward, and their legs in an upright position, and both alike. One of these, according to the descriptions in Diodorus and Strabo, and those who copy their writings, was the famous statue of Ozymandus, the largest of all the colossi. The height of them is about 58 feet. Three smaller female figures accompany each of the colossal statues, which are standing one on each side of the chair, and one between the legs of the principal figure; these are in bafio relief; and that on the pedestal or chair of the southern figure wants no charm of delicacy in the execution. It is on the leg of that figure, towards the north, on which the inscriptions are written of those illustrious ancient travellers who visited the statue of Memnon: there are innumerable inscriptions of names of all dates, and in all languages.

But Denon gives it as his opinion, which is also that of Ripaud, that the two statues now standing are the mother and son of Ozymandus; the figure of Ozymandus itself now lying in ruins, as was before described.

The great temples of Hermopolis; the great city of Mercury; of Tentyris, or Dendera; of Latopolis; of Karnac; of Apollinopolis, or Edfu; of the islands of Phile, and of Elephantine: are all now in ruins, covered with remaining examples of Egyptian sculpture, both in statues and in hieroglyphical representation, on the walls, and on the pillars and porticoes, within and without; many of which are works of great labour and care, as well as intelligence in art.

M. Ripaud says, the execution of the figures engraved on the exterior and interior walls at Dendera, is an example of the highest point of perfection to which the Egyptians attained. All the minute of their dress are finished with a purity and delicacy most admirable, considering the impracticability of the stone. The elevation of this temple is 72 paces in breadth, and 145 in length; the portico is 60 paces in length, and 30 in breadth. Its most remarkable decoration is the great zodiac, divided into two bands; it enriches the ceiling of the two last intercolumns to the right and left. The saloon succeeds to the portico, and is supported by fix columns, whose capitals display four figures of Isis, with the ears of a cat. The compartments of the walls are decorated with pictures, in which is a great number of female figures.

On the terrace of the great temple is a small one, the columns of which are like those of the portico: this temple forms a square of nine feet, and is the portico of a chapel, of which there are no traces. In the inner part of the temple is an apartment, which is adorned with a zodiac; it is circular, and occupies one-half of the ceiling. The apartment appears to be consecrated to astronomy. It is separated from another astronomical sculpture by a female figure in bas-relief, of a large size, occupying the whole diameter of the ceiling; it presents a contour easy, and of beautiful
SCULPTURE.

Beautiful proportions; its feet, well preferred, are in a beautiful style; it does not present any attribute, except a collar, which is often seen on figures of Isis; the hair is curled, and falls on each side of the face; and on each side of this figure are hieroglyphical inscriptions.

At Luxor, which is part of ancient Thebes, are the remains of a palace, having in its front two obelisks of granite; their height is twenty feet above the earth. Near these are two colossal figures buried up to the breasts; and judging from the size of what is above the earth, we may reckon that thirty feet are buried, which gives a hundred feet to these obelisks. They are in perfect preservation; the hieroglyphics upon them are most laboriously finished; the labour to cut them from the quarry must have been immense, as well as to transport them to the place where they now stand. The parts preferred of the two colossal pieces are admirable pieces of sculpture, and were finished in the most careful manner. Behind these are two great moles, which formed the gate; they are covered with sculptures representing chariots drawn by two horses, each having only one conductor.

It is remarkable, that neither the colossal figures, nor the monuments, are on a line with each other, nor with the gate; also, they are so close together, that the distance between the moles and the obelisks, comprehending the colossal statues between them, is but eleven paces; each of which objects in an insulated position, would astonish the beholder with its size.

The temple of Hermopolis was consecrated to Isis, whose delivery from Typhon is sculptured on the walls in baffle relief; it is a beautiful, elegant structure, but dreadfully ruined.

Eune, the ancient Latopolis, has a temple, the portico of which is in good preservation; it was dedicated to Jupiter Ammon, as appears from a medallion over the gate in the inner part of the ruin. The hieroglyphics and pictures represent a great number of sacrifices offered to this deity, and to rams, his emblems; the most curious of these represent the offerings made to crocodiles, and the worship of the Nile. The triumphs of the signs of Leo and Cancer are equally distinguished. Hieroglyphics are sculptured in relief on the columns, very beautiful for their workmanship. This temple is one of the most remarkable in Upper Egypt, as well for the perfect preservation of the portico, and its parts that till remain, and their fine execution, as for the very interesting pictures, which relate to those minutiae of Egyptian worship which are least known; here is also found one of the remaining zodiacs. This is one of the most beautiful monuments of antiquity; most perfect in proportion, and beautiful in execution, of all the temples in Egypt.

Edu, or Apollinopolis, is the most spacious as well as the best preferred of all the Egyptian temples, and where the Egyptian architecture displays itself with supreme magnificence. It was dedicated to Horus, the Apollo of the Greeks. Here it is that the huge materials have been employed with the greatest care, though many of the stones have not been placed perpendicularly on their capitals, and several of the columns vary in their diameters. The drawing of the figures is correct, and there is some appearance even of perspective in the statues of Isis, that decorate the frieze of the portico.

The sculpture is particularly beautiful in the capitals of the columns that decorate this temple, every one different, but every one beautiful; they are totally original in the composition of their ornaments, and perhaps equally excellent with the admired Corinthian, or Ionic.

The temples at Elephantine and Phila are by no means inferior to any in Egypt; they are likewise adorned with sculptures and paintings of the most perfect Egyptian workmanship.

But the abodes of the dead were particularly distinguished by the care of the ancient Egyptians. All the Lybian mountain, which is half a league to the west of the Memnonium, and ends opposite to Medinet Abou, is pierced from its base to three-fourths of its elevation, with a great number of sepulchral grottoes. Thoje which are nearest the surface of the ground are most spacious, as well as the most decorated; those which are in the most elevated part of the mountain, are much more rudely contrived and executed; while such as hold the middle place bear an adjusted proportion of space and ornament. Thoje which belong to the poor are the most interesting, because they always contain some representation of the arts which flourished, and the trades which were practised at that epocha. The plan of these grottoes is in a great measure the same. A door opening towards the east displays a gallery of about twenty feet in length, sometimes formed in a straight line; at other times it runs off from the entrance in an angle: it is indifferently supported by columns or pilasters. At the extremity of the gallery is a well that leads to the catacombs, where the mummies are deposited. The depth of these wells varies from forty to sixty feet; and they are connected by long subterraneous passages rudely shaped in the rock, which terminate in a chamber of about thirty feet square, whose sides are supported by pilasters, and contain large remains of the mummies. There are evident traces of numerous other subterraneous communications, which probably lead to other chambers that are at present concealed.

In the upper gallery are sculptured in baffle relief, or painted in fresco, a great number of subjects relating to funeral ceremonies. The most interesting pictures which are seen there, present a detail of circumstances connected with the ancient inhabitants of the country. There are represented their first occupations, such as the chafe and the fishery. Thence we may trace the progress of civilization in the employments of the fudder, the carpenter, the potter, the money-lender, the husbandman, and in the duties and the punishments of the military life. Each grotto is adorned with a ceiling painted with subjects of fancy.

The tombs of the kings are about six thousand four hundred paces from the river. They have been formed in a narrow valley in the centre of the Lybian mountain. The ancient way thither is not known, and the spot is now gained by an artificial passage. These sepulchres occupy a large ravine, which is flanked by the bed of a torrent. The plan of one of these tombs will be sufficient to explain the general disposition of the rept.

Every grot communicates with the valley by a large gate, which opens to a gallery hollowed in the rock; its breadth and height are generally about twelve feet, and its length is twenty paces to a second gate, which opens to another gallery of the same breadth, and twenty-four feet in length. To the right and left of this gallery are chambers of five feet in breadth, and ten feet long. There are found paintings of arms of coats of mail, tygers’ skins, bows, arrows, swords, lances, and quivers. In other sepulchral chambers are found housetop utensils, couches, chairs, floors, cabinets of exquisite forms; and if the artist has copied what existed, it is certain that the ancient Egyptians employed the wood of India carved and gilded; there are also other utensils equally elegant, as cups and vases in all variety. Other funerary chambers are consecrated to agriculture; others to the utensils of the ploughman; others to instruments of music elegantly executed. The detail of preparing food is also there represented.
SCULPTURE.

It is in one of these chambers where are seen the two harps which were copied by Bruce. A third gallery succeeds, of the same dimensions as the former, and leads to a chamber above the level of the other apartments, which is eighteen feet square; from this chamber is the entrance to a gallery of thirty-four paces in length. There is also an inclining gallery, whose length is twenty-eight paces. At its extremity is a corridor of sixteen paces, leading to a chamber of eleven paces, which is connected with another of the same size, by a gallery of fix paces: a square suloon then succeeds, supported by eight pillars; its length is twenty paces, and its breadth twenty; here is the sarcophagus which contained the mummy of the king. The Romans made some attempts to carry away this sarcophagus from the grotto where it is deposited; they had even tried to level the ground in order to facilitate its removal, but they very soon renounced the impracticable enterprise.

To the saloon of the sarcophagus another apartment succeeds, of twenty-five paces in breadth, and forty in length; the height of the tomb is seven, its length eight, and its breadth fix; the total length of the gallery is two hundred and twenty-five paces. The tombs of the kings, throughout their whole extent, are covered with pictures and hieroglyphics, but the greater part are painted in fresco, and represent the most phantastic subjects. The refearches into Herculanæum have discovered a great number of paintings executed in a similar taste.

One of the most interesting of these grottoes contains a sarcophagus that is still entire, and in its place; its length is sixteen, and height twelve, and its breadth fix; it still preserves the lid adorned with the figure of the king, which is a single block of granite. How this was transported across the mountain, and afterwards introduced through a subterraneous passage two hundred paces in length, we can have no conception.

From the time of Strabo there were reckoned seventeen tombs of kings; and we shall still find the same number, if we may comprehend in this enumeration a superb grotto, whose plan is equally large and beautiful with that of the sepulchres of the Theban sovereigns.

This grotto is half a league to the north of the Memnonium, and is scooped out at the bottom of a mountain, whose enclosure contains many other tombs: the entrance of several of them is closed, but the greater part of them have been violated. It appears that those of the ancient Egyptians, who had remained faithful to their worship, endeavoured to conceal the knowledge of the sepulchers of their kings from their conquerors, or from the professors of other religions.

Two of these grottoes remain unmarred, and a third is altogether without sculpture; and some others offer to view several decorative objects in a very unfinished state.

The quarries of Sísís, in Upper Egypt, present a species of façade cut into door-ways of immense size, and porticoes, in which are other door-ways leading into tombs, in the chambers and passages of which are figures as large as life, cut in the native rock, often only rough lewd, and the walls are both sculptured and painted. On the borders of the Nile we find these porticoes, entablatures, and cornices covered with hieroglyphics cut in the rock. Beneath these are a great number of tombs, all cut in the rock. They are formed into galleries, at the end of which are funeral chambers of seven feet by ten and eight feet by twelve; these chambers, and the passages leading to them, are ornamented with hieroglyphics traced upon the rock, and finished with coloured flucso, representing offerings; the ceiling are also Heccean with ornaments and serpills; often they are arched with an elegant elliptical arch, and painted and sculptured in an exquisite style, displaying an agreeable assortment of colours, and an effect rich and graceful.

Most of the tombs are entered by a single door and gallery, and have only a single chamber, in which are one, two, three, or four figures as large as life, cut out of the rock, perhaps two brothers and their wives: the men fit in the middle and the women on the outside, with their hands passed under the arms of their husbands, who fit each with their arms across upon their bosoms. Some tombs have but one figure, perhaps of one who led a single life; another has three figures, a man and two women; the man in the centre and the women on each side, with their hands passed under the arms of the man, who has his arms crossed upon his bosom. The figures of men have little square beards, with head-dresses hanging down behind the shoulders; those of women have the same head-dresses, but hanging before their naked breasts. In some chambers the floor is cut into many tombs, of dimension and form to receive the mummies, and in the same number as the sculptured figures. Sometimes the principal figure holds the flower of the lotus, an emblem of death. And on the side of the door-way, at the entrance, we often see the figure of a woman in some attitude of lamentation. Sometimes there are two galleries or entrance into a single tomb; and one tomb in these quarries of Sísís, the largest and best preferred of any, is 55 feet long in front and 15 high, with an entablature having five doors: the middle door is ornamented with an architrave covered with hieroglyphics; within the door is a gallery or passage 50 feet long and 10 wide, in the midst of which is another door-way leading to a chamber, at the further end of which are seven figures standing; and on the inlfe of the interior door are two niches, in each of which is a figure also standing: other figures are also in the passage or gallery, all cut in the rock. In the façade without is a niche, three large with figures, the others smaller; those with the figures are all cut in the rock, the rest of the rock remaining in its primitive form.

Such are the ruins of a nation so celebrated, that it was the place where the wife men of that truly wise people, the Grecians, reforted as to the school of science.

The universal and profuse employment of sculpture by the Egyptians, both in colossal and minute dimension, for public and domestic purposes, for the service of the living and the dead, all induce us to enquire into the principles and quality of their productions.

We have not only the written evidence of ancient authors, but the demonstrative evidence of remaining works, that almost all the whole of Egyptian sculpture was faced, that is, representing divine qualities, attributes, and perfections, if we except the historical figures on their tombs and palaces.

The Egyptian statues stand equally poised upon the two legs, having one foot advanced, and the arms either hanging straight down, each side; or if one arm is raised, it is at a right angle across the body. Some statues fit on seats, some on the ground, and some are kneeling; but the positions of their hands seldom vary from the above description. Their attitudes are of course simply rectilinear, and without lateral movement; their faces are flat; the eyebrows, eyelids, and mouths formed of simple curves, slightly but sharply marked, and with little expression. The general proportions are something more than seven heads high; the form of the body and limbs rather round and effeminate, with only the most evident projections and hollows: their tunics or other draperies are without folds in many instances. Winkelman has remarked, that the Egyptians executed quadrupeds better than human figures, for which he
he gives the two following reasons: first, that as professions in that country were hereditary, genius must be wanting to represent the human figure in perfection; and, secondly, that superstitious reverence for the works of their ancestors prevented improvement. This is an amusing but needless hypothesis, for there are statues in the Capitoline museum with as great a breadth and choice of grand parts proper to the human form, as ever they represented in their lions or other inferior animals. In addition to the other observations on Egyptian statues, we may remark, that the form of their hands and feet are gross; they have no anatomical detail of parts, and are totally wanting in the grace of motion. This last defect, in all probability, was not the consequence of a superstitious determination to perfilt in the practice of their ancetors; it is better accounted for in another way: Pythagoras, after he had studied several years in Egypt, sacrificed to an oxen for joy of having discovered that a square of the longest side of a right-angled triangle is equal to the two squares of the lesser sides of the same triangle; and thence it follows, the knowledge of the Egyptians could not have been very great in geometry at that time, which will naturally and sufficiently account for that want of motion in their statues and reliefs, which can only be obtained from observation of nature affihed by geometry.

The rate of Egyptian science in the time of Pythagoras being noticed, leads us to another consideration respecting the date of their architecture and sculpture. Most of their works are mentioned by the ancients as done in the reign of Sesostris, and afterwards. Sesostris lived in the time of Rehoboam, king of Israel, about the time of the Trojan war, or one thousand years before the Christian era, which shows the arts of Egypt and Greece were in a progressive state at the same time. And from the Greeks residing with them to study theology, philosophy, and science; from the great intercourse, political and commercial, between the two countries from the heroic times; from the Greeks being long settled in the city of Naucratis, and other parts of Egypt, we may fairly conclude their communication in arts was just as free as in other conccrns, which seems the more likely, as there is a considerable resemblance in the features and contour of the early Greek and Egyptian statues.

The Egyptian baso reliefs are (generally but not always) sunk into the back-ground, being left level with the highest part of the relief; for which practice two reasons may be assigned; first, that as many of these baso reliefs were cut in exceeding hard stones, basaltes and granite; as much time must have been consumed to clear away the ground about the figure, as had been employed to cut the figure itself; but besides the economy of time, when some hundreds or thousands of figures were engraved on the sides of a lofty obelisk, or the walls of a temple; the far greater number of them were at a great distance from the eye 50, 60 feet or more; in this case the ground, being left perpendicular to the figure the whole circuit of its outline, gave it a greater breadth of shadow and diffinseness to the spectator. These baso reliefs, which we comprehended in the general term hieroglyphics, or sacred gravings, represent different subjects, according to the place and purpose for which they were employed. On the walls of tombs they represent the profligions, actions, and funerals of the deceased: in palaces, wars, negotiations, triumphs, procelions, trophys, with civil, military, and domestick employment of kings. In temples, they were the symbolical register of theology and sacred facre. On obelisks, they express hymns to the gods, or the praises of their kings. Ammianus Marcellinus has preferred part of a translation by Hermaptopoia, the Egyptian, of the hieroglyphics on the obelisk which formerly stood in the centre of the Circus Maximus; and at present before the church of St. John de Lateran in Rome. It imports, that the fun, the lord of the universe, gives to Rameli the kingdom of Egypt, and dominion of all the earth in the city of Heliopolis. This translation seems sufficiently justified in the upper lines of the hieroglyphics, where a divinity is sitting, in the act of beholding on a man, who kneels before him, stretching his hands to receive. In the following line the same man is seen again taking possession of an altar, on the side of which is the ox Apsis, and on the top the mitred hawk, symbol of Ophis. Thus of the sacred emblems of Egypt.

The enormous works of Egypt have struck every foreign visitor with wonder and awe, from Herodotus to the members of the French Institute. Herodotus says, one of their buildings is equal to many of the most considerable Greek buildings taken together, and M. Ripaud observes, those works are so prodigious, they make every thing we do look little; and indeed, if we consider the execution of a statue 65 feet high, in so hard a material as granite, the boldest heart would be appalled at the incalculable labour and difficulties of the work.

In the Egyptian sculpture we shall find some excellent first principles of the art. Their baso statues are divided into seven heads and one-third, or seven heads and one-half; the whole height of the figure is divided into two equal parts at the os pubis; the rest of the proportions are natural, and not disagreeable. The principal forms of the body and limbs, as the breasts, belly, shoulders, biceps of the arm, knees, shin-bones, and feet, are expressed with a flvely roundness, although without anatomical knowledge of detail; and in the female figures their parts formed so as to convey a considerable elegance and beauty. The forms of the female face have much the same outline and progression towards beauty in the features as we see in some of the early Greek statues, and, like them, without variety of character; for little difference can be traced in the faces of Isis, in her different representations of Diana, Venus, or Terra, or indeed in the face of Ophis, although sometimes underflow to be Jupiter himself, excepting that in some instances he has a very small beard, in shape resembling a peg. The hands and feet, like the rest of the figure, have general forms only, without particular detail: the fingers and toes are flat, of equal thickness, little separated, and without distinction of the knuckles; yet altogether their simplicity of idea, breadth of parts, and occasional beauty of form, strike the skilful beholder, and have been highly praised by the best judges. The ancient and modern.

In their baso reliefs and paintings, which require variety of action and situation, are demonstrated their want of anatomical, mechanical, and geometrical science, relating to the arts of painting and sculpture. The king, or hero, is three times larger than the other figures. Whatever is the action, a siege, a battle, taking a town by storm, there is not the smallest idea of perspective in the place. or magnitude of figures or buildings. Figures in violent action are equally delirious of joints, and other anatomical form, as they are of the balance and spring of motion, the force of a blow, or the just variety of line in the turning figure. In a word, their historical art was informing the beholder, in the best manner they could, according to the rude characters they were able to make. From such a description, it is easy to understand how much their attempts at historical representation were inferior to their single statues.

What has been hitherto said of Egyptian sculpture describes the ancient native sculptor of that people. After
the Ptolemies, successors of Alexander the Great, were
kings of Egypt, and that sculpture was enlivened by Grecian
animation, and refined by the standard of Grecian beauty.
In proportions, attitude, character, and drees, Oisiris, Isis,
and Os, their three great divinities, put on the Macedonian
costume; and new divinities appeared among them,
in Grecian forms, whose characters were compounded
from materials of Egyptian, Eastern, and Grecian theology
and philosophy.

In the reign of the Roman emperor Adrian, a number of
statues, in imitation of the ancient Egyptian, were made
to decorate the Canopus in his magnificent villa of Tivoli;
several of which have been dug up, and placed in the Capitoli-
Museum. But Winckelmann has remarked of these,
that they may be known from the ancient Egyptian sculptur-
ture, having no hieroglyphics on them. But, besides this
distinction, they are entirely unlike the genuine Egyptian;
as the drawing and character are Roman, in Egyptian atti-
ures and drees.

The ancient authors, who give the most satisfactory ac-
count of Egyptian antiquities, are Herodotus, Diodorus,
Siculus, Jophesius, Strabo, Clemens of Alexandria, Jan-
blichus, and Ous Apollo.

The best modern books on this subject are Pococke's
Voyages, Savary's Travels in Egypt, Norden’s Egypt,
Denon’s Egypt; to which may be added, the most magnifi-
cent work of Ancient and Modern Egypt, now publishing
in Paris, which will occupy twelve folio volumes, contain-
ing 840 plates, from the observations, researches, accounts,
and drawings, of the learned men and artists of the French
nation, who formed the French Institute.

Of Grecian Sculpture.—After Egyptian sculpture, the
course of our subject naturally leads us to consider the fame
art in Greece, which is thought by some to have received
its first principle from Egypt, and certainly preferred the
character of Egyptian sculpture in many of its works,
down to a late date; as Pliny observes upon the works of
Egina.

In early times, the greater divinities were worshipped
under the form of rude flones; and afterwards the lifelefs
representation of the human figure was attempted, with the
eyes a little opened, the arms close to the sides, and the legs
united in one common pillar for the support of the mses.

But about 1200 years before the Christian era, a sculptor
appeared, who works exacted the praise of poets, the
speculations of philosophers, the record of historians,
and continued to be preferred with zeal, and spoken of with
repect, centuries after sculpture had risen to its zenith.
This was Daedalus, the countryman and contemporary of
Theseus, not inferior perhaps in fame and variety of adven-
tures to that hero. Born of a royal race, the occieional
friend and adversary of kings, admired for his works when
living, and honoured with a chapel by the Egyptians after
death! to him are attributed various mechanical inventions,
fabulous and real: a fine portico to the temple of Veget
at Memphis; the Cretan labyrinth, which was the copy of
a hundredth part of the Egyptian labyrinth. Diodorus
Siculus speaks of his works in Sicily. Paufanias mentions
those remaining in Greece in his time, nine in number, of
which three may be particularly noticed: one a naked Her-
cules of wood. The works of Daedalus are indeed rude,
fays Paufanias, and uncomely in aspect; but yet they have
something as of divinity in their appearance.

Paufanias, besides the high character given of this statue,
mentions it twice in his Grecian Tour; from which we must
understand that it was held in considerable esteem and veneration.
This would naturally lead us to hope we are not
without some copy of it in gems, coins, or small bronzes,
by which all the most famous works of antiquity were multi-
plied. In the British Museum, as well as in the other
collections of Europe, are several small bronzes of a naked
Hercules advancing, whose right arm, holding a club, is
raised to strike; whilst his left arm is extended, bearing the
lion’s skin as a shield. From the style of extreme antiquity
which characterizes these statues, the rude attempt at bold
action, the peculiarity of Daedalus, the general adoption of
this action in the early ages, the traits of savage nature in
the face and figure expressed with little knowledge but
strong feeling, by the narrow loins, turgid muscles of the
breast, thighs, and calves of the legs, we shall find reason
to believe they are copied from the above-mentioned statue.

The name author fays, the Gnoiffians had a chorus in
white fhone, made by Daedalus for Ariadne, which is men-
tioned in the 16th book of the Iliad, as youths and damsels
dancing hand in hand. The loft early Greek baffo re-
lievos and paintings represent charades of the Graces and
Hours in this manner.

Endeus, the disciple of Daedalus, made a fluate of
Minerva, which Paufanias faw in the Aeneas of Athens.
The learned author of the Introduction to the volume of
Sculpture, published by the Dillettian Society, supposes
the heads of Minerva, on the early coins of Athens, were
 copied from this fluate, which femea very reasonable, when
we compare the style and costume with other works of the
high loft antiquity. And here we must obferve, that in the
early times of which we are now speaking, the rude efforts
were intended to represent divinities and heroes only.
Jupiter, Neptune, and several heroic characters, have the
felf fame face, figure, and action, as the Hercules of Da-
edalus defcribed above; the fame narrow eyes, thin lips,
with the corners of the mouth turned upwards, and pointed
chin; the fame narrow loins, turgid muscular forms of
breast, thighs, and legs; the fame advancing position of the
lower limbs; the right hand raised before the head, and
the left hand extended: and their only distinctions were,
that Jupiter held the thunderbolt, Neptune the trident,
and Hercules his palm branch or bow; as may be seen in
ancient small bronzes and coins of Athens and Paflum, and
on the most ancient painted vases. The female divinities
were clothed in draperies, divided in few and perpendicular
folds; their attitudes advancing like those of the male
figures. The hair of both male and female statues or paint-
ings of this period is dressed with great pains, collected in a
club behind, and sometimes entirely curled, in the fame
manner as powdered by the native Americans, and the in-
habants of the South sea iflands. Daedalus and Endeus
first formed their statues of wood. Metal was also used for
various purpofes of sculpture in the loft ancient times, as
we learn from Homer, Hefiod, and Plutarch.

Dipnus and Scyllis, the Cretans, were celebrated for
their statues in marble, about 776 years before Chrifl; yet
retaining much of the ancient manner in the advancing po-
tion of the legs, the drawing of the figure, and the perpen-
dicular folds of drapery, disposed in zigzag edges. Soon
after elaborate finifhing was carried to excess, undulating
locks and spiral knobs of hair, like cockle-shells, as well as
the drapery, were wrought with the most elaborate care and
rigid exactness, whilst the tafteles and barbarous character
of the face and limbs remained much the fame as in former
times. This paflion for high finifhing in ftulture, will re-
conce to our reason a paflage in Pliny b. xxxv. c. 81, which
has frequently been thought to disagree with the general his-
tory of ancient painting: he fays, ‘that the picture of the
battle of Magnete, painted by Bularchus, was paid for,
with
SCULPTURE.

with its weight in gold, by Candaules, king of Lydia, who was coeval with Romulus, and lived in the 20th Olympiad, or about 750 years before Christ: thus," continues Pliny, "proving the fame and perfection of the art." Now, according to the fame author's account, the ancient painting did not arrive at its greatest perfection until after the time of Phidias, or two hundred and fifty years later; and therefore it is likely that Bularchus's picture was chiefly valued for the fame high mimicking we fee in the earlist marble statues, of which the following are examples:—colossal busts of Hercules and Apollo, in the British Museum, most likely those done by Diphæus and Scyllis for the Sicelians:—very ancient statues of Minerva, and a priest of Bacchus, lately in the Villa Albani, published by Winckelmann in his Monumenta Inedita, and Storia dell Arte. To these might be added examples of extreme finishing in early Greek pateras and other bronzes. This observation on Bularchus's picture, and the sculpture of the same time, will naturally lead to anothor of more general comprehension, that the improvements in sculpture we have reason to believe followed those in painting according to the dates, as far as we are able to ascertain them in remaining works. Soon after this time may be reckoned the Amynecian Apollo, described by Pauly as very ancient. The shrine, with the image fitting upon it, Paulya conjectured at not less than thirty cubits; he enumerates the subjects sculptured upon it; they comprehend the history of the fabulous ages underneath. The base is the sepulchre of Hyacinthus, which is entered by a brazen door. In the sepulchre are many works of sculpture. The figure of Apollo, Paulya describes as of very rude art. Paulya also mentions a brazen Hercules of ten cubits, as the work of a disciple of Dædalus.

Philocles the Egyptian, or Cuttinges the Corinthian, is said first to have introduced outlines among the Greeks, in the practice of which they were followed by Archilles the Corinthian, and Telephanes the Sicelian, who used other lines within the outline, to express the marking of the body and limbs, also writing the names of those they painted, which agree with the earliest paintings on Greek vases, as their attitudes and peculiarities agree with early sculpture. Cimon Cleonius invented catograpy, or the oblique representation of images, to give different views of the face, looking up, looking down, and looking backwards: he represented the veins, and the folds and plaitts or wrinkles in garments. This Cimon is mentioned as living before the time of Phidias, which affords an additional argument for believing improvements in painting to have preceded those in sculpture; because oblique views of objects, and the veins of the limbs and body, seem not to have been attempted in sculpture before the time of Phidias.

Fortunately for us, the compendious history of painting and sculpture, left by Pliny, was selected from the writings of the best Grecian artists, and arranged, with attention to the several improvements, in chronological order, with such perspicuity and comprehension, that whenever, from the brevity of the work, we do not find all we wish for, yet by attending to the information before and after, we shall be easily enabled to supply the defects from other writings or monuments of antiquity. In this manner we shall satisfy ourselves concerning the progress of sculpture, in the two hundred and fifty years which elapsed between the age of Diphæus and Scyllis and that of Phidias. The better drawing of the figure, with a more careful attention to its parts, more precision and variety of attitude, a less elaborate curling of the hair, the forms of the figure better shown through the draperies, are all certain signs of a nearer approach to the age of Phidias. If we add to these observations the different ages of writing on works of sculpture, what letters are wanting, and whether the inscription is in the Boulephedon or ploughing manner, we shall not err much from the date of the work.

From the few historical observations now offered, it is evident that sculpture was eight hundred years from the age of Dædalus, to the time immediately preceding Phidias, in attaining a tolerable representation of the human form, which proves the flow growth of art perfected by manual labour in the infant state of science; whilst the means of sublimity are precarious, the rights of individuals undefined, and the general attention of society employed on self-preservation and defence, rather than on the increase of comfort or civilization of manners. Poetry and oratory, the more independent efforts of mind, appear in the earlist states of society, distinguished as an intellectual and rational creature, scatter the first seeds of knowledge, lay down theories for the government of future generations, expand the mind, and direct the powers towards whatever is most useful and most desirable in the more perfect states of humanity.

The chief occurrences in the early history of Greece are, the Argonautic expedition; the war of Thebes; and the taking of Troy; in which particular heroism, or the united achievements of petty states, are interwoven with poetic fiction. Their confederations produced no considerable change in the manners of the people or the character of the country; but the battles of Marathon and Salamis, which destroyed the Persian armies, whose might, like locusts, wasted the country, crushed the first deadly blow to the Persian power, and gave a beginning to the Greek or third great monarchy of the world. An event of so much importance, by changing fortune and transferring power in to large a portion of the civilized part of mankind, raised the character of Greece, in proportion to the abatement of Persia. The Greeks, particularly the Athenians, the champions of the war, whose heroic ardour was increased by success, fought additional distinction by every great and praiseworthy exertion of body and mind in arts and arms. The accumulated wisdom of ages, and discoveries in science, were taught by their philosophers; their temples and public buildings were reared with a magnificence unknown before, and decorated with all the powers of art. Archilochus, Euripides, and Sophocles, enraptured the minds of the people by their dramatic poetry. The five exercices which formed the body to exertion and beauty, and the mind to fortitude and patriotism, were universally practised, cultivated, and honoured. In this general spirit of enterprise and improvement, sculpture appeared in the school of Phidas, with a beauty and perfection which eclipsed all former efforts.

About 490 years before the Christian era, Phidias flourished at the same time with the philosophers Socrates, Plato, and Anaxagoras; the idatemen and commanders Pericles, Miltiades, Themistocles, Cimon, and Xenophon, with the tragic poets above-mentioned. This period was as favourable in its moral and political circumstances, as in the emulation of rare talents, to produce the display and encourage the growth of genius.

The city and citadel of Athens had been burnt by the army of Xerxes; but the Greeks, being conquerors, raised more stately buildings in the room of those destroyed. Phidias was engaged by Pericles in the superintendence and decorations of the temple of Minerva, and other public works.

Superior genius, in addition to his knowledge of painting, which he practiced before sculpture, gave a grandeur

Vol. XXXII.
to his compositions, a grace to his groups, a softness to flesh, and a flow to draperies, unknown to his predecessors, the characters of whose figures were stiff rather than dignified; their forms either meagre or turgid; the folds of drapery parallel, poor, and representing geometrical lines, rather than the simple but ever varying appearances of nature.

The discourses of contemporary philosophers on mental and personal perfection, alluded him in felecting and combining ideas, which Stamph his works with the sublime and beautiful of Homer's verse.

How this sculptor was esteemed by the ancients will be understood by the following short quotations. Pliny says, "Phidias was most famous through all nations." And when enumerating the most celebrated sculptors of antiquity, he says, "but before all, Phidias the Athenian;" and Quintilian says, that "his Athenian Minerva and Olympian Jupiter, at Elis, possessed beauty which seemed to have added something to religion, the majesty of the work was so worthy of the divinity."

After such positive and magnificent testimony, there will be full room for our surprise, in the descriptions, fragments, and other authentic memorials, of some works only which he conducted and performed; such as the temple of Minerva, and the Acropolis of Athens, erected by Helenus and Callistratus, under the direction of Phidias; and to him it is we likewise owe the compositions, style, and character of the sculpture, in addition to much skillfulness in the drawing, modelling, and choice of naked figures and draperies, as well as occasional execution of parts in the marble.

Pliny says, the emulators of Phidias were Alcamenes, Critias, Nellonclus, Hegia; and twenty years afterwards, Agelades, Callon, Polycleitus, Phraddmion, Gorgias, Lacon, Myron, Pythagoras, Scopas, Parchus. In this list we certainly have the names of the sculptors employed on the temples of Minerva and Theleus; and as the styles of different hands are sufficiently evident in the alto and baso reliefs, so there might perhaps be so great difficulty in tracing some of the artists by resemblance to others of their known works.

The two pediments of the temple of Minerva were each eighty-eight feet long, filled with compositions of entire groups, and statues from eight to nine feet high. The story of the western pediment related to the birth of Minerva, or rather perhaps represented her introduction among the gods. The eastern pediment was occupied by the contention of Neptune and Minerva for the patronage of Athens. Forty-three metopes were charged with battles of the Lapithae and Centaurs, and a frieze of three hundred and eighty feet round the wall of the temple, under the portico, was decorated with the procision of the Grecian states, in honour of Minerva, in chariots, on horseback, leading animals for sacrifice, bearing offerings, and presenting the sacred veil, in presence of the gods, fitting on thrones to witness the solemn ceremony.

The marquis Nanteuil had a drawing made of the western pediment of this temple, when the statues were all, excepting one, in their places; and notwithstanding some mutilations of parts, the whole was sufficiently entire for the composition to be perfectly understood from the marquis Nanteuil's sketch, carefully compared with the original fragments in the earl of Elgin's museum. In the centre, Jupiter sits holding his sceptre in his right hand, the thunder in his left; on the right of Jupiter, in an advancing position, Minerva takes possession of her char, while the reins are governed by Thetis and Mars; from behind Theseus, a genius leads Victory forward to attend the patron of Athens; on the left of Jupiter, Vulcan stands by his mother Juno; Amphitrite sits next, whose foot rests on a dolphin; Latona succeeds, with her infants Apollo and Diana, beautifully implying that the maturity of divine wisdom was older than the sun and moon. The last group is Venus fitting on the lap of Ocean; the figures at each end of the pediment are not shewn, because they are mere contingeats, spectators only; not partaking in the action.

The idea of this composition seems to have been suggested by Homer's hymn to Minerva, a short poem, but one of the author's highest flights; in which he describes Pallas in full stature, and completely armed, leaning on the head of Jove; Olympus, the whole earth, and surrounding sea, trembling at the vibration of her spear; the fun flaying her couriers in their race, and partaking in the same amazement with the other immortals.

The statue of Minerva, in the Parthenon at Athens, one of the masterpieces of Phidias, is thus described by Pliny, Paufanias, and other ancient authors. It is in height twenty-fix cubits, formed of ivory and gold, standing upright, her tunic reaching to her feet, holding a Victory fixing her feet high in her right hand, and a spear in her left; the drapery is of gold; that the uncovered parts of the statue are of ivory; and the head of Medusa on the breast-plate of the goddes is of ivory; at her feet is her shield; in the convex part of her shield is the Amazonian war; in the concave part is the war of the gods and giants; in the base Pandora's history: the gods are here present thirty in number; the Lapithae and Centaurs are sculptured on her sandals; a serpent at her feet admirably executed; a sphyx on the top, and a griffon on each side of her helmet. The quantity of gold in this statue was forty talents. Plato says the eyes were of precious stones.

There was also, in the citadel of Athens, another statue of Minerva by Phidias, thus described by Paufanias. Of the spoils taken at Marathon by the Persians, Phidias made Minerva's statue of bract, in whose shield the battle of the Lapithae and Centaurs was engraved by Mys, and painted by Parrhasius, the son of Eucra. The top of the spear, and crest of the helmet, might be seen by those who fail by Saniun.

But the great work of this great master, the adornment and praise of after ages, was the Jupiter at Elis; thus described by Paufanias. The god is seated upon his throne, made of gold and ivory, a crown of olive branch on his head; in his right hand bearing a Victory, also of ivory and gold; she bears a fillet, and is crowned; the left hand of the god holds a sceptre of various coloured metals, an eagle of gold, fitting upon the sceptre; his garment is of gold, and on his garment are wrought animals and flowers, particularly the lily; his sandals also are of gold; the throne is variously ornamented with gold and gems, and also with ivory and ebony; on it animals are painted in their proper colours, and sculptured with great labour. Four victories, as in the dance, are on the hinder feet of the throne, two on each side; and on the front the children of the Thebans taken away by the sphyx; and beneath the sphyx, Niobe and her children slain by Apollo and Diana; on the frames that join the feet of the throne ornaments are carved; on that in front Hercules warring with the Amazons. Paufanias numbered upon them all together twenty-nine figures. Among Hercules' companions was also Theseus. There were also pillars which joined to the feet supporting the throne, equal in size to the feet. There is not an entrance under the throne, as under that of Apollo at Amulis. It is hollow, but the spectator cannot enter, because a wall includes the throne. Of this wall, that part which fronts the door is painted
SCULPTURE.

Painted blue; the sides have the pictures of Panænus. Among these is Atlas sustaining Heaven and Earth. Hercules stands near him lifting off his burden. Here are also seen Thefeus and Perithous, Græcia and Salamin, two figures; the last of which carries a rostrum in her hand. Hercules’ strike with the Nemean lion. Ajax under the reproach of Cassandra. Hyppodamia, daughter of Oenomaus, with her mother. Prometheus bound in chains, Hercules coming to his help; Hercules also, having slain the eagle, which was the punishment of Prometheus on Caicus, delivering him from his chains. On the hinder part is painted Penthesilea dying, Achilles supporting her. The two Herpides bearing the apples of which they had the keeping. Panænus, the brother of Phidias, who did these, painted also, in the Pecile of Athens, the battle of Marathon. Upon the throne, above the head of the god, Phidias carved the Graces and the Hours. Three of them large; these are called daughters of Jove. Upon the feat, lions of gold, and Thefeus warring with the Amazons. Upon the base of the throne, which great masts was wrought in gold, are other ornaments relating to the god. The rising Sun in his chariot, and Jupiter and Juno, and by them the Graces; these lead Hermes, and Hermes, Vesta. Cupid also from the sea receiving Venus, who was crowned by Perseus. Apollo was with Diana, and Minerva with Hercules; and on the lowest part of all was Neptune, and the Moon in her chariot urging on her horses.

The temple at Elan also, which contained this astonishing statue, was itself a noble work of Doric architecture; and the architect was Libon, an Elan. The sculptures on the outside of the temple have a relation to the great work within. A gilded Victory crowns the whole. In the front pediment is the contest of the chariot race between Pelops and Oenomaus, and in the back pediment the Lapithæ and Centaurs, with the nuptials of Perithous; and in the temple, and over the doors, the labours of Hercules in very many compositions, which are the work of Acalemenes. The temple has brazen doors and an interior portico, which opens an entrance to the statue of Jupiter; under the statue is inscribed “Phidias, the son of Charmides the Athenian, made me.”

It may be proper to take notice in this place, of another temple dedicated to Jupiter Olympus, at Athens, by the emperor Adrian, and in it a colossal statue of ivory and gold, described as not inferior to the colossal statues of Rhodes and of Rome.

Pausanias describes also a temple and statue of Æclepulius at Corinth, in the following manner. The statue of Æclepulius is almost half the size of the Olympian Jupiter at Athens. It is of gold and ivory, and is the work of Thrasymedes, the son of Arignatus, a man of Paros. He is seated on a throne, holding a great staff, and with his other hand presenting the head of a serpent; a dog lies at his feet; in his throne the acts of the Ægean heroes are sculptured: Belerophon killing Chimaera. Perseus holds Medusa’s head cut off. Above the temple are places where those who come to pray to the god repose.

Several other statues of great excellence, both in marble and bronze, are mentioned among the works of Phidias, particularly a Venus, placed by the Romans in the forum of Octavia. Two Minervas, one named Callimorphous, from the beauty of its form; and it is likely that the fine statue of this goddess in Mr. Hope’s museum is a repetition in marble of Phidias’s bronze, from its resemblance to the statue of an Athenian silver coin, in attitude, drapery, and helmet. Another statue by Phidias was an Amazon, called Eucnemon, from her beautiful leg; of which there is a print in the Museum Pium Clementinum.

Acalemenes was celebrated for his Venus Aphrodite, to which Phidias is said to have given the last touches. Praxiteles excelled in the highest graces of youth and beauty: Pliny says he not only excelled other sculptors by his marble statues in the Ceramicus at Athens; but his Venus was preferable to theirs, and all other statues in the world, to see which many failed to Gnidos. This sculptor having made two Venuæ, one with drapery, the other without; the Coans preferred the clothed figure, on account of its severe modell. The same price being set upon each, the citizens of Gnidos took the rejected statue, and afterwards refused it to King Nicomedes, who would have forgiven them an immense debt in return; being resolved, says our author, and with reason, to suffer anything, so long as the statue of Praxiteles ennobled Gnidos. The temple was entirely open in which it was placed; because every view was equally admirable. The figure is known by the descriptions of Lucian and Cedrenus; and it is represented on a medal of Caracalla and Plautilla, in the cabinet of France. This Venus existed in Gnidos during the reign of the emperor Arcadius, or about 400 years after Christ.

This statue seems to offer the first idea for the Venus de Medicis; which is likely to be the repetition of another Venus, also the work of this artist, mentioned by Pliny.

On the reverse of the empress Lucilla’s medals, is a clothed Venus, with an apple in her right hand; which, from the grace of its attitude, and its resemblance to several antique marble statues, is likely to be the clothed Venus chosen by the Coans.

Among the known works of Praxiteles, are his satyr, cupid, Apollo, the lizard-killer, and Bacchus leaning on a bawn.

The celebrated Venus of Gnidos was found, about eighteen years since, in the neighbourhood of Rome, which was afterwards the property of duke Bracchi, nephew of the late pope Pius VI.

Polyeuctus of Sicyon, the scholar of Agelades, was particularly celebrated on account of his Doryphorus, or lance-bearer; and Diadumenus, or youth binding a fillet round his head. This statue was valued at an hundred talents. The Doryphorus was called the Rule by artists, from which they studied.

The Difcobolus of Myron is ascertained by an antique gem, and the description of Quintilian, who apologizes for its forced attitude. An ancient example of this figure is in the British Museum.

The Difcobolus of Naucydus is uniformly admired for its forms and momentary balance.

The wounded man, in which might be seen how much of life remained in him, was the famous work of Ctesilas, and perhaps is the fame as the statue commonly called the Dying Gladiator, but more properly a dying herald, or hero, according to Winckelman.

Ctesilas, or Defilas, is known by his wounded Amazon. Pliny mentions the nine muses by Philiscus of Rhodes; and the muses also, brought by Fulvius Nobilius to Rome. From one of these series must be the greater number of those formerly in the pope’s museum, now in the gallery of France, of which the Comedy is remarkable for grace, and the Tragedy for grandeur.

The Hermaphrodite of Polyceles is one of the most delicate and graceful productions of antiquity. The Apollo Philiscus, or in love, by Cnachus, isHelvetica many fine repetitions in the different galleries of Europe.

The Ganymede, borne in the eagle’s talons, is exactly described by Pliny. An example of this work exists in the pope’s museum.
The Apollo Belvidere, believed by the learned Vifconti, to be Apollo Alexieaco, the deliverer from evil, the work of Calamis; mentioned both by Pliny and Paulania; and the history of its removal is given in the Museum Pium Clementinum. Only one small antique repetition of this statue is to be found; and indeed admirable and sublime, in its beauty as it is, there is a reason which might render it less popular among the ancients than the moderns. Maximus Tyrias describes a statue by Phidias very similar to this, but in greater motion, either discharging an arrow, or preparing to do so. (Ieom.) There are traces of this statue in some ancient ballo-releives; and it is possible the stronger expression of Phidias's work, together with the authority of his name, might have diminished the public attention to Calamis in a comparative production.

The Venus de Medici is so popular a favourite among the Greeks and Romans, that a hundred ancient repetitions of this statue have been noticed by travellers. The individual figure is said to have been found in the forum of Octavia. The style of sculpture seems to be later than Alexander the Great; and the idea of this statue seems to have its origin from the Venus of Gnido.

We may now notice some statues of great excellence, which Pliny has not mentioned. And no wonder they are omitted, when of more than 11,000 reckoned in his history, he professes to give a catalogue of about 500 only.

The colossal statues on Monte Cavallo in Rome we may fairly presume to be the works of Phidias and Praxiteles, as inscribed on their pedestals; because the animated character and style of sculpture seem peculiar to the age in which those artificers lived; and because, in the frieze of the Parthenon there is a young hero governing a horse, which bears so strong a resemblance to those groups, that it would be difficult to believe it was not a first idea for them by one of those artificers.

The heroic statue by Agafis the Ephesian, commonly called the Fighting Gladiator, is shewn by the ingenious and learned Abbate Fea, to be Ajax, the son of Oileus, as his figure is so represented on the coins of Locris, his country.

The Hercules Farneis was evidently one of the first favourites of antiquity, from its frequent repetitions in bronze and marble, gems and coins. Its history, according to thefe, seems to be this. The city of Perinthus was twice besieged by Philip of Macedon; the citizens, however, by the strength of their situation, their own valour, and the intervention of friends, preferred their liberty. As their city was dedicated to Hercules, they represented him on their coins relating from his labours. The flanding figure is the Hercules Farneis, which, on the coin, was copied; as usual, from an honoured statue in the city; most probably from the work of Glycon the Athenian, whose country once delivered them from the oppression of Philip. The style is later than the time of Alexander.

We shall now proceed to those precious monuments of art, the ancient groups; in which we see the sentiment, heroism, beauty, and sublimity of Greece, excelling before us.

The group of Laocoon, animated with the hopeless agony of the father and sons, is the work of Apollodoros, Athenodoros, and Agefander of Rhodes. The style of this work, as well as the manner in which Pliny introduces it into his history, give us reason to believe it was not ancient in his time.

Zeus and Amphion, tying Dirc to the bull's horns, an example of filial vengeance for a perfecuted mother, is as heroic in conception as vast in execution. The restorations of this group are so bad, that they only become tolerable by something like an assimilation of spirit in their union with the ancient and venerable fragment. It is the work of Apollonius and Tauros of Rhodes.

The group of Herecles and Anteus, in the Palace Pitti at Florence, may be a marble, from the bronze of which the copyist incribed the name of the original artist.

The groups of Atreus, bearing a dead Son of Thetides; Orestes and Electra; Ajax supporting Polydorus; are all examples of fine form, heroic character, and sentiment. There seems only to be one reason for their being omitted by Pliny, that they were too recent at that time to have obtained an equal rank in public estimation with the fine works of Phidias and Praxiteles, and their immediate descendants.

The group of Niobe and her youngest daughter, by Scopas, is an example of heroic beauty in mature age. The sentiment is maternal affection: the expostes her own life to shield her child from the threatened destruction.

The separate statues of the children all partake of the same heroic beauty, mixed with the passions of apprehension, dismay, or death.

To this series belongs that fine example of anatomical study, in difficult but harmonious composition, the group of The Boxers.

The beautiful and interesting group of Cupid and Psyche is not mentioned by Pliny, perhaps for the same reason that several other fine works are not noticed, because it was after the times of those great masters who were looked on as the standard of excellence in his days. It is most likely that had been produced after the reign of Augustus, when the Pythagorean philosophy was revived, from which its subject is taken.

From what has been said, it will appear sculpture did not arrive at its maturity until the age of Phidias, 490 years before the Chrillian era; and Pliny's catalogue of the most celebrated Greek artists continues 160 years later, or to 350 years before Chrill. After which time, however, the Laocoon, and several of the finest groups and statues, seem to have been executed: nor can we believe, from the admirable bulls and statues of the imperial families still remaining, that sculpture began to lose its grace until the reign of the Antonines; and, indeed, so strong were the flamina of Grecian genius in the art of design, that after the time of the Iconoclastes in the fifth and sixth centuries, when the noblest works were destroyed, when great works of sculpture were not required, even then, and until Conftantinople was taken by the Turks in the 15th century, the Greeks executed small works of great elegance, as may be seen in the dyptichs, or ivory covers to confular records, or facred volumes used in church service.

The works of sculpture, here enumerated, will also shew, that almost all the greatest and most valued productions were of marble, and not bronze, as some have been inclined to believe. And although several of the statues mentioned by Pliny were bronze, from which we have marble copies, yet all the groups, with two or three exceptions only, are marble; and some of the most celebrated statues, as the Vennes, and the Cupid by Praxiteles, with many others.

The principal schools of sculpture were Athens and Rhodes. The sculptors of the Laocoon, and the Toro Farneis, and the Colossus, were Rhodians; and it is almost incredible, that from this little island, only forty miles long, and thirteen broad, the Roman conquerors brought away 5000 statues. But we shall more readily believe this when we recollect that the force and enterprise of these inhabitants were sufficient to conquer the navy of Antiochus, commanded by Hannibal.

Sicily had long been the workshop of metals of all countries.
countries. Egina was also famous for bronze sculpture, and continued the Egyptian style.

Etruscan sculpture must be considered entirely the work of Greek colonists and their disciples.

The Sicilian sculpture is also Grecian. Some of their finest medals in particular are of the Corinthian school.

As the enterprise and taste of the present age have revived two noble examples of Grecian sculpture, the pediments of the temple of Jupiter Panellenius, in the island of Egina, and the frieze which surrounded the interior of the temple of Apollo Epicurus at Phigalaia, it may be proper to give some description of them in this place.

The figures, which were decorations of the east and west pediments of the temple of Jupiter Panellenius, were found among the ruins, nearly under the site in which they had been originally placed: their number was nine in the west pediment; that in the centre was the figure of Minerva; the right seemed to be combatants, as well in this pediment as in the east pediment. On each side of an ornament, in the centre of the west pediment, were two female figures; and at each corner of the pediment the remains of a griffin. The statues were in fine small nature; and, according to Pliny’s description, partaking of the Egyptian style of workmanship.

Among the ruins of the temple of Apollo Epicurus at Phigalaia, in the Argolis, were discovered, in many pieces, the frieze which adorned the interior of the temple. They represented the battle of the Athenians with the Amazons, and the Lapithæ with the Centaurs. The compositions are grand and energetic; the actions are natural, original, and elastick; the lines of the bodies and limbs are beautifully variegated by the draperies, as flowing from the motion of the figures, or flourished in the air by impulse of wind; the beauty of the figures and countenances is heroic; and the general style and character of the work resembe the altorelieves in the temple of Theseus. The figures are about two feet high; and the whole extent of the different bafse relieves, taken together, about ninety feet.

Of Roman Sculpture.—The earliest inhabitants of Italy, without doubt, practised the same kind of barbarous art, which is common in all early stages of society; but the accounts given by Herodotus, Diodorus Siculus, and other Greek writers of indubitable authority, concerning the emigrations of Greeks into Italy, who settled in that part which has been called Magna Graecia, comprehending nearly the whole western coast of that country, together with the evidence of nearly every work of art which has been discovered within those limits, prove satisfactorily, that all the early painting and sculpture, worthy to be called so, are properly colonial Greek, either the production of Greek artists themselves, or of natives who were their scholars.

We may observe upon their coins, that they all seem to have been derived from the earliest coins and weights of Greece. Their earliest cast money or weights, signed with an ox, lead to a strong supposition that they were imitations of similar weights alluded to by Homer, which had relation to the value of an ox. Their cast coins or weights are also marked with the head of Janus, with two faces on one side, and the prow of a ship on the other; but it is to be observed that this double-faced Janus, when bearded, is only an imitation of the Greek heads of Jupiter, or the eastern Bacchus, who, according to the earliest fyllables of philosophy, fees that which is pæt and that which is to come. When the head of Janus is without a beard, it sometimes seems to be a copy of the head of Hercules, and sometimes of Mercury: and in order to leave no chance of being deceived in the perfonage, he is represented with the petasus or hat upon his head, as well in the double as in the single head; besides which, all the divinities represented on such coins or cast weights, are but copies from well-known heads of Grecian divinities, as Jupiter, Hercules, Mercury, Ceres, &c.; and by far the greater number of them from Grecian heads of those divinities not earlier than the time of Phidias.

Concerning their painting, though it may be difficult to make the same assertion so positively and so extensively as that concerning their coins; yet we must allow that the subject was of their painting, whether on walls or earthen vases, represent Greek philosophy, Homerick personages and stories; scenes from the Greek tragedians or Grecian sacred rites; and that the superfluous to those paintings were written in Greek, expressing Grecian names of the artists who painted, or the perfons represented.

The sculpture also which has been called Etruscan has the same Grecian characteristics with the paintings; to which we may add, in many instances, that it represents Grecian arms and dresses.

The accounts given by Pliny of the figures of the Roman kings, and other illustrious personages of early times in the Capitol, together with the Terra Cotta figure of Jupiter Capitolinus; were from the Grecian schools of art eltablished in Eturia; and such were all the works of painting, sculpture, and architecture, executed for the early Romans, who do not appear to have polifhed any works of magnificence or distinguished merit, before the Scipios introduced them to an acquaintance with Grecian arts and letters.

After the enormous ravages and barbarities of Mummius at Corinth, and Sylla at Athens, the Romans ingrafted taste on rapine, and exhibited an inordinate cupiditi and ostentation for works of fine art, which palled in some instances for patronage. They filled their palaces, villas, theatres, and public places with the spoils of Greece.

Although some general heads of Greek art have been already delivered in this dissertation, yet as Pliny the Elder’s writings contain such satisfactorily accounts of Etruscan, Italian, and Grecian sculpture, it will be highly proper to give the English reader these accounts in his own words, which were collected from the writings and treatises of the ablest and most learned artists among the ancients. Pliny’s Natural History, l. xxxiv. c. 7.

The italque art was familiar in Italy in ancient times, as is shown by a Hercules confecrated by Evander, as it is said, in Foro Boario; which is called the Tumbral, by his having on the triumphal habit: besides the double Janus dedicated by king Numus, which exprsippes peace and war, and by its fingers signifies the number of days in the year, the god himself indicating the times and seasons of the year. There are also Tuscan italues differed very widely, which there is no doubt were made in Eturia; such were also believed to be their gods, except by Metrodorus Scæfus, which surname was given to him through the hatred of the Romans; for two thousand italues, when the Volscians were conquered, were difperfed abroad. We have wondered to fee the original italues of ancient Italy, of wood perhaps, or modelled in clay, the images of gods dedicated in temples until the conquest of Aetia, from whence came luxury.

It will be proper to speak of the first origin of expressing likenesses in that kind which the Greeks call modelling, and that it was prior to italique. This would extend to infinity in a work of many volumes, if any person should follow up the subjece: every one does what he is able.

When Scævus was ede, three thousand italues made the scene of a temporary theatre. Mummius, when he conquered Achæia, filled the city; but dying, left his daughter without a dowry, which was inexusable. Lucullus brought many; from Rhodes there are as many as three thousand italues.

Mutianus,
Mutianus, thrice consul, brought not fewer from Athens: from Olympia and Delphi, it is believed, a greater number.

What mortal can recount those which are most distinguishe, or noted for some reason or other; indeed, to have named the distinguishe artificers would be a pleasurable task. Their number also is infinite, when Lysippus alone produced to the number of 600 works, which were all famous; their number appeared at his death, when his heirs opened his treasuries; he was used, on receiving his payment, to deposit a golden denarius for every work. The art, in the succese of its darings, is elevated above human faith. One example of such succese we shall offer: the similitude expressed is not of God nor of man. Our age saw in the Capitol, before it was confumed in the fire of Vitellius's times, in the chapel of Juno, a dog of brasta, licking his own wound, whose most wonderful and unequalled verisimilitude suggested the reason why it was dedicated: the life of its keepers was pledged for its safety. Innumerable are such daring examples of art: mallese have been devised equal to towers. Statues which are called Colossi, such is Apollo in the Capitol, brought by M. Luellus from Apollonias, a city of Pontus, of 30 cubits: its expense was 300 talents. Such, in the Campus Martius, is the Jupiter dedicated by Claudius Cæsar, which is called the Pompeian, from its vicinity to Pompey's theatre. Such is that at Tarentum, made by Lysippus, of 40 cubits; admirable in this, the hand being stretched out and in danger of being broken by the stormy wind; the artif is therefore provided, it is said, within a little interval, an opposing column, to prevent a great wind from breaking his work. Consequently, because of its magnitude, and the labour required, Fabius Verrucosus did not meddle with it at the time he brought from hence the Hercules which is in the Capitol. But above all, as objects of admiration, was the Colossus of the fun of Rhodes, by Chares the Lindian, the disiphe of Lysippus before mentioned, 70 cubits in height. This statue, after 50 years, was thrown down by an earthquake, but lying prostrate it was still a wonderful spectacle; few could clasp round its thumb; its fingers were larger than whole statues. The vast caverns of its broken members were displayed within great mallese of stone, whose weight kept it readiant. Twelve years it was in making, at the expense of 300 talents, which were supplied by king Demetrius, being interrupted by the tediousness of delay. There are other less Colossi in this city, 100 in number, each of which would ennoble the place whereforever it was fixed. Besides these were those of the five gods made by Bryaxis, who made many Colossi in Italy, in particular an Apollo, which is seen in the Tuscan library of Augustus, 50 feet high, of fine brasta, and exquisite workmanship. Sp. Carvillus made a Jupiter, which is in the Capitol, from the breast-plates, helmets, and greaves taken from the Samnites, of an amplitude to be seen from the temple of Jupiter Latarius. The rest of the figures which are before the feet of the statue, are also from his file. Two heads also are admired in the same Capitol, which P. Lentulus, the consul, dedicated, one made by Chares above spoken of, the other by Decius, overcome in the comparison to that degree, as seemed by no means probable, according to the works of the artif. But in statues of that kind, Zenodorus in our age has excelled. He made a Mercury in the city of Gallia Arvernus, the labour of ten years, which was afterwards 70 approved, that he was called to Rome by Nero, where he was desired to make the colossal statue of that prince, 150 feet high, which should be dedicated to the fun, by way of reverence, and which is among the atrocities of this prince. It is wonderful that in his workshop there does not remain any clay model of this work of a large size, but there are many first sketches in small, like first attempts. This statue indicates that the art of founding in brasta is perished.

Nero had prepared liberally both gold and silver, and Zenodorus in modelling and carving was not considered as inferior to any of the ancients. When he had finished the statue for the Arvernians, Vibia Avitus, being the president of that province, two cups were sculptured by the hand of Calamis, which Germanicus Caesar highly valued, gave to his preceptor, Caius Syllanus, his uncle. As much as the excellence of Zenodorus was greater, so much may be found the decay in works of brasta.

The statues which are called Corinthian are for the most part such as may be carried from place to place. Such was that of the Sphynx, which Hortenfus, the orator, received as a present from Verres, and occasioned a reply from Cicero. When Hortenfus said, in altercation with him, "I do not understand your enigma," Cicero replied, "You ought, for you have the Sphynx at home." Nero, the emperor, it is said, took about with him a statue of an Amazon. And a little before our time, C. Cælius, the consul, always carried an image with him in the field of battle. Alexander the Great had a tent furnished by four single statues, of which two are now dedicated before the temple of Mars the Avenger, and the other two before the palace. The art is ennobled by almost innumerable letifer statues. Before all, Phidas the Athenian made a Jupiter of ivory and gold. He also made statues in brasta. He flourished in the 84th Olympiad, about 300 years from the building of Rome. It was celebrated that wealthy emperors were Alcaneus, Critias, Neocrese, and Hegias. Afterwards, in the 87th Olympiad, Agelades, Callon, Polyclese, Phradmus, Gorgias, Laccos, Myron, Pythagoras, Scopas, and Parches. Among these, Polyclese had for his disciples Argus, Aepodorus, Alexius, Arlistes, Phryone, Dinon, Athenodorus, Dames, and Myron. In the 95th Olympiad flourished Naucyes, Diniennes, Canachus, and Parches. In the 102d, Polyclese, Cepheidoros, Leochares, and Hyppodorus. In the 104th, Praxiteles and Euphranor. In the 107th, Echion and Thymarchus. In the 114th was Lysippus, in the time of Alexander the Great; and at the same time Lysiphatratus and his brother Sthenis, Euphranides, Solfratus, Ion, Silanion, who was admirable, none being more learned. He had for disciples Zeuxis and Jades. In the 120th Olympiad, Euthychides, Euthycrates, Dareiphalus, Cepheidoros, Timarchus, and Pyramoeus.

The art then ceased. And again, in the 127th, revived, though allowed to be inferior, yet approved; Anterus, Caligatiatus, Polyclese, Atheneus, Callixenus, Pythoeus, Pythis, and Timoques. We shall pass halfly over the most distinguishe of the celebrated artificers in their distinct ages. A Venus was made with a kind of emulative contention, as formerly they made an Amazon, which was dedicated in the temple of Diana, at Ephesus: that work was approved which every artif is judged to be next in merit to his own. This was the work of Polyclese; the next was Phidas, the third Cefillus, the fourth Cydon, the fifth Phradmon. Phidas, besides the Jupiter Olympius, which no one attempted to rival, made also, from gold and ivory, Minerva at Athens, which stands in the Parthenon. Of brasta, also, before that Amazon just mentioned, he made a Minerva of supreme beauty, from which it received the name of Callimorphos. He made also Cliduchus, or the key-bearer, and another Minerva, which Amillus Paulus dedicated at Rome in the temple of Fortune. Also two statues clothed in the pallium, which Catusus dedicated in the same temple, and another which was colossal, naked. He first discovered the art of alto relievo, and demonstrated its merit. Polyclese of Sicyon was the disciple of Age-
lades;
lades; he made a statue of tender youth, called Diadumenus, from his binding on a garland, valued at one hundred talents. Also one called Doryphorus, from his carrying a spear, a youth in the vigour of his age. He made also what by artists was called the Rule, seeking the lines of art from it as from a certain law. He was the only man who made art its own judge. He also made a strigili, and one throwing a die; also two boys at the dice, which are called Aftragalizones; they are in the emperor Titus's court. No work is judged to be more perfect than this. Also a Mercury, which belonged to Lytmachus, and Hercules pulling Antaeus from the earth, which is at Rome; also Artemon, an ephemeris voluptuary, who was called Periphehtetes, from his being born about in his couch. He was judged to have perfected the science. He was also highly skilled in alto relievo, which had been first discovered by Phidias. But what was particularly his own, he found out the balance of the figure on one leg; notwithstanding, as Varro reports, his figures were squared, and all imitated from one example.

Myron, born at Eleutheria, the disciple of Agesilaus, was very famous for a beifer, praiied in celebrated verses, whereas many are commended more by the ingenuity of others than their own. He made a dog and Dicobolus; Pericles, Eumolpus, and a fatyrs admiring the pipes; a Minerva; a Pentathletis, or master of the five exercitias; a panathlets or boxer; a Hercules also, which is at the Circus Maximus of Pompey the Great. He made also the monument of a grafs-hopper and locusts, to which Eunima refers in her verses. He made also Apollo, which the triumvir Antony took away, but it was restored to Epeus by Augustus, admonished for this purpose in a dream. No artist, for multitude of variety, surpassed Polycleitus, or was more accurate in symmetry; but although he was so curious in the representation of bodies, he did not express the feeling of the soul. The hair also, and the pudes, he made like the rude ancient work. Pythagoras of Rhegium surpassed him in a Paneratit, placed in Delphi; and also Leonitus, who made the pedestrian Alyson, which is shewn at Olympia, with Libys, the boy holding tablets, and one bearing apples, naked; a Syracusan, also fame, the sufferings of whose ulcer affect the beholder; also Apollo the harper, the serpent flain with his arrows, which is called Dicamus, and which was taken from Thebes by Alexander. He first expressed the nerves and veins, and the hair also with accuracy.

There was another Pythagoras of Samos, at first a painter, whose statues of the seven goddesses naked, and an old man, are very much praiied. This artist was said to have been indiscreet in the likenesses of the face. The disciple of Rhijnus is said to have been his father's son, called Soturus. Whereas Tullly affirms, that Lyppus was his disciple, which Doris denies. He first became a worker in brases, from hearing the answer of Eupompos the painter, who being questioned who should be followes of those before his time, answered, shewing a multitude of men, that nature should be imitated, not the artif. It is said that he made more statues than others, being more prolific in his art; among which is a man using the frigil, which Marcus Agrippa placed before his baths. This was very much admired by the emperor Tibere, who, not satisfied with it where it was, had it brought into his chamber, and another statue put in its place, at which the people of Rome were moved to repentment, and demanded it to be restored, which was done. Lyppus made a drunken piper, a hunting dog, and a chariot and four horses, with the fun of Rhodes. He made also Alexander the Great in many works, beginning from his childhood, with a statue of whom the emperor Nero being very much delighted, commanded it to be covered with gold; but afterwards, when the art was dif- covered to be destroyed by it, it was taken off; and it was esteemed more precious with the cuts and scars remaining in the work to which the gold adhered. He made also Heraklion, Alexander the Great's friend, which has been ascribed to Polycleitus, who was too years before him. Also Alexander hunting, which is consecrated at Delphos, and at Athens a crowd of satyrs: of Alexander's friends he made the strongest resembances. Metellus, when he conquered Macedonia, brought them to Rome. He made also chariots with four horses, of many kinds. He added much to the art of flatuaries, expressed the hair, made the head less than the ancient, the body more slender and dry than the ancient made theirs, by which the magnitude of the statues appeared enlarged. The Latins have not the word symmetry, which they most accurately observed, by a new and untried rule in changing the squared statues of the ancient; he said they made men as they are, he made them as they appear to be. He left sons and discipiles very much admired artists, such as Darius and Bedas; but above all, Euthycriates, although he emulated rather the complacency of his father, than his elegance, and was praiied with the auferere than the agreeable. Therefore he best expressed the Delphian Hercules, and Alexander, Theopis the hunter, and Thephaides, a battle of horsemens before Telephus's oracle, chariots and four horses, many statues of Medea, horsemans, and hunting dogs. His disciple was Diphales the Sicelitian, the nearest to Lyppus of all his followers, so that their statues are scarcely distingible; a Thban old man, king Demetrius, Peucides, Alexander the Great's preferrer, worthy of so much glory. Artificers, who have brought these things together in the volumes they have composed, celebrate Telephus, the Phoenian, unknown on other accounts, because in Thessaly, where he dwelt, his works are concealed; otherwise by the effigies of others he is equal with Polycleitus, Myron, and Pythagoras. His Larilla is praiied, and his Weatler with the thorns, and his Apollo. Some think he had no other demerit, but that he gave his workshops to Xerxes and Darius. Praxitels was also particularly happy, and also celebrated in his works of marble. He made also in brases beautiful works; the rape of Proserpine, the Sybil or prophetess, and the drunken woman Bacchus, and a most famous fatyrs, which the Greeks call Peribiodon; statues also which were before the temple of Pelis, and a Venus which was consumed in the fire of Claudius's palace; his marble, famous through the earth, was equalled by himself only. Also statues called Telephus, Splanome, Oenophorus, Harmodius and Aristogeiton, the Tyrannicides; which were taken by Xerxes, the Persian king, and were sent back to Athens by Alexander. He made also a youth, fleaping upon a lizard, which he approaches to strike with an arrow; it is called Sauronoton. He made two statues, expressing opposite effects, a mourning matron, and a rejoicing harlot; they think this to be Phryne, discovering in her the love of the artif, and the reward of the woman: this statue poiffes much grace. Calamis made a charioteer with four horses: in his horses are never found any defect, though he is thought to be defective in his men. The same Calamis made other chariots, both with four and with two horses, in which the men are not inferior. Nothing is nobler than his Alcmenes. The disciple of Phidias, Alcmenes, worked in marble; also in brases he made a Pentathlet, who is called Enerinomenes. But Arifides, the disciple of Polycleitus, made chariots both with two and four horses. And Laza, by Iphocrates, is praiied. This is the harlot who in the lyre and song was the familiar of Harmodius and Aristogeiton, and partook of their counsel in the Tyrannicide. She was tortured to death, and did not betray them to the tyrant; wherefore the Athenians willingly hold her in honour, not that
that they celebrate her as an harlot, but they have made an animal of her name; and that the cause of the honour might be understood, they forbade the artist to add the tongue. Bryaxis made Æsculapius and Seleucus; Bedas made Battus adoring Apollo, and a Juno, which are at Rome, in the temple of Concord. Ctesilus made a wounded man fainting; in which might be understood how much life remained; and an Olympian Pericles, worthy of the epitaph. He was admirable in his art, and noble men he made more noble. Cephisodorus made in the Athenian port an admirable Minerva, and an altar to the temple of Jupiter the favour, in the same port, with which few can be compared. Canachus made an Apollo naked; it is called Philæus in Didymæus: it is of the Ægæentic mixture of brass. Also, a deer suspended in his steps, that a line might be drawn under his feet; retained only in the alternate bite of his hoofs and heel, so that turning about his teeth to both parts, he starts from the repulse of his action by turns. He made also Cele- tizontes, or boys holding hatchets. Chares made Alexander the Great and Philip his father. Ctesilus, or Desilus, made a Doryphorus and a wounded Amazon. Demetrios made a Lyphmachus, who was priest of Minerva fifty-four years. He married a wife of Minerva, which is called the Musical; he killed the serpents in her Gorgon and found the stroke of the harp. He also made Simonides, the horfeman, who first wrote of horfmanship. Darius made, among his famous works, two boys using the tirigg. Dimonyes made Proteus and Pythodorus the wrestler. Euphron's work is Alexander Paris, in which we praise all that is intelligible at once; the judge of goddeses, the lover of Helen, and also the lover of Achilles. His is the Minerva at Rome, which is called Catulliana, being dedicated in the Capitol by Quintus Lutatius Catulus; also the statue of Good Fortune, in his right hand holding a patera, and in his left a spike of corn and a poppy. Aloa Latona, the nymph, in the temple of Concord, suffaining in her arms Apollo and Diana. He made also achairot with four, and another with two hores: also Cliduchon, or the key bearer, of the most perfect form; also Virtue, and Gracia, both of them colossal; also a woman, admiring and adoring; and Alexander and Philip, in a chariot and four hores. Eutychides made Eurotas, in which many saw that art was more liquid than the river itself. Heglias made Minerva, and king Pyrrhus, highly praisd; and Cezilizontes, boys; and Cal- ton and Pollux, before the temple of Jupiter the Thunderer. In the Parian colony is the Hercules of Tisodoros. Eleutherus, the Lycian, was Myron's disciple, who made (worthy of his preceptor) a boy, blowing the languard fire; and the Argonauts. Leochares made an eagle, who understood what he took away in Gunymede, and what he bore, fearfully touching the wet with his talons; also the boy Autolycus, victor in the Pancratium, on whose account Xenophon wrote his Symposion; Jupiter also, thundering in the Capitul, praised above all; also Apollo with a diadem. Lyceus made the boy Lagon, cunning, false, and impudent. Lycus made a boy offering incense. Menechmus made one, with his neck bended, and his face pressing his knee: this Me- nechmus wrote of his art. Naucyes made Mercury, and a Discobolus; and, as it is thought, a person sacrificing a ram. Naucerus made a wrestler, drawing his breath. Niceratus made Æsculapius and Hygeia, which are in the temple of Concord at Rome. Pyromachus made a chariot with four hores, governed by Alcibiades. Polycles made a Her- maphrodite, a noble work; Pyrrhus, Hygeia and Minerva; Phoenix, the disciple of Lytippus, Epitheatæ; Stipax, the Cyprius, one celebrated statue, an augur; here was the flame of the Olympic Pericles burning the entrails of a sacrifice, with a full mouth blowing the fire. Silanion made Apollodoros the most accurate among all in the art, and his own inimical judge, breaking the scarcely perfect statue, because he was unable to satisfy his own wishes in the art, and he was therefore furnamed the Madman: in this he expressed not the man made of brass, but rage itself; a noble Achilles he also made, and Epithe exercising the athlete. Strongylos made an Amazon, which, from the beauty of her leg, was named Eucnemon: the emperor Nero always carried it with him; he also made a boy, whom the love of Brutus of Philippi rendered illustrious with his name. Thedorus, who made the lab- yrinth at Samos, cast his own likenes in brars: besides the admirable resemblance, it is celebrated for the delicacy of its execution; the right hand holds a file and the left a squire; it was taken to Præneste. He also composed a car and driver, so small, that they might be covered with the wing of a fly. Xenocrates, disciple of Titocrates, or, as others say, of Euthyraces, excelled, both in the number of his statues, and composed volumes on his art. Many artists made Attalus and Eunenous fighting against the Galatians. Isthmous, Pyromachus, Stratonicus, and Antigonus, composed volumes on the art. Boethus, although more excellent in working silver, made a most beautiful infant slanting a goafe. But of all the works I have mentioned (says Pliny), the principal were dedicated by the emperor Vespasion in the temple of Peace, and his other buildings, being brought together by the rapine of Nero into the city, and disposed in situations in his golden hourse. Befides, there are other artists equal in their merits, but none of their works are pre- eminent; Ariston, who was used to work in silver; Callides, Cefitas, Cantharas of Sicyon, Dionysodorus, disciple of Critia, Deliades, Euphorion, Eunicus, and Heata. Among the sculptors in silver were Leboedex, Prodrus, Pythodorus, Polygenius; these were noble painters; also among the sculptors in silver; Stratonicus and Scymnes, who was the disciple of Critias. Pliny then enumerates those who made works of this kind, as Apollodoros, Androphulos, Alece- dorus and Alevas, who made philosophers; Apellas made adoring females; Antigonus and Peryxionemon made the Tyrannicides above spoken of; Antiachus and Athene- dorus made noble women; Arilodemus made wrestlers, and a chariot with two hores, with their charioteer; philosophers; an old woman, and king Seleucus; his Doryphorus also is a graceful work. There were two of the name of Cephildoros; the first made Mercury feeding the infant Bacchus; he made also an orator, with his hand raised up, but the person is uncertain; the other represented philosophers. Colotes, who worked with Phidias on his Olympian Jupiter, represented philosophers; also Cleon and Chen- charms, and Callicles, and Cephis. Chalcodon was a comedian, and an athlete; Daisippus made a dirigilist; Dai- chon, Democritus, and Daimon, the philosophers. Epigonus excelled almost all the rest already recorded, in his imitation of a trumpeter, and a mother piteously embracing her slain infant; and Eutholis counting by his fingers. Mycon made a beautiful Athleta; Menogenes a chariot and four hores. Nor was Niceratus inferior to them all, representing Al- cibiades in his attack; and Demartarius facriciating; his mother lighting a lamp. Tistracres made a chariot and two hores; Pitho placed a woman upon it; also he made Mars and Mercury, which are in the temple of Concord at Rome. Perillus, whom no one prises, more cruel than Phalaris the tyrant, made a bull, in which he promised that a man, by the power of fire, might be compelled to bellow, but he himself, by a more just act of cruelty, was made to experience it. Thus a most humane art was called away from the simi- litude of gods and men. Was it for this that so many laboured to rear an art that it might become a torment?
SCULPTURE.

Therefore one caufe of preferring his work was that, who-
soever should fee it might hate the hand that produced it. 
Sthenis made Ceres, Jupiter, and Minerva, which are at 
Rome, in the temple of Concord; also matrons weeping, 
and adoring, and sacrificing. Simon made a dog and an 
arcer. Scopas worked in all kinds; athletes, and soldiers, 
and sacrificers. Batten, Eucharis, Cnideus, Heliodorus, 
Hicamus, Lophon, Lyfion, Leon, Menadorus, Myiaigrus, 
Polycrates, Polydorus, Pythocrates, and Protagenes, who 
were famous in painting. Patrocles, Polis, Fofidonius, who 
also carved excellently in filver; they were Ephesians. 
Pericles, Philon, Sinenus, Timothenus, Theomneatus, 
Timarchides, Tinon, Tiffas, Thrafon; among all thefe 
the most known and remarked is Callimachus, always his own 
calculator, nor did he fee any limit to his accuracy; hence 
he was called Cacizotechonas: he exhibited memorable 
examples of his exoffive attention. His are the dancing Lae-
demonian females, an over-laboured work, in which all the 
grace was taken away by the accuracy; he also, as it is 
faid, was a painter. One fature alone of Zeno, Cato 
in his expedition to Cyprus, did not feer: not gratified with 
the brafs, nor with the art; but because it was the portrait of 
a philofopher; this we observe by the way, although it 
may turn out an ufefcale example. One fature we much 
miff mention and not pafs over, though the author is uncertain 
concerning the Rochurn at Rome, a Heracleus, clothed in 
a tunic of the Elean habit, with a frowning face, as fuffering 
in the highest degree from the tunic. On this are three 
inscriptions, L. Lucullus, imperator, from his fpoils; the 
other is the fon of Lucullus, a minor, from fenatus confu-
tum: the third is, T. Septimus Sabinus, a curule edile, 
from his private property restored to the public. This 
fature was thought worthy of fuch a diftinftion. Pliny, 
I. xxxiv. c. 16, &c.

Dibutades, a Scyphonian potter, first found the art of 
making likenefles of clay, in Corinth, by the help of his 
daughter, who being in love with a youth who was going 
on a journey, fcored lines round the shadow of his face 
by a lamplight on a wall, which her father impreffing 
with clay, made a type, or cast, and with the reft of his 
pottery placed to be hardened in the fire. It was pref-
werved in the Nymphceum till Mummius overturned Corinth, 
as it is faid. There are thofe who fay that Rhaccus and 
Theodorus firft found out modelling in Samos, before the 
Battides were driven from Corinth. Demaratus fled from 
that city, and in Etruria was the father of Tarquin, the firft 
king of the Romans; he was accompanied by Euchira and 
Euframus, the modellers; by thofe modelling was firft 
broad into Italy. Painting them red, or making them 
of red clay, was firft practifed by Dibutades; he is the firft 
who added marks to the extremities of tiles which threw 
off the flowers, which at firft were called protypes; after-
wards he made clypves, or moulds of them; hence arifing 
at the top of the tile, they were named models. The like-
fets of man was taken from the face itself in plater; and 
clay was produced in that form as poured into the plalter. 
Lyflafatus, the brother of Lyfippus the Scyphonian, improved 
this invention; he firft determined the representation of 
portraits; for before him, they endeavoured to make them as 
handfome as possible. He did the like in his fature. Since 
improvements were made that no fature was produced witho-
ut a model. It appears, therefore, that this art was more 
ancient than casting in brafs. Damophilus and Gorgafus 
were very eminent modellers; they were also painters, who 
exercifed both arts: in the temple of Ceres at Rome, and in 
the Circus Maximus, there are vefers ineribed in Greek, 
which signify that the work on the right hand was that of De-

mophilus, and on the left that of Gorgafus: before this all the 
work in this temple was Tuscan, as M. Varro fays. From 
this temple, when it was reftored, the surface of the walls 
being cut away, the pictures were included in frames; the 
flates from the roofs also were difpcrcd. Chalcithenes 
made unburnt models at Athens, in a place which was called 
Ceramicus, from his workfhop. M. Varro fays that he 
knew a man named Alcis, who made at Rome bunches of 
grapes and apples, which could not be difcerned from real 
ones. He alfo extols Arceflus, the intimate friend of Lucius 
Lucullus, whose cafs often fold for more than the other 
works of his art; by him was made a Venus Genitrix, in the 
forum of Cifar; it was placed before it was finifhed, from the 
halfe of the dedication. Afterwards by the fame hand, 
a fature of Felicity was to have been set up, but both defigns 
were frustrated by death. A cup was made for Octavius, a 
Roman knight, the model of which in platter cost a talent. 
Pailetes is praised, who fays modelling is the mother of 
figurative, fculpture, and engraving. This art was very 
much used in Italy, and chiefly in Etruria. Turianus, 
being called from Fregillum by Tarquin the elder, made the 
fature of Jupiter, to be dedicated in the Capitol; it was a clay 
model, and, as ufual, coloured red; his was also the model 
on the top of the temple of a chariot and four horses, which 
has often been fpoken of. In this way he made a Her-
cules, which at this day in the city retains the name of its 
material. Pliny, I. xxxv. c. 43. 45.

The firft of all who were famous for marble fculpture, were 
Dipaeus and Scyllis, born in the ifland of Crete. When it 
was under the dominion of the Medes, before Cyrus began 
to reign in Perifia, that is, about the 50th Olympiad, they betook 
themselves to Sicyon, which was a long time the workfhop 
for the metals of all countries. The images of certain 
gods they publicly placed at Sicyon, but before they had 
finifhed them, the artifts, complaining of some injury, fled to 
Etolia. Forthwith famine and barrenness invaded Sicyon, 
and direful afflictions. A remedy being alfked from Apollo 
Pythias, he immediately anfwered, "Let Dipaeus and Scyllis 
perfect the fatures of the gods." They were intreated to 
do this with great rewards and liberal offers. These images 
were Apollo, Diana, Hercules, and Minerva, which after-
wards were touched with lightning from heaven.

In their time there was, in the ifland of Chios, Malas, a 
sculptor; then his fon Misciades; and then his grandfon An-
thenus, a Chian, whose fons, Bupalus and Antemerus, 
were famous in this fience in the age of Hipponax, the 
poet, who, it is certain, lived in the 60th Olympiad. If 
this family had traced back their progenitors, they would 
have found art to have originated with the commencement 
of the Olympiads. Hipponax had a singularly ugly counte-
nance; wherefore his likenefs, produced in a vulgar joke, was 
held up to public ridicule: at which Hipponax, indignant, 
bore to hard upon them with the bitterrefs of his verfe, and 
compelled them to hang themselves. But this is an er-
ror, for many great fatures afterwards in the isles. 
In Delos, where the fong was compos'd, they 
could not escape the cenfure; but at昔 fome of 
Antemerus, the fon; and there is shown at Jaffus a 
Diana, made by their hands; and in Chios it is faid there 
is a Diana of their work, whose face is much above the 
fpicator's eye, and fo contrived, that to thofe entering the 
temple the appears fevere, but to thofe going out the ap-
pears exhilarating. At Rome their fatures are on the Pale-
tine Hill, on the top of Apollo's temple. In their country 
of Delos alfo are their works, and in the ifland of Leibos 
Dipaeus has certain works at Ambraecia, Argos, and 
Clone. All thofe artifts ized the white marble that comes 
from
SCULPTURE.

from the island of Paros; which Rome took the appellation of lychnites, because it was cut in the quarries by the light of the lamp, as Varro writes. Afterwards a much whiter kind was found; lately also in the quarries of Lunenum. But of the Parian a wonder is told: the finy glebe, divided by the wedges, fell apart, and an image of Silenus appeared within. It must not be omitted, that these arts, both of painting and sculpture, so anciently produced, were taken up by Phidias in the 3d Olympiad, 332 years afterwards: for Phidias brought forward the art of sculpture in marble. His Venus at Rome, which is in the forum of Octavia, is a work of the most beautiful perfection. He taught Alcamenes the Athenian, who, it is certain, is distinguished among the first of the Athenians; whose works are at Athens, in many sacred temples. Famed above the rest is his Venus without the walls, which is called Aphrodite in the Garden. It is said that Phidias put the finishing hand to this statue. His disciple was Agoranctus of Paros, so agreeable to that age; therefore many works are given about in his name. There was a trial of skill between the master and the disciple, in making a Venus. Alcamenes conquered not by his work, but by the suffrages of his city, which favoured him against a stranger. Under the condition that it should not be at Athens, Agoranctus sold his statue. It is a furnamed Nemefis. M. Varro preferred it to all statues. There are in the temple of Magna Mater, in the fame city, works of Agoranctus. Phidias is undoubtedly famous through all nations, which have understood the fame of his Olympian Jupiter. That thofe may know how deferestedly to praise his works, who have not seen them; we shall offer some arguments relating merely to his ingenuity; without comprehending the beauty of the Olympian Jupiter, and referring merely to the structure of the Athenian Minerva. It is 25 cubits, composed of ivory and gold: in her shield the Amazonian war is engraved; in the swathing of the buckler, and in the concave part, the war of the gods and giants; in her sandals the Lapith and Centaurs, every minute particular put together with the greatest art. In the base is engraved the birth of Pandora. Here are gods produced, twenty in number; Victory is chiefly admirable. The skillful have admired the serpent, and, under the crest of her helmet, the sphynx of brafs. There are tranfient observations: the art can never be sufficiently admired, whilst it is known that he was no lefs distinguished by fuch magnificence, than by the smalllefs things. We have spoken of Praxiteles, among the ftatutes of his age, as having excelled in the glories of marble, others, and alfo himfelf. His works are at Athens, in the Cerameicus. But before all, not only of Praxiteles, but on the whole globe of the earth, is Venus, which is viewed by multitudes who fail to Gnidus. He made and alfo fold two ftatutes, one clothed, by means of which it was intended that there might be a preference. The Count took one at the fame price, confidering that as the more fervent and modeled. That which was rejected was bought by the Gnidians. Immense the difference in their fame! Afterwards King Nicomedes would have purchafed that of the Gnidians, promising to pay the whole debt of the city, which was immense. But they rather bore all, nor without caufe, as long as the fame of Praxiteles embaffed Gnidus. Her little temple was wholly open, that the ftatue of the gods might be viewed from all points; the gods favouring them, as it was believed. No part was seen with lefs admiration than another. It is said, a certain perfon was enamoured with the ftatue, and bid himself in the temple all night. There are in Gnidus other ftatues of marble, by illuftrious artists: Bacchus, by Bryaxis; and another, by Scopas; and a Minerva. Neither is there any other fpecimen of the work of Praxiteles more excellent than the Venus, that fould be recorded among them by ifelf. Of the fame artist there is one a Cupid, objected by Ciceron againft Verres; it is that for which Theophras was visited. It is now in the Octavian Gallery. His is alfo another Venus; in a Parian colony of Propontis, like the Venus of Gnidus in noblenefs and alfo in injury. At Rome are works of Praxiteles: Flora, Triptolemus, Ceres in the Servilian gardens, Good Fortune, and another ftatue of Good Fortune in the Capitol; alfo the Mazandes, and thofe called Thaidyes and Caryatides; and Silenus in Afinius Pollio's monument, alfo Apollo and Neptune. Cephisidorus was the fon of Praxiteles, and the heir of his art as well as of his eflate; whose wor of children embracing is at Pergamos, a very much admired and a noble performance of art: the fingers seem to imprefs the body rather than the marble. At Rome his works are, Latona in a chapel of the palace, Venus in Afinius Pollio's monument, and in the temple of Juno, which is in Octavia's portico, Eceusium, and Diana. The fame of Scopas contains with his: he made Venus, and Potnon, and Phaethon, which are worshipped in the sacred ceremonies of Samothracia; alfo the Palantine Apollo. The fitting Vesta is very much praised in the Servilian gardens; two charioteers or companions around her fitting on the ground. Two like them are in Afinius's monument, where is a canephorous, or man bearing a bafket, by the fame artist. But the greatest honour in Cn. Domitian's temple, in the Circus Flaminius, belongs to his Neptune and Thetis, and alfo Achilles; Nereides fitting upon dolphins, sea-monsters, and hippocamps; alfo tritons, and a chorus of phoræ and prifles, which are different kinds of fsea-monsters, and many other marine fubjects, all by his hand. This was a moft famous performance, if it had been the whole wor of his life. Now, besides what has been faid above, we shall speake of things of which we are not certain. A Mars of his work, colossal, a fitting figure: it is in the temple of Brutus Calliacus, in the Circus. Besides a Venus, in the fame place, furprifing the Gnidian, taking a preference to that of Praxiteles: it would have emblazond any other place. Rome, from its greatness, has caufed that work to be forgotten; and the crowd of bufinefs and offices draw away from obfervation, becaufe admiration of fuch things is fitted to great silence and more lefure. Equal doubt is in the temple of Apollo S. Ilians, whether Nobe and her children were made by Scopas or Praxiteles. Alfo James the father, which Augustus brought from Egypt, and dedicated in his temple, but of whose hand it is fame does not tell us. Likewife in Curia Oetavia, there is on attention concerning a Cupid holding the lightning: though at length it is affumed to be the likeness of Alcibades at that age. Many other things are in the fame gallery, which pleafe, whose authors are unknown: four Satyrs, with Bacchus, one of whom holds a flying garment over his shoulder; another similer Bacchus; a third quixing a crying infant; a fourth with a cup, satisfying the thirst of another with drink; two winds with flying vefts. Nor is there lefs queftion who made Olympus, and Pan, and Chiron, with Achilles, in the Septis; particularly when their reputation has rendered them worthy of the pledge of their keepers' lives. Scopas had emulators in the fame age, Bryaxis, Timothaeus, and Leochares, who are always spoken of together, because they wrought together on the Maufolenum. This was the sepulchre of Maufolus, king of Caria, which his wife Artemis made for him, who died in the second year of the 126th Olympiad. It is a work reckoned among the feven wonders of the world, which thefe great artists made. It is from forth to north 65 feet, but shorter in front: its whole
whole circuit is 411 feet, raised in height 25 cubits, surrounded with 36 columns. To the east it was sculptured by Scopas; to the north by Bryaxis, to the south by Timotheus, and to the west by Leochares. But before the work was finished, queen Artemisia, to whose husband's memory, and by whose command, this work was built, herself died also. They did not, therefore, recede from the work, judging this monument necessary to the glory of their art. Adjoined to them was a fifth artist, who, above the pediment, added a pyramid on 24 steps, contrasting like a cone toward the summit. On the top of all is a chariot and four horses, of marble, which was the work of Pythis. This being added, the height of the whole is 140 feet. The Diana in the palace at Rome is by the hand of Timotheus. In great admiration is a Hercules, by Menelcatus; and a Hecate, in the Ephesian temple of Diana, behind the building; in the contemplation of which, the keeper of the building admonishes you to spare your eyes, such is the radiance of the marble. Not less admirable are the Graces, in the vestibule at Athens, which Socrates made. The painter is another person, as some think. But Myron, who is famous for works of brass, made a drunken old woman, which is celebrated in Smyrna. Pollio Afinius being a man of ardent courage, wished to exhibit it in the monuments he collected. Among these are statues carrying nymphs, by Architas; Thephiades, by Cleomenes; Oceanus and Jupiter, by Eutychus; Hippiaides, by Stephanus; Hermocrates, by Tauriscus, not the celebrated carver, but one belonging to Trallianus; Jupiter Hopstitialis, by Pamphilius, bishop of Praxiteles; Zethus and Amphion, and Diere and the bull, the coids being of the same stone; it was brought from Rhodes, the work of Apollonius and Tauriscus, with their parent, who contended concerning the work. Mencrates was seen here; but Artemidorus was perfect nature. In the same place Bacchus, by Eutycides, is much praised; Apollo in his own temple, on the portico of Octavia, by Phileicus the Rhodian; also Latona, and Diana, and the nine Muses, and another Apollo naked. He who holds the lyre, in the same temple, was made by Timarchus. Within the portico of Octavia, in the temple of Juno, the goddess herself, by Dionysius and Polycles; another Venus in the same place, by Phileicus; other statues by Praxiteles. Alto Polycles and Dionysius, sons of Timarchus, made a Jupiter, which is in the adjoining temple; Pan and Olympus wrestling; and in the same place Heliodorus, which is another of the noblest groups in the world; Venus washing herself; Daedalus futing, by Polycharmus. The work of Lyfias is held in great reverence, from the honour which it appears to have had: it is in the palace over the arch. Augursus Cæfar dedicated it to the honour of his father Octavius, in a little building adorned with columns; also a chariot and four horses running, and Apollo and Diana of one stone. In the Servilus gardens are found, very much praised, Apollo, by Calamis, the sculptor; Pytheas, by Daucydes; or, as other copies of Pliny have it, the pythia or pugiles by Dercyli; Callithenes, the writer of history, by Amphilothius. Of many the fame is more obscure, because fame in great works is obstructed by the number of artificers; for each cannot occupy the glory which many equally partake; as in Laocoön, which is in the emperor Titus's palace, a work to be preferred before all both of painting and statuary. It is made from one stone, both Laocoön and his children, and the wonderful connection of the serpents, by the conjured counsels of those greatest artists, Agelander, Apollodoros, and Athenodorus, the Rhodians. In the like manner, in the Palatine palace of Cæfar, abounding with approved statues of Craterus with Pythodorus, Polyeuktos with Hermolus, another Pythodorus with Artemon; a single statue, by Aphrodius Trallianus alone. Diogenes, the Athenian, decorated the Pantheon of Agrippa; and the Caryatides, on the columns of the temple, are approved among a few of his works, such as being placed at the top of the temple, because of the altitude of their place, are less celebrated. Unhonoured is one, not in the temple, a Hercules, to which the Carthaginians a great many years offered in sacrifice human victims. It stands on the ground, before the entrance of the portico that leads to the statues of the Nations. There are standing the statues of the Thephiades before the temple of Felicity, of which one was loved by a Roman knight, Junius Phiceculus, as Varro relates; admired also by Pavius, who wrote five volumes on the noble works in the whole world. He was born on the Italian Greek shore. Rich both in the city of Rome and its towns, he made a Jupiter of ivory, in Metellus's temple, which looks toward the fields. It befell him, that in a ship, in which were African wild beasts, flanding at a den and carefully observing a lion, which he meant to carve, a panther broke loose from another den, not of flight peril to the diligent artist. He made many works, as it is said; but of those which he made, the names are not reported. Arcesilaus also is very much praised by Varro, who himself had a marble lioness, as he says, and winged cupids sporting with her; of whom some hold her bound, others force her to drink from horns, others kick her with their shoes: all of one stone. He made also, for Coponius, fourteen nations, which are in Pompey's circus. I find Canachus (says Pliny) very much praised among statues for works he made of marble. Nor must Saurn and Battrachus be forgotten, who made the temple of Octavia, included in the portico. They were Lacedemonians. They are said to have been very rich, and they built this temple at their own expense; very carefully hoping to have an inscription, but it was denied them, notwithstanding they took another place and method to obtain it. There are, at this time, in the volutes of the columns, the signature of their names carved: a frog and a lizard. In Jupiter's temple is to be seen a picture, containing articles of dress, and all other things relating to women; for when the temple of Juno was completed, they and it carried in the statue, they are reported to have changed the moveables; and that being guarded by religion, even as the feat partitioned among the gods themselves: in the temple of Juno is consecrated that which ought to be Jupiter's. Pliny, l. xxxvi. c. 4.

Such is Pliny's account of ancient sculpture.

It is well known, from the testimonials of later authors, who have written on the subject, as well as from the names of Greek artists found on their works, that all the noblest productions of sculpture executed at Rome after the times we are speaking of, were the productions of Greek artists.

The busts of the twelve Caesars, from Julius to Domitian inclusive, are the finest productions of portrait sculpture. The whole imperial series, both in busts and statues, down to the emperors Balbinus and Pupienus, pollutes the highest merit, and scarcely in that period flowed the decline of art; but from the time of these emperors to that when Constantine fixed his capital at Byzantium, the decline was so evident, that the life and beauty of former times were nearly extinguished in their productions.

Before we quit ancient Rome, we must notice in a general observation some of the great works of art still remaining in that capital, which could not properly be introduced in the foregoing series.

The Trajan column is one of the most beautiful monuments of ancient Rome, and the most superb column in

SCULPTURE.
The world. It was raised about the commencement of the second century, by the Senate and people of Rome; in honour of the emperor Trajan, after the victory that he had obtained over the Dacians. This column is admirable for its height; and more still for the beauty of the bas reliefs with which it is ornamented; which represent the first and second expeditions, and the victory obtained over king Decebalus. These bas reliefs are correctly designed, and most beautifully executed. There are numbered more than 2500 figures, all in different attitudes, without counting those of horses, elephants, arms, machines of war, and an infinity of others; altogether forming a variety of objects, which no one can see without admiration. Upon the capital of this column is a pedestal, on which was a colossal statue of Trajan in gilt bronze. In the place of this statue, pope Sixtus V. caused to be placed, in the year 1588, that of St. Peter the apostle in bronze, which was modelled by Thomaso Porta. The fame pope caused also to be cleared away the earth which encumbered the pedestal. At the bottom of the pedestal, or base of the column, in one of the sides is a door, by which we mount to the top of the column. The Blair-cafe contains 185 steps, cut in the fame blocks as the column; and to them are made 44 windows, which light the Blair-cafe; and there is on the top a balustrade, by which we may walk around and enjoy the prospect of the whole city of Rome. The height of this column is 118 feet, comprising the pedestal of the column and the statue on the top. The column alone, with its base and capital, is 92 feet; the pedestal of the column is 17, that of the statue 9; the lower diameter of the column is 11 feet 3 inches, the diameter of the upper part is 10 feet. This column is formed of 22 blocks of white marble, fixed with lead one upon another. The shaft of the pillar is in 23 pieces; the pedestal in 8; the capital 13; and the pedestal of the statue another. The magnificence of this column answers to that of the ancient forum of Trajan, of which it occupied the centre. The Forum or Square of Trajan was surrounded by grand porticos, and the edifices were built with the greatest magnificence after designs by the celebrated Apollodorus. These consisted of a temple or palace, where the confuls sat in judgment; the temple of Trajan, where was the Upian library, ornamented with statues of the learned; a superb triumphal arch with four equal faces, that the Senate caused to be built to the honour of the prince after his death; and a beautiful equestrian statue of Trajan, in gilt bronze: the statues, the cornices, the architraves, and the friezes which ornamented these edifices, were also in bronze. It would be difficult to describe all the magnificence of this superb structure. Trajan caused a valley to be filled up, andlevelled one part of Mount Quirinal, to make a level for this beautiful situation.

The Antonine column has given its name to the place of which it is the principal ornament. It was raised by the Roman Senate, and by the emperor Marcus Aurelius Antoninus, in honour of Antoninus Pius, his father-in-law, whom he succeeded in the empire. His ashes were enclosed in a golden urn, and placed on the top, with his statue in bronze gilt; and because he had not obtained any one great victory in war, they caused to be sculptured around the column the victory over the Marcomanni. Time and various revolutions, and above all the fires, which had been so frequently in Rome, have much damaged this column. Pope Sixtus V. caused it to be repaired in the year 1589, and the statue of the apostle Paul, in bronze gilt, to be placed upon its summit. This column is of white marble, surrounded by bas reliefs from the base to the capital. The artist appears to have taken for his model the Trajan column; it is of the same style, though of inferior execution. The whole is composed of 28 blocks of marble; it is 15 feet in diameter, and 116 in height, without including the statue, which is 13; and the pedestal, on which it is placed, which is 9. The column contains a beautiful winding Blair-cafe of 190 steps, which conduct commodiously to the top; it is lighted by 41 windows.

The arch of Titus was raised by the Senate and people of Rome, to the honour of Titus Vespasian, for his conquest of Judea and the taking of Jerusalem. It is of the most excellent workmanship, but has very much suffered from the injuries of time. It is ornamented with beautiful bas reliefs, and two fluted columns of the Composite order. Under the arch is seen the triumph of the emperor, drawn in a chariot by four horses, accompanied by his victors; and in the triumph the famous candlestick of seven branches, the tables of the law, and other spoils of the temple of Jerusalem. The arch of Septimius Severus was raised by the Senate and people of Rome, at the beginning of the third century, to the honour of that emperor, for having subdued the Parthians and other barbarous nations. It is all of white marble, with three arches and eight fluted columns of the Composite order, ornamented with bas reliefs, of middling sculpture. It has suffered very much, and because it is partly buried in the earth, we cannot so well judge of its beauty; formerly there was an ascent to the top of the arch, by a Blair-cafe in the interior; and there was placed upon its roof the emperor Severus in a triumphal chariot drawn by six horses.

After the famous victory obtained over Maxentius by Constantine the Great, the Senate and people of Rome caused a triumphal arch to be raised to his honour: it is of the Corinthian order, having three arches; the two grand fronts are ornamented by eight fluted columns of yellow marble, and many bas reliefs of very different merit. Those that were made in the time of Constantine make us perceive the barbarity into which the fine arts were beginning to fall; the others, on the contrary, which were taken away from the arch of Trajan, present such beauties, as indicate an age when sculpture was in high perfection. These are twenty in number, of which ten are of a square form, and are in the upper part; eight are round, above the side arches, and two others more large under the grand arch. All these bas reliefs, and the eight figures of Dacians placed upon the columns, prove themselves to belong to the expeditions and victories of Trajan.

The arch of Marcus Aurelius formerly stood in the Flaminian way, now called the Corso, or principal street in Rome; it was taken down by Alexander VII.; two fine remaining bas reliefs from which are at present in the Capitol; one of these is an apotheosis of the empress Faustina, the other is an address of the emperor to the people of Rome. The figures are larger than life.

In general observations on the sculpture of the arches and columns here enumerated, we shall remark, that the earliest of them, the arch of Titus, must have been executed about the year 70 of the Christian era, consequently when sculpture had lost much of its primitive ideal beauty; we shall of course find in these works little of sobriety and more of coarseness in the forms, confiling of subjects which were confined to battles, oblems, triumphs, and acts immediately confined to them. The Roman generals and soldiers, as well as the barbarians whom they fought with and conquered, are represented with an individual vulgarity of face and person, very different from the choice felection of beauty in the works of Greece. The drapery and
armour are more complicated and divided than those of the ancient Greeks, added to the inferiority and confusion of parts, still augmented by the introduction of ships, bridges, piles of wood, battering rams, catapults and other military engines, &c., wholly omitted in the works of the belles-lettres. The contents are of the coarsest means, and of the most brutal force, unrelieved by any intercession of suprême beings, and unexcelled by the beauty of the ancients. With such a character in the whole, the sculpture on the arch of Trajan, now the arch of Constantine, is superior to the rest of these works. Upon the whole, although the bas-relief of the apotheosis of Paulina, formerly on the arch of Marcus Aurelius, is a more sublime conception, the sculpture of the Trajan column has a great variety of natural attitudes, according to the situations in which the per sons are placed, and the relief has that general breadth, which is best suited to the outline of the column in all views. The figures and groups on the Antonine column are carved with a bolder relief; but such as deforms the shaft of the column by its irregular hollows, producing something of the appearance of rock-work to the whole outline. The sculpture on the arch of Severus is still more deteriorated in its style and conduct; and such of the bas-reliefs on the arch of Constantine as were executed in the reign of that prince, have such a Gothicism and barbarity of execution, as would utterly exclude it from that class of sculpture, which has moderate pretensions to science, or any pretension whatever to sentiment.

We must not omit to mention some colossal statues, still existing entire or in parts in the city of Rome; from two colossal statues of marble on Monte Cavallo, standing before the pope's palace, each nineteen feet and a half high. The figures are in the prime of youthfully manly beauty; the faces are of the highest class of Grecian beauty; the figures seem to breathe and move; their position is advancing; with one hand each holds his charger. They have been called Callot and Pollux, Achillies and Patroclus, Alexander and Hephestion, also Achilles, at the moment when his horse declares the will of Jupiter; on the authority of two coins of Nero and Adrian struck at Corinth, bearing on the reverse a hero holding a horse, much resembling this group; it has been called Bellerophon holding Pegaseus. One of these statues bears the name of Phidias on its pedestal, the other statue seems to be of this original, revered by some other artist, to stand as its companion in some conspicuous situation.

In the court of the Capitol remains in marble of the colossal statue of Domitian, which appears to have been, when entire, about forty feet high; the head and neck to the bottom of the gaiter is of one tone, and about eight feet high; the feet are each six feet long; the knees, elbows, and some other fragments, are remaining. It appears to have been nearly naked, to have a cloak, to have had a chlamys hanging on the left arm; and is perhaps the same colossus of Domitian as that described by Philo Byzantius, according to his testimonies from different Latin authors.

There is, in the same court, a head in bronze, believed to be that of the emperor Commodus, which from other remaining fragments was a colossal statue also.

The equilibrated statue of Marcus Aurelius, considerably above the size of nature, in the centre of the Capitol, of noble workmanship, is sufficiently known to lovers of art by the prints of Perrier and other artists.

When Constantine removed the seat of empire from Rome to Byzantium, he and his successors are said to have taken from the ancient capital of the world, as many of the fine works of art as they could possibly remove. The Greek artists were employed in their own country to decorate the new capital, with the same magnificence indeed as in former times, and like their predecessors were employed in the cause of religion, not in emulation of Phidias's Jupiter or Praxiteles's Venus, but in the cause of that sacred person who disclosed, and of his followers who propagated the new dispensation of mercy. The architects were employed in building Sancta Sophia and other great sacred buildings in the city; and the painters and sculptors in the illustration of the Old and New Testament.

The controversies of religion and philosophy had been agitated with so much violence by the philosophers of Alexander against the Christian divines, as induced the successors of Constantine to abolish the schools both of Athens and Alexandria; they also filled orders for the removal and destruction of the pagan idols; and in the fourth and fifth centuries it is believed that the Olympian Jupiter at Elis by Phidias, and the Venus at Gnido by Praxiteles, with other of the most distinguished works of pagan sculpture, were destroyed, either by imperial orders or the ravages of barbarians. The Iconoclasts, and the irruptions of the followers of Mahomet and other barbarous people, very nearly destroyed all the remains of the fine Greek sculpture in the East as well as in western Europe. This destructive fury against the arts and artists, continued with interruptions for a hundred years; still, however, the Christian Greek compositions from the Old and New Testament, from the time of Constantine down to the thirteenth century, were followed as examples of character and composition by the revivers of art in western Europe, down to the times of Michael Angelo and Raphael.

After the sack of Constantinople by the Venetians, the only efforts of that feeble state were a few faint struggles for existence, previous to its destruction by the Mahometans.

To give some idea of the magnificent sculpture which adorned Constantinople, we shall insert the description given by Conius, of those fine works which decorated this city, before it was taken by the Venetians.

The Roman conquerors, who were of an avaricious temper even to a proverb, practised a new method of rapine and plunder, unknown to those who had taken the city before them; for breaking open by night the royal sepulchres in the great grove of Heroum, they sacrilegiously rifed the corpses of those blessed disciples of Jesus Christ, and carried off whatever was valuable in gold, rings, and jewels, which they found in these repositories of the dead. They spared neither the house of God nor his ministers, but stripped the great church of Sancta Sophia of all its fine ornaments and hangings, made of the richest brocades of inestimable value; but they no sooner cast their eyes on the brazen statues than they ordered them to be melted down. The fine statue of Juno in bronzes, which stood in the forum of Constantine, they chopped to pieces and threw into the forge. The head of this statue was so large, that four yoke of oxen could scarcely drag it. On the base of it was cut, in basso relievo, the figure of Paris presenting Venus with the apple of discord. The noble quadrilateral pillar, supported by several ranges of pillars, and which by its height overlooked the whole city, and was both the wonder and delight of the curious spectator, shared the same fate. This lofty column was adorned with rural representations of all kinds of birds, folds of cattle, and of sheep bleating and lambs frolicking and playing, &c. There was also engraved upon it a view of the sea and sea-gods, some of whom were catching fish with their hands, others ordering their nets, then diving to the bottom, while some in a
wanton manner were throwing balls to one another. This pillar supported a pyramid on the top of it, on which was placed the statue of a woman, which turned about with the wind, and was therefore called Anemode. This excellent piece was also melted down for coinage, as was also an equestrian statue, fixed upon a quadrilateral pedestal in the Tauris. This was a bold figure, of an heroic countenance, and surprizing stature. He was faid to be one of the Spies who were sent by Joshua, the Son of Nun. With one hand he pointed eastward, with the other to the west. But this statue was generally reported to be Bellerophon sitting upon Pegafus; for the horse was without a bridle, as Pegafus is most likely figured, couring the plain, defying a rider, flying and driving about in a headstrong manner. This horse and his rider were also united down; the barbarous soldiers expressing their utmost fury against the fine statues and most curious pieces of workmanship in the Hippocum. The great statue of the Hesperian Heracles, which was fixed upon a magnificent pedestal, and clothed in a lion's skin, which seemed to live and affright the spectators with his tremendous voice, felt the effects of military power. He was not armed with his quiver, his bow or his club; but stretching out his right leg and arm, he kneeled upon his left knee, and leaning upon his left elbow with his hand open, supported his head in a thoughtfuil manner, seeming to lament his misfortunes. This figure was broad-chested, the shoulders were large, the hair long, curled, and reaching to the waist; the arms were brawny, and as long as those made by Lyphimachus, which was the original of this, and was the first and last masterpiece of his skill. In short, of such a furious size was this statue, that his wrist was as thick as a man's body, and his leg equal in height to any ordinary person. This noble statue did not escape the rage of these mighty pretenders to virtue and honour. Besides this they also carried away the image of the aub and his driver, which figures were set up originally by Augilius Cesiar at Actium, of whom the story reports, that when he went out privately in the night time, to take a view of Antony's camp, he met a man driving an aub, and asking him who he was and where he was going; the man answered, "my name is Nicon and my aub's name Nicander, and I am going to Cesiar's army." The statues of the hyena, and of the wolf which ftruck Romulus and Remus, underwent the same fate, and were coined into little brazen flaters. The several statues also; of a man fighting with a lion; of the horse Nellus covered with scales behind; of an elephant with a moving probocis; of the sphynxes, beautiful as women and terrible as beails, which can occasionally walk or fly in the air; there was also the statue of a wild horfe, pricking up his ears, curvetting and prancing;—this and old Sylla were served in the same manner. She was figured like a woman to the waist, with a grim frightful look, as she appeared when she fent her dogs to destroy Ulyfes. There was also placed in the Hippocum a brazen eagle, which was the invention of Apollonius Tyanes, and a celebrated monument of his forcry. This impofor being requested by the Byzantines to heal them of the bitings of ferpents, which were then common among them, using charms and diabolical ceremonies placed this eagle upon a pillar. It was a pleafant fight enough, and deferved to be more narrowly infpeded, for it made an agreeable harmony, and has dangeroufs than the Syrens. Its wings were stretcnd out as ready for flight, and it was trampling upon a ferpent, which wreathed itself about the eagle. The ferpent deemed to make the utmost effort to bite the eagle; the eagle looked brisk and lively, and deemed to have obtained the victory, and to be ready to bear him through the air in triumph, de-

noting that the ferpents that tormented the Byzantines would hurt them no more, but fuffer themselves to be handled and itroked by them. But there were not the only curiosities to be oberved in this aquiline flature; for the twelve hours were engraved under his wings, under each wing fix, which showed the hour of the day, by the fun darting through a hole in each wing made for that purpofe. There was also a fine flature of Helen, whose charms laid Troy in ruins; her fine proportions, in breathing brafs, captivated all beholders; her habit fat hoile upon her, which discovered too great an inclination to gallertry; her long and delicate hair seemed to wave in the wind; it was braided with gold and jewels; her robe was girt about her and falling down to the knee; her lips seemed like opening roes, you would fancy they moved; and fuch an agreeable fmile brightened her fountenance, as entertained the spectator's eye with pleafure. There was also placed upon a pillar a more modern statue of a woman. Her hair hung down behind, combed close down from the forehead backwards, not braided up but bending, as if to the hand of the spectator. Upon the right hand of this flature flood the equantian flature of a man; the horfe stood upon one leg, the other bore a cup with liquor. The rider was of a large size; his body completely armed; his legs and feet covered with greaves; his air was manly, rough, and warlike. His horfe was mallefome and high couraged, pricking up his ears as if he heard the trumpet; his neck was high, his look fierce, as eager for the battle, rearing up his fore-feets and prancing as a war horfe. Near this flature, hard by the eafon general called Rufius, were a range of flatures of charioteers, dextrous in driving the chariot and turning the goal. They were very busy in managing their bridiles and养成ing their whips, and directing their horns, with their eyes fixed steadily upon the goal. There seemed to be defcribed in these figures all the tumult and fury of a chariot race, with the most vigorous struggle for victory. But what excited the greatest admiration was a large pedeftal, having on it an animal called in brafs as large as an ox, with a short tail and a moderate dew lap, something like the Egyptian cattle; it had no hoofs; it held in its teeth, ready to prong, another animal, clothed all over with scales that seemed impenetrable. This appeared to be a bafilik; it had a mouth somewhat like a ferpent's. These figures seemed to reprefent an odd kind of fight, each of them furiously striv-

ing for victory. The creature which seemed to be the bafilik was in colour like a frog, and was all over blooted from head to foot; he was calling out his venom upon his antagonist, to deftroy him, while he was reprefented as bear-

ing upon one knee and in a languifhing flate. There was also a figure of another animal, in whose jaws were reprefented a fmalher creature whose mouth was open, as almoft choked by the teeth which held him, striving to get loose but to no purpofe. His tail, which was very short, seemed to tremble; his shoulders, his fore-feets, and a part of his body, were hid in the mouth of his enemy and mashed by his jaws. This is the cafe with nations and kingdoms, which thus mutually deftroy one another.

For further satisfaction concerning the flate of sculpture in the fourth and fifth centuries, a short description of the column of Theodorus, erected at Constantinople, will be added.

This column was, in its general flape and fize, an imitation of that of Trajan in Rome; although, by the description of fuch travellers as faw it flanding, it appears to have been larger, and formed of the fame material, flatuary marble, decorated like that column, with a spiral bas relief, from the bottom to the top of the shaft, furmounted by a flature of the emperor. The pedeftal was covered with mi-

litary
The marble bas reliefs, on one side of which was the emperor fitting, crowned by two victories, with a glory, including the crofs. The shaft of the column was drawn by Gentile Bellini; the subjects are, the triumphal entry of Theodosius, Arcadius, and Honorius, as it is believed, with the captive Goths and Lefter Tartars; their idols, kings, generals, waggoners, horses, draymen, elephants, and oxen; the captive multitude, with embolism figures, representing the city of Conflantinopole: and the various figures of the virtues, complimentary to the emperors, particularly relating to their valour and clemency. Whoever desires to be more particularly informed of the remains of ancient sculpture which decorated Conflantinopole, may consult Glyfius and Du Frenes, and the Byzantine writers.

Of Modern Sculpture.—From the fourth century the art continued to decline, by the inroads, first of the Goths and Vandals, and afterwards of the Saracens: and this decline is manifest in fragments and ruins of the ages as they succeed each other.

Theodoric, king of the Goths, established the seat of his kingdom at Ravenna; his reign was long, and as he very much loved building, he applied himself in his capital, and at Rome, and in the principal places of Romana and Lombardy, to build several palaces and churches, which are yet to be seen, all of them of a rude character, remote from the principles of architecture, and the exact rules of the ancients; he caused palaces to be built at Ravenna, Pavia, and Modena, after a barbarous way; which were rather great and rich than of good architecture. The fame may be said of the church of St. Stephen at Rimini, of St. Martin at Ravenna, and of the temple of St. John, built in the same city in the year 438, by Gallia Placidia.

The capitals of column in buildings erected by Theodoric and his family, are grofs copies from the ancient Doric and Ionic, in which no attention is paid to the outline: the leaves and volutes are without relief; the whole malleys are coarse, and without effect: the sculpture of baffle relieve on the facrepofa of this king, his family at Rimini, which represents our Saviour and his Apostles, is without design, and of the rudest workmanship.

The church of St. Vitalis was built at Ravenna in 547. Queen Theodolinda caufed the church of St. John the Baptist to be built at Monza, where was painted the history of the Lombards; her daughter, queen Gundigera, caufed a church to be built at Pavia. They are all of the ancient Gothic.

By the ancient Gothic is here meant a grofs imitation of the Roman buildings and Roman sculpture, without harmony, proportion of parts, or design, as nearly as the unpractised barbarians could imitate from the ruins of Roman buildings, without any science, and with clumsy instruments.

If the Gothic kings who embraced the Christian religion had their painters, sculptors, and architects, they had also, to counteract these, cruel wars to support against the barbarians, who still remained averse to art and science; all Europe was involved in such confusion, that little satisfaction can be derived from the histories, and still less from the few barbarous remaining works.

In the year 496, Clovis, king of the Franks, was converted to Christianity; he built the church of St. Peter and St. Paul at Paris, which is now called St. Genevieve. The fame rude workmanship is in the church of St. Germain, built by Childebert, fon of this king. Although these two venerable remains of antiquity have been destroyed in the French revolution, yet specimens of the sculpture are preferred among the French monuments at the church of the Little Auguflina; some of which, said to be of this age, appear to be much later, as the statues of the kings in the portico of St. Germain de Pres, which appear rather to have been done in the eleventh century. The capitals in this collection of the age of Charlemaigne, brought from St. Denis, exhibit sculpture, if sculpture it may be called, in its lowest rate of abatement; it is wanting in every principle of art, both of design and execution, and it is not without attention that you can discover that its efforts were intended for the representation of human figures.

What we have said of the rate of sculpture in France will answer equally well for every thing that was done in England, Italy, Germany, and throughout the continent, at this time.

In the year 805, Charlemaigne built the church of the Apostles in Florence, which has always been esteemed by architects of singular beauty, so that Brunifchetti took it as a model for long afterwards as the year 1400.

In the eleventh century, when the terrors of the Norman invasions, in addition to those of former barbarians, had passed away, the governments began to be more regular and established; agriculture and commerce began to revive; and the crusades had diffused a ray of light among the northern nations, derived from the arts and literature of the East, fo that then the arts of design began that regular course of improvement which has been denominated their revival.

In 1016, the Pifans founded their great church, called the Dome of Pifa. The commerce they had by sea, and particularly into Greece, was a favourable means for the re-establishment of architecture and sculpture. They brought from thence several columns and fragments of ancient architecture, of marble, which they made use of in this church.

They brought together by these means several Grecian sculptors into Italy, and also Grecian painters, who worked after their own old methods, for using in their painting only simple lines, which they coloured all over equally, without any shadowing; their works were not very artificial, notwithstanding these remains of art taught the Italians the practice of painting in water colours, or fresco and molaco.

But among all the artists of that time was Bucchetto, a Grecian of Dulichium. The cathedral of Pifa was built under his direction; for besides the magnificence and fine plan exhibited in this church, he used with great dexterity those ancient pieces of Grecian architecture, to compound together with his; these were fragments brought from Greece.

This great building excited in all Italy, and particularly in Tuscany, those who had any genius for designing.

Thus the arts of designing began to be revived in Tuscany before they were known in other countries; and very great fabrics were reared in several cities of Italy. At Ravenna, in the year 1152, Il Buono, a sculptor and architect, built a great many palaces and churches: he also founded at Naples the calle of Capoano, now called the Vicarage, and called Delluno; also at Venice he built the temple of St. Mark.

In the year 1693, the spoils which the Pisans brought from Sicily enabled them to add to the magnificence of their cathedral. The capitals and fragments of pillars they had brought from Greece and Sicily, were employed in the cathedral church and in the Bell tower; in which latter building every capital almost is of fine ancient Greek workmanship. The sarcophagi, still preferred in the Campo Santo, formed the school in which Nicolo Pisano, and his successor improved their sculpture. The consequences of these improvements are seen in the works of Nicolo Pisano, which are the pulpit of Siena, the pulpit of the baptistry of Pisa, the bas relief
of St. Martin’s at Lucca, the bas-relief in the cathedral at Orvietto, and in other parts of Italy, in which his constant attention to the ancient bas-reliefs is everywhere observable. At this time the carvings had diffused such a spirit of piety, that magnificent churches were built all over Italy, in the designing of which, as well as in the decoration with sculpture, Nicolo Pisano and his scholars were universally employed.

On the basement in the west front of the cathedral of Orvieto, there is a series of bas-reliefs, the work of Nicolo Pisano and his school, containing the most important subjects of the Old and New Testament, from the Creation to the Last Judgment, with separate figures of the prophets. The different figures are contained in a running foliage, making the most rich and beautiful decoration to the four basements formed by the three doors in that part of the church. The figures are each about twenty-two inches high, very highly finished in flat and color. There is in many of them a beautiful simplicity of sentiment, in those of the Last Judgment, and the other bas-reliefs that immediately relate to it, there are various expressive mannerisms of passion and terror. The pulps also in the cathedral of Sienna, and in the basilica of Pisa, which were before mentioned, are magnificent architectural designs, richly adorned with sculptural bas-reliefs by this artist.

At Pisa, in 1274, William Oltramontano and Bonnano, a sculptor, founded the steeple of the dome. The royal gate of braies in this church was made by Bonnano.

John Cimabue was born at Florence in the year 1248; he very much improved the art of designing; his disciple Ghiberti was both a painter and sculptor. Cimabue learned his art of Greek painters, who were employed in Florence. At the same time with Cimabue, flourished Andrea Tafi, a Florentine painter in mosaics; he went to Venice to perfect himself in that art; having learned that there were several painters who worked in that way in Venice, he engaged Apollonius, one of them, to come and work with him in Florence, where they made several pieces. Tafi learned of this Grecian the art of making enamels and platters that would last a long time; he died in the year 1294.

About the year 1215 appeared Marchione, architect and sculptor of Arezzo, who worked much at Rome for the popes Innocent III. and Honorius III.; he made the fine chapel of marble at St. Mary Maggiore, with the epulchre of that pope, which is the chief work of Ghiberti. But one of the first architects who began to reform in Italy, was a German named James, who built of stone the great convent of St. Francis; he dwelt at Florence, where he made the chief fabrics; he had a son, named Jacopo Amalfo Lipo, who learned architecture of his father, and designing of Cimabue. He founded the church of St. Croce, at Florence, and several other buildings, the most considerable of which is the magnificent church of St. Mary del Fiore.

John Pisano was the son of Nicholas, and was also a sculptor and architect. In 1293 he was at Naples, and built there, for King Charles, the new castle, and several churches, and being returned into Tuscany, he made several pieces of sculpture at Arezzo, and also in other places in that province, and died in the year 1320.

John Pisano deviated from his father’s rigid imitation of antiquity, in giving a more waving line to his figures, and broader and less determined folds to his draperies, like the paintings and designs of Ghiberti. There is a general grace and delicacy in the character of his figures; of which the bronze statues of a madonna and angels in the cathedrals of Orvieto and Florence are examples; and there is so strong a resemblance between the styles of these statues and those of queen Eleanor at Northampton, Goddington, and Waltham, on her crooks; as affords reason to believe they were produced by one of the ablest of John Pisano’s scholars, if not from some statue or model by himself: nor is it here that the resemblance ceases, for this little is to be traced in most of the sculptures of Europe from this time to the reign of Henry VII. This sculptor had for pupils, Agostino and Agnolo Sanedi; they were, in the opinion of Ghiberti, the best sculptors of the time, who procured them the chief buildings of Tuscany. They worked also at Bologna and Mantua, and bred up several ingenious pupils, and particularly carvers in silver, as Paul Aringino, a goldsmith, Maestro Cione, and Jacomo Lauriano, a Venetian, and Peter Paul, of the same city.

Ghiberti made designs for the bas-reliefs in the baptistery of Florence, which were engraved by Andrew Pisano, who also made several figures of marble in the church of St. Mary del Fiore. Andrew was as famous for sculpture as Ghiberti was for painting. The bas-reliefs on the doors of the baptistery represent the life of St. John the Baptist, and pupils great simplicity and grandeur for the age in which they were produced.

Stephen Florentin, Taddeo Gaddi, and Peter Cavallini, were scholars of Ghiberti, and in 1350 they formed at Florence an academy of designing, which was the first that had been formed since the revival of the arts. Taddeo Gaddi began to collect ancient sculpture for his studies, and there is a fine Greek body of a man which belonged to him, which is kept in the ducal gallery, and is known by the name of Gaddi’s Torso.

This ingenious society was afterwards encouraged and assisted by the princes of Medici, which perfected at Florence the establishment of the arts of design, for there came out of that school a great number of painters, sculptors, and architects, who embellished that famous city, and all Italy, like another Sicily; where, in the time of the first ancients, the first academy of design had been established; this quickly flowed at Florence those great genius of Lorenzo Ghiberti, Donatello, and Brunelleschi, and many other ingenious contemporaries.

Bartoloccio Cione was a sculptor in bronze, gold, and silver, and father of Lorenzo Ghiberti, who, besides following his father’s profession, added to it the study of painting and architecture. He made the two fine doors in the baptistery of St. John, one of which represents the history of the Old Testament, which Michael Angelo said was worthy to be a gate of Paradise; the other gate is adorned with the principal acts of our Saviour’s life. Besides the beauty of the historical subjects in the pannels, the architraves and friezes of those gates are of exquisite design, containing flowers, fruits, plants, and animals, so perfect that they seem to have been cast from nature. He executed a figure of St. Matthew, in bronze, of a colossal size, in the church of San Michele, but this figure is inferior to his smaller works, from an attempt at excessive grace; the folds of drapery also are too minute, curvilinear, and not well accounted for. He executed some bas-reliefs in bronze, on the life of St. John the Baptist, on the baptismal font in the cathedral of Sienna; he also executed some painting in the same church when he was young. Ghiberti made also several curious fountains, and a triple crown for pope Eugenius; it was of gold and jewels, valued at thirty thousand ducats of gold. Afterwards he became supreme magistrate of Florence, but still practised architecture, managing for some time the building of the church of St. Mary del Fiore.

Donatello very much excelled the sculptors who had gone before him, in his copious compositions, and the passion and
SCULPTURE.

and life of his designs, and in the character of nature in his statues, which are to be seen in Florence; he was born in 1403, and lived to be above 80 years old. His statue of St. George is a youthful pedestrian figure, standing with his legs considerably apart, his two hands before him, leaning on his shield. Michael Angelo admired the head of this figure so much, that he copied it in the monumental statue of Julian, Duke of Normut. Donatello designed some fine bas-reliefs from the life of St. Anthony of Padua, which were executed by one of his pupils, and decorated the principal altar of the cathedral of Padua. He composed and executed the greater part of those noble bas-reliefs from the life of our Saviour, in bronze, round the two pulpits of St. Lorenzo, in Florence; the sentiment, passion, and composition of which, in parts, it seems impossible to excel. He executed different statues of St. John, and crucifixes in wood, the characters of which are rather vulgar, and consequently very inferior to his bas-reliefs. It was fad of this artist, upon the Pythagorean idea of transmigration, that either Michael Angelo's soul energized in his body, or his in Michael Angelo's. There is a bronze figure in the market of Florence, of Judith with the head of Holofernes, which, though by his hand, has nothing striking in the attitude; and its drapery is confuted. But there is another statue of a youth naked, about twelve or fourteen years old, in the ducal gallery, which is worthy to be ranked with the fine statues of antiquity.

Bruneleschi, the friend of Donatello, was an excellent sculptor, goldsmith, and architect, and revived the true and ancient way by his indefatigable care. The remains of his sculpture are very few; there is an admirable crucifix, carved in wood by him, in the church of St. Mary Novella at Florence.

About the year 1450 appeared Andrea Verrocchio and Dominico Ghirlandaio, sculptors and painters in Florence. Verrocchio was an excellent sculptor and engraver, not only in brons, but also in marble; he was also a good architect. He was esteemed of the first rank of sculptors, and preferred to Donatello and to Ghiberti, in making St. Thomas feeling our Saviour's side, which he constructed of brons for the oratory of St. Michael. He was the master of Pietro Peverino and Lionardo da Vinci, and other excellent pupils. His last work was the famous figure on horseback of Bartholomeo Cogoleto da Bergamo, which is at Venice, in the square of St. John and St. Paul.

Dominico Ghirlandaio was the master of Michael Angelo; he worked more in painting than in sculpture, particularly in mosaic for pope Sixtus IV. in the Vatican. He was particularly qualified as an instructor to that great man, from the delicacy of his genius as well as from his original and copious invention.

But the progress of art was greatly accelerated by the progressive discovery of those miraculous productions of ancient Greek art, which had been buried so many ages, and were by degrees restored from the bowels of the earth. Poggio, the secretary to Eugenius IV., in the year 1450, particularly enumerated all the remains of ancient magnificence in Rome existing at that time, among which he reckons only five statues; two of them were the colossal statues of Phidias and Praxiteles, on mount Cavallo; the third the equestrian statue of Marcus Aurelius, at that time before the church of St. John de Lateran; the two others, perhaps, were the figure called Marforio, which is a recumbent statue of the Ocean, now in the Capitol; the other a fragment of the group of Ajax supporting the body of Patroclus, called Palquin. The Lacoone was found in the year 1506.

In the year 1474 was born at Florence Michael Angelo Buonarroti; he was brought up to learning, but burying himself always in private about designing, which his father observing, put him to Dominico Ghirlandaio. In a little time Michael Angelo distinguished himself above his other disciples by the surprising facility with which he designed. This great genius was very fortunately favoured by prince Lorenzo de Medici, who, with great love to art, and desiring to allure men skilled and learned therein, established in the gallery of his gardens an academy, which he filled with fine pictures and pieces of sculpture, both ancient and modern, and bought out at Florence those young designers who promised well, to whom he allowed pensions to promote their studies. Those of the school of Ghirlandaio were chosen the first, and particularly Michael Angelo, who, having one day taken up a piece of marble, set about making a head, though he had never before handled a chisel, which so much surprised prince Lorenzo, and he conceived so great an affection for Michael Angelo, that besides allowing him the pension, he made him a companion at his table, and gave him a lodging at his palace. After the death of this prince, his successor, Pietro de Medici, continued Michael Angelo the same affection he had enjoyed from his father.

At Rome he made a marble statue of Bacchus, with several other marble statues. At his return to Florence, he applied himself with the same diligence, and made a David of marble, which was set up before the palace. Peter Soderini, the Gonfaloniere, and the citizens in general, were so charmed with the statue, that they required of him other works in bronze and in painting. The Gonfaloniere then ordered him to paint one half of the council-hall, and Lionardo da Vinci the other.

Michael Angelo in this work gave proofs of the excellence of his designing, both with respect to the composition of the subject, which was the war of Pisa, and in the correctness of his naked figures; and to have an opportunity to shew it the better, he chose the time when the soldiers were bathing in the river Arno, to introduce the figures naked. Raphael, and the artists his contemporaries, improved the grandeur of their designs from that cartoon.

Julius II. being raised to the papal chair, sent for Michael Angelo to Rome, resolving to engage him in a mausoleum in St. Peter's, which was intended to stand under the centre of the dome, to be the most magnificent of the kind ever raised, and the principal object in the church. This work, however, was delayed till the pope died, and then one of its faces only, and upon an inferior scale, was erected by his nephew in the church of St. Peter in Vincole. The figures which decorate the architecture of this tomb are those of the pope, Mofes, and allegorical virtues. Two statues of marble, which were to be part of this sepulchre, are now in the castle of Richelieu in France.

The execution of this monument was interrupted by Michael Angelo being at the same time engaged by the pope to paint in fresco the archband of the chapel of Sixtus IV., which so much raised his reputation, that besides the general applause that he received at Rome, the pope rewarded him also with several presents. Julius II. being dead, Leo X., his successor, honoured Michael Angelo no less than he had done, employing him on the architecture of the front of St. Lorenzo at Florence.

After this, in the popedom of Clement VII., he designed the architecture of the vestry, in the same church, for a mausoleum for the house of Medicis, and adorned the altar and walls with statues of Julian, duke of Normut, and
and the duke of Urbino, opposite to each other; with three
to the north side, the Virgin and Child, St. Peter,
and another faint. Both architecture and sculpture are
still admired among the finest productions of this artist.
The fortification of the city of Florence was committed
to him; he fortified mount St. Miniato; but when the
wars of Italy in 1525 obliged the artists to leave Rome and
Florence, Michael Angelo was one of the number, and
went to Venice; where the doge Gritti employed him,
and he made the design for the bridge of Rialto, which is
one of the master-pieces of architecture. He painted in
that city some pictures, and among others, that of Leda,
which he gave to the duke of Ferrara, who sent it to
Francis I.

The wars of Italy being ended, Michael returned to Rome,
and there finished the sepulchre of Julius II., after which
he painted, by order of Paul III., the great front of the
altar, whereon he represented the Last Judgment, it being
this only which was finished of all the paintings in the
chapel.
The Last Judgment, and the ceiling of the Sistine chapel,
may be considered, together, as the noblest production
of modern painting existing in the world; and it is to be
doubted whether any work of antiquity could be compared
with it for grandeur of conception and power of execution.
He painted also, in the Pauline chapel, the Conversion
of St. Paul, in which the Saviour descends in the midst of his
heavenly ministers, as he addresses the fallen convert, who is
surrounded by flying horsemen, and thoes on foot in dif-
ferent directions and inexpressible terror. The Crucifixion
of St. Peter, on the opposite side of the chapel, exhibits the
horror of the action, the patience of the saint, the grief
of attending friends, and the dolorous solemnity of the
surrounding multitude.

Michael Angelo, in his old age, applied himself more to
architecture than to sculpture and painting. After the
death of Anthony San Gallo, the pope appointed him chief
architect of St. Peter’s, and of the apostolic chamber, al-
though he would have excused himself from it; but having
accepted the charge, he went to St. Peter’s to examine
San Gallo’s model, which not approving, on account of its
being a composition of parts, without sufficient reference to
a whole, he cauè another model to be made, which not
only produced a much grander and more magnificent fabric,
but at one-eighth of the expense. And this great church
was finished according to the design of Michael Angelo,
excepting the front, which is not his. While he carried on
this building he made also several others, which constituted
part of the beauty of Rome; such as the palace of Farnese
and the Capitol.

After he had arrived at the age of 80, and had withdrawn
himself from most works of importance, except the building
of St. Peter’s, he gratified the piety of his own mind, and
amused his leisure hours in working on one large block of
marble a group of four figures, representing the dead body
of our Saviour supported by Joseph of Arimathea, attended
by two of the Marys; a pathetic and noble composition,
which he did not live to finish. It is now to be seen on the
back of the high altar in the cathedral of Florence.
Michael Angelo died at Rome in 1564. He was almost
90 years of age. This great man, besides the affection of
seven popes, whom he served, is said to have gained very
great reputation among the following princes; Solymn,
emperor of the Turks; Francis I., king of France; the
emperor Charles V.; the princes of the republic of Venice;
and all the princes of Italy, particularly with the great
duke of Tuscany, who reigned when he died; for when his
body was in the church of the holy apostles, and the pope
was about to set up a fine sepulchre for this great duke
called his body to be privately fetched away to be buried
in his capital city, and performed his funeral obsequies with
all imaginable pomp and splendour. This pomp was cel-
brated in the church of St. Croce, at Florence, attended by all
the academy of design, who on that occasion gave sufficient
testimony of the esteem they had for their matter by the
magnificent representation which the Italians call Cattalino,
and adorning the whole church with painting, and sculpture,
and lights. A panegyric was there pronounced over him
by Mellor Benedetto Varchi.

Michael Angelo’s character, as a man and an artist, was
equally honourable to painting, sculpture, and architecture;
his integrity is unimpeached; his generosity and gratitude
were princely; his piety and temperance were exemplary;
his studies were indefatigable; his genius was sublime
and original; and his execution equally powerful, beyond
all those who went before him and all his subfrequent
imitators.

John of Bologna was a sculptor of great merit, both in
bronze and marble, who lived rather later than Michael
Angelo: his groups are remarkable for the good composition
and fine undulation of his lines, of which the Rape of the
Sabines, in the market-place of Florence, is an instance.
His statue of Mercury rising from the point of his toe into
the air is also justly admired. Many smaller works by this
artist partake in the same grace and beauty, and may be
fludied with advantage.

Benvenuto Cellini, who was a goldsmith and sculptor in
metals, executed a fine colossal group, of Perseus holding
the head of Medusa in his left hand, with the sword in his
right, and standing on the body from which the head has
been separated: the pedestal is most whimsically adorned
with bas relief and chimerical figures relating to the sub-
ject.

After these artists, the Florentine school of sculpture
lingered into a late of inanity.

Bernini was employed in Rome by pope Urban VIII.,
and built the noble semi-circular porticoes of St. Peter’s
church. His best work of sculpture is the group of Apollo
and Daphne: he designed and modelled innumerable figures
for the colonnade of St. Peter’s and the bridge of St. An-
geo; he executed the monuments of Alexander VII. and
Urban VIII. in St. Peter’s; the colossal statue of St. Lon-
ginus; and four doctors, which support the chair of St.

This sculptor, whose works were so numerous, as he was
first a painter, and formed in the Lombard school, ende-
voured to embody Coreggio’s style of painting in sculpture,
forgetting the impossibility of representing flying draperies
and the extremities of hair in marble, which is to easily done
on canvas; and which, when universally attempted, remains
an equal testimony of the sculptor’s want of judgment, and
the impossibility of the attempt. Although there are fine
ideas in the general conception of both the papal monu-
ments above-mentioned, by this artist; yet his allegorical
figures are affected in their attitudes, smirking and con-
coited in their countenances; their forms are flabby and in-
correc; and their draperies confuted: yet this style, de-
praved and shony as it was, in spite of the beauties of
Nature, which continually appear before our eyes, and the
Grecian examples of rigid perfection which adorn the city
of Rome; notwithstanding these, it produced a train of
followers, Ruffon, Algardi, Mocc, &c. &c. who continued
to be employed, till within these fifty years, in Italy,
where
where the flimy materials upon which they formed themselves were entirely worn out; and the human intelligence returning to the essence of art, which is the imitation of Nature, began the work anew, studied the principles of the ancients, and applied themselves: with diligence to a representation of the human form divine.

This same mode of study has produced a new and a better school, which promises something like a just emulation of the bell days of Greece, in the works of that distinguished sculptor Mr. Canova, and some other sculptors, both natives and foreigners, in Italy.

The French nation, from its vicinity and intercourse with Italy, as well as from the friendship which the early kings of France cultivated with the emperors of Constantinople, always preferred a taste for fine art in that country, and supplied the means of its improvement, both in painting and sculpture. The large collections of fine Greek manuscripts, with their numerous beautiful illuminations, were imitated by the French painters, and the nearness of the countries to each other, enabled the French artists to study sculpture and architecture in Italy, as well as the kings of that country to supply their great public works with architects and sculptors from Italy also. In the reign of Francis I. Lionardo da Vinci, Benvenuto Cellini, and Primaticcio, laid the foundation of a school of fine art, similar to that in Italy, as improved from the lately discovered Grecian works. The natives, who distinguished themselves most immediately after this period in sculpture, were Pilon, Couin, and John Goujon, whose bas-reliefs on the fountain of the Innocents deserve admiration and praise. In them is an union of the elegance of Raphael's school, with the Grecian purity and delicacy. The genius and abilities of the people, added to national munificence, have kept up a respectable school of sculpture in France till the present time.

Whatever has been done in painting and sculpture in Spain, was also derived from Italy. The native powers and virtues of the Germans, which have contributed so largely to modern improvement in arts and letters, have not been deficient in the art of sculpture. Our present limits and object will not allow us to produce many examples; therefore we shall instance one which would be honourable to any nation, in any period. The monument of the emperor Maximilian, father of Charles V., stands in the church of St. Anthony at Innspruck; it is in bronze, and was made by Alexander Collins of Mechlin, the sculptor. The idea of this monument is as extraordinary as the effect is pathetic. Maximilian lies in his imperial robes upon his tomb, elevated about five feet from the ground. There are, at the distance of two feet from the tomb, marble steps about two feet high. On one step stand eight colossal statues of his illustrious relations; and on the opposite step as many more facing them. They represent distinguished royal persons from the time of Godfrey of Boulogne, of whom he was one. The spectator is awed by this silent and imposing assemblage, who stand in striking attitudes and solemn grief by their relation. The actions are bold and forcible; the armour is rich and elegant in the highest degree; but it may be objected that the ladies have something of masculine heroism in their characters.

There are several other fine statues in bronze, of inferior dimensions, representing German princes, in the same church. There is also a most noble monument by this artist in bronze, representing St. George, with one foot on the dragon, which he has just slain.

England, like the other nations of Europe, chiefly derived her arts and letters from her Roman conquerors. Also she is not without her obligations to Christian Greece as well as ancient Greece, for the arts and learning of the different ages. Those which were called Saxon architecture and sculpture, were in fact only barbarous imitations of the provincial Roman arts. The Norman architecture and sculpture of this country were likewise an imitation of Roman art; but through the more distant medium of the Norman French, subsequent improvements in the revival of arts were derived more or less remotely from Greek or Italian affinities; though, in justice to the genius of the English, it must be acknowledged that their progress in the art of sculpture, down to the Reformation, kept a respectable pace with their neighbours on the continent, as may be seen from the sculptures on the west front of the cathedral of Wells, completed in the reign of Henry III.: in Exeter, Litchfield, and Salisbury cathedrals, but more especially in the sculpture in Henry VIIIth's chapel in Westminster Abbey: in also reliefs of scripture subjects, monumental sculpture, and figure statues, to be seen in different ecclesiastical structures throughout the kingdom. From the time of the reformation, when painting and sculpture were exiled from the churches, the native genius of the country was left entirely without employment; and wherever painting was required for the decoration of palaces, or sepulchral sculpture for the churches, foreign artists were employed, and, with little exception, supplied the country with a degeneracy of French, Italian, or Flemish art. The best of the foreign sculptors who have been employed since that time were Cibber, who executed the statues of raving and melancholy madness on Bedlam gates, the bas-relief on the pedestal of the London column, the greater part of the kings in the Royal Exchange, and a multitude of other statues for different buildings in various parts of the kingdom; Roubiliac, who executed several monuments for Westminster Abbey, with much labour and attention to common nature, the compositions of which, however, are either conceits or epigrams, and the parts are too often mean and vulgar. Scheemaker executed some of the statues on St. Paul's, and the bas-relief in the pediment; but he is not distinguished by pre-eminence and ability.

Since the establishment of the Royal Academy, and the frequent employment of the sculptor's talents in public monuments, the art has been practised by natives, whose own industry, studies in Rome and foreign countries, and the zealous exercise of their profession, have raised works equally creditable to the country and their own talents. Mr. Bacon's works have been much admired. Mr. Banks has left statues and bas-reliefs which might be ranked with some of the ablest works of antiquity: and some of the public monuments by English sculptors of the present day, might be compared with advantage with the ablest productions of the fame kind on the continent.

In the general treatise on an art, we cannot pass over in perfect silence the productions of a great empire which has pretended to the highest antiquity in its cultivation; the ingenuity and beauty of whole finer manufactures and more delicate works have claimed universal attention, and have been admired and collected by most of the curiosities. The Chinese sculpture must be noticed; though, from the productions we have seen in Europe, and from the best authenticated inquiries, we have great reason to believe that such of their paintings and sculptures as can lay any just claim to those titles, have received most of their charms from European communication. There is great reason to believe that their smaller models and bronzes were improved from a very barbarous state. Among other branches of knowledge by Catholic missionaries
millionsaries who went over in the fourteenth century, their
casts received a further improvement from the learned and
ingenious Jesuits who visited them in the beginning of the seven-
teenth century; and again in the beginning of Louis XVIth's
reign, sixteen Chinese in the city of Paris were instructed
in the European arts of designing, light, and shadow; optics,
colour, and perspective; since which the painting and sculpture
of China have become more nearly allied to the European
practice of those arts than ever. These facts are attested
by the known attainments of the several missionaries who
have visited China; by the testimonies of the hell writers who
have written on that country; by the representation of Eu-
erpean head-dresses and fashions in their works; and by
Chinese subjects drawn and engraved by Jesuits who were
resident in that country, and whose style of designing flew
that the Chinese artists, of the same ages, formed their
school of art upon the works of these men.

MOTIVES FOR THE EMPLOYMENT OF SCULPTURE IN GREECE, AND THE
ENCOURAGEMENT GIVEN TO THE ART.—The first motive for the
employment of sculpture in Greece was religion, which
induced the several states and opulent individuals to vie with
each other in employing the choicest talents of their country-
men for the production of the most beautiful and approved
works, to adorn their temples and public places in honour
of the different divinities, which they believed to be their
more immediate patrons and protectors in that state of poly-
theism. This species of piety became more popular; and its
effects became more general from another motive, the
relation which most of the powerful families of Greece
claimed with the several divinities and heroes, by deducing
their own genealogies from some one or more of them.

In a state of society where the families of all lived nearly
in the same habits of simplicity, because the luxury and
magnificence of private life created a jealousy among fellow
citizens, likely to terminate in most tragical consequences;
in this state of society the more wealthy employed their
stores in building and equipping ships, raising troops of
horse or foot, increasing the temples, placing in them magni-
ficent tripods, beautiful statues, or other costly gifts; in
strengthening the walls of their cities, and all such public
works as provided for the safety, or increased the fame
of their country.

Patriotism, in addition to religion, was another motive, not
much less powerful than the former, for the encouragement
of sculpture in Greece. The Olympic games, instituted at
an early period in that country, encouraged the trials of
skilful to the utmost extent, which educated the human frame
in the greatest habits of strength, activity, and promptness
of exertion, for all the most useful employments of peace
and war. They also publicly exhibited the finest forms and
examples of personal beauty to the assembled of Greece at
the Olympian exercises, and by that means enabled the
philosopher to analyze, the physician to enquire and deduce,
the artist to form principles from nature for the perfection
of his works, and the generality of spectators to judge of
the phenomena of health, strength, activity, proportion,
and pleasing parts of the human form, among those who
were engaged in the exercises, and rendered themselves, by
their prowess, ability, and fortitude, the objects of universal
admiration and applause.

The immediate honours bestowed on the victor was an
herbal crown, rendered equal in value to the richest diadem,
by the approbation and congratulations of the whole state.
The victor was likewise honoured with a brazen statue on
the very ground where he had shewn himself properly quali-
fied to be a defender of his country in war; and for prudence,
activity, and fortitude, a valuable citizen in time of peace;
and if any one obtained the crown three times in these
exercises, he was not only honoured with a bronze statue on
the spot, but that statue was made an exact portrait of him,
not only in the face, but every part of his body and limbs.
These general remarks on the religion and public institu-
tions of Greece, will sufficiently account for the immense sums
expended in works of sculpture, and the prodigious multi-
itude of these works produced in that country.

The statue of the Olympian Jove, made of ivory and gold
by Phidias at Elis, was paid for by all the spoils taken from
the Persians. If we might calculate a small part of this
statue, only by the price of ivory at present, the covering
of ivory only, which must have been perhaps the least article
of expense in it, without the workmanship, could not have
cost less than 2000l. There were 8000l. brimming of gold in
the statue of Minerva made for the Acropolis, besides the
ivory, workmanship, and all other expenses.

We are besides told of another statue of the faze of nature,
valued at 15,200l.; and of another, the Venus of Gidors,
which was refused to be given up for the payment of the
debts of a whole city; and thus we cannot wonder that
works produced from the noblest motives, and rewarded by
the highest gifts that man can bestow on man, were of a su-
preme excellence, which have commanded the admiration and
interest of all succeeding ages.

CONCERNING GENERAL BEAUTY IN THE ANCIENT WORKS OF SCULPTURE.

—After a general view of the motives and circumstances
which produced these works in public, we shall next enquire
into the more private motives, attainments, and qualities
which enabled the artists to produce such works, and here
we must remember the observation of Socrates, that the
dispositions of the mind may be expressed by the forms of
the body; and as Socrates himself was a sculptor of no
mean excellence, and a philospher of the highest character
also, what he says upon this subject cannot be too carefully
attended to; and indeed it applies to the progressive improve-
ment in this art from the rude representation of the
human form to the most perfect; and to the separate con-
deration of the mind and its qualities, by which the human
form is animated.

As it has been observed in a former part of this article,
the earliest attempts to represent the human form in all na-
tions are almost equally barbarous and imperfect; we shall
therefore, begin our description of Grecian imitation, when,
by a more general comprehension of science, her imitation
of its archetype was superior to such barbarous primeval at-
ttempts in general.

These attempts and their improvement have always suc-
cceeded best in those parts of the human figure which are
nearest to our view, or present themselves to us as most
striking and important. In such representations, the fea-
tures of the face are more accurately represented than any
other part of the figure. The body, the arms, and legs at-
tract the most general and least distinct notice; therefore the
first improvements in the earliest statues of Greece remain-
ing, approach only to something like a more tolerable propor-
tion, express the arms in general meagre long forms, with
the shoulders somewhat more round and prominent, and the
fingers separated by nearly parallel channels. The body is
distinguished by the paps of the breast, the line of the ribs,
and the navel. The legs and thighs have little more of
variety in their forms than a small knee-pan, and some
projection of the calf of the leg, with feet and toes formed with as little attention to nature as the
hands. In this state of improvement little variety of action
will
SCULPTURE.

will conseqently be expected. Sitting, lying, running, or striking, will nearly comprehend the whole extent of the artist's variety in a single statue or bas relief. In this state of improvement it is in vain for us to expect any discrimination between the characters of gods and men; they were all represented by the same forms: and Jupiter, Hercules, Mercury, and Neptune, were only known from each other by the thunderbolt, the bow, the caduceus, or the trident.

According to the general improvement of science, as the observation of the course of the heavenly bodies, the divisions of land, and marking out the plans for building on the ground, had introduced some practical application of geometrical lines and figures, which must precede observations on the balance and motion of bodies; and as something more like anatomical knowledge was obtained from the sacrifice of animals, or observations on the dead left on the field of battle, or a human skeleton casually found; these affinities afforded light on the structure and movements of man; so the artist, applying principles as he became master of them, copied his example with more accuracy, and represented the parts more in detail.

The next state of improvement we shall observe is a nearer copy of ordinary nature, in which the hair, however, is straight, the eyes full, the eye-lids gently marked, the bottom of the nose and the line of the mouth curved upwards at the corners, giving a kind of smile to the face; the brow a little more prominent; some indication of the muscles of the abdomen by cross parallel lines; the hollow in the loins behind, and the general form of the blade-bones, more natural; more distinction between the breadth of the upper and lower portions of the thigh; the general forms of the feet and hands, more accurate according to their angles and divisions; and the biceps muscle marked in the arm, and the elbow. Specimens of these different steps of improvement may be seen on the Greek painted vases, particularly those which have black figures on them. There are also many small bronzes, which are demonstrations of the same progress of improvement.

In the age of Phidias, when geometry had made considerable advances, as we find by the writings of Plato, when anatomical researches had been prosecuted with care by Hippocrates, in addition to the advantages of seeing the human figure in more perfection, from the establishment of regular government, the more regular supplies of agriculture for living, and other improvements in civilization most favourable to the beauty of the human figure,—with these advantages, the human figure was represented with the distinction of youthful beauty and elegant proportion, as well as with the strength and agility which indicates a rather spare diet and great exercise, of which the statue called Theseus in Lord Elgin's collection is an example.

It is remarkable, that personal beauty of countenance and elegance of form frequently occur in works about the time the Parthenon was built; although in the same works there is an evident want of proportion and perspective in some of the parts, with the most careless confusion of the drapery. But we must remember that the course to excellence is progressive, even to the greatest genius, and that all arts are perfected by the accumulation of discoveries and long practice.

Having mentioned the first dawning of beauty in Grecian sculpture, this will be the place for some enquiry concerning that beauty which so eminently distinguished their best works. A people long acquainted with the naked human form, and the exertions of the human figure, would practically learn, that a particular make was favourable to a particular exertion, as long legs were favourable to walking and running; broad shoulders and a full chest were accompanied by strength. The observations of physicians would assist in ascertaining the more convenient form of all other parts of the body and limbs for strength and exertion; then inquiries into the animal economy of the body would assist their determinations relating to health or sickliness, in the whole or the parts, according to outward appearances. All this would assist the artist in the determination of what he should choose and what he should reject in his imitations. The bloom of youth, the prime of manhood, and the parts best formed for all the uses and exertions of the body, would become his standard example for the most fortunate attempts of his art; and having proceeded thus far, he would be able the more readily to distinguish the various characters of tender infancy, the venerable solemnity of advanced age, and the graceful forms of female elegance.

But other distinctions and other characters still remain for the artist to become acquainted with, to qualify him for the extensive representation of gods, demigods, and heroes, human creatures and internal beings; and this could not be done by the simple representation of common forms and common expressions, such as continually presented themselves, but by a selection from nature of whatever was most excellent in form, accommodated to the highest qualities of mind, to represent the higher orders of beings, and their opposites in those which are below humanity, and partaking ofnoxious and infernal nature.

Mere form, however harmonious in its proportions, or beautiful in the smoothness and perfection of its finisheued surface, without the expression of sentiment and action, is but dead, and no other than a corpse which has been quitted by its immortal spirit; therefore the artist's great and most important interest, after he had obtained the geometrical forms of body, was to watch the strongest mood of the soul to find a correspondent in form, to accommodate to the highest qualities of mind, in order to give animation to his works. It was his concern to investigate and represent decidedly the strongest affections, conjugal, parental, social, and sordid; the sentiments of piety and religion; the inclinations of passion in their different degrees, whether of love or hatred; for, by these means only his works fallen on the kindred affections of the spectator, and obtained his effect.

The Greek artists who gave their first mental improvements to their works, sought for nobility of sentiment and distinct characters of gods and heroes from the writings of Homer; illustrated by the speculations of Pythagoras and Plato upon the essential qualities of divinity, in their omnipotence and extent, and the limited powers of humanity, derived and finite.

From these they learned that all bodily perfections and beauty were derived from mental beauty and perfection; that as forms which expressed healthful bodies and their parts were the most perfect, as far as form and animal power extend; so the expressions of the most perfect mental qualities added the most perfect animation of beauty to those forms, and gave the most perfect characters of magnanimity, justice, benevolence, and dignity to the faces and figures of their divinities, and in an inferior degree to their heroes: and whatever perfection of face or person they would express, they found could only be done by the sentiment of that virtue and beauty of men by which it was immediately caused. Jupiter, the chief of their gods, was represented in the most perfect human form; powerful in his make, beauteous in his countenance, and of that mature age when wisdom is united to the full development of the bodily powers. His full beard and abundant flowing hair are consistent with the greatest dignity the human head is capable of; and the bonelike
like hair and forehead decide the magnanimity of the character. The broad chest, the strength and proportion of the limbs, the whole solemnity of the person, at the slightest view, announces, according to the Homeric expression, the father of gods and men.

The next divinity in dignity to Jupiter is Apollo, whom we can readily believe to be the exact representation of his father, in the dignity of youth; his features are his father's in youthful bloom and beauty; the form of his body and limbs partake of his father's strength in youthful lightness and agility; his countenance is adorned by his flowing locks, according to his age, more light and varied than his father's; his sentiment and employment are also suited to his age and more limited offices. Jupiter, seated on his throne, has little action or corporal employment; his mental energy regulates the universe by his rod; and his single exertion is the discharge of his irresistible thunder. Apollo is seen in love, in meditation of immortal poetry to accompany his lyre, destroying Python, meditating the cure of diseases, or inflicting death by his arrows.

Bacchus resembles his brother Apollo so exactly, that they cannot always be distinguished one from the other; yet he frequently partakes of a more feminine nature, according to the Orphic description of his double sex.

Mercury, with the same beauty as his brother, and the same youthful resemblance to his father, has a more athletic form, approaching to heroic, as being the patron of gymnastic exercises, and messenger of the gods. His hair is short; he wears a small round hat or petasus, which is winged; he has also wings to his ankles.

Mars differs little from Mercury in form or countenance, excepting that he is sometimes bearded, and frequently wears a helmet upon his head, or is dressed in complete armour.

Neptune resembles his brother Jupiter, but his hair is more disturbed, and he is in general entirely naked.

Pluto also resembles Jupiter and Neptune, but his eyes are more staring and spectre-like; his abundant hair falls more over his forehead, and gives a greater gloom to his countenance: he is clothed in a tunic and pallium, holds a sceptre in his left hand, and is attended by the triple-headed dog Cerberus.

The goddesses are less distinguished from each other than the gods. The height of female beauty, in dignified figure, with noble mien, is common to them all.

Juno is represented with a regal diadem and sceptre, generally clothed in the tunic and peplos, or large veil: her countenance is lovely; her eyes and lips are full; her hair is turned up, and tied in a knot behind in simple majesty; her veil is sometimes over her head.

Minerva is distinguished by the serene austerity of her countenance, and the wisdom of her character. She is armed with a helmet and aegis, and bears a spear in her hand, but in other respects is drest like Juno.

Venus is distinguished by her tender softness and graceful action; she is represented as parting her hair and rising from the sea, modestly covering her person as returning from the bath; or drest in a light and thin tunic or veil, and engaged in those concerns of the toilette to heighten or preserve beauty. She is frequently attended by Love, who is represented as an infant divinity.

Vesta and Ceres have much the appearance of Juno; the first distinguished by her lions and mystic drum; the other by ears of corn.

Diana has her hair collected on the top of her head; like her brother Apollo her tunic is incassê, not reaching lower than her knees, its length being shortened by the tyding of her zone; she wears bulkins, and is generally running, or in an attitude which relates to the chase.

Hercules, the first of their heroes, and who in early times was one of their greatest gods, was not represented with that irresistible strength and muscular force in the time of the first Greek sculptors, in which he was represented afterwards, and he changed his arms as well as his figure, for before the time of Archilus his arms were a bow and sheaf of arrows; but as his labours became such as required more natural force, according to later mythologists his bodily powers were increased, and his arms changed from the bow to the club. His strength is proverbial, and his powerful form is known to every one, by his numerous representations in sculpture and painting. It is well remarked by Winckelman, that in the likenesses found in the antique statues between the faces of Hercules and Jupiter, there is a character of the bull given to the head of Hercules, by the short hair and the bull forehead. As a proof that this mixture of the bull in the head of Hercules is not fanciful, there are bulls representing a mythological modification of the Herculean character, with the bull's ears, horns, and dewlap.

We shall describe the fawns as one class, companions and ministers of Bacchus; in this class we shall mention the Sileni, the fother-fathers or nurses of Bacchus, one of which is a dwarfish figure, with a round belly, fat limbs, a Socratic merry face, a bald head, a long beard, undulated and divided; his body is more or less covered with hair. This Silenus is also occasionally called Ampelus. The other Silenus is a well-proportioned elderly man, rather a spare figure, with a philosophical countenance, with a head and beard bearing some distasteful resemblance to Jupiter. Both these Sileni are crowned with ivy, and have pricked ears.

The fawns have round faces, short noses, and a grinning expression; their hair is short, thick, and like that of a goat. Their bodies are strong, their muscles tenuidous, like those of wild animals, and suited to the elaticity of their actions; they have short goats' tails.

The Satyrs have goats' legs, their bodily conformation like the fawns, they have pricked ears, sometimes long goath beards, and frequently faces resembling rams or goats.

The Titans and giants are Herculean figures to the waist; some of them have the lower limbs human, and corresponding to the upper part of their figures; others from the middle end in serpentine folds instead of human legs. Their heads have an Herculean character, swollen and terrible; there are serpents in their hands, perhaps relating to their infernal punishments.

Ocean and the divinities of seas are all Herculean figures, in countenance resembling the Saturnian family in youth or age; they are generally naked, though some are veiled downwards; and Ocean himself has a veiled head. The inferior divinities of the sea, as the family of the Tritons, and their various diatophins, have hair, faces, bodies, and arms like the fawns, but with slimy hair and gills, their lower halves ending in the tails of fishes, horns, bulls, &c.

The genii of mountains are robust figures, with solemn countenances, flowing hair and beards, crowned with pine, oak, &c.

The nymphs of Earth and Ocean are beautiful entire female forms, with hair sometimes flowing, sometimes tied in playful dispositions. The marine nymphs are frequently collected in affectionate groups, and employed in stretching out their flying veils to the wind.

The Three Graces are the beautiful female companions and attendants of Venus; they are represented as three beautiful
SCULPTURE.

beautiful virgins, in the flower of youth, embracing each other.

The nymphs of Diana are habited like their patronesses.

The Furies are handsome, but with a terrific expression of countenance; their hair dishevelled, winged, and with two small serpents rising from the tops of their heads. Their dresses are a succinea tunic, like Diana's, and they have snakes and torches in their hands, to torment the wicked.

What has been said is sufficient to convey a general idea of deified personification in Grecian mythology; but those who have occasion for a more intimate knowledge of their system of theology, and its different relations, as well as its innumerable allegorical forms and monsters, must be referred to their poetical and mythological writers, and the various publications of ancient painting and sculpture, with their illustrations by the learned.

Concerning the Beauty of Parts in the Human Figure, its Balance and Motion.—The ancients have observed that the human figure is inscribed within the square and the circle; the square, when the feet are close together, the posture upright, and the arms extended in a parallel line; when the length from the extension of the opposite finger is equal to the whole height, from the crown of the head to the sole of the foot; which general observation leads to the determination, not only in the position of the body and limbs, but to the balance of the figure, by geometrical lines. The human figure being laid upon its back, the arms and legs, extended like the spokes of a wheel, may be inscribed in a circle, the centre of which is taken from the navel. When the figure stands upright, equally poised upon both feet, the centre of gravity falls in a perpendicular line from the gullet between the two ankles.

When the figure rests on one foot, the centre of gravity falls from the gullet, perpendicularly on the bottom of the tibia bone of the leg on which it rehs.

If the figure is in equipoise, the centre of gravity falls from the gullet between the legs.

In advancing from that point before the leg, and in swift running, it is at every interchange of step far before the foot which is next to be placed on the ground.

The figure, in bending sideways to balance itself, must still retain an equality of weight round the centre of gravity, to preserve its balance by stretching out the opposite leg or arm.

For further satisfaction concerning the motion of the human figure, consult Borrellus de Motu Animalium; Copper on the Muscles; and Leonardo da Vinci on Painting.

To obtain a more positive idea of the form of the human figure, as well as its balance, together with the breadth of its parts, a reference to a geometrical figure is particularly useful. For instance, view it in profile, and we shall see that its column or general mass is not perpendicular, but consists of undulations, through the middle of which we may suppose the centre of gravity palled perpendicularly downwards. The head is thrown forward over the neck and the breast, to serve as a counterbalance with the breast against the projection of the shoulders; and the projection of the nates counterbalances that of the abdomen; so that the back-bone beginning from its uppermost joint, which immediately supports the skull, after being a little curved inwards, though nearly straight for the first seven joints, after wards forms a bold curve outwards between the shoulders for the next twelve joints downward to the loins, partaking in the same hollow with the ribs, to contain the organs of the thorax.

The projection of the thighs in front is opposed lower down on the opposite side by the projection of the calves of the legs; not only for a counterbalance, but also for counteraction; and for the same reason the bending forward of the body from the head downward is counteracted by the length of the foot, and its fulness for support.

The general form of the head, viewed from the top, is circular, being larger at the back of the head and narrower at the forehead. The general view of the head in front is egg-formed. The simplest character of the profile is that of the nose, little differing in straightness from the line of the forehead; the lips and chin making small projections, each about a quarter of a circle. This is the most general and simple idea of the human face, and that principle upon which most of the ancient ideal heads are formed. Force and passion are deviations from this principle by the application of curves in the outline; or else bold, and the face of infancy is described by one portion of a circle forming the forehead, and another the cheeks, with a small nose between.

In the ancient sculpture, the most perfect necks for youth, beauty, and strength, are nearly circular, like the portion of a column. The breasts are elevated and broad; the line of the ribs is nearly a portion of a circle gently expressed, a little below the nearly straight line, which terminates the breasts above. The abdomen has a gentle channel from the pit of the stomach to the navel. The lower muscles of the abdomen to the os pubes are a little swelled and nearly plain. The sides of the ribs under the arms are marked with gentle divi tions diagonally, tending downwards in front, which indicate the ribs and muscles which immediately cover them. The back of the trunk between the neck and the loins is a curve outwards, as has been already described; and the spine, or back-bone, which is the pillar of support to the upper part of the body, the arms, and the head, shews behind as an indentation between the two rounded portions of the back, on which the blade-bones and their muscles form a gentle and rounded flattened swell immediately below the neck. The commencement of the arms, as they are affixed to the body, has a bold and rounded form, in the upper part of which is united the head of the upper arm-bone, to the end of the collar-bone before, and the blade-bone behind; the arm, beginning at the separation from the trunk and continued to the wrist, is a diminishing cylinder. The upper arm finishing at the elbow is broader, and sideways flatter than the lower arm. The lower arm is flattened the contrary way, and less than the upper part of the limb. The wrist is a rounded flattened form in youthful bodies full of flesh. The hand is hollowed within and, a little rounded without; the thumb extends to the first joint of the first finger; the middle finger is the largest; the next finger outwardly is next in length; the finger between the thumb and the middle finger next in length; and the little finger shortest of all; they are less in bulk as they are shorter, and diminished downwards cylindrically. The male hand and finger has more of breadth and breadth; the knuckles are more square and decided even in youth. The female hand is more rounded and fleshy; the fingers are more perfectly cylindrical and tapered, the knuckles less decided, having little more distinction than gentle hollows in the more constricted positions of those knuckles, which unite the fingers to the hand. The nails in men are more squared, in women more rounded, long, and delicate.

The loins of the body are in the side view considerably curved in from the ribs, and project again in a gradual obliquity from the bottom of the ribs to the bottom of the nates. In the front of the figure, the trunk terminates at the os ilium or iliac bone, which is marked immediately before the projecting muscles, which terminate the line of
the trunk, and immediately above the setting on of the thigh, and is marked with a strong line obliquely descending to a point at the greatest projection of the os ilium in front, and forming from thence a nearly inverted semicircle to the top of the os pubis.

The thighs are fullest and roundest immediately at their separation about half way downwards: they gradually diminish toward the knee.

In the upright figure the knee-pan above, with the ilium and fat immediately below it, form what is altogether generally called the knee-pan, of an oval figure, and is the great distention of the knee in front, between the thigh and the leg. The inner line of the principal bone of the leg, or tibia, is a long curved outward in a hollow of about 30 degrees. The inner ankle is higher than the outward. The calf of the leg is most projecting, near one-third of the way from the joint to the bottom of the heel, and behind in a flatish forked division, sends a strong muscle united with the tendon of the heel, making together the backward profile of the leg. The outside of the leg has its principal curvature rather lower than the inside. The toes are shorter than the fingers; the longest toe is next to the great toe; the great toe is the broadest; and in those not used to wear shoes, divided from the second toe by a considerable separation. The three toes on the outside of the foot are shortened in a diagonal line. The characteristics of the male and female in this extremity are nearly the same as in the hand.

In stronger figures the joints are marked with more strength and complication, the muscles are more decided, more of the tendons are seen, and occasionally the veins, particularly towards the lower parts of the extremities. The flealthy projecting parts of the figure in old age are more flattened, which indicates the diminution of elasticity as well as muscular power.

The female figure is generally about one-tenth shorter than the male; its bones are more straight, and legs more rugged towards the joints, as the attachment of its muscles are stronger; the forms of the body and the limbs are more rounded; the differences of the male and female bosoms are well known. The shoulders of the female are narrower in proportion than those of the male; the loins are narrower and the hips are broader.

In infancy, although the proportions are very different from the adult male or female, yet the roundness of the limbs and body, little distinguished by the marking of bone at the joints or projecting muscle between the joints, approaches nearer to the smooth and generally rounded surface of the female figure.

Vitruvius informs us, from the writings of the most eminent Greek painters and sculptors, that they made their figures eight heads or ten faces high, and he imitates different parts of the figure measured according to that rule. The great M. Angelo adopted this rule, as we see by a print from a drawing of his. We shall adopt this method in giving the most general proportions of nature and the Greek statues.

Proportions.—Divisions of the human figure in length.
From the os pubis to the top of the head, one-half of the figure; from the same point to the sole of the foot, the other half.
There are three equal divisions from the acromion of the scapula to the bottom of the inner ankle. 1st. From the acromion to the point in the spine of the ilium, from which the rectus and tautorus muscles begin. 2dly. From thence to the top of the patella. 3dly. From the top of the patella to the bottom of the inner ankle.

From the bottom of the os pubis to the bottom of the patella is the same length as from the bottom of the patella to the sole of the foot, two heads each; but we must observe, that the ancients generally allowed half a nose more to the length of the lower limbs, exceeding the length of the body and head.

The arm, from the top of the humerus to the bend, one head and a half; and from the bend of the arm to the first knuckles, the same.

Breadth of the upper arm, one nose and a half; side view, two noses: lower arm, thickest part, one nose and a half; wrists, one nose.

Breadth of the shoulders, two heads; of the loins, one head and one nose; across the hips or trochanteres, one head and two noses. Depth of the cleft, one head and one-third of a nose; of the loins, three noses and one-third of the glutei, one head. Breadth of the thigh, three noses; of the calf of the leg, two noses; of the ankle, one nose. The foot is one head and one nose in length.

The female figure should not be too tall as the male. The shoulders and loins should be narrower, and the hips broader.

The proportion of the Herculeus Farnese and the Torso Belvedere are nearly one-fifth more in breadth than other statues.

But the ancients varied the proportion according to the character and age of the person. There are examples of the Silenus, and Hercules also, when he partook of the same character, exceedingly dwarfish, not exceeding four or five heads in height; and there are examples on some of the Greek vases of figures nine or ten heads.

Drapery.—To introduce our observations on the draperies of the antique statues, we will first enumerate a few of those garments in which they are most generally clothed; and we will begin with the largest and coarsest woolen garment, called the pallium, which was a large piece of square, or squarish cloth, perhaps about seven feet long, but not so wide; this was generally worn by being folded over, perhaps one-third of the breadth; one end applied to the left side of the body, carried under the right arm, and thrown over the left shoulder in front; it formed broad and simple muffs before and behind, with a few bold and distinct folds, which left the body and limbs well accounted for beneath. It was, according to the convenience of the wearer, thrown in a variety of different manners: sometimes one arm was wrapped in it, sometimes the other, and sometimes nearly both; all the statues of philosophers, excepting the Cynics, are clothed in this manner.

There were other garments nearly of this kind, which are very commonly seen; particularly the manly peplos. The figures of Jupiter and Eclipsus are sometimes seen wrapped in the peplos, which appears to have no other distinction from the pallium, than that it is made of a finer texture, consequently produces fewer and more numerous folds, and its corners are sometimes ornamented with tassels, or knots.

The chitone seems to have been a finer and lighter woollen garment than the peplos, much less, but, like that, of a long square; this garment is particularly appropriate to youthful heroes, and is seen on the colossal statues of Monte Cavallo, the Meleager, and many youthful heroic figures on Greek vases, and the young heroes in the frieze of Horfmen in the Parthenon at Athens.

The tunica, or kiltan, was an under garment, also worn by men in early times; this had no sleeves, and hung over the left shoulder, leaving the right shoulder entirely bare, not to impede action; in after times it had short sleeves, was full in the body, and when not girded, hung down below the mid-

SCULPTURE.

leg; but when collected by the girdle, did not reach lower than the knees. This seems to have been made in general of the same material with the chlamys. The chlamys is a military and hunting cloak, fastened with a button on the right shoulder, as that worn by the Apollo Belvidere.

Female Drapery.—The kiton, or tunic, was worn by the Greek women in very early times, but was generally made to pass over each shoulder, excepting Amazons, or female warriors, who sometimes had the right shoulder left bare; but the female kiton, or tunic, reached to the feet, and was lower than the ankles, even when girded by the zone. This was made of a finer material than that worn by men: it is called bombyx, and appears to have been produced from a thread woven by wafirs, or infants of that kind, and to have formed a delicate and fine texture, capable of producing long and varied folds, without lessening the distinct appearance of the figure underneath.

The peplos, or long veil, is described as a dignified garment by Homer; it was worn nearly in the same manner by women as by men, and is a characteristic of dignity, as Juno, Minerva, Vesta, and Ceres are seldom or never seen without it in a placid state.

Besides the kiton, the dignified female Greeks had another garment, which answered the name of toga, called the peplon, which appears to have been one piece of cloth doubled over at the top, folded round the left side, the left arm having passed through the top; open on the right side, which presented two cascades of folds: these are continually seen on the Greek vases.

Many other garments were worn by women, which frequently occur in statues, baso relevos, and painted vases, which answer to our shifts, petticoats, handkerchiefs, and bodices, and are easily distinguished in the works of ancient painting and sculpture; but as a more intimate acquaintance with these concerns the antiquary rather than the artist, we shall refer those who are curious on the subject to lexicons and scholiasts for further information.

The Roman toga appears to have been originally Italian, and was so entirely appropriated to the Romans, that they are thence called gens toga. Collected in its folds, it appears to have been of an oval figure, through the opening of which the head, the right arm, and half the body on the right side passed, the garment rolling on the left shoulder, being supported by the left hand, falling below the middle of the right leg, and presenting almost innumerable continued curvilinear folds, which encircle the figure before and behind from the left shoulder downwards. A lap of this garment was brought from behind over the left shoulder, tucked into the upper part in front under the right sleeve, which fold was called the cinctus Gabinus, and was laid to be a fashion brought from the city of Gabii. It was worn by emperors, consuls, noblemen, and Roman citizens: in general it was made of a fine woollen cloth, as most of the Roman garments were.

In reflecting on the beauty of drapery, we must always refer to the beauty of the human figure which it covers; and as garments are worn for a defence against the weather, or from motives of modesty, they should never be such an incumbrance as to impede action or overload the figure, either by their quantity or mode of wearing; which rule being observed, the general idea of form and action will always be intelligible underneath; and thus, however the figure may be covered, the plainer parts of the garment will give a breadth of light and shadow to the mass, and its folds a beautiful variety of form, either in harmony with, or in opposition to, the forms of the limbs and body.

The cascade, or zigzag fold of a long full garment hangs from the shoulder towards the feet, by the irregular geometrical effects of its light and shadow, shades the undulation of living forms on the opposite side of the figure, whether covered with drapery or not, with an advantageous variety.

The fine and web-like draperies, such as that of the Flora Farnef, shew all the forms of the body and limbs with nearly the same distinctness as if they had remained uncovered, at the same time that the gentle radiated curvilinear folds, upon a near examination, contral the beautiful forms of the body by a variation of lines tenderly afiliated with the flesh, in such a manner as induces the spectator to believe that the least motion of the body will produce a different, and equally pleasing new arrangement in the folds of the drapery.

What has been said concerning drapery comprehends the principles of the subject; for it was the intention on the fine statues of antiquity to produce a noble breadth by their draperies, conformable with the dignity of their most illustrious characters. In their more delicate characters they contrasted the beautiful form beneath by the graceful display of lines in the drapery; and in all their clothed figures, they adorned the forms of the naked figure by perpendicular, curvilinear, pendant, or zigzag folds, contrasting the forms and adding quantity, but leaving the figure and its position perfectly intelligible.

In the figure of Bacchus in violent action, the flying drapery becomes peculiarly ornamental; verging from the figure in undulating rays, which at its edges and extremities play upon the air in bolder forms, like the extremities of the poppy-leaf.

The Practice of Sculpture.—The first operation of sculpture, like that of painting, is design. The sculptor first makes his idea evident by a sketch or drawing; he then executes a small model, generally in clay, to try the effect of his lines, forms, and light and shadow, as well as the sentiment of his statue, or composition; but if the work requires the utmost accuracy and perfection he is able to give, he makes a model of the size in which the wood, marble, or bronze is to be executed.

He models his figure first naked in its just action, and accurate in its forms; he then lays on his drapery, either from studies made after the living figure, or drapery laid for the purpose on a lay figure, or maminikin.

The clay model, if large, must be supported by a framework of iron; and the mailes of clay may be kept together by a number of small wooden crosiers attached to the iron framework, by wires of different lengths differed in different parts of the clay. This method is used by Mr. Canova, the celebrated Venetian sculptor.

The tools used by the modeller are made of wood, or ivory, with ends pointed, rounded, square, or diagonal, with which he forms his models; marks out the hollows and dark parts; and does whatever he finds practicable to perform with his fingers only.

When the clay model is finished it must be moulded and cast in plaster; which cast must also be well supported and secured by bars of iron well cemented, to prevent the ruff of the metal from penetrating through the cast.

To copy the model in marble is performed in the following manner. A number of little black points must be marked upon the model, in every principal projection and hollow, to give the distances, heights, and breadth, sufficient to copy the marble with the greatest exactness from the model. The ancients performed this, by considering every three points on the figure as a triangle, which they made in the marble, to correspond with the same three points in the model,
model, by trying it with a perpendicular line, or some other fixed point, both in the marble and the model.

The moderns perform this operation in another manner. After, by taking rough measures, they have found that the block of marble is sufficient to make the statue equal in size with the model, they then fix it on a baulement of stone, or a strong wooden bench, called a banker; in the front of which is a long flip of marble, divided into feet and inches. A slip of marble, divided exactly in the same manner, is placed in front below the model; and a wooden perpendicular rule, the height of the whole work, which is capable of being moved from the slip of marble or scale under the model, to the slip of marble or scale under the marble, at the workman’s pleasure. This instrument being first placed upon the scale of the model, and the exact distance being taken, from its perpendicular, we will say, to the point at the end of the nose of the model, and the perpendicular rule being transferred to that scale on which the marble is placed; the workman cuts away the marble from the perpendicular rule at the same height, till he has arrived at nearly the same depth that the point of the model’s nose was from the rule; and by this means, he finds the point of the nose exactly where it should be in the marble. He proceeds in the same manner with all the other parts of the figure; for example, the top of the head, the chin, the shoulder, and every other part of the body and limbs; until, by cutting down the marble at the same height and depth from the perpendicular line of the rule that he defines to transfer from the model to the marble, he finds a corresponding point to that he has taken from the model; and so goes on until he has obtained the general proportions of the whole work.

When this is done, the sculptor proceeds to work over his statue with a flat-ended steel tool, called a chisel, whose square end is about five-eighths of an inch broad. In the naked parts of the statue, and wherever there is a flat surface, he proceeds in this manner: for instance, we will say, upon the breast of the figure, he cuts away the rough surface from a given point in a straight line, to another given point at some distance; he then cuts away the surface from one given point to another, exactly parallel to the course his chisel went before, he then cuts the marble in a line at right angles with the former direction of his chisel. He continues to work over the surface in the same manner, continuing to cut it away in lines parallel to each other, leaving the space of about one-eighth of an inch between each course of his chisel; he afterwards cuts away the remaining rough surface of one-eighth of an inch between each two courses of his chisel; thus obtaining a beautiful flat surface to his work, which can be done by no other means, and may be afterwards varied with the curvatures and indentures of leffer parts at his pleasure.

This method of cutting the stone is followed, as much as possible, in all parts of the work; that is, as much as all the varieties of outline and hollows will permit.

When hollows are so deep or intricate, that they cannot be cut out with small chisels struck by the hammer, drills of different kinds are used to produce the rough hollows, or by long tools fixed in wooden handles, used by the hand only, without the hammer.

A particular dexterity is requisite in producing the different characters of the hair with the chisel, to make it look light and soft, whether curled, crisp, or plain; and this may be done by the hand of the practised sculptor, with nearly the same effect as it can be by the painter, in laying on his colours with the pencil.

The finishing of flesh in imitation of the fulness of muscle; the apparent pliability of the fatter parts, the greater or leffer durabiliy of tendon and bone, may also be represented on marble nearly to deception; but then the sculptor must be well acquainted with the structure and appearance of the parts he represents, and accurate in copying the object of his imitation. To inform the mafs with life and sentiment, whether it be of marble, bronze, wood, ivory, clay, or wax, is the very end and purpoze of imitative art.

The last finish of marble, in the modern practice of sculpture, is performed by the use of raps, and afterwards of files. The belt raps for sculpture are those made in Italy; the teeth of these raps being cut more sharply than those made in England, at the same time that the ends of these raps and files are capable of being bent in any form, according to the use for which they are to be employed.

When a piece of sculpture is required to have an exceeding smooth surface, the punice-flone is used after the file; and sometimes the whole surface is rubbed or ground carefully over with small pieces of grit-flone, accommodated to the various forms of the surface, as to flat spaces, rounds, and hollows of different depths. But the hair, in all cases, must be finished with the tool; and for this purpose, the edge of the tool must be sharpened with great accuracy and acuteness; and if it is required that the work should be very highly finished, the last edge of the tool must be given by an oiled Turkey-flone.

Chisels may be sharpened, for the different kinds of work, either on one side, or on both sides, horizontally, diagonally, circular, or pointed.

The sculptor uses large square four-footed strong tools, with tops which turn round upon little balls of brass or iron, on which he places the marble statue he works on. His tools are steel chisels of different sizes and lengths; their ends being from an inch broad, and diminishing in succession, till they become perfectly pointed. These are worked with an iron-headed hammer, weighing from two to four pounds, according to the heaviness of the work. The first tools used in working away his marble are strong steel tools, sharpened nearly to a point; which, being struck with a heavy hammer obliquely, knock off the waffe marble in much larger pieces than a broader pointed tool would do.

The practice of the sculptor also requires the frequent use of the square and compasses, as his own ingenuity may direct.

There are some few fragments of marble statues, which have been found in different parts of Greece, especially where the works of sculpture have chiefly flourished, as Athens, Egin, and Corinth, which appear to be the remains of very early attempts in this art; perhaps in an age when making the proper tools was either not known, or during the infancy of their invention. From these specimens, the edges of the tools, and the manner of using them, appear to have been equally imperfect; the course of the tool is imperfect, indirect, and ragged; the surface it passed over, irregular. In the naked figure, the muscles are little determined, and the forms confused by the unpractised manner of working. In the draperies, the edges are undermined, and the hollows are few and shallow; a natural conformation of the workman’s want of power over his material; and therefore, of his desire to produce his idea in the groves, because he knew his incapacity to render a distinct and perfect detail.

High finishing in marble seems to have been a consequence of working in bronze, for two reasons: first, the working of metals requires a considerable knowledge in the tempering
tempering of tools; and, secondly, the first high finished specimens of remaining sculpture seem to be imitations of bronze statuettes, from the hardnecteds of execution resembling that of metal, and the rectilinear wavy forms of hair and drapery. Whether this manner of finishing marbles was first introduced by Diphæus and Scyllis, according to our former supposition, or whether it was practiced nearer the most diluting epoch of art, it is certain that the working of marble with the greatest possible dexterity, such as diluting small folds from one another, by cutting the marble to a great depth between them, was practiced considerably before the time of Phidias.

In the time of Phidias, it is certain the sculptor used chisels of all the different forms described above, of the most convenient forms possible for their works, and most perfectly tempered; of which we are assured, by tracing the forms of the several instruments in their execution, which is as free and characteristic of the parts imitated as could have been produced by the pencil of the painter.

The Laocoon, the Apollo Belvidere, and the Venus de M è d i c i s, appear to have been executed by the chiselled only, without the assistance of the rasps or file, though there is, in the body and limbs of the Apollo, some appearance of a smoother surface being obtained by rubbing with pumice-stone or wet grit-stone. Many others of the finest works of antiquity, statues, groups, and busts, appear to have been finished with the chiselled only, and the use of rasps and files does not seem to have been very common in the practice of sculpture, till after the time of the twelve Caesars.

The execution of sculpture seems to have depended from perfection in the same steps by which it rose to it. In the age of Adrian and the Antones, extreme high finishing was again in fashion; the surfaces were finished with a delicacy of smoothness which almost became a polish; the sculptor tried to make the extremities of his hair fly before the wind, and, for this purpose laboured his marble with a delicacy of tooling, and a complication of drilling, that is almost miraculous; and there are examples of hair, so laboriously executed in that age, that the spectator is left in doubt concerning the possibility of paying the sculptor for his work, the time necessary to accomplish the undertaking, and for the instruments requisite to produce his effect.

There are many examples of this kind in the portraits of M. Aurelius and Lucius Verus; particularly two colossal busts of these emperors lately existing in the Villa Borghèse.

But the extreme attention to a polished surface, and extreme perfection of inferior pursuits, having withdrawn the artist's mind from noble conceptions and sublime sentiment, he soon deserted from the sculptor to the stone-cutter, and left his distillation even as a mechanic, by adopting such a poverty of workmanship as was suited to his debased pursuits; and the age of Constanține exhibits the sculptor as incapable of following the noble conceptions of earlier times, as ofewing any skill in the mechanism of his art superior to the unmeaning and unsuccessful attempts of a barbarous age.

During the ages of the Roman emperors, when beautiful and expensive marbles were used to adorn their palaces and public structures, when the magnificence of effect was considered without relation to expense, porphyry all was manufactured for columns, pannels, and other architectural purposes: it was also occasionally employed in sculpture, in defiance of the extreme difficulty and expense of the labour, of which we shall be enabled to judge from an instance mentioned in Winckelman's History of Art: he says that a mason was employed to hollow out a vase in the Villa Albanè, the inside of which could not be above thirteen or fourteen inches deep, and eight or nine inches in diameter; he was ten months at work upon this, attending his labour regularly nine hours every day. Such a work in England, as masons are paid at this time, would cost sixty-five pounds; the payment of the journeyman sculptor should be reckoned at twice that sum.

There are fragments of drapery-figures executed in this material of fine talke and beautiful sculpture, the labour of which must be excessive; but the two greatest works remaining of this marble are in the pope's museum; one is the sarcophagus of Constanține, daughter of Constanține; the other of Helena, his mother; which last is of enormous dimensions, and covered with alto relievo of soldiers on horseback, and the heads of the emperor and his mother, angels fitting, with festoons on the top, &c. Many parts of the alto relievo on this sarcophagus were broken when it was removed into the pope's museum, which were repaired by the following procefs. The pieces of porphyry intended for the relievation were first rudely shaped with a picking hammer, that is, one end of the hammer being pointed, the workman knocked the stone with repeated blows of this hammer, until it broke off little pieces, when it was reduced to the general form required: in this manner another instrument was used, called a matting hammer, one end of the hammer being divided into four points, and being worked over with this instrument, the whole of the former very rough surface was made somewhat more regular; after this, pointed tools were used, file twice by a hammer, to take off as much as possible the still remaining roughness of the surface, and to make particular hollows more exactly, the workman wearing spectacles all the while to prevent the splinters of the stone from flying in his eyes, which otherwise would blind him in the course of a few minutes labour. The tools for this work are tempered to the hardnests of a razor, and seldom bear more than four or five blows with the hammer before the points are broken. The last process is to grind the surface down with grit-stone and emery, till a smooth face is obtained; the whole being a process of immense labour and expense. The Egyptian obelisks, which are of red granite, with the hieroglyphics upon them, must have been wrought by a procefs somewhat similar to the manner of working porphyry.

Of Wæx-Modelling. — Wæx-modelling is properly a branch of sculpture, inasmuch as it affords patterns and examples for very numerous articles of fine art in metals: although, from the nature of the material, no wax model of the Greek or Roman times has come down to us, they must have been almost innumerable during the hell ages of Greece and Rome, judging only from their small figures of divinities in bronze, of which, perhaps, upon an average, every perfon, rich and poor, might have half a dozen, so that the amount of these small images, from patterns of wax, would be nearly fixed times in number of the population of the civilized world at any one period. Wæx-modelling besides is required for the patterns of all goldsmiths' and chafers' ornamental work upon a small scale. All the fine medals of the popes were copied from small models in wax of the most distinguished sculptors.

To make the bell modelling wax, take two cakes of Virgin's wax, break them in pieces, put them into a clean pipkin, and add the quantity of the smallest hazel-nut of Venice turpentine, and about double the quantity of flake white reduced to the finest powder; place the pipkin over a low fire till the wax is melted, stir the composition together, and it is the bell wax which can be used for modelling.

Models of different coloured wax may be made by putting pounded red, blue, yellow, &c. instead of flake white, according to the colour required.
Wax-modelling is performed, like the same art in clay, by pointed instruments of wood and ivory.

Sculpture in bronze and silver is practised in the same manner by the model as Pliny describes it to have been done by the ancients, and is of three kinds. The subject is either cast from a model, or carved from the solid metal, or chased from a model upon a flat piece of metal, which is beat hollow on the one side, to produce the relief, out of which the chaser works the intended figure or figures on the other side. The instruments used in chasing are, for small works, a small hammer with a long elastic handle, which gives the blow a quick and artificial force; also chisels and points, somewhat like those used in the marble of a smaller scale.

The tools for carving in wood are so universally known to carpenters, upholsterers, and the different orders of wood carvers, that the description of them would be useless.

For further illustration of this article, the reader is referred to the engravings which are distinguished by the word Sculpture. These consist of select specimens of the sculpture of different ages and nations; particularly the finest examples of Greek and Roman sculpture.

SCULTENA, or Scultena, the Panaro, in Ancient Geography, a river which commenced on the south of the Apennine, and purifying a northerly course, discharged itself into the Padus or Po.

SCULTETUS, or Schultz, John, in Biography, a distinguished surgeon, was born in the year 1595 at Ulm, where his father was a water-man. The latter was enabled to afford his son a good education, and sent him to Padua, where he studied medicine under Spigelius, and took the degree of doctor in philosophy, surgery, and physic, in the year 1621. On his return to his native city, he was admitted into the college of physicians in March 1625; and for twenty years he practiced his profession with great reputation. Being sent for to Stuttgard, to administer professionally to a sick gentleman of that city, Scultetus was there attacked with a fit of apoplexy, which terminated his life on the first of December 1645. He appears to have practiced surgery extensively, and to have been very bold in his operations, especially in those of bronchotomy, of the trephine, and for empysema. His principal work is entitled "Armamentarium Chirurgicum, 43 Tabulis auncis Ornatum;" and was published after his death, at Ulm, in 1653. It subsequently passed through many editions, and was translated into most of the European languages. Eloy Dié. Hilt. de la Médecine.

SCUM, or Scupa, Scuma, a light excrement arising from liquors, when briskly stirred; called also foam or froth.

Scum is also used for the impurities which a liquor, by boiling, casts up to the surface; and also for those taken from off metals, when in fusion; these are also called scoria.

Scum of Lead, is a kind of recrement, of various colors, procured from melted lead.

Scum of Nitre. See Nitre.

Scum of Salt. See Salt.

Scum of Silver, is what we commonly call litarge of silver.

Scum of Sugar, in Agriculture, a substance sometimes used as a manure. See Sugar Scum.

Scum, Sugar of the. See Sugar.

SCUMA, a word used by some of the chemists for squama, the scales of any metal, and particularly applied to the flakes flying off from hot iron under the hammer. SCUOE, Skoë, or Skoe, in Geography, one of the Faroe or Feroe islands; 5 miles S. of Sandoe. See Feroe.

SCUPI, in Ancient Geography, a town of Upper Maffa, in Dardania, according to Ptolemy.

SCUPPERS, in a Ship, are certain channels cut through the water-ways and sides of a ship, at proper distances, and lined with plated lead, in order to carry the water off from the deck into the sea. The scuppers of the lower deck of a ship of war are usually furnished with a leathern pipe, called the scupper-hose, which hangs downward from the mouth or opening of the feeper. The intent of this is to prevent the water from entering, when the ship inclines under a weight of sail. Falconer.

Scupper Nails. See Nails.

SCUR, in Agriculture, a precipice faced with rock.

SCURCOLLA, in Geography, a town of Naples, in Abruzzo Ultra, 16 miles S. of Aquila.

SCURRELLUR, in Ancient Geography, a town of India, on this side of the Ganges, between the Pseudolitome and the river Baris. Ptolemy.

SCURF, in Medicine, Furfur, small branny or powdery exfoliations of the cuticle, which occur after slow inflammations of the skin, a new cuticle being formed underneath during the exfoliation.

Scurf may be formed upon any part of the surface of the body; for wherever the skin is inflamed, the cuticle never fails to be separated and fall off. This exfoliation, when the inflammation is considerable, as in scurblamina, takes place in the form of large flakes, or of smaller scales; but in the minor degrees of inflammation, such as of the formation of pimples, or in flinch erythematics affections, a mere fleckings ensues. In some cases of scurf, indeed, as in the sandriffle of infants, and in other forms of pityriasid, little or no inflammation is perceptible; but in other cases, as in the scurfy porrigo, affecting the heads of adults, the inflammation is often considerable, and accompanied by frequent itching. The scurf itself, indeed, if it be permitted to accumulate, becomes the source of excitement to the inflammation, as well as to the itching sensations.

The first step in the treatment of scurfy affections is, therefore, the careful removal of the scurf, as it is formed: but this must be effected by gentle means, and by washes which do not augment the inflammatory action, where that is considerable. Hence ablation with simple water, or some slight farinaceous decoction, as of bran, is to be preferred to soaps and other irritants. This clearance of the surface having been effected, some gently refringent lotion, such as lime-water, with or without a little of the liquor ammonize acetate, or a weak solution of the salts of zinc, may be employed with advantage; or if the irritability of the parts be considerable, the scurfine substances may be preferable. See PITYRIASIS.

SCURFF, in Ichthyology, an English name for a species of salmon, called also in some places the bull-troach. It never grows to any great size, and differs plainly from the salmon of the common kind in this, that its tail is even, and not forked; its head is short and thick, and its flesh is less red than that of most of the salmon kind. See TRUTTA under the article SALMO.

SCURGULO, in Geography, a town of Naples, in Capitanata; 7 miles S.S.W. of Dragonera.

SCURGUM, in Ancient Geography, a town situated in the most northerly climate of Germany. Ptolemy.

SCURRA, in Ornithology, a name by which the ancients have called the melanotus, or common jackdaw. See Corvus.

SCURRIZANO, in Geography, a town of Naples, in Capitanata; 5 miles N.E. of Arechi.

SCURVOGEL, in Ornithology, the name of an American bird, called by some the nnder-apoa, and by the Brasilians jabiruzuaca. See MYSTERIA.

SCURVY,
SCURVY.

SCURVY, in Medicine, Scorbuta, a formidable and often fatal disease, arising from imperfect nutrition, and other causes, and characterized principally by extreme desolation of the vital powers, together with spongy rents of the gums, ecchymoses, or purple bleats, on the skin, and spontaneous hemorrhages. From its frequent occurrence in long voyages, it is sometimes called emphatically the febrif; but it is by no means peculiar to seamen, and was described as an endemic of the land by the earliest writers.

After having stated this brief character of the disease, it can scarcely be necessary to remark, that the term febrif is most erroneously and absurdly used in popular language; being applied, in fact, to all ulcers of the skin, of a flow and chronic nature, however various in their essential character, and polliching nothing in common with the true febrif. The skin, in febrif, indeed, is not the seat of the disease, but is only changed, like other organs of the body, in the progress of the malady; and that derangement is totally different from the inflammatory, pimply, cutaneous, or febrif conditions of the skin, which occur in leprous, tertiers, and other cutaneous disorders, usually miscalled febrif.

This niflake requires correction, not merely as a matter of nomenclature, but because a great practical error results from it; namely, the administration of antifebrif remedies in these cutaneous disorders, which cannot be cured, and are often aggravated, by them. The late Dr. Willan conferred a benefit on the profession, by his definite discrimination of these last-mentioned disorders. See Cutaneous Ulcerations.

The febrif, properly so called, was first accurately described, and received its name, in modern times; and it is the subject of dispute, as in the case of some other diseases, whether it was known to the ancient physicians, or is a malady of more recent origin. The irj specific accounts of the disease appeared in the early part of the sixteenth century, when the name of the malady seems to have been familiar among the vulgar: but the symptoms were noticed by the early voyagers in the preceding century; for considerably more than half the crew, who accompanied Velco de Gama, in his voyage round the Cape of Good Hope, in the year 1497, were destroyed by this disease. Olaus Magnus, in his history of the northern nations, published in 1555, has described the disease at considerable length, and states that it was known to the inhabitants of Saxony by the name of fæbrus, or febrif; whence the Latin term febrifus, and our appellation febrif. The term signified foremouth, and was probably applied to the disease in consequence of the puffy ulcerations of the gums, with hemorrhages, and looseness of the teeth, which are among the more severe symptoms of the complaint. Dr. Lind, however, fugghets, with still more probability, that the name was derived from a Scavonian word, febrif, signifying disease; the febrif being endemic in the northern countries of Europe, from whence we borrowed the appellation.

Most of the continental writers have maintained that, although the ancients have not described the symptoms of febrif, as a single distinct disease, there have, however, mentioned several concurring symptoms, which can scarcely be supposed to belong to any other malady: while Drs. Freind, Lind, Trotter, and some other authors of this country, contend, that the Greeks, Romans, and Arabians, residing in southern climates, and unpracticed in long voyages, probably never witnessed the febrif, and thence have no where accurately described it. The rarity of the disease, under such circumstances, will probably account for the imperfect descriptions which they have left: but sieges and feasons of great dearth were not uncommon in those times, and gave rise at least to the ignis facer, which appears to have been nearly allied to febrif; and the following observations relate to no other known disease.

Hippocrates, when describing the ulcers of the spleen, mentions some symptoms which accompany the enlargement of that organ. "The colour of the body," he says, "is changed, and becomes black and pallid, like the rod of a pomegranate; the breath is fetid, and the gums also emit a fetid smell, and fall away from the teeth; ulcerations break out in the legs, resembling cutaneous parts: the limbs are emaciated, and the bowels do not discharge their contents." (Lib. de internis Affeq.) And again, in his second book of prognostics, Hippocrates observes, "In those who have tender spleens, the gums are diseased, and the mouth emits a fetid odour; but those whose spleens are enlarged, without any concomitant hemorrhages, such persons are attacked with ill-conditioned ulcers in the legs, and black etcars." Here we have an additional symptom of febrif mentioned, viz. the hemorrhages, which were omitted in the former description. Thoie, however, who expect to find only the utmost accuracy in the works of Hippocrates, will perhaps be surprised to find that he has again described, still more distinctly, the symptoms of febrif, under another appellation. For in the same book (refpefting internal diseafes) in which he has noticed the enlarged spleens, he mentions the symptoms of the "lesus hematorum (-like objecit)," or bloody febrif. We have the same disease begins in the autumn, and exhibits the following symptoms. The mouth and teeth emit a fetid smell, and the gums separate from the latter, and blood flows from the nose; sometimes also ulcers break out in the legs, and while some of the head, others break out afire; and the skin about them is of a black colour, thin, and tender." This may be deemed a good brief description of febrif; and if the commentators are right in their correction, the concluding symptom is equally characteristic: "the patient is indisposed to walk, or to use any exertion." The suffage, as it flounds in Hippocrates, however, affists the affirmative, that the patient is disposed to exertion; a circumstance inconsistent with ulcerations of the legs, hemorrhages, and the other symptoms, that the commentators agree that the negative particle must have been omitted. Van Swieten remarks, that the epithet of thin or tender-skinned (scorbos), which Hippocrates applies to these patients, is particularly characteristic of the febriful state; since "we observe in the febrif, that the slightest injuries break into the skin, and leave rubbiul ulcerations in it; and this more remarkably happens in the legs, where only scratching them with the finger-nails will often raise an excoriation, that is followed by an ulcer of long continuance." (Comment. in Boerl. Aph. 1448.)

Cellus, when treating of the affections of the spleen, mentions this indisposition of ulcers to heal; "Ut hic in omnino non saneta, aut certe electricum virf receptum." And we may add, that the opinion of the commentators, respecting the sentence above mentioned, is confirmed by the statement of Cellus, who distinctly afferts, that exertion is painful and difficult. (De Medicinâ, lib. vi. cap. 9.) Paul of Jégina (lib. ii. cap. 99), and Avicenna (lib. iv. tom. 17, tract. 2), as well as other Greek and Arabian physicians, describe the same febriful symptoms as connected with tender spleen. Modern observation has occasionally detected enlargement of the spleen in febriful cases, as in an instance related by Dr. Mead (Manuscrit Precico. Med. 1. book 4). Such an enlargement is not always present, and it is probably that Hippocrates and the ancients, who saw the disease but seldom, had generalized too hastily from a
limited experience, when they pronounced these symptoms as exclusively connected with enlarged spleen.

A disease is also mentioned by Strabo and Pliny, as occurring in the Roman armies in particular situations, which can only be referred to scurvy. In this disease, which Pliny ascribed to drinking the water of a certain well, when it occurred in the army of Germanicus while encamped near the Rhine, an affection of the gums, with a falling out of the teeth, is said to have been combined with a loss of muscular power in the lower extremities; the former affection being called frowncaces, (quasi stomatik xanos, aris vitium) and the latter fcelerybe. (Phin. Nat. Hist. lib. xxv. cap. 3.) Similar affections, to which the same appellations are given by Strabo, are said to have prevailed in the army of Aælius Gallus, when in Arabia. (Geograph. lib. xvi.) Some authors, however, have denied that this fcelerybe could be a scurvy-like symptom; because Galen has stated fcelerybe to be a kind of paralysis, in which the patient is unable to walk straight: but such a term might be sufficiently appropriate to that rigidity of the joints, which often occurs in scurvy.

On the whole, therefore, we are disposed to believe, with the early writers upon this subject, that the scurvy was known to the Greek, Roman, and Arabian physicians; although, from its comparative rarity in southern climates, it did not occur so often, or so extensively, as to claim their attention very strongly. That it may occur in any climate where there is a dearth of fresh food, is very obvious; for it is found equally at sea and on the land, in Greenland or in the great South sea, in besieged towns, in frozen countries, and in ships, when fresh food is not to be obtained. Poupart has very correctly remarked, that the malignant scurvy of Paris bore a considerable resemblance to the pestilential ignis facer, described by Lucretius (lib. vi.); an opinion which Dr. Lind, confounding this ignis facer with the plague of Athens, described by Thucydides, considers as deserving no serious confusion. But the ignis facer was extremely different from the true plague, as well as from the pestilence described by Thucydides (see Plague); it seems to have been, like scurvy, the result of dearth, the καινομ μετο λιμον, of which we hear so much in ancient history; it had feverish symptoms in common with scurvy, but was a febrile disease; and has been ascribed in modern times to diseases of corn, instead of the scarcity and deficiency of that nutriment.

See Ergot; Ignis Sacer; Krisbel Krankheit; &c.

For the observations of Poupart, see Memoires de l'Acad. des Sciences, an. 1699.

Symptoms of Scurvy.—The first indication of the approach of scurvy is an aversion to any sort of muscular exertion; a lassiness, or strong inclination to lie still or to lie in bed; which is accompanied with a spontaneous latitude, or a fenfe of heaviness in every part of the body, and especially in the muscles of the limbs and loins, like that which arises from great fatigue, which soon becomes actual feebleness, so that the least exercise, especially in ascending or descending a declivity, induces fatigue and shortness of breath. With this aversion to motion and diminished power of exertion, there is also a very early a change of the complexion, which becomes pale and bloated, or fallow, especially about the lips and corners of the eyes, where there is a greenish tinge. These two symptoms, indeed, the disinclination to exertion, and the fallow countenance, often portend the approach of scurvy, while the patient eats and drinks heartily, and seems otherwise in good health; and the speedy latitude and difficulty of breathing upon motion, are among the most constant concomitants of the distemper throughout its course.

As the disease advances, other symptoms appear. Among these the flomaaces, or morbid condition of the mouth, is one of the first that presents itself. The gums become hot and painful, and soon swell, growing soft and spongy, and of a livid hue, and afterwards extremely putrid and fungous, constituting one of the most distinguishing features of the disease. This occasions great fever in the breast, and the looening of the teeth, which become moveable in their sockets, and may be taken out without force or pain, and even fall out spontaneously. Hemorrhages also take place from the slightest pressure on the gums, or even without any apparent cause, as well as from the nose; and ultimately from other parts of the body, where the cuticle is delicate, or the surface broken, in consequence of the apparent loss of cohesion in the solids, and especially in the vascular system.

From this cause the skin also exhibits some of the most striking characteristics of scurvy. It becomes dry, and spotted over with discoloursations of a red, blueish, purple, and black hue, of various sizes, from the petchie, or spots like flea-bites, to the most extensive ecchymoses, of the size of a hand-breadth, or larger, such as are produced by the seveelt bruises. These appear chiefly on the legs and thighs; but often also on the arms, breast, and trunk of the body; and sometimes, though more rarely, on the head and face. They consist, in fact, of effusions of blood under the cuticle, from the rupture of the small vessels. As the disease advances, this laxity and loss of cohesion in all the solids becomes still more manifest, by the frequent and profuse bleedings which are liable to occur from different parts of the body; especially from the nose, gums, mouth, bowels, lungs, kidneys, and bladder, and from the ulcers and fungous excrescences which arise on the surface. In some patients, the hemorrhages from the bowels are accompanied by severe pains and diarrhoea; while others, without either a purging or gripes, discharge great quantities of pure blood by the anus. Other marks of laxity appear in the edematous swelling which takes place in the legs, beginning first about the feet and ankles; which, however, is more painful than common anaemia, and retain longer the impression of the finger. They appear remarkably also, in the great facility with which the slightest bruises and wounds degenerate into foul fungous ulcers, as well as in the spontaneous appearance of such ulcers, and the breaking out of long-healed sores, and even the diffusion of old fractures in bones. "Whatever former complaints," Dr. Lind observes, "the patient has had, especially bruises, wounds, &c.; or whatever present disorders he labours under, upon being afflicted with the scurvy, his old complaints are renewed, and his present rendered worse." Indeed the scurvy often first shews itself by the changes in diseased parts. "Thus, when a person has had a preceding fever, or a tedious sickness, by which he has been much exhausted, the gums for the most part are first affected, and a latitude constantly attends; whereas, when one has been confined from exercise by having a fractured bone, or from a bruise or hurt, these weak and debilitated parts become almost always first scurvylike. As for example, if a patient labours under a strain of the ankle, the leg, by becoming swelled and painful, and soon after covered with livid spots, gives the first indication of the disease. And as old ulcers on the legs are very frequent among seamen, in this case likewise the legs are always first affected, and these ulcers put on a scurvy-like appearance, although the patient seems otherwise perfectly healthy, and preserves a frech good colour in his face." (Lind.) The effect of the disease upon former maladies is strongly depicted by the elegant writer of lord Anlon's voyage. "But a most extraordinary circumstance," says that gentleman, "and
**SCURVY.**

"... and what would be scarcely credible upon any single evidence, is, that the scars of wounds which had been for many years healed, were forced open again by this virulent diftempor. Of this there was a remarkable instance in one of the invalids on board the Centurion, who had been wounded above fifty years before at the battle of the Boyne; for though he was cured soon after, and had continued well for a great number of years past, yet on his being attacked by the scurvy, his wounds, in the progress of his disease, broke out afresh, and appeared as if they had never been healed. Nay, what is still more astonishing, the callus of a broken bone, which had been completely formed for a long time, was found to be thereby disjoined, and the fracture seemed as if it had never been consolidated." (A Voyage round the World in 1740-4, by Lord Anson, compiled by the Rev. R. Walter, chaplain to the Centurion, p. 101.) The ulcers, which occurred in the legs of the scurvy patients on this occasion, are said to have been "of the worst kind, attended with rotten bones, and such a luxuriance of fungous flesh, as yielded to no remedy." The edges of these scurvy ulcers are of a livid colour, and puffed up with the fungous excrescences, which are not inaptly called by the sailors, *bullock’s liver;* since to this substance, when boiled, Dr. Lind says, they bear a near resemblance, both in consistence and colour. They often arise in the course of a night to a monstrous size, and although destroyed by cauteries, or the knife, in which last case, a copious bleeding commonly ensues, are found at the next dressing as large as ever. Dr. Lind affirms, however, that "they continue in this condition a considerable time without tainting the bone." (Lind on Scurvy, pt. ii. ch. 2.) These scurvy ulcers, which are singular and uniform in their character, are distinguished from all others by being remarkably offensive, bloody, and fungous.

In addition to these affections of the lower extremities, (to which however they are not exclusively confined,) in the advanced stage of the scurvy, "the patients most commonly lose the use of their limbs, having a contraction of the tendons in the ham, with a swelling and pain in the joint of the knee. Indeed, a stiffness in these tendons, and a weakness of the knees, appear pretty early in this disease, generally terminating in a contracted and swelled joint." (Lind, loc. cit.) We have given this description in the words of Dr. Lind, in order to shew how distinctly it answers to the account of the *feolyerbe,* occurring in the Roman armies, in conjunction with the *flomacare.*

In the progress of the scurvy, the patients commonly complain of pains, which are often moving from part to part. Some complain of a general pain in their bones, which is most violent in the limbs and loins, and especially in their joints and legs; and a pain, with tightness and oppression in the breath, is very common. The head is fickle or never affected, unless the patient is feverish, which is uncommon; for, as Dr. Lind well observes, the disease is altogether of a chronic nature, and fever may be justly reckoned among its adventitious symptoms. It is remarkable, indeed, that in the worst stages of the scurvy, with all the fever symptoms above described, with painful spreading ulcer of the surface, with contracted limbs, hemorrhages, spogy, putrid, itching gums, over-run with sprouting flesh, and often deeply ulcerated, with inability to make the least muscular exertion, without fainting or perhaps dying; yet the patient, even in this stage, have a good appetite, with their lefves entire, and, though easily dejected and made low-spirited, yet, when in bed, they make no complaint of pain or sickness, and appear to be in tolerable health. This singular character of the disease is well depicted by the reverend author before quoted. "Indeed, the effects of this disease," he says, "were in almost every instance wonderful; for many of our people, though confined to their hammocks, appeared to have no inconsiderable share of health; for they eat and drank heartily, were cheerful, and talked with much firmness, and with a loud strong tone of voice; and yet on their being the least moved, though it was only from one part of the ship to the other, and that in their hammocks, they have immediately expired; and others, who have confided in their seeming strength, and have resolved to get out of their hammocks, have died before they could well reach the deck. And it was no uncommon thing for those who were able to walk the deck, and to do some kind of duty, to drop down dead in an instant, on any endeavours to act with their utmost vigour; many of our people having perished in this manner during the course of this voyage." Lord Anson's Voyage, loc. cit.

Few of the authors, who have described the disease, have been very industrious in the examination of the bodies of those who have died. The most ample account of the diffe-asions of scurvy patients has been given by M. Poupart, in his account of the disease, as observed at the hospital of St. Louis at Paris. The principal phenomena described by him were the results of the general extraction of blood, and of the dissolution and separation of parts naturally united. Thus the bodies of the muscles were often swelled and hard, from the blood fixed among their fibres, so that the limbs remained bent or contracted; and the epitypalsy of the bones were found separated, the cartilages of the ilium were loosen from their union with the bony part of the ribs, and the ligaments of the joints were corroded and loose. He adds, that the menseenteric glands were generally obliterated and enlarged, and the spleen three times bigger than natural, and fell to pieces as if it consisted of coagulated blood.

**Causes of Scurvy.**—The predisposing causes of scurvy, or those circumstances which produce a predisposition to the complaint, are various. Preceding diseases, whether of the acute or chronic kind, render persons more liable to the scurvy, where the existing causes exist: and inactivity and indolence greatly facilitate the attack of the malady. Those who are recovering from fevers, or who have been weakened by long attacks or relapses, most readily fall into scurvy; and the marines on ship-board, who have left work, commonly suffer in a much larger proportion than the sailors. On the other hand, however, excessive fatigue and over-exertion, which exhaust the strength, as well as want of sleep, contribute to accelerate the attack of scurvy. An attention to this point was one of the most effectual means employed by captain Cook for the prevention of scurvy among his crews, as well as the avoiding of cold and moisture, from which much predisposition to the disease arises. A state of defiency and gloominess of mind contributes also materially to invite and aggravate the scurvy; it attacks the discontented and repining, while persons of more cheerful dispositions escape. Hence perhaps newly-impressed seamen are found to be particularly liable to it; and the inhabitants of behiged towns are observed to be very susceptible of its impregnations.

The principal exciting cause of scurvy appears to be the use of a certain kind of diet; and it is probable that every species of diet, which, either from being difficult of digestion, or from containing but little nutriment, fails to nourish the body, is capable of producing the disease under certain circumstances: we say, it is probable; for we shall have occasion to shew hereafter, that this notion is not entirely consistent with all the facts, and is somewhat inconsistent especially
especially with the nature of the remedies. As the disease is most frequently occasioned in modern times by a fea diet, it has been ascribed to the use of falted meats; but this opinion is altogether erroneous, and has been amply refuted by Drs. Lind, Milman, and others. It has occurred, indeed, to a great extent, where falted meats were not used; but it has been equally prevalent where the diet consisted principally of farinaceous or other unfermented vegetable matters, such as hard biscuits, peas, and beans, or of smoke-dried fish or flesh, cheese, &c. In some experiments, made by Dr. Stark in his own person, relative to the effects of particular articles of diet, symptoms of scurvy were induced by living a short time exclusively upon sugar. (See Stark's whole works, 4to. Lond. 1788.) And in the Russian armies, at the siege of Athos, in 1736, and subsequently in their march to Oczakow, the scurvy prevailed to a great extent, although their diet did not consist of falt-provisions. They had little fuel to enable them to dress their victuals, and the fat indigestible fish of the river Don, being half-cooked, and their bread ill-baked, produced frequent sicknesses, and ultimately the scurvy. (See Dr. Nitzch's account of this disease in the Russian armies, quoted by Dr. Lind.) The famine calamity occurred in the imperial army in Hungary, about the same period, although the army had fresh beef in plenty; but their other food consisted of a groat and viefold bread, or other farinaceous matters, and especially of a sort of glutinous pudding, called rollatfchen, which was principally eaten by the Bohemians, who were indeed almost the only people, who suffered from the scurvy. (See Geo. Hen. Kramer. Diff. epistolaica de Scorbuto; which contains the case of the imperial troops, addressed to the college of physicians at Vienna.) There is no doubt, therefore, if we examine the history of the malady, that persons predisposed to it, if they live upon any species of indigestible food, whether it be of an animal or vegetable nature,—whether preferred with fat, or not at all impregnated with it,—will be equally attacked with scurvy; and those persons are observed to suffer the most, who make the freest use of these indigestible substances. In all these instances, however, fresh vegetable substances did not probably constitute any considerable portion of the diet.

Other exciting causes, however, must co-operate with this diet to produce the scurvy, especially in its severer degrees. And hence whatever contributes to impair the health, and depress the mind, during the use of such food, materially accelerates the occurrence of scurvy; and we have already stated the effects of indolence, over-fatigue, and the depressing passions, in predisposing the constitution to take on this disease. Indolence and inactivity conduces to excite the scurvy, because the hard and indigestible diet just alluded to requires a certain degree of exercise to subdue it in the stomach. The influence of exertion was curiously exemplified in the cases of those persons who have wintered in high northern latitudes. The scurvy was the source of fatality which they had to dread: and it is singular, that those who went prepared to spend the winter in these frozen climates, and supplied with provisions, clothing, fuel, &c. have uniformly died of the scurvy; while those who have been accidentally left, without any provision, have escaped that disease and enjoyed good health. In 1693 two trials were made by the Dutch of establishing wintering-places at Spitzbergen and on the coast of Greenland, in latitude about 77° or 78°. Seven sailors were left at each, amply furnished with every article of clothing, provision, and utensils, thought necessary or useful in such a situation. The journals of both companies are preferred. The men at Greenland began to make a constant fire to fit by in October, served out their allowance of brandy, and now and then killed a bear: but in March they were all very ill of the scurvy; and on April sixteenth the first man died, and all the rest were entirely disabled, except one person. This poor wretch continues the journal to the last day of April, when they were praying for a speedy release from their miseries. They were all found dead. The men left at Spitzbergen killed but one fox for the whole time. The scurvy appeared among them so early as November twenty-fourth, and the first man died January fourteenth: the journal ends February twenty-fifth; and these too were all found dead. Accident, however, soon afterwards gave rise to an experiment which had a very different result. For on the same side of Spitzbergen, and in nearly the same latitude, a boat's crew, consisting of eight Englishmen, who had been sent ashore to kill deer, were by some mistake left behind, and reduced to the deplorable necessity of wintering in that dreadful country, totally unprovided with any of the necessaries. Taking advantage of a large substantial wooden building, erected for the use of the cooperings belonging to the fisheries, they rendered it warm and comfortable by building a smaller one within it, and by deer-skin beds, &c. They were tolerably supplied with fuel from old caffes and boats, which they broke up, and, before the cold weather set in, they laid in a considerable stock of provision, having killed a good number of deer, the greater part of which they roasted, and flowed in barrels, reserving some raw, which became frozen. This provision, with a few beavers and bears which they killed from time to time, constituted their whole winter's provision, except a very unfavourable article, which they were obliged to make out with, at first two and afterwards four days in the week, which was whale's fritters, or the froggs of fat after the oil has been pressed out. Their only drink during the whole time was running water, procured from beneath the ice on the beach, till January; and afterwards snow-water melted by hot irons. The melancholy of their situation was aggravated by the absence of the sun from the horizon, from October fourteenth to February third, of which period twenty days were passed in total darkness. They contrived, however, to keep their fire and lamps continually burning during this period. At the approach of spring, they had the good fortune to kill several white bears which proved excellent food; and these, together with wild fowl and foxes which they caught, enabled them to dispense with their fasting days on the mouldy fritters, and soon improved their vigour. Upon this simple fare, without spirits or fermented liquors, they were able to pass this rigorous winter, unaffected by scurvy or any other disease: at the return of the hours on May twenty-fifth, they all appear to have been in health; and all returned in safety to their native country. (See Mem. of the Literary and Philos. Society of Manchester, vol. i. p. 80. et seq.) Another still more striking illustration is related by Dr. Aikin, in the paper just referred to, in the case of four Russians, who were left at Spitzbergen, and also found a hut in which they resided above six years, living on the bears, deer, and foxes, which they caught, and drinking the running water in summer, and melted ice in winter. "Three of them remained entirely free from the scurvy during the whole of their abode; but the fourth died of it, after lingering to the fifth year. This person, it is remarked, was of an indolent disposition, and could not conquer his aversion to drinking the rein-deer's blood. The continual exercise, required by the hunting of these animals, appears to have been the great source of health, and to have kept at a distance the scurvy, which is endemic in Lapland, Norway, Sweden, Russia, and in latitudes much less northerly than Greenland."
SCURVY.

Other circumstances, both on ship-board and on land, by impairing the general vigour of the constitution, conspire to produce the scurvy. Thus it was observed to be endemic at particular places in Holland, while others, where the same diet was used, remained entirely free from it. Bonnefous, a very able and accurate writer on the subject, remarks, that it was much more frequent in his time at Amsterdam and Alkmaar, than at Gouda and Rotterdam; and at Dort it was hardly ever to be seen. He observed, indeed, that universally in all parts of the country, where the soil was fertile and damp, it raged with the greatest violence; and that the weather had great influence upon it, southerly winds, if long continued, multiplying the disease, and rainy seasons rendering it quite epidemic and malignant. The changes that have taken place in the condition of the land, and in the mode of living, since the wealth of Holland has increased, have rendered the disease much less frequent, and have confined it almost exclusively to the poor, who inhabit the low damp parts of the provinces, and continue to live upon dried meat and coarse bread, and to drink unwholesome flagrant water.

The effect of certain depriving palliatives, not only in predisposing to the scurvy, but in exciting and aggravating it, has been strongly manifested. Vander Mye exhibits a curious and diversified picture of the operations of the pallsions of the mind during the famous siege of Breda, when the scurvy committed great havoc in that town. Upon the report of bad news, it always spread affrightingly: but it was in a manner altogether checked by the arrival of agreeable intelligence. And the writer of Lord Anson's voyage observes, "it was most remarkable in all our reiterated experience of this malady, that whatever discouraged our people, or at any time dampened their hopes, never failed to add new vigour to the dilimeter; for it usuallly killed those who were in the last stages of it, and confined those to their hammocks, who were before capable of some kind of duty; so that it seemed as if the acuteness of mind and fanguine thoughts were no contemptible preservatives from its fatal malignity."

On the Prevention and Cure of Scurvy.—It is customary in medical discussions, after stating the symptoms and causes of any disease, to proceed to point out the essential nature, or proximate cause, as it is technically termed, of the malady, before treating of the method of cure, which should generally be deduced from the consideration of the whole of those circumstances taken together. In this case, however, we can scarcely difcuss the nature of the proximate cause, without a previous knowledge of the means by which the malady is prevented or removed; since these means tend to elucidate the nature of the symptoms which they remedy. We shall, therefore, first detail the means of prevention and cure.

The prevention of scurvy will consist chiefly in removing or counteracting the predisposing and exciting causes, which have already been enumerated. Much is done, therefore, by preserving a due degree of general health in the individuals exposed to the exciting causes; especially by avoiding cold and moisture, by means of proper clothing, warm cabins, &c.; and by avoiding indolence and inactivity on the one hand, and over-fatigue, watching, &c. on the other. The effects of the former are exemplified in the comparative exemption of even the petty officers in a ship of war, while the crew suffer severely. "The Channel fleet," says Dr. Milman, "has often buried a hundred men in a cruise, and landed a thousand more afflicted with scurvy, and yet among these there has not been a petty officer. How does the condition of the petty officer differ from that of the common sailor? The one as well as the other is obliged to live on the ship's provisions. The only difference is, that the petty officers sleep in close births, as they are called, with canvas hing round, by which they are sheltered from the inclemencies of the weather. Besides the advantage of warm cabins, they are more warmly clad, and having a greater plenty of clothes to shift, they are less liable to continue wet, or to be too unclean as the common men." (Milman on Scurvy, p. 31.) But the security from scurvy, obtained by attention to these points of general health, was most strikingly manifested in the judicious management of Captain Cook, by which he was enabled to repeat the voyage, in which the scurvy had proved so fatal to lord Anson's crew, without losing any man by that disease. The great navigator studied and enforced the rules of general health with great affability, and his success was complete. He was especially careful to guard against the too great fatigue of his men, and to secure them as much as possible from the effects of cold and moisture. In the first place, he divided them into three watches instead of two, (except upon some extraordinary occasions,) by which means they had eight hours rest for four of duty, and did not get the broken sleep, which men in their situations have generally obtained. They had thus time to re-ecruit their strength before they were summoned to return to their labour, and they were likewise less exposed to the weather, than if they had been at watch and watch. If the men get wet, they had generally dry clothes provided to shift themselves. Proper methods were taken to keep the ships clean, and dry between decks. The hammocks and bedding, every day that was fair, were not only ordered upon deck, but each bundle was unlathed, and fo spread out, that every part might be exposed to the air. Besides the ordinary methods of washing and scraping the decks, captain Cook had some wood put into a proper floe, kindled, and carried successively to every part below deck; which not only contributed to dry the ship, but by heating the impure air below, and rendering it specifically lighter than the common air, to make it rife and pass through the hatchways into the atmosphere. In the torrid zone, he shaded his people from the scorching sun, by an awning over his deck; while in his course under the antarctic circle, he had a coat provided of a substantial woollen stuff, with the addition of a hood to cover their heads. The Ruffian bour, Dr. Milman remarks, seems to be greatly indebted to similar means for his preservation from the scurvy: for, though he lives in an extremely cold climate, eats a good deal of salted meats, has no fresh vegetables for six months of the year, and breathes during that time the foul air of an unventilated apartment; yet, clothing himself in warm flannels, covering himself at night with warm sheep-skins, providing for his cleanliness with the regular use of the warm bath, he is seldom afflicted with this calamity.

Captain Cook also attended to the nutriment of his men. Hard and salted meats require afflachment in their solution and digestion in the stomach, and a plentiful supply of water was always carefully provided by him. Salt-water, indeed, may be rendered sweet by distillation, which deprives it of its saline parts, and may be made more palatable by impregnation with carbonic acid gas, or with robs and acid juices. This method, however, was not known to captain Cook. In attending to the diet of his men, he would not suffer the fat, which is boiled out of salt beef and pork, to be given to his men, as is customary. It did not escape that sagacious officer's notice, that such gross indigible matters had a great tendency to excite scurvy. Thus,
Thus, then, by an attention to cleanliness and ventilation, by guarding against fatigue, cold, heat, wet, &c. and by providing at all times plenty of fresh water, captain Cook's feamen lived with impunity on their fat provisions. And a familiar instance is mentioned by Dr. Trotter, in the case of the Intrepid, a ship of sixty-four guns, with a complement of five hundred men, in lord Rodney's fleet, which did not lose a man, except from wounds, for the space of two years and a half. "This ship was in a very sickly state when captain Molloy took the command of her; but by the complete mode of discipline, and attention to the cleanliness of the crew and ship, which he established, health was preserved in a climate reputed to be unwholesome; and that too, when exposed to the hardships which follow a flate of frequent or constant preparation for action." (Trotter on the Scurvy.) Even where the exciting causes exist, therefore, the scurvy may be prevented by extraordinary and continued discipline in the care of the general health.

Something still further, however, has been attempted, in the way of prevention, by diminishing the extent of the chief exciting cause; although it may be questioned, whether much has been effected in this way. The Dutch were supposed to have preferred their feamen from scurvy by the use of four krount with their salt provisions, and this article was recommended to the British navy by Dr. Lind: but it is prepared by a fort of fermentation, which produces the acidity; and this fort of acetic acid, the product of fermentation, does not appear to be a substitute for the acid of fresh vegetables. Dr. Trotter, however, is of opinion, that the virtues of this substance as an antiscorbutic are very trifling, and that it has cost the government in its preparation more than it is worth. Another substance has also been employed in the British fleet, as a substitute for fresh vegetables in preventing scurvy, on the recommendation of Dr. McBride, viz. the essence or extract of mait. It was recommended upon the hypothetical notion, that it contained much of the cementing principle, as he called it, or that principle which, when present in animal and vegetable substances, prevents the process of putrefaction; and that by retorting this principle to the blood, the disaease, which arises, like scurvy, from a putrid diathesis, (thus heaping hypothesis upon hypothesis,) would be prevented and cured. The truth, however, is, that there is, little or no carbonic acid in this substance; and the favourable accounts received at the admiralty of its beneficial effects, which induced them to establish the use of essence of mait as a part of naval victualing, are to be ascribed rather to its being a wholesome, nutritious, and digestible substance, consisting principally of vegetable mucilage with some sugar, than to the specific antiscorbutic properties. This appears to be the opinion of Dr. Trotter, and Dr. Lind speaks of it only as "a very nourishing liquor, well adapted for scorbutic patients." It does not appear, however, that these articles are sufficient substitutes for fresh vegetable productions; and they certainly do not possefs the same powers, with the latter, of curing the scurvy, when it already exists. With the proper acids, which have been generally adopted since the time of captain Cook, they contribute to the support of the general health, and therefore to the prevention of scurvy.

There is another species of vegetable matter, however, which appears in some measure to supply the particular substance, which fresh vegetables afford, and which is used both as a preventive and a cure for the scurvy, namely, the acid of limes, lemons, and other similar fruits, which the art of chemistry has for some time supplied in a concrete flate. These substances, we believe, are now considered as among the necessaries for a long voyage, and are probably much more efficient than the four krount, essence of mait, &c.

Cure of Scurvy.—When the preventive measures have been neglected, or ineffectually employed, and the disease has already appeared, it is very difficult to remove it, while the circumstances of diet, &c. remain unchangeable. Where these circumstances, however, admit of a change, experience has shown that the cure is very simple, and often very expeditious. A pure, dry, warm air, with the use of fresh vegetables, almost of any sort, commonly proves effectual. The instinctive feelings of the sick, indeed, direct them strongly to the use of the chief remedy; for there is perhaps no desire so intense, as that which the scorbutic patient feels for the use of green vegetables, fruits, and acids; infomuch that the sailors of lord Anton's ships greedily devoured the grafs, which was the first vegetable matter obtained. The vegetables and fruits which contain the greatest proportion of acid, are the most effectual remedies for the symptoms of sea-scurvy; whence forrel and such like plants, but above all limbs, lemons, oranges, apples, currants, &c. act in a manner as specific in relieving the disease. All succulent vegetables, and thse especially, which are of an aromatic nature, are useful, particularly when combined with the acid ones; whence scorury-grafs, horbe-radifh, cawees, purflam, and the tetradynamic, are ranked among the antiscorbutics, and numerous plants have been specified by different writers as polesfied of special virtues. On the whole, however, the acid juices appear to be most speedy and effectual remedies for scurvy, especially thse which approach to the nature of the citric acid.

The testimonies in favour of the specific curative powers of these acids in scurvy are so numerous as to leave no doubt of the fact. Even Dr. Lind, with whose hypothesis respecting the nature of the disease the fact was not quite compatible, admits, in his postscript, their striking efficacy. "To what has been already said," he observes, "of the virtues of oranges and lemons in this disease, I have now to add, that in feemingly the most desperate cases, the most quick and feeible relief was obtained from lemon-juice; by which I have relieved many hundred patients, labouring under almost intolerable pain and afflication from this disease, when no other remedy seemed to avail." As the acid is apt to operate violently upon the stomuch and bowels of thse who are much weakened, Dr. Lind recommends the addition of wine and fugar, as confounding the belt antiscorbutic, and was in the practice of ordering about four ounces and a half of lime or lemon-juice, and two ounces of fugar, to be put into a pint of Malaga wine, which was sufficient for any weak patient to take in twenty-four hours.

Dr. Trotter testifies the extraordinary cure of these scorbutic symptoms by the use of these acids, even though at the same time they produce a very lax or purging flate of the bowels, and a some degree of emaciation; while, on the other hand, the use of fresh animal food, strong broths, and wine, produces comparatively very little benefit upon scorbutic persons, although debility is the most marked symptom of the disease. This diet and the Peruvian bark will often produce no favourable change upon scorbutic ulcers, and the most powerful stimulent applications will not alter the condition of these fores: yet in less than twenty-four hours after the use of lemon-juice, the livid complexion of the fores, with the black clot of blood on their surface, will often disappear, and they will put on a florid and healthy character. The farther effects of the lemon acid are thus described by Dr. Trotter. "The patient in the inverterate stage of the disease seems to gather strength even from the
fight of the fruit; the spirits are exhilarated by the taille itself; and the juice is swallowed with emotions of the most voluptuous luxury. The gums are gradually hardened, and the teeth fixed in their sockets. The dull eye and bloated looks in a few days put on the clear healthy complexion, which also extends to the whole surface of the body. The absorption of the effused blood in different parts goes on rapidly, and by marking the spots, you may calculate the progress of the absorption, and the cure of the disease. This absorption bespeaks a degree of irritation communicated to the lymphatic system as well as the sanguineous, as soon as the blood has received a sufficient quantity of the vivifying principle. From the effects of the juice upon the bile, the colour of the fluids is changed, and a lax state of the bowels is the consequence. But it is to be observed, that this laxity of the intestines may be moderated by giving the fruit in smaller quantities: a speedy cure, however, demands that they should be given ad libitum, and the greater the number of lemons taken in a day, the recovery will be more rapid in proportion. Loc. cit. p. 142.

While, on the one hand, these fresh vegetables and vegetable acids speedily remove the symptoms of scurvy, experience has fully ascertained, on the other, that the medicines called tonics, such as the mineral acids, steel, Peruvian bark, and the various vegetable bitters, which have also been considered as antifeptics, or antidotes of pinterfaétion, are incapable of affording any effectual relief. And wine, which has been found a valuable remedy in some low fevers, gives but a momentary lassitude; but it does not retard the disease, nor afford any permanent relief alone. It was clearly proved, too, in lord Anson's fleet and elsewhere, that abundance of fresh provisions of animal substances and fish, even with plenty of fresh water, did not tend to arrest the progress of the disease. The use of mercury appears to be injurious under every stage of the scurvy.

In speaking of the predisposing causes of scurvy, we have mentioned the effect of the deprevying pains in inducing and aggravating the disease, and we have now to mention, on the other hand, the remarkable effects of hope, and the exciting pains, in aiding the cure of the disease. The following striking example of this medicine of the mind is related by Vander Mye, in his account of the disease, when it occurred during the siege of Breda, spreading dearth and death around. "On the 2d of May, 1625, when the prince of Orange heard of their distress, and understood that the city was in danger of being delivered up to the enemy by the soldiers, he wrote letters addressed to the men, promising them the most speedy relief. These were accompanied with medicines against the scurvy, fail'd to he of great price, but of still greater efficacy: many more were yet to be lent. The effects of this deceit were truly astonishing! Three small phials of medicine were given to each physician, not enough for the recovery of two patients. It was publicly given, that three or four drops were sufficient to impart a healing virtue to a gallon of liquor. We now displayed our wonder-working balms. Nor were even the commanders let into the secret of the chest put upon the soldiers. They flocked in crowds about us, every one soliciting that part might be referred for their use. Cheerfulness again appears on every countenance; and an universal change proceeds in the foreign virtues of the remedy. The herbs now began to spring up above the ground, we of th'se made decoctions, to which wormwood and camphor were added, that by their prevalent flavor the medicines might appear of no mean efficacy. The flint contrasted limbs were anointed with wax melted in rape-seed or linseed oil. The invention of new and untried phyllic is boasted; and amidst a defect of every necessary and useful medicine, a strange medley of drugs was compounded. The effect, however, of the delusion was really astonishing: for many were quickly and perfectly recovered. Such as had not moved their limbs for a month before, were seen walking the streets found, upright, and in perfect health. They boasted of their cure by the prince's remedy: the motion of their joints being restored by a simple friction with oil, nature now of itself well performing its office, or at least with a small assistance from medicine. Many who declared that they had been rendered worse by all former remedies which had been administered, recovered in a few days, to their inexpressible joy, and the no less general surprise, by the taking (almost by their having brought to them) what we affirmed to be their gracious prince's cure." This account of the curative influence of the phials is fully sanctioned by the statement in lord Anson's voyage, already quoted, and by a fact mentioned by Mr. Ives, in his journal. On the 30th of January, 1744, there were nearly seventy persons ill of scurvy in the Mediterranean fleet; yet the joy of approaching the enemy's fleet, and the hope of beating them, had such an effect, that on the 11th of February following, when the engagement happened, there were not above five men not at their fighting quarters. Many remedies have been mentioned by different writers, who have treated of scurvy, and many local applications and methods of curing particular urgent symptoms, such as haemorrhages, pensive gums, ulcerations, diarrhea, swellings of the tendons, &c. have been detailed; but it is unnecessary to repeat them; since the only effectual mode of alleviating particular symptoms is the radical cure of the constitutional disease. "Fomentations, the warm-baths, &c." Dr. Trotter observes, 'have been often tried for the rigid tendons, and hardness of the muscles, but without effect; stimulant applications have been equally unsuccessful. For the difficult breathing and tightness of the breast, blisters and the whole train of expectorants are insufficient to relieve them. Opium itself, our last and only refuge in other cases of acute pain, affords no refreshing sleep or ease to the febrile sufferer. We have heard much of feverishness and opening the pores of the skin and softening the surface; but this is trifling with the complaint. It is only the produce of fresh vegetation, that can administer to him the reviving cordial; and a few lemons will do more to allay his anguish than the whole art of pharmacy.' P. 251.

On the Nature of Scurvy.—Various hypotheses have been framed at different times, according to the prevalent pathological doctrines, to account for the phenomena of this singular and formidable disease; and like most other medical hypotheses, they have hinged chiefly upon two principles, by one of which they are referred to certain morbid conditions of the blood or circulating fluids, and by the other to morbid changes in the properties of the living solids. If we take into consideration, however, the whole phenomena of the disease, its causes, and remedies, we shall find considerable difficulty in admitting either of these hypotheses exclusively, and not a little in giving any satisfactory view of the subject, even by allowing the partial truth of both.

All the older writers, being of the humoral school, maintained the doctrine of a morbid state of the fluids, as the proximate cause of scurvy. Boerhaave and his adherents referred the disease to an astringency of the fluids, which they supposed would be of a different quality, according to the different causes which produced it; thus it would be an alkaline astringency from salt and putrid provisions and foul water,
water, and an acid acrimony from bad sorts of bread or vegetable gluten, combined with a sedentary life. (See Boerhaave, Aph. 1153.) Dr. Cullen, too, though he relinquished much of the humoral pathology, was of opinion that scurvy was the effect of "a preternaturally false, and consequently diffused state of the blood," which was occasioned by a greater advance towards putrefaction, from the absence of the corrective of vegetable matters. (See First Lines, par. 1812—13.) And sir John Pringle maintained a similar doctrine, that scurvy was the result of "a gradually accumulating putrefaction" in the blood, from the putrefacions of fish, from that notion, which it is the chief cause of the disease. (See his Obs. on Dif. of the Army, Appendix, p. xci.) In fact, the general opinion, for a long period, deemed scurvy the most characteristic example of a putrid disease. And this putridity of the fluids was inferred from the feator of the breath, and of the ulcers; from the black colour and loose consistence of the blood; from the putridity of the urine; from the purple blotsches on the skin, &c. But this is a gratuitous and erroneous inference: for we have no less authority than that of Dr. Lind, who made numerous experiments on the subject, for ascertaining that blood, drawn from scabrous persons, even in a dying state, discovers no fungible tell of either acrimony or putridity, by the tache or the smell; that the serum of such blood is as taftelefs as the white of an egg, and without odour; that it corrupts in the air no sooner than the blood of healthy persons; and that thin slices of mutton, immersed in this serum, continued sweet and free from taint, as long as in the serum of persons in health. We know, indeed, from actual experiments, that if the smallest quantity of putrid matter be injected into the blood-veffels, it is followed by speedy death. (See a Diff. by Dr. Scybert, on the Putrefaftion of the Blood, Philadelphia, 1793.) The ordinary fcrotions from the blood are not putrefcent, as has been ascertained. Dr. Lind affirms, "the urine in this diseafe was not found to be more offensive to the smell, nor to corrupt sooner, than that of a person in health; and their sweat is not fetid, or more disagreeable than when they are in health: the fame may be laid of their flocks." (Poll. Script. p. 515.) The fame experienced physician judiciously observes, "the offensive smell from the mouth of scabrous persons, when alive, seems to me to proceed solely from the corrupt ftate of the gums. For in their dead bodies I never perceived any unusual marks of putrefaftion; they were neither more offensive, nor liable to corrupt sooner, than any other corpe." In a word, the notion of a putridity of the circulating blood is but only unsupported by actual evidence, but is refuted by all know facts and observation; and these experiments of Dr. Lind prove that there is not even a proneness to putridity existing in either foids or fluids.

Carefully account, then, for the phenomena of scurvy upon the other hypotheses, which affcribes the malady to certain morbid conditions of the living foid? This view of the subject was ably advocated by doctor, now sir Francis Milman, in one of the most elegant medical effays in the English language, published in the year 1782, (Enquiry into the Source of the Symptoms of Scurvy and Putrid Fevers, &c.) and, in fact, it affords the most rational explanation of most of the symptoms of the disease, according to the physiological and pathological doctrines which modern inquiries have established. It is not at preftent, therefore, necessary for us to enter into any minute detail of the symptoms, with the view of explaining them upon the principle of a weakened and impaired condition of the nervous fystem, and of the muscular irritability. This has been accomplished at great length by Dr. Milman, taking this ample enumeration of Boerhaave, in his Aphorism, as the text, to which we refer the reader.

This view of the subject appears also to accord better, on the whole, with our knowledge of the pre-disposing and exciting causes of the disease above detailed. The various kinds of diet, under which scurvy occasionally originates, is ill calculated to produce any particular acrimony of the fluids; and the dry pulse and glutinous pudding of the Bohemians on shore could not have the same tendency to putrefaction as the salted animal diet of seamen. Yet all these substances might equally fail, from their indigibility, or from the defect of nutritious matter which they contained, to support the strength and vigour of the moving fibre, and would equally contribute, therefore, to produce that languor of the vital powers, which is so conspicuous in the progress of scurvy. The analogy of scurvy with the ignis facer, admirably described by Lucrctius, which appears to have been commonly the refult of famine, and often called pestilence, (whence M. Poupart was correct in comparing the epidemic scurvy of Paris with some of the ancient plagues) seems to support the fame doctrine. (See Ignis Facer.) And all the pre-disposing causes, on the one hand, which are principally debilitating causes, fatigue, indolence, want of fufficient sleep, cold and moifure, and the means of prevention, on the other, which are fuch as support the general vigour of the constitution, moderate exercise, fufficient sleep, fresh air, warmth, &c. concur in evincing the flate of the moving fibre to be the source of the morbid symptoms. The fame opinion is also farther supported by the extraordinary influence of mental impressions in producing and in preventing or curing the disease. These impressions cannot suddenly change the chemical condition of the fluids; but their influence upon the living folid, through the medium of the nervous fystem, is manifest both in health and disease, to a degree that unlearned fersons will scarcely credit. (See Imagination, Influence of, and Imitation.) The fcharcs of blood from the relaxed and enfeebled of the foids, the gangrenous and confequently putrefcent tendency of the gums, and other delicate parts, the fainting and even dying on the lightest exeretion, the droptical elfeets, the labouring breath, the opprefion about the heart, &c. &c. appear to be the refult of mini- fified strength in all the muscles, and of enfeebled action in all the foids, the confequences of a general failure of the vital or nervous powers.

Such then, appears to be the advantage, in point of argument and analogy, which the doctrine of diseased foids polleflies over that of acrimony and putrefacions in the fluids. Nevertheless this theory is by no means satisfactory: it is in some measure, indeed, incompatible with the mott striking and well acertained fact, that this scurvy is not curable by those means which appear to contribute in general to the strength and activity of the foids, fuch as fresh animal food, wine, bark, foupes, &c.; while it is fpeedily and certainly removed by the use of vegetable acids, which contain no nutritive quality, and are so far delusive of corroborating power, that they even induce emaciation, while they cure the disease. In truth, we can give no satisfactory theory of this disease: but our polleflion of a certain remedy, and our knowledge of the means of prevention, may fairly supercede all hypothefes upon the subject. In this, and in all other diseases, experience and observation are the only guides which the judicious physician will follow. The infalliible demands of theick point out the source of relief, as hunger and thirst lead us to food and drink; and it is enough to have observed, that, by gratifying these demands, the
the disease is cured, and to have inferred, that by anticipating them it is prevented from occurring. This is the true source of all our knowledge, medical or physical; and our hypotheses respecting the obscure agencies of nature, which are incomprehensible, as the empires of old widely maintained, are at least superfluous; for they are not the cause, but the result of our practical information. "Repetis deinde medicinae remedii, homines de rationibus eorum differere capiisse; nec poss rationem medicinam esse inventam, sed potentiam medicinam, rationem esse quæsitam." Cellus, Prefat.

Before we conclude, however, we may be allowed to notice one theory, to which modern chemistry has given rise, but which appears to us to be as imperfectly developed as those to which we have already alluded. Dr. Trotter has advanced this doctrine; and we believe the late Dr. Beddoes has maintained a similar opinion. As the acidifying principle which exists, but is rather loosely combined in the vegetable acids and green vegetables (the oxygen of modern nomenclature), appears to be wanting, not only in the salted and other animal substances, but also in the lactic and unfermented vegetable food, which has given rise to scurvy, it has been suggested, that this oxygen may be the remedy for scurvy, and its absence from the fluids and fluids of the body, the proximate cause of the disease. This supposition Dr. Trotter considers as farther confirmed by the blackness of the blood discharged, and by the speedy change to a florid hue, which the fungous ulcerations assume, within a few hours after the acids have been administered. For it is well known, that such a change is always the result of the contact of oxygen with the blood, and that it takes place regularly in the lungs, during inspiration, the black blood of the veins being converted into florid arterial blood by that process. There is some plausibility in this view of the subject; but it affords no means of explaining the concurrence of the symptoms, and does not lead us to any additional expedients for the cure. In the application of the remedies all agree, and their peculiar explanations of their operation are of slight importance. For, as the sanguinary empirics of antiquity contended, "nilit itas cogitationes ad medicinam pertinere, eo quoque duci, quod, qui diversa de his fenferint, ad eadem tamen sanitatem homines perduerint." Cellus, loc. cit.

There is a singular disease, which, in many of its symptoms, resembles the scurvy, and is commonly confidered to be of the same nature; but which differs very materially in the circumstances under which it originates, and in the remedies which it requires, of which we have already treated at length under its proper head. This has been described under various denominations, such as land-scurvy, petechial, flat, florid, fine, flat, hemorrhatic, purpurea, &c. See Purpurea, and Hemorrhæa.

SCUTARI, in Geography, a town of European Turkey, in the province of Albania, anciently the residence of the kings of Illyricum, situated on a lake to which it gives name; now the residence of a beglerbeg, a Greek archbishop, and a Latin bishop; 52 miles S.W. of Ragusa. L. lat. 42° 27'. E. long. 14°. - Alfo, a town of Alpine Turkey, in the province of Natolia, on the Bosphorus, opposite to Constantinople, called by the ancients "Chryopeolis," as being the emporium where the Perians collected the tributes of their acquired dominions: this town, after having experienced many vicissitudes of prosperity and adversity, is now full of houses and mutes. It is a fashion for the Turks at Constantinople to be interset at Scutari.

SCUTARIENSE PROMONTORIUM, in Ancient Geography, a promontury of Asia Minor, in the Thracian Bosphorus, N.E. of Byzantium. SCUTARIUS, among the Romans, besides its ordinary signification of a shield-maker, was used to denote one of the emperor's life-guards, because their whole body was covered with armour.

SCUTCHEON. See Escutcheon. SCUTCHEON-Grafting. See Engrafting. SCUTE, a French gold coin of 3s. 4d. in the reign of king Henry V. And Catharina, queen of England, had an assurance made her of sundry cables, manors, lands, &c. valued at the sum of four thousand scutes, every two of which were worth a noble.

SCUTELLA, in Botany, a little dish, or saucer, is used by Dillenius, Linnaeus, and their followers, for the peculiar receptacle of the seeds in most species of Lichens, see that article; and which is nearly all that we know of their fructification. This receptacle consists of a smooth disk, almost always of a different colour from the rest of the plant, as well as from its own border. Its internal substance is of a dense spongy, corky, or waxy texture, filled with innumerable parallel vertical cells, each of which contains a row of seeds, usually eight in number, one above another. The disk itself is either flat, slightly concave, or somewhat convex, bordered by a rim, formed out of the leafy or crullaceous frond, and sometimes by an elevation of its own sub stance. The latter is the case with those Lichens denominated tuberculata, whose disk often becomes so much elevated as to overtop, or obliterate, this kind of border. The rim formed out of the frond is termed by Acharius margo accessorius; which is of the substance of the disk is his margo proprio.

Some confusion has arisen in the English denomination of the part in question, which is now universally called a festa, in preference to Dillenius's word saucer; nor will any one, surely, disapprove of the change. The source of the Latin festella is festum, a feast, and Linnaeus, in his Philosophia Botanica, appears to have intended using festella, a little shield, instead of festella, a little dish. If he had kept to the former, our English word would indeed have been more strictly correct, but it is still sufficiently to preclude any necessity of altering what is now generally adopted.

Gen. Ch. Cal. Perianth inferior, of one leaf, very short, tubular; rim almost entire, after flowering closed with a lid, permanent. Cor. of one petal, ringed. Tube very short, bent backwards; throat long, compressed. Upper lip concave, trid: the middle segment concave, emarginate; lateral ones flat, rather acute, lying under the middle one. Lower
Lower lip broader, emarginate. *Stam.* Filaments four, concealed under the upper lip, two of them longer; anthers small. *Pil.* German superior, four-cleft; style thread-shaped, resembling the filaments in situation and length; stigma simple, incurved, pointed. *Peric.* none, except the closed calyx, which is shaped like a helmet, triangular, burrowing at the lower margin. *Seeds* four, roundish.

Obf. This genus is easily and sufficiently distinguishable from all others by the fruit alone, for the closed calyx, containing the seeds, with its crest and lid, somewhat resembles a helmet.

Eff. Ch. Rim of the calyx nearly entire, closed, and covered with a lid after flowering.

1. *S. orientalis.* Yellow-flowered Skull-cap. Linn. Sp. Pl. 834. Sm. Fl. Græc. Sibth. t. 580, unpublished. (Califide orientalis, chamaedrys folio, folio luteo; Tour. It. v. 2. 129, with a plate.)—Leaves with deep parallel teeth; downy beneath. Spikes cylindrical, slightly quadrangular.—Native of Barbary and the Levant, flowering from May to July. *Stems* nearly a foot high, branched from the bottom, spreading on the ground, taking root at the lower joints. *Leaves* flaked, almost pectinate, more or less downy; green above, but white underneath. *Spike* rather short, composed of bright-yellow very handifome flowers, with ovate brown bracteas. The whole herb is bitter. In the *Systema Vegetabilium* the corolla is said to be purple with a white lip; confounding it perhaps with the next species.

2. *S. grandiflora.* Large-flowered Skull-cap. Ait. n. 2. Sims in Curt. Mag. t. 635.—Leaves heart-shaped, deeply crenate, downy on both sides, shorter than their flalks. *Spike* very short, quadrangular. *Corolla* hairy, four times longer than the bracteas.—Native of Siberia, and introduced by Mr. Loddiges in 1804. It flowers in July. A hardy perennial, like the last, of which indeed it may possibly be only a variety. The *spikes* are shorter, and the *corolla* is larger in proportion to the size of the bracteas, lilac-coloured, with a yellow palate. *Leaves* rounder, less downy beneath, but soft on both sides. Dr. Sims says it approaches very nearly to the variety of *S. orientalis* found in Georgia by Tournedos, and described in his travels.

4. *S. lupulina.* Tartarian Skull-cap. Linn. Sp. Pl. 835. “Schmidel. Tc. 272. t. 73.”—Leaves heart-shaped, serrated or jagged, acute, smooth. *Spike* imbricated, roundish or slightly four-fid. *Bracteas* the length of the flowers.—Native of Siberia and Tartary, flowering from June to September. *Stems* shrubby and trailing. *Leaves* jagged at the edges, smooth on both sides. *Flowers* white, or blue, sometimes yellowish-white, very large. In habit greatly resembling the last, but different in colour, and having much more *bracteas.*

The flowers of this species resemble those of the following in height and habit, but are somewhat larger. *Leaves* flaked, ovate, serrated. *Flowers* in lateral clusters, small, blue, each partial falk bearing two fideae.*bracteas.*

6. *S. nervosa.* Ribbed Skull-cap. Purif. n. 2.—*Stem* nearly simple, smooth. *Leaves* sessile, ovate, toothed, ribbed. *Clutter* terminal, lax, leafy.—On the banks of rivulets in Virginia, flowering in July and Augult. This perennial herb has blue flowers, which are larger than those of the foregoing species. *Purif.*

8. *S. haftifolia.* Hafted-leaved Skull-cap. Linn. Sp. Pl. 835. (Scutellaria folio non farrato; Rivin. Monop. Irr. t. 77.)—Leaves quite entire; lower ones haftate; upper arrow-shaped. Found on the shores of fresh waters, in Sweden and Austria, but not very common. It flowers in June and July. *Root* creeping. *Spike* generally simple. *Leaves* blunter than in the preceding, not at all notched, cared at the base. *Flowers* axillary, solitary, in pairs, blue, larger than in the last species, to which it is very closely allied, and of which both Linnæus and Scopoli hint that it may be only a variety.

10. *S. humilis.* Dwarf Skull-cap. Brown Prod. Nov. Holl. v. 1. 507.—Leaves ovate or heart-shaped, coarly crenate; dotted and rather downy beneath. *Flowers* axillary. *Calyx* smoothish, half as long as the corolla.—Found by Mr. Brown at Port Jackson, as well as in the south parts of New Holland. We received specimens, in 1793, from Dr. White. This agrees in size, and somewhat in habit, with the last, but the leaves are smaller, more rounded, deeply notched, with curved thinly hairs about their ribs and margins. *Flowers* solitary, opposite, spreading different ways.

14. S. carolina. Carolina Skull-cap. Lamarck DC. f. 7. 706. Illust. t. 515. f. 3. Pursh n. 6.—Branching, very smooth. Leaves ftalked, linear-lanceolate, acute, entire. Clusters lax, leafy. Calyx obtufe."—Gathered in Carolina by Mr. Frazer. Point. Root perennial. Leaves about two inches long; the upper ones much diminished, accompanying the flowers, which are the size of S. galericulata, yellowish-white, spotted at the apex with blue.

15. S. urceolata. Germander-leaved Skull-cap. (S. integrifolia; Linn. Sp. Pl. 836, excluding the reference to Alnus. S. carnea virginiana glabra, lamii, aut potissim teurci, folio, minor; Pluk. Almaggd. 338. Phyt. t. 313.f. 4. S. teurci folio marilandica; Rait Hist. v. 3. 310.)—Leaves fefile, ovate; the lower ones bluntly and diftantly ftalked; upper entire. Flowers axillary, ftolitary, on hairy ftalks. Native of North America. The fllem is above a foot high, unbranched, fender, fquarce, smooth, leafy. Leaves resembling Veronica Teurcium, about an inch long, nearly fefile, ftightly dotted beneath, smooth, except the ribs and margin, which are clothed with curved ftilhairs. Flowers turned one way, small. Calyx hairy at the ribs and margin. Corolla hairy, blue. Such is the plant Linnaeus intended as his integrifolia, which he received from Kalm, along with another fpecimen, pafted on the fame paper, which he did not perceive to be merely a smoothift variety of his own hyfypofolia, and which led him to quote Gronovius's Flora Virginica improperly in this place, as well as to choose the name of integrifolia. This appellation, however, being erroneous, and having caufed much confusion among fubfquent botanifts, is here laid aside, and we have preferred one taken from the very apt fynonym of Pluketen and Ray. The figure of the former however represents the ftoofalks too long, and the floral leaves too small. Mr. Pursh seems not to have recognized this plant. At least we can refer it to none of its fpecies.

16. S. byfypofolia. Hyfilop-leaved Skull-cap. Linn. Sp. PI. 836. Mant. 414. Wild. n. 12. (S. integrifolia; Ait. n. 10. Pursh n. 7. Michaux Boréali-Amer. v. 2. 12. S. virginiana, hyfypus angustis folis, flore caeruleo; Pluk. Almaggd. 338. t. 441. f. 6. S. folis integerrimis; Gron. Virg. ed. 1. 67, excluding the references to Pluketen and Ray.)—Leaves linear-lanceolate, obtufe, entire, withftalked, finely downy; copiously dotted beneath. Clusters compound, rather lax, leafy, downy. On dry hills, in a rich foil, from New York to Carolina, flowering from July to September. Perennial, very variable in the fize and figure of the leaves, fimple or branched flems. Flowers large, handfome, blue. Pursh. We fee no reason to transfer the name of integrifolia to this, which has already one fo greatly preferable. The whole herb, as well as the calyx and corolla, are finely downy and somewhat hoary.

17. S. ferrata. Great Serrated Skull-cap. Andr. Repoft. t. 494. Pursh n. 8.—Leaves ovate, pointed, ftalked, finely downy. Clusters compound, rather lax, densely, leafy downy. Bracteas lanceolate. In fields and meadows, from Virginia to Carolina, flowering from July to September. Pursh. The fllem is three feet high. Leaves two or three inches long, and above one broad, tapering at the base. Flowers copious, large and handfome, of a fine deep blue. This is a very ornamental perennial herb, worthy of cul-
almost as long as the leaves. *Spikes somewhat aggregate, erect, dense, many-flowered, hairy, two or three inches long. *Bractæ ovate, entire, longer than the calyx. *Flowers all turned one way. *Calyx covered with very long dense hairs, spreading in all directions. *Corolla downy; its upper lip pale lilac; lower, as well as the tube, greenish-white.

24. *S. albida. Pale Hairy-cupped Skull-cap. *Linn. Mant. 248. *Wild. n. 2. Ait. n. 3. *Sm. Fl. Græc. *Sibth. t. 581, unpublished. (S. teucrid face; Bauh. Hist. v. 3. 291.)—Leaves heart-shaped, serrated, downy as well as the stem. Spikes elongated, unilateral. *Bractæ two-ranked, ovate, flaked, nearly equal to the flowers. *Corolla downy, its lower lip entire.—Native of the Levant; found by Dr. Sibthorp on Mount Olympus. Very nearly akin to the last, and not in the least resembling orientalis, to which *Linæus, in his *Syntagma Vegetabilum, by some unaccountable error, compares this species. It is, if possible, more strange that he should at one time have confounded *albida with *alpina, as appears by his herbarium. *S. albida differs from *peregrina in having broader, more coarsely serrated leaves, more crowded and numerous flowers, whose *corolla is cream-coloured, downy, not clothed with long hairs; the edge of its lower lip even and entire, not lobed, undulated, or notched. The *calyx, on the contrary, bears much longer hairs than that of *peregrina.

25. *S. albilina. Tall Skull-cap. *Linn. Sp. Pl. 836. *Wild. n. 16. Ait. n. 15. (S. *Columbar; *Allion. Pedem. v. 1. 42. t. 84. f. 2. *Wild. n. 14. *Cafidra; *Columnus Ecphr. v. 1. 187. t. 189. *C. orientalis albilina, urtica folio; *Tourn. Cor. 11.)—Leaves heart-shaped, serrated, acute, nearly smooth. Spikes elongated, unilateral. *Bractæ ovate, acute, flaked, shorter than the *calyx.—Native of Italy, Mount Caucasus, and the Levant. *Miller cultivated it in 1731, and one of his own specimens, compared with those of *Allioni, have enabled us to verify the above synonymy, and to reduce two reputed species, of this difficult and confounded genus, into one. The present differs from both the last, in having leaves twice their faze, besprinkled with only a few minute scattered hairs, so as to feel nearly smooth. But its most essential character consists in the finalness of the *bractæ, whose points do not extend beyond the *calyx. The *fides therefore appear almost naked, consisting of numerous purple downy flowers, whose *calyx, like the flower-flanks and *bractæ, is rough with glandular vilous hairs. The last species in *Linæus, *Willdenow, and *Aiton, *S. cretica, require to be expunged, being the very same plant as *Teucrium Arbauti, *Linn. Mant. 81, and announced as such in *Sm. Prodr. *Fl. Græc. *Sibth. v. 1. 392. *Itself and habit accord with *Teucrium, not with *Scutellaria.

*Scutellaria, in *Gardening, contains plants of the hardy, herbaceous, perennial kind, of which the species cultivated are; the entire-leaved skull-cap (S. integrifolia); the *florentine skull-cap (S. peregrina); and the tall skull-cap (S. albilina).

*Method of Culture.—These are all raised from seed, which should be sown in autumn or spring, but the former is the better season in the places where they are to remain, or in a border to be removed afterwards. When the plants are up they should be properly thinned out and kept free from weeds.

They afford variety in the borders, clumps, and other parts of pleasure-grounds, when properly planted in them.

*SCUTELLUM, in *Botany, a little shield, sometimes used for the fructification of *Lichens, instead of *Scutella, see that article.

*SCUTELLUM, or Esuthein, in the History of Insects, is the posterior part of the thorax; it is frequently triangular, and appears to be separated from the thorax by its intervening furrow, as in that of the coleoptera.

*SCUTHINON, in *Botany, a name given by the ancient Greeks to a yellow wood, called also *thamnium, *chrysocolon, and *Scytheicum lignum. It was of a beautiful colour, and was used in dyeing and in colouring the hair yellow, which was the favourite colour of that time.

The same authors have sometimes also called it *cythinon, or *cuthinon: this is only the former word with the initial / taken away, as it was common with them to do in regard to many words; thus they called the *milax *milax, the *smaragdus *maragdus, and so of many more.

*SCUTIFORME Os, in *Anatomy, the chief bone of the knee, called also *patella, *mala, &c.

*SCUTIFORMIS, *Cartilago, one of the pieces composing the larynx. See *Larynx.

*SCUTTLE, in *Agriculture, the name of a shallow basin, or fort of wicker-bowl, much used in the barn and for other purposes. The large ones have handles, but the small ones are without them. They are often also employed for flable purpofes.

*SCUTTLES, in *Ship-Building, are square openings cut through the decks, much less than the hatchways, for the purpose of handing small things up from deck to deck. There are also scuttles cut through the ship's side, for the admission of air and light into the cabins, &c. between decks, and some between the ports of smaller vessels, through which the *foups are used, to row the vellet along in calms.

*SCUTTLE-Hatch, in a *Ship, the little hatch that covers the scuttle.

*SCUTTLING, in *Sea Language, the act of cutting large holes through the bottom or sides of a ship either when the ship is stranded or overfet, and continues to float on the surface. It is commonly designed for taking out the whole or part of the cargo, provisions, *flores, &c. with all possible expedition.

The decks are scuttled sometimes to put pumps down to assist the chain-pumps on emergency or failure.

*SCUTTOCK HILLS, in *Geography, hills of the United States of America, in the district of Maine; 8 miles N. of New Bristol.

*SCUTTOCK POINT, a cape on the coast of Maine. *N. lat. 44° 18'. *W. long. 69° 58'.

indexed, inserted below the petals, and about equal to them in length; anthers oblong, curved. Pfl. Germen imbedded in the calyx; style thread-shaped, as long as the flamenus; stigma simple. Peric. Berry formed of the calyx, thickened, of eight cells. Seeds solitary, somewhat compressed.

E. Ch. Calyx entire, becoming pulpy. Petals five. Berry of eight cells.

The berries of this genus are said to be of an astringent, strengthening quality, vying with those of the myrtle.

Scutula reihs entirely upon Louerei's authority. Some parts of his description we have omitted, as unintelligible.

The genus may possibly be referable to Moncreyon.

SCUTUM SORIESEK, Sobieski's Shield, in Astronomy, a constellation formed by Hevelius; the stars of which in his catalogue are: four of these are enumerated in the Aquila in the Britannic catalogus. See Constellation.

SCUTUM, in Natural History, the name of a genus of the echinii marini; the characters of which are, that it is a shell of an irregular figure, which on the lower part represents, in some measure, a shield; on the superstructure it has the shape of a five-leaved flower; its mouth is in the middle of the base, and the aperture for the anus at the edge.

Of this genus of the echini there are two kinds, the angular and the oval.

Of the first of these kinds, the angular feuta, there are only two known species: the first a lower flatfish kind, and the second a more elevated one.

Of the second, or the oval feuta, there are three known species. Klein's Echinod. p. 28.

SCUTUM, in Pharmacy, a name given to a solid pomacious topic, whether made in form of a ball, with medicinal ingredients seceded in it, or of a platter. It is always fashioned into the shape of a shield. The platters, for this purpose, were used to be made of the warm pomacious gums, and the bags were filled with the warm pomacious powders; and they were worn to warm and strengthen the stomach, correct a cold in temperature, and promote digestion, and prevent vomiting.

The patella, or knee-pan, is also sometimes called by anatomists scutum.

SCYBALA, σκύβαλα, in Medicine, an appellation given to the excrement of the bowels, when it is hard, dry, and formed into small malleable, or little balls, resembling the excrement of sheep. This form is always given to the stools by their remora or delay in the intestines, and is sometimes merely the refect of ordinary constipation, and is then probably produced in the cellular surface of the colon, or great intestine; but in some cases, scybalae are lodged higher in the canal, exciting great irritation in the bowels, and even violent purging of thin flimsy stools, together with much fruitless straining, or tenesmus; which consituire, in fact, one form of the dyentery, or flux. In these cases, it is obvious that, if allrigments are given, with a view of checking the purging, the disease must be aggravated; for the enemy is thus closer locked up in the bowels; and that effectual cathartics must be administered by the mouth, to expel the accumulated excrement. Accordingly the appearance of scebyala in the

Accordingly the appearance of scebyala in the
SCY

SCYLDWIT, in our Old Writers, a mulcet or fine for any fault.

It comes from the Saxon *silede*, i.e. *delicium*, and *weop*.

SCYLITZA, John, *Europalates*, in Biography, a Greek historian, known for his abridgment of history from the death of Nicerius Logothetes in 811, to the death of Nicephorus Botaniates, in 1081. This history, from the year 1067, is the same as that of Cedrenus, which has caused a discussion among the learned, which of the two was the plagiarist. Scylitta is thought to have been a native of Leffler Afa, and a prefect of the guards before he attained the dignity of eurupalates. A Latin translation of his history entire, was published at Venice in 1570: and the part concerning which there is no dispute was printed in Greek and Latin, at Paris, in 1647. Moreni.

SCYLLA, in *Ancient and Modern Geography*, a rock at the entrance of the Straits of Messina, about 200 feet in height, now cape *Scipio*; which bee. Scylla was famous in antiquity for the danger which it presented to navigators who approached it. The rock, perished by Homer in his Odyssee, and represented as a devouring monster, has been destroyed by a late earthquake. Concerning its situation with regard to Charybdis, and other particulars, we refer to Charybdis.

Scylla, or *Scylus*, a town of Italy, in Brutium.—Allo, a desert island in the vicinities of the Thracian Chersonesus.

SCYLLA, in *Natural History*, a genus of the Vermes Mollufca class and order, whose generic character is, body compressed, and grooved along the back; the mouth consists of a terminal toothless aperture; the tentacula or arms three on each side, and placed beneath. There are only two species.

* Pelagica. The body of this species is fixed; the four extreme arms are alike; the middle ones papillous. It inhabits the ocean, and is generally found among floating seaweed. Independently of its specific character, it is described as having a roundish oblong body; broader behind, and obtuse; the mouth is placed at the end of the smaller extremity; the back is grooved with a crenulate hollow, by which it affixes itself to sea-weed; the extreme arms are smaller and rounded; the middle pair is oblong, foliaceous, bending over and sprinkled within with papillae.

* Gympophenous. The body is detached; the first pair of arms is naked and hollow at the tip; the others have branched fibres within. The body is about an inch long, pellucid, yellowish, with ruddy brown dots; the back is flat, dotted with brown at the margins, with a row of blue dots down the middle; the tail is compressed, with an elevated rounded back, and furnished on each side with small branched fibres; the abdomen is dotted with blue, and rough, with a row of five which papillae down the middle of each side; the first pair of arms is the tender, the rest are contiguos, with a denticulous margin.

SCYLLA PROEMINORUM, in *Ancient Geography*, the promontory of Scylla, or of Skilos, that part of the Argolid which advances toward the southward.

SCYNNITAE, the people of Asteria, a Sarmatia, between the Sorphemas and the Amazon, according to Ptolemy.

SCYMNAS, in *Ithology*, a name used by Elian, Appian, and many other of the old Greek writers, for the fish called *sulcun* by Aristotle. This is a species of the fuguvs, called by Ares and others the fuguus with the pinnas and placed in the midit, between the anus and tail:

* Catulus vulgaris and catulus major of authors.

SCYPHOPHORUS, in Botany, from *skeuus*, a large kind of drinking cup, and *opous*, bearing, alluding to the dilated cup-shaped stalks, resembling wine-glaizes, borne by the leaves, on whose margins the fructifying tube are seated. This is the denomination of the 21st tribe, or section, of the *Lichenes*, see that article, in the *Prodromus* of Acarians, which are well known to the vulgar, as well as the learned botanist, by the name of Cup-mols, or *Lichenes pyxidiatum*. The above name is however sunk in that of *Bozomyces*, in the *Methodus* of that author; though Michaux uxes it generally in his *Flora Boreali-Americanus*, v. 2. 328.

SCYPHUS, among the Romans, a very large kind of drinking cup. The seyphus was called the cup of Hercules, as that of Bacchus, *liberi patris*, was named cantarbus.

SCYPPIUM, in *Ancient Geography*, a town of Aeg. Minor, in Ionia, on the confines of the country of the Colophonians, according to Pausanias.

SCYRA, in our Old Writers, a fine imposed on such as neglected to attend the *feyregemot court*, which all tenants were bound to do.

SCYRAS, in *Ancient Geography*, a river or stream of Laccania, which discharged itself into the gulf of Laccania. Near it was a temple of Apollo, and an altar of Jupiter. Pausanias, lib. iii. Lacc. c. 25.

SCYREGMOT, or *Scyremot*, in *Ancient Cylomons*, a county-court held twice every year by the bishop of the diocese, and the caldorman, or sheriff; in which both the ecclesiastical and temporal laws were given in charge to the county.

In the time of Canutus the *feyregemot* was held thrice every year. Edward the Confessor appointed it to be held twelve times in the year.

SCYRIS, in *Ancient Geography*, a people of Iudia, in the vicinity of Ariana.

SCYRUM MARMOR, a name given by the ancients sometimes to a white, and sometimes to a yellowish marble, both used in the public buildings of the Romans, but seldom in statuary, not being capable of a high polish.

SCYROS, in *Ancient Geography*, an island in the Archipelago, situated to the E. of the isle of Eubச, and very near it. The ancients pretend that Achilles spent the first years of his life here, disguised like a female, in the court of Lycomedes. It was in alliance with Troy, as appears from Agamenon's having made a conquest of it. See Sciro.

SCYTALA, an island of the Arabic gulf.

SCYTALA, in *Mechanics*, a term which some writers use to a kind of radius, or spoke, standing out from the axis of a machine, as a handle or lever, to turn it round, and work it by.

SCYTALA LACONICA, in *Antiquity*, a frigatage, or device, of the Lacedemonians, for the secret writings of letters to their correspondents; so that if they should chance to be intercepted, nobody might be able to read them.

To this end they had two wooden rollers, or cylinders, perfectly alike, and equal; one of which was kept in the city, the other by the person to whom the letter was directed. For the letters, a skin of very thin parchment was wrapped round the roller, and on this the letter was written; when done, it was taken off, and sent away to the party, who, upon putting it in the same manner upon his roller, found the lines and words, which were before its application to the roller consubiously disjoined, and altogether unintelligible, in the very same disposition as when they were first written. Plint. in Vit. Lyfand.

This expedient they fet a very high value on; though, in truth,
truth, artless and gross enough: the moderns have improved vastly on this method of writing. See CIPHER.

It should seem, that besides this fycyata, used for political and military purposes, private persons made use of a contrivance somewhat similar, to prevent deceits in contracts; but there were exactly like our tallies.

SCYTALIE, in Zoology, the name given by the ancients to a species of serpent, which was very long and thin, and equally big all along the body, so that the tail was not easily distinguished from the head.

Linnaeus mentions two animals under this title; one, a species of anguis or snake, and the other a species of the boa; which fee.

SCYTALIA, in Botany, elegantly so named by Gart-ner, from ρυεα, a skin, or hide, and ραιλα, a thong, in allusion to the leathery subulance and colour of the skin of the dried fruit, as also to the little shield-like tubercles, with which its outside is beset, resembling a coat of mail. Schreber has followed this author; but the same genus was published two years afterwards by Loureiro, under the name of Dimocarpus, indicating its double or twin fruit, which Willdenow has unawares retained, though in every respect less eligible. Hence the latter appellation is also adopted in the Hortus Kewensis, the plan of this book being, as much as possible, to follow Willdenow. Had we been aware that it would have done so in the present instance, we might perhaps have yielded our better judgment to convenience, and have given the history of the genus under the head of Dimocarpus; but this not being the case, we shall exhibit it here, acknowledging our preference for Scytalia.—Gartn. Sem. v. 1. 197. t. 42. Schreb. Gen. 262. (Dimocarpus; Loureiro. Cochin. 233. Willd. Sp. Pl. v. 2. 346. Ait. Hort. Kew. v. 2. 354. Euphoria; Jull. 247. Lamarck Illutr. t. 306.)

Gen. Ch. Cal. Perianth inferior, of one leaf, very small, with five minute teeth. Cor. Petals five, small, reflexed, hairy on the inner surface, sometimes wanting. Stam. Filaments eight, sometimes but fix, awl-shaped, hairy, longer than the petals, dilated at the base; anthers heart-shaped, incumbent. Pfl. Germens superior, two-lobed, somewhat falkated; style shorter than the flammes; frigmas two, spreading. Peric. Berries two, ovate or globose, with a coriaceous warty coat, pulpy within, each of one cell. Seed solitary, large, elliptical, polished, obliquely cut away at the base, where it is inserted into the flitely elevated bottom of the pericarp.

Obi. Gartner has described as a feedy tame of the seed, which is really only the dried pulp of the berry.

1. S. Litchi. Lee-chee, or Apetalous Scytalia. (Dimocarpus Litchi; Ait. Hort. Kew. v. 2. 354. Loureir. n. 1. Litchi chinensis; Sonnerat Ind. Or. v. 2. 230. t. 129. Sapindus edulis; Ait. ed. 1. v. 2. 36.)—Flowers with fix flammes, and no petals. Fruit with prominent warts.—Native of China, Cochinchina, and Tonquin. The celebrated governor Hallings is said to have sent this plant to England in 1786, and it is marked as flowering in the House at Kew, in May and June. The younger Linnaeus, however, appears to have obtained a specimen of the leaves, from the collection of the marquis of Rockingham at Wimbledon, during his stay in England in the spring of 1782. The Litchi is described by Sonnerat as a large tree, with a soft white wood, abounding in pitch. The leaves are alternate, flanked, abruptly pinnate, confining of three or four pair of opposite, stalked, elliptic-lanceolate, pointed, entire, equal leaflets, quite smooth on both sides, evergreen, each furnished with a midrib, and numerous small interbranching veins, the latter scarcely visible but in a dried state. Each leaflet is three or four inches long. Panicles terminal, compound, repeatedly branched. Flowers small, greenish, with a very downy calyx, but no petals. In some we find eight flammes, but in the same panicle others have only five. The berry, usually solitary when ripe, is nearly globular, concave at the base, an inch or more in diameter, reddish, covered with very numerous, clove, prominent tubercles. It is of an agreeable flavour, and said to be one of the heil fruits of the countries where it grows. The Chinese dry it in ovens for exportation. Some which we have tasted, in England, contained a firm very acid pulp, not unlike the taste of tamarinds.

2. S. Longan. Longan, or Many-petalled Scytalia. (Dimocarpus Longan; Ait. Hort. Kew. v. 2. 354. Loureir. n. 2.)—Flowers with eight flammes and five petals. Fruit nearly smooth.—Native of China. Cultivated in that country, Cochinchina, the East Indies, the Mauritius, &c. This is also a large tree, with a sweet and grateful fruit, not half the size of the last, more precisely globular, and either quite smooth, or slightly scaly, not warty. The leaflets are rather more numerous than in the former, shorter, blunter, and more elliptical; at least in our East Indian specimens. In one from the ile de Bourbon, marked Longan, the leaflets are oblique, or unequal, at the base, alternate, and taper-pointed. The fruit is quite smooth. We suspect this to be rather some Sapindus, confounded with the true Longan.

Loureiro mentions two more species unknown to us, one of which, his Dimocarpus itermitis, seems to be the wild flate of the Litchi, in the woods of Cochinchina. He speaks of the wood of all the four of an excellent quality, heavy and hard, of a brownish-red. The same author relates, that the Litchi, being impatient of cold, as well as of great heat, is most cultivated in the southern provinces of China, and the northern ones of Cochinchina. As the fruit will not ripen at Pekin in the ordinary way of cultivation, trees in flower are sent thither by water, so as to yield ripe fruit, for the emperor's use, on their arrival. This is attended with great labour and expense.

SCYTIE, Scyth, among the Athenians, a designation sometimes given to the officers, more usually called lexarchi.

They had the name Scythe, because they were often natives of Scythia who were chosen lexarchi, as being braxy and sturdy fellows.

SCYTHARION, in Botany, a name given by the ancient Greek writers to a tree, whose wood was of a fine yellow colour, and was used in those early times to dye things yellow: it was called also Scythium lignum, from its country, and Chrysoxylon, or golden wood, from its fine yellow colour. It has been supposed that this was the name with the colinus cotiaris of the Romans; but this is an erroneous conjecture, since the wood of this tree dyed a yellow colour, and that a brownish-red, or a clear and pure red, according as the infusion was made more or less strong. This feytherion, therefore, could not be the same with the colinus, but it certainly is the same with the thysium of the Greeks.

SCYTIE, in Agriculturc, the implement used in mowing, being a crooked blade joined at right angles to a long pole, or handle. It is sometimes written Sîthe, or Sythe. See MOWING.

Common seytheres are of several different constructions and kinds,
kinds, in different counties. In most of those more towards the northern extremity of the island, they are of a much greater length than those which are employed in the southern districts of the kingdom. Both the extremes are, however, probably disadvantageous in some respects. Those which are neither too long nor too short are unquestionably the best fitted for general use, and capable of being employed with the greatest ease and convenience by the labourer. The tool is commonly furnished and fitted up differently for different purposes, as has been noticed under the heads to which they belong. See Mowing, Raking, &c.

The fluff Flemish scythe is in use in some places for cutting bean, and other strong crops of the corn kind. It has the name of bean peck in some parts of Essex; and though it is thought by some to beat out the seed too much, in the hands of workmen who understand the use of it, very good clean work can be made with it, without any fluch mischief taking place, and they rid work in this way much faster than by the common tool and method.

In Cheshire, they make use of a strong tool of this sort, called the boddin-scythe, the blade of which is about twenty inches in length, but curved in a different way to the common scythe, the edge being nearly in one way of it, in a straight direction from the heel to the point; but the flat part of the blade forms a curvature, which varies about four inches from a straight line. The handle or sheath, to which the blade is fixed, is about three feet six inches long, and has one scythe-like handle placed about eighteen inches from the top. When the work is performed, one hand is placed upon the top of the shaft or sheath, and with the handle in the other, the crown of the rush root is scooped out by the concave part of the blade, in consequence of a smart stroke being given by the tool. The early spring is considered as the most proper season for effecting this sort of husbandry; and it is advisable to carry off the rush roots, and form a compost with them; the hod-holes, or cavities made by the tool, being filled level with the surface of the ground with some earthy material, and sown with hay or grass-seeds. This tool is yet but little known, except in the above districts, where it has been used to considerable extent in many parts, with the most beneficial effects in clearing the lands from rushes; many scores of acres of low meadow and marshy lands having been in this way freed from them, and with the aid of gutters, rendered of more than double their former value.

Short strong fluff scythes are made use of in most places, for clearing away and removing all parts of shrubbery plants from grounds, such as those of the broom, briar, furze, and several other similar kinds.

SCYTHIA, in Ancient Geography, is a vast territory, which has been confounded by some geographers with Tartary or Tartary, of which it is only a part (see Tartary), extended from the Iler, or Danube, that is, from about the 25th to almost the 116th degree of E. longitude. It was divided into Scythia in Europe, and Scythia in Asia; including, however, the two Sarmatias, or Suevomarias, now the Circassian Tartary, which lay between and separated the two Scythias from each other. Sarmatia was also distinguish'd into European and Asiatic, divided from the European Scythia by the river Don or Tanais, which falls into the Palus Mazotis, and from the Asiatic by the Rha, now Volga, which empties itself into the Caspian sea. (See Sarmatia.) Accordingly the two Scythias were only parted by the boundaries of Europe and Asia, that is, by the river Tanais, descending, as it is supposed, from the Riphean mountains into the Palus Mazotis. For, beyond these mountains northward, the Scythians did not advance into any of those remote regions; so that there were the proper confines of the Asiatic Scythia on the west. The northern boundaries reached to the Hyperborean or Frozen sea, called also by the ancients the Scythian sea, the Cronian, Amalchian or Almabian, the Dead sea, and by some other names equally expressive of extreme cold and ice. On the east, they are supposed to have extended to the promontory of Tabi, and to have been bounded by the Carpathian mountains, which parted Scythia from the kingdom of Seres, now Kaitai, Cathay, or Northern China; and even this line was by some of the ancients taken for part of Eastern Scythia; so that, on that side, it had no other boundaries, according to Ptolemy, than the unknown tracts beyond it; and on the south it was bounded by the Indian sea, by mount Caucasus, and the Caspi. As to the more northern parts of Scythia, it is, on account of its extreme cold, uninhabitable, except by wolves and other wild beasts; and hence they seem to have been unknown to the ancients beyond the 60th degree north. The territory beyond that degree was demarcated Terra incognita. But the southern regions, better known to them, were divided into three parts, viz. Scythia within, and Scythia without, or beyond Imaus, and Sarmaetia, which, as we have already said, lay between the former and the European Scythia, and which had been so blended with it, that the only difference between them was the name. Accordingly, Ptolemy bounds the Scythia on this side of Imus on the west by Asiatic Sarmaetia, by mount Imaus on the east, by the Terra incognita on the north, and on the south and south-east by the Sace, Sogdian, and Margian. The principal mountains in this part Ptolemy reckons to be the Alani to the east; the Rhymnici, from which flowed the Rhynmus into the Rha; the Norusin, from which sprang the Daix, the Apfii, the Sapuri, the Syebi, and the Anaci. The rivers were the Rhynmus, the Daix, the Jaxartes, the Jata, the Polytemus, and the Oxus. The inhabitants of this part, according to the same geographer, were, towards the north, the Alani, Sufobeni, and Agathyr; and next to these, the Sazieni, the Mafiei, and the Syebi; near the Imaus were the Thaces; near the eastern sources of the Rha, the Rhobacii, Azani, and Jordan; to the south, and near the river, was the country called Conadipfas regio; and near this, Corapsii, Orgazi, Jotza, and Aonii; next to these, the Jaxartes, a considerable nation, on the river of the same name; to the south of the Sazieni were the Molonii, and next to them the Sammite; and below the Mefieni and the Alani mountains were the Zarets and the Sazones; to the east of the Rhynmus mountains were the Tybiace; and below them the Zarets, Tabeini, Jaite, and Macgeni, near mount Norolius; above them were the Orobes and Norossi; and more to the south, the Cachass Scythia; to the west of the Apfii, the Apfii Scythe; and east of them, the Galactophagi Scythe; and east of the Syebi, the Tapurei, and the Aftatanae Scythe. The Anaci lay to the south of the Agathyr, and to the east of the Tapurei. The Aftatanae extended to mount Imaus; and near the Jaxartes, between the mouths of the two rivers, were the Ariae, the Sagarane, and the Rhibi, near the Oxus. The Scythia beyond Imaus, according to the same geographer, was bounded on the north by the mountains, on the east by Serica, on the south by part of India on this side of the Ganges, and on the west by the interior of Scythia and the Sace. The mountains of this part are the Auxacii, Cafini, and Emodi. The inhabitants were, towards the northern part, the Abi; to the south, the Hippophagi Scythe, those of the Regio Auxacii, and the Regio Caia, the Chata-Scythe; and near the Emodi, the Charasini-
SCY

Scythia. The towns were Auzacia, Ildedon Scythica, Charana, and Seta. Pomponius Mela assigns to the Scythians much the same extent and boundaries. The Scythia Pontica was called by the Greeks Maenia. The Astatic Scythia, therefore, comprehended in general Great Tartary, and Russia in Asia; and, in particular, the Scythia beyond or without Imaus contained the regions of Bogdoi, or Oftiacoi, and Tunzuri. The Scythia within or on this side of Imaus comprehended Turkistan, and Mongolia, the Ufbeck or Zagmat, Kalnuck and Nogaun Tartars, besides Siberia, the land of the Samoiedes, and Nova Zembla. The three last mentioned countries, not being so far inland as the former, were wholly unknown to the ancients; and the former were peopled by the Bactrians, Sogdians, Gandari, Sacæ, and Maffagetæ. Sarmatia contained Albina, Iberia, and Colchis, which now constitute the Circassian Tartary and the province of Georgia. (See Circassia and Georgia.) The seas of Scythia, besides the Frozen and Indian ocean, were the Caspian, the Euxine, and the Palus Meotis. The rivers, besides those already mentioned, or the Rha or Volga, and the Tanais or Don, were the Obi, Lena, Amur, and Helum, all of which are in Great Tartary: to which we may add the Jaxartes and the Oxus, which discharged themselves into the Caspian sea; in which sea were islands called the Scythian islands. The most noted mountains were the Taurus, Imaus, and Caucasus.

European Scythia, whose confines westward have been fixed at the Tanais, reached towards the south-west to the Po and the Alps, by which it was divided from the Celts, or Celto-Gallic, and by the Rhine northward. On the south it was bounded by the Ilterr or Donube, and the Euxine sea; which boundaries were continually changing, on account of the mutual encroachments of the Celts and Scythians; and as to its northern limits, which have not been precisely ascertained, they have been supposed to stretch to the spring-heads of the Borylthenes or Dnieper, and the Rha or Volga, and so to that of the Tanais. The ancients divided this country into Scythia Arimaspea, lying easterly, and joining to Asian Scythia, and European Scythia on the west; which were contiguous to each other, and stretching for some interval from north to south, without any perceptible line of separation. In Scythia, properly so called, were the Arimaspea on the north; the Getæ, or Dacians, along the Danube, on the south; and the Natri between these two. It therefore contained the European Ruffia, and the leffer Crim Tartary, easterly, and on the west, Lithuania, Poland, part of Hungary, Transylvania, Walachia, Bulgaria, and Moldavia. This Scythia had no other sea besides the Sarmatian, or Marc Scythicum, now called the Baltic, with the gulfs of Bothnia and Finland, and the White sea joining to the Northern ocean, all unknown to the ancients, if we except the Euxine and Palus Meotis, which bounded it on the south. Its lakes were those of Ladoga and Onega in Finland, unknown to the ancient Sarmatians. Their chief rivers on the south were the Donetz or little Tanais, Borylthenes or Dnieper, Bog, Tiras or Dniester, and the Ilterr or Danube, all which discharged themselves into the Euxine; and on the north-east the Great and Little Dvina, which run, the first into the White sea, and the other into the gulf of Finland, and therefore unknown to the ancients; and on the west the Viltula, which flowed into the Scythian sea, and divided Sarmatia from Germany.

The whole extent, therefore, of both Scythias, including the two Sarmatias, reached in longitude from the 20th to the 8th degree, or even beyond, and from the Alps to the promontory of Tabis, and traits of Anian; and in latitude, from Caucasian to the Arctic circle, above 28 degrees. Herodotus indeed says, that the Hyperboreans were not of Scythian race, but another kind of people, some of whom were Androphagi, or men-eaters, fierce and cruel; and others, viz. the Bald-heads, or Argrippians, a wife and peaceable people, esteemed feared by all their neighbours; but he speaks of them merely by report, and with diffluence; so that these regions were probably then unknown, if not uninhabited. The five cities of Scythia, which we have mentioned, were probably built after the time of Herodotus, who takes no notice of any metropolis; though he mentions a considerable branch of Scythians, called Royal Scythians, whom he places along the banks of the Tanais; this river, as he says, dividing them from the Astatic Sarmatians. The original Scythians of Herodotus (I. iv.) were confined, by the Danube and the Palus Meotis, within a square of 4000 italids (400 Roman miles). Diodorus Siculus (vol. i. i. ii. p. 155. ed. Wolf.) has marked the gradual progress of the name and nation. From the mouth of the Danube to the sea of Japan (says Gibbon, vol. iv.), the whole longitude of Scythia is about 110 degrees, which, in that parallel, are equal to more than 5000 miles. The latitude of these extensive defects cannot be so easily or so accurately ascertained; but from the 40th degree, which touches the wall of China, we may accurately advance above 1000 miles to the northward, till our progress is stopped by the excessive cold of Siberia. In that dreary climate, instead of the animated picture of a Tartar camp, the smoke which issues from the earth, or rather from the snow, betrays the subterraneous dwellings of the Tartoufes and the Samoiedes. The want of horses and oxen is imperfectly supplied by the use of rein-deer, and of large dogs; and the conquerors of the earth infensibly degenerate into a race of deformed and diminutive savages, who tremble at the sound of arms. Anc. Un. Hilt. vol. iv. See Scythians and Tartars.

SCYTHIAN, a word used very often in the old Greek writers on the materia medica, to distinguish the peculiar fort of gum, or other drug, brought from the Scythians. The Scythian and Indian drugs have been by many supposed different kinds of the same medicine; but this is an error; for it appears very obvious, on comparing the writings of Galen, Aetius, Magaceta, and other of the later writers among the Greeks, with those of Dioscorides, Theophrastus, and the other old ones, that the word Scythian and Indian mean the same thing, and that what the old writers have called Indian, these have called Scythian.

The meaning of this is, that those things were called Scythian, which were brought from the country of Indian-scythia, or that part of Scythia which lay at the offis of the river Indus; but it is to be observed, that though the later Greek writers mean this by their term Scythian, yet the word is used in a very different sense by the Arabian, Aviceقن, Serapion, and others; and that wherever they mention a drug under the name of Scythian, they mean that it comes from the northern parts of Scythia, on the confines of Europe. These authors having misunderstood this Scythia what the Greek writers have said of the other, have made no small errors in regard to the history of drugs, having given ibellium, and many other gums, the produce of only the Scythia of the Greek medical writers, to the frozen Scythia, before mentioned.

SCYTHIANS, in Ancient Geography, the inhabitants of Scythia, confounded by some geographical authors as the same people with the Tartars, or, as they are more commonly,
commonly, though erroneously, called, Tartars. (See Tar-
tars.) With regard to the etymology of the name of
Scythians we have many different conjectures. Plliny
seems to intimate, that this appellation is derived from
Sacaı, a people known by a similar name to the Greeks
and Persians. Bryant deduces it from Cuthia. Colonel
Valancey traces its origin to words denoting navigation;
or others derive it from the Greek word φῆται, which
expresses the fierceness of their countenance and natural
temper; and others again deduce it from the Teutonic
word feheno, to seat, in which art this nation is said by Her-
odotus, Lucian, and others, to be so expert, that the name
is given them on that account, the word Scythian properly
signifying a great boaster or archer. As the Tartars and
Muscovites called themselves Mogli, supposed to be an
abbreviation of Magogi, the sons of Magog; that of Scy-
thian might be either given to them by other nations, or
perhaps by the Celts, whose language did not originally
much differ from the Scythian or Teutonic. Sir William
Jones observes, that neither Scythian nor Tartar is a name
by which the people now under our consideration have ever
distinguished themselves.

The Scyths have been considered by some writers,
with regard to their antiquity and origin, as the same
people with the Goths, and as being the descendants of
Gomer, the eldest son of Japheth. To this purpose Her-
odotus, Ptolemy, and Justin have called the Scythians, who
emigrated into Asia, by some names, and attributed some
actions and places to them, which, upon closer examina-
tion, are found to have belonged to the Celts or Gome-
rians, whom they had driven out of their European terri-
tories. Strabo informs us, that the old Greek histori-
gans gave the name of Scythians and Celto-Scythians to all
the inhabitants of the northern regions, though it is plain
that many of them were properly Celts or Goths. And
he also adds, that some of those people who inhabited
beyond the Caspian sea, which should be the Scythians,
were, by the same Greek historians, called Scæc, and
others Mallagetae, though the former of these names, at
least, belonged only to the Celts. Hence many learned
men have chosen to reckon them as one people, branched
out into that variety of names and characters, under which
they are distinguished in history. See Celts.

Joscophas, who affirms the Scythians to be descended
from Magog, the next brother of Gomer, has been fol-
lowed by many of the fathers, and by many moderists,
because they could find no better authority. In the migra-
tion of the Scythian tribes into Europe, if Gomer's de-
cendants turned towards the N.W., those of Magog may
be reasonably supposed to have spread themselves towards
the N.E. into both Scythias, where we find the ancient
Muscovites or Tartarians; distinguished by the name of
Mogli, corrupted or abbreviated possibly from Magogi,
the sons of Magog. To these conjectures it may be
added, that there is scarcely a nation under heaven, that
so fully answers the fierce and dreadful character which
the Scriptures give us of Gog and Magog, as that of
the barbarous Scythians; though in fact this character
was too applicable to their neighbours in those early
ages.

Sir Isaac Newton is of opinion, that both the Celts
and Scythians had spread themselves over Lesser Asia
and Europe, before the year of the flood 1220, that is, about
the latter period of the Israelitish judges. How soon the
Scythians began to establish a regular government, and
what kind of government it was, it is impossible even to
conjecture. It appears, however, from the testimony of
Herodotus, that one or two tribes at least, that is, the royal
and free Scythians, were under a kind of monarchy, and
that these two distinguished themselves more than all the
others. Herodotus informs us, that in process of time,
when the Scythians were likely to be invaded by Darius,
their king, daring the invaders, invited all the Scythian
princes, viz. those of the Taurians, Agathyrhs, Neus-
rians, Androphagi, Melanchemians, Budeians, and Sarmat-
ians, to unite in giving him assistance. All these tribes
seem to have been branches of the same stock, but differing
much in their manners and customs. In consequence
of this application, the three last named nations joined
with the king of Scythia, but the others refused to succour
him, alleging that he was the first aggressor. Hence we may
conclude, that they had emancipated themselves from the
yoke of the royal Scythians some time before. As to what
the laws of the royal and free Scythians were, we may form
some judgment from the excellent character that is given of
them by ancient historians. Justin (lib. ii. cap. 2.) gives
the following account of them. The Scythians were a
nation, which, though inured to labour, fierce in war, and
of prodigious strength, could nevertheless control their
passions, that they made no other use of victories than to
increase their fame. Theft among them was reckoned to
be a great crime, and was so severely punished, that they
could let their numerous flocks wander from place to place
without danger of losing them. Thence they esteemed their
greatest wealth, living upon their milk, and clothing
themselves with their skins. Instead of houses, they used
to convey their wives and children about in covered wagons,
drawn either by horses or oxen, and made capacious enough
to carry all their other furniture. Gold, silver, diamonds,
pearls, and other costly stones, were as much defiled by
them, as they were esteemed by other nations, so that they
could not covet that which was of no use. What is still more
wonderful, those virtues, which the Greeks in vain endeav-
oured to attain by learning and philosophy, were natural
to them, and they reaped those advantages from their igno-
rance of vice, which the others could not derive from their
knowledge of virtue. A nation of this character and way
of life could therefore want but few laws to secure their
property; some others they had with relation to religion,
customs, and polity, which forbade, under pain of death,
any alteration in either; which excluded their women from
the benefit of marriage, and every man from allying at
their royal seal, till he had killed an enemy. Some other
of their laws we shall have occasion to mention in the sequel.
Upon the whole, what appears of them seems wholly cal-
culated to prevent luxury, fraud, and covetousness, and to
cherish that martial spirit, for which they are so justly famed
in history.

Some of the Scythian tribes, indeed, bear a quite dif-
ferent character, being represented of such fierce and cruel
disposition, as even to eat the flesh of their enemies. Thence,
if under the same government, were at such great distance
from the centre of it, as to be out of the reach of its laws.
As the inconstancy of the air in these remote regions might
probably incline them to cruelty; so the distance and bar-
renness of their country might make them less heeded, and
probably more incapable of being restrained by the com-
mon regulations of society. However, it must be owned,
with respect to the warlike temper even of the true Scy-
thians, that it was not without a mixture of cruelty, if
they have not been willfully misrepresented by the Greek
historians.

If we may reason from some successions which we find men-
tioned in history, it seems their crown was hereditary, and
yet
yet their kings not so despotic as not to be deposed, or even put to death, for the violation of their laws.

When any one of their monarchs fell sick, it was their constant custom to send immediately for three of their most famous prophets, who commonly told him that some Scythian, whom they named, had perjured himself by sacrificing to the royal throne, which it seems was their most solemn oath. The accused person was therupon seized, and brought before the king. If he denied the fact, more prophets were sent for; if they confirmed the evidence, the man was immediately beheaded, and his goods were divided among the three first accusers. But if they acquitted him, a supply of goods was to be sent for; and if the majority of them absolved him, then the first accusers were tied hands and feet, and set in a cart loaded with faggots, and drawn by oxen: after they had flung the false prophet’s mouth, as he was then flayed, they set fire to the wood, which consumed the cart and man, and seldom failed burning the oxen to death. Our author adds, that the male children of those whom the king condemned to death seldom escaped the same fate.

Another instance of their great respect to their monarchs is the pompous solemnity of their funerals, which was performed as follows: the embalmers received the body covered with wax, they opened and cleansed the belly, and having filled it with bruised cypresses, incense, parsley, and aniseeds, they sewed it up again, and placed the corpse in a chariot, and conveyed it from one tribe to another throughout all the provinces of the kingdom. Every province, where they received the funeral procession, was obliged to imitate the royal Scythians in their mournful ceremonies, which consisted in cutting off one part of the ear, shaving the head, and piercing the left hand with an arrow; in this guise, they accompanied the hearse to the next province, till it reached that of the Gerrians, which was the remotest in the kingdom, situated along the part of the Borylthenes, where it begins to be navigable. Here the corpse was deposited in a large square hole made in the earth, upon a bed enveloped round with ipcars, which they covered with timber; and spread a canopy over the whole monument. In the vacant places of it they deposited one of his favourite concubines, his head cook, groom, a waiter, a meflanger, some horses, all jangled, and a number of necessary utensils, and among others some golden cups. Then they threw the earth upon it, so as to raise a high mound, or artificial mountain. As soon as the year was expired they chose fifty young men of the king’s officers, who were always to be Scythians of quality. These, with an equal number of horses, were strangled, their bowels were taken out, and their bellies stuffed with straw. The bodies of the men were set allride upon the horses, and fastened to them by an iron stake. The horses, thus mounted, were set upon semicircular boards, supported by four pieces of timber, and placed at a convenient distance from each other round the monument, the horses having a loose rein fastened to another poll set up for that purpose.

The Scythians worshipped a plurality of gods and goddesses, but that which they reckoned their principal deity was Veja, whom they called Tabit. The two next in generation were Jupiter, whom they called Papeus, and Apia, or the Earth, which they esteemed his wife. Jupiter, it seems, they challenged for their progenitor, and Veja for their queen, as appears by the answer which one of their kings sent to Darius, when he came to subdue them to his empire; besides these, they worshipped Apollo, the celestial Venus, and Neptune, under the names of Octyru, Strippafa, and Thamimafades. But their favourite deity seems to have been the god of war, to whom alone they dedicated temples, altars, and images. How his temples were built, Herodotus doth not tell us; neither is it easy for us to guess. It doth not even appear from any ancient authors, or other monuments, that ever they built any properly so called. Groves indeed they were familiar for erecting to this deity. In these they affected the see one or more oaks of a mighty size, which were accounted so sacred, that to top them as much as a branch or twig, or even to wound the bark, was accounted sacrilege, and punished with death. These oaks they never failed to sprinkle plentifully with the blood of their victims, infomuch, that the sand of some of the olden of them was covered or even encrusted with it. We are therefore inclined to believe, that Herodotus, who learned these things by report, might, for want of a good interpreter, mistake them for temples, and suppose them to be built like those of other nations.

Besides the deities above named, we are told that some of them worshipped fire as the principle of all things, and gave it the name of Vulcan; they used to swear by the wind, and the sword, the one as the author of life, and the other of death. They likewise looked upon Zamoizis as a deity, to whom they committed the spoils of the dead, and offered sacrifices on their behalf. The royal Scythians are confirmed by Herodotus to have acknowledged all the deities above named, and to have offered sacrifices to Neptune in particular; for all these various deities they had not, indeed, temples, but altars and groves, and a set of priests appropriated to each.

How sanguine those groves must have been, may be seen in the last quoted antiquarian, or be guessed at by the vain extent of the altars, which Herodotus tells us they erected in them to Mars, their favourite deity, one of which at least they were obliged to have in every district. It was made of small wood tied up into bundles, and covered three filda of land in length and breadth, though it was not proportionable in its height. The top of it, which was quadrangular, had three sides perpendicular; and the fourth had a gradual declivity, to render the top of it easy of access. One hundred and fifty loads of faggots were to be brought yearly to each altar, to supply those which had been decayed by the inclemency of the winter. On the top of each of those heaps was erected an old iron emblem, which floated there as the image, or rather emblem of the deity. To him, besides all other cattle, in common with their other gods, and in much greater number, they sacrificed horses; and what was more shocking, every hundredth man they took prisoner from their enemies. The priest having poured a libation of wine upon the captive’s head, cut his throat, and received his blood into a bowl, with which ascending to the top of the altar, he washed the deity’s sword. As to the victims, they only cut off his right arm close to the shoulder, and throwing it up into the air, left it exposed in the place where it fell, and the rest of the body in that where it was killed.

Of the victims which they sacrificed to Mars or to any other deity, the horse was esteemed the noblest, and the most acceptable. As for oxen they detested them, and would not suffer any to remain among them. The Scyths also offered to their gods the first fruits of the earth, the firstlings of their cattle, and a part of the spoils they took in war; sending a considerable part of the latter to the Delphic Apollo, by a number of their honourable virgins, under a sufficient escort.

Their alliances and contracts were ratified with the following ceremonies: they poured some wine into an earthen vessel,
SCYTHIANS.

vefpel, into which the contracting parties were to mingle fome of their own blood, which they drew by a flight in-
cifion made in the finger, hand, or fome other part of the
body. They then dipped into the mixture the point of
fome warlike weapon, fuch as a feimtar, arrow, dart,
javelin, or battle-ax. The parties then uttered fome dire
imprecations on the first breaker of the covenant, and,
having each of them taken a draught of the liquor, they
defined fome of the moft confiderable among the by-
flanders to pledge them, and to be witnesses of the con-
tract, which was reckoned fo sacred, that they thought
no punishment fevere enough, either in this life or in the
next, for thofe by whom it fhould be violated.

Their warlike temper and exploits were sufficiently
known to the ancients; scarcely is there any nation to be
met with in history, fo famous for conquering wherever
they carried their arms, even as auxiliaries, and themselves
remaining ftill unconquered. Their frugal and fimple
manner of life, may indeed be fuppofed to have been a great
prefervative againft fuch invasions, as other more opulent
and luxurious nations were expofed to. But it is plain,
this was not always the cafe, fince we find they were once
invaded by the king of Perfta at the head of a moft puiffant
army, from the power of which nothing but their valour
and policy could have delivered them. Upon the whole,
fuch were their ftrength and courage, whenever they entered
into an offensive or defensive war, that, as Thucydides him-
felf tells us, no nation, either in Europe or Asia, could equal
them either for ftrength, valour, or conduct; nor could
any thing refit their power, when they were unanimous
among themfelves.

Such care they took to cultivate this martial genius,
that even their women were inured to it betimes, infomuch
that no woman could be admitted into matrimony till she
had killed at lead one enemy with her own hands. As
for their youth, they were not without confiderable en-
couragements to infpire them with martial valour, or rather
ferocity, if we may rely upon the information of Her-
odotus, who tells us that they were wont to drink the blood
of the firft prisoner they took, and to prefent the heads of
all the men they killed in fight to their monarch; there
were either returned or registered, and the warrior enjoyed
privileges in proportion to the numbers he had slain. They
ufed to take the skins of the slain, to fretch, dry, and tan
them, and then hang them at their horfes' bridles, where
they ferved both for trophies and napkins to the owner;
he being alfo moft elfeemed, who had the greateft num-
erb to display. Their pride, or rather barbarity, went fo
far, that they took off and dreffed the whole skin of the
flain, and covered both their quivers and horfes, and some-
times decked their own bodies with them; and ufed their
skulls for drinking cups.

Had they only exercifed this kind of favage pride againft
thofe who came to invade them, it might indeed admit of
fome excuse; but it doth not appear that they gave much
better quarter to thofe whole territories they invaded.

In confequence of their living free from ambition and
care, and eating plentifully of animal food, they acquired
ruddy complexities, and became fo plump and fameine,
that, to prevent their growing too unwieldy, they not only
ufed a great deal of exercife, but even cauterized their
arms, shoulders, backs, and breasts, with a view to draw
off superfluouf moifure. They were remarkable for their
fidelity and friendship, which they elfeemed and glorified
above all things. They commonly confirned their friend-
ship by fome religious ceremony or oath, as we have
lately mentioned, but a Scythian feldom diffufed his attach-
ments to more than two or three individuals, elfeeming it
very difficult, if not impossible, to keep it inviolate with a
greater number. And when fuch a friendship was once
contracted, there was no danger or death which they would
not expose themselves to for one another.

They were not more difposed to friendship, than addicted
to resentment and revenge. If a man had received an in-
jury, which he was not in a capacity to retaliate, the cupof
was for him to sacrifice a bullock, and to roaf the flefh of
it in fmall pieces. Then he defpanded the hide upon the
ground, and fat upon it, holding his hands down behind
him as if they had been tied; upon which was all that
beheld him, whether friends, relations, or strangers, came
to inform themselves about the injury and injurer, and if
they favoured his caufe, took up a piece of the meat, fet-
ing their feet upon the hide at the fame time, promifing
affifiance accordingly; one perhaps sent him five men and
horfes, another ten, more or lefs, according to their cir-
cumstances, or the nature of the injury.

How populous the Scythians were, we have not been
able to discover. If it be allowed that they made frequent
and bloody invadings one upon another, we cannot but but
fuppofe that it muft have leffened their numbers exceedingly.
On the other hand, if we confider their plain and laborious
way of living, their climate, confant exercife, and other
advantageous circumftances, which rendered them hardy
and fit for proflific and long lived, we can hardly conceive
they could be other than a populous nation: for we are
told, that very few died of ficknefs, but that in general
they lived to a good old age, infomuch, that many of them
being weary of the world, before death took them out of
it, it was usual with fuch to defeat their exit by throwing
themselves from an eminence into the sea, or into some river.
Herodotus, however, who feems in doubt whether they
were fo populous as fome, or fo thin as others reprefent
them, gives us an authentic instance and monument in
favour of the former, which is as follows: they had, it
feems, a cupof, not uncommon to other nations, at their
firft taking of the field to mutter their fighting men, and
to make every man call an arrow into a proper receptacle,
which at their return from the expedition was again taken
up. By this expedient they could easily compute not only
the number of their men, but alfo that of their fkins, or
of thofe who either deferted, or abfonced themfelves from
the war. It was at some fuch mufher as this, that one of
their kings, whom Herodotus names Ariantes, being pre-
fent, and obferving these heads of arrows to amount to an
immense bulk and weight, as he had indeed a prodigious
army under him, ordered them to be melted and caft, and
made a large capacious veftel, which our author tells us
was still extant in his time; and, though full fix inches
thick, was large enough to hold fix hundred amphorae,
that is about fifty hogheads, and remained a monument
of this prodigious army. What feems to be a stronger
argument of their being populous, is, the fuccedence of colonies
which they fent out, chiefly towards the southern parts
of the world.

The Scythians cultivated no arts or sciences, except
that of war, nor did they pay much attention to trade or
commerce, or any fpecies of agriculture except paffurage.
Their mode of living was altogether incompatible with
commerce. They do not feem to have known any thing of
writing, until they brought it with them from Asia, after
their twenty-eight years' invasion of that country.

Their language is very much unknown to us; but the
extent of their territories and their intercourse, and inter-
mixing with various other nations, muft occasion a great
number
SCYTHIANS.

number of dialects, from which most probably have sprung the Muscovith, Slavonic, Polich, Danish, Swedish, Saxon, and many others; between which one can but barely discover affinity enough to evince their origin from the same mother. A great number of words and phrases that are found not only in those northern languages, but also in the Latin, Greek, Arabic, and Peric, show them to have been so many dialects of the old Celt. If those few relics of the Scythian, which we have left in the names of their kings, tribes, and districts, do not so plainly appear to be of the same extraction, we must remember they have passed through so many different hands, and have so often changed their drefs, especially among the Greeks, that they may be easily suppos'd to have quite lost their ancient form. We may add, that some of them are perfectly Greek, or translated from the Scythian into that language. Of this kind is the name of the Oecenes, a Scythian tribe, so called in Herodotus, from their living upon the eggs of wild-fowl, and derived from the Greek ἑεα. The Nomades were so called from ὑπαρχ, past, Of the fame extraction were the Hyppodes, Androphagi, and some others.

Their chief manufactures feem to have consist'd mostly in building waggon's for their families and baggage, which being covered with the skins of beasts, shews that they must have had some notion of tanning and d'ressing leather. We may likewise reasonably suppos'e, that they fabricated their own weapons, which were scimitars, javelins, axes, but especially bows and arrows, at which they are said to be fo expert, that their very children were trained to shoot at a mark, even as they rode on horseback; infor'mu'm that it became a common proverb, "that the Scythians were as dextrous at their bows as the Greeks were at their lyre." Hence Cyxares, king of Media, is reported to have sent his son to be brought up under them, to learn the use of the bow. They were fo expert in horfemanship, as to have acquired the epithet of ἑτοδυναμον by Herodotus and Lucian. Their women are affirm'd to have been so well trained to riding and shooting, that they did not fall short of the men in those exercises. The ancients observe, that they had neither mules nor asses; and the reason they give is, that the country was too cold for those creatures. Experience has shewn the contrary, at least with respect to the latter; but the true reason seems to be, that the horses, which they bred in great numbers, could answer all the purposes of the other two species, and at the same time be more swift and expeditious.

As for agriculture, it doth not appear that they had any. Herodotus indeed tells us of one province, whose inhabitants called themselves Olbiopolitans, and the Greeks Bothyrians, as they lived on the north side of that river; and these he likewise called husbandmen, because they sowed grain, not for food, but for sale. But the rest of the Scythians wholly neglected it, chusing rather to roam where they found the best pasturage for their cattle, and contenting themselves with the spontaneous products of the earth, without being at the trouble of manuring it. And this is in all likeliness the cause we read of so many deferts, forsets, and large uninhabited tracts of land between tribe and tribe, in the writings of ancient historians and geographers. How they dispof'd of the wool of their flocks we know not, but, by their clothing themselves with the skins of wild or tame beafts, we may conclude they did not manufacture it into cloth; and as those skins were of their own d'ressing, they wanted hall the help of foreign manufactures. Smiths they must have had for making their arms, waggon's, and other necessary tools. As to their arrows, darts, and javelins, if their heads were made of copper, they were probably cast in moulds. They used standards of a particular make, which, when blown open by the wind, exhibited the figures of serpents and dragons of several shapes, and these were commonly borne by men on horseback.

Their chief riches and food consisting in their numerous herds, they entrusted the care of them to shepherds, who were a lower rank of Scythians, below the martial men, though they too had slaves and captives in their service. They used to move from pasturage to pasture, with the persons and families which were unfit to go to the wars. These chiefly lived upon honey, cheese, and milk, more especially that of their mares, from which creature, if Herodotus was rightly informed, they had a strange way of forcing plenty of it, by blowing wind into the privities; but their chief and choicest food was the venison they killed. What provisions the warlike Scythians made, when they were absent from their flocks, we cannot guess; it is probable when they came into an enemy's country, they feiz'd upon all the cattle they could meet with; and when that failed, they had recourse to a composition they carried about them, of which we shall speak presently.

From an instance or two of their kings, we conclude, they allowed of polygamy, and were not over-strict in their marriages. Plato seems even to intimate that they had their women in common, though, if any such custom prevailed among them, it must have been only among the more savage part, for the royal and free men had wives; and some of their kings we read of, who took them from other nations, and of one of them who married his own father's widow; but whether the fame liberty was allowed to private men we cannot affirm. The reason the Scythians gave for abhorring the Bacchanalian feats of the Greeks, namely, that it was abus'd to suppos'e, that a god should drive men to all the violent transports of madness, seems to shew that drunkenness was not common among them. And indeed we do not find that they were much addicted to feasting. Plutarch, in his Banquet of the Seven Wife Men, says, "that they neither had vines, nor players on instruments, nor public games." One wine-feast they kept however once a-year in every district, for those who had signalized themselves by killing one or more of their enemies. Another we read of, which was used at funerals. Some others they might have upon other occasions not worth enquiring after; but in general, they were remarkably abstemious, except in their affections for their favourite women. They talked little, but concisely and nervousl, especially about their warlike affairs. They commonly travelled on horseback, or in their domestic vehicles. When they had any rivers to cross, they laid their horse's faddle and weapons upon a skin filled with cork, and so well, that not a drop of water could get into it; they then laid themselves down on it, and taking hold of their horse by the tail, made him swim to the other side. They carried with them a certain composition, in small pieces like pills, one of which, upon occasion, would yet afford sufficient nourishment for several days. Pliny adds, that they used the like expedient with their horses, by means of what he calls the Scythian weed, upon the strength of which they could travel ten or twelve days without eating or drinking.

When any person died, his nearest relations caused his embalmed body to be carried in a chariot from house to house among his friends and acquaintance, who received and seated them in their turn, setting part of the banquet before the deceased. This ceremony was continued forty days, after which the person was buried, and his attendants
endants purified themselves, not by any ablution, but by
the smoke of some hemp-feed peculiar to the country,
which being thrown upon burning fumes, emitted a much
more agreeable perfume than the frankincense used in
Greece, and intoxicated the company, who concluded the
ceremony with hideous thicks. This served instead of
washing, which the Scythians never practiced; not even
the women, who used instead of it to anoint their bodies
and face with a paste, made of cypreces, cedar, and franki-
cence, ground upon a rough floue, and soaked in water,
which paste being taken off next day, rendered their skins
clean, firming, and sweet.

Hitherto we have confined our chief attention to the
royal Scythians; but there were other tribes or petty king-
doms that demand some transient notice.

The Samiritans are affirmed by Herodotus to have been
the offspring of the Scythians and Amazons. These war-
like women, or as their Scythian name, Aior Patta, im-
ports, man-flayers, in their flight from the Grecians, having
landed near the precipices of the Plaius Maotis belonging
to the free Scythians, and having been persuaded to be
married to them, did in their turn prevail upon them to
leave that part of Scythia, where they pretended they could
not conveniently live with them, and to pass into the pro-
vince of Sarmatia on the other side of the Tanais. Hence,
our author says, the Samiritan women retained still the
Amazonian temper and way of life, being more warlike
than the rest of the Scythian females, and the language of
the country became a corrupt Scythian, because the Amaz-
ons never could perfectly learn that language, but taught
it their offspring, corrupt as themselves spoke it. Here it
chiefly was, that a virgin was unqualified for marriage,
till the had dispatched an enemy in the field.

The Taurians had this inhuman custom, that they sacri-
fied to a virgin all that were shipwrecked, and all the
Grecians whom they caught upon their coasts. This
bloody offering was performed by knocking the person
on the head with a club, after many dire imprecations, and
flinging his carcasse down the hill on which their temple
was built, or as others told our author, by burying the
body, and referring only the head to be stuck on a pole.
These Taurians pretended, that the virgin daemon whom
they thus worshipped, was Iphigenia, Agamemnon's daughter.
They lived chiefly by war and rapine, and were very cruel
to those that fell into their hands. The Agathyrians are
said to have had their women in common, in order to link
the men more strictly together, and to prevent jealousies,
and other ill effects of matrimony. The Neurian province
being infested with dangerous serpents, they were at length
forced to leave it for that of the Buddians. They observed
the customs of Scythia in most particulars, only pretended
to greater skill in magic than they, and were reported to
be transformed into wolves for some part of the year, after
which metamorphosis, they resumed their own shape; an
allegory which is supposed to mean no more than their
wearing of skins with the fur outward during the cold
weather. The Neurians are mentioned also by Pliny, Mela,
and Steph. of Byzantium.

The worst of all were the Androphagi, or men-eaters,
who observed neither laws nor justice, and had nothing in
common with the rest, but their drear and occupation of
breeding cattle. The Melanchemenas were so called for
afflicting to go always in black; they followed the Scy-
thian customs, except that they fed upon human flesh,
which the free Scythians did not; nor indeed did any other
tribes use it, at least as common food, but only on some
particular occasions. The Buddians were a populous nation,
famed for blue eyes, and red hair: in this province, above
all the rest, did they build them a city, and called it Ge-
lonus, whose houses and high walls were of timber, and
each side of the walls was three hundred feet in length;
it had temples and chapels dedicated to the Grecian gods;
and here they celebrated the Bacchanaalia triennially.
The people of the province differed from those in the city,
in that the former applied themselves to the keeping of cattle,
and to the tillage and planting gardens, living upon the
products of them, and of their corn fields: in a word, these
Gelonians were so much more civilized in their manners
than the Buddians, that they seemed quite another people.
They are suppos'd to have been of Greek extract, and to
have been in time quite blended with the Buddians, who
were of Sarmatian origin, and contiguous to them; and
Herodotus observes, that each preferred their own native
language. The Gelonians learned, among other things, the
custom of painting their bodies from the Sarmatians, whence
that verse in Virgil's Georgics, xii. v. 115.

"Eosque domos Arabum pictoque Gelonos."

This province abounded with otters and beavers, which
afforded skins for wearing, and called for medicine.

The Iatria, Grecians, having taken the country on the
north-west of the Caspian sea, and the Massagetes on
the west. For an account of the Amazonis, we refer to
that article. The Nomades differed but little from the royal
Scythians, except in this appevative, that it is needless to say
more concerning them, than that they led a wandering life,
living no longer in one place than they found plenty of
pasture for their cattle; which being consumed, they
removed to fresh grounds; and, when called to the wars,
left their families and flocks, with their shepherds, till
their return. Pliny places them on the left side of the
Caspian sea, and says the river Panticas parted them
from the Georgi. Strabo adds, that they lived in waggons
instead of houset. (See Nomades.) For an account of the
Massagetes, see Massagetes.

Madyes was a warlike prince, and it was under his con-
duct that the Scythes, having driven the Cummerians, or
northern Celts, out of Europe, and pursued them into Afa,
invaded the country of the Medes, and held the greater part
of Upper Afa in subjection for twenty-eight years. As
Scythia did not afford a sufficient supply of food for its
numerous inhabitants, they discharged the superfluous mult-
tudes towards the more fertile south; and having rapidly
passed into Afa, their victorious army was led into Egypt.
Here they made some incursions into the land of the Phi-
litines; and in this expedition they are said to have taken
the city of Bethanc from the tribe of Manafelah, on this
side of Jordan, and to have called it, after their own name,
Scytopolis,
Scythopolis, or the city of the Scythians. In their return to Syria, some of them plundered the temple of Venus at Acalon, and for their sacrilege were punished with a kind of flux of blood, common to the female sex, which descended to their posterity as a mark of infamy. Thomyris, or Tamiris, was that heroine whom, we are told by Herodotus, Cyrus the Great demanded in marriage. Indathyrus was the magnanimous prince who, having received from Darius, the Persian king, the proud challenge implied in the demand of earth and water as a token of subjection, sent him this remarkable reply; that as he acknowledged no lord but his progenitor Jupiter, and Vella, queen of the Scythians, he would shortly fend him a more suitable present, such as might, perhaps, make him repent of his arrogance. This present, confining of a bird, a mouse, a frog, and five arrows, was afterwards dispatched to him, without any application. Gobiros explained to Darius the meaning of this present, which the king had understood to be a token of submission, intimating that the Persians must not hope to avoid the effects of Scythian valour, unless they could either fly like birds, plunge under water like frogs, or bury themselves in the earth like mice. The Persian monarch invaded the Scythian territory; but the result of the expedition was that he was forced to retire with the loss of the greatest part of his numerous army, and glad to escape with his own life, though at the expense of his glory. Saulius was the king of Scythia, according to Jullian, was Laminus. For further particulars relating to the Scythians, we refer to Herodotus, Diodorus Siculus, Jullian, Mela, Anc. Univ. Hist. vol. iv.; Gibbon's Hist. of the Decl. &c. of Roman Emp. vols. i. iv. v. vi.; and Sir W. Jones's Fifth Difcourfe, apud Works, vol. iii. or Af. Refercures, vol. ii. See also Celts, Gete, Goths, Hunis, Sarmatians, Saxons, Scandians, and Vandals.

SCYTHICUM LIGNUM, in Botany, a name given by the ancients to a tree called feytharia by the later writers of the Greeks.

SCYTHOPOLIS, in Ancient Geography, a town of Syria, in a province called Decapolis.

SCYTHRANUS PORTUS, a port of Africa, in Marica, between Antipyrus and the Catanun Promontorium, according to Ptolomy.

SCYTHROPS, in Ornithology, a genus of birds of the order Pice. The generic character is, bill large, convex, sharp-edged, channelled at the fides, hooked at the point; nostrils naked, rounded at the base of the bill; the tongue is cartilaginous, split at the point; the feet are formed for climbing. This genus, of which only a single species is known, is nearly allied to the Ramphastus, from which it principally differs in the greater strength and fleshy parts of the bill, and in having the tongue entire at the fides, and bifid at the tip.

Species.

PSITTACEUS. This bird has obtained different trivial names. From the circumstance that it is found in New Holland; where, by the way, it is sometimes seen in small flocks, but more frequently in pairs, generally in trees, and uttering, during flight, a loud screaming noise, not unlike the crowing of a cock; it is called by some the Australafian Channel-bird; by others, the New Holland Channel-bird; and by some, Psittaceous Hornbill. By Dr. Shaw, it is specifically described as the lead-coloured channel-bill, with the tail-feathers barred with black and white. It is about the fize of a crow, and measure in total length about seventeen inches, of which the bill measures four inches. The general proportions of the bird somewhat resemble those of the cuckoo, but with a longer and more cuneated tail. The colour of the upper parts of the body, wings, and tail, is deep blueish ash-brown, the tips of the feathers somewhat more intense than the reft; the head, neck, and under parts of the bird, are of a pale grey, or dove-colour; the two middle tail-feathers have a black bar near the tip, which is white; all the remaining tail-feathers are ash-brown externally, but on the inner webs are white, crossed by numerous black bars, and marked, like the middle ones, by a broader black bar near the end, the tips being white; the eyes and nostrils are feated in a reddish naked skin; the bill and legs are of a pale yellow, the former are marked on the upper mandible by a longitudinal dusky streak or two, and on the lower by three or four dusky bars near the base. Dr. Shaw has given a figure of this bird, but it may be doubted whether, with respect to magnitude, it is calculated to convey just ideas of the bird itself.

SCZEBRZESZIN, in Geography, a town of Austrian Poland, in Galicia; 5 miles W. of Zamoieie.

SCZEDRONHORST, a town of Lithuania; 60 miles S.E. of Brzez.

SCZUCZY, a town of Poland; 35 miles S.W. of Sandomirz.

SDUR, a town of Arabia, in the province of Hadsjas; 20 miles S.S.E. of Sucz.

SE, or Tse, a city of China, of the second rank, in Ho- nan. N. lat. 36° 25'. E. long. 114° 14'.

FE, Felo de. See Felo.

FE, Per. See Perfe.

SEA, Mare, in Geography, is frequently used for that vast tract of water encompassing the whole earth, more properly called Ocean; which lee.

For the cause of the saltiness of the sea, fee Saltiness.

Sea is more properly used for a particular part or division of the ocean, denominated from the countries it washes, or from other circumstances.

Thus we say the Indic sea, the Mediterranean sea, the Baltic sea, the Red sea, &c., which see respectively.

Till the time of the emperor Julian, the sea was common and open to all men; whence it is that the Roman laws grant an action against a person who shall prevent or molest another in the free navigation or fishing therein.

The emperor Leo, in his fifty-sixth novel, first allowed such as were in possession of the lands, the sole privilege of fishing before their respective territories, exclusive of all others; he even gave a particular commiffion to certain persons to divide the Thracian Bosporus among them.

From that time, the foreign princes have been endeavouring to appropriate the sea, and to withdraw it from the public use. The republic of Venice pretends to be far more in their gulf, that there is a formal marriage every year between that kingdom and the Adriatic.

To confirm this right, those who contend for it have alleged the example of Uladius, king of Naples, and the emperor Frederic III., and of one of the kings of Hungary, who requested the Venetians to permit them to pass through their sea. The empire belongs to the republic to a certain distance from the coast, in the places of which it can keep possession, and which it is of importance to hold in regard to its own safety, appears, says Vattel, to be incomprehensible; but he very much doubts, whether any power is at present disposed to acknowledge her sovereignty over the whole Adriatic sea.

In these last ages, the English have particularly claimed the empire of the sea in the Channel, and even that of all the seas encompassing the three kingdoms of England, Scotland, and Ireland.
Ireland, and that as far as the shores of the neighbouring states. In consequence of which pretension it is, that children born in these seas are declared natural Englishmen, as much as if born on English ground. The justice of this pretension is strenuously argued between Grotius and Selden, in the *Mare liberum,* and *Mare clausum.*

The use of the open sea consists in navigation and fishing; along its coasts it is likewise of use for the procuring of several things found near the shore, such as shell-fish, amber, pearls, &c. for making of salt, and, in short, for the establishment of places of retreat and security for vessels. The open sea is in its own nature not to be exclusively possessed, as no one is able to settle there so as to hinder others from passing. But a nation powerful at sea may forbid others to navigate it and to fish in it, declaring that it appropriates its dominions to itself, and that it will destroy the vessels that shall dare to appear in it, without its permission. Vattel, a highly approved writer on this subject, investigates its right to do this. It is evident, in the first place, that nobody has a right to appropriate to himself the use of the open sea: for he who navigates or fishes in it does no injury to any one, and the sea, in both these respects, is sufficient for all mankind. Nor does nature give to any man a right of appropriating to himself things that may be innocently used, and that are inexhaustible, and sufficient for all; since, every one being able to find in their state of communion sufficient to supply their wants, to undertake to render themselves sole masters of them, and to exclude all others, would be to deprive them, without reason, of the benefits of nature. Although the law of nature approves the rights of dominion and property, which put an end to the primitive manner of living in common, this reason could not take place with regard to things in themselves inexhaustible, which cannot therefore be equally appropriated.

If the free and common use of a thing of this nature was prejudicial or dangerous to a nation, the care of its own safety authorized it to submit, if possible, that thing to its dominion in order to permit the use of it, with such precautions as prudence should direct. But this is not the case with the open sea, in which people may fall and fish without the least prejudice to any person, and without putting any other people in danger. No nation then has a right to lay claim to the open sea, or to appropriate the use of it to itself to the exclusion of others. The kings of Portugal have formerly arrogated to themselves the empire of the seas of Guinea and the East Indies; but the other maritime powers gave themselves little trouble about such a pretension. The right of navigating and fishing in the open sea being then a right common to all men, the nation which attempts to exclude another from that advantage does an injury, and gives a sufficient caufe for war: nature authorizing a nation to repel an injury; that is, to make use of force against any one who would deprive it of its rights. Besides, a nation which, without a title, would arrogate to itself an exclusive right to the sea, and support it by force, does an injury to all nations whole common right it violates; and all are at liberty to unite against it, in order to repel such an attempt. However, as each has the liberty of renouncing its rights, a nation may acquire exclusive rights of navigation and fishing by treaties, in which other nations renounced, in its favour, the right they derive from nature. These are obliged to observe their treaties, and the nation they have favoured has a right to maintain by force the possession of its advantages. Thus, the House of Austria has renounced, in favour of England and Holland, the right of sending vessels from the Netherlands to the East Indies. Many examples of like treaties may be found in Grotius, "De Jure Belli et Pacis," lib. ii. cap. iii. § 15. The rights of navigation, fishing, and others that may be exercised on the sea, are imprejcribible; they cannot be lost for want of use; consequtently, when a nation finds that itself alone has from time immemorial been in the possession of a navigation or fishery in certain seas, it cannot, on this foundation, attribute to itself an exclusive right to them. But it may happen, that a want of use may be attended with the nature of a consent, or a tacit pacif, and thus become a title in favour of one nation against another. When a nation in the possession of the navigation and fishery in certain latitudes, pretends an exclusive right, and forbids any other interfering in it; if these obey that prohibition with sufficient marks of acquiescence, they tacitly renounce their right in favour of the other, and establish a right which the other may afterwards lawfully maintain against them, especially when it is confirmed by long use.

Nevertheless, the sea near the coasts may become property; so that the nation to which the coasts belong may appropriate to itself an advantage which it is considered as having taken possession of, and made a profit of, in the same manner as it may possess the domain of the land which it inhabits. But if, so far from taking possession of it, it has once acknowledged the common right of other nations to come and fish there, it can no longer exclude them from it; it has left that fishery in its primitive freedom, at least, with respect to those who have been in possession of it. The English not having taken the advantage from the beginning of the herring fishery on their coast, it is become common to them with other nations.

A nation may likewise appropriate things, where the free and common use of them would be prejudicial and dangerous. This is a second reason for which powers extend their dominions over the sea along their coast, as far as they are able to protect their right. It concerns their safety and the welfare of the state, that the whole world be not permitted to come near their possession, especially with men of war, as to hinder the approach of trading nations, and disturb navigation. These contiguous parts of the sea, thus subject to a state, are comprehended in its territory; nor can any one navigate them in spite of that nation. But it cannot refuse access to vessels not suspected, for innocent uses, without violating its duty; every proprietor being obliged to grant a passage to strangers, even by land, when it may be done without damage or danger.

It is not easy to determine to what distance a nation may extend its rights over the sea by which it is surrounded. Bodinus pretends that, according to the common right of all maritime nations, the prince's dominion extends even thirty leagues from the coast. But this exact determination can only be founded in a general consent of nations, which it would be difficult to prove; each state may, in this respect, ordain what it shall think best, in relation to what concerns the citizens themselves, or their affairs with the sovereign; but between nation and nation, all that can be reasonably said is, that, in general, the dominion of the state over the neighbouring sea extends as far as is necessary for its safety, and it can render it respected; since, on the one hand, it can only appropriate to itself a thing that is common, as the sea, so far as it has need of it, for some lawful end; and, as to the other, it would be a vain and ridiculous pretension to claim a right that it was no ways able to cause to be respected. The fleets of England have given room to its kings to attribute to themselves the empire of the seas which surround that island, even as far as the opposite coasts. (See Selden's "Mare Clauum.") Selden relates a solemn act, by which it appears that this empire, in the time of Edward I., was...
acknowledged by the greatest part of the maritime nations of Europe; and the republic of the United Provinces acknowledged it, in the same manner, by the treaty of Breda, in the year 1667, at least so far as related to the honours of the flag. But solidly to establish a right of such extent, it is necessary to shew very clearly the express, or tacit, consent of all the powers concerned. The French have never agreed to this pretension of England, and in the same treaty of Breda just mentioned, Louis XIV. would not even suffer the Channel to be called the English Channel, or the British sea.

The banks of the sea belong incontestibly to the nation that possesses the country of which it is a part. The ports and harbours are manifestly a dependance, and even a part of the country, and consequently are the property of the nation. The same observation is applicable to the bays and islets. With regard to islets in particular, that serve for a communication between two seas, the navigation of which is common to all, or to many nations, he who possesses the islet cannot refuse others a passage through it, provided that passage be innocent, and attended with no danger to the state. Nothing but the care of his own safety can authorize the master of the islet to make use of certain precautions, and to require the formalities commonly established by the custom of nations. He has a right to levy small duties on the vessels that pass, on account of the inconvenience they give him, by obliging him to be on his guard; by the security he affords them in protecting them from their enemies, and keeping of pirates at a distance; and the expense he incurs by maintaining light-keepers, sea-marks, and other things necessary to the safety of the mariners. As to the right of wrecks, see Wreck.

If the sea is entirely enclosed by the land of a nation, with only a communication with the ocean by a channel, of which that nation may take possession, it appears that such a sea is no less capable of being occupied and becoming property than the land; and it ought to follow the fate of the country that surrounds it. The Mediterranean was formerly included within the lands of the Romans; and these people, by rendering themselves masters of the islet that joins it to the ocean, might subject it to their empire, and add it to their domain. They did not by these means injure the rights of other nations; a particular sea being manifestly defined by nature for the use of the countries and the people who surround it. Besides, in defending the entrance of the Mediterranean from all suspected vessels, the Romans secured at once the immense extent of their coast; and this reason was sufficient to authorize their possession of it. And as it has an absolute communication with none but their state, they were at liberty to permit or prohibit the entrance into it, in the same manner as into any of their towns and provinces.

When a nation takes possession of certain parts of the sea, it enjoys the empire, as well as the domain. Those parts of the sea are within the jurisdiction of the territory of the nation; the foreign commands there, he makes laws, and may punish those who violate them; in a word, he has the same rights there as at land, and in general all those given him by the law of the state.

It ought to be observed, however, that a nation may possess as property the domain of a state at land or sea without having the sovereignty; it may happen also that it may have the empire of a place where the property of the domain with respect to the belongs to some other nation. The English have never pretended to have a property in all the seas over which they have claimed the empire. Vattel's Law of Nations, b. 1. ch. 23.

The term sea is variously applied by sailors, to a single wave, to the agitation produced by a multitude of waves in a tempest, or to their particular progress or direction. Thus they say, a heavy sea broke over our quarter; or, we shipped a heavy sea; there is a great sea in the offing; the sea lets to the southward. Hence a ship is said to head the sea, when her course is opposed to the setting or direction of the forges. A long sea implies an uniform and steady motion of long and extensive waves; on the contrary, a short sea is when they run irregularly, broken and interrupted, so as frequently to burst over a vessel's side or quarter.

Sea, General Motion of. Mr. Duffie of Paris, in a work published about a century ago, has been at great pains to prove that the sea has a general motion, independent of winds and tides, and of more consequence in navigation than is usually supposed. He affirms that this motion is from east to west, inclining toward the north, when the sun has passed the equinoctial northward, and that during the time the sun is in the northern signs; but the contrary way, after the sun has passed the said equinoctial southward; adding, that when this general motion is changed, the diurnal flux is changed also; whence it happens, that in several places the tide comes in during one part of the year, and goes out during the other, as on the coasts of Norway, in the Indies, at Goa, Cochinchina, &c. where, while the sun is in the summer signs, the sea runs to the shore; when in the winter signs, from it. On the most southern coasts of Tonquin and China, for the fixed summer months, the diurnal tide runs from the north with the ocean; but the sun having repassed the line toward the south, the tide advances also southward. Phil. Trans. N° 135.

Sea, Baion of the, Flandes maris, a term used by geographers, and other writers, to express the bottom of the sea in general.

Mr. Boyle has published a treatise on this subject, in which he has given an account of its irregularity and various depths, founded on the observations communicated to him by mariners.

The ingenious count Marigli has, since his time, given us a much fuller account of this part of the globe, mostly from his own experiments in many places, particularly along the coasts of Provence and Languedoc. The entire basin of the sea is of such immense extent, and covered in many places with such an unbottomable depth of water, that it is not to be expected that it can be traced in every part; but as the whole may be guessed at, from some part of it, and as its general figure is of no consequence in a search of this kind, the observations of this curious author are of great value, in forming a judgment of the whole.

The materials which compose the bottom of the sea, may very rationally be supposed, in some degree, to influence the table of its waters; and Marigli has made many experiments to prove, that fossil coal, and other bituminous substances which are found in plenty at the bottom of the sea, may communicate in great part its bitterness to it. See Saltness.

We are not, however, to judge hastily, that there are not so many beds of these at the bottom of the sea, as would be necessary for such a purpose, or to judge too hastily against the existence of any other substances there, because we do not find proofs of them by the plummet, which in foundling brings up other substances, and not these; for the true bottom of the sea is very often covered and obscured from us by another accidental bottom, formed of various substances mingled together, and often covering it to a considerable depth.

The entire gulf of Lyons, situated between Cape Quier
in Rouillon, and Cape Croifit in Provence, forms a bank above the surface of the water at the shore, of the exact and perfect figure of an arch; and within this there is formed another such arch, making the bottom of the sea in that place for a very great way from shore, which is of different depths in various places, but usually between fixty and seventy fathom. See Sea-Shore.

It is a general rule among sailors, and is found to hold true in a great many instances, that the more the shores of any place are steep and high, forming perpendicular cliffs, the more deep the sea is below; and that, on the contrary, level shores denote shallow seas. Thus the deepest part of the Mediterranean is generally allowed to be under the height of Malta. The observation of the Irata of earth, and other fossils, on and near the shores, may serve to form a very good judgment as to the materials which are found in its bottom.

The veins of salt and of bitumen doublefs run on the same, and in the same order in which we see them at land; and the Irata of rocks, that serve to support the earth of hills and elevated places on shore, serve also, in the same continued chain, to support the immense quantity of water in the basin of the sea. It is probable also, that the veins of metals, and of other mineral substances, which are found in the neighbouring earth, are in the same manner continued into the depths of the sea. The particles of metals in this case, are probably carried off into deep water, and sunk among the softer matter of the bottom, but some of the lighter minerals seem to have given colour to those beautiful crufits, which are found upon many sea-substances, and which lose their lustre in the drying. The subterranean rivers, and currents of water, make great changes in what would be the natural surface of the bottom of the sea, where they arife, each having a peculiar basin of its own. We are formed by numerous infusions of subterranean currents, and as we fee them break out in rivers on the surface of the earth in some parts, so in others we may be well assured that they break up the bottom of the sea, and empty their fresh waters into the salt mafs.

In this case, the rushing up continually of such a body of water makes a roundish cavity, and its running some one way, lengthens and carries on that cavity, till by degrees it is lost, as the fresh water by degrees becomes blended with the salt. Thus every river that arifes in the bottom of the sea, alters the form of its surface, and makes a basin for itself, in which it runs a considerable way. Many seas near the shore, and when the water is tolerably clear, shew the traces of these currents to the naked eye from the surface, and the water taken up from them is found more or less fresh.

The coral fisheries have given us occasion to observe, that there are many, and those very large caverns, or hollows in the bottom of the sea, especially when it is rocky; and that the like caverns are sometimes found in the perpendicular rocks, which form the steep sides of those fishery. These caverns are often of great depths, as well as extent, and have sometimes wide mouths, equal to their largest diameter in any part, but sometimes they have only narrow entrances into large and spacious hollows. It is the common opinion of the people about the place, that these caverns are prepared by nature for the circulation of the sea-water; but that operation, however necessary, may be performed as well without, as with these caverns, and they seem in reality to be only accidental.

We daily meet with immense hollows and caverns, naturally made in rocky mountains; and as this part of the bottom of the sea is almost all rock, and its sides of the same nature, it is no wonder that the same accidents should happen, and like hollows be found, though with no particular intent of Providence in their use. Nay, there is this further reason to expect them in the rocks buried under the sea than in those in hills, that the latter are in a state of rest and quiet, whereas the former are in continual reach of water, which will inflate itself into every crack or crevice nature has left in them, and may be safely supposed to have burrowed its way in a small hole made by nature, till it has formed of it a very large one.

From such observations it is inferred, that the basin of the sea was at the creation, or at its second formation after the universal deluge, covered with or composed of the same substances, as the surface of the rest of the earth is, that is of rocks, clay, and sand, and other such substances. Over the sea there is an artificial bottom formed of muddy tartaronous incrustations, dead weeds, broken shells, and other bodies of the same kind, cemented together into a firm mass or crust; and in those places where this crust has never been formed, or where it has been broken, the bottom of the sea is of the same nature with the Irata of the earth.

The bottom of the sea is covered with a variety of matters, such as could not be imagined by any but those who have examined into it, especially in deep water, where the surface only is disturbed by tides and storms, the lower part, and consequently its bed at the bottom, remaining for ages perhaps undisturbed. The foundations, where the plummet first touches on approaching the shores, give some idea of this. The bottom of the plummet is hollowed, and in that hollow there is placed a lump of salt; this being the bottom of the lead, is what first touches the ground, and the loft measure of this is placed into it forming part of those substances which it meets with at the bottom of the sea; this matter, thus brought up, is sometimes pure sand, sometimes a port of sand made of the fragment of shells, beat to a port of powder; sometimes it is made of a like powder of the several sorts of corals; and sometimes it is composed of fragments of rocks; but besides these appearances, which are natural enough, and are what might very well be expected, it brings up substances which are of the most beautiful colours.

Things of as fine a scarlet, vermilion, purple, &c. as the finest point could make them, and as yellow as a solution of gamboge, are common; and sometimes, though not so frequently, the matter brought up is blue, green, or of a pure snowly whiteness. These coloured matters sometimes seem to have made up the whole bottom or mafs of the surface, but more usually they have been formed upon other things, as upon the mud, or upon larger pieces of shells, corals, and the like, in the manner of tartarous crusts, and those in some degree resembling the crustaceous coats of some of the sea plants. The colours of these substances are not merely superficial and transient, but many of them are so real and permanent, that they may be received into white wax melted, and poured upon them, or kept in fusion about them; and when thus examined, they seem as if a proper care might make them of great value, as paints of the finer kinds, where little is to be used.

The same coloured matters that thus coat the substanies, found at the bottom of the sea in these places, are also sometimes found extended over the surface of marine substanies of the harder kind, which are found in deep water. They are always, in this case, in a sort of liquid form, being lodged within, or embodied among a sort of jelly or glue of a transparent substanie, which in those cases perfectly coats over the whole. In this state it gives the naturalift, who is present at the fishing up of his treasures, a transient prospect of
of a very elegant kind, but this vanishes while he admires it. A piece of coral, or other hard substance, thus coated over, appears, as it rises to the surface of the water, of a delicate green, blue, or purple; but when taken above water it is found that this fine colour is only in the coat of glue or jelly which covers the substance; as soon as this is wiped off, the colour is carried away with it, and the coral shows its own native tinge; and it is to no purpose to attempt the preparing of it, by sucking this glue to dry upon the coral, for the colour flies away by degrees, as the moisture evaporates, and the coral, &c. whatever it be, is only so much the less beautiful, than it naturally would have been, as it is covered with a dry yellowish dirty looking horrid matter. These are beauties in the sub-marine productions, therefore, which can only be seen by those who venture out in order to take them up.

The small quantities of these elegant colours, which we thus find spread over the surfaces of marine bodies, as we approach deep water, may give a rational idea of what we should find, were we able to examine the bottom of the sea in its deep and unfathomable recesses. It is easy to conceive, that in these places we should find great quantities of the most beautiful substances. Marigl, Hist. Phys. de la Mer.

Dr. Donati, in an Italian work, containing an essay towards a natural history of the Adriatic sea, printed at Venice in 1750, has recited many curious observations on this subject, and which confirm the above account of Marigl; having carefully examined the sea and productions of the various countries that surround the Adriatic sea, and compared them with those which he took up from the bottom of the sea, he found that there is very little difference between the former and the latter. At the bottom of the water there are mountains, plains, valleys, and caverns, similar to those upon land. The sea consists of different strata placed one upon another, and for the most part parallel and correspondent to those of the rocks, islands, and neighbouring continents. They contain stones of different sorts, minerals, metals, various patinated bodies, pumice-flour and lavas formed by volcanoes.

The adjacent countries, as well as the bottom of the Adriatic sea, consist of a mass of a whitish marble, of an uniform grain, and of almost an equal hardness; and this marble, in many places under both the earth and sea, is intercepted by several other kinds of marble, and covered by a great variety of bodies, such as gravel, sand, and earths more or less fat. To this variety of soils, he ascribes the varieties observed with respect to the nature and quantity of plants and animals found at the bottom of the sea.

One of the objects which most excited his attention, was a crust, which he discovered under the water, composed of crufltaceous and terebellate bodies, and beds of polypes of different kinds, confusedly blended with earth, sand, and gravel; the different marine bodies, which form this crust, are found at the depth of a foot or more, entirely petrified and reduced into marble; these, he supposes, are naturally placed under the sea when it covers them, and not by means of volcanoes and earthquakes, as some have conjectured. On this account, he imagines, that the bottom of the sea is constantly rising higher and higher, with which other obvious causes of ineradic concurs; and from this rising of the bottom of the sea, or of the level of the water naturallly results; in proof of which he writer recites a great number of facts. Philosopf. Transf. vol. xlix. p. 585, &c.

SEA. Dead. Dr. Perry made several experiments on the water of the Dead sea, in order to find what particles it contained. Upon infusing some scrapings of galls in it, it becomes of a bright purple colour, but that not till it has stood a considerable time. On adding oil of tartar per dilution to it, it becomes turbid, and looks as if globules of fat were fluctuating in it; this unctuous matter, upon its long standing in repose, comes together in form of a sediment at the bottom. On pouring spirit of vitriol into it, it deposits a milk-white greasy sediment, which, after standing twelve hours, occupies about one-fifth part of the liquor. On putting a small quantity of facecharne faturni to it, it deposits a small quantity of greyish powder; being severely and separately mixed with a solution of sublimate, with spirit of sal ammoniac, and with sugar of violets, it neither ferments nor deploys any sediment, nor changes colour, except with the sugar of violets, with which it becomes green.

It is highly satured with fust, so that it is to common water in specific gravity, as five to four; and it has so acid and typhic a taste, that on being held in the mouth, it constricts it in the manner of alum.

It appears, that this water is impregnated with a sort of an acid and alkaline nature, and a matter partly of a fulminating, partly of a bituminous nature. Philos. Trans. N° 346. p. 56. For the observations of other writers on this subject, see ASPHALTITE lake, and DEAD SEA.

SEA, luminous of the, is a phenomenon, which has been taken notice of by many nautical and philosophical writers. Mr. Boyle, after reciting several circumstances attending this appearance, ascribes it to some chemical law, or cullom of the terrestrial globes, or at least of the planetary vortex.

Father Bourzes, in his voyage to the Indies, in 1704, took particular notice of this phenomenon, and very minutely describes it, without assigning the true cause.

The abbé Nollet was long of opinion, that the light of the sea proceeded from electricity, and others have had recourse to the same hypothesis. M. Bayon, in his "Mémoires pour servir à l'Histoire de Cayenne, &c." Paris, 1757, informs us, that, having made a great number of experiments, in different places, in order to find out the true cause of this phenomenon, he always found, that the luminous points in the surface of the sea were produced merely by friction.

However, there have been two hypotheses, which have most generally been received, for the solution of this phenomenon; one of which ascribes it to the shining of luminous insects or animalcules, and the other to the light proceeding from the putrefaction of animal substances. The abbé Nollet, who at first considered the luminousness of the sea as an electrical phenomenon, having had an opportunity of ascertaining the circumstances of it, when he was at Venice in 1749, relinquished his former opinion, and concluded that it was occasioned either by the luminous aspect, or by some liquid or effluvia of an insect which he particularly describes; but does not altogether exclude other causes, and especially the spawn or fry of fish.

The same hypothesis had also occurred to M. Vianelli, professor of medicine in Chioggia near Venice; and both he and M. Grizzellini, a physician in Venice, have given drawings of insects from which they imagined this light to proceed.

A similar conjecture is proposed by a correspondent of Dr. Franklin, in a letter read at the Royal Society in 1756; the writer of which apprehends, that this appearance may be caused by a great number of little animals, floating on the surface of the sea, which, on being disturbed, might, by expanding their fins, or otherwise moving themselves, expulse such a part of their bodies as exhibits a luminous appearance, somewhat in the manner of a glow-worm, or fire-fly; that these animals may be more numerous in some places than others, and, therefore, that the appearance above-mentioned,
tioned, being fainter and rarer in different places, might be owing to this cause; and that certain circumstances of weather, &c. might invite them to the surface, on which, in a calm, they might sport themselves and glow, or in storms, being forced up, make the same appearance.

Mr. Fothergill, in his account of a voyage round the world with captain Cook, in the years 1772, 1773, 1774, and 1775, describing this phenomenon as a kind of blaze of the sea, and having attentively examined some of the illuminated water, expresses his conviction, that the appearance was occasioned by innumerable minute animals of a round shape, moving through the water in all directions. One of these luminous spars, which stuck to his finger while he was lifting his hand with his hand, was examined by the common magnifier of Mr. Ramden's improved microscope, and was found to be globular, transparent like a gelatinous substance, and somewhat brownish; by means of the greatest magnifier, the orifice of a little tube was discovered, which entered the body of the animal; within which were four or five intestinal bags connected with the tube. He imagines that these animals may be the young fry of some species of medusa, or blubber, and considers them as the source of the power of shining, or of withholding their light at pleasure.

M. Dagelet, a French astronomer, falling into the bay of Astongil, in the island of Madagascar, observed a prodigious quantity of fry, which covered the sea above a mile in length, and which he at first took for banks of sand, on account of their colour; they exhaled a disagreeable odour, and the sea had appeared with uncommon splendour some days before. On another occasion, having perceived the sea to be remarkably luminous in the road of the Cape of Good Hope, during a perfect calm, he remarked that the oars of the canoes produced a whitish and pearly kind of luster; when he took in his hand the shining water, he discerned in it, for some minutes, globules of light as large as the heads of pins; upon pressing these, they seemed to be a soft and thin pulp, and some days after the sea was covered, near the coasts, with whole banks of these little fish in innumerable multitudes.

M. Dagelet, in his return from the Terra Australis in 1774, brought with him several kinds of worms, which shine in water when it is fat in motion; and Mr. Rigaud affirms, that the luminous surface of the sea, from the port of Brest to the Antilles, contains an immense quantity of small, round, shining polypus.

M. le Roi, after giving much attention to this phenomenon, concludes that it is not occasioned by any shining insects, especially as, after carefully examining with a microscope some of the luminous points, he found them to have no appearance of any animal; and he also found, that the mixture of a little spirit of wine with water just drawn from the sea, would give the appearance of a great number of little spars, which would continue visible longer than those in the ocean; the same effect was produced by all the acids, and various other liquors. M. le Roi is far from allowing that there are no luminous insects in the sea; for he allows that the abbe Nollet and M. Vianelli had found them; but he is satisfied that the sea is luminous chiefly on some other account, though he does not so much as offer a conjecture with respect to the true cause.

Other writers, equally dissatisfied with the hypothesis of luminous insects, for explaining the phenomenon, which is the subject of this article, have ascribed it to some substantia of the phosphoric kind, arising from putrefaction.

The observations of F. Boursier, above referred to, render it very probable, that the luminousness of the sea arises from slimy and other putrefactive matter with which it abounds, though he does not mention the tendency to putrefaction, as a circumstance of any consequence to the appearance.

The correspondent of Dr. Franklin, part of whose letter has been already recited, observes, that several gentlemen have been of opinion, that the separated particles of putrid animal, and other bodies, floating on the surface of the sea, might cause this appearance, for putrid fish, &c. will cause it; and the sea animals which have died, and other bodies putrefying in it since the creation, might afford a sufficient quantity of these particles to cover a considerable portion of the surface of the sea; which particles being differently dispersed, might account for the different degrees of light in this appearance; but he adds, this account seems liable to an obvious objection, viz. that as putrid fish, &c. make a luminous appearance without being moved or disturbed, it might be expected that the supped putrid particles on the surface of the sea should always appear luminous, when there is not a greater light; and, consequently, that the whole surface of the sea covered with those particles should always, in dark nights, appear luminous, without being disturbed, which, he says, is contrary to fact. Franklin's Experiments and Observations, p. 274, &c.

This difficulty is, in a great measure, removed by the experiments of Mr. Canton, recited in the Philosophical Transactions, vol. lxi. p. 446, &c. which have the advantage of being easily made, and leave no room for doubt, that the luminousness of the sea is principally owing to putrefaction. Having put a fresh whiting into a gallon of sea-water, neither the whiting, nor the water when agitated, gave any light; Fahrenheit's thermometer, placed in the collar where the pan was placed, standing at 54°; the following evening, that part of the fish which was even with the surface of the water was luminous, but the water itself was dark; however, on drawing through it the end of a flick, the water appeared luminous behind the flick all the way, but gave light only where it was disturbed: when all the water was stirred, the whole became luminous, and appeared like milk, yielding a considerable degree of light to the fides of the pan, which it continued to do for some time after it was at rest. The water was most luminous when the fish had been in it about twenty-eight hours, but would give no light by being stirred after it had been in it three days. He then put a gallon of fresh water into one pan, and an equal quantity of sea-water into another, and into each pan he put a fresh herring, of about three ounces; the next night the whole surface of the sea-water was luminous without being stirred, but much more so when put in motion, and the upper part of the herring, which was considerably below the surface of the water, was also very bright; while at the same time, the fresh water, and the fish that was in it, were quite dark. There were several very bright luminous spots on different parts of the surface of the sea-water, and the whole, when viewed by the light of a candle, seemed covered with a greasy scum. The third night the light of the sea-water, while at rest, was very little, if at all, less before; but when stirred, its light was so great as to discover the time by a watch, and the fish in it appeared as a dark substance. After this its light was evidently decreasing, but was not quite gone before the seventh night; the fresh water, and the fish in it, were perfectly dark during the whole time. The thermometer was generally above 60°. Having made artificial sea-water, determined by an hydrometer to be of the same specific gravity with the sea-water, by adding four ounces avoirdupois of salt to seven pints of water, wine measure, he put into a gallon of this water a small herring; and another into a gallon of water, in which two pounds of salt had been dissolved.
SEA

folved. The next evening, the whole surface of the arti-

ficial sea-water was luminous without being stirred, but
gave much more light when it was disturbed, and exhib-
ited the same appearances with the real sea-water in the
preceding experiment; while the other water, which was
almost as faint as it could be made, never gave any light.
The herring which was taken out of it the seventh night,
and washed from its salt, was found firm and sweet; but the
other herring was very soft and putrid, much more so than
that which had been kept as long in fresh water. If a
herring, in warm weather, be put into ten gallons of arti-
ficial sea-water, instead of one, the water, Mr. Canton says,
will still become luminous, but its light will not be so
strong.

These experiments confirm an observation of Sir John
Pringle, that the quantity of salt contained in sea-water
hastens putrefaction; but since that precise quantity of salt
which promotes putrefaction the most, is less than that
which is found in sea-water, it is probable, Mr. Canton
observes, that if the sea were less salt, it would be more
luminous. See **Putrefaction**.

Mr. Canton observed, as Mr. Ant. Martin Swed. Ab-
hand. vol. xxxiii, p. 225. had done, that several kinds of
river-fish could not be made to give light, in the same cir-
cumstances in which any sea-fish became luminous. He
says, however, that a piece of carp made the water very
luminous, though the outside, or scaly part of it, did
not shine at all. See this subject farther discussed under
the article **Exhibition of Light from Living Animals**.

SEA, **Perils of the, in Marine Insurance**, denote, in a large
sense, all the accidents or misfortunes to which persons
engaged in maritime adventures are exposed; but it has
been found convenient to distinguish the losses to which
ships and goods at sea are liable, by the "immediate cau-
ses" to which they may be ascribed. Accordingly the perils
of the sea mean only such accidents or misfortunes as proceed
from mere sea-damage, that is, such as arise from terrors of
weather, winds, and waves, from lightning and tempests,
from rocks and sands, &c. A loss by the perils of the sea
therefore happen, 1st, by the ship's foundering at sea, in
which case it must generally be total; or, 2dly, by strand-
ing, which is either accidental, in consequence of the
ship's being driven on shore by the winds and waves, or
voluntary, where she is run ashore either to prevent a worse
fate, or for some fraudulent purpose; this strand
ning may be followed by shipwreck, which occasions a total
loss, and if the ship be got off in a condition to prosecute her voyage,
the damage fullfled and the expenses incurred will incur
only a partial loss of the nature of a general average; or,
3dly, by the ship's striking against a rocky rock, or some-
thing else under water, which may occasion the springing
of a leak, or absolute shipwreck. If a ship be not heard
of within a reasonable time, she shall be presumed to have
foundered at sea. In some countries there is a limitation
of time for this presumption; thus in Spain, if a ship has
not been heard of for six years from her departure on a
voyage to or from the Indies, she is deemed lost; but in
France, after a year from the ship's failing, in common
voyages, and two years in distant voyages, the injured may
abandon and demand payment, without other proof of loss.
In England there is no such limitation of time. When an
interval, thought to be reasonable by those who are con-
versant in maritime affairs, has elapsed, a liberal under-
writer will pay his loss; and if there be any ground for
doubt, he may either demand security from the injured to
refund the money, in case the ship should afterwards arrive
safe, or he may trust to his remedy by action, for recovering
it back. If a ship be driven by terrors of weather on an
enemy's coast, and be there captured, this is a loss by
capture and not by perils of the sea, for which the injured
may recover upon a policy against capture only; and yet
it has been held, that capture is a loss by the perils of
the sea, as much as if it were occasioned by shipwreck or
tempet. If flames be thrown overboard, on account of a
scarcity of water, occasioned by the captain's mistaking his
course; this is not a loss by the perils of the sea. The
cafe is the same, if the flames die for want of food, occasioned
by the extraordinary length of the voyage. And if a ship
be destroyed by worms, the loss is not attributable to perils
of the sea. As to the cafe of throwing flames overboard
in order to lighten a ship and preserve it in a storm, the
practice has been justly reproved by Rear-Admiral Marshall.
Every thing on board, however precious, as he humane and
rationally observes, should be thrown into the sea sooner
than the meanest flame. Pullendorff also maintains, that
whoever, under pretence of saving the ship, shall throw men
into the sea, whether they be freemen or slaves, and whether
it be done by or without lot, is guilty of homicide; for no
man, in order to save his own life, has a right to take away
the life of any other human being, who does not attack
him.

If, by some extraordinary accident, as the violence of the
winds or waves, it becomes necessary to ship a cable, or a
cable be broke, and an anchor lost, or a sail or yard be
continued, this is a loss by the perils of the sea within
the policy. Also, if animals be injured, their death, oc-
casioned by tempells, by the shot of an enemy, by jettison
in a storm, or by any other extraordinary accident, is a loss
within the policy; but it is otherwise if their death be
owing to dilate. The injury occasioned by one ship's run-
ing foul of another at sea, is a loss within the policy, unless
it be imputable to the misconduct of the master or mariners
of the ship injured. In such case, however, this misconduct
would, as rear-admiral Marshall conceives, amount to baratry,
and the insurer would be liable for the loss; but an action
would lie against the master of either ship, to whom the
misconduct is imputable, for the loss which he has occasioned.
A loss occasioned by an accidental fire, not imputable
to the fault of the master or mariners, is a loss within the
policy; and in many places the insurer is held to be liable
even when the fire happens by the fault of the master or
mariners; but in France the insurer is not held answerable
in such case, unless, by the policy, he be liable for baratry.
For every loss occasioned by capture, whether lawful or un-
lawful, and whether by friends or enemies, the insurer is
liable. Marshall on Insurance, vol. ii. See **Recapture,
Risks, and Salvage**.

SEA-Adder, in Ichthology, an English name for a sea-fish
of the acus kind, called by Willughby the **new plumbeiformis**.
See **Acus and Syngraphes**.

It is a small fish of a cylindric shape, without scales, and
of a greenish-brown colour, with some admixture of a
reddish-yellow.

Their finot is long and hollow, and the mouth opens
upwards at its end; the eyes are small, and their iris red;
the gills are four on each side, but are covered by a
membrane, and the whole body divided into rings like the
common earth-worm; it is usually about three or four inches
long, and of the thicknes of a goose-quill; it has but one
fin, which is situated on the back. The anus is much nearer
the head than the tail, and under the finot there is always
a fleshly tubercle.

The fish is common on the coast of Cornwall. Willughby.

SEA-Army. See **Naval Army**.

R
SEA-Afrole. See Astrolabe.

SEA-Banks. (See Bank.) Maliciously destroying sea-banks, by which lands may be overflowed, is made felony without benefit of clergy by 6 Geo. II. c. 25, and 10 Geo. II. c. 32.

SEA-Bat, in Ichthyology. See Chelidon Vespertilio.

SEA-Bea, in Zoology, the Phoca Ursina of Linnaeus, called also by some writers the sea-cat, and by Pennant the Ursina seal, inhabits together with the sea-lion and manati, from June to September, the isles that are scattered in the seas between Kamtschatka and America, in order to copulate, and bring forth their young in full security. In September they quit their station in a very emaciated state; some returning to the Asiatic, and others to the American shores, but, like the sea-otters, they are confined to those seas between latitude 50° and 56°. These animals are also common about New Zealand, Staten-Island, New Georgia, and the Falkland Islands.

The urane seals lead, during the three months of summer, a very indolent life; they are confined for several weeks to the same spot, keep the greatest part of their time, eat nothing, and are totally inactive, the employment of the females in suckling their young excepted. They live in families, each male having from eight to fifty females, which he guards with jealousy; and though they lie by thousands on the shore, each family, confining sometimes of one hundred and twenty, keeps itself separate from the rest.

The old animals, which are deserted by the females, live apart, and are exceedingly sullen and quarrelsome, very fierce, and so attached to their old haunts, that they would die sooner than quit them; in defending these, discord is sometimes spread through the whole shore. The other males are also very irascible, and the canes of their disputes are generally such as these; an attempt to seduce any of their females, the intrusion of one upon the station of another, and interference in their mutual quarrels. Their battles are fierce and bloody, and when they terminate, the combatants throw themselves into the sea, to wash away the blood.

The males are very fond of their young, of which the female generally brings but one at a time, and never more than two; but they are very tyrannical towards the females, which, on the other hand, are very fawning and submissive.

The sea-bears swim very swiftly, at the rate of seven miles an hour; when wounded will feizze on the boat, bear it away with impetuosity, and sometimes sink it. They can continue a long time under water. When they want to climb the rocks, they fallen with the fore-paws, and draw themselves up. They are very tenacious of life, and will live for a fortnight after receiving such wounds as would immediately destroy any other animal.

The males of this species are much larger than the females; their bodies are of a conical form, thick before, and tapering to the tail; the length of a large one is eight feet, the greatest circumference five feet, and near the tail twenty inches; the weight 800lbs.; the nose projects like that of a pug dog, but the head rifies suddenly; the nostrils are oval, divided by a septum; the lips thick, and in the inside red and ferrated; the whiskers long and white; the teeth, which are thirty-six in number, lock into each other when the mouth is closed; the tongue bid; the eyes are large and prominent, and capable of being covered at pleasure with a fleshy membrane; the ears are small and sharp-pointed; the length of the fore-legs is twenty-four inches; the feet are formed with toes, but covered with a naked skin, so as entirely to appear a shapeless mass; the hind-legs are twenty-two inches long, and fixed to the body behind, but capable of being brought forward, and the feet are divided into five toes; the tail is only two inches long; the hair is long and rough, under which is a soft down of a bay colour; the general colour of these animals is black, but the hairs of the old ones are tint with grey. The females are cinnereous. The skins of the young, cut out of the bellies of their dams, are useful for clothing.

The fat and flesh of the old males are very nauseous, but the flesh of the females resembles lamb, and the young ones roaled are as good as sucking-pigs. Pennant's Hist. Quadr. vol. ii. p. 526, &c. See Phoca Ursina.

SEA-Bisket. See Bisket.

SEA-Boat, in Naval Language, a vessel that bears the sea firmly, without labouring heavily, or straining her masts or rigging.

SEA-Breaches, a term used by the farmers to express the overlowing of their low lands near the sea by the sea-water.

Sea-fall, moderately used, is a great improvement to all lands, but too much of it kills all sorts of vegetables, except such as nature has intended to live among it. See Salt.

The sea breaking in upon lands thus, injures them greatly. The owner is to stop the breach by which it entered with all possible diligence, and then trenches and drains must be cut through all parts of the land to carry the salt-water into some one low place, from which it may be emptied by means of an engine; or if it be small in quantity, it may be laded out by hand over the bank; or if yet less, the sun and winds may dry it away; but in either case, the place where it was fenced to rest must be covered with a large quantity of fresh earth, to take off from the too great saltiness of the other; and the whole land should be ploughed for three or four years, to let in the rains and air to refresh it.

SEA-Bream, in Ichthyology, the English name for the fish called by the generality of authors the Pagarus and Pharus. According to the new system of Arrédi, it is a species of the Sparus; and is distinguished by the name of the red Sparus, with the skin carried into a furis at the roots of the back fins, and the pinna ani. See Sparus.

SEA-Buckthorn, in Botany. See Hippophae.

SEA-Brief, in Marine Insurance. See SEA-Letter.

SEA-Cabbage, in Gardening, the common name of an useful garden plant. See Brassica and Crambe. See also SEA-Kale.

SEA-Calf, Phoca vitulina, in the Linnean system of Zoology, is the common seal, with large black eyes, large whiskers, oblong nostrils, flat head and nose, tongue forked at the end, two canine teeth in each jaw, fix cutting teeth in the upper jaw, four in the lower, no external ears, body covered with thick short hair, short tail, and toes furnished with strong sharp claws; its usual length is from five to six feet; the colour various; dull, brindled, or spotted with white or yellow. This species inhabits most quarters of the globe, but is found in greatest number towards the north and south; they swarm near the Arctic circle, and the lower parts of South America, in both oceans near the southern end of Terra del Fuego, and among the floating ice as low as lat. 60° 21' S.

They are also found in the Caspian sea, in the lake Aral, and lakes Baikal and Onar, which are fresh waters, but these are less, and more fat than those of the salt-water. Seals bring forth two young at a time in autumn, which are for a short time white and woolly, and fuddle them till they are fix or seven weeks old in rocks or caverns, when they take to sea; as they cannot remain long under water, they
they frequently rise to take breath, and often float on the waves.

In summer they sleep on rocks or sand banks; if surprized,
they plunge into the sea, and when at a distance fling up the
fand with their hind feet, and make a piteous moaning;
as they feramble along; and if they are overtaken, vigorously
defend themselves with their feet and teeth; they are driven
by a flight blow on the nose, otherwise they will fur-
vive many wounds.

These animals swim with great strength and speed;
and in their own element sport without fear about ships and boats,
which, says Mr. Pennant, may have given rise to the fable
of sea-nymphs and fyrne. They are gentle and docile; they
feed on all sorts of fish; are themselves good food,
and eat by voyagers: they are killed for the sake of the oil made
from their fat, of which a young feal will yield eight gallons;
their skins are useful in making waitcoats, covers for trunks,
and other conveniences; and they are the wealth of
Greenlanders, supplying them with every necessity of life.

We have a draught of this animal in the Philosophical
Transactions, No. 459, by Dr. Parsons, who observes, that
Aldrovandus, Johnston, Rondeletius, and Gencer, have made
several mistakes in the figures of this creature, so as to con-
vey no just idea of it.

Upon dissecting one of these animals, the stomach, intesti-
tines, bladder, kidneys, uriner, diaphragm, lungs, great
blood-vessels, and pudenda, were like those of the cow; the
hair of the whiskers very hairy and clear; the spleen
was two feet long, four inches broad, and very thin; the
liver consisted of six lobes, each hanging as long and as lank
as the spleen, with a very small gall-bladder. The heart was
long and flabby in its contexture in general, having a large
foramen ovale, and very great columna carnosea. In the
lower stomach were about four pound weight of flinty
pebbles, all sharp and angular, as if the animal chose them
of that form for cutting the food. The uterus was of
the horned kind, each of the cornua being thicker than the
body or duct leading to them: the ovarie were very large,
being granulated on the surface with the ova, under a very
thin membrane; and the opening into the tubes leading to
the cornua is a great hole.

The authors who have treated on this animal, are Ariftotle,
Pliny, Aldrovandus, Rondeletius, Gencer, Wolfgangius,
and Johnston.

This animal is viviparous, and suckles its young by the
mamillae, like quadrupeds; and its flesh is carnious and mu-
cular. That dissected by Dr. Parson was seven feet and
an half long, though very young, having scarcely any teeth,
and having four holes regularly placed about the navel,
in which time became papillae. (See Phoca Vitulina.) See
a description of other species of seal, with figures, by Dr.
Parsons in Phil. Trans. vol. xlvii. p. 109, &c. and Pen-

SEA-Chart. See Chart.

SEA-Clay, in Agriculture, a muddy sort of clayey matter
found on the shores and borders of the sea, which is of a blackish
or bluish appearance, and often of a very ill tenacious qulity,
not coldly mixing with earthy soils. It moistly lies under-
neath the sandy orzy matters that are collected in such situ-
tations. See SEA-Sand.

In Lancashire they make use of a fat sort of sea-clay, which
is dug out clofe to the shore on the lefts isliff forts of land, when
in the state of fallow for wheat, in the proportion of about
200 single horse cart-keys to the acre, and believe it to an-
swer better than the common fea-fand, or even sandy mud. It
may probably be of a marly nature.

SEA-Coal. See Coal.

SEA-Coap. See Compass.

SEA-Cow, in Zoology an English name of the manatus, a
species of fish fo different from all the other cetaceous tribe,
to which it properly belongs, that Artedi, in his new syslem
of ichthyology, allotted it a peculiar generic name, which is
trichecus; in the Linnean sylltem it is the Trichecus manatus,
which see. This species has thick lips, very small eyes,
two small orifices in the place of ears; neck short, and
thicker than the head; the great thickness of the body
is about the shoulders, from which it grows gradually smaller
to the tail, which lies horizontally, being broad, and thick-
ly in the middle, and growing thinner to the edges, and
quite round. The feet are placed at the shoulders; beneath
the skins are bones for five complete toes, and externally
are three or four nails flat and rounded; near the base
of each foot in the female is a test; the skin is very thick
and hard, having a few hairs scattered over it, whence the
name trichecus, formed of 9{1}/2 hoars, and i{1}/2 hoars. Those
animals of this species, that were measured by Dampier in
the Wett Indies, were ten or twelve feet long; their tail
twenty inches in length, fourteen in breadth, and four or five
thick in the middle, and two at the edges; and the largest
of them weighed twelve hundred pounds; some have
been mentioned, the length of which has been sixteen feet
and a half, and even twenty feet.

According to Dampier, those which inhabit fresh waters
are much less than the others; they inhabit the rivers of
Africa, from that of Senegal to the Cape of Good Hope,
and abound in certain parts of the eastern coasts and rivers
of South America, about the bay of Honduras, some of the
greater Antilles, the rivers of Oronoque and of the
Amazons.

They sometimes live in the sea, and often near the mouth
of some river, into which they come once or twice in twenty-
four hours, for the sake of feeding on the marine plants,
and they are fond of brackish or sweet water than of the salt;
and delight in shallow water near low land, and in places
secure from forges, and where the tides run gently. They
are laid to frolic and leap sometimes out of the water to
a great height. Their flesh and fat are white, sweet,
and palatable; and the tail of a young female is much esteemed,
and a fucking roasted highly delicious. The thicker part
of the skin, cut into lengths of two or three feet.

This animal is called by Herrera taurus manatus, or the
sea-bull, and by others the tuckas y la dona. The French
call it lamanin, or lamainin, and the Portuguese pezze muller.

It may be slame, that so ill-shaped a creature as this
should have given rise to the fancies of the fyrne and mer-
maids, the sea-men and sea-women, yet there is great reason
to believe, that all the fabulous accounts of these monsters,
are owing to the sight of this animal, and of the common
seal, when raising their head and shoulders above the water.

SEA-Mud. See SEA-Mass.

Mr. Pennant has described an animal of this species;
which he calls the whale-tailed manatus, and which the
Russians distinguish by the name of the mpalkia kerweno, or
sea-cow. This animal, whose feet are merely pectoral fins,
and serve only for swimming, brings forth in the water;
and, like the whale, suckles its young in that element; like the
whale,
whale, it has no voice, and, like that animal, has an horizontal broad tail, without even the rudiments of hind feet. It inhabits the seas about Bering's, and the other Aleutian islands, between Kamtchatka and America.

In calm weather these animals swim in great droves near the mouths of rivers; when hurt, they swim out to the sea, but soon return again. They live in families near one another, each consisting of a male, female, a half-grown young one, and a very small one; the females oblige the young to swim before them, while the other old ones surround, and, as it were, guard them on all sides. The affection between the male and female is very great; for if she is attacked, he will defend her to the utmost, and if she is killed, will follow her carcass to the very shore, and swim for some days near the place where it was landed.

They copulate in the spring, in the same manner as the human kind, especially in calm weather, towards the evening; the female swims gently about, the male pursues, till tired with wantoning, the flings herself on her back, and admits his embraces; the seminal and urine faills copulate after the same manner on shore. Steller says, they go with young above a year, and bring forth one at a time, which they suckle by two teats, placed between the breasts. They are very voracious and glutinous, and feed not only on the fins that grow in the sea, but such as are flung on the edges of the shore; and when they are filled, they fall asleep on their backs. Their back and sides are generally above water, and as their skin is infested with a species of louse peculiar to themselves, numbers of gulls are continually perching on their backs to pick out the insects.

They continue in the Kamtchatkan and American seas the whole summer, but in winter are very lean. They are taken by harpoons fastened to a strong cord, but after they are struck, it requires the united force of thirty men to draw them on shore. When one is struck, its companions repair to its help, some will endeavour to overturn the boat, by getting under it; others will press down the rope, in order to break it, and others strive at the harpoons with their tails, with a view of getting it out, in which artifice they sometimes succeed. Their noise is like the snorting of a horse, which is occasioned by hard breathing. They are of an enormous size, some being twenty-eight feet long, and eight thousand pounds in weight; the head is small, oblong, and almost square; the nostrils filled with short bristles, the lips double, and the mouth, near the junction of the jaws, full of white tubular bristles, which serve to prevent the food from running out with the water; the lips are also furnished with bristles, which serve instead of teeth to cut the roots of the sea plants; in the mouth there are no teeth, only two flat white bones, one above and another below in each jaw, with undulated surfaces, which answer the purpose of grinders. The eyes are small; instead of ears there are two small orifices; the tongue is pointed and small, the neck is thick, and the head always hangs down. Near the shoulders the circumference of the body is twelve feet, about the belly twenty, near the tail four feet eight inches; the head is thirty-one inches, and the neck nearly seven feet; which dimensions render the animal extremely deformed. Near the shoulders are two feet or fins, two feet two inches long, without fingers or nails; the tail is thick, strong, and horizontal, ending in a stiff black fin, slightly forked. The skin is thick and black, and full of inequalities, and so hard as scarcely to be cut with an ax, without hair; beneath the skin is a thick blubber, which taints like oil of almonds. The flesh is coarser than beef, and will not soon putrefy. The young ones taste like veal; the skin is used for shoes, and for covering the sides of boats. Pennant’s Hist. Quad. vol. ii. p. 536. &c.

The sea-cow of the gulf of St. Lawrence weighs from fifteen hundred to two thousand pounds, and produces from one to two barrels of oil, which is boiled out of a fat substance that lies between the skin and the flesh; it carries its young about nine months, and seldom brings forth more than one at a time. The skin is cut into flces of two or three inches wide, and exported to America for carriage-tracks, and to England for glue. The teeth afford an inferior sort of worry, which very soon turns yellow. Philos. Transl. vol. lv. part 2. p. 249, &c.

SEA-Crow, in Ornithology, a name given by the common people of many counties of England to the puffin; which see.

SEA-Crow is also a name given by Edwards to the cut-water of Cateby and Pennant, and to the black skimmer of Latham. See Rynchops Nigra.

SEA-Cyprin, in the Verme Zoophyta, a name given by Ellis to the Sertularia Cypreifla; which see.

SEA-Daffodil, in Botany. See Panchtum.

SEA-Drewit, in Ichthyology, an English name for the rana pijcatris, or Lophius pijcatarius of Linnaeus; a very remarkable species of fish, of a middle nature between the cartilaginous and bony fishes. See Lophius Pijcatarius.

The bronchial holes are three on each side, which are situated deep in the mouth, and open in the mucous and fasciculi on the side of the head, the sides of which are the branchioplae, having several long slender cartilaginous bones, running longitudinally for their support, analogous to the branchial legons of other fishes; and these lacets, Dr. Parsons conjectures, may answer two ends, first, to form the membrane branchioplae; and, secondly, to make a convenient receptacle for the young till they are able to shift for themselves. If this fish does not bring forth its young perfect, Dr. Parsons thinks there can be no use assigned for these laces; but if they are viviparous, then the young may probably be harboured in them, being capable of crawling into them, as we may see by the pectoral webs on the underside: besides, as these fishes crawl on the bottom of shoal places, watching and alluring their prey, the young must be protected by the parent, till they are able to provide for themselves, which may probably when they grow too large to enter into these membranaceo.

This fish has either no nostril, or else they are hid within the head, and has a sort of membraneous rim running around the commissures of its sides and belly. Its flesh, when boiled, tastes like that of the frog. Willoughby’s Hist. Pisc. p. 85, Philos. Transl. vol. xvi. p. 126, &c.

SEA-Drages, or Draco marinus, a species of Trachinus; which see.

SEA-Drages, among Mariners, are such things as hang over the flup in the sea, as shirts, coats, and even the boat, &c. when towed.

SEA-Drage, or Draco marinus, in Ichtyology, a species of the raia, with a smooth body and a long ferratted spine on a finny tail. See Raia Aqulia.

SEA-Eel. See Eel and Meraza.

SEA-Egg, or Sea-apple, the name of the roundish centronia, with crooked or falcipinate spines. See Centronia and Echinus.

SEA-Fan, and Sea-feathers. See Gorgonia and Spongia.

SEA-Faring, denotes the condition of a mariner.

SEA-Fight. See Engagement and Signal.

SEA-Fin, a species of Serturaria; which see.

SEA-Fox, in Ichtyology, an English name for a fish of the fquals kind, called also the sea-ape; both names being given
given on occasion of the length of its tail in proportion to the body.

The old Greek writers have called it alopecia, and the later vulpes marina, and fimiæ marina, whence the names sea-fox, and sea-ape. See Sea-Fox and Squalus Vulpes.

SEA-Grage. See Altitude and Gage.

SEA-Gate, at Sea. When two ships are aboard one another, by means of a wave or billow, the seamen lay, they lie aboard one another in a sea-gate.

SEA-Goof, in Ornithology, the Ana leucoptera. See Duck.

SEA-Grape, in Botany. See Coccoloba.

SEA-Gudgeon, in Ichthyology, an English name given to the fish called by the generality of writers gobius niger, and the gobius marinus.

Artedi, who has made a genus of the gobii, excludes the common gudgeon, or gobio fluviatilis, from it, but he admits this fish as a genuine species of it.

Atheneus tells us of three kinds of gudgeons, the black, the yellow, and the white. This seems to have been very plainly the black gudgeon of that author. Salvin, in his figure of this fish, has given three fins on the back, but it really has only two. See Gobius Niger.

SEA-Hair, a species of Sturlaria; which fee.

SEA-Hare, in the Histories of Infestis, the name of the lcnna; a species of the Aplysia and alio of the Testis; which fee.

SEA-Hen, in Ornithology, a name given by some to the longwia, a web-footed bird, common on our coasts, and called the guillemot, or kidburn. See Columbus Troile.

SEA-Holly, in Botany. See Exyngium.

SEA-Hoarse, in Ichthyology, the English name of the hippocampus, a species of the acus, according to the older writers, and one of the syngnathi of Artedi. See Syngnathius.

The many idle tales reported of this vast amphibious creature, such as his method of bleeding himself when distempered, his vomiting fire when enraged, and the like, have made people, in almost all ages, delirious of seeing the animal. The Romans were fond of exhibiting it in their shows of wild beasts, and the description Pliny gave of it thence, was all the world knew of the creature for many ages. That author’s account, however, of its feeding on grubs on the banks of the Nile, no way agrees with the teeth we find its mouth furnished with.

The skeletons of these animals, as rare as they are with us, at present in their recent state, yet are found not unfrequently, in part at least, buried under ground, and that at great depths. The bones of the head are different from those of any other known animal, and when found in some parts of France, had always puzzled the wisps of the naturalists there, who, had in vain compared them with those of oxen, horses, &c. But at length one of the heads of these animals being sent over to France, cleared up the whole difficulty. The two jaws of this weighed forty-five pounds, and were two feet long, a foot deep, and a foot and a half wide.

It is easy to conceive from this, that the accounts we have of the size of the animal are not fabulous, these bones corresponding very well with them. Mem. Acad. Par. 1724.

Sea-hoarse is also a name sometimes, but improperly, given to the river-hoarse, or hippopotamus.

Sea-hoarse is also a name given to that species of seal called walrus.

SEA-Kale, in Gardening, the common name of a highly nutritious and palatable culinary vegetable. It is an early effluent plant, the young shoots of which are used somewhat in the manner of asparagus, and may, if it be said, be grown, by the method of cultivation which is given hereafter, to a size and of a delicacy of flavour greatly superior to that which is commonly brought to the table. See Crambe.

In addition to what has been offered under that term, it may be noticed that the plant grows naturally the belt in a sea sandy soil, or one which is of a loamy gravelly nature near the shores of the sea. In the cultivation of it in the garden, the improved method which has lately been advised, is to prepare the ground for it by trenching it two feet and a half deep, about the close of the year or in the beginning of it; when not that depth naturally, and of a light quality, it is to be made so by artificial means, such as the applying of a suitable proportion of fine white sand, and very rotten vegetable mould; if the ground be wet in the winter season, it should be completely drained, that no water may stagnate in it near the bottom of the cultivated mould, as the strength of the plants depends upon the dryness and richness of the bottom soil. After which the ground is to be divided into beds, four feet in width, with alleys of eighteen inches between them; then, at the distance of every two feet each way, five or fix feet are to be found, in a circle of about four inches diameter, to the depth of two inches. This business should be performed in a strictly regular and exact manner, as the plants are afterwards to be covered by means of pots for blanching them, and the health and beauty of the crops equally depend upon their standing at regular distances. If the seeds which were found and perfect, they will come up and flower themselves in the fall spring or beginning summer months; which as soon as they have made three or four leaves, all but three of the strong and well plants should be taken away from each circle; planting out those which are pulled up, which, when done by a careful hand, may be performed so as for them to have the whole of their top-root in a spare bed for extra forcing, or the repairs of accidents. The turnip fly and wire worm are to be carefully guarded against, the latter by picking them by the hand from out of the ground, and the former by the use of lime laid round the young plants in a circle. When the summer months prove dry the beds should be plentifully watered. As soon as the leaves decay in the autumn they should be cleared away, and the beds be covered with light fresh earth and sand to the thickness of an inch; the compost thus used having lain some time in a heap, and been turned several times, so as to be free from weeds, and the own insects as well as grubs. Upon the sandy loam dressing, about six inches in depth of light flake litter is to be applied, which completes the work of the first year.

In the spring of the second, when the plants are beginning to push, the flake litter is to be raked off, a little of the most rotten being dug into the alleys, and another inch depth of loam and sand applied. Cutting this year is to be refrained from, notwithstanding some of the plants may rise strong, and the beds managed exactly as before during this winter season.

In the third season, a little before the plants begin to show the covering laid on for the winter is to be raked off, and an inch in depth of pure dry sand or fine gravel now laid on. Then each circle of plants is to be covered with one of the blanching-pots already alluded to, pressing it firmly into the ground, so as to exclude all light and air, as the colour and flavour of the shoots are greatly injured by exposure to either of them. When the beds are twenty-six feet long, and four wide, they will hold twenty-four blanching-pots, with three plants under each, making twenty-two plants in a bed. They are to be examined from time to time, the young stems being cut, when about three inches above the ground, care being taken not to injure any of the remaining...
ing buds below, some of which will immediately begin to swell. In this way a succession of gatherings may be continued for the space of six weeks, after which period the plants are to be uncovered, and their leaves suffered to grow, that they may acquire and return nutrient to the root for the next year's buds. When seeds are not wanted, the flowers should be pinched off by the finger and thumb, as long as they appear. Where the expense of blanching-pots is objected to, the beds must be covered with a large portion of loose gravel and mats; but the faring is tripping, when the time and trouble of removing and replacing the gravel, for the cutting of the crop and securing the plant, are considered. By this mode of management, sea-kale is said to have been cut which measured ten, eleven, and even twelve inches in circumference, and that each blanching-pot on the average afforded a dish of it twice in the season.

The blanching-pots for this use are somewhat of the same shape and size as the large bell-glasses commonly employed in market gardens for raising tender vegetable crops, but made of the same materials as the common earthenware, having a handle at the top. They may be about a foot and a half in diameter at the rim where they apply to the ground.

Forcing Sea-Kale.—It is supposed that no vegetable can be so easily and cheaply forced as this, or require so little trouble; as the dung is in the finest state possible for spring hot-beds, after the common crop has been cut and gathered. The principal circumstance necessary in this business, is that of being very attentive and particular in guarding against too great a heat. The temperature under the blanching-pots should contrastly be kept as near fifty-five degrees of Fahrenheit's scale as possible, and on no account higher than sixty at any time. In this intention, in either of the two concluding months of the year, the sea-kale may be wanted more early or late, a suitable quantity of fresh stable dung should be collected and prepared, to cover both the beds and the alleys from two to three feet in height; as in the quantity to be laid on, a great deal must always be left to the judgment of the gardener, as well as to the state of the season as to mildness or severity.

It should invariably be well pressed down between the blanching-pots, heat-flicks being placed at proper intervals, by the occasional examination of which the heat below will be readily shewn. When the dung has remained in this situation four or five days, the pots should be examined to see the state of the shoots. It not unfrequently happens that worms spring above the surface, and spoil the delicacy of flavour in the young shoots. In order to prevent this, it is best to cover it with dry sea-coal ashes, which have been sifted neither very small nor very large. Salt has also the power of destroying them in an effectual manner, without injuring the kale-keil.

The crop, it is said, will be ready to cut and gather in three weeks or a month from the first application of the heat; but as much danger and mischief are the consequence when this is violent, it is advised to begin soon enough, and to force slowly, rather than in too quick a manner. It is likewise necessary to cut the leaves off a fortnight or three weeks before they decay, in those plants which are intended to be forced at a very early period.

It is also supposed that the blanching-pots used in forcing should be made in two pieces, the uppermost of which should fit like a cap upon the lower; as the crop might then be examined at all times without disturbing the hot dung. See Transactions of the Horticultural Society of London, vol. i. p. 13.

Sea-Lark, in Ornithology. See Charadrius hiaticula, and Emberiza unicolor.

Sea-Laurel, in Botany. See Phyllanthus, and Xylophylla.

Sea-Law. See Laurus of Oleron, Uses and Customs of the Sea, and Marine Insurance.

Sea-Leech. See Hirudella Marina.

Sea-Letter, or Sea-brief, in Marine Insurance, one of the documents expected to be found on board of every neutral ship. This specifies the nature and quantity of the cargo, the place from which it comes, and its destination. This paper, however, is not so necessary as the passport, which is the permission from the neutral state to the captain or master of the ship to proceed on the voyage propounded, and usually contains his name and residence, the name, description, and destination of the ship, with such other matters as the practice of the place requires. This document is indispensable necessary for the safety of every neutral ship. Hubner says that this is the only paper that is rigorously insisted upon by the Barbary corsairs, by the production of which alone their friends are protected from insult. The passport in most cafes supplies the place of the sea-letter.

Sea-Lion, Phoca Leoena of Linneus, in Zoology, is a species of seal, which inhabits the seas about New Zealand, and the islands of Juan Fernandez, the Falkland Islands, and that of New Georgia. The animals of this species are seen in great numbers in June and July, the breeding season, on the island of Juan Fernandez, where they rest to give birth, and leave them in the sea, until September; they bring forth two at a time; and during this season, the female is very fertile. They arrive on the breeding islands very fat and full of blood, and their blubber has been found a foot thick; one of them has been known to yield a butt of oil, and the blood has filled two hogheads.

Lord Anson's people eat the flesh, calling it beef by way of distinction from that of the common seal, which they called lamb. The old animals, except at the breeding sea, are very timid; and to prevent surprise, each herd places a sentinel, who gives certain signals at the appearance of danger; they associate in families, like the sea-bears, and are equally jealous of their miffrels. They are of a lethargic nature, and fond of wallowing upon one another in muddy places; they grunt like logs, and snort like horses.

During the breeding sea, they abstain from food, and become very lean; at other times they feed on fish and the smaller seals. The male has a projecting snout, hanging five or six inches below the lower jaw; the upper part conveys of a loose wrinkled skin, which the animal when angry has the power of blowing up, so as to give the nose an arched appearance; the feet are short and dasy, having five toes on each, furnished with nails; the hind-feet appear like laminated fins; the eyes and the whiskers are large; the hair on the body is short and of a dun colour; that on the neck a little longer, and the skin very thick. The length of an old male is twenty feet, and the greatest circumference fifteen. The nose of the female is blunt and taworous at the top; the nostrils wide; the mouth breathing very little into the jaws; two small cutting teeth below; two small and two large above; two canine teeth, remote from the preceding, five grinders in each jaw, and all the teeth conical; the eyes oblique and small; no auricles; the fore-legs twenty inches long; the toes furnished with oblong flat nails; the hind parts, instead of legs, divided into two great bifurcated fins; no tail; and the whole covered with short ruf/coloured hair. The length from the nose to the end of the fins is four yards, and the greatest circumference two and a half. Pennant's Hist. of Quad. vol. ii. p. 531. See Phoca Leoena.
SEA-

**SEA-Loaf**, *pediculus marinus*, a name given to the *Molucca crab.*

**SEA-Lungs**, in the *History of Infusium*, the English name of a species of medusa.

**SEA-Man.** We have many accounts, even from authors of credit, of something resembling the human figure seen at sea, and fancy has carried them to such a height, that the truth of the description is lost in most of them.

The fyrens, which we have accounts of even in Bartholin, and the sea-man, or *homo marinus*, as it was called, seen and described by Barchewitz, give the greatest credit to the story; but writers are so fond of telling marvellous things, that great allowances are to be made in the reading.

The general description of the sea-man is, that from the navel downwards the whole is only a shapeless lump of flesh, without any of the limbs, either of limbs, fins, or tail. On the breast there stand two pecoral fins, which are each composed of five bones or rays, resembling the human hand, and connected together by a membrane like the toes of a duck, or some other water-fowl’s foot.

These fins are what have the appearance of something human, and when seen without the body of a white-bellied fish, may be taken for hands with short arms, and the resemblance of a head is easily fancied. These fins are not peculiar to any one kind of fish; but the manati or sea-cow, the rana pescatoris or luphostis, and many others, have them. It is probable, from most of the accounts we have, that the manati, or sea-cow, is the creature which, being seen raising its head above water at a distance, and extending these pecoral fins, which are what it swims with, has given rise to the idea of the upper parts of a human figure.

As to the description of a shapeless lump of flesh making up the lower part of the animal, it seems too contrary to the course of nature in all other sea-animals, to have any foundation in reality, and probably was only the invention of the describer, to make out what he did not see above water.

It is true, that Barchewitz takes great pains to prove that the sea-man, or *homo marinus*, he describes, was a wholly different creature from the sea-cow; but his description of it carries too little the air of any thing in nature, to meet with an easy credit.

It is wonderful, that so judicious a writer as Artedi should give any faith to the existence of so strange a fish as this, but he mentions it with a great air of doubt, and wishes a more perfect history of it, if it any where exists.

The public are often imposed upon by cheats, who shew different things under the name of sea-men, mermaids, and fyrens; but if we may judge of the generality of these creatures, thus shewn, by the latest instance among us, they are very wretched counterfeit indeed. This creature was said to be a young mermaid taken on the Acapulca shore, and maintained its credit so well in London, as to afford the proprietor a comfortable subsistence for ten months among us, though no other than a human fucus of about eight months, with a hydropophaeus head, and with the two legs growing together, and covered by one common membrane: the toes of this fucus were bent out in a resemblance of fins.

**SEA-Mark.** A point and conspicuous place distinguished at sea. See LAND-MARKS, BEACON, and BUOY.

**SEA-Mos.** See CORALLINE and CONVEXA.

**SEA-Moufe.** In the *History of Infusium*, the English name of the aphrodita.

**SEA-Mud.** In *Agriculture*, that sort of muddy deposition which is often taking place on the shores and coasts of the sea, and which occasionally forms a constituent part of the soil of the lands in such neighbourhoods. In some instances it is of a rich improving quality, but in the other cases it partsakes of a clayey unproductive nature, especially that which is of a black, tough, crude description. In some places where this material is found of use as a manure, they distinguish it into two kinds, or that which is taken from the surface, and called *green-mud* mud, or sludge, and that which is raised or taken before it is covered with green earth, denominated *red* mud. The former is by much the richest and strongest as manure, therefore the best calculated for application in this way, where it can be procured.

It is sometimes employed in preference to marle, though that substance may be more ready at hand, in the proportion of about three roods to the flat acre, being laid on the land ground in autumn, that is to be broken up in the following spring months. It is mostly got by digging it up only one foot depth from the surface. After being spread out, and well broken down and reduced, it is turned down into the soil by the plough. It is useful for oat, barley, potato, and wheat crops, producing a large return. It is also very durable as a manure of this nature, lasting longer even than marle, and being never liable to injure grass-lands. This sort of rich sea-mud is mostly met with on the banks or shores near the mouths of large rivers which empty themselves into the sea, but in other cases its fertilizing properties are often less to be depended upon.

The muddy material which is combined with sandy materials on the sea-coasts in some districts, is also found of great utility as a manure.

**SEA-Nettle.** See NETTLE.

**SEA-Oak**. See WEEK, and FOCUS.

**SEA-Officer.** See OFFICER.

**SEA-Union.** In Botany. See SCILLA.

**SEA-Otter.** See OTTER.

**SEA-Oufe.** In *Agriculture*, a rich sort of mud or deposition raised from the sea-shores in different parts of the kingdom, and which has been found in many cases of much use as a manure. It might probably be found good, and in large quantities, in many situations on the sea-coasts, where it has not yet been thought of by the farmer. As there can, however, be no doubt of its possessing a highly enriching property, it should be diligently provided in all places where it can be had. It is flated, in the Norfolk Agricultural Survey, that Mr. Palgrave, at Culterhal, uses much sea-oufe mud scraped up by the bear from the bottom of Yarmouth Haven. He lays on forty loads per acre, and has thus manured seventy acres; the improvement is very great. It was found on trial that it is a calcareous oufe-mud; and that on felds or burning-places, and sand or gravel, it forms a cold bottom, and is an effectual cure. Fifty loads per acre of sea-oufe have been used on the upland loams of Warham with very great success; superior crops the consequence. And another subsistence may be considered under this head, though in the above Agricultural Survey it has been described under that of sea-weed, which it does not seem to properly belong to. It is found on the coast at Thornham, being marked in Mr. Faden’s map of the country for what is termed crabs, scalps, and oak-roots. It is flated by the write on examining it, to be obviously the ruins of a forest of large trees, the roots and roots remaining, but in such a state of decay, that with a spade he dug into the centre of many, and might have done of all, with as much facility as into a mass of butter. Where the stumps are not found on digging, a black mass of vegetable fibre, apparently consisting of decayed branches, leaves, warches, &c. is turned up; to what depth this vegetable stratum extends, has not been ascertained, but at some creeks
creeks on the very edge of the sea at low water, there is a very fine foamy sea-otique at two or three feet depth; the extent of this once sylvan region, which every common tide now covers, can scarcely be less, in one place only, than from five to six hundred acres. There is not an appearance of any tree lying at present from the flump, as if blown down or left after falling, but rather that of a foret cut down in halfe, the flumes cleared and hurried away, leaving the branches to rot; but this is mere conjecture. It is remarkable that, on the contrary, in the salt and brackish water, there is often a rank luxuriance, or rather a rank barbarity of vegetation, which is very remarkable and very offensive to the sense of sight and smell.

Two of the most esteemed productions of the sea, which are found to be of the most importance, are the sea-otique or sea-wrack, and the sea-mosses. The sea-otique is the common name of what is called in botany Pissum vulgare, which is a lumpy, or more properly a flumpy sea-otique. The sea-mosses are a class comprehending those that are lignonous, or of a woody hardnes, which were called lithophyta by the ancients, as if their hardnes approached to that of stones; these, Marigli says, consist of two substances, a cortical and an internal; the cortical part, while in the sea, is soft, but in drying becomes as hard as chalk, and easily crumbles between the fingers; the internal substance seems more of the nature of horn than of wood; when burnt it throws out a pumice, or froth, like that which horns or feathers of animals yield in the fire, and their smell in burning is of the fame kind; the branches of these are very pliable, bending in the manner of whalebone, and giving the fame resistence to a knife in cutting. The third clafs comprehends those plants which are of the hardnes of flone, and which should properly be called the lithophyta; these are the several species of corall, madrepora, and the like.

Marigli endeavours to explain the differences of these several substances, and to account for the manner of receiving nourishment, agreeably to the system which prevailed in his time, and which appropriated them to the clafs of vegetables. Marigli, Hift. Phys. de la Mer. Mem de l'Acad. Par. 1710.

By later experiments and observations, it has been sufficiently demonstrated by M. Peyssonnel, Bernard de Jussieu, Donati, &c. that those marine substances which Marigli thought to be plants, are the work and habitation of animals. See on this subject the articles CORAL, AND CORALLINES.

Dr. Lifter apprehends, that those substances which, in his time were thought to be sea-plants, serve to render a great deal of the sea-water fresh, and give it in mists to the clouds, whence it again falls on the earth; this is easily proved by experiment, thus; if a quantity of sea-water be put into a long glass body, and into it there be put a large and vigorous sea-plant, such as the common seawrack, and the head placed on the glass, and a receiver fitted for it without cutting the joints, there will daily distill into the receiver, without giving any fire below, a clear and sweet water, fresh and potable, and without any disagreeable or unwholome quality. The quantity is but small that is obtained in this way, but it is evident, that in the same manner a very immense quantity of the sea-water is every hour made fresh, and raised up into the air from the infinite number of plants that grow in it. Dr. Lifter even thinks that the tropic winds, which blow constantly one way, may be owing to this fort of caufe. Philos. Trans. N° 156. See TROPIC winds.

SEA-PHALEON, in Botany. See ARENILEX.

SEA-Quadrant. See BACK-SCAFF, and QUADRANT.

SEA-ROOM, denotes a sufficient distance from the coast, as well as from any rock and shallows, by which a ship may drive or flud without danger of shipwreck.

SEA-SALT. See SALT.

SEA-SAND. See SAND, and Common SALT.

SEA-SAND, in Agriculture, that fort of fand which is thrown up in the creeks and other places on the coasts of the sea, and which is very often useful as manure. The sea-fand, which is thrown up in creeks and other places, is very rich and proper for this purpose. In the western parts of England, which lie upon the sea-coasts, very great advantage is made of it. The fragments of sea-shells, which are always in great abundance in this fand, add to its virtues; it being always the more esteemed by farmers, the more of these fragments there are among it. The fand of this fort, which is used as a manure in different parts of the kingdom, is of three kinds: that about Plymouth, and some other of the southern coasts, is of a blue-grey colour, like ashes, which is probably owing to the shells of muscles, and other

fifth
fish of that or the like colour, being broken and mixed with it in great quantity. Wellward, near the Land's-End, the sea-fand is very white; and about the isles of Scilly it is very glifhen, with small particles of tale. On the coafts of the North the sea is yellow; brown, or reddish, and contains so great a quantity of fragments of cockle-shells, that it seems to be chiefly composed of them. That for sea-fand is accounted bell, which is of a reddish colour; the next in value to this is the blueclif, and the white is the world. This kind of fand is the best when taken up from under the water, or from land-banks, which are covered by every tide. And it is remarked, that the small-grained sand is the most sullen in its operation, and it is therefore best for the tenant who is only to take three or four crops; but that the coarse, or large-grained sand, is much better for the landlord, as the good it does lasts many years. Where sand is dredged out of the sea, it is usually much dearer than where it is taken from land-banks.

In the northern parts of Lancashire, and in Cornwall, the more light farts of land in the vicinity of the sea-fhores, are in many cases much improved by the application of sea-fand upon them. The practice is to lay it on in a pretty thick manner, in order that it may be well incorporated with the foil, by the different ploughings before the wheat is sown. In this way large crops are often afforded, and the effects of the dressing last several years. It is likewise found very beneficial when applied thinly over the surface of grass-lands in rendering the herbage more fine and sweet. It is a substanfice that might in many situations be much more extensively made use of than has hitherto been the cafe. See Sands, Shelly.

This fort of sand is considered as a vast treafure by the farmers in some parts of the county of Cornwall, as has been already hinted at, especially where the sea-coast is extensive. It is supposed to be a substance that feeds the corn, as well as pulfe-crops and roots, well, and which is highly useful on pafture-land; it being material to the value of farms whether they are near to or remote from it. It is, however, procured from great distances in some cafes. Its goodness greatly depends, however, upon the quantity of calcareous and animal matter which it contains, in addition to the mechanical effects which it affords; with some kinds of it, fliny, earthy, ligneous vegetable, and animal matter, are combined, in which cafe it is denominated lig or liggan, and thought of great value for potatoe crops. The large-sized coral sand is fuppofed the moft lafting in its effects; but the smaller grained and shelly farts are extenfively used in some places.

When this fort of sand is applied alone, either on tillage or grafs-land, it is called clean fanding; but it is more usufally laid on in mixture with earth and dung in the way of a compoif. It is employed in all the proportions of from three hundred to thirty facks of sixteen gallon each, to the customary acre of that diftrift. Its utility depends much on the nature of the lands, being more beneficial on the moory and the thinner farts of foil, than on the deep loamy kinds.

It is computed that more than 54,000 cart-loads of it are taken from the harbour of Padiflow alone, and that the ex- pense of land-carriage for this article only, for the whole diftrift, is more than 300,000 l. a-year.

In some of the northern parts of the county of Lancifter, sea-fand was formerly much had recourse to on tillage and other land, as has been seen above, but it has latterly been lefs employed. They apply it from 80 to 300 or 400 finge- horfe cart-loads to the customary acre, every ten or twelve years, mostly for the wheat crop. The dry sea-fand was formerly made ufe of, but very seldom at present, as the muddy, or that dug from some depth, and intermixed with mud, is now found much better. It is of a blackish appearance, and faid to laft longer in the soil, and produce better crops than the common fand. It is sometimes, likewife, laid upon the grafs, it is laid, with good and lafting effects. In three fmall trials made with it by the Rev. Mr. Steanbank, it feemed however to be of little utility. He applied it on two ridges, on common pafture, on meadow and on ploughed land, in the quantity of 200 fingle horfe cart-loads to the customary acre of each, and found not the leafl alteration or improvement in the crops of any of them. It is, however, remarked, in the Agricultural Survey of the North Riding of York, that in many cafes in the vicinity of the sea, use has been made of sea-fand as a manure with con- fiant success, and that for the diftrifts of Cleaveland, and the coast where the wet adhesive clays want draining and breaking, and in most parts of which it might be easily procured, it would be equally ufeful. It is fuppofed to be there disregarded in confequence of its great plenty, and being capable of being provided without ex pense. See Sand.

SEA-Scorpion. See Scorpio.

SEA-Serpent. See Sea-Snake.

SEA-Shells, in Agriculture, such as are formed and dug from the creeks and bays on the sea-coast. They are con- stantly very beneficial in improving land in all situations where they are met with in sufficient quantity. But the great ufe of marine shells is more shewn in the following passage in the statitical account of the parish of Kirkmabreck, in Galloway. The principal manure used there for improving land is sea-shells, of which there is an almost inexhaustible quantity, not only within the high-water mark on this fide of Wigton bay, but also in the dry land, several hundred yards from the shore. These shells are sold at five- pence per ton, twenty-five of which are sufficient for an acre; and prove a cheap and excellent manure, preferable to either lime or marle. Many thousand tons of these shells are annualy carried (by villains constantly employed in the busines) all round the coast, and sometimes even to the Isle of Man. Thefe shells have been used with great advantage for the improvement of barren heathy land, infomuch, that many hundreds of acres in this parish, originally not worth more than 25. per acre, have been made worth from 100. to 150. per acre. Yet this, like every other advantage that is easily attained, is not duly prized; for upwards of one thousand acres in this parish, though capable of cultivation, lie in a rate of nature, covered with heath, and almost good for nothing. A little calculation might serve to fhew landlords, that on nothing could they lay out their money to so much advantage. As for a tenant, where he has only a leafe for nineteen years, and perhaps his encouragement not great otherwife, it cannot be expected he should do much in the cultivation of barren land. The tenant, however, might well lay these sea-shells on land already cultivated. This hint should be duly at- tended to by the cultivators of such lands, in situations where such manusres can be readily provided. It is observed, that in Loch Tarbet there is an immense number of oyster-shells, almost unmixed with any fand, when the thin litter above them is removed: the extent of this allufifying mass of shells is unknown, but it is probable it can never be exhausted. A vast tract of improvable moorifh land in the neighbourhood, may, some time or other, fhew that Providence did not place this fund of manure in vain so near it. For such moorifh heathy ground, these sea-shells are the fittest ma-
nature, but their use ought not to be confined to it. In order to make the carriage lighter, and the effect the quicker, perhaps it would be worth while to burn them first, as is sometimes done to marl. The kiln might be made with one or two eyes, running into it about half way at the bottom, with some flags or stones rudely arched over them, the kiln then filled with shells, and fed with fire for a day or two, as might be found necessary. Lime is burned in this way in the space of two or three days, and shells already in a mouldering state, would take much less both of time and fuel. The operation would not be hindered by the tides, as these shells are found also under the surface beyond the seamark. Strata of these oyster-shells are also to be found at the head of Loch Caoles port; but there (so it flow is the progress of the improvement!) they have not yet begun to use them as manure; probably the time is not distant when these sea-shells will become an article of commerce, and be carried at least along all the shores of Kintyre.

And it is stated by the author of the Agricultural Report of Norfolk, that in East Winch and Well Bilney, and many other towns in the county, there is a remarkable bed of oyster-shells in sea-mud; the farmers use them at the rate of ten loads an acre for turnips, which are a very good dressing; they are of particular efficacy on land worn out by corn. Mr. Forster several years ago laid twenty loads an acre on some worn-out land, and they had an amazing effect in producing grass, when laid down in seeds, giving a deep luxuriant hue like good dung: the benefit very great at the present time. They are found within two feet of the surface, and as deep as they have dug, water having stopped them at sixteen or eighteen feet deep. They are used again and again on the same land, and with the same effect. At East Winch, Mr. Crowe has acres together of this most valuable manure. They fall to powder on being fired. All sea materials of this nature should constantly be well attended to, and collected when wanted to be employed as manure by the farmer. Where they are in a solid state, they only require to be in some measure broken down into a sort of coarse powder. See SAND and SHELLS.

It may be noticed, that in the first mentioned district, the price of the shells is now higher than it was formerly.

SEA-Sorrel, is said to be prevented by drinking sea-water mixed with wine.

SEA-Shell-Grapes, in Botany. See COCCOLORA.

SEA-Splinters, or POLYPOD, a name given by Ellis to the Seriularia lehennstrum.

SEA-Sun-Crown, American. See AMERICAN, &c.

SEA-Sea-Crow, in Ornithology, the name of the Sterna hi-
runda, common on our coasts. See STERNA.

SEA-Tamarisk, a name given by Ellis to the Seriularia ta-
mariska.

SEA-Tangle, in Agriculture. This is another name by which the same weed which is usually made use of as a manure is known in some districts, especially those of the north, where it is sometimes collected, and applied, either in its simple state, or when made up into compot with some sort of earthy sub-

SEA-Turtle Dove. See Sea-Turtle Dove.

SEA-Wall, in Rural Economy, that fort of wall or defence which is thrown up and provided against the sea on the different coasts of the kingdom. It is formed of various kinds of materials, according to the nature of the situation and circumstances, such as those of earth, flones, shells, strong gravel, and many other matters, so as to constitute a fort of embankment. See EMBANKMENT and EMBANKING.

Walls or banks of this nature should constantly have a good degree of slope backwards, whatever the nature of the materials may be which are employed in their construction, as this form always affords great safety and protection to them. The bases or foundations of them should likewise be securely laid, and well guarded and protected by every possible convenient means which their situations and circumstances will admit of; and the internal parts have a sufficient weight of earthy or other material thrown up and laid against them, in order to counteract the weight of the water during the time of the tides. In Essex, Mr. B. Dudley is said to have endeavoured to give a new direction to a shifting bank of shells, as a guard to a sea-wall, which had been newly re-

See SEA-Water, in Agriculture, a term frequently applied to the weed thrown up by the sea in many situations, and which is collected and made use of as a manure, and for other pur-

SEA-Water, that briny bitter fluid which constitutes the sea. See WATER.

SEA-Water, in Agriculture, that which is brought by the sea, and much impregnated by saline matters. It is fugg-

SEA-Weed, in Botany, the Submerged Algae of some scientific writers, are such cryptogenic plants as grow under water, in the sea, fixed by their base, originally, to some rock, flone, or shell, but often found floating without any attachment. Their seeds are, in many instances, known, but the economy of their fructification has not yet been fa-

SEA-Weed, in Agriculture, the wreck or weed thrown up by the water on the sea-coasts, and sometimes cut from their

SEA
sides. It is the plant known by the name of quercus marina. And it is a material much used as a manure in some districts, as those of Kent, and the northern counties, as well as in the islands of Jersey and Guernsey. It is found to become tender and easily reduced by remaining some time in heaps, and taking on the processes of fermentation. It is strongly impregnated with saline matters, and of course proves a beneficial application for land.

It is said to have been found, in the practice of Mr. Rudd in Yorkshire, to answer well in composition with kelp, ashes, slamm from the alum-works, and lime, the whole being mixed up with earth. But in many places it is used made of its simple state, after having undergone a degree of fermentation, or after being incorporated with yard-dung. In the Agricultural Survey of Argyllshire it is stated, that along all the coasts it is much used as a manure, though not always valued as much as it ought. Its effects are not to fail as that of dung, nor is it so great when laid on in winter as in April or May, when it is riper, and more impregnated with salts. What comes afloat during summer after the ground is frozen, the more careful farmers gather into heaps, and spread on lay-downs. In either way it turns to little account. Much of the heaps melt away, and much of what is spread dries and shrivels to nothing. If mixed with earth, ashes, fern, weeds, &c. in a compost, it would produce a quick and strong fermentation, and all its juices would be preserved. This is the way to make the moss of this great gift of Providence, and the farmer andcottager both should thus increase their store of manure wherever it can be done.

It is likewise noticed, that in the above islands, where this weed has been long employed, it is cut twice in the year, the first cutting in February or March being applied as a manure on the pature grounds, nursery lands, and those sown with barley. It is used in the proportion of two cart-loads, weighing two thousand pounds each, with six cart-loads of stable dung to a 1000 feet square. The second cutting, which is performed in July, is laid to dry on the sea-shore, and afterwards made use of as fuel; the ashes of which are found an admirable manure, especially on clay land. It is spread over the surface of the land in the winter season, or early in the spring, in the proportion of about half a bushel to the perch. It is laid to have a great effect in giving a full ear to the grain, and to prevent its being laid.

But it has yet been ascertained upon what sorts of land the weed in its simple state has the most effect. It is found to afford great vigour of growth to plants in all kinds. It has generally been supposed to have little effect beyond the immediate crop; but when duly blended and incorporated with other proper earthy or other materials, it has been found to be more lasting in its effects, and to be more proper in this application. See Manure.

The plants of this sort, however, which are made use of as manure on the sea-coasts of this country and Ireland, consist of many distinct species of fucus, algae, and confervæ, according as they prevail in different parts. Sir Humphrey Davy found by different processes, in the common fucus, which is commonly the most abundant of any on our sea-coasts, in one mode one-eighth of gelatinous substance similar to mucilage, and in treating it another way, nearly four-fifths of its weight of water, but no ammonia; the ashes contained sea salt, carbonate of soda, and carbonaceous matter. The gaseous matter was small, and chiefly carbonic acid, gaseous oxyl of carbon, and a little hydro-carbonate.

This manure is said to be transient in its effects on land, not lasting more than a tingle crop, which may be readily accounted for from the large proportion of water, or the elements of water, which it contains. It decays, on exposure to the atmosphere, without any heat being produced, seeming to melt down as it were, and dissolve away. A large heap has been known to be wholly reduced to a little black fibrous matter in less than two years. The firm part of the fucus being let remain in a jar with atmospheric air for a fortnight, became much shrivelled, and the sides of the jar covered with dew, the air being found to have lost oxygen, and to contain carbonic acid gas.

The fermenting this sort of weed to ferment before it is used, is thought wholly unnecessary, as there is no fibrous matter rendered soluble in the process, and a portion of the manure is lost. The practice of the best farmers in the western parts of this country, is to be that of using it as fresh as it can be had, and that the results of this method are exactly in conformity to the theory of its operation. "The carbonic acid formed by its incipient fermentation must be partly dissolved by the water set free in the same process; and thus become capable of absorption by the roots of plants." That the effects of this weed as a manure chiefly depend upon this carbonic acid, and the soluble mucilage it contains; and it has been found that some fucus which had fermented so as to have lost about half its weight, afforded less than one-twelfth of mucilaginous matter, from which it may be fairly concluded that some of this substance is destroyed in fermentation."

There is unquestionably a great loss sustained in this and perhaps other ways, where earthy matters are not used with it.

Sea-Willow. A name given by Ellis to the Gorgonia acuta.

Sea-Worthy. See Worms.

Sea-Worthy, in Marine Insurance, a term applied to a ship, denoting that she is "tight, staunch, and strong, properly manned, and provided with all stores," so as to be in all respects fit for the intended voyage. In every insurance, either on ship or goods, there is an implied warranty that such is the state of the ship, so that the insurer may gain the premium for indemnifying the insured against certain contingencies; for if the ship is incapable of performing the voyage, there is no possibility that the insurer should gain the premium; and in that case, the contract, on his part, would be without consideration, and consequently void. The insurer undertakes to indemnify the insured against "the extraordinary and unforeseen perils" of the sea; and it would be absurd to suppose that any man would insure against those perils, but in the confidence that the ship is in a condition to encounter the "ordinary perils," to which every ship must be exposed in the usual course of the voyage proposed. In France every ship is surveyed, before the commencement of her voyage, by officers appointed for that purpose, who make their report; but the report upon such survey was not sufficient proof of sea-worthiness, and it still relied with the insurers to shew the contrary. A ship should be presumed not to have been sea-worthy, unless it be made to appear that her disability arose from sea-damage, or other misfortune. It is a wholesome rule, all circumstances considered, says Jerceant Marshall, that the insured shall be held to pretty strict and cogent proof of the ship's being sea-worthy, fit for performing the voyage insured, with the proposed cargo on board, and in all respects fit for the trade in which she is intended to be employed. It is also a wholesome rule, that this proof shall not only be cogent and strong to shew the ship's sufficiency at the time when the failure, but also that the insured shall bring forward all the evidence which he has upon this subject; particularly what relates to the state she was in when the loss happened,
or when she was condemned as unfit to proceed on the voyage. If any thing should be withheld, which the injured might have produced, it will always throw great suspicion on his case. If, on the other hand, it appears from the facts of the case, that the loss may be fairly attributed to sea-damage, or any other unforeseen misfortune, but yet the insurers mean to allege that the ship at her departure was not sea-worthy, the onus probandi will lie on them. This seems to be the simplest rule; and the simplest rules are always the best, particularly in matters of commerce. If it be clearly ascertained that the ship, at the time of her departure, was not in a condition to perform the voyage injured, neither the innocence nor ignorance of the insurers, nor any precautions he may have taken to make her sea-worthy, will avail him against the breach of his implied warranty. If the ship be not sea-worthy, the policy will be void, though both the injured and the captain believed her to be sea-worthy; and though the insurers knew the state she was in as well as the owners. Where the goods injured have sustained a damage in the voyage, from the insufficiency of the ship, the question, whether the owner or master of the ship be liable to make good the loss, depends on the question whether the ship was in a condition to perform her voyage at the time of her departure, or became defective from stirs of weather and the perils of the sea. But it is sufficient if the ship be sea-worthy at the time of her failing. She may cease to be so in twenty-four hours after her departure, and yet the underwriters will continue liable. The question, however, in such cases, will always be, whether her disability arose from any defect existing before her departure, or from a cause which occurred afterwards. But if a ship, within a day or two after her departure, become leaky and founder at sea, or be obliged to put back, without any visible or adequate cause to produce such an effect, the natural presumption is, that she was not sea-worthy when she failed; and it will then be incumbent on the insured to shew the state she was in at that time.

It is unnecessary to make any representation of the condition of the ship to the insurer, previous to the effecting of the policy; for it is a rule that no representation must be made of matters relating to the risk which are covered by a warranty.

But a ship, to be sea-worthy, must not only be tight, staunch, and strong, and provided with all necessary stores for the voyage proposed; it is, as has been already observed, a condition or warranty, implied in the contract, that the ship shall be properly manned, by persons of competent skill and ability to navigate her. And therefore, if she be suffered to fail in a river, or other place of difficult navigation, without a pilot properly qualified, the underwriters will be discharged; for this is a breach of the above condition. Marshall's Treatise on Insurance, vol. ii. See Ship and Warranty.

**SEA-Wreck**, the name by which the sea-weed, collected and prepared for manure, is known in some places. See **SEA-Weed and Wreck**.

It is said to be fed upon by sheep and black cattle, in some places; eating it from the rocks on which it grows, in its falt or flate, during the ebbing of the tides. As a manure, it is often used fresh with earth and sand in a fort of compost, without any lofs.

**SEA-Yoke.** See Yoke.

**SEA, Head.** See Head Sea.

**SEA, High.** See High.

**SEA, Lie under the.** See Lying.

**SEA, Pacific.** See Pacific.
the structure of the germen, and situation of the embryo.

SEAGAN, in Geography, a town of Persia, in the province of Iarak; 50 miles E.N.E. of Hirabad.

SEAGRIM, the common name sometimes given to a troublesome field weed. See Ragwort.

SEAH, in Jewish Antiquity, a measure of capacity containing six cabs. See Cae and Measures.

SEA-HORSE ISLAND, in Geography, an island in Hudson's bay. N. lat. 62°. W. long. 92° 50'.

SEA-HORSE POINT, a cape on the east of a peninsula in Hudson's bay. N. lat. 54°. W. long. 82° 10'.

SEAGONNET Rocks, rocks on the coast of Rhode island, in the entrance of Narragansett bay.

SEAL, Sigillum, a pincushion, or piece of metal, or other matter, usually either round or oval, on which are engraved the arms, device, &c. of some prince, state, community, magistrate, or private person, often with a legend or inscription; the impression of which in wax serves to make acts, instruments, &c. authentic.

The king's great seal is that by which all patents, commissions, warrants, &c. coming from the king are sealed: this consists of two impressions, one being the seal itself, with the effigies of the king impaled upon it; the other has an impression of the king's arms in the figure of a target, for matters of smaller moment, as certificates, &c. that are usually pleaded sub pede sigillii.

The keeping of this seal is in the hands of the lord high chancellor, who is hence also denominated Lord Keeper.

The office of lord chancellor, or lord keeper, whose authority by 5 Eliz. c. 18. is declared to be exactly the same, is with us at this day created by the mere delivery of the king's great seal into his custody, without writ or patent.

The king's privy-seal is a seal usually first set to grants that are to pass the great seal. See Patents.

The use of seals is very ancient, an instance of which occurs in Daniel, chap. vi. 17. But seals are still older than this; for Jezebel, in 1 Kings, chap. xxii. seals the orders she sent for Naboth's death with the king's ring. See also Jerem. xxxii. 10, &c.

In effect, as the ancient seals were all engraved on the collets, stones, &c. of rings, and as the original use of rings, it is asserted, was only to be used in readiness for the sealing of acts, instruments, &c. seals should seem to be as ancient as rings themselves.

These sealing rings, called annuli signatorii, sigillares, cirgraphi or ceroaphi, it is said by ancient authors, were first invented by the Lacedemonians, who, not content to flut their chuds, armories, &c. with keys, added seals to them; and to this end, at first they made use of worm-caten wood, the impressions of which they took on wax, or soft earth; but at that length found the art of engraving figures, or rings, the impressions of which they took in the same manner. This, however, must be granted, that even in Moses's time, the art of engraving, not only on metals, but also on precious stones, was known.

Indeed, it does not appear that the ring had any other use among the primitive Jews besides ornament: but at length it was used to seal instruments, contracts, diplomas, letters, &c. inclusions of which we have in the first book of Kings, xxi. 8. Elsewhere, viiio. Xenophon, Hellen. lib. i. Quint. Curt. lib. vi. Juft. lib. xliii. cap. iii. where we learn, the keeping of the emperor's seal became a particular office. Lucian adds, that Alexander gave his seal to Perdiccas, thereby appointing him his successor.

Pliny observes, that in his time there were no seals used any where but in the Roman empire. At Rome, he tells us, they were become of absolute necessity, insomuch that a testament was null without the testator's seal, and the seals of seven witnesses; but it does not appear that the Romans had any such things as public seals; nor that their edicts and contracts were sealed, not even in the times of the emperors.

In France the custom anciently was, instead of sealing their instruments, &c. only to seal them; as appears from an infinity of ancient charters, which are not sealed at all; the reason of which was, that in those days very few people were able to write; fearfully any body, indeed, could read and write but clerks; and the custom continued when learning made its way among them, though the reason for doing it had ceased.

In England, the first sealed charter we find extant is that of Edward the Confessor, upon his founding of Westminster Abbey; yet we read of seals in the MS. history of king Offa.

And Sir Edward Coke relies on an instance of king Edwvyn's making use of a seal about an hundred years before the Conquest; though some have doubted the authenticity of this charter, because it is certain that sealing was not then in common use.

Before the time of William the Conqueror, the English did not seal with wax, but only made a golden cross on the parchment, and sometimes an impression on a piece of lead, which hung to the grant with a filken string, and was deemed an abundant authorizing of the grant itself, without either signing or witnesses.

This practice of affixing the sign of the cross proceeded from their inability to write; which is honestly avowed by Caedwalla, a Saxon king, at the end of one of his charters: "propria manu pro ignoranria literarum signum faciete crucis expressi et subscripti."

The fame circumstance is related concerning the emperor Justin in the East, and Theodoric, king of the Goths, in Italy.

The colour of the wax with which William's grants were sealed, was usually green, to signify that the act continued for ever fresh, and of force. The usual impression on all laymen's seals, till the year 1218, was a man on horseback, with a sword in his hand; afterwards, they began to engrave their coats of arms on their seals; only the archbishops and bishops, by a decree of cardinal Otto, who was legate here in 1237, were to bear in their seals their title, office, dignity, and even their proper names.

Dr. Cheene observes, that none below the dignity of a knight had any right to a pendant seal, called Authenticum.

The emperors long sealed all their acts of importance with a golden seal; and the golden bull of Charles IV. for the election of an emperor, takes its name from the gold seal hanging to it, which is called bull.

The pope has two kinds of seals, the first used in apostolical letters, and private letters, &c. called the Sigiliter's ring. This is a very large ring, on which is represented St. Peter drawing his net full of fishes.

The other is used in bulls, representing St. Peter's head on the right, that of St. Paul on the left, with a croz between the two; on the reverse are sometimes the pope's name and arms.

The impressions of the first seal are taken in red wax; but those of the second, always in lead.

Theod. Hopink, a German lawyer, has furnished the world with a learned and curious work on the subject of seals, printed in 1642, at Nuremberg, in quarto, under the title,
title, "de Sigillorum prisco & novo Jure, Traditatus Practicus," &c. We have another work of the like kind by Humeccius, in folio, printed at Frankfort and Leipsic in 1709, under the title, "de Veteribus Germanorum alarumque Nationum Sigillis, eorumque Ufu & Praelectione, Syntagma Historicum." 

SEAL is also used for the wax or lead, and the impression thereon, fixed to the thing sealed.

The manufacturers' seal, frequently applied to their stuffs, &c. is to be of lead. That of knights, by the French law, is to be of hard wax; that of agents, of soft wax.

Some seals are stamped on the paper or parchment itself, others hung by silken strings.

The French seal their edicts with green wax; arrets with yellow wax; expedients for Dauphiné with red wax. And the letters of the French academy are sealed with blue wax.

See Wax.

SEAL, Heretical. See Heretical.

SEAL, Lady's, in Botany, a species of Bryony.

SEAL, Solomon's, or lily of the valley. See Convalla-

Nia.

SEAL, in Zoology. See Phoca, and also Sea-Bear, and Sea-Calf.

SEAL, Hair of the, in Agriculture, is a substance made use of as a manure, in the way of top-dressing, in combination with rabbits' dung and lime, but which can seldom be provided in any sufficiently large quantity, nor is it found very beneficial for the purpose. See Manure.

SEAL, in Geography, a small island near the coast of Donegal, Ireland, called in Arrowmith's map Glahedich; it is near the entrance of Strabagh bay, and about four miles south of Malin Head.

SEAL, Island, an island near the S. W. coast of Nova Scotia. N. lat. 43° 25'. W. long. 66°—Alfo, an island in the Atlantic, near the coast of Maine. N. lat. 48° 50'. W. long. 68° 40'.—Alfo, a small island W. of King George the Third's Sound, on the S. coast of New Holland; 3 miles N.W. of Baldhead.

SEAL, Islands, a cluster of small islands in the Atlantic, near the coast of Maine. N. lat. 44° 45'. W. long. 67° 40'.—Alfo, a cluster of small islands near the east coast of Labrador. N. lat. 53° 15'. W. long. 55° 30'.

SEAL KEY, a small island in the Spanish Main, near the Mouth of the Orinoco. N. lat. 12° 54'. W. long. 82° 40'.—See also Lobo.

SEAL, River, a river of North America, which runs into Hudson's bay.

SEALCOTE, a town of Hindostan, in the country of Lahore; 50 miles N.N.E. of Lahore. N. lat. 31° 44'. E. long. 73° 56'.

SEALER, an officer in chancery, appointed by the lord chancellor, or keeper of the great seal, to seal the writs and instruments there made in his presence.

SEALING, in Architecture, the fixing of a piece of wood or iron in a wall, with plaster, mortar, cement, lead, or other solid binding.

For staples, hinges, and joints, plaster is very proper.

SEALING-WAX. See Wax.

SEAM, or Seme, in Rural Economy, a term applied to tallow, grease, hog's lard, before it is rendered and formed into lard, &c. in some places.

SEAM, a term applied to a horse-load of three hundred weight. In Cornwall, a seam of sand weighs two hundred weight. The seam also differs very much in the weight of different articles of other kinds. It likewise varies in different districts of the kingdom.
cover the cavities within; and after their distances are marked on the outside with chalk, they make use of another search that has only one point, about which a mixture of wax and tallow is put, to take the impression of the holes; and if there are any a quarter of an inch deep, or of any considerable length, the gun is rejected as unserviceable to the government. The gun is thus proved and searched twice.

SEARCHER, in Rural Economy, an implement used for boring in searching for coals, &c. See Borer.

SEARCHING, the operation of boring or sinking into the bowels of the earth, for the discovery of the different materials which it may contain. For the detection of marbles, coals, or other similar substances, the use of the borer may be sufficient. But where difficulties arise in performing it, in this way, from the obstruction of stones, &c. a narrow shaft, such as a well, may, Mr. Marshall thinks, be carried down, without much expense, to the depths at which it can be wrought with advantage. See Borer and Marle.

SEARCHING of Neutral Ships, in Political Economy, a practice authorized by the law of nations, in order to prevent the commerce of contraband goods, or such commodities as are particularly used in war, and the importation of which to an enemy is prohibited. Accordingly Vattel, and other writers of the same description, maintain that there is a right of searching. Some powerful nations have indeed at different times refused to submit to this. But at present a neutral ship refusing to be searched, would from that proceeding alone be condemned as lawful prize. But to avoid inconveniences, violence, and every other irregularity, the manner of the search is settled in the treaties of navigation and commerce. According to the present custom, credit is to be given in certificates and bills of lading, produced by the master of the ship, unless any fraud appear in them, or there be very good reasons for suspecting their validity.

SEARCHING for the Stone, called also sounding, denotes, in Surgery, the operation of introducing a metallic instrument, named a found, through the urethra into the bladder, with a view of ascertaining whether a stone is really lodged there or not. In this manner, the surgeon actually makes the instrument strike against any calculus which may be present; and the collision produces such an impression on the fingers of the surgeon, and on the ears of every bystander, as leaves no doubt respecting the matter of the case. Sounding is in fact the only infallible way of learning that the bladder contains a stone. The symptoms of the complaint resemble those of several other diseases, and may deceive us (see Lithotomy); but when we both hear and feel the collision of the instrument against the calculus, we obtain that kind of information which does not admit of error.

The most advantageous posture for sounding is that, in which the patient reclines back upon a sofa, or couch. A chair of large size, with a back that can be made to fall backwards to a convenient distance, is sometimes used, and may be seen in most of our hospitals.

As the stone is generally situated at the lowest part of the bladder, the extremity of a found is usually not curved as that of a catheter, in order that it may more easily touch any thing situated immediately behind and below the neck of the bladder. The found is only a particular kind of probe, and as its chief use is to convey information through the medium of the organ of touch, its handle should be smooth and highly polished, so that as many points of its surface as possible may come into contact with the fingers.

The found is introduced exactly in the same manner as the silver catheter, either with the concavity or convexity of the instrument towards the abdomen. When the last method is preferred, as soon as the point has arrived in the perineum, it is to be kept stationary, while the handle is made to describe a semicircular movement downward, so as to turn the concavity of the instrument towards the pubes, previous to its passage through the membranous and prostate portion of the urethra. This is the plan which the French surgeons have called "le tour de maitre."

When the extremity of the found is in the bladder, it is to be pushed downward for the purpose of ascertaining whether the stone lies beneath its convexity, or is most commonly the case where one is present. If the extraneous body should not be felt in this manner, the blow of the instrument may be turned first to one side of the cavity of the bladder, then to the other. Should the calculus not be touched by these movements of the found, the instrument may be drawn forward, for the purpose of learning whether the stone is more anteriorly situated. Frequently the stone cannot be felt till the whole of the urine has been expelled, and the bladder has become contracted. Sometimes, the found may be made to hit the stone, by introducing the finger into the rectum, and thus bringing the extraneous body upward. In this way, the calculus may often be plainly felt by the finger.

We shall conclude this short article, with earnestly cautioning surgeons never to perform lithotomy, unless they can distinctly feel the stone with the found, or its position immediately before the operation.

SEAR-CLOTH, or Cere-Cloth. The word fear-cloth is supposed to be a corruption of cere-cloth, and to be derived originally from the Greek σκια, wax.

In Surgery, it denotes a form of external remedy, somewhat harder than an unguent, yet softer than an emplastro, though it is frequently used both for the one and the other.

The fear-cloth is always supposed to have wax in its composition, which distinguishes, and even denominates it. In effect, when mixed with an unguent, has enough wax in it, it does not differ from a fear-cloth.

Sear-cloths are a kind of habiliments to friction, and are sometimes used for other purposes; the bold are compounded of resolvent drugs, as aloes, myrrh, and aloes, incorporated with wax and gums, as galbanum, gum ammoniac, and sapanum; the whole tempered with wine.

SEARSBURG, in Geography, a township of America, in Bennington county, Vermont; 12 miles E. of Bennington.

SEASE, Seasion, or Seasing, in a Ship. See Seize.

SEASONING, in Ship-Building, a term applied to a ship kept lying a certain time after she is completely timbered and dubbed out for planking, which should never be less than six months.

Seafamed timber or plank is such as has been cut down and converted, or sawn out one season at least, particularly when thoroughly dry, and not liable to shrink.

SEASONING of Timber. See Timber.

SEASONINGS, in the West Indies, a kind of aquilious delimer, which foreigners are much subject to at their first coming.

SEASONS, in Cosmography, certain portions or quarters of the year, distinguished by the signs which the sun then enters, or by the meridian altitudes of the sun; consequent on which, are different temperatures of the air, different works in tillage, &c.

The word is formed from the French saisons, which Menage derives from the Latin saeason, whence the Italians have formed stagione; Nicod derives it from saeason, tempus saeason, sowing time.
The year is divided into four seasons, spring, summer, autumn, and winter; the beginnings and endings of each of which, see under its proper article.

It is to be observed, the seasons anciently began differently from what they now do; witness the old verses:

“Dat Clemens hyemem; dat Petrus ver cathedratus; 
Æsitubus autem; autumnat Bartholomaeus.”

SEAT, in AGRICULTURE. See SHEAT.

Seat, in the MANGE, is the posture or situation of a horseman upon the saddle.

To seat a horse upon his branches or hip, see PWT.

Seat, in Ship-Building, the planks or part trimmed out for a stack, &c. to lay to.

Seat-Transom, that transom which is fayed and bolted to the stem-timbers, next above the deck-transom, at the height of the port-fills.

Seating, that part of a floor which lays on the deadwood; and of a transom which fays against the post.

SEATNESS, in Geography, a cape on the S.W. coast of Shetland. N. lat. 55° 46′. W. long. 1° 36′.

SEATON, a small sea-port town in the hundred of Colyton, county of Devon, England, is situated at the distance of three miles S. from Colyton, and 156 S. from London. This place is called Suetetone in Domesday book, and was undoubtedly the Moridunum of the Iter of Antoninus. Rifdon says it is “memorable for the Danish princes landing there in the year 937, as also for the attempt of the inhabitants of Colyton to make a haven there, which they had solemnly named Collyton haven, and procured a collection under the great seal of England for the levying of money to effect the fame, of which work there remaineth no monument, only a remembrance of such a place among strangers that know not where it stands.” At present Seaton is chiefly noted as a well frequented sea-bathing village. The church is an ancient building of freeclone, dedicated to St. Gregory, and contains a very elegant monument in memory of W. Walrout, esq. and his lady. According to the parliamentary returns of 1811, the parish of Seaton comprised 523 houses, and 1524 inhabitants. The History of Devonshire, by the Rev. Richard Polwhele, three vols. folio, 1797. The Chronographical Description or Survey of the County of Devon, by Trillam Rifdon, 3 vol. 1714, 2d edit. with additions, 8vo. 1811.

SEATON, or Port Seaton, a small sea-port of Scotland, in the county of Haddington, in the Frith of Forth; 5 miles W.N.W. of Haddington. N. lat. 55° 58′. W. long. 3° 59′.

Seaton Nest, a cape of England, on the E. coast of the county of Durham, at the mouth of the Tees; 5 miles S.S.E. of Hartlepool.

Seaton Sluice, a sluice which opens into the German sea, on the coast of the county of Northumberland.—Also, a town of England, called “Seaton Delaval,” in Northumberland, deriving its name from an artificial harbour constructed by Sir Ralph Delaval, in the 17th century; 10 miles N.E. of Newcastle. N. lat. 55° 6′. Seaton, a river of England, which rises near Leekward, and runs into the English Channel, three miles E. of Looe, in Cornwall.

Seaves, in Rural Economy, a term used to signify rufhes, especially the soft rufhe.

Seavy Ground, such ground as is covered or overrun with rufhes.

SeauM, in Geography, a town of Hindoostan, in Lahore; 18 miles W. of Kahoon.

SEAWOLVES ISLAND, an island in the gulf of St.

Laurence, near the W. coast of Cape Breton. N. lat. 46° 21′. W. long. 61°.

SEBA, ALBERT, in Biography, a native of East Friesland, was by profession a druggist at Amsterdam, and a member of the Academy Naturae Curiosorum. He published a descriptive catalogue, in Latin and French, of the vast collection of objects in natural history which he had brought together, in four vols. folio, illustrated with a great number of engravings. He likewise communicated several papers to the Ephemeris. Nat. Curios.

SEBACA, in Geography. See MARIOUT.

SEBACEOUS GLANDS, in Anatomy, small glandular bodies in the skin, secreting the unctuous matter which covers the surface of the body. They are particularly manifest about the axes of the nofe, and in the folds of the external ear. See INTEGUMENTS, EAR, and NOSE.

SEBACIC ACID, in Chemistry, is an acid produced from the decomposition of animal fat, particularly hog’s-lard. The acid fumes which are evolved during the burning of fat at a heat short of inflammation, was formerly considered as a peculiar acid, which was called the acid of fat, and afterwards the sebacic acid. From the experiments of Therard it has since been proved not to be a peculiar acid, but the acetic acid disguised with some other product of the decomposition. During the experiments, however, he found that by the distillation of tallow, he obtained an acid having peculiar properties, which he still called the septic acid. The following is the process he recommends. Dittill hog’s-lard from a retort, by a heat which will decompose the fat; carbonic acid and carburetted hydrogen first come over, and a yellowish fluid containing acetic acid, but still no septic acid. This receiver must now be removed, and a new one adapted; the heat being continued, an oily matter comes over of the consistence of butter. It is in this substance that the septic acid is found. It is sepurted by first boiling it in water; and evaporating the liquid till the septic acid falls down in crystals. This deposition is increased as the liquid cools.

He also recommends, instead of getting the crystals by evaporation, to add acetate of lead to the water in which the oily matter has been boiled; a flaky precipitate is formed, which is the febat of lead, and which is to be well washed and dried. When to this substance sulphuric acid is added, and heat applied, a fatty liquid floats on the top, which is to be collected; this being dissolved in hot water, forms crystals of pure septic acid, which are depoited on cooling.

The lard affords but a very small proportion of the acid. Rose informs us that it requires a pound of lard to produce forty grains of acid.

Sebacic acid, thus obtained, is in the form of a crystalline mass, of a white colour. It has no smell, but its taste is agreeably acid and slightly bitter; like most other acids it changes some vegetable blues to a red colour.

When heated, it melts like fat into a transparent fluid, but on cooling it re-attains its white consistence and crystalline form. It is said to be volatile by heat, still retaining its properties, but a strong heat decomposes it.

It is sparingly soluble in cold water, and boiling water diffuses about one-fourth its weight; it affords the crystals on cooling, which are in the form of prisms. Alcohol diffuses it in considerable quantity. It is also soluble in oils. From the lait, and some other properties, it bears a strong resemblance to the benzoic acid. This last analogy has been pointed out by Berzelius. He found also that the fats formed by this acid have a strong resemblance to the benzene. These facts go far to shew so strong an analogy between the two
two acids, as almost to establish their identity. See Ben-
zoic Acid.

SEBACOOK, or SEBAGO, in Geography, a pond or
lake of America, in the state of Maine, equal in extent
to two large townships, and connected with Long Pond
on the N. by Sungo or Songo river; these waters reach
nearly 30 miles from N.W. to S.E.; 18 miles N.W. of
Portland.

SEB.AEA, in Botany, a name adopted by Mr. Brown,
from Dr. Solander's manuscript, in memory of Albert
Seba, an apothecary of Amsterdam, who prepared a
splendid description, with plates, of his own museum,
in four large folio volumes, which came out between the
years 1734 and 1765. The author indeed died in 1756,
so that his three latter volumes were posthumous publica-
tions. Many Cape plants are here engraved, and amongst
them one of the present genus. Yet Seba does not
deleve to rank as a scientific botanist, nor did Linnæus,
who knew him, and by whose recommendation he
employed Artedi to arrange his filæs, ever think him
worthy to be commemorated in a genus. If, however,
we compare him with numbers who have been so
commemo-rated, he will not appear to so much disad-
vantage; for as a collector he stands rather high. Brown
Prodr. Nov. Holl. v. 1. 451.—Claws and order, Tetra-
andra Monogynia. Nat. Ord. Rosales, Linn. Gentiana, pul-
divided into four ovate, acute, keeled, slightly spreading,
permanent segments, folding over each other at the base.
Cor. of one petal, petioled, filar-shaped; tube swelling,
the length of the calyx, contracted at the upper part; limb
in four deep, elliptical, spreading segments. Stam. Flä-
ments four, thread-shaped, inserted into the tube, pro-
jecting out of its mouth; anthers erect, shorter than the,
lobe, blending longitudinally, subfinely recurved and
callous at the tip. Pila. Germen superior, roundish,
filling the tube; style thread-shaped, erect, the width of
the flaments; stigmas two, oblong. Peric. Capsule round-
dish, with a furrow at each side, compressed, of two cells
and two valves, the length of the calyx; partitions from
the inflexed margins of the valves, invested into the edges
of the large central receptacle, from which they finnally separate. Seeds
numerous, minute.

Obi. The flowers in some species are five-cleft.
Eff. Ch. Calyx deeply four-cleft, keeled. Corolla falc-
shaped, with an inflated tube. Anthers burbling longitu-
dinally; finally recurved and callous at the point. Cap-
sule with two furrows, two cells and many seeds; the
partition from the inflexed margins of the valves. Stigmas two.

Mr. Brown has separated the present genus from Exacum,
whose genuine species, according to him, are E. fessel and
pedunculatum of Linn. Sp. Pl. with which the albicans
and bordonatum of the Supplementum are, in the latest-mentioned
work, confounded. (See EXACUM.) Perhaps also, as
Mr. Brown conceives, E. pontifilium of the flax work may
make a third, and a non-descript East Indian one in his pol-
iction, a fourth, species. It confiders with as essential to Exacum
a leaf-deeply divided calyx; anthers without a callous tip,
burling by a bore, or short slit, and continuing straight
after the flowers fade; style declining; an undivided stig-
ma; and receptacle of the seeds connected with a partition
originating from the middle of each valve.

1. S. albens. White Seb. (Exacum albens; Linn.
Suppl. 125. Wild. Sp. Pl. v. 1. 673, but not E. pedan-
culatum; Sp. Pl. 1. 163. Centaurium hybridoides foliis,
florus comitis; Burm. Afr. 207. t. 74. f. 4; excluding
the reference to Plukkenet.)—Flowers in the upper forks of
the stem filæs.—Gathered by Thunberg, Sprarrmann, and
Vol. XXXII.

others at the Cape of Good Hope. The root is annual,
fibrous. Stem erect, four or five inches high, much branched,
reciprocated forked, leafy, smooth, with four sharp angles,
level-topped, many-flowered. Leaves small, scarcely at all
decurrent, ovate, entire, smooth, felty, somewhat glaucous.
Flowers four-cleft, though Sprarrmann describes them
otherwise; the lowest more or less stalked, as well as those
which crown the ultimate lateral branches; but those situ-
ated in the upper forks of the stem are quite sessile. Segments
of the calyx slightly keeled, their points a little recurved.
Corolla apparently whitish, or pale pink. Thunberg's spe-
cimen agrees best with Sprarrmann's figure; that of Sprar-
mann has broader leaves and larger flowers; yet we cannot
trace out a satisfactory diffinition. One of them may pos-
ibly be the unpublished Cape species, announced by Mr.
Brown, without any definition or description, but we can-
not guess which, and, all things considered, we do not feel
authorized in separating them.

2. S. aurea. Yellow Sebæa. (Exacum aureum; Linn.
albens, flocculos numeros, eithiocipicum; Pluk. Alm. 94.
t. 275. f. 53.—All the flowers reduced.—Gathered by Sprar-
mann, at the Cape of Good Hope. About half the size
of the last in every part. Flowers yellow, four-cleft, each
on a slender quadrangular stalk, even from the uppermost,
as well as the lower, forks of the stem. Linnæus justly com-
ments Plukkenet's figure, though he had originally, in Sp.
Pl. cited that synonymy doubtfully under his Exacum fessel,
a widely different plant. It is remarkable that he de-
scribes the calyx in the Supplement as of five leaves, whereas it
has only four; as it ought, the corolla being four-cleft.

3. S. cordata. Heart-shaped Sebæa. (Exacum cor-
But not E. fessel, Sp. Pl. 163. Gentiana exacoides;
Linn. Sp. Pl. 332. Centaurium perflosum, florum calycis
membranaceous ventricofum; Burm. Afr. 208. t. 74. f. 5.
C. perflosum eithiocipicum, flocculos eignus flavocentius,
ex caleyculis magnis quadruprimatis erumpentibus; Pluk.
Alm. 94. t. 275. f. 4. "C. calparis minus, cepidul
quaratio alis donata; Seb. Misc. v. 1. 122. f. 7.)—
Flowers five-cleft. Segments of the calyx with a dilated,
half-heart-shaped, veiny keel. Leaves heart-shaped.—Na-
ture of the Cape of Good Hope. The size and habit agree
with the first species, but the flowers are larger, appar-
ently yellow, with a longer tube, and five-cleft limb. Calyx dif-
tinguished by the dilated veiny keel of its segments, which
are five, not (as Plukkenet and Seba say), four only. All
the flowers have partial stigmas, though shorter in the upper
ones than the lower. The whole history of these three
species, in the Supplement, was written by Linnæus him-
self, not by his son, who only described the fourth, Exacum
pontifilium.

ovatum; Linn. Labill. Nov. Holl. v. 1. 38. f. 52.)—Flowers
five-cleft. Segments of the calyx simply keeled. Leaves
oval.—Gathered by M. Labillardiere at Cape Van Diemen,
and by Mr. Brown at Port Jackson, New South Wales.
Taller and more slender than the foregoing, being about a
span high. Such of the upper flowers, as grow from the
forks of the stem, are nearly sessile, like those of S. albens.
Segments of the calyx lanceolate, with a simple, not dilated,
keel. Corolla with a small, short, five-cleft limb; nothing
is recorded of its colour.

SEBAGENIA, in Ancient Geography, a town of Cape-
docia, in the prefecture of Cilicia. Ptolomy.

SEBAIA, in Geography, a town of Arabia, in the pro-
vince of Hidijas; 33 miles S. of Medina.

SEBAKT
SEBAKET, i.e. the lake of king Baldwin, a narrow lake of Egypt, near the Mediterranean about fifteen miles long; 2 miles E. of Catech.  
SEBALA, a town of Arabia, in the province of Hadsjas; 27 miles S. of Medina.  
SEBAMA, or SABAMA, in Ancient Geography, a town of Palestine, on the other side of the Jordan, in the tribe of Reuben, according to the book of Joshua.  
SEBANZARRO, in Geography, a town of Abyssinia; 80 miles E.N.E. of Axum.  
SEBAR, or CEVAR, in the Materia Medica, a name by which the Arabians call the lignum aloes, or aloe-wood, a perfumed aromatic drug.  
SEBARIMA, in Geography, one of the mouths of the river Oroonoko.  
SEBASTACOOK, a river of America, in the state of Maine, which rises in lakes nearly N. from its mouth, and after receiving, in the windings, many tributary streams, joins the Kennebec at Taconet Falls, where Fort Halifax was erected, in 1754: the fall is 18 miles from Fort Western, which was constructed in 1752. Its numerous streams abound with small fish.  
SEBASTE', a miserable deserted village of Syria, the depopulated remains of Samaria, which acquired its new name in honour of Augustus Caesar; 34 miles N.E. of Jerusalem, See Samaria.  
SEBASTE, in Ancient Geography, an island and town of Cilicia Propria, on the other side of the promontory of Corycus. Strabo says that this town was called Eleusa, and that Archelaus made it the place of his residence, when Augustus gave him Cilicia Trachea.—Allo, a town of Asia Minor, in Phrygia.—Allo, a town of Asia Minor, in Galatia.  
SEBASTIAN, in Biography, king of Portugal, was the pollihumous son of the infant John, by Joanna, daughter of the emperor Charles V. He succeeded to the crown at three years of age, on the death of his grandfather, John III., in the year 1557. By his education he acquired an extravagant admiration for valourous exploits, and an enthusiastic zeal against all the foes of the Christian religion. Under the influence of this passion, he, at the age of twenty, undertook a sudden expedition to Africa, in which, however, he performed nothing of any importance; but availing himself of the application for aid of Muley Hamet, king of Fez and Morocco, who had been dispossessed of his crown by his uncle Muley Molech, he resolved to renew the attempt against the Moorish monarch with all the force he could bring together.  
In vain was he diffused from the enterprise: he was insensible to all admonitions. Having stripped his country of its military strength, and the flower of the nobility, he left behind, in the summer of 1578, and proceeded to Arzila. There he was met by a much more numerous army, with Muley Molech in person, who was so debilitated by sickness that he was carried in a litter. In the battle that ensued, the onset of the Portuguese army was so furious that nothing could withstand them; and Muley, in rallying his men, was so much exhausted that he died in the attempt. Sebastian, who was not less dexterous in the use of arms than brave, fought till two horses were killed under him, and most of his attendants were slain by his side. At length, however, he disappeared, nor was he ever known, with any degree of certainty, what became of him, though a body, supposed to be his, was received as such from the Moors, and interred at Belem. But in a slaughter so dreadful, that not more than fifty of the Portuguese army are said to have escaped, it is no wonder that a single body, and probably flayed, should not be recognized. Such, however, was the attachment of the nation to a prince, whose romantic valour had revived in their minds the heroic times of Portugal, that they refused to give credit to his death, and long entertained the full expectation of seeing him return from his supposed concealment. Of this opinion many impostors availed themselves, who assumed his character, and obtained a portion of respect due to their favourite sovereigns; for more than a century it was believed that he would be again seated on his throne.  
SEBASTIAN, St., in Geography, a town of Spain, and the most important of the district of Guiptisca, situated on the coast of ancient Cantabria, now Baquio, between two arms of the sea, which form a peninsula of it, and at the mouth of the little river Urumea, or Gurumera, which was the Menesium of the ancients. On the sea-side there is an eminence which serves as a dike. This town, flanked with bastions and half-moons, appears defended by a castle or citadel of little importance, placed upon an almost circular and tolerably high mountain, which is bare, without trees, almost smooth, and ascended by a spiral road. St. Sebastian has a small harbour inclosed by two mole's, that leave a very confined space for the passage of ships, which are afterwards protected from the winds, on arriving at the bottom of an eminence of rocks which covers this harbour, where there is a large square tower; it holds at most five and twenty or thirty vessels. The town is very airy; it contains twenty streets, several of which are straight, long, and broad, and all paved with large smooth flones. There are from six hundred and fifty to seven hundred houses in it, and many of them are pleasant enough. It is the residence of the governor of the province, who had the title of captain-general until the beginning of the present century. It has a governor, a king's lieutenant, a major, an aide-major, a small garrison, and a naval academy; two parishes, and a third in the suburbs, which are very populous; two convents of monks, three convents of nuns, and an hospital. There are in this town and its suburbs five manufactories of hides and leather, some tanning-yards established in the faubourg St. Martin, a manufactory of anchors for the royal navy in the faubourg of Sta. Catalina, and rope-walks, where cables are made.  
St. Sebastian has always carried on a considerable trade. In 1728, the Philippine company was formed by Philip V., with which that of the Caraccas was afterwards united. This company was very serviceable, as it procured for Spain a lucrative branch of trade, which was in the hands of the Dutch. In consequence, however, of mal-administration, and the loss of 1,500,000 piastras, which it sustained at the commencement of the war between England and America, this company sank and was supphed. However, a trade with the province of Caraccas was continued by private merchants from this port, and the cocoa, tobacco, and leather which are from thence imported, form no inconsiderable branch of trade with the interior and the other parts of Spain, and a still more important one with foreign countries. Hence its harbour is very much frequented by English, Dutch, French, and other ships. It receives the produce of foreign industry, and returns, in exchange, iron anchors, cables, leather, wool, and sometimes cotton. This trade attracts a considerable population to the town, which is estimated at 13,000 inhabitants.  
The port of St. Sebastian, though free, is not what is called abilitado. This word means a privilege to fend merchandise directly to America.  
The environs of St. Sebastian are pleasant, though the soil is sandy; we enjoy at the same time a view of the sea and of the Pyrenees. Those who love the country, take pleasure in visiting the pleasant valley of Layola. We go to
to it through the gate of France, following a kind of promenade, which leads to a wooden bridge, where persons who are fond of it amuse themselves in filling for falmon, in a river which bathes the fortifications of the town; this filth is found there in such abundance, that it is sold for three farthings a pound. As we proceed, we perceive on the left a convent of Franciscans, the whole appearance of which inspires veneration, seeming deftuous of concealing itself under masses of foliage, formed by groups of trees. On that side, however, they have begun to form a public promenade parallel to the little road which leads to Paffage Port. We travel along a loose foil, which is covered by the high tides; we afterwards ascend and descend, proceeding along a steep coast; the path is fladed by a high wood, and embellished with fragrant jellamines; after crossing another wooden bridge, we enter the valley of Layola. Bounded on one of its sides by hills covered with trees, it here has a gloomy aspect; but on the opposite side we behold the richest productions, displaying a scene of various colours; highly embellished by the rays of the setting-fun. A river bounds this valley in a semicircular form, and waters a great number of fruit-trees planted on its banks.

The sky at St. Sebastian is not very ferene, but it is often cloudy; the air is generally damp, and sometimes loaded with fogs. The proportions are cheaper than in most of the other parts of Spain; and here are two tolerably good inns. In 1719 the French made themselves masters of this town; and in 1794, August 3d, it was invested by the republican troops of France, and capitulated the next morning: the garrison, confining 2000 men, surrendering themselves prisoners of war, and more than 180 pieces of brass cannon were taken, with considerable magazines and stores. On August the 13th, 1813, it was taken by storm by the British troops; 22 miles W.S.W. of Bayonne. N. lat. 43° 10'. W. long. 2° 4'.—Alfo, a port of Africa, in the kingdom of Anta, on the Gold Coast, belonging to the Dutch.

SEBASTIAN, St., or St. Sebastian, a town of the island of Tercera, situated between mountains, about half a mile distant from the sea.

SEBASTIAN del Pastor, St. See La Plata.

SEBASTIAN, St., or SEBASTIÁN, a town of Portugal, in Algarve; 6 miles N.W. of Loule.

SEBASTIAN, St., a town of Mexico, in the province of Chiainetan, on the Mazatlan; 45 miles N.W. of Chiainetan. N. lat. 23° 35'. W. long. 106° 30'.—Alfo, a small island in the Atlantic ocean, near the coast of Brazil. S. lat. 23° 45'.—Alfo, a town of South America, in the province of St. Martha; 10 miles W. of Los Reyes. —Alfo, a bay of the Indian sea, on the coast of Africa. S. lat. 32° 22'.

—Alfo, an island of Mexico, in Nicaragua lake, with a town near the E. coast. N. lat. 11° 48'. W. long. 85° 6'.—Alfo, a river of Mexico, which runs into the Pacific ocean, N. lat. 25° 20'.—Alfo, a town on the E. coast of Gomera, one of the Canary islands. N. lat. 28° 5'. E. long. 17° 12'.

—Alfo, a town of Terra Firma, on the E. side of the gulf of Darien.

SEBASTIAN, Cape St., the eastern point of the gulf of Darien, on the coast of the Spanish Main, 10 leagues from the western point of Cape Triburun. The city which formerly existed here has been abandoned, on account of its unhealthy situation.—Alfo, a cape on the coast of California. N. lat. 45°. W. long. 116°.—Alfo, a cape on the N. coast of Madagascar. S. lat. 11° 20'. E. long. 54° 44'.

—Alfo, a cape on the E. coast of Africa. S. lat. 22°. E. long. 33° 20'.—Alfo, a cape of Spain, on the E. coast of Catalonia. N. lat. 51° 52'. E. long. 5° 6'.

SEBASTIAN'S Bay, St., a bay on the S. coast of Africa. S. lat. 34° 40'. E. long. 21°. It is also called St. Catherine's bay.

SEBASTIAN River, St., or Spanjih Admiral's creek, a river on the E. coast of Ealt Florida, which communicates with Indian river. The admiral of the Plate fleet perished in 1715, opposite to this river, and the rest of the fleet, fourteen in number, were lost between this and the Beach yard.

SEBASTIAN'S Sound, St., an inlet in the straits of Magellan, on the coast of Terra del Fuego; 48 miles S. of Sweepstakes foreland.

SEBASTIAN de Buenavista, St., a town of South America, in the province of Caracas, at the entrance of the gulf of Darien; 140 miles S.S.W. of Caracas. N. lat. 8° 19'. W. long. 76° 20'.

SEBASTIAN de los Reyes, St., a town of South America, in the government of Caracas; 60 miles S. of Leon de Caracas. N. lat. 9° 35'. W. long. 66° 56'.

SEBASTIÁN, St. See St. Sebastian.

SEBASTIEN, St. See St. Sebastian.

SEBASTOCRATOR, in Antiquity, a title of honour given to some distinguished person of the imperial family. It was introduced by Alexius Comnenus, in order to reward the piety of his brother Isaac, without giving himself an equal. The happy flexibility of the Greek tongue allowed him to compound the names of Augustus and emperor (Seballes and Autocrat), and the union produced the honourable title of Sebastianator. He was exalted above the Cefar on the first step of the throne; the public acclama tions repeated his name; and he was only distinguished from the favours given to some peculiar ornaments of the head and feet. The emperor alone could assume the purple or red clubs, and the chas dian, or tiara, which imitated the fashion of the Persian kings; instead of red, the buffalo's of the Sebastianator and Cefar were green, and on their open coronets or crowns the precious gems were more sparingly distributed. The five titles of Defpot, Sebastianator, Ce far, Panhyperchaitoitos, and Protopofoebetes, were usually confined to the princes of the emperor's blood; they were the emoluments of his majesty; but as they exercised no regular functions, their existence was useless, and their authority precarious.

SEBASTOPOLIS, of Dioscurias, in Ancient Geography, the name of one of the principal towns of that part of the Colchide which was to the right of the Phasis.—Alfo, a town of Alfa Minor, in the Cappadocian Pontus, on the road from Tavia to Sebastia.

SEBASTOPOLIS, in Geography. See SYVANTOPOL.

SEBAT, in Chronology, the fifth month of the civil year of the Hebrews, and the eleventh of the ecclesiastical year, answering to part of our January and part of February.

SEBATIS, in Chemistry, a genus of plants, formed by the union of the fuculent acid with the different fuculent bases. For an account of these, see the different fuculent bases; for instance, for fuculent of lime, see Lime; and fo on for any other.

SEBABA, or Seven Capes, in Geography, a cape or headland on the coast of Algiers, the vicinity of which is occupied by perons of a brutal and ferocious disposition, who live in caves, expelled out of the rocks. These people, called "Kabyle," run on board to the coast when any vessel is disabled, or in the course of failing, approaches it, and vicerate their horrid wilds, that God would deliver it into their hands; and probably the name of "Bonjarone," or "Catalanis," was first given by the Italian geographers to these capes, on account of the savage disposition of their inhabitants. N. lat. 37° 8'. E. long. 6° 32'.

SEBBAH, a town of Africa, in the country of Fezzan.

T 2

60 miles
60 miles N. of Mourzouk. Here the large remains of an ancient city, built upon a hill, and of other venerable ruins, that, in point of extent, are compared to those of Lebida, impress on the mind of the traveller the melancholy idea of departed greatness; while, on the other hand, the humble dwellings of the modern inhabitants, and the rich vegetation of their neighbouring fields, present to his eye an ample store of all that is requisite for the sufficiency of man. Dates, barley, Indian corn, pumkins, cucumbers, fig-trees, pomegranates, and apricots, and for meaneer purposes, the white thorn and Spanish bean, are described as but a part of the numerous vegetables that reward the industry of the people. The animals in which they most abound are the common fowl, and the brown long-haired and broad-tailed sheep. At the distance of two days' journey from Sebba is "Godoua," a town of similar produce; and in two days more the traveller arrives at Mourzouk.

SEBEDA, in Ancient Geography, a port of Lycia, according to the Periplus of Arrian.

SEBEL, an Arabian name for the disorder of the eye usually called a pannus.

SEBEN, in Geography, a town of the bishopric of Brixen, on the site of an ancient town named "Sabiona," destroyed by Attilla; eight miles S.W. of Brixen.

SEBENDUNUM, in Ancient Geography, a town of Spain, in the Tarragonensis, the country of the Castellani. Ptolemys.

SEBENICO, in Geography, a sea-port town of Dalmatia, situated on the Kerkia, near the Adriatic; one of the strongest towns on the coast, with a large harbour, defended by four citadels; erected into a bishopric in 1298. It is said to have been founded by a number of banditti, who lived on the rock which is the present site of the castle, and who plundered any vessels that approached the coast. In process of time they built some colleges, and inclosed them with a kind of palisades called "fibue," whence was formed Sebenico. The city was enlarged by an increase of robbers; and afterwards, when the ancient city of Scardona was destroyed, its inhabitants retired to Sebenico. The inhabitants, appalled by the king of Hungary, who was then sovereign of Dalmatia, surrendered themselves in 1412 to the republic of Venice. This city, whatever may have been its origin, is the most pleasantly situated of any in Dalmatia, and also the best built, containing the greatest number of noble families, next to Zara. On one side it is defended by a castle on a hill; and towards the sea, upon a narrow channel at the mouth of the harbour by another fort, a noble work of Sammicheli, whose gate resembles that of Verona, by the same celebrated architect. Among the buildings of Sebenico, the dome or cathedral deserves particular notice, account of its general fabric, and more especially of its roof, which is composed of large pieces of marble, connected together. In the sixteenth century the arts and sciences flourished here more than in any other city of Dalmatia. It has several buildings in good style of architecture, and it has produced many eminent men; 25 miles N.W. of Spalatro. N. lat. 44° 20'. E. long. 16° 15'.

SEBENYTES Neum, in Ancient Geography, a nome of Egypt, between the branches of the Nile, called the Pharaonic and Aethiopic, and near their mouth. Ptolemys divides this nome into the Upper and Lower.

SEBENYTTICUM Ostrum, the name of one of the seven mouths of the Nile, E. of that called the Ballititium. Ptolemys.

SEBENYTUS, a town of Egypt, in the Delta, and capital of the Sebennytic nome.

SEBENSTAIN, in Geography, a town of Austria, 10 miles S. of Ebenfurth.

SEBER, WOLFGANG, in Biography, a German philosopher and divine, was born at Sula, in the district of Hennepburg, in 1573. He left his father in early life, and had to struggle with all the difficulties incident to poverty. He completed his studies at Leipsic, and became rector of the school of Schlefeningen, afterwards superintendent and pastor at Wafungen, and finally inspector of the gymnasium, and azeffor of the confistory at the former place. In old age he was afflicted with blindness, and died in January 1634. He bequeathed his library to the gymnasium of the place of which he had been the rector, and left a fund for the yearly maintenance of fix students in theology. His " Index omnium in Homero Verborum," has frequently been reprinted. An edition of it was published at Oxford in 1780. He edited several learned works, and was author of various poems, epistles, and orations.

SEBER, in Geography, a river of Naples, which rises about six miles from Mount Veluvius, and runs into the sea near Naples, supplying the fountains and aqueducts of that city.

SEBESE, or Paulo Bices, a small island in the lrounds of Sunda. N. lat. 5° 50'. E. long. 105° 27'.

SEBESTEN, SEBESTENA, Myka, in Pharmacy, &c. the fruit of a species of corda, resembling a little plum or prune, which, when ripe, is of a deep red colour, bordering on black; very sweet, and the flesh, or pulp, glutinous or sticky.

The Syrians make a kind of glue, or birdlime, of the febbles, called "birdlime of Alexandria." The fruit has been esteemed pectoral, cooling, and emollient; though it is now disdained by the colleges both of London and Edinburgh.

The flone within it is triangular; it brought its name from Arabia, whence Pliny observes it came in his time into Italy.

SEBESTENA, in Botany, a flight alteration of its Arabic name Sekbisen, is retained by Gartner, instead of the Limnan appellation of the genus Cordia; which latter, preserving the memory of one, if not two, highly meritorious botanists, surely ought not to be set aside. See Cordi, p. 1.

SEBESVAR, in Geography, a town of Transylvania; 22 miles W.S.W. of Colofar.

SEBETUS, or SEBETHIS, in Ancient Geography, a river of Italy, in Campania, which watered the town of Neapolis.

SEBIEZ, in Geography, a town of Ruffia, in the government of Polotk; 40 miles N. of Polotk. N. lat. 56° 10'. E. long. 28° 14'.

SEBIFERA, in Botany, a genus of Loureiro's, named from fubnum, tallow, because it produces a similar substance, used for making candles.—Loureiro, Cochinch. 637.—Clav. and order, Diospyro Polyadephos. Nat. Ord. Tiliaceae, foli. 7th. Gen. Ch. Male, Coll. Perianthium of four roundish, convex, hairy, spreading leaves. Cor. none. Stam. Filaments about one hundred, capillary, longer than the calyx, distributed into ten fets; anthers ovate, of two cells.

The wood is light, pale, easily wrought, used for poles and beams in houses. The branches and leaves exude a glutinous fluid; and being bruised and macerated in water, they make a sort of gum, used for mixing with plaster or stucco, in order to render it more tenacious and durable. A great quantity of thick, white, fatty oil is extracted from the berries, of which the vulgar make candles, resembling those of tallow or wax, but of a disagreeable smell.

We cannot satisfactorily refer this account to any plant described in botanical works; and yet the tree should seem to be well known in its native country.

SEBINIKVAR, in Geography, a town of Transilvania; 6 miles S. of Weilienberg.

SEBIUS, or SEBISCH, in Biography, the name of a family which distinguished itself at Strasburg by the celebrity of the physicians whom it produced, and who successively adorned the professorial chair in that city for the space of 134 years, without interruption, in the persons of four individuals only. The first, second, and fourth of these physicians were named Melchior; the third, John Albert; and all, with the exception of the first, succeeded their fathers in the chair. The first Melchior Sebius, was the son of George Sebius, a doctor of laws, and counsellor of the duke of Ohmitz. Melchior was born in 1539, at Falken-borg, in Silicia, and was at first intended for the profession of the law; but in 1563 he changed his plans, and began the study of medicine. For this purpose, as was the custom of the times, he began his travels to different universities: he was at Montpellier in 1566, and three years afterwards he went to Italy; and subsequently visited France, where he took the degree of doctor at Valence, in Dauphiné, in August 1571. On his return to Germany, he practised his profession first at Hagenaus: but having gone to Strasburg in 1574, he determined to settle there. His talents soon raised him to the rank of professor, and he practise with great celebrity until his death, which took place in June 1625; in the eighty-fifth year of his age.

SEBIZIUS, Melchior, the son of the preceding, was born at Strasburg in 1578. He began his education under his father, and is said to have studied in twenty-seven universities, among which he chose that of Bâle as the place of his graduation in 1610. So early as the year 1612, his reputation raised him to the professorial chair, which his father resigned, or rather, perhaps, he became his father’s colleague at that time. His increasing reputation obtained him the favour of the emperor Ferdinand II., who created him a count palatine in 1630. But no dignities could seduce him from the practice of his profession, or the duties of his chair; and during the space of sixty-two years, while he taught, and was a professor of the faculty at Strasburg, he examined one hundred and sixty-three candidates, and imposed the doctoral cap on fifty-five physicians. Enjoying uninterrupted health until his last illness, never using spectacles, and suffering no infirmity except a very slight deafness, he lived to the age of ninety-five, and died in January 1674. He was the author of numerous works, especially academical dissertations, in which there is more learning than originality or discovery; whence Haller pronounced him "eruditus vir, parum usus propriis experimentis." Eloy occupies a page in the detail of the titles of his works.

SEBIZIUS, John Albert, succeeded the former, his father, in the professorial chair. He was born at Strasburg in 1615, and graduated in 1639, after having studied in the universities of Bâle, Montpellier, and Paris. In 1642 he was appointed to the professorship of anatomy. He succeeded his father as physician to the city, and was elected above twenty times dean of the faculty. He died in February 1665, in the seventieth year of his age. He was the author of some academical essays, and of a volume of "Exercitatioe pathologicae," relating to the diseases of the head and chest.

SEBIZIUS, Melchior, the son of John Albert, was born in 1664. After studying medicine at Paris, he returned to Strasburg, and took the degree of doctor in 1688; and in 1701 was elected professor of medicine. He held this office, however, but three years, and died in 1704, being at that time rector of the university. See Eloy Diet. Hist. de la Médecine.

SEBNITZ, in Geography, a town of Saxony, in the margravate of Meißen; 20 miles E.S.E. of Dresden. N. lat. 50° 59'. E. long. 14° 35'.—Allo, a river of Saxony, which runs into the Rollenitz; two miles N. of Schandau.

SEBOIM, in Ancient Geography, the name of one of the four towns of the Pentapolis, which were conformed by fire from heaven, with Sodom, Gomorrah, and Adama. Euebisto and Jerome speak of a town of this name which subsisted in their time, and which was situated on the western coast of the Dead sea. The town itself therefore have been rebuilt.

SEBOLA, in Geography, a town of Portugal, in the province of Beira; 21 miles N.N.W. of Caffel Branco.

SEBO, or SEBE, a river of Africa, which passes by the city of Fez, and runs into the Atlantic a little below the Marmora.

SEBOZ, a town of Bohemia, in the circle of Bohemia; 3 miles S.E. of Mchnik.

SEBOU, a small island near the N.E. coast of Cape Breton.

SEBRAJEPOUR, a town of Bengal; 13 miles W.N.W. of Dacca.—Allo, a town of Bengal; 13 miles S.E. of Koyou.

SEBRIPA, in Ancient Geography, a town of the African Sarmatia, on the banks of the river Tardanus. Potamia.

SEBRITHITES, a name of Egypt, from which king Pyathres sent to Solomon 1000 men for building the temple, according to Eusebius.

SEBRUD, in Geography, a river of Paphia, in the province of Khurasan, which runs into the Tisus, 6 miles S.E. of Zaweh.

SEBU. See SIBU.

SEBUAEI, a sect among the ancient Samaritans, whom St. Ephphains accuses of changing the time expressed in the law, for the celebration of the great annual feasts of the Jews.

Serrarius conjectures, that they were thus called from their celebrating the feast of the passover on the seventh month, called in the Hebrew, fetha, seventh. Durlius rather takes them to have been denominated from Sibai, the leader of a sect among the Samaritans. Scaliger derives the name from the Hebrew, fetha, weeb, because of the celebrating every second day of the seven weeks between Leiter and Whitsuntide.
SEBUE, in Geography, a town of Abyssinia; 90 miles S. of Mina.

SEBUNTA, in Ancient Geography, a town situated in the interior of Arabia Petraea. Ptolemy.

SEBURAI, Seburai, a name which the Jews give to such of their rabbins or doctors, as lived and taught some time after the finishing of the Talmud.

The word is derived from יושב, sebar, I think: whence נזר, sebora, opinion; and thence נזר, sebor, opinionation.

The reason of this appellative, say the rabbins, is, that the Talmud being finished, published and received in all the schools and synagogues, these doctors had nothing to do but to dispute for, and against, the Talmud, and its decisions. Others say, it was because their sentiments were not received as laws or decisions, as those of the Mifchnim and Gemarim were; but were held as mere opinions. Others, as the author of Schalkeheleth Hakabala, or chain of tradition, tell us, that the perfection the Jews underwent in those times, not allowing them to teach quietly in their academies, they only proposed their opinion in the composition of the Mifchnim. The first and chief of the Seburai was R. Judah, who began to teach in the year 79 of the era of contracts; which, according to R. David Gault, falls on the year of the world 4236, and who, according to R. Abraham, was thirty-eight years president of the Jewish academy.

The era of contracts is the name with that of the Seleucid, the 787th year of which falls on the year of Chr. 176, which, of consequence, is the era of the origin of the Seburai, whose reigns did not hold long: Bustorff says, not above fifty years; R. Abraham, and others, say not fifty. The half of them was R. Simoena. They were succeeded by the Gaons or Geonim.

SEBURG, in Geography, a town of France, in the department of the North; 5 miles E. of Valenciennes.

SEBZ. See KENF.

SEBZVAR, a town of Persia, in the province of Khordad; it was taken, in 1381, by Timur Bace, but upon its revolt and being again reduced, he caused 2000 of the inhabitants to be piled in a heap, with mortar and bricks, and thus buried alive; 180 miles N.W. of Herat. N. lat. 36° 11'. E. long. 56° 12'.

SECA, LA, a town of Spain, in the province of Leon; 24 miles S.W. of Valladolid.

SECALCUL, in the Materia Medica of the Ancients, a name given by Avicenna, Serapion, and others, to a root which was like ginger, and was brought from the East Indies, and used as a provocative to venery.

The interpreters of their works have rendered this word irignes, and hence some have supposed that our eryngium, or eryngo, was the root meant by it: but this does not appear to be the cafe on a strict enquiry, and there is some reason to believe that the famous root, at this time called gaiinca, was what they meant.

SECALE, in Botany, a name in Pliny, which some etymologists, among whom is De Theis, derive from the Celtic fegat. This, he says, comes from fega, a fickle in the language, and thence fegat, the Latin appellation of all grain that is cut with a similar implement. Those who have looked no further for an etymology than the Latin fega, to cut or mow, have come to the same conclusion. Rye.—Linn. Gen. 39. Schreb. 53. Willd. Sp. Pl. v. t. 471. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. t. 178. Juss. 32. Lamarck Illus. fr. 49. Gen. t. 81.—Clavis and order, Triandra Digynia. Nat. Ord. Gramina.

Gen. Ch. Cal. Common receptacle toothed, elongated into a spike. Glume containing two flowers, and consisting of two opposite, dilata, erect, oblong, pointed valves, smaller than the corolla. Floris. A testifer. Cor. of two valves; the outermost harddest, tumid, pointed, cleft, fringed at the keel, and ending in a long awn; the inner flat, lan-

The nation of this district, so generally cultivated, grain is hardly to be guessed. Mr. Pursh says, it frequently occurs, apparently wild, in North America, flowering in June. For its agricultural history, and mode of cultivation, see Rye. The root is fibrous and annual. Herbaceous, somewhat glabrous. Stem jointed, slightly branched at the bottom, smooth, leaves linear, rough towards the point. Spike terminal, solitary, erect, three or four inches long. Stem erect, straight, rough, four or five times the length of the glumes.

2. Silvestrum. Tufted Rye. Linn. Sp. Pl. 124. Willd. n. 1. Sm. Fl. Grec. Sib. v. 4. 77. v. 97. (Graeen phytolacca febrilis, glumis villosis et aris longiflumina definitibus; Tourn. Laur. 518. G. phytolacca maximum; Park. Theatr. 142. G. phytolacca fytolacca, glumis ciliaribus; Tourn. Cor. 39. Buxb. Cent. 5. 21. t. 44.)—Glumes of the calyx wedge-shaped, abrupt, fringed with tufts of hairs.—Native of the south of Europe, and the Levant. Gathered by Dr. Sibthorp in the fields of Cretan and Zante. The root is fibrous and annual. Stems numerous, erect, twelve or eighteen inches high, leafy, smooth; their lower joints bent. Leaves spreading, flat, hairy on both sides, with tumid smooth sheaths. Spike about as long as the former, but twice as thick. Calyx bordered with remarkable tufts of fine hairs. This should seem to be cultivated in the above-mentioned islands, but we know nothing of its agricultural merits.

3. S. orientale. Dwarf Oriental Rye. Linn. Sp. Pl. 124. Willd. n. 3. (Graeen orientalis febrilis, spicis brevi et lati; Tourn. Cor. 39.)—Glumes of the calyx ovato-lanceolate, strongly ribbed, tapered-pointed, hairy all over.—Native of the Archipelago, in a fuddy soil. Root annual, with white downy hirs. Stems about six inches high, slender, smooth, often zigzag. Leaves linear, narrow; the upper one short, with a long, smooth, inflated sheath. Spike hardly an inch long, thick and broad, composed of closely imbricated, two-ranked piskalets, whose glumes are rigid, deeply furrowed, uniformly hairy, each tapering into a short, straight, rough point or awn, not so long as the glume itself.

4. S. creticum. Tall Cretan Rye. Linn. Sp. Pl. 125. Willd. n. 4; excluding the synonym of Tournelort, which belongs to Hordeum bulbosum. (See Hordeum.)—"Glumes of the calyx externally fringed."—Native of Crete. We have never seen a specimen. Desfontaines affirms that this is distinct from Hordeum bulbosum of Linnaeus, his strictum, which
S E C

which is Gramen creticum picipatum scCalnum aitilimum, tuberoso radice; Tourn. Cor. 39; and that he himself was 
pfolished of specimens of both. Both were also collected 

SECAMONE, an Egyptian name, apparently corrupted 
by the modern inhabitants of Egypt from the Greek 
σκαμόν; for Proper Alpinus tells us that the plant which bears 
this name, Periploca Secamone of Linnaeus, is esteemed, by 
that people, a fort of Scammony, and its yellow burning 
juice is, when dry, reckoned by them a powerful purg, for 
expelling thin humours. Yet he adds that he knew nothing 
of their making use of the plant in medicine. Since being 
the origin of this name, we are obliged to protest against it, 
as unclassified.—Brown Transf. of the Wernserian Society, 
v. 2. 75.—Clafs and order, Pentandria Digynia. Nat. Ord. 

of five leaves. Filaments combined, with external append-
egages. Malies of pollen erect, attached in four rows 
to the unfurrowed summit of the stigma. Follicles with comose 
feeds.

A genus of upright or twining, nearly smooth shrubs. 
Leaves opposite. Cymes forked, between the footstalks. 
Flowers minute.—Mr. Brown declares this genus to be per-
fectly natural and distinct, though, from the extreme minute-
ness of the parts, very difficult to determine. It is the con-
necting link between the true Ajcephalae and his Periploca.
Five species have been aecertained by the learned author of 
the genus.

1. S. egyptica. Egyptian Secamone. Ait. n. i. (Seca-
mon; Alpin. Egypt. 113. t. 134. Periploca Secamone; 
Linn. Mant. 216. Willd. Sp. Pl. v. i. 1249. Thumb-
Prodr. 47.)—Stem twining. Leaves elliptic-oblong, smooth. 
Corolla hairy.—Native of Egypt, and the Cape of Good 
Hope. A green-hose shrub, cultivated by Miller before 
the year 1752, and flowering in July. A Cape specimen 
from Thumberg is in the Linnaean barbierum. The stem 
is woody, twining, with smooth, round, leafy branches. Leaves 
about an inch and a half long, on shortish stalks, bluntish, 
entire, coriaceous, smooth, with one rib and many parallel 
transverse veins; pale, and somewhat glaucous, beneath. 
Cymes shorter than the leaves, repeatedly forked, many-
flowered; their filaments clothed with silky hairs, of a dusky 
blue in the dried plant. Flowers hardly a line in diameter, 
white. Corolla smooth at the back, its upper surface co-
overed with short dense hairs.

2. S. emetica. Emetic Secamone. (Periploca emetica; 
f. 2. Sp. Pl. v. i. 1250.)—Stem diffuse. Leaves lanceo-
late, smooth. Corolla smooth.—Native of the Eait Indies. 
The Rev. Dr. Rottler sent it from Madras. The roots are 
fried to be used instead of Ipecacuanha. This is a spreading, 
scarcely twining, shrub, of a more slender habit than the 
former, with much narrower leaves. Corollas axillary, small, 
not a quarter as long as the leaves, of few flowers, with 
downy silky filaments. Our specimen is in too early a state 
to display the corolla, but Retzius and Willdenow say it is 
smooth.

3. S. campestis. Hoary Secamone.—Stem twining, with 
downy branches. Leaves ovato-lanceolate; downy beneath. 
Corolla downy at the back.—Sent from the Eait Indies, by 
the late Dr. Roxburgh, in 1789. We presume this is what 
Mr. Brown mentions as his third species. Our plant has 
long, twining, round, pale-green branches, finely downy and 
hoary, in a young state, like all the flasks, the calyx, outside 
of the corolla, and backs of the leaves; which last are two 
or three inches long, rounded at the base, tapering gradu-
ally to a bluntish point. Flowers numerous, somewhat 
umbrellate; their common filaments about equal to the foot-
stalks.

1. 1.—"Stem erect. Leaves elliptical, pointed, smooth. 
General and partial flower-stalks downy. Corolla naked."

2. 1.—"Stem divaricated. Leaves ovate, acute, smooth. 
General and partial flower-stalks nearly smooth. Corolla 
cluded.«—Found by Mr. Brown, in the tame country as the 
fall.

SECANT, in Geometry, a line that cuts another, or 
divides it into two parts. See Line, &c.

Thus the line A M (Plate XIII. Geometry, fig. 4.) is a 
secant of the circle A E D, &c, as it cuts the circle in B. 
It is demonstrated by geometors: 1. That if several secants, 
M A, M N, M E, &c, be drawn from the same point M, 
that passing through the centre, M A, is the greatest; and 
the rest are all so much the less, as they are more remote 
from the centre. On the contrary, the portions of them 
without the circle M D, M O, M B, are so much the greater, 
as they are farther from the centre. The least is that 
of M A, which passes through the centre.
2. That if two secants, M A and M E, be drawn from 
the fame point M, the secant M A will be to M E as M D 
and M B: or M E X M D = M A X M B = the square of 
a tangent to the circle drawn from the point of concurrence 
M.

SECANT, in Trigonometry, denotes a right line drawn 
from the centre of a circle, which, cutting the circumference, 
proceeds till it meets with the tangent to the same circle. 
Thus the line F C (Plate Trigonometry, fig. 4.) drawn from 
the centre C, till it meets the tangent E F, is called a se-
cant; and particularly, the secant of the arc A E, to which 
E F is tangent.

The secant of the arc A H, which is the complement of 
the former are to a quadrant, is called the co-secant, or se-
cant of the complement.

The line of an arc, A D, being given, to find the secant 
of it, F C, the rule is, as the co-fine D C is to the whole 
line, so is the whole fine, or radius, A C, to the secant C F: 
or the secant is a third proportional to the co-fine and radius. 
See Sine.

To find the logarithm of the secant of any arc, the line 
of the complement of the arc being given, multiply the 
logarithm of the whole line by two, and from the product 
subtract the logarithm of the fine complement; the remainder 
is the logarithm of the secant. The reason of which opera-
tion is obvious; because E C = C F; and, therefore, 
from the nature of logarithms, twice the log. of E C = 
the log. of D C = the log. of C F.

SECANTS, Line of. See SECTOR.

SECAS, in Geography, a chiller of small islands in the 
Pacific ocean, near the coast of Veragua. N. lat. 8° 20'. 
W. long. 83° 16'.

SECATABBAS, a town of Asiatic Turkey, in the 
province of Diarbekir; 75 miles S.W. of Moful.

SECCA, a small island near the coast of Ilitra. N. lat. 
4° 5'. E. long. 14° 5'.

SECHE, a small island near the coast of Ilitra. N. lat. 
45° 14'. E. long. 13° 30'.

SECHHIA, a river of Italy, which runs into the Po, 
3 miles N. of Quilltello, in the duchy of Mantua.

SECEDERS,
SECEDES, from the Latin word secedo, to separate or withdraw, in Ecclesiastical History, an appellation comprehending those who are dissenters from the established church of Scotland. This kind of secession took place in the year 1727, when John Glas, disapproving every establishment of a national church, maintained that all churches ought to be congregational; or, in other words, that no general church should be formed for a nation, but that each religious society in a kingdom or state should be self-constituted, and controlled only by itself. For this and some other opinions he was suspended from his ministerial functions; and, for continued contumacy, deposed from the rank of minister, first by a provincial synod, and afterwards, viz. in 1730, by the general assembly of the Scots church. Perceiving, however, in the propagation of his sentiments, both by preaching and writing, he formed several congregations, of which the most numerous was that of Dundee. The secession of Mr. Glas and of his immediate disciples was followed by that of several other divines, who, on different grounds, determined upon withdrawing from the establishment. The two brothers, Ralph and Ebenezer Erskine, enfranchised, about the year 1730, in this number, and contributed very much to give reputation and influence to their cause. The seceding ministry alleged various infringements in the constitution of the kirk; but as they deplored or refuted, they resolved to establish new congregations. They complained of the laws of patronage and wished for a popular election of ministers; they pleaded that the right of protest against the proceedings of the assembly had been invaded, and that the rulers of the kirk not only acted arbitrarily, but suffered its doctrines to be corrupted. For the freedom of their animadversions on these points, four ministers were suspended from their parochial functions in 1731; and though they were reinstated by the assembly in the following year, the ground of complaint remained, and they refused to rejoin the establishment. From the clergy and laity they gained an ascendency of strength, more particularly after they had published a second "Testimony of the Reasons of their Secession." Upon a citation to appear before the assembly, the jurisdiction of which they refused to acknowledge, they were debarred, in 1740, from the exercise of all clerical functions in the church, and excluded from all its emoluments. The Seceders are rigid Calvinists, strict and severe in their discipline, and somewhat austere in their manners.

When the secession had formed three presbyteries, a division took place among them, in 1747, in consequence of an oath, which some of them deemed inconsistent with the sentiments avowed in their "Testimony." This was the ordinary oath of a burgess, in support of the true religion established by law. We cannot, said one party, call "Antiburghers" conscientiously honour with that appellation the establishment from which we have seceded; while the other members of the synod, denominated "Burghers," contended that the oath might safely be taken, as the religion of the state was still the true faith, though many of its offerable vassals had departed from its principles, or loosely professed it. The Antiburghers prevailed in the contest, and obtained a vote, that the oath was incompatible with the testimony; and they even excommunicated the members by whom it was vindicated. This dispute long continued to maintain the separation of the Seceders in distinct synods. Of these two classes, the Antiburghers are said to be the more confined in their sentiments, and least disposed to associate with any other body of Christians.

Under this article we may mention another party in Scotland, who quitted the establishment, and assumed the title of the "Reformed Presbytery." Lamenting the defection of the national rulers, and the majority of the people, from the true principles of the reformation, a party of religious malcontents renounced all connection with the "revolution kirk," and, under the guidance of Mac-Millan and Nairn, formed a seceding presbytery. By these ministers, others were selected for the same functions; and the secession has been continued to the present time. Besides the congregations of this complexion in North Britain, there are several in Ireland, and some in North America. The members profess to follow the scripture as their principal guide, and the ordinances of the Westminster assembly in the next place. They disapprove the high authority assumed by the rate over the church of Christ, as the result of worldly policy, rather than a claim justified by the genuine spirit of religion. Yet they submit peaceably to the higher powers, and do not indulge in the clamours of sedition, or the murrms of dissatisfaction. Their public worship is conducted much in the same manner with that of the dissenters in South Britain.

Another considerable fact departed, in the year 1732, from the Scotch establishment. A minister named Gillies, who opposed the reception of a new minister, whose appointment was not agreeable to the majority of the inhabitants of Inverkeithing, was expelled from the church in which he officiated; and he was soon joined by others, who, like himself, wished to be elected by the people; and they formed a congregation in Dunfermline. The "Presbytery of Relief," in alliance to the defied relief from the arbitrary rigour of the laws of patronage, was the denomination assumed by this body of seceders. More liberal than the generality of Presbyterians, they were willing to admit into their communion all those who seemed worthy of being called Christians, however they might differ with regard to particular points. Their congregations multiplied; and about the close of the last century, the allocation polled above sixty places of worship. Both classes of the "Seceders" and "Relief" include about 300 ministers, who are strict Presbyterians, though they secede or dissent from the established church of Scotland. Adam's Religious World displayed, vol. iii. Cooke's edition of Moehl's Ecc. Hist. vol. vi.

SECCRETE, in Ancient Geography, a town of Spain, in the Tarragonensis, upon the route from the Pyrenees to Castrum, between Aquae Voconiae or Voconia and Praetorium, according to the Itinerary of Antonine.

SECESPITA, among the Romans, a knife with a round ivory handle, adorned with gold and silver, which the flamen and priest used at sacrifice.

SCEELLES, in Geography, a cluster of rocky isles in the Indian sea, composed of a reddish granite, and generally low. On these are found some marine animals and vegetables, with different species of palm-trees. S. lat. 4° to 5°.

SECHES. See Secas.

SECHI, in Biography, an excellent performer on the hautbois, in the service of the elector of Bavaria, in 1772, who, if we had never heard Fretter, would have delighted us much more than the spirit of parallel would allow. However, in a duet with Rheiner, a performer of great merit on the balloon, we were reminded of the two Bezzozzis at Turin; for as their instruments, so their genius and abilities seemed made for each other, there was a like correspondence in both.

SECHEN, in Geography, a town of Persia, in the province of Kerman, on the north coast of the Persian gulf; 141 miles S. of Sirjan.

SECHIUM,
SECHIUM, in Botany, a name given by Dr. Patrick Brown to this genus, and most probably derived from σχιζειν, to fatten, the fruit being used in Jamaica to fatten hogs. In this case, however, favs professor Martyn, it should have been called Secium.—Brown, J. A. 355. Sc. 664. Willd. Sp. Pl. v. 4. 627. Mart. Mill. Dict. v. 4. Juss. 391. Lamarck Dict. v. 7. 50.—Clas. and Order. Monacria Monadelphia. Nat. Ord. Euphorbieae. Jull.

Gen. Ch. Male. Cal. Perianth inferior, of one leaf, tubular, clavate half way down; tube bell-shaped, spreading; segments of the limb lanceolate, flat, pointed, widely spreading. Cor. of one petal; tube the size and figure of the calyx, and adhering to it; limb clavate into five, ovate, flat, acute segments, nearly twice as long as the calyx, and much spreading. Nectary consisting of ten cavities in the upper part of the tube of the corolla. Stem. Filaments five, formed into an erect cylinder, five-cleft at the top, spreading; another on the top of each filament, all the five together forming a continued, undulating, polliniferous line. Female on the same plant. Cal. as in the male, but placed on the germin, deciduous. Cor. as in the male, but with larger cavities in the nectary. Petals German superior, obturate, downy, five-furrowed; style cylindrical, erect, the length of the calyx; stigma very large, peltate, reflexed, five-cleft at the margin. Peric. Apple very large, ovate, turbinate, five-furrowed, fleshy, unequally gibbous at the top, furnished with harmless prickles, one-celled above. Seed solitary, nearly ovate, flat or compressed, fleshy, obtuse at each end.

1. S. edu. Chocho Vine. Willd. n. 1. Swartz. Ind. Oec. 1150. (Sicyos edulis; Jacqu. Amer. 258. t. 163.)—Native of the West Indies, where it flowers and fruits in September. Root annual. Stem herbaceous, climbing or procumbent, greatly divaricated, roundish, fimbriated, smooth, thick. Leaves alternate, stalked, angularly heart-shaped, eight or ten-lobed, toothed at the margin, rough on the upper side, rugose beneath, often a fpan long. Tendril opposite to the leaves, horizontal, very long. Flowers monococcous, axillary, yellow, ficient.

Jacquin informs us that the Chocho Vine is used by the inhabitants of Cuba in their soups and puddings; and that it is served up as a vegetable with boiled meats.

SECHURA, in Geography, a town of Peru, in the bishropic of Truxillo, and jurisdiction of Piura, situated on the banks of the river Piura, about a league from the Pacific ocean. The town contains about 200 houses, constructed of cane, and a handsome brick church. The inhabitants, who are all Indians, compose nearly 400 families, and are employed chiefly either in fishing or driving of mules. The defect of Sechura is a waste of land, extending 30 leagues, of difficult and dangerous passage; 180 miles N. N. W. of Truxillo.

SECIUM, among the Romans, a term used to signify ever thing the priest cut with the knife fexipia, as the libum, plateui, &c.

SECK, RENT. Sec Rent Sec.

SECK, in Geography, a town of Germany, in the principality of Nassau-Dillenburg; 4 miles W. of Mengers-Kirchen.

SECKACH, a river of Germany, which runs into the Jax, at Meckmuhl.

SECKAU, a town of Stiria, the fee of a bishop, suffra-

Vol. XXXII.
and to this must be ascribed his fidelity to his employers, and the uncommon probity which he displayed in the management of public affairs. He polished great acuteness and discernment, which enabled him to extricate himself from many embarrassments; and by his indefatigable application, he found means to arrange and go through labours, which would have overwhelmed almost any other person. His works are very numerous, but the most important and considerable is his "Commentary on Lutheranism," which was undertaken with the view of confuting Maimbourg. Duke Ernelt had solicited him to write the History of the Reformation, or at least that part of it which related to Saxony; which, in 1682, he agreed to undertake. So highly were his talents illuminated, that as soon as his intention was known, most of the German princes opened to him their libraries and archives, and furnished him with such documents as might be useful to his project. A part of the work came out in 1688; but it was not till 1692 that the whole of it was given to the public, under the following title, "Commentarius Historici et Apologeticus de Lutheranismo, libri de Reformazione Religionis D. M. Lutheri in magna Germania, latalique Regionibus et speciis in Saxonia recepta et stabilita," &c. 2 vols. fol. This work was received with great applause by the learned of all parties. Bayle, in speaking of it, says, "Whose is deharrus of being thoroughly acquainted with the history of that great man (Luther), needs only to read the extensive work of Seckendorf. It is, of its kind, one of the best books that have appeared for a long time." Among the other works of Seckendorf, those most deserving of notice are, "The State of the Princes of Germany;" "A Defence of the Relation concerning Annette de Bourignon, or a Refutation of that false Fanatici;" "Historical and Apologetic Difficulties on the Doctrine of Luther in regard to Mans, published by Caplar Sagittarius;" "The State of the Christians, in which Christianity is examined in itself, and defended against Atheists." Gen. Biog.

SECKENHEIM, or SOHERNHEIM, in Geography, a town of the duchy of Baden; 4 miles E. of Mainz.

SECKER, Thomas, in Biography, a celebrated archbishop of the church of England, was born in 1603, at Sibthorp, in Nottinghamshire. His father was a Protestant divine, who lived upon a small paternal estate, and who was enabled to give his son an excellent education. He was first placed at a school at Chelford, whence he was removed to an academy at Attercliffe, near Sheffield, intended for the education of young men designed for the ministry among dissenters: after this, he was sent to a similar institution in the neighbourhood of Tewksbury. When he was about the age of 19, he had attained to a good knowledge of the classics, the Hebrew language, and of those branches of the mathematical sciences which were taught young men as preparatory to their studies in theology. From this time, till he was about 23 years of age, he pursued his theological course with great vigour; when, for some reasons which we are unacquainted, he determined to abandon his plan and study physic, and after attending lectures two years in London, he went to Paris for farther improvement, and carried his attention to all the branches of medicine, including surgery and midwifery. During this period he kept up a close correspondence with Mr. (afterwards bishop) Butler, who had been a fellow-student at Tewksbury. His friend had already confirmed, and persuaded Secker to follow his example, affuring him of the patronage of bishop Talbot. Secker now began to think seriously of those prospects which were held out to him in the established church. He was already amply provided with theological knowledge, and he had expressed a dissatisfaction with the divisions existing among the dissenters, and with the authority too frequently allumed by the heads of their congregations; he therefore closed with the invitation held out to him. It was thought right by his friends that he should have a degree from Oxford, with this view; and in order to expedite the process, he took the degree of M. D. at Leyden, in the year 1721, on which occasion he did himself great credit by a thesis which he delivered on the occasion, "De Medicina Statica." He then entered himself a gentleman-commoner of Exeter college, Oxford, and in a few months obtained the degree of B. A. in that university. He was ordained by Dr. Talbot, at that time bishop of Durham, and preached his first sermon in March, 1723. The preamble now took him into his family as chaplain, in which office he had Dr. Rundel for an associate. In 1724 he was presented to the valuable rectory of Houghton-le-Spring, in Durham; and being in a situation to maintain a family, he married the daughter of Mr. Denon, afterwards bishop of Gloucester; and Mrs. Talbot, the widow of the prelate, by whose advice Secker had conformed, came to live with Mr. and Mrs. Secker, from whom she received, to the end of life, the most affectionate attentions, in return for the services he had received from her late husband.

Secker now set himself down seriously to the duties of a country rector; but the place in which he lived did not agree with the health of Mrs. Secker, and he exchanged Houghton for a prebend of Durham, with the rectory of Ryton. He continued to reside in the north till 1735, when, being nominated one of the chaplains of the king, he came to the metropolis, and in the following year he was presented with the rectory of St. James. Upon this occasion he went to Oxford, to take the degree of doctor of laws, not being of sufficient standing for that of divinity, when he preached what was denominated an act sermon, "On the Advantages and Duties of Academical Education," which was regarded as a master-piece of sound reasoning and good composition. It was printed at the desire of the heads of the houses, and passed through several editions; and the reputation derived from it was thought to be the principal means of his advancement to the episcopal bench, which took place in January, 1734-5, when he was consecrated bishop of Bristol, Dr. Benison, his brother-in-law, being at the same time consecrated to the see of Gloucester. In his high office as prelate he exhibited the most striking proofs of a conscientious attention to all parts of his duty. He now delivered, twice a-week, in his parish church, a course of lectures on the church catechism, which were afterwards published, and which were generally regarded as admirably adapted to give a compendious view of the principles of the Christian religion as professed by the church of England, and as established by law.

In 1737, Dr. Secker was translated to the see of Oxford, which he held more than twenty years, and no one could perform with greater sufficiency and earliness the essential duties of his function; his exterior deportment likewise was grave, dignified, and perfectly adapted to the importance of the character which he maintained. In 1748, Mrs. Secker died, leaving no issue, and the bishop did not marry again. In 1750 he exchanged his prebend of Durham and rectory of St. James for the deanery of St. Paul's; and in 1758 he was raised to the archbishopric of Canterbury. His original education among the dissenters did not render him less zealous in the interests of the church to which he had conformed: he even went farther than most of his contemporaries.
poraries in endeavouring to extend the authority of the church of England, and advocated the measure of establishing bishops in the American colonies. On this subject he was attacked by Dr. Mayhew of Bolton, to whom he replied with much temper. The argument in favour of American bishops turned upon the incompleteness of an episcopal church without them, and the great inconveniences experienced by the clergy of that remote country in the necessary communication with the mother establishment. The archbishop knew that he was quite sincere in his wishes for the establishment of episcopacy in America, by bequeathing 1000£ towards effecting the purpose. The subsequent separation of the colonies from the British government, however, put an end to this project further than concerned Canada.

During the time that archbishop Secker held his high pre-ferment, the Methodists made very rapid strides in the propagation of their principles: some of the bishops had declared against them; but Dr. Secker acted with his usual prudence, and recommended to his clergy moderation and kindnefs in their behaviour towards those whom he wished to consider as his future friends, but whom others were disposed to treat as enemies.

The archbishop had for many years been a great sufferer from the gout, which latterly brought on severe local pains. These were at first confined to the thigh, and terminated in an extensive caries of the thigh-bone; one of the fatal consequences of which was a sudden fracture of that bone upon the mere raising him up on his couch. Shortly after this he died, Aug. 3, 1768, in the 75th year of his age.

To the many benefactions for useful and charitable pur-poses which he bequeathed in his life-time, he made large additions by his will. Besides his "Lectures on the Church Catechism," he was author of "Eight Charges delivered to the Clergy of the Dioceses of Oxford and Canterbury; with Instructions to Candidates for Orders," and a Latin Speech, intended to have been made at the opening of the Convocation in 1761; "Fourteen Sermons, preached on several Occasions;" and "Sermons on several Subjects," in four volumes, published after his death by his chaplains, Drs. Porteus and Stinton. The various works of this useful and able prelate have established his character as one of the most useful and rational preachers among the English divines. Their style is simple and without ornament: they have no pretence to oratory and fine writing; but they display more knowledge of the human heart, and the real motives of action, than is usually found in those kinds of compositions. They are truly didactic, and "come home to men's busines and bofoms" in a remarkable degree.

He was attached to those political principles which placed the house of Hanover on the throne; and on the breaking out of the rebellion in 1745, he exerted himself most con-spicuously in support of government. He enlisted himself under the banners of no ilate party; but his chief parliamentary connexions were with the duke of Newcastle and Lord Hardwicke. Life of Secker, prefixed to his Sermons.

SECKINGEN, in Geography, a town of Baden, on the Rhine, the waters of which surround it; 4 miles W. of Laufenburg. N. lat. 47° 34'. E. long. 8°.

SECKEL, a town of the State of Utrecht; 13 miles W. of Utrecht.

SEELIA, a name by which some authors have called wormwood.

SECLIN, in Geography, a town of France, in the department of the North, and chief place of a canton, in the district of Lille; 4 miles S. of Lille. The place contains 2500, and the canton 8,679 inhabitants, on a territory of 102.5 square miles, in 16 communes.

SECO, a town of Africa, in Kaarta; 65 miles E. of Kemmou.—Allo, a river of Peru, which runs into the Pacific ocean, S. lat. 7° 6'.

SECOANI, in Ancient Geography, a town of Asia, in Syria, situated in the mountains, E. of the Mediterranean sea, and W. of the river Orontes, in the territory of Apanae.

SECOMUS, in Natural History, the name of a genus of fossils, of the class of the septaria; the characters of which are, that they are bodies of a dark hue, divided by septa, or partitions of a sparry matter, into several more or less regular portions, of a moderately firm texture, not giving fire with red, but fermenting with acid menstrua, and easily calcining.

The septaria of this genus are, of all others, the most common, and are what have been known by the little expressive, or mistaken names of the waxen vein, or huls Helmontii. We have many species of these bodies common among us. Of the whitish or brownish kinds we have thirteen; of the yellowish, five; and of the ferruginous ones, four.

SECOND, in Anatomy. See Secundi generis.

SECOND, in Geometry, Astronomy, &c. the sixtieth part of a prime, or minute; either in the division of circles, or in the measure of time.

A degree, and an hour, are each divided into sixty minutes, marked thus '; a minute is subdivided into sixty seconds, marked thus "; a second into sixty thirds, marked thus "; &c.

We sometimes say, a second minute, a third minute, &c.

A pendulum, three feet three inches and two-tenths of an inch long, vibrates seconds, according to Sir Jonas Moore's reduction of Huygens, three feet eight lines and a half of Paris measure to English measure. See Pendulum.

SECOND, in Myth, denotes one of the musical intervals; being only the distance between any found, and the next found, whether higher or lower.

As in the compass of a tone there are reckoned nine sensibly different founds, which form these twelve intervals called comas, one might in strictness say there are eight kinds of founds.

There are three kinds of founds occurring in practice, the less, the greater, and the superfluous found; to which, if the enharmonic genus were restored, we might add the diminished found. The less found is the semitone, which being either major or minor, there must be two great seconds; one nearly equal to 85 comas, and the other to 93 comas; but practitioners usually confound these two. The superfluous found is a tone major, and semitone major; the other superfluous found, arising from the tone minor, and semitone minor, is not in use. Lastly, the diminished found is a semitone minor less than the less found; that is, equal to the diatonic enharmonics. Thus, between E and F, or between A and B, would be a diminished found, as also between G sharp and A. This last has been practised by Mr. Handel, in the oratorio of Sampson, in the second part of the song, "Return, return, O God of Hosts." See Interval.

Some authors, as Ozanam, call the semitone minor by the name of diminished found; but this is contrary to the analogy in like cases, where diminished is usually applied to intervals a semitone minor less than a true diatonic interval.
Thus the diminished seventh is a semitone minor less than the flat seventh, or seventh minor.

SECOND, Diminished. See Diminished Second.

SECOND de l'Oreille, in Anatomy, a name given by Vieussens and others to a muscle of the ear, called by Cowper and others *flaplicaudus* and *flaplicauda*; and by Albiniu *flapividium*. Winlock calls it *le muscle de l'oreille*.

SECOND Captain. See Captain.

SECOND Coast. See CAUSE and EFFICIENT.

SECOND Deliverance, Seconda deliberatione, in Law, a judicial writ that lies after consent of the plaintiff in replevin, and a *retrou nolet* of the cause replevied, and adjudge him to that discharged from the command of the same cattle, upon security given by the plaintiff in the replevin for the re-delivery of them, if the defendants be justified. It is a second writ of replevin, &c. F. N. B. 68.

SECOND Flush, Notice, Order of Courses, Rate. See the substantives.

SECOND Sight, an odd qualification, which many of the inhabitants of the Western Islands of Scotland are said to be possessed of. The thing is attested by many credible authors (among whom is Mr. Martin, author of the natural history of those islands, and a member of the Royal Society); and, notwithstanding the strangeness of it, many have fdlately believed it.

The second sight is said to be a faculty of seeing things to come, or things done at a great distance, represented to the imagination as if actually visible and present. Thus, if a man be dying, or about to die, his image, it is pretended, will appear distinctly in its natural shape, in a mirror, with other funeral apparatus, to a second-sighted person, who, perhaps, never saw his face before; immediately after which, the person feen certainly dies.

The quality of second-sightedness, they say, is not hereditary; the person who has it cannot exert it at pleasure; nor can he prevent it, or communicate it to another; but it comes on him involuntarily, and exercises itself on him arbitrarily; and often, especially in the younger second-sight, to their great trouble and terror.

There is a great number of circumstances said to attend these visions; by observation of which, the particular circumstances, as to time, place, &c. of the death of the person, &c. are learnt. The method of judging of them, or interpreting them, grows into a kind of art; which is very different in different persons. Second-sightedness is held a difdiferent in the country; so that none, they fay, will counterfeit it; but that many conceal and dissemble it. See Johnson’s Journey to the Western Islands of Scotland, p. 248, &c.

SECOND Surcharge, Writ of, in Law. See Surcharge.

SECOND Terms, in Algebra, those where the unknown quantity has a degree of power less than it has in the term where it is raised to the highest.

The art of throwing these second terms out of an equation; that is, of forming a new equation, where they have no place, is one of the most ingenious and useful inventions in all algebra.

SECOND Title. See Title.

SECONDARY, or Secondary, an officer who acts as second, or next to the chief officer.

Such are the secondaries of the courts of king’s bench and common pleas; the secondaries of the compters, who are next the sheriffs of London in each of the two compters; two secondaries of the pipe; secondaries to the remembrancers, &c.

Secondary is more frequently used in an adjective sense, by way of opposition to primary, or principal.

SECONDARY After. See Actor.

SECONDARY Affections. See AVERSION.

SECONDARY Circles of the Eclipc, are circles of longitude of the stars; or circles which, passing through the poles of the ecliptic, are at right angles to the ecliptic. See CIRCLES OF LATITUDE.

By the help of these, all points in the heavens are referred to the ecliptic; that is, any planet, star, or other phenomenon, is under-footed to be in that point of the ecliptic, which is cut by the secondary semicircles, which pass through each star, or phenomenon.

If two arcs be then referred to the same point of the ecliptic, they are said to be in conjunction; if in opposite points, they are said to be in opposition; if they be referred to two points at a quadrant’s distance, they are said to be in a quadrat aspect; if the points differ a sixth part of the ecliptic, they are said to be in! a sextile aspect.

In the general, all circles which intersect one of the five greater circles of the sphere at right angles, may be called secondary circles. As the azimuth or vertical circles in respect of the horizon, &c. the meridian in respect of the equator, &c.

SECONDARY Collateral Points. See COLLATERAL.

SECONDARY Consequences, in Law. See DERIVATIVE.

SECONDARY Dials. See DIAL.

SECONDARY Fever is that which arises after a crisis, or the discharge of some morbid matter; as after the declension of the small-pox, or measles. See FEVER, Small-Pox, &c.

SECONDARY Motion. See Motion.

SECONDARY Place. See PLACE.

SECONDARY Planets, those moving round other planets as the centres of their motion, and along with them round the sun. See PLANET.

SECONDARY Qualities, Rainbow. See the substantives.

SECONDARY Use, in Law. See Use.

SECONDIGNY, in Geography, a town of France, in the department of the Two-Seine; and chief place of a canton, in the district of Parthenay; 6 miles W.S.W. of Parthenay. The place contains 1,425, and the canton 6140 inhabitants, on a territory of 172,500 square kilometres, in seven communes.

SECONDINE. See SECONDINE.

SECORA, in Geography, one of the branches of the river Darah, which joins the main stream at Timelik.

SECOAT, a town of Candahar; 150 miles S.E. of Candahar.

SECOURSSE, DENYS-FRANCOIS, in Biography, was born at Paris in 1691. He was one of the earliest pupils of the celebrated Rollin, and being brought up to the bar, he was for some time a pleader. This profession, however, he quitted in order that he might devote himself entirely to literature, in which the study of French history was his principal object. In 1723 he was admitted into the Academy of Inscriptions and Belles Lettres. The office of censor-royal was conferred upon him, and he was appointed, in 1746, to examine the public documents preferred in the newly conquered towns of the Low Countries. He died at Paris in 1754. His publications were, the Collection of Royal Ordoneances, from the second to the twelfth volume inclusive; “Mémoire sur l’Histoire de Charles le Mauvais,” two vols. 4to.; an edition of the “Mémoires de Condé,” six vols. 4to., in conjunction with the abbé Lenglet; and several dissertations in the “Mémoires de l’Acad. des Inscriptions.”

SECOZANO, in Geography, a town of the county of Tyrol; 13 miles N.N.E. of Trent.

SECRETARIUM, among the Romans, a reclusse room, where
where the judges considered the causes that had been litigated before them, and came to a resolution what sentence they were to pass from the tribunal. It was most usually separated from the tribunal by a veil.

SECRETARY, an officer, who, by order of his master, writes letters, dispatches, and other instruments, which he renders authentic by his signature.

Of these there are several kinds, as secretary of state, secretary of war, secretary of the treasury, secretary of the admiralty, secretary of the lord chancellor, &c.

SECRETARIES of State, are officers attending the king, for the receipt and dispatch of letters, grants, petitions, and many of the most important affairs of the kingdom, both foreign and domestic.

The king's secretaries were anciently called the king's clerks and notaries, regis a commentariis. As for the name secretary, it was first applied to such as, being always near the king's person, received his commands, and were called clerks of the secret; whence was afterwards formed the word secretary, regis a secretis; and as the great lords began to give their clerks also the quality of secretary, those who attended the king were called, by way of distinction, secretaries of the commands, regis a mandatis. This continued till the reign of our Henry VIII. 1559; when, at a treaty of peace between the French and Spaniards, the former observed, that the Spanish ministers, who treated for Philip II. called themselves secretaries of state; upon which, the French secrétaires de commandements, out of emulation, assumed the same title; which thence paffed into England.

Till the reign of king Henry VIII. there was only one secretary of state; but then, business increasing, that prince appointed a second secretary; both were of equal power and authority, and both styled principal secretaries of state. Before queen Elizabeth's time, the secretaries did not sit at the council board; but that princes admitted them to the place of privy counsellors, which honour they have held ever since; and a council is never, or at least very seldom, held without one of them. On the union of England and Scotland, queen Anne added a third secretary, on account of the great increase of business, which, as to Britain, was equally and distinctly managed by all the three, although the last was frequently styled secretary of state for North Britain. We have had also a secretary of state for the American department. But both these offices are now abolished, and there still remain three principal secretaries, viz. one of the home department, another of foreign affairs, and the third of the colony and war department, who have under their management and direction the most considerable affairs of the nation, and are obliged to a constant attendance on the king; they receive and dispatch whatever comes to their hands, be it for the crown, the church, the army, private grants, pardons, dispensations, &c. as likewise petitions to the sovereign; which, when read, are returned to the secretaries for answer; all which they dispatch according to the king's command and direction.

Ireland is under the direction of the chief secretary to the lord lieutenant, who has under him a resident under-secretary.

Each of the three principal secretaries has two under secretaries and one or more chief clerks, besides a number of other clerks and officers, wholly depending upon them.

Our secretaries of state are allowed power to commit persons for treason, and other offences against the state, in order to bring them to their trial. Some have said that this power is incident to their office; and others, that they derive it in virtue of their being named in the commissions of the peace for every county in England and Wales.

The secretaries of state have the custody of that seal, properly called the signet, and the direction of the signet office; in which there are four chief clerks and three deputies employed, who prepare such things as are to pass the signet, in order to the privy or great seal. All grants, signed by the king, are returned hither, which, transcribed, are carried to one of the principal secretaries of state, and sealed, and then called signets; which, being directed to the lord privy-seal, are his warrant.

On the secretaries of state is likewise dependent another office, called the paper-office, in which all public writings, papers, matters of state, &c. are preferred.

All the under secretaries and clerks are in the choice of the secretary of state, without referre to any person; the under secretaries receive orders and directions from them, for writing dispatches, foreign or domestic, which they give to the chief clerk, who distributes them to the under clerks.

The secretary at war belongs to the war-office, and has under him a deputy secretary, with his private secretary, and a number of clerks and other officers.

SECRETARY of an Embassy, is a person attending an ambassador, for the writing of dispatches relating to the negotiation.

There is a great difference between the secretary of the embassy, and the ambassador's secretary; the last is domestic, or ministerial of the ambassador's; the first a servant, or minister of the prince.

SECRETION, in Physiology, is that vital process, in which some substance, either designed to answer a purpose in the animal economy, or to be thrown out of the body as useless or injurious, is separated from the blood by an organ of glandular structure. It agrees with nutrition, with the exhalations from the skin, membranes, adipous and lymphatic cells, in being the separation of something from the blood, but it is distinguished from these processes by the circumstance of its being performed by glands. The word secretion however is often used more loosely by medical writers, in application to any living process, by which matters are separated from the blood. The organic structures, in which secretions are carried on, the material agents of these processes, and the powers by which they are executed, are considered under the article gland.

SECT, SECTA, a collective term, comprehending all such as follow the doctrines, or opinions, of some famous divine, philosopher, &c. For the Scriptural meaning of the term sect, see HERESY.

The sects of philosophers among the ancients, particularly in Greece, were numerous: as the Pyrrhonians, Peripatetics, Epicureans, Stoics, Peripatetics, Academics, &c. See each under its proper article.

In later times, the sects of philosophy have been chiefly reducible to three; viz. the Cartesians, Peripatetics, and Newtonians. See CARTESIAN, &c.

In theology, the sects are much more numerous; yet the ancients had many sects, now extinct; as Machiavel, Gnostics, Montanists, &c.

The principal now on foot are the Lutherans, Calvinists, Anabaptists, Arians, Socinians, Armenians, and Unitarians.

The religious sects and faiths, with the distinguishing characters and opinions of each, see under LUTHERAN, CALVINIST, &c.

Sect, Ionic. See Ionic.

Sect, Italic. See ICAITAL.

SECTS OF HINDUS. It has been long known that the Hindoos are divided and subdivided into a number of sects, tribes, or calls. Under our articles BRAHMA, CAST, and GENTOO, we have given the substance of what has been communicated
Sects of Hindoos.

Communicated by early and later travellers to eastern regions on the subject of these distinctions. In common with these writers, we have also used the term caste, or caste, though we are not aware of any classical authority for the word. We are disposed to think it introduced by the Portuguese; and it is now, and has been for many years, as common in the mouths of natives as of Europeans, especially on the coast of Coromandel. We do not affirm that the word is not of Sanscrit origin, and in truth it sounds very like it; but we have never met with the word in earlier writings, nor heard it used by natives beyond the reach of European colloquial influence.

In considering the division and subdivision of the numerous race of Hindoos, we are disposed to separate them into theological, civil, and philosophical classes or tribes. Theologically we find two grand divisions, the Saivas, who worship Siva, and the Vaishnavas, who worship Vishnu; these are numerically subdivided, as we shall presently see, as are the many sects who essentially or trivially differ from both, and are probably numerically equal to both, under the generic denomination of Buddhás or Bandis, and its various specific varieties. The civil grand divisions are four, viz. Brahman, Kshetriya, Vaifya, and Sudra. As the two former theological grand divisions comprise the whole race of Hindoos (leaving for the present the sects or philosophies of the question), so do likewise these four civil tribes or grand divisions of either of the four may be theoretically a Saiva or a Vaishnava, as his parents may have taught, or his feelings led him. These four civil grand divisions are subdivided into almost innumerable distinctions and varieties. Here follows a brief outline of the distinctions of these four grand civil tribes.

1. Brahman. This is a small tribe in point of number; but in power paramount. Intellectual is power and, with a few exceptions, the intellectual wealth of India is confined to the Brahmanical treasury. As among the Jews all priests were taken from the tribe of Levi, so with the Hindoos the tribe of Brahman exclusively furnishes the priesthood. All Hindoo priests are therefore Brahman, but all Brahman are not priests. Ministers and public officers of state are very commonly Brahman, even in Mahomedan governments; and they are occasionally merchants, and even soldiers. In both the British and native armies of India, are many Brahman. The two Maharrattas generals whose names are well known in England, Purseran Bhon and Hurry Punter, were both Brahman. A Brahman is pointedly prohibited from becoming a king; royalty appertains to the second tribe. (See Peshwa.) In the Gita, a work profoundly venerated by numerous sects, the duties of the four tribes are very concisely and plainly stated. "The natural duty of the Brahman is peace, self-restraint, zeal, purity, patience, rectitude, wisdom, learning, and theology." Gita, p. 130. (See Mahabharat.) The word Brahman means a theologian or divine; derived from Brahman, the divinity. Pandit, corruptly Punt, means a learned Brahman, or philosopher; hence panditya, philosophy. Among the Maharrattas, where Brahman are very numerous, the title of Punt is assumed by many individuals: seldom, if ever, by those in low stations. In very low or base occupations Brahman are, indeed, never seen. The names of individuals often indicate their sect. Purseran Bhon, above-mentioned, we should infer to have been of the grand division Vaishnava, and of the sect of Ramanuj. (See Paradu Ramla, which is the classical mode of writing and pronouncing his name, and Ramanul.) Hurry Punt, is from his name known to have been a Brahman (Pandit) of the grand division Saiva; Hari (corruptly Hurry) being a name of Siva. See Siva.

2. Kshetriya, usually pronounced Ketri, or Kshetri, is the second civil grand division. It is the warrior tribe; comprising all soldiers, who alone can lawfully become kings. (See Peshwa.) All the other tribes, however, furnish soldiers; and, indeed, princes too, if the ambitious individual can effect it. "The natural duties of the Kshetri are bravery, glory, fortitude, rectitude, not to flee from the field, generosity, and princely conduct." (Gita, ib.) This grand division is very numerous. Some hundreds of different sects might be enumerated as belonging to it, and many hundreds would still be omitted. The Ayin Akbary states, (vol. ii. p. 87. Calcutta ed.) that of the tribe of Kshetri, there are upwards of five hundred subdivisions, fifty-two of whom are in edem, and twelve particularly so. Of one of these subdivisions, that of Rajput, the same authority says there are upwards of a thousand different sects. The term Rajput, or rather Rajaputra, means offspring of kings; a title assumed by various warrior tribes in the north of India; individuals of which are prettily numerously spread in the southern and other provinces, wherever good pay invites their services.

3. Vaifya, vulgarly called Vais, or Bhyse, is the tribe next in rank to the military. This is a very numerous tribe, comprising merchants, traders, and cultivators. In this, that is, practicing its avocations, are found many individuals of the three others: The natural duty of the Vaifya is, according to the Gita, "to cultivate the land, tend the cattle, and buy and sell." (Ibid.) This tribe is numerically subdivided like the others. It contains a great proportion of wealthy individuals. The subdivision of Vania, or Bania, called by the English Banyan, belongs to this class, and is said to comprehend eighty-four different sects; it being only itself a tribe of this third grand division, or of Vaifya.

It is understood, that all the individuals of the three first tribes or sects above named, are incapable of regeneration, by a mysterious initiation in the Gayatri, and the investiture of a holy thread called zennaar. Such individuals are called twice-born. See our articles O'ra and Zennaar for further notice of these particulars.

4. Sudra. In this is comprised mechanics, artisans, and labourers of every description. In the profession of the Sudras' avocations, individuals of the second and third tribes or classes will be found; and occasionally, though comparatively but rarely, of the first. Many mechanics and artisans are of the third class. "The natural duty of the Sudra is servitude." Gita.

This arrangement into castes or sects, tribes or grand divisions, is, as before noticed, of very early origin. In the Institutes of Menu, (see Menu,) we find it laid down as of the remotest antiquity; and, as is usual with every thing relating to the Hindoos, traced to a mythological source. "That the human race might be multiplied, he (the supreme lord, or Brahma) caused the Brahman, the Kshetriya, the Vaifya, and the Sudra, (so named from the scripture, protection, wealth, and labour,) to proceed from his mouth, his arm, his thigh, and his foot." Ch. i. v. 31.

In early times it is probable that these distinctions or separations were kept up and observed with considerable strictness, both in respect to intermarriages and avocations. Those times were, however, anterior to the Institutes of Menu, who gives names to the spurious offspring of fictitious intermarriage; wisely endeavouring to correct, what his authority would prove unequal to prevent, or materially restrain. Denunciations, however, against these illicit practices, sexual and handicraft, abound in the books of law; and abomination from the sin thus incurred is doubtless one, and
and no trifling, source of the revenue and power of the priesthood.

We shall notice a few of the chief religious sects into which the race of Hindoos comprised in the above four grand civil classes are subdivided. To enumerate them all would be fearlessly possible, even with the aid of learned native; and to place them in their relative rank, altogether impracticable: for it is a point involving great differences of opinion; as may be imagined when the religious feelings and pride of many individuals clash, and where great scope is afforded for their display in a field bounded by no precise authority.

Five principal sects are recognized who worship exclusively a single deity. These are 1. The Siva, who worship Siva. 2. The Vishnu, who worship Vishnu. 3. The Sauras, who worship Surya, or the sun. 4. The Ganapatyas, who worship Ganesa. 5. The Saktas, who worship Parvati. But if we examine closely the relation which they respectively bear to each other, we shall find the fourth and fifth to be ramifications of the first, or sect of Siva; of which may be traced these distinctions. 1. Siva, the adorers of Siva under his phallic emblem called Linga. (See Linga and Ling.) 2. Lingi, the adorers of Siva under his phallic emblem called Linga. (See Linga and Ling.) 3. Saktas, the adorers of Parvati, under her symbol the Yoni. (See Saktas and Yoni.) 4. The Ganapatyas, worshipers of Ganesa, one of the Vedic deities, from Varavara and Siva. (See Pollear.) These four sects, and many divisions and subdivisions of them, may be deemed as comprehended in the first named, Siva, or Siva-bhakti. The worshipers of Baghees, or Siva, are sometimes called Siva Siddhanta.

The first great sect of Vaihnavas is also variously divided and subdivided. Two principal divisions or branches are the Gokulgas and Ramanuj. or worshipers of Vishnu, in two of his grand incarnations of Krishna (one of whom names is Gokul), and of Siva. These two principal sects of Vaihnavas are each divisible into three. The Gokulgas are 1. Those who exclusively worship Vishnu as Vishnu himself; and this sect is extensively considered as the true and orthodox Vaihnavas. (See Krishna and Vaishnavas.) 2. Those who exclusively worship Radha, as the female of Krishna. (See Radha, Saktas, Sakti.) This sect is sometimes called Radha-bhakti. 3. The worshipers of Krishna and Radha conjointly. The three divisions of Ramanuj are 1. Those who worship Rama only. (See Rama and Ramanuja.) 2. Those who worship Sita only. 3. Those who worship both Rama and Sita conjointly. See Sita.

The sect of Ganapatyas we have considered as a division of that of Siva; and the sect of Saura, worshipers of Surya, or the sun, are divided to clafs under that of Vaihnavas; for although Siva be the sun as Vishnu, yet the latter, and more particularly in his incarnation of Krishna, is more generally reckoned the archetype of the solar deity; or, what amounts to the same thing, the sun, a symbol of the sun, or Virun. Individuals of several sects of Saivas do not doubt mix their adorations with the solar worship; as do also many sects of the Vaihnavas. See Saura.

Under our article Sakti we have observed that the Hindoo mythology has personified the abstract and attractive powers of the divinity, and ascribed to these mythological personages. The Sakti, or energy of an attribute of God, is female, and is fabled as the comfort of that personified attribute. Hence has arisen such a series of fictitious comprehending all natural and moral phenomena, obscured by mythological and sexual allegories, as it is fearfully possible to explain. (See Lakshmi, Parvati, and Saraswati.) Respecting the Saktas, that is, those who worship exclusively or chiefly the Sakti or female power, this distinction has been noticed; some of them, adopting what is called a left-handed path, accompany their devotions by divers obscene and indecent acts: others do not. The sect of Radha-ballabhi, who are supposed to worship the female energy in Lakshmi, under her form of Radha, are accused of these indecencies. (See Radha.) Among the Saktas of the Saiva tribes there is also a left-handed or indecent, as well as a right-handed or decent mode of worship; and those who adopt the former are said to go the length of extreme profligacy. (See Saktas.) We should be disposed to class all the individuals who thus, either in the right or left-handed path, adore the female power, under the denomination of Tonijar, or worshippers of the Yoni; the symbol more especially of Parvati: but for this, though a reasonable classification, we cannot quote any immediate authority. (See Yoni.) None of the sect of Ramanuj are accused of the left-handed enormities. In most parts of India they are, when known, held in reserved detestation; and the decent Saktas forbid making any censure of proficion of their tenets, or wearing on their foreheads the mark of their sect, lest they should be suspected of belonging to the other branch of it.

There is another very numerous sect of Vaihnavas, called Bhagavatas, of more modern origin than the other. Their tenets and practices are grounded on the eighteenth Purana, which is chiefly a history of the life, adventures, and doctrines of Krishna, and is entitled Sri Bhagavata, which fee. The work is ascribed to Vasudeva, who endeavored to reconcile and unite all sects, by recognizing the deities of each, but as subordinate to the Supreme Being, as or as attributes or manifestations of God. This is, in fact, the doctrine of the Gita; but that work, as well as the Sri Bhagavata, while professing to uphold a unity in the deity, claims that pre-eminence for Krishna; and although the sect of Bhagavata is very numerous, and includes individuals of or from many other sects, is a purity of doctrine is far distant from all, while a mythological paraphrase continues clothed in the attributes of the Almighty. For all the other sects, or at least a portion of the most enlightened and liberal individuals among them, are sufficiently ready to profess a belief in the unity of the deity, if their claim of that awful designation for the object of their own adoration be conceded. See Krishna, Saraswati, and Siva.

The Bhagavatas, while recognizing the five divinities worshipped by the other sects respectively, and even paying them in turn their daily adoration, and on particular occasion extending it to other deities, still deny the charge of polytheism, and repel the imputation of idolatry. It may be easily imagined that but few, we may almost say none, of the numerous followers of this sect can fully comprehend the doctrines they profess. They incline much to real polytheism, but do at least reject the derogatory notions of the deity which the other sects seem to have adopted. The practice of adoring images of celestial spirits, they justify by arguments similar to those which have been elsewhere employed in defence of image worship. (See Gentleness and Idolatry.) If the doctrines of the Veda, and even those of the Puranas, be closely examined, the Hindoo theology will be found consistendent monothism, though it contains the seeds of polytheism and idolatry. See Purana and Veda.

Modern Hindoos seem to have misunderstood the numerous texts in their sacred books, which declare the unity of the godhead,
SECTS OF HINDOOS.

godhead, and the identity of Vishnu, Siva, the Sun, &c. Their theologics have entered into vain disputes on the question of which, among the attributes of God, shall be deemed characteristic and pre-eminent?

Sinkara-charya (see the article under his name) the celebrated commentator on the Veda, contended for the attributes of Siva, and founded or confirmed the sect of Saiva, who worship Siva as the supreme being, and deny the coequal or independent existence of Vishnu and other deities. Madhava and Vallabha, both also famed Acharyas, denoting literary dignity, have in like manner established by their comments the sect of Vaisnava, who adore Vishnu as God.

Under the article Saraswati we have noticed, that there is now no sect, who exclusively or principally worship Brahma: no one hath hitherto been discovered named after him, denoting the creative power to be the object of exclusive adoration. Still by some legends he is described as the Almighty; leading us to infer, that he was once factually addressed as the other two members of the triad now are. His facts, Saraswati, is described in some passages as all-productive, all-powerful, and all-wise. It may be reasonably inferred, that there are many more sects among the Hindoos than have hitherto been ascertained.

Molt of the sects, however, approach or melt into each other on close inspection; as may in all such cases be supposed, when they must all have originated in one common source. This union is with the Hindoos marked with their usual extravagant sensual mythology. Siva and Parvati, they say, had a contest on the question of the comparative potency or eminence of their several worship; in other words, the worshippers of their symbols, the Linga and Yoni, contested the point. To appease this physiological difference between the god and his comfort, Vishnu interpolated, and his navel, or rather as time, came at length to be considered as the fame with the Yoni; confounding the Vaihnavas with the Yojias: but we must refer to our article Yoni, and the other articles and the works therein mentioned, for farther particulars on this point.

In the early part of this article, we have adverted to the numerous schismatics, under the generic term of Baudhas, followers of the doctrines of Buddha or Boodh. (See Boodh.) Thence, under various designations, we are disposed to class as heretical Vaihnavas, worshipping Vishnu under one of his avatars or incarnations, that of Buddha; as the Gokalathas and Ramanjus do under others; those of Gokal, or Krihitna and Rama. “In respect to the number of followers,” the author of the Hindo Pantheon observes, “and the extent over which they have spread, the doctrines of Buddha have probably obtained greater dominion than those of any other religious persuasion. Although now comparatively trivialed on the continent of Hindostan, his doctrines and followers are still found, differing in externals, and divided into sects, throughout China and its tributary nations; in the great empires and states of Cochinchina, Cambodia, Siam, Pegu, Ava, Afam, Tibet, Budan or Bootan, (see those several articles,) many of the Tartar tribes, and generally all parts eastward of the Ganges; including those vast and numerous islands in the seas eastward and southward of the farther Indian promontory, who inhabitants have not been converted to Islamism. In these great and distant parts of the globe the tenets of Buddha, distinguished by various appellations, may be recognized as forming the religion of the people; an extent exceeding that either of the Mahomedan or Brahmanical superstition, and outnumbering, perhaps, the followers of the religion of Jesus Christ.” P. 240.

Budhism, like other distinctions of faith among Hindoos, is divided into sects. If it be reckoned the grand generic fehism, we may deem the sect of Jaina and Mahiman, specific varieties; and there appears no good reason why they should not all be classed with the other sects, who adhere exclusively one of the avatars or incarnations of Vishnu, under the comprehensive denomination of Vaihnavas. Of these avatars see under the article Vishnu; and for some account of the hereof of Budha and its subdivisions, see Boodh, Jaina, Saka, and the other articles thence referred to.

Molt oriental people seem to have prided themselves on distinguishing their deities by a great many names. These names are, however, mostly, perhaps almost, significant and characteristic; of which early enquirers were of course ignorant. The prevalence of this pride will be seen in our articles Parvati, Siva, and others. In the instance of Budha, another proof might be exhibited of the fame feeling. He is distinguished by different names in the same and in different parts. Boodh, Budha. Bapta, and others of nearly similar sound, are mere varieties, in different parts of India, in orthography and pronunciation; and so perhaps is the Bud, or Wud, of the ancient Pagan Arabs. Pout in Siam; Pott, or Poti, in Tibet; and Bot in Cochinchina, are the same; the Chinee having, it is said, no B or D in their alphabet, and their language being monosyllabic, softened his name into Fo, or Fo-e. (See Fo.) They call him also Xa-ka; a variation, perhaps, of the Sanscrit Saka. (See Saka.) That the Toth of the Egyptians, and the Woden of the Scandinavians, and other northern nations, is the same name and deity, is upheld by some; but the supposition is derided by others: some, indeed, will not recognize him in the Fo of China. A Buddha, whether the ninth incarnation of Vishnu or not may be disputed, has been deemed to answer in character with Mercury; so has the Gothic Woden. Each respectively gives his name to the same planet, and to the same day of the week. Buddhva is, very extensively in India, whether among Baudhas, Vaisvas, Vaihnavas, or Mahomedans, the name with Dios Mercurii, or Woden's day; whence some have derived our Wednesday.

The common reproach of the Brahmans is that the Baudhas uphold the dangerous dogma of the eternity of matter and the perishability of the soul. But we ought to receive accounts of the tenets of a holy sect with caution; and of the Baudhas and Jaines we have yet but little else. Like the Jaines, their worship is confined to deified saints; and the name for the chief of them is, as stated in another place, derived from the Sanscrit word budh, to know; hence Buddha is philosophy: and hence has been derived the Saxon and English verbs budian, to bode, forebode, &c.

The Jaina, or votaries of Jaina, are probably the most ancient of Hindoo sectaries. They reject, like the Baudhas in general, the authority of the Vedas; and are the most scrupulous of any sect in their cautions against the even accidental extinctions of animal life. (See of this under our article Jaina.) In the Vedas the slaughter of animals is not only allowed, but on some occasions enjoined. (See Veda.) The adoration of the Jaines is exclusively offered to deified mortals, or rather, as they affirm, through them to the deity: and in the clas of deified mortals may be included many of the gods of the Hindoos, although they profess to reject the polytheism and incarnations of the latter. The doctrine of transmigration is found among the Jaines; how extensively it is not ascertained; the belief of a future state of rewards and punishments, and an extensive
Portion of the Puranic history, is common to them with the orthodox Hindoos. Formerly powerful and widely diffeminated, this sect is supposed to have suffered great diminution from the extension of the modern heresy of Buddha. And at present its more opulent members are said to find it convenient to assume the orthodox persuasion, which may be done without much difficulty, and must greatly tend to a diminution of its members and respectability.

Several of the facts noticed in the articles of this work named after them, are described as distinguished by marks on their foreheads, arms, and breasts. The forehead mark is the chief distinction, and when horizontal or parallel with the eye-brows, it is understood to denote a Saiva, while a Vaishnava is recognized by its perpendicularity. One, two, or three of these lines, red, white, or yellow, accompanied by circles and dots, differing in position and colour, together with many other symbols and hieroglyphics, afford an infinite variety of indications of the sectarial bias of the individual so decorated. When convenient, and no especial objection exists, it is said to be held necessary, that these marks be daily renewed; and, of course, by the hand of a Brahman. One of that tribe cannot perform his daily sacrifices, ablations, &c. without the completion or contemplation of this distinction; and it is held irreverent in one of an inferior tribe to approach a holy man, or to ask his blessing, without, or in view of, this sectarial decoration. The second plate of the Hindoo Pantheon contains some scores of these mystic symbols, and a full explanation of their sectarial application.

Another sect, who worship fire, or its personification in Agni its regent, is noticed under the article SAGNIKA, (which see). This is referrible to the grand division Saiva, Agni being of that line of parentage. See PAKAYA.

Having, under the article PHILOSOPHY OF THE HINDOOS, given the names of the principal sects, or schools, and referred for a brief explanation of the several doctrines to the articles of this work, under which they are respectively noticed, we shall not, in this place, offer any thing farther thereon. For some of the particulars of this article we are indebted to Mr. Colebrooke's Ellay on the Religious Ceremonies of the Hindoos, in the ninth volume of the Asiatic Researches, and to the Hindoo Pantheon.

From what precedes it will appear, that an individual of either of the four civil tribes may select his own theological sect: a Brahman, or a Sudra, is at liberty to choose what form of worship he may think proper, and to what deity he will offer it; observing, of course, due consilience and conformity with the ritual. He may thus, without offence, beyond incurring some displeasure, perhaps, from his hankerish family, and Guru, or pator, change from a Linti to a Youja, or associate one with the other; or from a Saura to a Ganapatya; or he may combine all, and more; and, seeing all in Krishn, become a Bhagavata; he may, without incurring sin, or, as the idea is better understood in Europe, without losing caste, turn from a Saiva to a Vaishnava. All these are venal, and admit of easy expiation. He is still under the spiritual dominion of the same priesthood, and while he observes the ordained feasts and festivals, performs pilgrimages, is liberal in alms, and conforms to the externals that serve to rivet the mental chains forged for him by the Brahmans, all is well. He may also study, and, under certain limitations, believe and profess, whichever philosophical doctrines he prefers. It would not, perhaps, be thought decorous in a Brahman, especially if he were a priest, to make an oration display of the doctrines of a free-thinking founder, whole tenets border on a denial of the existence of the mythological beings, reverence to whom is the base on which rests the spiritual sanctity of his own tribe. But there are still many individuals among the Brahman who think deeply; and who, in reasoning on the grossness and absurdity of their mythological legends, cannot but reject them. See VEDANTA.

It is in the civil distinctions that the Hindoo law is fo guarded against innovation. Here every possible care has been taken to keep the tribes apart; and sexual intercourse, the principal apprehended cause of confusion, is regulated and legitimated with great precision. These regulations vary in minute particulars in different tribes and countries, but agree pretty nearly in the main point of degrading the offspring of forbidden intercourse. Such degradation does not, however, necessarily result. Rich delinquents can arrest immediate ecclesiastical censure; and the lapse is soon forgotten. With the poor such things are of less moment; excising perhaps little else than the passing scandal of the neighbourhood; uncles in cafes where the Brahmanical dignity or purity may be implicated in a manner too gross or notorious to be overlooked. Fornication or adultery between a male Sudra and a Brahmani would be deemed of this nature. So would eating or drinking together of individuals of remote or different tribes. But the latter, if not frequent or wilful, admit of expiation; expiatory and vexations is proportion to the wealth of the offenders, and the degree of enormity in the offence.

Some writers have told us of the cafe with which the Hindoo, and even the Brahman, seem to change their religion; "with as much facility," say they, "as their garments." The theological change of fet, as above noticed, is not attended with much difficulty; they are still Hindoos, and can find priests of their new persuasion, who will afford them the confusions and benefits of religion, such as they are. But the work of conversion altogether from that religion, and liberation from the trammels of pieties, have ever been, and ever will be found, a task of much greater difficulty; to be accomplished only by the potency of continued persuasion, superadded to the aid of example in the preceptors.

In concluding this article on the sectarial divisions of the Hindoos, we may observe that there is strong reason to believe many of them to be of modern origin. The Veda, the scripture of the Hindoos, affords no authority for such extravagances as worshipping deified heroes, female powers or indecent symbols, or avatars. See Veda.

We shall here subjoin a brief account of Sanihsy, omitted in its proper place. Sanishya denotes an order of Hindoo mendicants, who arrive at this distinction by divers acts of pervercing penance and supposed piety. We are not aware of any material distinction between this description of saints, and those called Yogi and Yati by different sects. In the Gita, as translated by Mr. Wilkins, Krishna declares him to be both a Yogi and a Sanishya, who performeth that which he hath to do independent of the fruit thereof. Sanishya, or a forsaking of the world, is declared to be the fame with Yogi, or the practice of devotion. He who can bear up against the violence produced from lust and anger in this mortal life, is properly employed, and a happy man. The man who is happy in his heart, at rest in his mind, and enlightened within, is a Yogi, or one devoted to God, and of a godly spirit. The soul of the placid, conquered spirit, is the same in heat and cold, in pain and pleasure, in honour and disgrace. To the Yogi, gold, iron, and flames are the same. The man is distinguished whose resolution, whether amongst his companions and friends, or in the midst of his enemies, with those

Vol. XXXII.
who love and with those who hate; in the company of fainds or sinners, is the fame. The Yogi conftantly exercifieth the spirit in private. He is a reftoration of a fubdued mind, free from hope, and free from perception. He planteth his own foot firmly upon a foot that is unfounded, and fitteth upon the facred grafts, jufis, covered with a skin and a cloth. (See KUS.) There he, whose businefs is the reftaining of his passion, fhould fit, with his mind fixed on one object alone, in the exercise of his devotion for the purification of his foul, keeping his head, his neck, and body fteady, without motion, his eyes fixed on the point of his nofe, looking at no other place around. To be a Sanialy, or refline, without application, is to obtain pain and trouble.

This divine discipline is not to be attained by him who eateth more than enough, or lefs than enough; neither by him who fleepeth too much, nor by him who fleepeth not at all. A man is called devout, when his mind remaineth thus regulated within himfelf, and he is exempted from every luft and inordinate difeffe. The Yogi of a fubdued mind, thus employed in the exercise of devotion, is compared to a lamp standing in a place without wind, which wavereth not. He becometh acquainted with that boundles pleafure, which is far more worthy of the understanding than that which arifes from thefenefes; depending upon which, the mind moveth not from its principles; which having obtained, he refpe& each no other acquisition fo great as it; on which depending, he is not moved by the fevereit pain. Supreme happiness attendeth the man whose mind is thus at peace; whose carnal affections and passions are thus subdued, who is thus in God, and free from sin. The Yogi is more exalted than the Tapasvi (see Tapas); the zealot who harrafes himfelf in performing penances, he is refpe& above the learned in fience, and superior to thofe attached to moral works.

The above paffages from different pages of the Gita, may serve as a fpecimen of that extraordinary work; fuppofed to have been composed by Vyafa, many centuries before the Christian era. See Vyafa, Jaina, Yati, and Yogi, for fome farther notice of Hindu penance and devotion; and Tapas, for infances of their aulterity.

Individuals calling themselves Saniyafts and Yogis, are flill feen wandering about India; fometimes defcending to the ocean, fometimes ftching, and fometimes being stripped to deferve a hot bath, and fticked in the mud. They do not have fuch defcendants as the Sairsa (which fec) that the god Siva being reprefented fo powdered. Sometimes they have, like him, a tiger's skin to fit on; and at others, carry one of Vishnu's emblems, the chakra, of which fec under Vishnu and Varana. In the latter cafe, the individuals are probably of the fec of Vajbana, which fec.

**SECTA regalis**, a fuit by which all persons were bound twice in a year to attend the sheriff's tour, and was called regalis, because the sheriff's tour was the king's feet; wherein the people were to be obliged by oath to bear true allegiance to the king, &c.

**SECTA unica torum facienda pro pluribus hereditatiuis**, a writ that lies for an heir who is deftrained by the lord to do more fuits than one, in refpect of the land of divers heirs deftrained to him.

**SECTA**, among the Romans, pavements laid with fones cut into various forms. Suetonius diliugfes them from thofe that were telicotated.

**SECTINEUS**, in Anatomy, a small, flat, and pretty long fphere, broad at the upper part, and narrow at the lower; fitted obliquely between the os pubis, and the upper part of the os femoris.

It is commonly a single fphere, but is fometimes found double. It is fixed above by flefhy fpheres to all the sharp ridges, or criflata, of the os pubis, and to a small part of the oblong notch, or defcription, on the fide of the vertebra, in which the upper extremity of this fphere is lodged; and thence it runs down obliquely towards the little trochanter, under, and a little behind which it is inferted obliquely by a flat tendon, between the superior infertion of the varius internus, and inferior infertion of the triceps femoris, with which it is united. Winflow.

**SECTIO CESAREA.** See CESARIAN Section.

**SECTION**, Sectio, formed from secio, I cut, a part of a thing divided; or the division itself.

Such, particularly, are the subdivisions of chapters, by others called paragraphs, and sometimes articles. The mark of a fection is §.

The ancients negle&ted to divide their books into chapters and fections; that was a talk left for future editors and critics.

**SECTION**, in Geometry, denotes a fide or furface appearing of a body, or figure, cut by another; or the place wherein lines, planes, &c. cut each other.

The common fection of two planes is always a right line; being the line fuppofed to be drawn by the one plane in its cutting or entering the other.

If a fphere be cut in any manner, the plane of the fection will be a circle, whose centre is in the diameter of the fphere.

The fections of the cone are five, viz. a circle, triangle, parabola, hyperbola, and elipife. See each under its proper article. See alfo Cone.

**SECTIONS**, Conic. See CONIC SECTIONS.

**SECTION**, Axis of a Conic. See AXIS.

**SECTION**, Centre of a Conic. See CENTER.

**SECTION**, Diameter of a Conic. See DIAMETER.

**SECTION**, Tangent of a Conic. See TANGENT.

**SECTIONS**, Following, SECTIONS SEQUENTES, in Conics, may be thus conceived: fuppofe two right lines, as A B, C D, (Plate XIII. Analysis, fig. 5.) mutually interfecting one another in E, which point E is fuppofed to be the common centre of the opposite hyperbolic fections F, G, H, I, and whose common afymptotes, the propped lines A B, C D, also are. In this cafe, the fections G, F, and H, I, are called fectiones sequentes; becaufe they are placed following one another in the contiguous angles of two interfecting right lines.

If the determinate diameter, H G, of one of the fectiones sequentes (which is cofident with the fuppofed indeter-minate diameter of its oppofite) be equal to the vertical tangent K L, applied between the afymptotes in the point G, of the diameter G F; then Apollonius calls fuch fections, conjugate fections. See Genesis of the Hyperbola, under CONIC SECTIONS.

**SECTIONS**, OPPOSITE. See OPPOSITE.
SECTIUS non Paciendus, in Law, a writ brought by a woman, who for her dowry, &c. ought not to perform suit of court.

SECTOR, in Astronomy, the name of two different astronomical instruments, for measuring small angular distances in the heavenly regions; one of which has a motion in or parallel to the equator, and the other is directed to the zenith. The construction and use of each of these instruments may be seen under the respective titles of Equatorial Sector, and Zenith Sector.

SECTOR, in Geometry, a part of a circle comprehended between the radii and the arc.

Thus the mixed triangle \( \triangle ACD \) (Plate XIII. Geometry, fig. 5.) comprehended between the radii \( AC \) and \( CD \), and the arc \( AD \), is a sector of the circle.

It is demonstrated by geometers, that the sector of a circle, as \( \triangle ACD \), is equal to a triangle, whose base is the arc \( AD \), and its altitude the radius \( AC \).

If from the common centre of two concentric circles be drawn two radii to the periphery of the outer, the two arcs included between the radii will have the same ratio to their peripheries; and the two sectors, the same ratio to the areas of their circles.

To find the area of a sector \( DCE \); the radius of the circle \( CD \), and the arc \( DE \), being given. To 100.314, and the radius \( DC \), find a fourth proportional number; this will be the semimperiphery; then to 180 degrees, the given arc \( DE \), and the semimperiphery just found, find another fourth proportional; this will give the arc \( DE \) in the same measure in which the radius \( DC \) is given: lastly, multiply the arc \( DE \) into the semimperiphery, and the product is the area of the sector.

In order to find the area of any sector of a circle, Dr. Hutton, in his "Menuration," has given the following rules.

Rule 1.—Multiply the radius by half the arc of the sector, and the product will be the area, as in the whole circle. For the demonstration of this, see the article Circle. Putting \( r \) = the radius of a circle, \( d \) = the diameter, \( A \) = the area of a sector of it, \( a \) = the length of the arc of the sector, \( b \) = the degrees in \( \frac{1}{2} a \), \( s \) = half the chord of the arc \( a \), or the sine of \( \frac{1}{2} a \), and \( v \) = the versed sine of \( \frac{1}{2} a \); then, by multiplying the radius by half the arc, by a variety of rules which Dr. Hutton has stated, we shall have,

\[
1. \quad A = \frac{1}{2} ar = 1.1475329 \text{ brr.}
\]

\[
2. \quad A = \sqrt{\pi d} \times (1 + \frac{v}{2.3.3} + \frac{3v}{2.4.5.5} + \frac{3.5v}{2.4.6.7}) \text{ &c.}
\]

3. \( A = \frac{rs}{3} \times (1 + \frac{3s}{2.3r} + \frac{3s^2}{2.4.5s} + \frac{3s^3}{2.4.6.7s}) \text{ &c.}
\]

4. \( A = 4 \sqrt{\frac{s + \frac{v}{2}}{3}} = 4 \sqrt{\frac{2rv}{3} - \frac{s}{3}}
\]

5. \( A = rd \sqrt{\frac{3v}{2d - v}} \text{ nearly.}
\]

6. \( A = \frac{r}{9} \times (5d \sqrt{\frac{5v}{5d - 3v}} + 4 \sqrt{\frac{2v}{d}} \text{ nearly.}
\]

It appears that the area of the sector might be expressed in several other ways; such as by the tangent, cofine, &c. of its semi-arc; but the forms above given are those that are the most useful.

Rule 2.—As 360° is to the degrees in the arc of the sector, so is the whole area of the circle to the area of the sector.

SECTOR also denotes a mathematical instrument, of great use in finding the proportion between quantities of the same kind; as between lines and lines, surfaces and surfaces, &c.: whence the French call it the compas de proportion.

The great advantage of the sector above the common scales, &c., is, that it is made so as to fit all radii, and all sectors. By the lines of chords, sines, &c. on the sector, we have lines of chords, sines, &c. to any radius between the length and breadth of the sector when open.

The sector is founded on the fourth proportion of the sixth book of Euclid; where it is demonstrated, that similar triangles have their homologous sides proportional. An idea of the theory of its construction may be conceived thus. Let the lines \( A B, AC \) (Plate XIII. Geometry, fig. 5.) represent the legs of the sector; and \( A D, AD \), two equal secions from the centre; if, now, the points \( C \) and \( D \) be connected, the lines \( CB \) and \( DE \) will be parallel; therefore the triangles \( ADE, ABC \), will be similar; and, consequentiy, the sides \( AD, DE, AB \), and \( BC \), proportional; that is, as \( A: D = D: B \); &c.; whence, if \( A \) and \( D \) be the half, third, or fourth part of \( AB \), \( DE \) will be a half, third, or fourth part of \( CB \); and the same holds of all the rest.

If, therefore, \( AD \) be the chord, sine, or tangent, of any number of degrees to the radius \( AB \); \( DE \) will be the same to the radius \( BC \).

SECTOR, Description of the. The instrument consists of two rulers, or legs, of brass or ivory, or any other matter, representing the radius, moveable round an axis or joint, the middle or which expresses the centre; whence several scales are drawn on the faces of the rulers. See Plate XIII. Geometry, fig. 7.

The scales generally put on sectors may be distinguished into single and double. The single scales are such as are commonly put upon plain scales; the double scales are those which proceed from the centre; each scale is laid twice on the same face of the instrument, viz. once on each leg; from these scales, dimensions or distances are to be taken, when the legs of the instrument are in an angular position.

The scales commonly put upon the bent sectors are

<table>
<thead>
<tr>
<th>Inches, each inch divided into 8 and 10 parts</th>
<th>Decimals, containing 100 parts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inches, Chords, Sines, Tangents, Rhumbs, Latitude, Hours, Longitude, Incre. Merid. of the Numbers, Sines, Vered lines, of Tangents, Lines, or of equal parts, Chords, Sines, Tangents to 45°, Secants, Tangents to above 45°, Polygons,</td>
<td>marked</td>
</tr>
</tbody>
</table>
SECTOR.

The manner in which these scales are disposed of on the sector, is best seen in the figure.

The scales of lines, chords, lines, tangents, rhumbs, latitudes, hours, longitude, incl. merid. may be used, whether the instrument is shut or open, each of these scales being contained on one of the legs only. The scales of inches, decimals, log. numbers, log. lines, log. verified lines, and log. tangents, are to be used with the sector quite opened, part of each scale lying on both legs.

The double scales of lines, chords, lines, and lower tangents, or tangents under 45 degrees, are all of the same radius or length; they begin at the centre of the instrument, and are terminated near the other extremity of each leg; viz. the lines at the division 10, the chords at 60, the lines at 90, and the tangents at 45; the remainder of the tangents, or those above 45 degrees, are on other scales beginning at one-fourth of the length of the former, counted from the centre, where they are marked with 45, and run to about 76 degrees.

The scantals also begin at the same distance from the centre, where they are marked with 10, and are from thence continued to as many degrees as the length of the sector will allow, which is about 75 degrees.

The angles made by the double scales of lines, of chords, of lines, and of tangents, to 45 degrees, are always equal. And the angles made by the scales of upper tangents, and of scantals, are also equal, and sometimes these angles are made equal to the scale made by the other double scales. The scales of polygons are put near the inner edge of the legs, their beginning is not so far removed from the centre, as the 60 on the chords is. Where these scales begin, they are marked with 4, and from thence are figured backwards, or towards the centre, to 12.

From this disposition of the double scales, it is plain, that those angles which were equal to each other, while the legs of the sector were close, will still continue to be equal, although the sector be opened to any distance it will admit of.

The scale of inches is laid close to the edge of the sector, and sometimes on the edge; and contains as many inches as the instrument will receive when opened; each inch being usually divided into eight, and also into ten equal parts.

The decimal scale lies next to this: it is of the length of the sector, when opened, and is divided into ten equal parts, or primary divisions, and from these into ten equal other parts; so that the whole is divided into a hundred equal parts: and if the sector admits of it, each of the subdivisions is divided into two, four, or five parts, and by this decimal scale, all the other scales, that are taken from tables, may be laid down. The length of a sector is usually understood when it is shut; and, therefore, a sector of six inches makes a ruler of twelve inches when opened; and a foot sector is two feet long, when quite opened. The scales of chords, rhumbs, lines, tangents, hours, latitudes, longitudes, and inclinations of meridians, are such as are described under Plane Scale.

The scale of logarithmic or artificial numbers, called Gunter's scale, or Gunter's line, is a scale expressing the logarithms of common numbers, taken in their natural order.

For the construction of this scale, and also of those of logarithmic lines, logarithmic tangents, and logarithmic verified lines, see Gunter's Line, and Gunter's Scale.

We shall here observe, that all these scales should have one common termination to one end of each scale, i.e. the 10 on the numbers, the 90 on the lines, the 0 on the verified lines, and the 45 on the tangents, should be opposite to each other; the other end of each of the scales of lines, verified lines, and tangents, will run out beyond the beginning (marked 1) of the numbers; nearly opposite to which will be the divisions representing 35 minutes on the lines and tangents, and 168 2/3 degrees on the verified lines.

The double scales are constructed in the following manner. The line of lines is only a scale of equal parts, whose length is adapted to that of the legs of the sector; thus, in the six-inch sector, the length is about 5 1/2 inches. The length of this scale is divided into primary divisions; each of these into ten equal secondary parts; and each secondary division into four equal parts. The accuracy of the divisions may be determined by taking between the compasses any number of equal parts from this line, and applying that distance to all the parts of the line; and if the same number of divisions be contained between the points of the compasses in every application, the scale may be received as perfect. The line of lines is constructed by making the whole length of this scale equal to that of the line of lines; and from this line, taking off severally the parts expressed by the numbers in the tables of the natural lines, corresponding to the degrees, or to the degrees and minutes, intended to be laid upon the scale; and then by laying down the several divisions on the scale, beginning from the centre. In scales of this length, it is customary to lay down divisions, expressing every 15 minutes, from 0 degree to 60 degrees; between 60 and 80 degrees, every half degree is expressed; then every degree to 85; and the next is 90 degrees. The length of the scale of tangents is equal to that of the line of lines, and the several divisions upon it (to 45 degrees) are laid down from the tables and line of lines, in the same manner as the former; observing to use the natural tangents in the tables. The scale of upper tangents is laid down, by taking 1/4 of such of the natural tabular tangents above 45 degrees, as are intended to be put upon the scale. The beginning of this scale, at 45 degrees, though the position of it on the sector reflects the centre of the instrument, is distant from the centre 1/4 of the length or radius of the lower tangents.

The distance of the beginning of the scale of scantals from the centre, and the manner of laying it down, are the same as those of the upper tangents: except that in this the tabular scantals are to be used.

For the scale of chords; its length is to be made equal to that of the lines; and the divisions, which are twice the length of the lines of half the degrees and minutes counted from the centre, express every 15 minutes from 0 degrees to 60 degrees, to be laid down as in the scale of lines.

The scale of polygons usually comprehends the fides of the polygons from 11 to twelve sides inclusive. The divisions are laid down by taking the lengths of the chords of the angles at the centre of each polygon, and laying them down from the centre of the instrument. When the polygons of four and five fides are also introduced, this line is constructed from a scale of chords, where the length of 90 degrees is equal to that of 60 degrees of the double scale of chords on the sector. Instead of some of the double scales above describ'd, there are found other scales on the old sectors, and also on some of the French ones, such as scales of superficies, of folds, of inscrib'd bodies, of metals, &c.; but these are left out to make room for others of more general use. See Caliber.

In describing the use of the sector, the terms lateral distance, and transverse distance, often occur. By the former is meant the distance taken with the compasses on one of the scales only, beginning at the centre of the sector; and by the latter, the distance taken between any two corresponding
responding divisions of the scales of the same name, the legs
of the sector being in an angular position: but in taking
these transverse distances, it is to be observed, that each of
the several scales hath three parallel lines, across which the
divisions of the scales are marked, and that the points of the
compasses must be always set on the inside line, or that line
next the inner edge of the leg, which is the only line, in
each scale, which runs to the centre.
For the use of the logarithmic scale of numbers, see
Gunter’s Line.

Sector, Use of the Line of Lines on the. 1. To divide a
given line into any number of equal parts ; e.g. 9. Make
the length of the given line, or some known part of it, a
transverse distance to 9 and 9; then will the transverse
distance of 1 and 1 be the 3rd part of it; or such a sub-
multiple of the 3rd part, as was taken of the given line:
or the 3th part will be the difference between the given line
and the transverse distance of 8 and 8.

Hence, 2. To make a scale of a given length, to contain
a given number of equal parts; e.g. let the scale to the map
of a survey be 6 inches long, and contain 140 poles, and let
be required to open the sector, so that a corresponding
scale may be taken from the line of lines. Make the tran-
verse distance 7 and 7 (or 70 and 70, *viz. 110) equal to 3
inches (= 2); and this position of the line of lines will
produce the given scale.

3. To divide a given line (e.g. of 5 inches) into any
aligned proportion, as of 4 to 5. Make 5 inches, the
length of the given line, a transverse distance to 9 and 9, the
sum of the proposed parts; and the transverse distances of
the aligned numbers, 4 and 5, will be the parts required.

4. To two given lines, *viz. 2 and 6, to find a third pro-
torical. Take between the compasses the lateral distance
of the second term, *viz. 6; set one point on the division
expressing the first term, *viz. 2 on one leg, and open the
legs of the sector till the other point will fall on the cor-
responding division on the other leg; keeping the legs of
the sector in this position, take the transverse distance of
the second term, *viz. 6, and this distance is the third term
required, which distance, measured laterally from the centre,
will give 18, the number required: for 2 : 6 :: 6 : 18.

Otherwise, take the distance 2 laterally, and apply it tran-
versely to 6 and 6, the sector being properly opened; then
the transverse distance at 2 and 2, being taken with the
compasses, and applied laterally from the centre of the
sector on the scale of lines, will give the third term, when
the proportion is decreasing; for 6 : 2 :: 2 : 4. If the legs
of the sector will not open so far as to let the lateral distance
of the second term fall between the divisions expressing the
first term, then take 4, 4, or any aliquot part of the
second term, that will conveniently fall within the opening
of the sector, and make such part the transverse distance of
the first term: then, if the transverse distance of the second
term be multiplied by the denominator of the part taken
of the second term, the product will give the third term.

5. To three given lines, *viz. 3, 7, and 10, to find a fourth
proportional. Open the legs of the sector, till the tran-
verse distance of the first term, 3, be equal to the lateral
distance of the second term, 7, or some part of it; then
will the transverse distance of the third term, 10, give
the fourth term, required; or such a submultiple of it, as
was taken of the second term; for 3 : 7 :: 10 : 20.

Otherwise, set the lateral distance, 7, transversely from
10 to 10, opening the sector accordingly; and the transverse
distance, at 3 and 3, applied laterally, will give 24; for

6. To diminish a line of four inches, in the proportion

8 to 7. Open the sector till the transverse distance of
8 and 8 be equal to the lateral distance of 7: mark the
point, where four inches, as a lateral distance, taken from
the centre reaches; and the transverse distance taken at that
point will be the line required. If the line should be too
long for the legs of the sector, take 4, 7, or 5 or 8, &c. part
of the given line for the lateral distance, and the corre-
ponding transverse distance, taken twice, thrice, or four times,
&c. will be the line required.

7. To open the sector, so that the two scales of lines shall
make a right angle. Take the lateral distance from
the centre to the division marked 5; between the points of
the compasses, and set one foot in the division marked 4, on
one of the scales of lines; and open the legs of the sector
till the other foot falls on the division marked 3, on the
other scale of lines, and then the above scale stand at right
angles to one another; for the lines 3, 4, 5, or any of their
multiples, constitute a right-angled triangle.

8. To two right lines given, *viz. 40 and 60, to find a mean
proportional. Set the two scales of lines at right angles; find
the half sum of the given lines, *viz. 65, and the half
difference, *viz. 25, and take with the compasses the lateral
distance of the half sum, 65, and apply one foot to the half
difference, 25, the other foot transversely will reach to 60,
the mean proportional required; for 40 : 60 :: 60 : 90.

Sector, Use of the Scale of Chords on the. 1. To open
the sector so that the two scales of chords may make an
angle of any number of degrees, *e.g. 40. Take the distance
from the joint to 40, the number of degrees proposed on
the scale of chords: open the sector till the transverse
distance from 60 to 60, on each leg, be equal to the afore-
said lateral distance of 40: then do the scales of chords
make the angle required.

2. The sector being opened, to find the degrees of its
aperture. Take the extent from 60 to 60, and lay it off
on the scale of chords from the centre: the number, where
it terminates, shews the degrees of its opening. By applying
lights on the scales of chords, the sector may be used to
take angles, as a surveying instrument.

3. To protract or lay down an angle of any given number
of degrees. 1. Let the number of degrees be less than 60,*
viz. 46. At any opening of the sector, take the transverse
distance of 60 and 60 on the chords: and with this open-
ing describe an arc: take the transverse distance of the
given number of degrees, 46, and lay this distance on the
arc described, marking its extremities: from the centre of the arc, through these extremities, draw two
lines, and they will contain the angle required. 2. When
the degrees given are more than 60, *viz. 148; describe
the arc as before; take the transverse distance of 4 or 4 of
the given degrees, 148, *e.g. 2 = 494 degrees: lay this
distance on the arc thrice: and from the centre draw two
lines to the extremities of the arc thus determined, and they
will contain the required angle. N.B. If the radius of the
arc or circle is to be of a given length, then make the tran-
verse distance of 60 and 60, equal to that alligned
length.

4. To find the degrees which a given angle contains.
About the vertex describe an arc, and open the sector till
the distance from 60 to 60, on each leg, be equal to the
radius of the circle: then taking the chord of the arc be-
tween the compasses, and carrying it on the legs of the
sector, see what equal number, on each leg, the points of
the compasses fall on: this is the quantity of degrees the
given angle contains.

5. To take an arc, of any quantity, from off the cir-
cumference of a circle. Open the sector till the distance

from 60 to 60 be equal to the radius of the given circle; then take the extent of the chord of the number of degrees, on each leg of the sector, and lay it off on the circumference of the given circle. By this use, any regular polygon may be inscribed in a given circle, as well as by the line of polygons: e.g. in a circle whose diameter is given to describe a regular polygon of 24 sides. Make the given diameter a transverse distance from 60 to 60 on the scales of chords; divide 360 by 24, and take the transverse distance of 15 and 15, the quotient, and this will be the chord of the twenty-fourth part of the circumference. In order to prevent errors, where the distance is to be repeated several times, it will be best to proceed thus: with the chord of 60 degrees divide the circumference into six equal parts; in every division of 60 degrees lay down, first, the chord of 15 degrees, and next the chord of 30 degrees, and then the chord of 45 degrees, beginning always at the same point. Thus the error in taking distances will not be multiplied into any of the divisions following the first.

**Sector. Use of the Line of Polygons on the.**

1. In a given circle to inscribe a regular polygon, e.g. an octagon. Open the legs of the sector till the transverse distance of 6 and 6 be equal to the given diameter, then will the transverse distance of 8 and 8 be the side of an octagon, which may be inscribed in the given circle. In like manner any other polygon, the number of whose sides does not exceed 12, may be inscribed in a given circle.

2. On a given line to describe a regular polygon, e.g. a pentagon. Make the given line a transverse distance of 5 and 5; at that opening of the sector, take the transverse distance of 6 and 6; and with this radius, on the extremities of the line, as centres, describe arcs intersecting each other; and on the point of intersection, as a centre, with the same radius, describe a circumference passing through the extremities of the given line; and in this circle may be inscribed the pentagon, whose side is given, the length of a line process may any other polygon, of more that 12 sides, be described on a given line.

3. On a right line, to describe an isosceles triangle, having the angles at the base double that at the vertex. Open the sector till the ends of the given line fall on 10 and 10 on each leg; then take the distance from 6 to 6; this will be the length of the two equal sides of the triangle.

**Sector. Use of the Scales of Sines, Tangents, and Secants on the.** By the several lines disposed on the sector, we have scales to several radii: so that, 1. having a length, or radius, given, not exceeding the length of the sector when opened, we find the chord, sine, &c. there: e.g. suppose the chord, sine, or tangent, of 10 degrees to a radius of three inches required. Make three inches the aperture, or transverse distance, between 60 and 60 on the scales of chords of the two legs; then will the same extent reach from 45 to 45 on the scale of tangents, and from 90 to 90 on the scale of sines on the other side: so that to whatever radius the line of chords is set, to the same are all the others set. In this disposition, therefore, if the aperture, or transverse distance, between 10 and 10, on the scales of chords, be taken with the compasses, it will give the chord of 10 degrees; if the transverse distance of 10 and 10 be in like manner taken, on the scales of sines, it will be the sine of 10 degrees: lastly, if the transverse distance of 10 and 10 be in like manner taken on the scales of tangents, it gives the tangent of 10 degrees to the same radius.

2. If the chord, or tangent, of 70 degrees were required, for the chord, the transverse distance of half the arc, viz. 35, must be taken, as before; which distance, being repeated twice, gives the chord of 70 degrees. To find the tangent of 70 degrees, to the same radius, the scale of upper tangents must be used, the other only reaching to 45; making, therefore, three inches the transverse distance between 45 and 45 at the beginning of that scale; the extent between 70 and 70 degrees, on the same, will be the tangent of 70 degrees to three inches radius.

3. To find the secant of an arc, make the given radius the transverse distance between 0 and 0 on the line of secants; then will the transverse distance of 10 and 10, or 70 and 70, on the said lines, give the secant of 10 degrees, or 70 degrees.

The scales of upper tangents and secants do not run quite to 76 degrees; but those of a greater number of degrees may be found by the sector in the following manner. Thus, the tangent of any number of degrees may be taken from the sector at once; if the radius of the circle can be made a transverse distance to the complement of those degrees on the lower tangent. E.g. To find the tangent of 78 degrees to a radius of two inches. Make two inches a transverse distance of 12 degrees on the lower tangents; then the transverse distance of 45 degrees will be the tangent of 78 degrees. In like manner the secant of any number of degrees may be taken from the lines, if the radius of the circle can be made a transverse distance to the cosine of those degrees. Thus, making two inches a transverse distance to the sine of 12 degrees, then the transverse distance of 90 and 90 will be the secant of 78 degrees.

Hence it will be easy to find the degrees answering to a given line, expressing the length of a tangent or secant, which is too long to be measured on those scales, when the sector is set to the given radius. Thus, for a tangent, make the given line a transverse distance of 45 and 45 on the lower tangents; then take the given radius, and apply it to the lower tangents: and the degrees, where it becomes a transverse distance, give the tangent of the degrees answering to the given line. And for a secant, make the given line a transverse distance to 90 and 90 on the lines: then the degrees answering to the given radius, applied as a transverse distance on the lines, will be the cosine of the degrees answering to the given sector.

4. If the converse of any of these things were required, that is, if the radius be required, to which a given line is the sine, tangent, or secant; it is but making the given line, if a chord, the transverse distance on the line of chords, between 10 and 10, and then the sector will stand at the radius required; that is, the aperture between 60 and 60, on the said line, is the radius.

If the given line were a sine, tangent, or secant, it is but making it the transverse distance of the given number of degrees; then will the distance of 90 and 90 on the lines, of 45 and 45 on the lower tangents near the end of the sector, and of 45 and 45 on the upper tangents towards the centre of the sector, and of 0 and 0 on the secants, be the radius.

5. If the radius, and any line representing a sine, tangent, or secant, be given, the degrees corresponding to that line may be found by setting the sector to the given radius, according as a sine, tangent, or secant, is concerned; taking the given line between the compasses, applying the two feet transversely to the scale concerned, and sliding the feet along till they both rest on like divisions on both legs; and the divisions will shew the degrees and parts corresponding to the given line.

For the method of determining the degrees answering to any tangent, or secant, that cannot be thus measured, see above.

6. To find the length of a transverse line to a given number of degrees, and a given radius. Make the transverse distance
tance of 90 and 90 in the sines equal to the given radius; take the tranverse distance of the fine complement of the given degrees; if the given degrees are less than 90, the difference, but if greater, the sum of the fine complement and radius gives the vered fine.

7. To open the legs of the secter so that the corresponding double scales of lines, chords, sines, tangents, may make, each of them, a right angle. On the lines, make the lateral distance 10, a distance between 8 on one leg, and 6 on the other leg; on the lines, make the lateral distance 90 a tranverse distance from 45 to 45, or from 40 to 50, or from 30 to 60, or from the line of any degrees to their complement; or, on the lines, make the lateral distance of 45 a tranverse distance between 30 and 30.

SECTOR, in Trigonometry. Use of the. 1. The base and perpendicular of a right-angled triangle being given, to find the hypotenuse. Suppose the base $AC$ (Plate Trigonometry, fig. 5.) 40 miles, and the perpendicular $AB$ 30; open the secter till the two scales of lines make a right angle; then, for the base, take 40 parts on the scale of lines on one leg; and, for the perpendicular, take 30 on the same scale on the other leg; then the extent from 40 on the one to 30 on the other, taken in the compasses, will be the length of the hypotenuse; which line, applied to the scale of lines, will be found 50 miles.

2. The perpendicular $AB$ of a right-angled triangle $ABC$ being given, 30, and the angle $BCA$ 37 degrees; to find the hypotenuse $BC$. Take the given side $AB$, and let it over, on each side, on the fine of the given angle $ACB$; then the parallel distance of 90 and 90 or radius, will be the hypotenuse $BC$; which will measure 50 on the scale of lines.

3. The hypotenuse and base being given, to find the perpendicular. Open the secter till the two scales of lines be at right angles; then lay off the given base on one of those scales from the centre; take the hypotenuse in your compasses, and setting one foot in the term of the given base, let the other fall on the scale of lines on the other leg; the distance from the centre to the point where the compasses fall will be the length of the perpendicular.

4. The hypotenuse being given, and the angle $ABC$; to find the perpendicular. Make the given hypotenuse a parallel radius, i.e. make it the extent from 90 to 90 on the scales of lines; then will the parallel line of the angle $ACB$ be the length of the side $AB$.

5. The base and perpendicular $AB$ given, to find the angle $BCA$. Lay off the base $AC$, on both sides the secter, from the centre, and note its extent; then take the given perpendicular, and to it open the secter in the terms of the base; the parallel radius will be the tangent of $BCA$.

6. In any right-lined triangle, two sides being given, with the included angle; to find the third side. Suppose the side $AC$ (fig. 6.) 20, the side $BC$ 30, and the included angle $ACB$ 110 degrees; open the secter till the two scales of lines make an angle equal to the given angle, viz. 110 degrees; lay off the given sides of the triangle, from the centre of the secter, on each of the scales of lines; the extent between their extremes is the length of the side $AB$ sought.

7. The angles $CAB$ and $ACB$ given, and the side $CB$; to find the base $AB$. Take the given side $CB$, and turn it into the parallel line of its opposite angle $CAB$; and then the parallel line of the angle $ACB$ will be the length of the base $AB$.

8. The three angles of a triangle being given; to find the proportion of the sides. Take the lateral lines of the several angles, and measure them in the scale of lines; the numbers answering to which give the proportion of the sides.

9. The three sides being given, to find the angle $ACB$. Lay the sides $AC$, $CB$, along the scales of lines, from the centre, and set over the side $AB$ in their terms; so is the secter opened, in these lines, to the quantity of the angle $ACB$.

10. The hypotenuse $AC$ (fig. 7.) of a right-angled spherical triangle $ABC$, given, $r.$ gr. 43 degrees, and the angle $CAB$ 20 degrees; to find the side $CB$. The rule is, as radius is to the line of the given hypotenuse, 43 degrees, so is the line of the given angle 20 degrees to the line of the perpendicular $C$. Take then 20 degrees from the centre, along the scale of lines, in your compasses, and set the extent from 90 to 90 on the two legs; and the parallel line of 45 degrees, the given hypotenuse, will, when measured from the centre on the scale of lines, give 13° 30', the side required.

11. The perpendicular $BC$, and the hypotenuse $AC$, given, to find the base $AB$. As the fine complement of the perpendicular $BC$ is to radius, so is the fine complement of the hypotenuse to the fine complement of the base. Therefore make the radius a parallel line of the complement of the given perpendicular, $r.$ gr. 73° 30'; then the parallel line of the complement of the hypotenuse, $r.$ gr. 47°, measured along the scale of lines, will be found 49° 25', the complement of the base required; consequently the base itself will be 40° 35'.
CD, bisect each other at right angles in E (Plate XIII. Geometry, fig. 9.) Make AE a transverse diameter to 90
and go on the lines; and take the transverse distances of 10°, 20°, 30°, 40°, 50°, 60°, 70°, 80°, successively, and apply those distances to AE from A towards A, as at the points 1, 2, 3, 4, 5, 6, 7, 8; and through those points draw lines parallel to EC; make EC a transverse diameter to go and go on the lines; take the transverse distances of 80°, 70°, 60°, 50°, 40°, 30°, 20°, 10°, successively, and apply those distances to the parallel lines from 1 to 2, 2 to 3, 3 to 4, 5 to 6, 6 to 7, 7 to 8, and so many points will be obtained, through which the curve of the ellipsis is to pass. The fame work being done in all the four quadrants, the elliptical curve may be completed. In the construction of foliar eclipces, instead of using the lines to every ten degrees, the lines belonging to the degrees and minutes corresponding to the hours and quarter hours, are to be used.

7. To describe a parabola whose parameter shall be equal to a given line. Draw a line to represent the axis, in which make AB (fig. 10) equal half the given parameter; divide AB, like a line of fines, into every ten degrees, as at the points 10, 20, 30, 40, 50, &c. and through these points draw lines at right angles to the axis AB. Make the lines Aa, 10b, 20c, 30d, 40e, &c. respectively equal to the chords of 90°, 80°, 70°, 60°, 50°, 40°, etc. to the radius AB, and the points a, b, c, d, e, &c. will be in the curve of a parabola; and a smooth curve line drawn through those points, and the vertex B, will represent the parabolic curve required.

N. B. As the chords on the sector run no farther than 60, those of 70, 80, and 90, may be found by taking the transverse distance of the lines of 35°, 40°, 45°, to the radius AB, and applying those distances twice along the lines 20, 10b, etc.

8. To describe an hyperbola, the vertex A, and asymptotes BH, BI, being given (fig. 11.) The asymptotes BH, BI, being drawn, the line BA bisecling the angle 1BH, and the vertex A taken, draw AI, AC, parallel to BH, BI. Make AC a transverse distance to 45 and 45, on the upper tangents, and apply to the asymptotes from B so many of the upper tangents taken transversely as may be thought convenient, as BD 50°, BE 55°, BF 60°, BG 65°, BH 70°, &c. and draw Dd, Ee, &c. parallel to AC. Make AC a transverse distance to 45 and 45, on the lower tangents; take the transverse distances of the co-tangents before used, and lay them on those parallel lines; thus, make Dd = 40°, Ee = 35°, Ff = 30°, Gg = 25°, Hb = 20°, &c. and through the points A, d, e, f, g, h, &c. draw a curve line, which will be the hyperbola required.

Sector, in Surveying, Use of the. The bearings of three places, as A, B, C (Plate VII. Surveying, fig. 1.) to each other, i.e. the angles ABC, BCA, and CAB, being given; and the distance of each, from a fourth standing among them, as D, i.e. BD, DC, and AD, being given; to find the distances of the several places A, B, C, from each other, i.e. to find the lengths of the sides A, B, C, A. Having drawn the triangle EFG (fig. 2) similar to ABC, divide the line EG in H, so that EH may be to HG, as AD to DC, having already directed; and after the like manner much EF be divided in I, so that EI may be to IF as AD to DB. Then continuing the sides EG, EF, Fay, as EH - HG is to HG, so is EH + HG to GK; and as EI - IF is to IF, so let EI + IF be to FM; which proportions are easily wrought by the scales of lines on the sector. This done, bisect HK and IM in the points L, N; and about the said points as centres, with the distances LH and IN, describe two circles, intersecting each other in the points O; to which, from the angles E, F, G, draw the right lines EO, FO, and GO, which will have the fame proportion to each other, as the lines AD, BD, DC. Now, if the lines EO, FO, and GO, are equal to the given lines AD, BD, DC, the distances EF, FG, and EG, will be the distances of the places required. But if EO, OF, OG, be less than AD, DB, DC, continue them till PO, OR, and OQ, be equal to them; then the points P, Q, R, being joined, the distances PR, RQ, and PQ, will be the distances of the places sought. Lastly, if the lines EO, OF, OG, be greater than AD, DB, DC, cut off from them lines equal to AD, BD, DC, and join the points of section by three right lines; the lengths of the said three right lines will be the distances of the three places sought.

Note, if EH be equal to HG, or EI to IF, the centre L and N will be infinitely distant from H and I; that is, in the points H and I there must be perpendiculars raised to the sides EF, EG, instead of circles, till they intersect each other; but if EH be less than HG, the centre L will fall on the other side of the base continued; and the same is to be understood of EI, IF.

The sector is of especial use for facilitating the projection of the sphere, both orthographic and stereographic.

See on the construction and use of the sector, Bion's Construction, &c. of Mathematical Instruments, by Stone, p. 54, &c. edit. 1. and Robertson's Treatise of Mathematical Instruments, &c. p. 30, &c. edit. 2.

Sector of a Sphere, is composed of a segment less than a hemisphere, and of a cone having the fame base with the segment, and its vertex in the centre of the sphere. The sector of a sphere, generated by the revolution of the sector of a circle C A E (Plate III. Geometry, fig. 12.) about the radius AC, is equal to a cone, whose base is equal to the portion of the spherical surface generated by the arc AE, or to the sector described with the radius AE, and whose height is equal to CA the radius of the sphere. Arch. de Sphera. et Cyl. Maclaurin's Fluxions. Intro. p. 15. See SPHERE.

SECU LAR, in Geography, a town of European Turkey; 5 miles S.W. of Niemecz.

SE CULAR, something that is temporal; in which sense the word stands opposite to ecclesiastical.

Thus we say, secular power, secular arm, secular jurisdiction, &c.

Secular is more peculiarly used for a person who lives at liberty in the world; not shut up in a monastery, nor bound by vows, nor subjected to the particular rules of any religious community.

In which sense the word stands opposed to regular.

The Romish clergy is divided into regular and secular.

The regulars pretend, that their state is much more perfect than that of the seculars. Secular priests may hold abbeys and priories both simple and conventual, though not regularly, but only in commendam.

It is a maxim, in their canon law, secularia secularibus, i.e. secular benefices are only to be given to secular persons; regular only to regular.

Secular Corporation. See Corporation.

Secular Games, Ludi Seculares, in Antiquity, were solemn games held among the Romans, once in an age; or, in a period deemed the extent of the longest life of man, called by the Greeks aXayv, and by the Latins secularum.

The secular games were also called Terentian games, ludi Terentini, either because Manius Valerius Terentius gave occasion to their institution; for having been warned, in a dream,
dream, to dig in the ground in a place near the Campus Martius, called Terentum; he there found an altar incribed to Dis, or Pluto and Proserpine; upon which, as had been foretold in his dream, three of his children, born blind, obtained their sight; and he, in gratitude, performed sacrifices on the same altar, for three days and three nights successively. Or, finally, by reason here an altar of Pluto buried deep under ground, because the water of the Tyber, terram terret, eat into the ground in this place.

The secular games lasted three days, and as many nights; during which time sacrifices were performed, theatrical shows exhibited, with combats, sports, &c. in the Circus.

Their origin and institution are delivered at length by Val. Maximus; the occasion of which, according to this writer, was to stop the progress of a plague. The first who had them celebrated at Rome, was Valerius Publicola, the first consul created after the expulsion of the kings, in the year of Rome 245. The ceremonies to be observed in them were found prescribed in one of the books of the Sibyls; in which was contained a prophecy to this effect; viz. that if the Romans at the beginning of every age should hold solemn games in the Campus Martius to the honour of Pluto, Proserpine, Juno, Apollo, Diana, Ceres, and the Paze, their city should ever flourish, and all nations be subjected to their dominions. Accordingly, they were very ready to obey the oracle, and in all the ceremonies used on this occasion conformed to its directions.

At the time of the celebration of the secular games, heralds were sent to invite all the world to a solemnity which nobody had ever seen, nor was ever to see again.

They were introduced with extraordinary preparation, under the direction of the quindecemviri; who distributed to the people flannel and sulphur, and wheat and other grain, for an offering. On the first day after they had offered sacrifices to the above named deities at the Capitol, they returned to the Campus Martius, where they had assembled, and held sports to the honour of Apollo and Diana. On the second day, at the hour appointed by the oracle, the noble matrons went to the Capitol to sing hymns to Jupiter; and on the third day of the feast, twenty-seven boys, and as many girls, sung in the temple of Palatine Apollo hymns and verses in Greek and Latin, to recommend the city to the protection of those deities, whom they particularly honoured by their sacrifices.

Authors are not agreed as to the number of years in which these games returned; partly because the quality of an age or seculum, among the ancients, is not known; and partly on other accounts: some will have it, that they were held once every hundred years; and that the seculum, or age, was our century. This Varro and Livy seem to express in very plain terms; yet others will have it, that seculum comprehended a hundred and ten years; and that the secular games only returned in that period, that is, at the beginning of every 11th year; which opinion is countenanced by Horace, in his Secular Poem, ver. 21.

Be this as it will, it is certain they sometimes did not fly for the 11th, nor even for the 100th year, for the celebration of these games. The first were held A. U. C. 245, or 298; the second, A. 305, or 408; the third, A. 518; the fourth, either A. 656, or 668, or 678. Augustus held them in the year of Rome 736, and Claudius again in the year of Rome 800, and of Chrilt 38, viz. sixty-four years after the former; and Domitian, again, in still lesser times; viz. in the year of Rome 847, or of Chrilt 79, at which Tactius alluded in quality of quindecimvir, as he himself tells us, Annal. lib. xi. cap. 11, and this was the seventh time that Rome had seen them from their first institution. The emperor Severus exhibited them the eighth time, that is, a hundred and ten years after those of Domitian. Zosimus says, these were the last; but he is mistaken, for in the year of Rome 1800, that is, fifty years after those of Severus, the emperor Philip had them celebrated with greater magnificence than had ever been known. Those that were celebrated by permission of the emperor Honorius, after having received the news of the victory of Stilicon over Alaric, were the last recorded in history. Zosimus ascribes the decline of the empire to the neglect of these games among the Romans. We find them represented on many medals.

Secular Poem. See Seculare Carmen.
Secular Year, the fame with jubilee.
SECULARE CARMEN, Secular poem, a poem sung, or rehearsed, at the secular games.
Of this kind we have a very fine piece among the works of Horace; it is a sapphic ode, which usually comes at the end of his epodes. In some editions, the twenty-first ode of the first book is also called "Carmen Seculare."

SECULARIZATION, the action of secularizing, or of converting a regular person, place, or benefice, into a secular one.

Almost all the cathedral churches were anciently regular, i.e. the canons were to be religious, but they have been since secularized.

For the secularization of a regular church there is required the authority of the pope, that of the prince, the bishop of the place, the patron, and even the consent of the people. And in France all this must be confirmed by parliament.

Religious that want to be released from their vows, obtain briefs of secularization from the pope.

SECULUM, in Antiquity. See Age and Secular Games.

SECUNDA AQUA, among Chemists, &c. See Aqua Secunda.

SECUNDA super operations pasturae. See Surcharge.

SECUNDANI, in Ancient Geography, a people of Gaul, who inhabited the town of Arausio, situated in the interior of the country.

SECUNDANS, in Mathematics, an infinite series of numbers, beginning from nothing, and proceeding as the squares of numbers in arithmetical progression, as 1, 4, 9, 16, 25, 36, 49, 64, &c.

SECUNDARAH, in Geography, a town of Hindostan, in the fubah of Delhi; 28 miles S.E. of Delhi. N. lat. 28° 22'. E. long. 78° 7'.

SECONDARY, or Secondary. See Secondary.

SECUNDERPOUR, in Geography, a town of Hindostan, in Benares, on the Ganges; 35 miles N.E. of Gazypour.—Also, a town of Hindostan, in the circar of Jeynagar; 15 miles S.E. of Parafaool.

SECUNDI GENERIS, in Anatomy, a distinction among the lalceal vessels. There are two kinds of lalceals; viz. primary, or those of the first kind, primi generis; and secundi generis, secondary, or of the second kind.

The first carry the chyle from the intestines into glands dispersed in great numbers throughout the mefentery. The second carry it from these glands, after its being diluted there with lympha, into the common receptacle. See LALCEALS.

SECUNDI internodiis pollis extensor. See Extensor.

SECUNDIANS, in Ecclesiastical History, a sect of Valentinians in the second century, whose chief, Secundus, one of the principal followers of Valentine, maintained the doctrine of two eternal principles; viz. light and darkness, from whence
whence arofe the good and the evil that are observable in the universe.

**SECUNDINES, in Anatomy and Midsowery, the placenta, umbilical cord, and membranes including the fatus, which, being expelled from the uterus after the fatus, constitute the after-birth. They are described under the article Embryo.

Dr. Grew, in his Anatomy of Plants, applies the term fucundine to the fourth and laft coat or cover of seeds, because this performs nearly the fame office in plants, that the membranes, involed the fatus, do in animals. And indeed Pflay, Cohnemull, Apuleius, &c. have used fucundine in the fame sense.

**SECUNDO. Propriofo de Secundo adjacent. See Proposition.

**SECUNDRA, in Geography, a town of Honduras, in the eircar of Sirhind; 90 miles E. of Sirhind.—Alto, a town of Honduras, in Doab; 15 miles W. of Canage.

**SECUNDUS, Johannes, in Biography, is the literary name of John Everard, a celebrated Latin poet, the fon of Nicholas Everard, an eminent jurisft, and prefident of the council of Mecklin under Charles V. He was born at the Hague in 1511, and at an early age studied the law at Bourges. He, however, showed a decided attachment to polite literature in preference to jurifprudence, and contracted intimacies with fome of the moft distinguished Latin poets of his time. He travelled into Italy and Spain, and was made secretary to cardinal Taver, archbishop of Toledo. He followed Charles V. in his expedition against Tunis, but the delicacy of his constitution not permitting him to undergo the fatigues of war, he returned to the Low Countries, where he died at the early age of twenty-five. Few modern Latin poets have poifomed more facility and sweetness than Secundus. A volume of his elegies, epigrams, odes, and miscellaneous pieces, together with a narrative in prole of his different journeys, was published. Of all his poetical works, the "Balía" have been the moft popular, on account of their fentence, and the delicate volupptuousnefs of their painting. They are still read, and new editions are frequently printed. Johanne had two brothers, who were also elegant Latin poets, known by the names of Nicolas Grudius, and Adrian Marius. They have united in an affectionate commemoration of their decailed brother, annexed to his poems. Secundus himself practifed the art of engraving, and to his volume is prefixed a portrait of a female, with the following inscription: "Vatis amoris Julia culpata manu."

Secundus, in Botany, a term not very eafy, in the technical fene of Linnaeus, to translate. One-ranked may generally express its meaning. This term is applied to a racemus, or clufser, whose flowers are all turned to one fide, as in *Pyrola fecondani*, Engl. Bot. t. 517.

Secundus Malls, in Anatomy, a name given by Daverney, and fome others, to one of the muscles of the ear. It is the internus auris of Cowper and others, and is moft properly named by Albinus tenor tympani.

**Secundus Occlus Moeotis, a name given by Vefalius to that muscle of the eye, called by Riolanus and others fuperbus, and elevator oculii, and by Albinus the fubducitor, one of his four muscles reft of the eye.

**Secundus Peronaeus. See Peronaeus.

**Secundus Scaleus. See Scaleus.

Gen. Ch. Cal. Perianth inferior, small, deciduous, of three, ovate, coloured leaves, the uppermost of which is opposite to the flandard, the others accompanying the keel. Cor. papilionaceous, of five petals; wings much spreading, very obtuse; flandard of two leaves, oblong, ftrait, united to the keel at the base, reflexed at the tip; keel as long as the wings, nearly cylindrical, its border dilated, bearing a little, obtufe, plaited appendage. Stam. Fila- ments eight, combined at the bottom; anthers oblong, erect. Pfl. German superior, ovate, terminating in an awl-shaped fyle; stigma flat, dilated, toothed at the tip. Petio. Le- gume ovate, of one cell, ending in a ligulate wing. Seed foltary, oblong.

Obf. In this genus is very nearly allied to *Polygala*, but it is polypetalous, and the fruit has only a fingle cell, refembling the capsules of *Banifhieria*.

Eff. Ch. Calyx of three leaves. Corolla papilionaceous: the flandard of two leaves within the wings. Legume ovate, of one cell and one seed, ending in a tongue-shaped wing.

2. *S. velubils*. Climbing Securidaca. Willd. n. 3. Swartz Prodr. 104. (Sparium flandani, fructu alato, flora rubro; Plum. Lc. t. 247, f. 1.)—Stem twining. Leaves oblong, acute.—Native of South America, and the Wef Indies. Found in Jamaica by Browne, and at Carthagena by Jacquin.—A twining plant, whole younger, leafy branches are changed into very ftrong tendrils. Leaves alternate, oblong, pointed, fcarcey falked. *Flowers in loofe, lateral clufers, red, feen tufces.*

3. *S. angusta*. Wood-like Securidaca. Willd. n. 5. Swartz Prodr. 104. (Sparium alterum, fructu alato, flora rubro; Plum. Lc. t. 144, f. 1.)—Stem twining. Leaves round, ftvel obtufe.—Native of Jamaica and Hispaniola. Swartz is of opinion, that Browne's fifth species in his History of Jamaica, must be this, and not *S. erecta*, as Linnaeus fuppofed. We know of no further defcription of this species than what is quoted above. For Securidaca of Tournefort, Miller, and Garton, fee CORONILLA.

**Securinaga, so denominated by Commerson, from securis, a hatchet, and naga, to deny, or refuse to yield; in allusion to the extreme hardness of the wood, called *Bois dur* by the French, in the Ile de Bourbon. Some also call it, according to Commerson's manuscripts, *Bois de Té*, and others Quin-quin. The English, who met with this tree in Oethebe, named it, from the appearance of the leaves, Othebe Myrtle.—Jull. 388. Willd. Sp. Pl. v. 4, 761. Porte in Lamarck Dict. v. 7, 691, Ait. Hort. Kew. v. 5, 383.—Clafs and order, Diadelphi Penicularea; (or rather *Mena- delphus*.) Nat. Ord. Euphorbiaceae, Jull.

Female, on a different tree, Cal. Perianth as in the male, inferior, permanent. Cor. Nectary as in the male, permanent. Pfl. German superior, nearly globular, three fidced; stigmas round.

**Stilbus, in Botany, a term ap-
SEC

styles three, short, permanent; stigmas obtuse. Peric.
Capsule three-lobed, three-celled. Seeds solitary?

Female, Calyx and nectary as in the male, permanent.
Capsule superior, three-lobed, three-celled.

Syn. v. 2. 673." Ait. n. i. (S. duriffima; Gmel. Synth.
Nat. v. 2. 1008. Poiret in Lam. Dict. v. 7. 632.)—Native of the isles of Mauritius and Bourbon, as well as of Otaheite, where it was observed by the late Mr. Christopher Smith. Living plants were brought to Kew by admiral Bligh, in 1793. This is treated as a flow plant, flowering in spring and summer. In the Mauritius it is a tall tree, with alternate, round, minitely warty branches, and very hard yellowish wood. Leaves alternate, stalked, ovate, various in size and blunt nuts, from one to three inches long, and about one broad, entire, smooth, with one rib, and many fine interbranching veins. Flowers numerous, in dense, fiffle, globular, axillary tufts. Commeron describes fix flaments, but we find only five, according to the general observation of the authors above quoted.

SECURIS, John, in Biography, an English physician of considerable character in his day, was born in Wiltshire, and studied with great reputation in New college, Oxford, in the reign of Edward VI. From thence he went to Paris, where he diligently pursued the study of astronomy and medicine, the latter under the celebrated professor Silvius. On his return, he settled at Salisbury, and was much respected to on account of his skill in the practice of physic. He published annual tracts, which he called "Prognosticons;" and which appear to have been a kind of almanacs, accompanied with astronomical predictions and medical precepts. Anthony Wood had seen two of them, for the years 1579 and 1586. To the latter was added, "A Compendium, or brief Instructions how to keep a moderate Diet." Securis was likewise the author of "A Detection and Querysmy of the daily Enormities and Abuses committed in Physic, concerning the Three Parts thereof." Lond. 1666. This is a little tracts, written with learning and pliability, on the often repeated complaint of the intrusion of irregularly educated persons into the practice of physic, and the presumption of surgeons and apothecaries in taking upon them to act the physician. A peroration in verse, addressed to the two universities, is subjoined. This work was thought to have so much merit, that it was reprinted in 1662, and published along with Recorde's " Judicial of Urines." The author is not named in the title-page, but is called "A Doctor of Physick in Queen Elizabeth's Days." In this tract there is a reference to one which Securis had published about the year 1554, with this odd title; "A great Galley lately come into England out of Terra Nova, laden with Physicians, Surgeons, and Potheurists." See Ankin's Biography.

Memos of Med.

SECURITE PACEs, in Law, a writ which lies for one who is threatened with death or danger, against the person who threateneth him. It is taken out of chancery, directed to the sheriff. See PEACE and SURETY.

SECUROTEM invocandi quod se non diversit ad partis exteras, fine licentia regis, an ancient writ lying for the king against any of his subjects, to lay them from going out of this kingdom into foreign parts; the ground whereof is, that every man is bound to serve and defend the commonwealth, as the king shall think fit.

SECURUM, Si te fuerit. See Si te fuerit.

SED

SECUTOR, among the Romans, most commonly signified an attendant upon great men.

SECUTORES, in Antiquity, a kind of gladiators among the Romans, who fought against the retiarii.
The word is formed from the verb seque, to follow; because the secutores used to pursue the retiarii, when they failed to call the net, and fled to put in order.
The secutores were armed with a sword and a buckler, to keep off the net, or noose, of their antagonists; and they wore a cloak on their head. Some confounded the secutores with myrmillones, because both had nearly the same weapons.

Secutor was also the name given to such gladiators as took the place of those killed in the comb; or who fought the conqueror. The poet Tullus taken by lot. In ancient inscriptions we also meet with secutor tribuni, secutor duti, secutor Cefaris, &c., who were officers attending the tribunes and generals; perhaps like our aids-de-camp.

SECEZENIAGA, in Geography, a town of European Turkey, in Dobrud Tarty, on the Danube; 20 miles N. of Kirlova.

SEDA, a town of Portugal, in Alentejo; 6 miles W. of Altor do Chao.

SEDAB, in Botany, a name given by the Arabian physicians to the wild, or mountain rue, a plant common in Syria, Greece, and other places. Avicenna supposes the gum, which he calls gentum, or jenum, to be produced from this plant, but very erroneously, that gum being obtained from the roots of the thapsia, or deadly carrot.

SEDALLE, Michel Jean, in Biography, a French dramatic writer, was born at Paris in 1719. His father, an architect, having left his family entirely destitute, the subject of this article was obliged to work as a common mason, to maintain his mother and two younger brothers. By his laudable industry he became a master mason, but his fondness for the theatre having led him to make some attempts at dramatic composition, which were attended with a confiderable portion of success, he was, in 1754, engaged by Monet, director of the comic-opera, to devote himself to the service of the stage. His talents were so well exerted, that he brought full audiences to that theatre, which had, before his time, been nearly deserted, and he passed many years in this employment, generally beloved and esteemed by the literary characters of the time. He died in the year 1797, in the 78th year of his age. Sedaine was the author of a great number of pieces, chiefly of the light kind, and accompanied by music. Some of them were eminently successful; the "Le Deferteur" was represented one hundred times. He had a perfect knowledge of stage effects; his dialogue was easy and natural, though extremely incorrect; hence his works were more adapted to the stage than to the closet.

SEDAKI, in Geography, a town of Japan, in the island of Nippon; 40 miles N.W. of Nambu.

SEDAN, a town of France, and principal place of a district, in the department of the Ardennes, situated on the Meuse; strongly fortified, and reckoned one of the keys of France. It is divided into the north and fourth parts: the former contains 5984, and its canton 11,471 inhabitants, in 14 communes; the latter has 4560, and its canton 13,124 inhabitants, in 22 communes. Both comprehend 320 kilo- metres. This town has a manufacture of cloth; and before the revocation of the edict of Nantes, it had a flourishing Protestant university; 133 polls S.S.W. of Liege. N.lat. 49° 42'. E. long. 5° 0'.

SEDAN Chair. See Chair.

Y 2
SEDANG, in Geography, a town on the N.W. coast of the island of Borneo. N. lat. 2° 15'. E. long. 116° 48'.
SEDAREE, a town of Perian Armenia; 30 miles S.E. of Erivan.
SEDASHYGR, a town of Hindoostan, in Canara, on the coast; 6 miles N.W. of Carwar.
SEDASIER, a town of Hindoostan, in the country of Coorga, where a battle was fought in 1799, between the troops of Tippoo Sultan, and the British, under general Stuart, in which the former were defeated; 7 miles from Periapatan.
SEDATIVE, in Medicine, from sedare, to still, or allay, a term which was used by the older writers, nearly in the same acceptation with anodyne; namely, to denote such medicines as were calculated to allay pain. But among the moderns it has been employed in another sense, and it stands in opposition to stimulant. In the modern pathology, all the actions of the animal frame are ascribed to the agency of the nervous power; and whatever increaseth or excites that power, or its actions, is thence called a stimulant; and those agents, on the contrary, which diminish or restrain that power, or its actions, are therefore denominated sedatives. Of the former class, wine, alcohol, camphor, ether, aromatic substances, &c. may be enumerated as examples; of the latter, tobacco, digitalis, sugar of lead, &c. In the school of Bruen, however, where the word stimulant is in constant use, the existence of a direct sedative is absolutely denied; for the Brunonian hypothesis maintains, "That life is the result of the action of stimulants on the principle of excitability, and, consequently, that every thing which acts must be stimulant." (See Excitability.) It farther maintains, that a sedative action is not real, but apparent; or rather, is not direct, but indirect; that is, it is the result of the previous stimulation; and therefore, that an actual sedative is a non-entity. But this argument, like many others of the Brunonian school, is an obvious petitio principii in logic: it is founded upon two unproved propositions; first, that life is solely the result of excitation, and, secondly, that a previous excitation occurs, where it is not cognizable, as in the case of digitalis, and the suprachiasmatic lead, and some other narcotics, which appear to influence directly the action of the heart and arteries, and to depref the whole nervous power. The use of sedatives for medicinal purposes, is principally confined to the regulation of the arterial sytem, as in cases of hemorrhage, especially from the lungs, in diseases of the heart, &c.
SEDATIVUM SAL. See Sedative Salt.
SEDAU, in Geography. See Supply.
SEDERGH, a market-town in the west division of the wapentake of Staintcliffe and Ewefore, West Riding and county of York, England, is situated in the parish of Sedergh, at the distance of 27 miles N.W. by N. from Settle, and 27 miles N.W. by N. from London. This place, which, according to the late population returns, contained 344 houses and 1805 inhabitants, is chiefly indebted for its support to the manufacture of iron articles. The market is held on Wednesday, weekly; and there are fairs annually on the 20th of March, and the 29th of October. Here is a free school, but neither it nor the church is in any way remarkable. Beauties of England and Wales, vol. xvi. by John Bigland, 8vo. 1813.
SEDE, a lake of Egypt, separated from the Mediterranean by a neck of land, which extends from Aboukir to within a mile or two of Alexandria. It communicates with the sea by a narrow opening, and westly the British army opened a channel to form a communication with lake Mareotis: it is also called the "lake of Aboukir."—Allo, a lake of Egypt, producing pasture; 55 miles N.W. of Cairo.
SEDEANA, a town of Italy, in Friuli; 10 miles W.S.W. of Udina.
SEDEEE, a town of Egypt, on the left bank of the Nile; 7 miles S. of Abutighe.
SE DEFENDENDO, in Latus, a plea for him who is charged with the death of another; alleging, that he was forced to do what he did in his own defence, the other so affronting him, that his death was not done as he did, he must have been in danger of his own life. See SEDITION, HOMICIDE, and MANSLAUGHTER.
SEDELLA, in Geography, a town of Spain, in the province of Grenada; 12 miles N. of Velez Malaga.
SEDEM ATOLENS, in Anatomy, a name given by Veleus and others to the muscle, now more generally known by the name of levator ani.
SEDETARIIUM Os, a name given by some anatomical writers to the protuberance of the os coccyxidis, on which the whole weight of the body rests in sitting.
SEDER OLAM, in Philology, a Hebrew term, literally signifying, order of the world; being the title of two chronicles in that language.
They are both very short, though the one more so than the other; for which reason the one is called sedar olam zuta, that is, the great sedar olam; and the other, sedar olam zutu, i.e. little sedar olam.
Seder Olam, the Great, commences at the creation of the world, and comes down as low as the war of the pseudo-melliah Barchochebas, under Adrian, fifty-two years after the destruction of the temple of Jerusalem; and from the hundred and twenty-second year of Christ. It is almost all taken from the Scripture, excepting the end. It is the work of R. Jofa, son of Hepheta of Tipporsa, who lived in the second century, about the year 130, and was master of the famous R. Juda Hakka- dofch, the compiler of the Mishana.
Seder Olam, the Lesser, is an abridgment of the former, brought down as far as Mar Sutra, who lived 450 years after the destruction of the temple, or 522 years after Christ. F. Morin, continually bent upon diminishing the antiquity of the principal books of the Jews, endeavours to prove this to have been written about the year of Christ 1124, as indeed it is expressed in the beginning; but R. Dav. Gantz has overthrown this opinion in his Tehmah David, and flown that the date in the beginning is an interpolation.
The two chronicles were first printed at Mantua in 1514. 4to.; again at Basii, from Frobeniis, in 1580, 8vo.; at Venice, in 1545, 4to.; and at Paris, with a Latin version of Genevraed, in 12mo. They have been since reprinted at Amsterdam, in 1711.
SEDERON, in Geography, a town of France, in the department of the Drôme, and chief place of a canton, in the district of Nyons. The place contains 614, and the canton 7334 inhabitants, on a territory of 375 kilometres, in 18 communes.
SEDEF, a town of Egypt, on the left bank of the Nile; 3 miles S. of Bata.
SEDGE GRASSES, in Agriculture, a title given to various sorts of grasses of the poor hard earth kind, which are very hardy in their nature, and prevail much in most heath land. They are fearely ever touched by live- stock, being what may be called the fork end of herbage. See Carex and Weeds.
SEDGEFIELD, in Geography, a market-town in the north-east division of Stockton ward, county palatine of Durham, England, is situated at the distance of 11 miles S.E. by E. from Durham, and 255 N. by W. from London. The position of this town is one of the finest that can be imagined, being that of the summit of a gentle swell, surrounded on all sides by a country in the highest state of cultivation. On the south and south-east is a delightful prospect of Cleveland, Rosberry-Topping, and a long range of lofty hills, with the borders of the river Tees, down to the German ocean; on the south-west is a beautiful country decked with a variety of fine feats; and on the north and north-east appear the towns of Bishop Middleham, and Fildburn and Trimdon. The celebrated Dr. Aikew called Sedgefield the Montpelier of the north of England, and very frequently recommended his patients to it for the benefit of the air. In the centre of the town is a spacious market-place ornamented with a handsome cross. On one side of it stands the church, which consists of a nave, transept, chancel, and three aisles, with a lofty tower rising from the intersection of the nave and transept. The pillars of the interior are clustered, and support light pointed arches. Between the nave and the chancel is a rich screen of tabernacle work in oak, having three arches on each side, divided by beautiful light columns, and covered with canopies. The whole chancel is wainscotted with oak, panneld, and ornamented with cherubs. In this church were formerly two chantries, one dedicated to St. Catherina, and the other to St. Thomas; also a guild, dedicated to St. Mary. Here are numerous monuments; and among others two curious brasses, representing skeleton figures in winding sheets.

Sedgefield became a market and fair-town in 1312, by grant from bishop Kellawe. The market-day is Friday, weekly; and the fair is held on the eve of St. Edmund. Here is an hospital, founded by the trustees of Thomas Cooper, surgeon of this place, who died in 1703; also a free grammar-school, situated near the church. According to the parliamentary returns of 1811, this town contained 291 houses; and a population of 1507 inhabitants. The History and Antiquities of the County Palatine of Durham, by William Hutchinson, F.A.S. vol. iii. 4to. 1794.

SEDGE RIVER, a river of Patagonia, which runs into the Straits of Magellan. Its water is excellent, and on each side are very fine trees, which commodore Byron says, would supply the British navy with the best masts in the world; some of them being of a great height, and more than eight feet in diameter. Among these woods are many parrots, and other birds of most beautiful plumage. Geese, ducks, and fish, and fresh provisions are abundant. The traces of wild beasts were perceived in the land, but none were seen. Many huts and wigwams were seen, but no Indian was observed. The mouth of this river is in the W. part of Port Famine.

SEDGMOOR, a large tract of English land, in the county of Somerset, memorable for the defeat of the duke of Monmouth in the year 1685; situated between Somerset and Bridgewater.

SEDGWARA, a town of Hindoostan, in Guzcrat; 20 miles E. of Surat.

SEDGWICK, a town of America, in the state of Maine and county of Hancock, on Naskeag Point, which bounds Penobscot on the N.E., extending to the town of Penobscot, and distant 315 miles E. from Boston. It contains 1523 inhabitants.

SEDHOUT, a town of Hindoostan, in the cirque of Cuddapa; 6 miles N.E. of Cuddapa.

SEDILLO, a town of the island of Sardinia; 30 miles N.E. of Orilagghi.

SEDIMENT, formed from the Latin sedimentum, which Matthias Sylvaticus derives a divituna fede, the settlement or dregs of any thing; or that gros, heavy part of a fluid body which, upon relicking, sinks to the bottom of the vessel.

Some physicians have found means to discover much of the nature of the disease, from the sediment of the urine. Dr. Woodward maintains, that, at the deluge, the whole terrestrial globe was divided into one uniform mass; and that the new world, arising thence, was perfectly spherical, and without any inequalities, confining of several strata, which the earthy sediment gradually produced, as it drained.

SEDINA, in the Materia Medica, a word used by some writers to express dragon's blood.

SEDINI, in Geography, a town of the island of Sardinia; 10 miles S.E. of Callet Argonene.

SEDITY, among Civilians, is used for an irregular commotion of the people, or an assembly of a number of citizens without lawful authority, tending to disturb the peace and order of society. See REBELION.

This offence is of different kinds: some seditions more immediately threatening the supreme power, and the subversion of the present constitution of the state; others tending only towards the redress of private grievances. Among the Romans, therefore, it was variously punished, according as its end and tendency threatened greater mischief. (See lib. i. Cod. de Seditionis, and Matth. de Crimin. lib. ii. n. 5. de Leta Majestate.) In the punishment, the authors and ringleaders were justly distinguished from those, who, with less wicked intention, joined and made part of the multitude.

The fame distincion holds in the law of England, and in that of Scotland. Some kinds of sedition in England amount to high treason, and come within the flat. 25 Edward III. as levying war against the king. And several seditions are mentioned in the Scottish acts of parliament as treasonable. (Bayne's Crim. Law of Scotland, p. 33; 34.) The law of Scotland makes riotous and tumultuous assemblies a species of sedition. But the law there, as well as in England, is now chiefly regulated by the riot act made 1 Geo. I.; only it is to be observed, that the proper officers in Scotland to make the proclamation thereby enacted, are sheriff, lieutenants, and bailies of regalities, or their deputies; magistrates of royal boroughs, and all other inferior judges and magistrates; high and petty constables, or other officers of the peace, in any county, lieutantry, city, or town. And in that part of the island the punishment of the offence is death, and confiscation of moveables; in England it is felony. See Riots.

SEIDLEY, Sir Charles, in Biography, a dramatic writer, born in 1639, was son of Sir John Sidley of Ayleford, in Kent. He was educated at Wadham college, Oxford, and after leaving the university, he passed his time in retirement till the restitution. On that event he came to court and was one of the licentious circle round Charles II. His first essays in writing were some amatory poems, chiefly distinguished by their voluptuous cast. At this period of his life he was guilty of some public indecency, on account of which he was fined 500. Sir Charles's fortune being impaired by this course of life, he got into the house of commons, and he sat in three parliaments during that reign, in which he was frequently speaker. In the following reign he took a patriotic part, which would have been highly to his credit, if private pique had
had not been the principal motive of his conduct. It appears, notwithstanding the laxity of his own morals, that he was much offended with James II. for taking his daughter for a mullet off, in which quality she was raised to the title of countess of Dorchester, an elevation that, as her father indignantly said, only rendered his infamy the more conspicuous. Sir Charles joined the earl of Dorset in a steady opposition to the design of keeping up a standing army after Monmouth's rebellion, and he concurred in all the measures which produced the revolution. For the latter he gave the humourous reason, that as the king had made his daughter a countess, he would in return do all in his power to make his majesty's daughter a queen.

Sedley long continued to be regarded as a fine gentleman, a lively companion, and a judge and patron of poetry, in which last capacity he was instrumental in bringing Charles Montague, afterwards earl of Halifax, into notice. He is supposed to have lived to beyond his eightieth year. His works, in two vols. 8vo., consist of poems, speeches in parliament, and a number of dramatic pieces, none of which are retained on the stage. Biog. Brit.

SEDLEZANY, in Geography, See SELTSCHAN.

SEDLITZ, or GREAT SEDLITZ, a town of Saxony, in the margravate of Meissen; 2 miles S.W. of Pirna.— Also, a village of Bohemia, in the circle of Saazt, where Hoffmann, in the year 1729, discovered a medicinal spring, from which is prepared a purgative salt, near Molf.

SEDMA, a word used by some as a name for the lapiss hemaitis.

SEDNEVO, in Geography, a town of Russia, in the government of Tchernigov; 24 miles N.E. of Tchernigov.

SEDORP, a town of the duchy of Holstein; 8 miles N.E. of Segeborg.

SEDOSA, a town of the island of Corica; 12 miles N.W. of Corte.

SEDSCHERROI, in Ancient Geography, a people of Pontus, in the vicinity of the river colibus, according to Tacitus.

SEDR, oR SEDRE, the high priest of the sect of Ali, who usually confers the dignity on his nearest relation.

The jurisdic-tion of the sedr extends over all effects de- limed for pious purposes, over all mosques, hospitals, colleges, fepulchers, and monasteries. He dispenses of all ecclesiastical employments, and nominates all the superiors of religious houses. His decisions, in matters of religion, are received as so many infallible oracles; he judges of all criminal matters, in his own house, without appeal; and is, without contradiction, the second person in the empire.

The sedr, however, has not any indelible character, but frequently quits his post for another purely secular one. His authority is balanced by that of the muditchid, or first theologue of the empire.

SEDRE PASSAGE, in Geography, a narrow channel of the East Indian sea, on the N. coast of Sumatra, between Pulo Nanci and King's Point.

SEDULIUS, CADIUS Cælius, or CEELIUS, in Biography, a priest and poet, who flourished about the year 170. He is known only by his writings, of which the principal is a Latin poem in heroic verse, entitled "Pachale Carmen," in five books, the first of which relates to the histories recorded in the Old Testament, and the last four to the life and miracles of Christ. This work is chiefly esteemed for its subject, though the style is flowing, and, for the age in which it was written, is tolerably pure. It has been printed several times, and is contained in Mattaire's "Corpus Poetarum." An edition of it was printed in 1724. A prose work of the same writer is extant, entitled "Pachale Opus.

Eff. Ch. Calyx five-cleft. Petals five, with five nectariferous scales at the base of the germ. Capsules five, superior.

The herbage of this genus is succulent, and moist, though not invariably, smooth. The flowers are either of a yellow, white, or reddish colour.—Willdenow enumerates twenty-nine species, which are divided, after Linnaeus, into two sections, Planitia and Tereflolia; the former including such as have flat leaves, the latter such as have round, or cylindrical ones. To these however we have several to add, some of which are British. As a selection from the whole genus, the following are the most remarkable.

Sed. 1. Planitifa.—Leaves flatish.

S. Telephium. Origine or Live-long. Linn. Sp. Pl. 616. Engl. Bot. t. 1319. Curt. Lond. sene. t. 3. 25.—Leaves flatish, serrate. Corymbe leafy. Stem erect. Found in dry fields, about hedges, and on bushy hills in Britain and most parts of Europe, on a gravelly or calcareous soil, flowering in August.—Root perennial, tuberous, fleshy, white. Stems two feet high, erect, simple, leafy, round, smooth, purplish. Leaves fleshy fleshy, ovate, fleshy, flat, toothed in a serrate manner, rather glaucous, smooth. Flowers purple, occasionally white, forming terminal, manyflowered, crowded, leafy twigs. This species is found to vary in the colour of its flowers and the serration of its leaves, as well as in the size of all its parts.

S. Anacampheros. Evergreen Origine. Linn. Sp. Pl. 616. Curt. Mag. t. 118. (Anacampheros minor, rotundifolius, sempervirens; Tourn. Infl. 264.)—Leaves wedge-shaped, attenuated at the base, nearly fimbriate. Stems decumbent. Flowers corymbosae.—Native of the south of France, mostly in the crevices of rocks. It flowers in July and August.—Root perennial, fibrous. Stems reddish, trailing at their base, more upright and glaucous towards the top. Leaves numerous, alternate, or falted, ovate, fl. dotted at the tip, of a blueish-green colour. Flowers deep lilac or purple, rarely white, in compact, leafy, terminal tufts.

Sedum.

Auguft.—Root slightly fibrous. Stems herbaceous, erect, a little wavy, spreading, about a foot in height, frequently of a bright red colour. Leaves alternate, remote, on longish stalks, slightly lobed, turning of a brownish-red colour, flabby.

In habit and appearance, this plant greatly resembles Saxifraga rotundifolia.

S. tetraphyllum. Four-leaved Stone-crop. Sm. Prodr. Fl. Græc. Sibth. n. 1048. "Fl. Græc. t. 448."—Leaves in fours, spatulate, entire, obtuse.—Found by Dr. Sibthorpe in Peloponnesus, and also in Sicily.—Root annual, fibrous, white. Stem upright, hairy, branched at the base; the branches rather decumbent. Leaves four together, numerous, fleshy, club-shaped, flabby, fringed with hairs. Flowers in long, terminal, leafy spikes, white, tipped with a pink rib. The whole plant is of a yellow-brown hue, dotted with red, and thickly beset with hairs.

S. dasyphyllum. Thick-leaved Stone-crop. Linn. Sp. Pl. 618. Engl. Bot. t. 566. Curt. Lond. fusc. 3. t. 26.—Leaves opposite, ovate, obtuse, flabby. Stem weak. Native of Europe. —Found on walls or rocks in many parts of Britain, and if introduced into a garden, it propagates itself freely upon artificial rocks and garden walls; flowering copiously in June. Root apparently biennial, white and fibrous. Stems decumbent, creeping, tufted, thread-shaped, a little vilifed, leafy; flowering branches erect. Leaves mostly opposite, imbricated, gibbous, very succulent, entire, glaucous, tipped with red. Flowers three or four together, white with a purple streak, forming small, spreading panicles.

S. anglicum. English Stone-crop. Sm. Fl Brit. 486. Engl. Bot. t. 171.—Leaves thick, ovate, gibbous, and loose at the base, alternate. Cyms of two branches. Native of Great Britain, but not a common plant. It has been gathered near Dumfartons castle, on the sandy downs near Yarmouth, and other maritime and mountainous situations, flowering in July. Root annual, fibrous. Stems tufted, decumbent at the base, smooth, ruby-coloured, leafy. Leaves frequently alternate, or inclining to opposite, very thick, flabby, obtuse, slightly glaucous, with a protrusion at their base. Flowers at first thickly clustered, afterwards more remote; the petals white, with a reddish rib, and generally dotted with red at the tip. Caffules smooth, corymbose.

S. acris. Biting Stone-crop. Wall Pepper. Linn. Sp. Pl. 619. Engl. Bot. t. 839. Curt. Lond. fusc. 3. t. 32. Wood. Suppl. t. 231.—Leaves alternate, somewhat ovate, flabby, gibbous, fixed to the stem by their inner side above the base. Cyme three-cleft, leafy.—This brilliant little flower is conspicuous enough about midsummer, and for some time afterwards, on walls, roofs, and dry banks or sandy ground, in which it clothes as if with a cloth of gold, in defiance of the drought and most searing sun.

—Root perennial, fibrous. Stems tufted, branched, decumbent, smooth, round, leafy. Leaves alternate, imbricated, erect-spreading, grass-green coloured, protuberant at the back. Flowers corymbose, golden-coloured, in terminal, solitary, three-cleft, leafy panicles. —The whole herb is acrid, hot and biting to the taste, whence its common name Wall Pepper. Dr. Woodville quotes several authorities to prove its use in febrilitic and febrifulous disorders.

S. fassquale. Infapid Stone-crop. Linn. Sp. Pl. 620. Engl. Bot. t. 1445. Curt. Lond. fusc. 4. t. 53.—Leaves in fix or seven rows, somewhat cylindrical, obtuse, flabby, spreading, fixed to the stem by their inner side above the base. Cyme three-cleft, leafy.—Occasionally to be met with in dry, sandy places, about walls, flowering in June and July. In habit this perennial greatly resembles the last species, but it is generally rather larger. The leaves are more cylindrical, not ovate, about three together in alternate whorls, producing in the whole leafy stem or branch fix or seven angles or rows. Cymes terminal, of two larger flowers, and a small one. Flowers pale yellow.

The foliage frequently turns red. The whole herb, though unpleasantly audite, is delirious of all acid pungency of flavour.

SEDUM.

a span high, round, leafy, branched, smooth, decumbent at the base. Leaves scattered, spreading horizontally, rather glaucous, fleshy, and extremely juicy. Panicle terminal, rather cymose, many-flowered, smooth. Flowers white or reddish.

S. ochroleucum. Pale Stone-crop. Sm. Prodr. Fl. Gr. Sibth. n. 1923. Sm. in Trans. of Linn. Soc. v. 10. 6. (Sempervivum sediforme; Jacq. Hort. Vind. t. 81.)—Leaves glaucous, scattered, acute; the lower ones round; upper elliptical, deflexed. Segments of the calyx rather acute. Found on walls, stones, and banks, as well as about shady enclosures, in the south of Europe. It flowers in July. An interesting account of this species is given by Sir J. E. Smith, in the volume of the Linnean Transactions above quoted, where it is shewn to be the Sempervivum sediforme of Dioscorides, who describes it thus: "Several flender flents spring from one root, thickly encrusted with little, round, succulent, sharp-pointed leaves. It throws out, moreover, a flent towards the middle, about a span high, with an umbel of flender (greenish or) pale yellowish flowers."

This plant, when pounded, is used at Athens as a cooling cataplasm to bruises or to gouty limbs.

S. glaucum. Glaucous Stone-crop. Engl. Bot. t. 2477. (S. reflexum; Sm. Fl. Brit. 490. S. minus hematoideus; Ger. Em. 512.)—Leaves glaucous, awl-shaped, scattered, loosened at the base; those of the branches thread-shaped. Flowers in a cyme. Segments of the calyx lanceolate.—Native of this country, flowering in July and August. It differs from the last (of which it has till lately been considered but as a variety) in its more glaucous hue, and more flender leaves, especially those of the branches.

S. Forsterianum. Forsterian Stone-crop. Engl. Bot. t. 1822.—Leaves thick, awl-shaped, clustered together in many rows, spreading, loose at the base. Flowers in a cyme. Segments of the calyx short and rounded. Gathered by E. Forster, jun. efq. near the Devil's bridge, Cardigan- shire, in 1806. It flowers in July. This species has hitherto been confounded with rupestris, from which however (says the author of English Botany) it differs "in having the leaves of the barren branches spreading in a rofaceous form, not close-piled or erect, and especially in the want of a glaucous hue in the leaves, stem, and calyx. The petals also are more elliptical and blunt."

SEDUM, in Gardening, contains plants of the hardy herbaceous succulent kind, of which the species cultivated are; the orpine stone-crop (S. telephiurn); the evergreen orpine (S. anacampseros); the yellow stone-crop (S. aizoon); the poplar-leaved stone-crop (S. populifolium); the starry stone-crop (S. flittatum); the purpure-leaved stone-crop (S. cespitum); the thick-leaved stone-crop (S. dasyphyllum); the rock stone-crop (S. rupestris); the Spanish stone-crop (S. hispanicum); the white stone-crop (S. album); the biting stone-crop, or wall pepper (S. acre); the infiph stone-crop (S. saxifragulare); the English or mild white stone-crop (S. anglicum); and the annual stone-crop (S. annuum).

In the first fort there are several varieties, as with purple flowers, with white flowers, with broad leaves, and the greater orpine.

In the sixth fort there is a variety which has the stem more erect, and the lower leaves in threes or fours, the next opposite, and the uppermost alternate.

The seventh fort, when introduced into a garden, propagates itself freely upon walls, in waife places, and about garden pots; and no plant is better adapted to the purpose of decorating rock-work, as it grows without any trouble, in any aspect, multiplying very much by young shoots, and always looks beautiful.

The ninth, as well as the preceding forts, are cultivated in Holland and Germany to mix with lettuces in fellawds. The eleventh fort is eaten by some as a pickle.

Method of Culture.—These plants are all raised without much difficulty, by proper care and attention to have the foil dry, and of the poor sandy kind.

Culture in the Orpine Sorts.—These may all be readily increased by planting cuttings, during the summer months, in light mould in a shady situation, or in pots placed in similar situations. The plants in the open ground, as well as those in pots, should be kept clean from weeds, and be watered frequently when the weather is dry. They may likewise be raised by parting the roots, and planting them in a similar manner in the spring or autumn. When the plants are once well established, they spread rapidly, and require little or no care.

These plants are sometimes cultivated for medicinal use.

Culture in the Stone-crop Kind.—These are raised without much trouble, by planting out their trailing stalks in the spring or summer season, which readily take root. They thrive most perfectly on old walls, buildings, or rock-works. Where cuttings or roots of the perennial kinds are planted in some soft mud, placed upon such situations, they quickly take root and spread into the different joints and crevices, covering the whole in a very short time.

The seeds of the annual sorts also, when sown soon after they become ripe in such situations, soon come up and support themselves without further trouble.

Most of the perennial sorts are kept in the nurseries in full plants, fit for setting out in the borders, pots, &c., either in the spring for flowering the same year, or in the autumn to flower in the following year. These plants may be planted out in any dryish light soil, in borders, beds, and other places, and in the sides of dry banks, or in any elevated rubbishy soil, as well as in pots to move to different parts occasionally; or also some of the evergreen kinds, to introduce in their pots among winter plants under shelter, to increase the variety. In most forts, they may also be introduced as rock plants, to embellish artificial rock-works, ruins, and other similar places in pleasuregrounds. The stone-crops and other low trailing kinds may also be made to occupy the tops of any low walls, pent-houses, fedhs, or other low buildings.

And further, the twelfth and thirteenth forts may like-
wife be disposed in patches towards the fronts of borders, &c. as they spread thick and tuftly close to the ground, and flower abundantly; and being planted in pots, are proper to place on the outside of windows, copings of low walls, and in balconies, and court-yards, in allelamb to other lower fancy plants; they will clothe over, spread the surface, and flower profusely as far as they extend in such situations.

**Sedum Acre**, Wall-stone Crop, or Wall-pepper, in the *Materia Medica*, a common Britsh plant, growing on houses, walls, and gravelly banks, is, in its recent state, extremely acid, like the hydropiper; and, therefore, if taken in large doses, it acts powerfully on the prime vae, proving both emetic and cathartic; and applied to the skin, as a cataplasm, frequently produces vesications and eruptions. Boerhaave, therefore, imagined that its internal employment must be unsafe; but experience has discovered, that a decoction of this plant is not only safe, but of great efficacy in scurvy complaints: for which purpose, a handful of the herb is directed by Below, a Swedish physician, to be boiled in eight pints of beer till they are reduced to four; of which three or four ounces are to be taken every, or every other, morning. Milk has been found to answer this purpose better than beer. Not only ulcerous, simply scurvy, but those of a scrophulous and even cancerous tendency, have been cured by the use of this plant, of which Marquet relates several instances. He likewise found it useful as an external application in destroying fungous flesh, and in promoting a discharge in gangrenes and carbuncles. Another effect for which this plant has been esteemed, is that of stopping intermittent fevers. Woodv. Med. Bot.

**Sedum Majus**. See **Sempervivum**.

**Seduni**, in *Ancient Geography*, a people of Gallia Narbonenensis, in the vicinity of the Nantuates and Veragri, which jointly occupied the country that lies between the Allobroges and the higher Alps.

**Sedunoa**, in Geography, a town of Ruffia, in the government of Irkutsk, on the Lena; 12 miles N. of Orkengia.

**Sedusii**, in *Ancient Geography*, a people of Germany, who fought under Ariovistus against Caesar.

**Sedziszow**, in Geography, a town of Poland, in the palatinate of Sandomirz; 35 miles S. of Sandomirz.

**See-amol**, a small island in the East Indian sea, near the eait coast of Borneo. N. lat. 5° 27'. E. long. 118° 48'.

**Seeassee**, a small island in the Sooloo Archipelago. N. lat. 6° 25'. E. long. 120° 50'.

**Seeaxur**, a river of Hindoooland, which runs into the bay of Bengal, near Pondicherry.

**Seebach**, a town of Austria; 1 mile S.S.W. of St. Jorgen. — Allo, a river of Saxony, which runs into the Muldan, 2 miles S. of Elnburg.

**See-dangog**, a small island in the East Indian sea, near the east coast of Borneo. N. lat. 4° 15'. E. long. 118° 24'.

**Seebergen**, a town of Germany, in the duchy of Gotra, in which is a celebrated observatory, erected by the late duke; 4 miles E.S.E. of Gotra.

**Seebugunge**, a town of Hindoooland, in Bengal; 12 miles S. of Goragot.—Allo, a town of Hindoooland, in Bengal, on the left bank of the Ganges; 5 miles N. of Boghgiore.—Allo, a town of Bengal; 45 miles N.E. of Furracah.—Allo, a town of Bengal; 40 miles N.N.E. of Natore. N. lat. 25°. E. long. 89° 32'.

**Seebo**, the largest river in West Barbarie; it rises in a piece of water situated in the midst of a forest, near the foot of Atlas, eastward of the cities of Fez (Fas) and Mequinex (Mequinias), and winding through the plains, passes within five miles of Fez. Another stream, proceeding from the south of Fez, passes through the city, and discharges itself into this river. This stream is so valuable to the inhabitants of Fez, as it supplies the town with water, that it is called "Wed El Juhor," the river of pearls, a term indicating its value. Some auxiliary streams, proceeding from the territory of Tezza, fall into the Seebbo in Liah, or the period between the 20th of December and 30th of January inclusive. This river is impassable, except in boats, or on rafts. At Mehduma, or Mamora, where it enters the ocean, it is a large, deep, and navigable river; but the port being evacuated, foreign commerce is annihilated, and little shipping has been admitted since the Portuguese quitted the place. This river abounds more than any other in that rich and delicate fish called shebel. If this country afforded any encouragement to industry, corn might be conveyed up the Seebbo river to Fez at a very low charge; whereas it is now transported to that populous city by canoes, the expense of the hire of which often exceeds the original cost of the grain. Jackson's Account of the Empire of Morocco.

**Seebpoor**, a town of Bengal; 12 miles N. of Hoogly.

**Seeburg**, a town of Prussia, in the province of Ermelland; 55 miles S. of Konigberg. N. lat. 53° 31'. E. long. 20° 40'. — Allo, a town of Welfphalia, in the county of Mansfeld; 5 miles E. of Eifzeleben. N. lat. 51° 31'. E. long. 11° 51'.

**Seed, Jeremiah**, in *Biography*, a learned divine of the church of England, was born at Clifton, in Cumberland, and educated at Queen's college, Oxford, where he took his degrees in the arts, and obtained a fellowship. He was afterwards prefented to the rectory of Eham, in Hampshire, where he died in 1747. His sermons, which are very highly esteemed, are published in 4 vols. 8vo.

**Seed, Semen**, in the *Animal Economy*. See **Semen and Generation**.

**Seed, in Botany**, is that most important organ in the fructification of vegetables, the perfecting of which is indeed the sole object of all the other parts: to this end they are subervient either in forming, perfecting, or dispersing it. A seed is composed of many essential parts. See **Emery, Cottyledones, Albumen, Vitellus, Testa, Hilum**.

Besides these, there are various accedary parts, or appendages, to seeds, which come under the following denominations. See **Pellicula, Arillus, Papus, Cauda, Rostrum**. To these we must add **Ala**, which our predecessor has neglected to describe as a seminal appendage, in its proper article. (See that article.) The **Ala**, or **wing**, is a dilated membranous appendage to seeds, serving to waft them along in the air; it is commonly solitary, except in some umbelliferous plants. Seeds are occasionally furnished with spines, hooks, scales, crested appendages, particularly a little gland-like part sometimes called **Sripophiium**, and situated near the **Hilum**.

The various modes by which seeds are dispersed, in order to accomplish their germination, cannot fail to strike an observing mind with admiration. Indeed this is a most amusing branch of the science of vegetable economy. See **Introd. to Bot. ed. 3. 210—232**.

**Seeds, Echiniate.** See **Echinate**.

**Seeds, Naked.** See **Naked**.

**Seeds, Winged.** See **Winged**.
SEED.

SEED-Down. See Pappus.
SEED-Fell. See Pericarp.

Seed, in Agriculture, the grain or other product of a plant, whereby the species is propagated, upon its being tawn or put into the earth.

It may be observed, that the choice of the seed intended to be tawn, is an object of greater importance than many farmers seem to imagine. It is not sufficient that the finest grain be chosen for this purpose, unless it be likewise clear from weeds. In procuring feed, it should, therefore, be a rule with the farmer to purchase or reserve such as is the most full, plump, found, clean, and healthy, whatever the small of italk, more little as it is much as kinds new, found, that and must be perfed. Besides, there are other circumstances which ought to be taken into the account, in providing of feed corn, such as that it be new, and recently threfhed from the straw, and that the skin be clear and thin; for it is found that grain which is fresh, and only just threfhed out, is in a much more proper state for quick vegetation, than such as has been long kept, consequently less liable to perish in bad feafls; and that while the rind or skin is of a bright colour, and thin, a much larger proportion of fine farmaceous or mealy matter is yielded from the same quantity of grain, which renders it of course more valuable to the cultivator. This is particularly the case in wheat, and the same thing probably takes place in other sorts of corn.

And the writer of the Synops of Husbandry has shown, by some experiments, that wheat, after being kept fix or seven years, though there may not be any perceptible difference in its appearance from such as is new, is wholly unfit for being used in the taise of feed, on account of only a small portion of it being capable of vegetating; a circumstance that may probably, in many cases, be owing to the grain being more depofed, under such conditions, to take on the putrefactive fermentation, or become rotten, than to the abfolition of oxygen, which is believed to be essential to the procefs of vegetation in the early stage, as stated by Mr. Gough in the Manchester Transacions; and besides this effect, where the moisture and juice of the grain is much taken away, as is the case in keeping it for a great length of time, the plants that are produced from it may even be less vigorous and luxuriant, as happens in gardening to some kinds of seeds, as that of the melon, which is frequently kept for several years, in order to effect this purpose in a more perfect manner.

On these accounts, therefore, it must be evident that, on such principles, grain, in order to secure perfect vegetation, should not be placed too much out of the influence of the atmospheric air; and that the bed of mould, or earth, in which it is deposited, be in as fine a powdery state as possible; as, under such circumstances, the air is more uniformly admitted, and the feed, from being in a more equal temperature, and more equally supplied with moisture, is expofed in the most favourable circumstances to the combined effects of the causes that have been found to promote the sprouting, growth, and prosperity of the young corn plant, as has been fully shewn by Mr. Gough, in his excellent paper on the vegetation of seeds. And there should likewise be a constant attention, that no such grain as is in any way diseased should ever be made use of as feed corn; as the fowing of this forfed, though it may have been advised by some cultivators, who have not been sufficiently cautious, or who have placed too much confidence on the efficacy of feeds, can only disappoint the views and hopes of the farmer, by propagating various fatal maladies, or producing scanty crops of good grain.

A great many different methods have been pursued, in the view of securing such grain as is healthy and proper for the purpose of fowing; but that which is the most readily executed is probably that of selecting from among the corn plants, while they are growing in the fields; and in this way an opportunity is afforded of choosing such heads or ears of the plants of different kinds as are the most perfect, the most forward, and most vigorous in their growth, and which contain such feeds as are the most plump, and full, and the best ripened. These benefits or advantages may likewise, in some measure, be attainted in the most valuable sorts of grain, by having them picked over by hand, after being threfhed out; but this is a tedious practice, and not at certain of having the feed from the most healthy and best ripened plants, as the above and some others; therefore, to have the most perfect sorts of feed, and at the same time the most healthy and proper for vegetation, the most vigorous plants should be selected, as well as such as are the most forward and early in respect to the feed; and that these, while they are growing, be so preferred, that they may not be injured by having weaker plants of the same kinds near them; as the art of having good feeds does not, it is con- tended by an experienced farmer, depend so much upon obtaining new feeds from places at a considerable distance, as upon collecting and reserving the best feeds or roots of our own production. Dr. Priestley, in a paper in the first volume of Communications to the Board of Agriculture, has remarked that this method of practice has been had recourse to, in consequence of its having been found that though vegetables of all kinds are extremely liable to changes, in respect to the time of their maturation, or ripening, and other properties, the best feeds never fail to produce the best plants. It is likewise remarked, in addition, that in the preferring of feed grain, by collecting it in the ears from the stacks or sheaves, there may, however, be disadvantages in the way of lessening the produce, by choosing the largest ears, which have rarely more than one a stalk, and by taking such as become ripe at different periods.

It is observed that many different modes have been proposed for ascertaining the goodness of grain or feed-corn; but the farmer generally depends upon the appearance that it exhibits, preferring such as is full, plump, and well fed, and that has a certain brightness and starness, without any thrivelling or shrinking in the husks or external covering. But it may perhaps be ascertained with greater accuracy by other means, as the weighing of a certain measure or quantity; and from its being well known that grain or feeds, on being immered in fluids, leave the more light and imperfect floating on the surface, while the better and more perfect sink to the bottom; solutions well saturated with saline substances, from their gravity being much increased, become useful in ascertaining the goodness of the corn, as none but such as are perfectly found sink in them. And
the author of the Philosophy of Gardening conceives, that the weight of a given measure of grain may also be a tolerably certain method of discovering the quantity of bulk or bran contained in it, compared with a quantity of flour: as that grain which is cut too early, or which is otherwise not quite ripe, as happens in wet seafons, shrinks in the barn or granary, and becomes wrinkled, and has thus a greater proportion of skin or bran than that which has been more perfectly ripened, and weighs lighter in proportion to its bulk. And another method, which he supposes may be had recourse to in order to distinguish light from heavy grain, is that of winnowing, as the surfaces of light grains, from their being greater in proportion to their solid contents, may be carried further by the current of air afforded in the operation; of course in passing them through a screen, the heavy grains may be liable to run further out on the floor from their being more propelled by their greater gravity; without the resistance of the air on their surfaces being increased, and be consequently more proper for feed-corn in general. 

See Change of Seed.

But lately, however, a very different notion from the above has been entertained by Sir Joseph Banks, though we do not find it supported by the teft of experiment in the field. The result of a single trial, made under the circumstance of a hot-houfe, can never be satisfactory to the farmer. He thinks, that although the seeds of wheat may be rendered by the exhausting power of a fungus so lean and thrifted, that scarcely any flour fit for the manufacture of bread can be obtained by grinding them, these very fees will, except in the very worst cases, answer the purpose of feed-corn as well as the fairest and plumpest sample that can be obtained, and in some respects better; for as a bushel of much blighted corn will contain one-third at least more grains in number than a bushel of plump corn, three bushels of such corn will go as far in feeding land as four bushels of large grain. And that the use of the flour of corn in furthering the process of vegetation, is to nourish the minute plant from the time of its development till its roots are able to attract food from the manured earth; for this purpose one-tenth of the contents of a grain of good wheat is more than sufficient. The quantity of flour in wheat has been increased by culture and management calculated to improve its qualities for the benefit of mankind, in the same proportion as the pulp of apples and pears has been increased by the same means above what is found on the wildings and crabs in the hedges. Further, that though it is customary to let aside or to purchase for feed-corn the boldest and plumpest samples that can be obtained, that is, those that contain the most flour, this is unnecessary waste of human subsistence; the smallest grains, such as are sifted out before the wheat is carried to market, and either consumed in the farmer's family or given to his poultry, will be found by experience to answer the purpose of propagating the sort from whence they sprung as effectually as the largest. Every ear of wheat is composed of a number of cups placed alternately on each side of the straw; the lower ones contain, according to circumstances, three or four grains nearly equal in size; but towards the top of the ear, where the quantity of nutriment is diminished by the more ample supply of those cups that are nearer the root, the third or fourth grain in a cup is frequently defraded of its proportion, and become shrivelled and small. These small grains, which are rejected by the miller because they do not contain flour enough for his purpose, have nevertheless an ample abundance for all the purposes of vegetation, and as fully partake of the sap (or blood, as we should call it in animals) of the kind which produced them, as the faroist and fullest grain that can be obtained from the bottoms of the lower cups by the waifeful process of beating the sheaves. But, however further and more numerous experiments may establish this doctrine, the best practice of the farmer is probably, at present, to make care to have good well-ripened grain, clear from all adulteration of seeds of the weed kind; without any blackness about the extremities of the grains, being free from that dark-brown colour that indicates its having been heated too much in the flack; and that it have no signs of mouldiness from being badly secured, or of shrivelling from being cut in too green a state. It has also been lately suggested by Mr. Leop, who has been engaged in many interesting experiments on the subject, not by any means to procure feed grain from a soil north of that on which it is to be grown, but from a district south of it; as he considers it a general rule, that the product of seed improves in going from the south to the north, but decreases in virtue in passing from the north to the south.

And with respect to the proportion of feed that may be proper to be sown on different soils and situations, attention will not only be necessary to their peculiar nature, and to the periods of sowing or putting the seed into the ground, but also to the nature of the feafon, and the mode in which the sowing is executed in it. For crops in general, the strong, wet, and richer sorts of land will demand a larger quantity of feed than such as are more mellow, thin, and light; for coarse strong wet loams, and light retentive clays, must require more feed than light mellow loams, and sandy gravelly or even thin chalky lands. But where lands of the rich loamy kinds have been well reduced and broken down by the operations of tillage, it is observed, that if the feed be not sown in too great a proportion, an opportunity is afforded for the plants spreading themselves from the roots, many stems often issuing from the same root, in conformance of which the crops frequently become, even when thinly sown, extremely thick upon the ground; and from the great nutritive power of rich soils, or what is mostly termed strength by the farmers, would be greatly too much so, if a large proportion of feed were at first put in. And that in the case of root crops, whether such as are formed upon or within the soil, where such lands are in a sufficiently mellow and friable state for producing them, the seeds or sets should not on the same account be sown or put in too great a quantity, or too thickly. While in the strong, stiff, wet, retentive soils, from the plants seldom striking, or branching off much from the roots, except in particularly favourable circumstances of season, a much greater proportion of feed will be necessary, in order to secure such full crops as lands of this kind are capable of supporting and bringing to maturity in most corps.

But where the soils are light and thin, a less quantity of feed will be sufficient, according to Mr. Donaldson and others; as, if a large proportion be put into such kind of ground, from their poling up much less strength the crops will rarely, except in particular seasons, be well formed in the ear, or have the grain plump and well fed. It is likewise a practice in the best grain districts, on all sorts of land to sow smaller proportions of feed on lands of the same quality, in the early periods of the feed time, than in those of the latter. The reason of this, according to the above writer, is, that grain sown early in the season takes deeper root, and has more time to branch out additional shoots, than that which is later sown, which, when the soil is not very free as well as fertile, generally runs up into one single stalk, so that if a liberal quantity of feed be not allowed, the crop, however luxuriant in respect to the plants, must be feanty in the
the article of grain or produce. And for this there may also be other reasons, as where the seed is put in at a later period, especially in the spring, it will not have time fully to establish itself in the soil, before it becomes retarded by the hot and dry summer weather, unless a large quantity of seed be employed to afford protection by the clodens of the growth of the plants. And in the late autumnal sowings, the grain may not become well fixed and rooted in the soil before the frosts begin to affect them; and on that account a larger proportion of seed be required than under other circumstances would be necessary. Something may likewise depend on the state of the weather in sowing or putting seed into the ground; as where the season is very dry, and there is but a small proportion of moisture in the soil, more of the seed may fail in vegetating, than where the contrary is the case; which also shews the propriety of sowing and putting in the seed in such dry seasons, immediately after the plough has performed its work.

And it must likewise vary according to the manner in which it is deposited in the earth; as where the grain is scattered over the whole of the land, in some measure at random, as in the common broadcast method of sowing, a much larger proportion of seed must be sown, than where the grains are deposited with equality and exactness, but only on certain portions of the land, as in drilling and dibbling. And as some disadvantage may attend the first method, in respect to the vegetation of the seed, a larger proportion may also be requisite on that account. It is consequently evident, that the quantity of seed must vary according to different circumstances, and that it is a matter of much difficulty to fix upon a proportion that may be suitable to all the circumstances and sorts of soil. It is, however, commonly supposed that from two and a half, to three and a half bushels to the acre, may be the proportion that may be the most proper both in the spring and autumn sowings. Mr. Middleton has suggested, that for sowing wheat broadcast about the latter end of September, two bushels and a half is the most advantageous quantity on soils of medium quality; but that for every fortnight later, four quarters of seed should be added to that proportion. But the tabular view given below of the proportions that have been found to answer well in practice in an extensive midland district, on soils of different qualities, may afford a more satisfactory notion of the nature of feeding soils of different kinds and qualities.

It may be necessary, before sowing this however, to shew the quantities in ufe in a great southern grain district with wheat. In Norfolk, in practice of the best farmers, the proportions of seed wheat usually made use of, according to the late Agricultural Survey of that district, are about Walton, when dibbled, fix or seven pecks, in the practice of some; but with others, when sown before Michaelmas, two bushels, afterwards two and a half. Alto near Dereham, the quantity is four bushels broadcast, and when dibbled, from ten pecks to three bushels. At Wisken ten pecks dibbled, and three bushels broadcast; and at East Bilney, and the adjoining parishes, only from two and a half to three. But in the practice of Mr. Henry Blythe of Burnham, seven or eight pecks are plowed per acre; but the common quantity broadcast, from ten to twelve. And in the clays of Marthland, from five to fix pecks are sown broadcast. And about Wymondham they dibble in from fix to eight pecks, but in the broadcast method few three bushels. In some situations they however complain of lofs from too thin a plant in this sort of crop.

</table>

The exact proportion of seed that may be required, however, under different clods and circumstances of lands, in order to afford the most full and productive crops, cannot by any means be ascertained, much constantly depending on the judgment of the seedman, who must always decide in respect to the necessary proportion for the particular circumstance, having a due regard to the nature and quality of his seed, as well as the time and manner in which it is put into the ground, as well as other circumstances. See Sowing.

The most usual quantities and proportions of seed that are made use of in all the different sorts of field-crops, are mentioned under the particular heads to which they belong. See the particular crops.

The writer of the work on "Agricultural Chemistry," thinks
thinks that, in the general selection of seeds, it would seem that those arising from the most highly cultivated varieties of plants, are such as give the most vigorous produce; but that it is necessary from time to time to change, and, as it were, to cross the seeds, which may easily be done by proper means. Mr. Knight has found great advantages to arise from it in wheat, merely by sowing the different sorts together; and states, that "in the years 1795 and 1796, when almost the whole crop of corn in the island was blight ed, the varieties obtained by sowing alone escaped, though sown in several sorts, and in very different situations. By sowing two varieties of peas, a large fine pea has also been produced, which may probably be cultivated by the farmer with great benefit."

The seeds which are the most perfect and healthy in their nature, are always found to sprout and grow in the best manner as crops, as may be more fully seen under their proper heads. See Germination and Vegetation.

It is concluded, from a great number of experiments detailed in a paper in the third volume of the Transactions of the Highland Society, "On the Influence of Frosts, &c. on ripening Corn," that barley and oats in every period of their growth may be exposed to much variety of bad weather, without being destroyed, and that they even continue to acquire additional weight, although frequently exposed to severe degrees of cold, and occasionally even to frost. That when the field is dry, they not only suffer little from it, but often continue to fill; yet, where moisture prevails with it, they are soon wholly destroyed. But that although this may be the case, exposure in this way renders them very unfit for feed: as while every feed of good corn will vegetate and thrive when properly placed in the soil, where it is good, a great proportion of those which have been thus exposed never appear above the surface, and the plants of those that actually grow are so weak, that the crop is not only small in quantity, but the corn of inferior quality. That, though it seems in using well-ripened corn for feed, the crop which it yields depends, in a considerable degree, on the weight of it, yet this does not happen in any evident degree with corn that has suffered from frost, as the plants arising from corn that has been exposed to much of it are constantly weak, and the produce small, even although the feed be of the common weight. That frost appears still more hurtful to pulse crops as feed, and in other ways, than to those of the grain kind, as well as to grasses. That no corn which has been thus exposed to frost should ever be used as feed; but that which is for this purpose, should always be procured from southern situations, where there is no danger of this sort. That, on the score of economy, the feed which has been so exposed should never be employed; as nearly twice the quantity of it will be required; while the quantity as well as the quality of the produce will be vastly inferior. That this sort of grain is easily distinguished from good corn; the latter being plump, full, and of a peculiar healthy appearance, and mottly free from chaff; while the former is curled and pinched in, and never entirely full, being bleached and chaffy. Where these marks are not present, the mere vegetation of the seeds is, it is said, by no means sufficient, though often depended upon. That, when light feed is made use of, the crops more readily suffer with blight and other diseases, and it would seem that many morbid affections of plants, especially such as give rise to the generation of infects, are particularly apt to spread and communicate the contagion to others that are weak; which, like animals in a state of debility, do not so readily resist it, or the formation of those vermin by which they are most liable to be destroyed, as those plants which are found and in a vigorous state. That this therefore should be considered as a powerful motive for using only the best corn for feed, a maxim that cannot be too strongly inculcated; as the opinion which has already been hinted at prevails with many, of all feeds that vegetate being nearly equally fit for the production of crops, they frequently make use of the weak light part of their corn for feed, and convert all the rest of it into flour or meal; and thus, for a temporary advantage, continue to perpetuate the production of crops that are both small in quantity and of very inferior quality. That, for the prevention of these hurtful consequences, none but the best feeds of every kind should be sown. That, with this view, farmers should not procure feed that has been well ripened, but such as has been well kept, and never injured by frosts, snows, or rains. That it would also be much for their interest, to wash the whole of their feed-corn in strong brine; not only their wheat but their barley and oats, as well as their beans, peas, and tares; as nothing renders corn so fit for feed as this operation, when properly done: as it not only carries off all the light feeds, but also the feeds of a great many weeds which cannot in any other way be completely separated from it.

That it is thought, that the preference commonly given to new corn for feed, is not well founded; as it was found that the produce of old corn was equal, both in quality and quantity, to that of the best corn newly reaped. This is the case too with all the grass-feeds that are commonly sown. One of the best crops of hay, which is recollected to have been seen, was produced from a mixture of red, white, and yellow clover, rib-grass, and hay-grass, which, by accident, had been neglected, and kept for five years. An acre, or thereabouts, was sown with this mixture, while the rest of the field was sown with the feed of the preceding year, and the crop was equally good over the whole. That it is hence advisable, that in very warm seasons, when all the grass-feeds are commonly good, such farmers as have it in their power should provide a large quantity of those that they usually sow, to make use of when they are scarce and bad, which constantly happens after cold or wet seasons. That it is on this principle, of the feeds of plants retaining their power of vegetating for a long time, that we account for the sudden appearance of many of the grasses, and other plants, where they had not grown for a long period of time before. After the great fire in London in 1666, broom and clover, it is said, appeared upon the site of almost every house in the space of a few months, although the whole had been occupied with fires for several centuries. We daily perceive, it is said, in Scotland and other parts, that white clover appears almost as soon as the heath or other matters are destroyed, with which lands had been occupied before; and it is thought probable, that corn, pulse, and grass-feeds, where they have been found and good at first, and properly kept afterwards, will be found quite fit for feed, even when a good many years old. See the Paper.

Seeds, in Gardening, the small grains or other differently formed bodies, which are produced by plants, trees, or shrubs of almost all kinds after flowering, and which contain in them the little embryo, or off-spring of the future plants, of each particular sort, which consists of several different parts, but the principal of which are the: the cotyledons, or the little heart, the point of life, or essential point or part from which the future vegetable is to be produced, and which is the small point or speck that is placed in the centre of each seed, between what are called the cotyledons or the lobes of it, and which is attached thereto, being distinctly visible in most of the bean kind, as well as in almost every other sort of leguminous seas. It consists of two parts, the
the rostellum and the plumula; the former of which constituting the radical or defending part, which strikes downwards into the earth, or soil, and becomes the future root; the latter, which becomes the ascending part, or that which shoots upwards, and constitutes the item, branches, and other parts of the future plant. This point, or spot in the seed, is likewise sometimes termed punctum vitalis.

The cotyledons, or fide-lobes, are the perihedral fide-lobes, or parts of the seed, which involve, contain, and for some time nourish and support, the corculum, or embryo plant. These fide-lobes are for the most part two in number, which are very clearly seen in the bean kind of seeds, as well as in other kinds derived from the leguminous tribe of plants, especially when they have been previously laid a short time in earth or water. When the seed has been committed to, and deposited in the ground or soil, the corculum, or point of life, if the seed be good, is seldom long before it begins to sprout or germinate and exert itself in it, but the exact length of time which is necessary, is somewhat different in different cases, circumstances, and kinds of seeds; the cotyledons expand, bursting open the outer coverings, and rise in a gradual manner out of the earth or soil, in the form of blades or leaves, which are commonly, in most sorts, termed the feed-leaves, in which displaying the fist, or primary visible foundation and rudiments of the infant plant; accompanying it for some length of time after its eruption or fist breaking from the ground, as until the first proper leaves are formed in the centre of the vegetable, and advanced a little in their growth, when the lobes or feminal leaves becoming useless, they wither, decay, and are destitute. See Germination.

In general, plants are furnished with two cotyledons, or feed-leaves, especially almost the whole of the tribe of fibrous-rooted herbaceous plants, all trees and shrubs; but there are some which have only one cotyledon, as is the case in most of the bulbous plants of the liliaceous tribe, which rise out of the ground in the manner of a blade; and there are some seeds which have no cotyledons at all, for instance, such as the ferns, mosses, flags, and fougues.

The other parts of seeds are the alae, or wings, and the cornicles, or horns; in the former, many of which are winged, or furnished with thin membranous web or film, by which it means that they fly and are qualified being dispersed about, as in the fir, birch, maple, asf, elm, hops, and a great number of other sorts; and in the latter kind many of the seeds are crowned, and some surrounded with a pappose substance, or a sort of feathery or hairy down, especially in many of the compound and other descriptions, which serve for the purpose of their dissemination, when being thus framed for flying, in a somewhat similar manner to the shuttlecock, so as to be easily carried and transported by the wind to very considerable distances from their natural situations, examples of which are to be met with in hawk-weed, groundsel, dandelion, and many other plants; this, however, is not much the case with garden-seeds of the common kinds. But there are full numerous sorts of seeds which are perfectly simple, having neither any thing of the wing or pappose substance about them; as in most of those employed by the gardener.

It may likewise be observed, that the number, form or shape, size or dimensions, and the substance or solidity of different seeds, are extremely various, as produced by different kinds of garden plants. In respect to the particular number, it may consist of from one, to several hundreds, or even thousands, in a single feed-veil, according to the particular plant from which it is taken; for though some plants do not afford more than one or two, others three or four, there are many which have vast numbers of seeds, and are of amazing fertility; as, for instance, in the tobacco-plant, one simple feed-veil frequently contains not less than about one thousand seeds; and in that of the white poppy plant it is often not lower than eight thousand; the whole produce of one single tobacco-plant is certainly upwards of forty thousand; but some have suspected it to be more than three hundred thousand; and that of one single flax of flaxen-wort is conceived from calculation to be above one million of seeds. This is mostly in flower and other plants, but rarely in the culinary sorts.

In regard to what concerns the forms of garden seeds, they are, in general, either round, oval, kidney-shaped, heart-shaped, angular, flat, or some other form approaching to some of these. And in relation to the fizes and dimensions of such seeds, they are very different according to the plants from which they are taken, varying from the magnitude of the large nut kind, down to the very minute feeds of creoles, and others, which are still much smaller in their fizes. With respect to the substance and solidity of seeds they vary greatly, some seeds are soft, pulpy, fleshy, others hard and firm without any fleshy matter, some membranous, others hard and long in their nature, which is the case in all the different kinds of the nut tribe, as well as in the flones of many sorts of berries and other fome fruits.

Seeds of the garden sorts are likewise either covered or naked; the covered feeds are all such as are contained and concealed in some vesseles of the capsie, pod, berry, apple, pear, cherry, or some other similar kinds; the naked feeds are all those which are not contained in any vessele, but lodged in their receptacles, or in the bottoms of the cups belonging to the different plants or flowers.

There is an almost endless variety in the modes which nature has provided for the disseminating and dispersing the feeds of plants, which is truly wonderful, though of but little conuenaience in garden culture; in a very great many plants, the fruit or vesseles containing the feed, are raised above the ground, either by erect firm items, or by climbing flaxes, so that the fruit being elevated from the ground, it may be more readily and easily shaken by the wind which blows the feeds not unfrequently to a great distance; for the same reason, also, that description of feed-veils which is called capsiule, in some instances, opens at the top, in order that the feeds may be more fully and completely, as well as more daily, dispersed or thrown about. And from a great number of feeds being winged, as has been seen above, they are in that way spread far and near by the winds, and find their passage into different soild and territories. Besides, some feed-veils are ended with a remarkable degree of elasticity, by means of which they dart and throw their feed with great force to a very considerable distance; of this kind are the plants called touch-me-not, and the spiriting cucumber, as well as some others. There are many feeds and feed-veils too, which are armed with a fort of hooks, hairs, &c. by which they attach themselves to different kinds of animals, or other matters, and are thereby dispersed; such for instance, as in the feed of the carrot, hemp, agrimony, burdock, &c. Further, the feeds of many sorts that are devoured by birds, being carried and voided by them in an entire and perfect flate in different parts, often at a very great distance, not unfrequently take root and grow. In berries, as well as other pulpy fruits, which have been eaten as food, the feeds and kernels of many kinds of which pass through the body uninjured, and falling to the ground, likewise not seldom take on a growing flate. Seeds are also very frequently carried, disseminated, and dispersed by brooks, rivers,
SEED.

rivers, torrents, and all forts of running waters and tides to a great number of leagues distance from their native soils and exposures, where, after being left in such different grounds and climates, they, however, not unfrequently establish and render themselves familiar and agreeable in such new situations. These circumstances are necessary to be known to the gardener, in order that he may guard against the introduction of weeds, &c. more perfectly.

The duration or lasting of seeds, in so far as respect their powers or properties of vegetating or producing new plants, is very considerable indeed; as for instance, tho' the cucumber, melon, and gourd, not seldom retain their powers of vegetation for eight, ten, or twelve years; and it has been confidently asserted that those of the mimofa, or sensitive plant, will retain or preserve the principle of life or growth for thirty or forty years or more; while, on the other hand, a far greater number of seeds will not keep good, or in a germinating state, for more than one or two years; and many, or indeed the greatest part of these, will not vegetate properly, if more than one year old, nor some even when kept this short length of time. There are some indeed which require to be sown or put into the ground soon after they become ripe, or they will not grow until the succeeding year; others, unless they are sown immediately after they have been gathered, will not grow at all, as is not unfrequently the case with the berries of the coffee-plant. It has, however, been remarked, that almost all sorts of seeds which have been sown the first year after being collected or gathered, in general rife much sooner, and a great deal stronger, than such as have been kept for a greater length of time; for which reason it is principally advised to have recourse to new seeds, or such as are not more than one year old, wherever it can possibly be done; except in the particular cases of cucumbers and melons, in which seeds of two or three years old, or more, are often more to be preferred, as the plants of this kind, when raised from new seeds, are liable to run or grow much too vigorously to items or stalks, without becoming either tolerably expeditiously fruitful, or producing fruit in any sufficient quantity.

In regard to the keeping of garden seeds, all such as are produced in dry capsules, or other dry seed-vessels, are found to keep much better and longer in such vessels than, if taken out of them; but it is probable that most kinds of seeds will keep and retain their germinative property the longest and most perfectly in the bowels of the earth, when they have been accidentally deposited and buried to a considerable depth, and out of the reach of the influence of the sun and the air or atmosphere. For it has been noticed respecting the seeds of corn fallad in particular, which have been buried by accident to the depth of three feet or more in the ground for thirty years or more, that on the soil being turned up that depth to the top, they have begun to vegetate and have grown freely. The same thing has likewise been remarked of many other kinds of seeds, which have by chance been deposited in the earth to the depth of several feet; and in the bottoms of wells, vaults, ponds, ditches, and many other similar situations, and which have not been flurred for many years, as is evident from the circumstances of the cases; as when occasion has required the soil or earth to be thrown to the top of the surface, and to be exposed to the sun and air, many seeds have vegetated and plants arisen, which had not been remembered to have been sown in such places any time before, or at least for a very great length of time. Most sorts of garden seeds should therefore be kept constantly in the capsules, hulks, and other parts in which they are included.

It may also be remarked, that most sorts of seeds, if sown too deep, remain inactive, and some never exert their vegetative properties at all, while others, notwithstanding, preserve their power of vegetation and growth; and whenever the ground or soil is again fresh stirred, or newly turned up, such of them as happen to approach towards the upper part, will frequently show themselves, and come up, which fully demonstrates the power and effect which the sun and free air have, in promoting and bringing forward the vegetation of seeds as well as plants. On this account, therefore, it is advised that seeds of this sort should never be sown too deep in the ground, but constantly, in some measure, in proportion to their size, or the quantity of matter which they contain, as from about a quarter or half an inch deep, in the smaller sorts, to about one, two, and sometimes three inches in the middling and large kinds. See Sowing of Seeds.

In relation to the vegetation, germination, or growth of seeds, after they have been regularly sown or deposited in the earth or soil to a proper depth, it is very quick in some sorts, while in others it is slow; as for instance, the seeds of celeries, mulard, turnips, and many other sorts, vegetate and come up in a few days, some other sorts in one, two, or three weeks; as in most of the eculent kinds of the kitchen garden, and a great many others of the herbaceous clafi; but the seeds of parsley and some other kinds of plants often remain in an inactive state for a month or six weeks, and there are still some other sorts which lie one or two years or more in the ground before they germinate and rife in plants. With respect to the seeds of shrubs and trees, there are some which will rife in the course of a month or six weeks, or even in a much shorter time, while others require two or three months to vegetate and grow, and there are some kinds which lie a whole year or more, before they begin to vegetate and grow, as in the case of the hawthorn, the holly, and mect others of the very hard long-seeded kinds.

On the whole, these seeds are the deciduous parts of the vegetables to which they belong, each of which includes the rudiment of a new plant, and is endowed with a vital or living principle by means of the sprinkling of the pollen or male dust, which they are capable of retaining for a very considerable length of time when properly kept and preserved.

It is of great importance in the practice of gardening, to be careful in collecting seeds from the best sorts and varieties of the different kinds of plants, to preserve them in a proper manner, and to put them into the ground with due attention to their nature and qualities. Much advantage may likewise be gained in some cases, by keeping them in a suitable manner, and by producing a change in them, from the mixing or combining of different varieties of the same plants, in raising those from which they are taken. Peas have been very greatly improved in this way.

With proper precautions, and with a zeal in any degree resembling that of the late Dr. Solander, of Mr. Blake, who had formed a plan of procuring the seeds of all the vegetables produced in China, which are used in medicine, manufactures, or food, or are in any way serviceable to mankind, and to forward to Europe not only such seeds, but the plants producing them (see Kippis's edit. of Biog. Brit. art. Blake), and of Sir Joseph Banks; we might obtain a great variety of curious and useful plants now uncultivated in this country.

The seed of fruit-trees, it is said, should not be chosen from those that are the most fruitful, so much as from the most solid and fair; nor are we to covet the largest acorns, but the most weighty, clean, and bright. Porous, insipid, mild sorts of seeds, are to be sown as soon as ripe; hot, bitter seeds, ought to be kept a year before they are sown. See Seminary.

The
The shape and weight of seeds direct how they are to be let; most of them, when they fall, lie on one side, with the small end towards the earth; which shews that posture to be best to let any stone or nut in; if they be heavy, sow them the deeper. Acorns, peaches, &c. are to be sown two or three inches deep. See Semination.

There is a common method of trying the goodnes of many sorts of seed, which is by putting them in water; and those which sink to the bottom are esteemed good, but those that swim on the surface are rejected. This rule, Mr. Miller observes, is not universal; for having saved the seeds of melons which floated on the surface of water, they were washed from the pulp, and keeping them two years, they grew very well; but the melons they produced were not so thick-flushed as those which obtained from heavy seeds of the same melon. The lightness of many sorts of seeds he ascribes to their not having been sufficiently impregnated by the farina succundans; and, therefore, care should be taken that this operation be properly performed, by not excluding plants that are in flower from the external air, or even by affluting nature in conveying the farina of the male flowers to those of the female. Miller's Gard. Dictionary, art. Seed.

Seed, Change of, a term used by the farmers to express the common, and, as they suppose, necessary custom, of changing one another the seed of their lands, as wheat, and the like; it being a received opinion, that the seed produced on one land will grow better on another than on that which produced it, though the same species of plant be sown.

Seeds, in their natural climate, do not degenerate, unless culture has improved them; they then indeed are liable, upon omission of that culture, to return to their natural state again. Whatever benefit arises to the farmer from the changing of the seed of the same species, is from causes which are themselves the effects of different climates, such as heat and moisture, which may vary very much in the same neighbourhood.

Laurremburgius has carried this notion of degeneracy and change from the soil, so far as to affirm that wheat will, in some places, degenerate into rye; and in other places, rye will be exalted into wheat by the soil; but those who are acquainted with botany know, that a horse might as soon be changed into a bull by feeding in an improper pasture, as one plant degenerate into another by fault of the soil. Tull's Husbandry, p. 116. See Change of Seed.

Seeds, Steeping of, in potable liquors, is a practice that has occasionally prevailed, and it is not of modern invention. The Romans, who were good husbandmen, have left us several receipts for steeping of grain, in order to increase the powers of vegetation. In England, France, Italy, and in all countries where agriculture has been attended to, a variety of liquors has been recommended for this purpose. The practice is founded on a presumption, that, by filling the vessels of the grain with nourishing liquors, the germ, with its roots, would be invigorated. On this subject Dr. Hunter observes, that all his experiments demonstrate, that steeping has no inherent virtue; having found more than once the same seed, steeped and unsteeped, all other circumstances being alike, he never found the least difference in the growth of the crop. When, indeed, the light seeds are skimmed off, as in the operation of brining, the crop will be improved, and diseases prevented; but these advantages proceed from the goodnes of the grain itself, and not from any prolific virtue of the steep. In this opinion many rational farmers, determined by their own experience, concur. Duhamel speaks in the strongest terms against the practice of steeping, so far as it supposes an impregnation of vegetative particles. Dr. Hunter, having sprouted all kinds of grain in a variety of steeps, affirms the farmer, that the radicle and germ never appeared so vigorous and healthy, as when sprouted by elementary water; whereas it appears, that the seed requires no affilience.

Upon the whole he concludes, that as no invigorating or fructifying liquor, however pompously introduced, has ever stood the test of fair and correct experiment, it may be laid down as an established truth, that plump seeds, clear of weeds, and land well prepared to receive it, will seldom disappoint the expectations of the farmer; and upon these he should rely for the goodnes of his crop. Hunter's Evelyn's Silva, p. 15, &c.

Seeds, in Pharmacy, &c. The medicinal seeds, especially those imported from the Indies, Levant, &c. are severally described under their respective articles; which fee. Among those used with us, the principal are, the four greater balsam, and the four greater cold seeds, as they are called. The first are those of anise, fennel, cummin, and caraway; the latter, those of gourd, citral, melon, and cucumber.

The chief use of the four cold seeds is for the making of emulsions, cool refreshing drinks, pastes for the hands, and oils used by the ladies for the complexion.

Seeds, in Agriculture, a term applied to young grasses, or to lands newly laid to grass, in many cafes. Seed-Furrow, the furrow or ploughing on which the seed is sown, or put in. It is usual, in the last ploughing before sowing, to have the furrow left turned than in other cafes. See Ploughing.

Seed-Graft, a term used to signify cultivated herbage, or grass, raised in opposition to natural grass. See Artificial Grasses.

Seed-Lip, a sort of basket, in which the former carries his feed, in order to sow it. It is sometimes written feed-lap, or feed-lap.

A great improvement has lately been made on the common fowing-basket, by a farmer at Malden, in the county of Essex. He has contrived it in such a manner, that the bottom is a wire-sieve, which sifts out the seeds of weeds from the grain, in the motion of sowing; a cloth bag being attached beneath, for the purpose of catching them.

Seed-Room, the room or place where garden seeds are kept and preserved in, either for the purpose of sale, or future use in sowing and raising crops. Rooms for this purpose should have but little air, be perfectly free from all sorts of moisture, and be fitted up with every kind of convenience for receiving, hanging, and keeping all descriptions of seeds.

In the arrangement with other garden buildings, the seed-room should have a place as near the hot-house and fruit-room as possible; but where there are no other buildings, it may have any situation which is ready and convenient for depositing the seeds.

Seed-Scam, the interface between two plots, as left by the plough; also the channels made by floating, drilling, &c.

Seed-Weeds, such weeds as arise from the sowing or disper- sion of their seeds, and which do not propagate them- selves by the roots. See Weeds.

Seed, Amber, Anise, Lac, Linen, Mustard, Worm. See the respective articles.

Seed of Pearl. See Pearl.

SEEDLING, among Gardeners, denote such roots of gillflowers, &c. as come from seed fown. Also the young tender shoots of any plants that are newly fown.
SEEDLY, in Geography, a town of Morung; 55 miles
N.W. of Amerpourt.

SEEDNESS, in Agriculture, provincially used for seed
time.

SEEDSMAN, a term applied to the labourer or perfon
who scatters, diperfes, or puts the feed in or on the ground,
in fowing for different forts of crops, before it is covered.
Certain peculiarities of step and caft are requisite in good
feedmen, which are only to be acquired by time, practice,
or experience. Expert feedmen are, of course, but rarely
to be met with among farm labourers, though they are of
very material importance, in fo far as the fuccesfs, goodnefs,
and beauty of the crops are concerned, as well as in faving
much expence in the feed, and other ways: consequently
the farmer who does not perform this fort of bufinesf him-
self, will find it to be greatly his interest to have contantly
the bell, moft able, and experienced men of this kind proc-
cured for executing the work of fowing; as he will thereby
have not only conforable immediate saving, but the ad-
vantages of a more certain and favourable appearance, and
much greater produce in his crops. It is hardly to be con-
ceived, except by thofe converfent in the matter, how great
the waffe and injuries are, which are committed by feedmen
who are not well acquainted, experienced, and expert in
the bufinefs of fowing. They are, besides, in many incal-
capable of getting on with the work with that expedi-
tion which is neceffary; which is a very great inconvenienc
and lofs to the farmer at this very busy fefon of the year, when
every thing of this fort ought to be in the greatest activity.
See Seed and Sowing.

It is also a term which is made ufe of to dignify the perfon
who keeps a thop, or other place, for the fale of feeds,
either to the farmer, or the gardener, or any other perfons.
Thfe feed-dealers have fometimes the name of garden
feedmen. The London feed-dealers are a very conforable
clef of men, who do much bufinesfs in the difpofing of all
forts of feeds which are neceffary to be employed in the
practice of farming and gardening, as well as in different
other ways.

The garden feedman is commonly the gardener himfelf,
other perfons being never, or very rarely, employed in fow-
ing any fort of garden crop.

SEEDY, in the Brandy Trade, a term ufed by the
dealers to express a fault that is found in feveral parcels of
French brandy, and which renders them unfealeable. The
French fuppofe that thefe brandies obtain the flavour,
which they exprefs by this name, from the weeds which
grow among the vines, from whence the wine, of which this
brandy was made, was preffed.

However it be, the thing is evident, and the taste not of
any one kind; but fome pieces of brandy fhall taste strongly
of anifeed, fome of caraway seed, and fome of other of
the strong flavoured feeds of plants, principally of the um-
beflterious kind; fo that it fhall be rather taken for anifeed,
caraway, or fome other water, than for brandy.

The proprietor of fuch brandies is alwajs at great trouble
to get them off, and ufually is reduced to the necelity of
mixing them in small quantities with pieces of other brandies,
fo as to drown and conceal the tale; and where he has not
opportunities of doing this, he is obliged to fell them on
very difadvantageous terms.

The bufinesfs of rectification of spirits is very little under-
stood abroad, though much practifed with us; and a man
in France or Holland, who could take off this tale from
thefe brandies, might get great advantages by it. There
is no doubt but that the fame means, which we ufe to rec-
tify malt spirits, that is, to clear it of its noifous and
finking oil, which always arises with it in the firft diftil-
tation, would alfo serve to purify thefe brandies, and by
leaving the extraneous oils behind, render them as well tailed
as any others; for there is no question, but that the oil of
malt, which is a principle of the fame ingredient with the
spirit, is more firmly united to it than these flavoured oils
in the brandy, which are not the produce of the grape, but
of fome foreign matter only accidentally mixed with it. See
Brandy and Spirits.

It is a miftake to imagine, that all brandies made in
France are fo fine as thofe which we meet with on the quays
of London; on the contrary, there are many hundred pieces
made every year, which are as badly flavoured as our coarfe-
falt spirit. But the cafe is this, they fend the fmall brandies,
and the fmall wine, to England, where they can get the fmall
prices for them. In Holland, on the contrary, the mark
of goods of all forts, it is sometimes difficult to felct a
piece of good brandy out of fifty, the general run of them
being either feedy, or mufly, oily, or otherwife infected
with fome unnatural and difagreeable ftravours: and these
are the forts which in France they defpair of curing by re-
diffilation, or bringing to the flate of three-fifths, or trois
cinques, as they exprefs their fronger brandies. Shaw’s
Effay on Distillery.

SEEDY Abd El Abbs, in Geography, a town of Tunis, an-
ciently called “ Multi;” 16 miles N.E. of Keft.

SEEDY Meddub, a town of Algiers, in the province of
Tremonz, on the coaft of the Mediterranean, having a
good road for fhips. It derives its name from a celebrated
prophet, whose tomb the inhabitants hold in great venera-
tion; 4 miles S.W. of Mejeda.

SEEDY Meddub, a town of Algiers, in the province of
Tremonz, at the conflux of the Arhew and the Shelliff, held
as a functury; 30 miles E. of Mufiyannim.

SEEDY Bofgannim, a town of Tunis; 40 miles S.W. of
Keft.

SEEDY Bofron, a town of Morocco, on the coaft of the
Atlantic; 10 miles N. of Mogadir.

SEEDY Doude, a town of Africa, in the kingdom of
Tunis, at the north extremity of the peninsula of Dackul,
surrounded with the ruins of the ancient Miffa. Its pre-
fent name is derived from Doude, or David, a Moorish
faint, whose fepulchre, as they faw it, is five yards long.
But, according to Dr. Shaw (in his Travels), this is re ally
a fragment of fome Roman prætorium, as he is led to con-
jecture from three tellelattated or mofaic pavement, wrought
with the moft exaft symmetry; and executed with all the
artful wreathings and variety of colours imaginable, and with
an intermixture of figures of horfes, birds, fhrubs, and trees,
curiously inlaid, fo that they appear more gay and lively
than many tolerably good paintings; 10 miles S.W. of
Cape Bon.

SEEDY Efchab, a town of Algiers, anciently called Sava;
25 miles S. of Boujeiah.

SEEDY Meddub, a town of Africa, in the kingdom of
Tunis; 20 miles N. of Gabs.

SEEDY Nedja, a town of Algiers; 26 miles E. of Burg
Hamza.

SEEDY Ocubba, a town of Africa, in the province of
Zaab, famous for a tomb of an Arabian general of that
name, and for that of Seedy Laffar, its tufcular faint; 15
miles S.E. of Bifcara.

SEEFELDT, a town of Auffria; 6 miles W. of
Laab.

SEENHAUSEN, a town of Brandenburg, in the Old
Mark.
Mark, on the river Aland, which almost surrounds it; 40 miles N.W. of Brandenburg. N. lat. 52° 53'. E. long. 11° 59'. — Alfo, a town of the duchy of Bremen; 3 miles W. of Bremen. — Alfo, a town of Welfphalia, called "Sommerenchesburg," in the duchy of Magdeburg; 18 miles W. of Magdeburg.

SEEHAUSZ, a citadel of Germany, in the lordship of Schwarzenberg, on a lake; 6 miles S. of Scheinfeld.

SEE-HOO, or Si-HOOU, a lake of China, on the borders of which stands the wealthy and extensive city of Hang-choo-foo, or Hang-tseem-fou; which is this lake, with the surrounding scenery, is accounted one of the grandest, as well as most beautiful, spots in all China. The Luf-fang-ta, or tower of the thundering winds, standing on the point of a promontory, jutting into the lake, forms a bold object. It is said to have been built in the time of the philosopher Confucius, who lived centuries before the Christian era. The vale of tombs has an almost infinite variety of ornaments. Naked coffins in great abundance lie scattered upon the ground, and the sides of the hills that rise from the vale are thickly set with groups of sarcophagi, in the shape of small houses, arranged in such a manner as to have the appearance of so many Lilliputian cottages. In the plates annexed to Staunton's Voyage, we have an interesting view of this lake.

SEEHURAH, a town of Hindooftan, in Gurry-Mundella; 25 miles N. of Gurrah.

SEEING, the act of perceiving objects by the organ of sight; or, it is the sense we have of external objects, by means of the eye.

For the apparatus, or disposition of the parts necessary to seeing, see Eye. For the manner in which seeing is performed, and the laws of it, see Vision.

Our health anatomists differ greatly as to the cause why we do not see doubly with the two eyes. Galen, and others after him, ascribe it to a coalition, or decoupling of the optic nerve, behind the os sphenoides. But whether they decouple or coalesce, or only barely touch one another, is not so well agreed.

The Bartholines and Vesalius say expressly, they are united by a perfect confusion of their substance; Dr. Gibbon allows them to be united by the closest conjunction, but not by a confusion of their fibres.

Alhazen, an Arabian philosopher of the 12th century, accounts for single vision by two eyes, by supposing that when two corresponding parts of the retina are affected, the mind perceives but one image.

Delcartes, and others, account for the effect another way; viz. by supposing that the fibrillae constituting the medullary part of those nerves, being spread in the retina of each eye, have each of them corresponding parts in the brain; so that when any of those fibrillae are struck by any parts of any image, the corresponding parts of the brain are affected thereby.

Somewhat like which is the opinion of Dr. Briggs, who takes the optic nerves of each eye to consist of homologous fibres having their rise in the thalamus nervorum opticorum, and being thence continued to both the retinas, which are composed of them; and farther, that those fibrillae have the same parallelism; but in both eyes; consequently, when an image is painted on the same corresponding sympathizing parts of each retina, the same effects are produced, the same notice carried to the thalamus, and so imparted to the soul. Hence is that double vision ensuing upon an interruption of the parallelism of the eyes; as when one eye is depressed by the finger, or their symphony is interrupted by disease: but Dr. Briggs maintains, that it is but in few subjects there is any decoupling; and in none any conjunction more than mere contact.

Dr. Briggs's notion is by no means consonant to facts, and is attended with many improbable circumstances.

It was the opinion of Sir Isaac Newton, and of many others, that objects appear single, because the two optic nerves unite before they reach the brain. But Dr. Porterfield insists, from the observation of several anatomists, that the optic nerves do not mix, or confound their substance, being only united by a close cohesion; and objects have appeared single, where the optic nerves were found to be disjoined. To account for this phenomenon, this ingenious writer supposes, that, by an original law in our natures, we imagine an object to be situated somewhere in a right line drawn from the picture of it upon the retina, through the centre of the pupil; consequently the same object appearing to both eyes to be in the same place, the mind cannot distinguish it into two.

In answer to an objection to this hypothesis, from objects appearing double when one eye is distorted, he says, the mind mistakes the position of the eye, imagining, that it had moved in a manner corresponding to the other, in which case the conclusion would have been just; in this he seems to have recourse to the power of habit, though he disclaims that hypothesis. This principle, however, has been thought sufficient to account for this appearance.

Originally, every object making two pictures, one in each eye is imagined to be double; but, by degrees, we find that when two corresponding parts of the retina are impressed, the object is but one; but if those corresponding parts be changed by the distortion of one of the eyes, the object must again appear double, as at the first. This seems to be verified by Mr. Cheffelden, who informs us, that a gentleman, who, from a blow on his head, had one eye distorted, found every object to appear double, but by degrees the most familiar ones came to appear single again, and in time all objects did so without amendment of the distortion. A similar case is mentioned by Dr. Smith.

On the other hand Dr. Reid is of opinion, that the correspondence of the centres of two eyes, on which single vision depends, does not arise from custom, but from some natural constitution of the eye and of the mind.

M. du Tour adopts an opinion, long before suggested by Gallendi, that the mind attends to no more than the image made in one eye at a time; in support of which he produces several curious experiments; but as M. Buffon observes, it is a sufficient answer to this hypothesis, that we see more distinctly with two eyes than with one; and that when a round object is near us, we plainly see more of the surface in one case than in the other.

With respect to single vision with two eyes, Dr. Hartley observes, that it deserves particular attention, that the optic nerves of men, and fuch other animals as look the same way with both eyes, unite in the fella turcica in a ganglilion, or little brain, as it may be called, peculiar to themselves, and that the allocations be tween synchronous impressions on the two retinas must be made faster; and cemented stronger on this account; and that they ought to have a much greater power over one another's images than in any other part of the body. And thus an impression made on the right eye alone by a single object, may propagate itself into the left, and there raise up an image almost equal in vividness to itself; and, consequently, when we see with one eye only, we may, however, have pictures in both eyes.

It is a common observation, says Dr. Smith, that objects seen with both eyes appear more vivid and stronger than they do to a single eye, especially when both of them are equally good.

Whence it is that we see objects erect, when it is certain that the images of them are painted invertedly on the retina, is another difficulty in the theory of seeing.

Debarne: accounts for it hence, that the notice which the soul takes of the object does not depend on any image, nor on any action coming from the object, but merely on the situation of the minute part of the brain whence the nerves arise. E. gr. the situation of a capillament of the optic nerve correponds to a certain part of the brain, which occasions the soul to see all those places lying in a right line therewith.

But Mr. Molyneux gives us another account: the eye, he observes, is only the organ or instrument; it is the soul that sees. To enquire, then, how the soul perceives the object erect by an inverted image, is to inquire into the soul's faculties. Again, imagine that the eye receives an impulse on its lower part, by a ray from the upper part of an object, must not the violate faculty be hereby directed to consider this stroke as coming from the top, rather than the bottom of the object; and, consequently, be determined to conclude it the representation of the top?

Upon these principles, we are to consider, that inverted is only a relative term, and that there is a very great difference between the real object and the means or image whereby we perceive it. When all the parts of a distant prospect are painted upon the retina (supposing that to be the seat of vision), they are all right with respect to one another, as well as the parts of the prospect itself; and we can only judge of an object being inverted, when it is turned reverse to its natural position with respect to other objects which we see and compare it with.

The eye, or viile facility, (says Molyneux) takes no notice of the internal surface of its own parts, but uses them as an instrument only, contrived by nature for the exercise of such a faculty. If we lay hold of an upright fick in the dark, we can tell which is the upper or lower part of it, by moving our hand upwards or downwards; and very well know, that we cannot feel the upper end by moving our hand downwards. Just so, we find by experience and habit, that upon directing our eyes towards a tall object, we cannot see its top by turning our eyes downwards, nor its foot by turning our eyes upward; but must trace the object the same way by the eye to see it from head to foot, as we do by the hand to feel; and as the judgment is formed by the motion of the hand in one cafe, so it is also by the motion of the eye in the other. Molyneux's Dior. p. 109, &c. Mutchonrook's Introd. to Phil. Nat. vol. vi. p. 762. Ferguson's Lec. p. 132. See on the subj. of this article, our account of the physiology of the eye, under Eye.

SEEING Faith. See Faith.

SEEKIRCHEN, in Geography, a town of the archbishopric of Salzburg, on the Waller See; 4 miles N. of Salzburg.

SEEPORUM, a town of Hindooftan, in Boggicund; 35 miles N.E. of Rewah.

SEEL, in Agriculture, a term provincially applied to time or season in respect to crops, as hay feal, or hay time, barley feel, or barley feed time, bark feel, or the barking seafon, &c. It is sometimes written seel.

SEELAND, in Geography. See Zealand.

SEELANG, a small island in the East Indian fea, near the S. coast of the island of Bahian, with which it forms a good inner and also outer harbour.

SEELBURG, or SEIPPHILLIS, a town of the duchy of Courland, on the Dwina, where the bishops of Semigallia formerly resided, and who, on that account, were called bishops of Seelburg; 50 miles S.E. of Riga.

SEEING. A horse is said to feel when he begins to have white eye-brows, that is, when there grows on that part about the breadth of a farthing of white hairs, mixed with those of his natural colour, which is a mark of old age.

It is said a horse never feels till he is fourteen years old, and always does before he is sixteen. The light forrel and black sooner feel than any other.

Horse-jockies usually pull out those hairs with pincers: but if there be so many that it cannot be done without making the horse look bald and ugly, then they colour their eye-brows, that they may not appear old.

SEEING, in Falconry, is the running a thread through the eye-lids of a hawk, when first taken, to make her endure the hood the better.

SEEING, at Sea, is used in the same sense nearly with heeling: when a ship lies down conftantly, or steadily, on one side, the seamen say the heeds; and they call it feeling, when she tumbls on one side violently and suddenly, by reason of the sea forfaking her, as they call it, i.e. the waves leaving her for a time in a bowling sea. When a ship thus tumbls to leeward, they call it leeward; and in this there is not much danger, even in a storm, because the sea will presently right her up again; but if she rows or feels to windward, there is fear of her coming over too short or suddenly, and so by having the sea break right into her, be either foundered, or else have some of her upper works carried away.

SEELINGAN, in Geography, a small island in the Soooloo Archipelago. N. lat. 6° 4'. E. long. 118° 15'.

SEELKGEN, a town of Prussia, in the province of Nattenberg; 9 miles W.N.W. of Liel.

SEELLOW, a town of Brandenburg, in the Middle-Mark; 10 miles W. of Cullin.

SEEM, or SEME. See SEAM.

SEEM-A-KOANG, in Biography, a Chinefe mandarin and philosopher of the eleventh century, who enjoyed the favour of the emperor, and had several important places, which he resigned and retired to a solitary place, where he wrote a history of China, commencing at the 403d year before the Christian era. He was author likewise of some moral treatises.

SEEEMO, in Geography, a town of Africa, in Kaffion. N. lat. 14° 25'. E. long. 8° 45'.

SEENENDOONG, a small island in the East Indian f ea, near the N. coast of Borneo. N. lat. 7° 48'. E. long. 117° 45'.

SEENCHOO, a large town of the Birman empire, situated on the Irawaddy, having in its neighbourhood, and for a great distance along the eastern bank of the river, small temples built close to the water; 10 miles S. of Pagan.

SEEBER, a town of Hindooftan, in Malwa; 50 miles E.S.E. of Shajehanpour.

SEEPARRAN, a small island in the East Indian sea, near the eait coast of Borneo. N. lat. 4° 8'. E. long. 118° 25'.

SEEER, Principality of, a petty sovereignty of Arabia, extending from Cape Muffendo to the Perian gulf. The Persians call it the country of Desulfar, another cape near Muffendo. The Europeans also call the inhabi-
SEF

SEFATIANS, a sect of Mahometans, who held the opposite opinion to the Moatazalites, with respect to the eternal attributes of God, which they affirmed, making no distinction between the essential attributes, and those of operation; and hence they were named Sefatians, or Attributes. See Moatazalites.

The doctrine of the Sefatians was that of the first Mahometans, who were not yet acquainted with these nice distinctions; but this sect afterwards introduced another species of declarative attributes, or such as were necessarily used in historical narration, as hands, face, eyes, &c. which they did not offer to explain, but contented themselves with saying they were in the law, and that they called them "declarative attributes." At length, by introducing various explications and interpretations of these attributes, they divided into many different opinions; some, by taking the words in the literal sense, fell into the notion of a likeness or similitude between God and created beings, to which it is said the Karaites or Caraites among the Jews, who are for the literal interpretation of Moses's law, had shewn them the way:—others explained them in another manner, saying that no creature was like God, but that they neither understood, nor thought it necessary to explain the precise signification of the words which seem to affirm the fame of both; it being sufficient to believe that God hath no companion or similitude.

The sects of the Sefatians are, 1. The "Afsharism," or followers of Abu'l Hafan al Afshar, who allowed the attributes of God to be different from his essence, yet so as to forbid any comparison to be made between God and his creatures; and who, as to predetermination, maintained that God hath one eternal will, and that he will fill both the good and evil, the profit and hurt of men, and who have even said, that God may even command man to do what he is not able to perform; and as to mortal sin they taught, that if a believer guilty of such a sin die without repentance, his sentence is to be left to God, whether he pardon him out of his mercy, or whether the prophet interfere for him, or whether he punish him according to his deserts, and afterwards, through his mercy, admit him into paradise; but that it is not to be supposed he will remain for ever in hell with the infidels:—such were the more rational Sefatians, who were very different from—2. The "Mofhábhehites," or "Affiliators." (See Mosbáhibhites.) 3. The "Keramians," called also "Mojaffamians," or "Corporalists," who declared God to be corporeal. (See Keramians.) 4. The "Jabarians." (See Jabarians.) 5. The "Morgians," said to be derived from the Jabarians, who teach, that the judgment of every true believer that hath been guilty of a grievous sin, will be deferred till the resurrection, and that disobedience with faith is not injurious, but, on the other hand, that obedience with infidelity doth not profit. The Morgians are distributed into four species; three of which, according as they happen to agree in particular dogmas with the "Kharejites," the "Kadarians," or the "Jabarians," are distinguished as Morgians of those sects, and the fourth is that of pure Morgians, and this species is subdivided into five others. The opinions of Mokatel and Balbar, both belonging to a sect of Morgians, called "Thaubaunians," are as follows. The former asserted that disobedience in not sin which profeoffs the unity of God and is endowed with faith, and that no true believer shall be cast into hell; he also taught that God will certainly forgive all crimes besides infidelity; and that a disobedient believer will be punished at the resurrection, on the bridge laid over the midst of hell, where the flames of hell-fire shall catch hold on him, and torment him in proportion to his disobedience, and that he shall
shall then be admitted into paradise. The latter held, that if God do call the believers guilty of grievous sins into hell, yet they will be delivered thence after they shall have been sufficiently punished; but that it is neither possible nor consistent with justice, that they should remain there for ever.

Sale’s Koran—Pref. Dile.

SEFIDROU, in Geography, a town of Persia, in the province of Farisian; 144 miles S.W. of Schiras.

SEFROI, a town of Africa; 20 miles S.E. of Ferz.

SEFURA, a town of Africa, in Fouta. N. lat. 10° 30'. W. long. 10° 25'.

SEG, in Rural Economy, the name of a castrated bull.

SEGAGHEE, in Geography, a town of the Birman empire, on the Irawaddy; 6 miles from Deneebow.

SEGALLA, a gold mine of Africa, in the kingdom of Bambyuk.

SEGAR, Sir William, in Biography, garter king at arms, was author of “Honour Civil and Military,” Folio, 1602. He was imprisoned for granting the royal arms of Aragon, with a canton of Brabant, to George Brandon, the common hangman, but it being very evident that he had been impoused upon he was released. He died in 1633. Edmondson’s Baronage is said to have been principally taken from Segar’s MSS.

SEGAR, in Geography. See SADSKAR.

SEGARDEE, a town of Hindoostan, in Golconda; 30 miles W.N.W. of Hydrabad.

SEGARGIUM, a town of Thibet; 52 miles S.W. of Tsangra.

SEGEBORG, a town of the duchy of Holstein, the name of which is derived from a castle built there by the emperor Lotharius in the year 1137, of which few vestiges now remain; 18 miles N.W. of Lubeck. N. lat. 53° 58'. E. long. 10° 19'.

SEGED, a town of Nubia; 30 miles S. of Sennaar.

SEGEDA, in Ancient Geography, a very celebrated town of Spain, in Bactia, in the interior of the country, between the coast of the ocean and the river Tader, according to Pliny.—Allo, a large and powerful town of Spain, in the latter belonging to the people called Beifi, according to Appian.

SEGEDIN, in Geography. See ZEGEDIN.

SEGEDUNUM, in Ancient Geography, a town on the confines of Dacia, on the river Tiberius, which belonged to the Jaziges.

SEGEDUNUM, one of the eighteen flattons on the wall of Severus, in English “Counfins-town,” being the first flatton reckoning from east to west, three miles five furlongs and one and a half chain from the next flatton to the west of it.

SEGEBERAD, in Geography, a town of Norway, in the province of Chriftiania; 24 miles W. of Chriftiania.

SEGELOCUM, in Ancient Geography, a town of the isle of Albion, in the 8th Iter of Antonine, between Lindum and Dunam. All our antiquaries agree in placing Segelocum, which is called Anglecum in 8th Iter, at Litchborough, between Lincoln and Doncaster, where Roman coins, altars, and other ancient remains have been found.

SEGELSBERGH, in Geography, a town of the duchy of Bremen; 5 miles E. of Bremen.

SEGERA, a town of Arabia, in the province of Hæsia; 5 miles S. of Medina.

SEGERS, or SEGERS, GERARD, in Biography. This eminent painter was born at Antwerp in 1550. He was first a pupil of Henry van Balen, but afterwards entered the school of Abraham Jansens, and had made considerable progress in the art when he went to Italy. On his arrival at Rome, he attached himself as a disciple to Bartolomeo Manfredi; and from him adopted a taste for the vigorous style of Michael Angelo Caravaggio. To the strength of his fancy, which he thus adopted, he added somewhat of the tone and colour he had brought with him from his native country; producing the powerful effect of candle-light, though often falsely applied in subjects which appertain to the milder illumination of the day. By skilful productions of this nature, he acquired very considerable fame, and was at length invited by the cardinal Zappar, the Spanish ambassador at Rome, to accompany him to Madrid. He accepted the invitation, and was prefented by the cardinal to the king, who received him in the most gracious manner, and engaged him in his service, with a considerable pension. He employed himself at Madrid in painting several historical subjects, and some musical conversation pieces, which were greatly admired; but after remaining there some years, the desire of reviving his native country induced him to request permission to retire. His renown had reached Flanders, and his fellow-citizens were impatient to possess some of his productions; yet, when he had arrived there, and executed some paintings in his strong manner, they, whole eyes had been accustomed to the pure brilliant hues, and clear contrasts of Rubens and Vandyke, were unable to yield him that harvest of praise to which he had been accustomed, and he was obliged to change his manner, and adopt a more tender and agreeable style. The facility with which he effected this change, proves his power over the materials of the art, and his judgment in his principles; and many of his latter pictures bear evident testimony in support of his general ability. His most esteemed productions are or was the principal altar-piece in the church of the Carmelites at Antwerp, the subject of which is the Marriage of the Virgin. Vandyke painted his portrait among the eminent artists of his country, which is engraved by Pontius. He died in 1651, aged 62.

SEGERS, DANIEL, was the younger brother of Gerard, and born at Antwerp in 1590. His taste leading him to design fruit and flowers, he was placed as a disciple with J. Bruegel. At the age of 16 he entered the society of the Jeluaists, and abandoned painting during his novitiate there, but when that term expired, he obtained permission of his superior to visit Rome, where his brother was then flourishing with distinction; and he also acquired considerable celebrity, by the fidelity and skill with which he imitated the beauty and variety of those objects of creation, as flowers, plants, and insects, which he chose for his models.

His productions were sought after with avidity, and his talents were not unproductive even to his convent, which received valuable tributes in return for those ingenious and entertaining treasuries of art. He appears, indeed, to have painted more for the benefit of the wily society to which he had attached himself, than for his private advantage; and when he had produced his most celebrated picture, at the command of the prince of Orange, it was presented to that monarch in the name of the society, which was sufficiently recompensed in return. He frequently painted garlands of flowers, as borders for pictures, which were filled up with historical subjects by the first painters. He died at Antwerp in 1663, aged 70.

SEGESTA, or Segesta, or Segelle, in Ancient Geography, a town in the interior of Sicily, W. of Panorma. It had a harbour and gulf of the same name. The harbour was called “Segellanorum emporium,” according to Ptolemy.

Thucydides represents it as a maritime town, and speaks of the navigation at Segella. This ancient name is said to have
have been given to the place by Egeillus the Trojan, who is
said to have been one of its founders; but the Romans pre-
tend that it was founded by Eneas. Its ruins are still
visible. The mineral waters of this place were called "Se-
gestus aquae," and they are placed in the Itinerary of
Antonine on the route from the Lilybaran promontory to
Tyndaris, between Drepanum and Parthenicum.

SEGETA Tigullium, Seferi, a town of Italy, in the interior
of Liguria, towards the east. It was anciently con-
derable.

SEGSTAN, or Seisital, in Geography, a province of Peru-
na, formerly called "Minrofe," from a fabulous tra-
dition that it was once under water, and that it was drained
in the short space of half a day by the Genii, comprehends
part of Ariana and the country of the Sarangeans, and is
bounded on the N. and N.W. by Khorasan, E. by Candah-
har and Zahledan, and S. and S.W. by Mekran and Ker-
man. The greater part of this province is flat, sandy,
and uninhabited. A wind blows for a hundred and twenty
days, during the hot months, with such violence as to overwhem
with clouds of dust, bones, gardens, and fields. Although
Segestian is now reduced to a deplorable condition, it once
rivalled in prosperity the most flourishing provinces of the
empire. The noble river Heermund (the ancient Eym-
ander), navigable for boats from Boit to Zarang, flows
through the extent of it, from the mountains of Hazara,
beyond Cabul to the lake of Zerrah. Capt. Christie, who
travelled in 1810 through the heart of Seistan, reports that
from Noofsky, in northern Mekran, to the banks of the
Heermund, the country was a mere desert, interfaced with
sand-hills, and that he did not see a single town, or even
village, in the way; the only inhabitants of this wild being
a few Balouchie and Pathan shepherds, who lived in tents
pitched in the vicinity of the springs. He reached the Heer-
mund in N. lat. 30° 24', E. long. 64° 16', and followed
the banks of that river for about seventy or eighty miles.
Its course lies through a valley, varying in breadth from
one to two miles, the defect rising on either side in per-
pendicular cliffs. The valley, irrigated by the waters of the
river, is covered with verdure and bruffwood. Our traveller
found an astonishing number of mixed towns, villages,
and at one of these, Kulcanpul, a noble palace in a tolerable
state of preservation. The remains of a city, named "Poolkee," he describes as immense. The Heer-
mund is four hundred yards wide, very deep; the water
being remarkably fine, and the banks cultivated for half a
mile on each side. The present capital of Seistan is "Doo-
fhak," supposed to be the fame with the ancient Zarang; and
now the residence of the prince of Seistan, situated in N.
lat. 31° 8'. E. long. 63° 10'; about eight or nine miles
from the river. It is small and compact, but the ruins cover
a vast extent of ground. It is populous, has a good bazar,
and the inhabitants, dressed in the Persian manner, appeared
more civilized than the other natives of the province, who
are either Pathan or Balouchie shepherds, men of wandering
life, and pitching their tents under the ruins of ancient pal-
ces. The country in the vicinity of the town is open, well
cultivated, and produces wheat and barley sufficient for ex-
portation to Herat; the palmarage also is good and abundant.
The revenues of the chief of Seistan amount to no more
than 80,000 rupees, and he can bring into the field about
3000 men. Twenty-five miles N. of Doofhak are the
ruins of a very large city, named "Peshawaran," and a few
miles beyond that the remains of another, called "Jouen."
Ferrah, or Perah, is distant fifty-five miles from Doofhak;
and it is described as a very large walled town, situated
in a fertile valley, on a river which flows into the lake of
Zerrah, or Zara, and nearly half-way between Candahar and
Herat.

Seistan is, at present, divided into a number of small in-
dependent states, governed by chiefs, who live in fortified
village, situated principally on the banks of the Heermund.
About ten days' journey from Doofhak is the city of Kuh-
ber, situated in the midst of the desert, fifteen days' march
from Kerman and sixteen from Yezd. The whole of the inter-
mediate space is an arid waste, interfaced with one or two
ranges of mountains. Through this desert is a path, by
which Carlists, or couriers, can go from Kerman to Herat in
eighteen days; but the risk of perishing is so great, that a
peron of that description demands 200 rupees for the car-

SEEGSTE, in Ancient Geography, a town of Ifria,
belonging to the Carith, according to Pliny. Strabo places it
in Pannonia, at the confluence of several navigable rivers,
so that the Romans establised their magazines in it, during
their war with the Dacians.

SEESTE, a town of Italy, in Liguria, S.E. of Portus
Dolphins.

SEGESVAR, in Geography, See Schesburg.

SEGETICA, in Ancient Geography, a town of European
Myria, or of Micia, of which Caflus gained posseffion,
according to Dions Caffius.

SEGZ, in Geography, a river of Ruffia, which forms a
communication between the lakes Siga and Viga, in the govern-
ment of Olonetz.

SEGZAR, in the Manufacture of porcelain and pottery,
are cafes formed of coarser clays, but which are capable of
sustaining the required heat without fusion; in which dif-
ferent kinds of earthenware are baked. See Porcelain
and Pottery.

SEGGERA, in Ancient Geography, a town of Africa
Proper, according to the Itinerary of Antonine.

SEIGIDA, a town of Spain, in Celtiberia. Steph.
Byz. and Strabo.

SEGILMESSA, in Geography, See Segulmessa.

SEGISA, in Ancient Geography, a town of Spain, in the
Iarragonensis, in the interior of the country of the Ba-
rilani.

SEGISAMA, and Segisama Julia, a town of Spain, in the
Tarragonensis, depending upon the Vaceanea, according to
Ptolemy. It was situated S. of Lacobriga, and E. of
Pallentia.

SEGLINGE, in Geography, a small island in the Baltic,
near the coast of Finland. N. lat. 60° 14'. E. long.
20° 30'.

SEGLORA, a town of Sweden, in West Gothland
25 miles E. of Gothenburg.

SEGMENT of a Circle, in Geometry, a part of a circle,
comprehended between an arc and its chord; or, it is a part
of a circle comprehended between a right line less than a
semi-diameter, and part of the circumference.

Thus the portion A F B A (Plate XII. Geome-
try, fig. 12) comprehended between the arc A F B and the
chord A B, is a segment of the circle A F B D, &c.; so is
also A D B A a segment comprehended between the arc
A D B and the chord A B.

As it is evident every segment of a circle must either be
greater or less than a semicircle, the greater part of the circle
cut off by a chord, i.e. the part greater than a semicircle,
is called the greater segment, as A F B; and the lesser part,
or the part less than a semicircle, the lesser segment, as
A D B, &c.
The angle which the chord A B makes with a tangent
L B, is called the angle of a segment. It is demonstrated,
that the angle included by a tangent to a circle and a chord, drawn from the point of contact, is equal to the angle in the alternate segment.

Some also call the two mixed angles comprehended between the two extremes of the chord and the arc, angles of the segment; but those are in reality the same with those of the chord and tangent.

**SEGMENT, Angle in the.** See Angle.

**SEGMENTS, Similar.** See Similar.

The height of a segment \( \mathbf{DE} \), and half its base, or chord, \( \mathbf{AE} \), being given, to find the area of the segment. Find the diameter of the circle. On this describe a circle, and draw the base of the segment \( \mathbf{AB} \); draw the radii \( \mathbf{AC}, \mathbf{BC} \); and find the number of degrees of the arc \( \mathbf{AB} \). From the diameter had, and its ratio to the periphery, find the periphery itself; and from the ratio of the periphery to the arc \( \mathbf{AB} \), and the periphery itself, find the length of the arc \( \mathbf{AB} \). This done, find the area of the sector \( \mathbf{ABCD} \); and that of the triangle \( \mathbf{ABC} \). Lastly, subtract the triangle from the sector, and the remainder is the area of the segment.

If the area of the greater segment \( \mathbf{AFA} \) were required, the triangle \( \mathbf{ABC} \) must be added to the sectors \( \mathbf{ACF} \) and \( \mathbf{BCF} \). For other methods of finding the area of a segment of a circle, we refer to Hutton's *Mensuration, p. 133.*

**SEGMENT of a Sphere.** A part of a sphere terminated by a portion of its surface, and a plane which cuts it off, passing somewhere out of the centre. This is more properly called a section of a sphere.

The base of such a segment, it is evident, is always a circle whose whole centre is in the axis of the sphere.

The solid content of a segment of a sphere is found, by multiplying the surface of the whole sphere by the altitude of the segment, and then dividing the product by the diameter of the sphere, and to the quotient adding the area of the base of the segment; or, if it be less than a hemisphere, thus: take the altitude of the segment from the radius of the sphere, and by the difference multiply the area of the base of the segment, and subtract this product, from that which will arise by multiplying the semi-axis of the sphere into the convex surface of the segment; then divide the remainder by 3, and the quotient is the solidity sought.

The latter method supposes the axis of the sphere to be given; if not, it may be found thus; let the altitude of the segment be called \( a \), and its semidiameter, \( r \), then will

\[
\frac{r^2}{2} \cdot \frac{2r}{a} = \frac{r^3}{a} + \frac{a^3}{2} + \frac{a}{2} \text{ and that shall give the axis sought.}
\]

See FRUSTUM, and SPHERE.

**SEGMENT, Resistance of.** See Resistance.

**SEGMENTS is sometimes also extended to the parts of ellipses, and other curvilinear figures.**

**SEGMENTS, Line of.** On Gunter's sector there are usually two lines, called *lines of segments,* they are numbered with \( 5, 6, 7, 8, 9, 10 \), and lie between the lines of lines, and those of superficies. They represent the diameter of a circle, so divided into one hundred parts, as that a right line drawn through those parts, and normal to the diameter, shall cut the circle into two segments, of which the greater shall have that proportion to the whole circle, which the parts cut have to one hundred.

**SEGMENT-LACEs, a denomination given by botanists to those leaves that are cut and divided into many furs or slices, as fennel, &c.**

**SEGMENTUM, among the Romans, an ornament of lace used by the women on their shoulders, which, according to some, resembled our shoulder-knots.**

Segmenta were likewise a kind of tessellated or Mosaic pavements, made up of pieces of various shapes and colours, but which had an uniform and regular arrangement.

**SEGMODIAL VALVES, in Anatomy, are little valves of the pulmonary artery; thus called from their resembling segments of circles, but more usually called semilunar valves.**

**SEGNA, in Geography, a sea-port town of Morlachia, on the coast of the Adriatic, declared a free port, and erected into a bishopric by the emperor Joseph II., in the year 1785. It is a free town, under the protection of Austria. The city is ill built, wofe paved, and weakly fortified. It lies on the brink of the sea, on a foundation of concreted ground, at the mouth of a narrow valley, surrounded by marble hills. Segna is supposed to have been formerly situated almost three miles farther from the valley, on a spot where are found traces of ancient habitations and funeral monuments. The sea seems to have covered the bottom of the valley as far as the city, which stood on the site of a hill, and formed a tolerable harbour. The walls of this city were not constructed before the 16th century; and this, together with other circumstamces, affords a further proof that Segna does not occupy the site of the ancient Senia. The wind from the mountains sometimes blows with such violence, that it is dangerous in winter to encounter it in the street. Horses loaded with fat are frequently thrown down in the market-place of Segna; and the roofs of houses, though covered with heavy flizes, are removed. When hurricanes occur, the ships that happen to be in the harbour run the greatest risk of being lost; nor are they preferred without great labour and expense. The sea in the month of the channel of Segna, oppositeto the valley, is hardly ever calm; but notwithstanding all these perils and disasters, the inhabitants had, about the beginning of the last century, fifty merchant-ships at sea; and they acquired wealth by exporting the corn, wood, wax, honey, tar, and iron of the Turkish state, on which they border, as well as the timber felled in the ancient forests of Vilchw; and by importing, besides many other articles of merchandise, salt, oil, and wine, for the supply of the interior provinces. At length, however, the inconvenience of their situation disconcerted their marine and commercial enterprises, so that at present Segna has but few ships belonging to it. Another damage was fupplied by this city, in consequence of the regulation made by the court of Vienna in 1741, which depriv'd it of 60,000 florins a year in money, 45,000 fls of cloth, and 20,000 measures of grain, given yearly by the emperor to the inhabitants of Segna, who were a warlike people, and formed a kind of barrier against the Turks on that side. When the Austrians took the country of Lika from the Turks, and formed all the inhabitants into militia, Segna lost its importance. The soil is so unproductive, that, with the utmost labour, it supplies scarcely provisions sufficient for two months in the year; and they are under a necessity of procuring water from a spring at the distance of twelve miles. The population of Segna is at present computed at less than 7000; and yet the people, amidst all their disadvantages, manifest a civility and politeness of manners, which are not met with in any other place of the Austrian coast, nor even among the Venetian subjects of their parts. N. lat. 45° 4'. E. long. 15° 3'.

**SEGNI, BERNARDO, in Biography, an early Italian historian and man of letters, was born at Florence about the close of the 15th century. He was educated at Padua, where he pursued with great avidity the study of the Latin and Greek languages. He then engaged in legal pursuits, which were interrupted by a commision from his father to manage some commercial business at Aquila. Re-
turning to Florence, he was employed in public affairs by the republic, and by duke Cosimo, who in 1541 sent him on an embassy to Ferdinand, king of the Romans. He was, in 1542, appointed confuol of the university of Florence, then in very high reputation. He wrote a history of Florence from the year 1527 to 1555, which in every respect is considered as one of the best productions of the age. It was seen by no one during his life, and was not printed till the year 1713, when it appeared, together with a life of Niccolò Capponi, gonfalonier of Florence, Signi's uncle. This writer likewise translated into the Italian language several treaties of Aristotle, which were printed at Florence in 1549-50. He died in 1559.

Segni, in Geography, a town of the Campagna di Roma, the fee of a bishop, under the pope. Organs are said to have been invented in this town; 25 miles S.E. of Rome.

Segni, in Ancient Geography, a people of Gaul, who are supposed to have occupied a territory, which is the site of a small town, called "Sinei," or "Signi," on the frontier of Namur, and to have founded it.

SEGNTZ, in Geography, a town of the duchy of Wurzburg, on the Main, 12 miles S.E. of Wurzburg.—Alto, a town of Germany, in the principality of Anspach; 4 miles S.W. of Mayrhohrnheim.

SEGNO, Ital., in Maffe, a sign or mark of reference, for the repetition of any strain, or portion of a strain. It is usuall y an S, the initial of signum or segno, dotted on each side, thus °; of more use in rondeaux than in any other movements. The sharp a, natural e, and flat b, are accen
tual signi, as in the diefs x, or double sharp. The paufe, or corona o, is a segno di filenter, as well as a final terminating sign. (See all these terms under their several heads.) The ° is likewise used in canons and catches written on a line, to mark the places where the several parts come in.

SEGO, in Geography, a city of Africa, and capital of the kingdom of Bambara, situated on the Joliba or Niger. Mr. Park, whose death we have now reason to lament, arrived at this city in his first African expedition; and to him we are indebted for the following account of it. He says, that it consists of a very large portion of the country, formed altogether a prospect of civilization and magnificence, which our traveller little expected to find in the bosom of Africa. From the best inquiries he could make, he had reason to believe, that Sego contained altogether about 30,000 inhabitants. The king of Bambara constantly refides in the largest quarter of the city, called Sego See Korro; he employs a great many slaves in conveying people over the river; and the money thus obtained, though the fare is only ten cowries for each person, furnishes a considerable annual revenue to the king. The boats on the Niger are of a singular construction, each of them being formed of the trunks of two large trees, rendered concave, and joined together, not side by side, but lengthways; the junction being exactly across the middle of the boat. They are, therefore, very long, and disproportionately narrow; for Mr. Park observed in one of them a group of a great many people, crossing from a ferry. It was at a village near this city that Mr. Park was ordered by the king to take up his abode; but the inhabitants being indigested, either from aversion or from fear, to accommodate him with lodging and entertainment, he was under a necessity of sheltering himself, in a form of thunder and rain, under a tree. For an account of the hospitable treatment he received on this occasion from a poor Negro woman, see the article Africa. When he received, on the third day of his abode, an order from the king to depart from the vicinity of Sego, Manfeng (the king) willing to relieve a white man in distress, sent him 5000 cowries, to enable him to purchase provisions in the course of his journey. The messenger added, that if Park's intentions were to proceed to Jenne, he had orders to accompany him as a guide to Sanfanbon. Sego is situated in N. lat. 14° 10' 30", W. long. 2° 26'.

SEGOBRIGA, in Ancient Geography. See Segorbe.

SEGDUNUM, a town of Galia Celtica, belonging to the people called "Rutani," or "Ruteni," according to Ptolemy. In the Peutingerian Table, it is called "Segodum," and it afterwards took the name of "Rutena," or "Ruteni," and at length that of Rhodes.

SEGOLTA REX, one of the Hebrew accents, usuall y anfwering to our fennifon, and marked with three points over a letter, thus ♫ or ♫.

SEGONTIA, in Ancient Geography, a town of Spain, in the Tarragonen, upon the route from Emerita to Saragossa, between Cadiz and Arcobrega, according to the Itinerary of Antonine.

SEGONTIA Parana, a town of Spain, in the Tarragones, belonging to the people called "Varduli." SEGONTIACI, a people of the ile of Albion, who inhabited with the Trimobantes, and were of the number of those who submitted to Caesar.

SEGONZAC, in Geography, a town of France, in the department of the Charente, and chief place of a canton, in the district of Cognac; 6 miles S.E. of Cognac. The place contains 2549, and the canton 12,386 inhabitants, on a territory of 222 ½ kilometres, in 19 communes.

SEGOR, in Ancient Geography, a town of Palestine, in the Pentapolis, at the southern extremity of the Dead sea. It escaped the destruction of the four other towns of the Pentapolis. Its first name was "Bala," but Lot having obtained permission to flee from Sodom, called it Segor, or the little town.

SEGORBE, in Geography, a town of Spain, in the province of Valencia, with the title of duchy, agreeably situated in a very fertile vale, abounding in grain and fruit, on a river of the same name, which there takes that of Murviedro or Murviedro. Its population consists of 12,000 families, or about 60,000 souls. Some people relying on the similarity of names, pretend that this is the ancient "Segobriga," which we find on many Roman medals; others, on the contrary, place that ancient town in Catalonia; and others in Aragon. Segorbe is the fee of a bishop, suffragan to Valencia, the diocese of which comprehends 43 parishes. The clergy of its cathedral are composed of four dignitaries, ten canons, twenty-four benefactors, and thirty-three chaplains. The town has four convents of monks, a convent of nuns, a seminary, a hospital, five hermitages, oratories or chapels; a provisor, who is at once official and vicar-general of the diocese; nine gates, and six squares. It abounds in fountains, three of which are public, and about forty in private houses. It was taken from the Moors in 1245, by James I., king of Aragon.
The cathedral church has some paintings of the school of Joannez, and of that of Ribalta. The church of the convent of nuns is of good architecture, and has some good paintings. The feminary is kept in the ancient house of the Jesuits. Antony Ximen, a poet in the commencement of the 16th century, and Juan Valero, a theologian of the beginning of the 17th century, were born in this town. At a quarter of a league from Segorbe stands the Carthusian monastery of Vel de Chirilo, founded by the infant don Martin, son and successor of Peter IV., king of Aragon. Here are some good paintings by Vergara, Camarou, Danofo, Joannez, and Orrante. The monks have enriched it with a paper manufactory at Altura, a village of about 1500 inhabitants, which belongs to them, and which is at a quarter of a league's distance between their monastery and Segorbe.

N. lat. 39° 58'. W. long. 6° 39'.

SEGORTIALACTA, in Ancient Geography, a town of Spain, in the Parragonensis, which belonged to the Arevaci. Po&mey.

SEGOSA, a town of Gaul, marked in the Itinerary of Antonine between Aqu and Bourdeaux. It is now the place called "Écoufré."

SEGOSTAEO, in Geography, a town of Russia, in the government of Kolovan; 44 miles W. of Krafnoarik.

SEGOVELLAUNI, or Segalauni, in Ancient Geography, a people of the interior of Gallia Narbonensis, in the vicinity of the Rhone. Phiny.

SEGOVIA, a town of Hitler Spain, south of Cauca; famous for its aqueduct, said to have been constructed in the time of Trajan.

SEGOVIA, in Geography, a town of Spain, in Old Castile, in which the arrangement of its buildings exhibits the figure of a ship, with the stern to the eait, and the prow to the west, commanding an immense rock, and appearing buried between two deep valleys, one lying to the north, and the other to the south. The first is watered by a stream, called Clamareo, which forms a junction with the Erofa, that waters the laff, on which are five handsome bridges. This river, whose banks are clothed with wood, formerly bore the name of Areva, whence the appellation of Arevaci was given to the inhabitants of these valleys. The city is surrounded with walls; and a range of towers, at equal distances, is planted on the ramparts. The number of houses has been estimated at 5000, but the population does not exceed 10,000 souls. The streets are almost all narrow and crooked, and irregularly paved. The four suburbs are on more even ground, and contain several manufactories. Segovia is the see of a bishop, suffragan of the archbishop of Toledo, whose diocefe includes the cathedral chapter of Segovia, the collegiate chapter of St. Idefonso, and 433 parishes. The cathedral chapter is composed of 8 dignities, 37 canons, 7 prebends, and 19 sub-prebends; and besides these, 23 chaplains are attached to the church. In Segovia are reckoned 24 parishes, a chapel of the hospital of the confraternity of St. John, and 21 convents for both sexes. This city is the residence of the intendent of the district, which assumes its name; and under the superintendence of a corregidor, an alcalde, and a fixed number of regidores. Here are a statitical society, the members of which assume the title of "friends of the country;" and a military school, destined for the instruction of young engineers. Segovia was once a commercial and opulent town, eminently distinguished for its cloth and woollen manufactories; and it has been calculated, that 44,100 quintals of wool were consumed in the looms of this town, and that 34,199 persons were employed by them; but its manufactures and trade declined, so that, in the 18th century, the fabrication of stuffs and cloths employed no more than 120 looms, in which only 4318 quintals of washed wool were consumed. Between 40 and 50 years ago, this manufacture revived; and in 1790 there was an addition of 63 looms, which employed 800 or 900 quintals of wool, and afforded occupation to 2400 manufacturers. This city has still a manufactory of delfi-ware, but it is of little importance. Among its public edifices we may reckon the mint, producing at present only copper, which is a handsome building, constructed in the 15th century by Henry IV., and in part re-edified by Philip II.; it is divided into two compartments, with simple Doric pillars, arranged in double rows, and on each side a tower supported on a piazza by ten columns;—the church of the Jeronimites of Parral;—the cathedral church, which presents a mixture of Gothic and Grecian architecture, though constructed in the 19th century, with the principal altar of marble, and having in the middle a flat statue of the Virgin, and several other ornaments;—and the alcazar, formerly the residence of the Caflilian kings, bearing the characters of venerable antiquity, where Alphonso the Wise composed his astronomical tables, and in which are apartments fretted with mosaic work, still fresh; and a series of 52 statues of painted wood, and each bearing an appropriate inscription. The noblest monument of Segovia is its aqueduct, which has been referred by some writers to a very remote antiquity, and ascribed to the architrets who built the Egyptian temple of Serapis; but which much more probably originated with the Romans, at an uncertain period, but perhaps with the authority of Licinius, Larcius, or Trajan. The materials are of rough free-stone. It commences at a large stone fountain, (about 50 paces from the town,) from whence it proceeds through an open canal towards the south. At its origin the fabric is erected on a long range of 75 arches, of which the first is 14 feet 6 inches in height; the last, which is at the convent of St. Francisco, is 33 feet 6 inches. At this point begins a double row of arches, supported one over the other, which run in the direction of east and west, and cross the valley and the place of Azoquejo; of these the greatest elevation is 80 feet 10 inches. The whole range comprehends 159 arches, supported on pilasters, most of which measure 6 feet 11 inches in the front surface, and 9 feet 4 inches on the interior side. The aqueduct terminates at the alcazar, after having distributed the greater part of the water through different quarters of the town. In modern times, this noble work of Roman architecture has been disfigured by the erection of several houses on its pilasters, a disposition highly injurious to the majesty of the original edifice. It is built of freestone blocks, which are placed one on the other, without any appearance of cement. Segovia was the native place of Alphonso de Ledefma, a good poet, who flourished at the commencement of the last century; of Domenico Soto, the son of a gardener, who published an essay "De Justitia et Jure," two books "De Naturae et Gratiae," and Commentaries on St. Paul's Epistles to the Romans. At Segovia was born the Jesuit Francis Ribera, who died at Salamanca in 1591, well known for the erudition and acumen displayed in his Commentaries on the minor prophets. Segovia is distant 46 miles N.N.W. of Madrid. N. lat. 41° 3'. W. long. 4° 1'.

SEGOVIA, Nueva, a town of the island of Luzon, founded in 1598, the see of a bishop, defended by a fort and a garrison; situated near the N. coast of the island; 250 miles N. of Manila.—Alfo, a town of Mexico, in the province of Bb.
viance of Nicaragua; 70 miles N.N.E. of Leon. N. lat. 13° 30'. W. long. 89° 56'.—Alfo, a town of South America, in the government of Caraccas, and province of Venezuela, founded by the Spaniards in 1552; 130 miles S.W. of Caraccas. N. lat. 8° 50'. W. long. 68° 16'.

SEGOVIA, Nueva, or Yare, a river of Mexico, in the province of Colta Rica, which runs into the Spanish Main, N. lat. 13° 10'. W. long. 83° 5'.

SEGURA, a river of Spain, which rises in the N. part of Catalonia, and joins the Ebro, on the borders of Aragon, near Mequinez.

SEGRAIS, John Regnault de, in Biography, a man of letters, was born of a good family at Caen, in 1624. He was intended for the church, but a courtier, charmed with the sprightliness of his conversation, carried him to Paris when he was about twenty years of age, and placed him with Mademoiselle de Montenier, who first gave him the title of her almoner in ordinary, and then of her gentleman in ordinary. He became known to the literary world by his lyric and pastoral poetry, and in 1656 he published a collection of pieces of this kind, together with some little stories called "Nouvelles Françoises," by which he obtained considerable reputation. He was thought to have been particularly happy in his Eclogues, in which he attempted to unite elegance with the simplicity appropriate to his subject. He aimed at a higher strain in his metrical translation of Virgil's Æneid, which was well received by the public, though it was not free from faults, which were heavy drawbacks on its merit. The reputation of Segrais gave him admission, in the year 1663, into the French Academy. In 1672 he quitted Mademoiselle de Montenier, and was domiciliated with Madame de la Fayette, whom he visited with his advice and correction in the composition of her romance of "Zayde," and he engaged his friend the learned Huet to prefix to it his Dissertations on Romances. He at length retired to his native city, and married a rich heiress, who was his cousin. Being now at his ease, and somewhat incommoded with deafness, he declined engaging in the education of the duke of Maine, observing that experience had taught him that at court both good eyes and good ears are requisite. He collected the dispersed members of the academy of Caen, and gave them an apartment to meet in. He died in 1701, at the age of 70.

After his death, there appeared his translation of Virgil's "Georgics," and a miscellany of anecdotes and literary opinions.

SEG, in Geography, a town of France, and principal place of a district, in the department of the Maine and Loire; 18 miles N.W. of Angers. The place contains 558, and the canton 9247 inhabitants, on a territory of 206 kilometres, in 15 communes.

SEGRET, a term used in Heraldry for a griffin, when drawn in a leaping posture, and displaying its wings, as if ready to fly.

SEGREGATA, Polymammia, in Botany, the last order of the class Syngenesia, in which the flowers are doubly compound, each floret, or assemblage of florets, having a partial calyx.

SEGRO, in Geography, a town of Naples, in Capitanata; 10 miles N.E. of Manfredonia.

SEG, in Rural Economy, provincially the name applied to fedges, or fedge-grais.

SEGSTADT, in Geography, a town of the duchy of Wurzburg; 5 miles E. of Hasturt.

SEGUITANO. See Chequetan.

SEGUE, in Italian Muses, is often found before ario, allegro, allettajab, amon, &c., to acquaint performers that such movements immediately follow the last bar of the preceding piece, over or after which such notice is written. But if the words si pie, or ad libitum, are added, they imply that such movements may be performed or not, at pleasure.

SEGUIZENZA, Ital. in Ecclesiastical Music, is a kind of hymn sung in the Roman church, generally in prose. The sequenza are generally sung after the Gradual, immediately before the Gospels, and sometimes in the vespres before the Magnificat. They were formerly more used than at present. The Romish church has retained three sequenza, called by the Italians, il tre sequenze dell'anno: which are, "Lauda Sion salvatorum, &c., "Vittima pacifali laudes, &c., "Veni Sancte Spiritus." These are few, in many places, to figurative music. There is also one beginning "Dies ira, dies ille," in the funeral service, which has been admirably set by all the great composers a cappella of Italy, and among the Catholics of Germany.

Seg. Cal. Perianth inferior, spreading, permanent, of five, oblong, coloured, concave leaves. Cor. none. Stam. Filaments numerous, capillary, spreading, longer than the calyx; anthers oblong, flat-tipped. Pist. Germen superior, oblong, compressed, membranous at the top, thicker on one side; style very short, at the thicker side of the germen; stigma simple. Peric. Capsule oblong, augmented by a very large wing, thicker on the straight side, with three smaller wings on each side at the base, of one cell, not gaping. Seed solitary, oblong, smooth.

1. S. americana. American Seguieria. Linn. Sp. Pl. 747. Jacq. Amer. 170. "Pict. t. 82."—Stem climbing, prickly. Leaves lanceolate, emarginate. Chilters branched, leafy.—Native of South America, especially in woods and copses near Carthagea, flowering in September. The stem of this shrub is generally twelve feet in height, with very long, round, green flowering branches, by which it is supported. Leaves alternate, slaked, ovate, entire, shining, with recurved prickles. Flowers in terminal clusters, white, smell disagreeably. The unripe fruit is said to resemble that of Scutidaca.

SEGUN ISLAND, in Geography, a small island on the coast of Maine, in Casco bay.

SEGULAM, one of the Fox islands, in the North Pacific ocean. N. lat. 53° 35'. E. long. 187° 50'.

SEGUNTIAS CIVITARUM, in Ancient Geography, a town of Spain, in Celtiberia. Livy.

SEGUR, in Geography, a town of France, in the department of the Corrèze; 12 miles W. of Uzerche.—Alfo, a town of France, in the department of the Aviron; 12 miles E.S.E. of Rhodes.
SEGURA, a town of Spain, in the kingdom of Aragon; 23 miles S.E. of Daroca.—Alfo, a river of Spain, which rises in the mountains of Murcia, 10 miles S.S.E. from Segura de la Sierra, traverses the province of Murcia, and the south part of Valencia, and runs into the Mediterranean, 16 miles S.S.W. of Alicante.—Alfo, a town of Spain, in Guipuscoa; 18 miles S.S.W. of St. Sebastian.—Alfo, a town of Portugal, in the province of Beira, near the frontier of Spain; 6 miles N. of Rofmarilha.—Alfo, a town of Spain, in Estremadura; 25 miles S.E. of Xeres de los Caballeros.

SEGURA de la Frontera, a town in Mexico, in the province of Tlaxcala, built by Cortes; 50 miles S. of Tlaxcala.

SEGURA de la Sierra, a town of Spain, in Murcia; 60 miles S.W. of Chinchilla.

SEGUS, a town of France, in the department of the Upper Pyrenees; 4 miles N. of Argeloz.

SEGUS, in Ancient Geography, a river of Germany, the banks of which were inhabited by the Sicambri, according to Caesar and Tacitus.

SEGUSIANS, the inhabitants of Segusia. Their country, in Cisalpine Transpadane Gaul, towards the sources of the Duria Minor, formed a small state, of which Cottius was the only king upon record. This prince retired to the mountains, and escaped subjection to the Roman yoke by his obfuscity. But he fought security in an alliance with the Romans, and with this view he flattered Augustus by assuming the name of Julius Cottius. He made many efforts for rendering the passage of the Alps practicable in that part which he occupied. Claudius, upon augmenting his small territory, gave him the name of king. After his death, Nero united this country to the empire; but the memory of Cottius was long resented in the country which he governed. In the time of Ammiianus Marcellinus, that is, about the year 370 of our era, the tomb of Cottius was shown at Segusia. One part of the Alps took its name, "Cottian," from him.

SEGUSIANS, or Seyfisani, a people of Gallia Celtica, or Lyonnaesis. To the N. were the Ceduica and Secquiri, to the E. and N. the Allobroges, and to the W. the Averni. Pliny says, that these people were dependent on the Ceduici in the time of Caesar; but that they rendered themselves independent under the empire of Augustus.

SEGUSIO, Szue, a town formerly not inconsiderable, in Transpadane Gaul, among the mountains, on Duria Minor. Under the Romans it obtained the title of municipal. In later times, its rulers were designated by the title of marquis. At present it is comprehended in Piedmont. Among other things found in this place is the triumphal arch on which were inscribed the appellations of the people who were subject to Cottius in the time of Augustus. See SEGUSIANI.

SEGUSTERO, Sistieron, a town of Gallia Narbonensis. From its Celtic name we are led to presume that it existed, or at least that its territory was inhabited, before the Romans came into Provence. Some have thought that this town depended on the Avantici.

SEGWAH, in Geography, a town of Hindoostan, in Baghana; 20 miles S.S.E. of Damaun.

SEHALOUR, a town of Hindoostan, in Myoure; 36 miles N. of Seringapatam.

SEHAN, a town of Arabia, in Yemen; 3 miles W.N.W. of Doran.

SEHAURUNPOUR, a town of Hindoostan, and capital of a circar, to which it gives name, between the Jumnah and the Ganges, in the lubah of Delhi; 86 miles N. of Delhi. N. lat. 30° 41'. E. long. 77° 15'.—Alfo, a circar or province of Hindoostan, in the subah of Delhi, bounded on the N. by mountains, which separate it from Thibet, on the E. by the Ganges, which divides it from Sumbul, on the S. by the district of Delhi, and on the W. by Sirhind, from which it is divided by the river Jumnah. Its chief towns are Seharunpour, Merrett, and Hurdwar. It is about 90 miles from E. to W., and nearly the same from N. to S.

SEHESTEN, a town of Prussia, in the province of Natangen; 54 miles S.E. of Konigberg.

SEHIMA, in Botany, so called by Forskål, from its Arabic name; a genus of that author’s, separated from Ijdehunum, but apparently without sufficient reason.

SEHIRMAN, in Geography, a mountain of Arabia, in the province of Yemen; 8 miles S. of Kataba.

SEHAN, a town of Seeelatan, on the Sinde; 66 miles N.E. of Nusfepour. N. lat. 26° 5'; E. long. 69° 16'.

SEIAL, a town of Persia, in the province of Adirbeizan; 50 miles S.E. of Ardebil.

SEJANT is a term used in Heraldry, when a lion, or other beast, is drawn in an effcuteon, fitting like a cat, with its fore-feet straight.

SEJANUS, AElius, in Biography, celebrated in the history of Rome for the tyranny of his administration, was a native of Vulfini, in Estruria. His father, Seius Strabo, a Roman knight, was commander of the praetorian guards in the reigns of Augustus and Tiberius. AElius, when young, attached himself to Caius Cæsar, the grandson of Augustus. After the death of that prince, and of Augustus, he was associated with his father in his command, by Tiberius, with whom he refe to great favour, and was appointed governor to young Drusus. When the theatre of Pompey was destroyed by fire, the emperor, at the time that he declared his intention of rebuilding it, pronounced an eulogy on Sejanus before the senate, on which that servile body decreed him a statue, to be placed in the new edifice. Having by his artifices and dissimulation obtained a complete ascendency over the mind of Tiberius, he applied himself to strengthen the fabric of his power, and pave the way to higher honours. With this view he ingratiated himself as much as possible with the praetorian guards, and he created a great personal interest in the senate, by means of his recommendations to lucrative places, and he is said to have secured the wives of many men of high rank by secret promises of marriage. The imperial family being, as he thought, a confiderable obstacle to his projects of ambition, he determined upon their destruction; and beginning with Drusus, the son of the emperor, who had manifested a jealousy of his influence, he entered into a criminal intrigue with his wife Livia, the sister of Germanicus, by means of whom he was supposed to have caused a false poison to be administered to that prince, which occasioned his death. He next endeavoured to persuade Tiberius to quit Rome, and retire to a life of repose, that the whole care of government might devolve upon himself, and that nothing should reach the emperor’s ears but through a channel subject to his control. This he effected in the twelfth year of Tiberius’s reign, and from that moment Sejanus was master of Rome. The dislike manifested by the emperor to the widow and family of Germanicus was inflamed by the minister, till his perfecution of them ended in the banishment and death of Agrippina and her two sons. Every kind of homage was now paid to the minister, Rome was crowded with his statues, and the senators all vied with each other in adulation of the favourite. At length Tiberius began to be suspicious of his designs,
but for a time he concealed his suspicious in his own breast, and even while under the fear of danger, he conferred upon his minister additional marks of his favour, making him his colleague in the confuishment. He however gradually withdrew from him the tokens of his confidence, and finding that the symptoms of this change had greatly diminished the crowds that attended his levees, he proceeded, though with much caution, to the measures for his destruction. He now appointed another commander of his pratoiars. Sejanus, knowing the extent of his own guilt, began to be alarmed; he called together his friends and followers, and held forth to them the most flattering promises, and having increased the number of his partisans, formed a bold conspiracy, resolved by any means to seize the sovereign power. A powerful league was formed with alorning rapidity, and great numbers of all descriptions, fanatics as well as military men, entered into the plot. Among these, Saturnus Secundus was the confidential friend and prime agent of the minister, who, for reasons that are not known, resolved to betray his master. For this purpose he addressed himself to Antonia, the daughter of Antony the triumvir, the widow of Drusus, and the mother of Germanicus. When this illustrious woman, who was highly esteemed by the people, as well as honoured by the court, heard the particulars, she sent dispatches to the emperor by one of her slaves. Tibetrius was alonnedi, but not at all dismayed: the danger increased, and he determined to take decisive measures. He sent Macro to Rome with a special commission, and giving him ample powers that might be adapted to all emergencies. Early in the morning of the 15th, before the kalends of November, a report was spread that letters had arrived at Rome, with the view of augmenting still farther the honours of Sejanus. The senate was summoned to meet in the temple of Apollo, near the imperial palace. Sejanus attended without delay, and a party of pretorians followed him. Macro met him in the vestibule of the temple. He approached the minister with all demonstrations of profound respect, and taking him aside, told him not to be surprised that he had not received a letter from the emperor himself, but, says he, I am this day to deliver the emperor’s orders. Sejanus, elated with joy, expecting some unlooked-for dignity, entered into the senatus, and Macro followed. He opened his commission by reading a long letter in the senate, to the confuls from Tibetrius, which concluded with an order to seize his person; instantly the whole assembly loaded with insults and reproaches the man at whose feet they lately bended, and the people began to throw down and treat with every indignity the statues before which they had been accustomed to offer sacrifices. His person was seized, and thrown into prison, and being accused of high treason, he was condemned without a single defender. On the same day he was executed, and his body thrown into the Tiber. A massacre of his relations took place, and even his infant children were inhumanly butchered. This catastrophe took place in the year 31 of the Christian era, and it furnished Juvenal a fine instance of the miscibility of fortune, of which he took advantage in his tenth satire.

SEIBERSHOLZ, in Geography, a town of Bavaria, in the principality of Aichfatt; 3 miles N. of Aichfatt.

SEIBERSTORF, a town of Austria; 8 miles N.E. of Ebenfurth.

SEIBO, or Zeybo, a town of the island of Hifpanola; 50 miles E.N.E. of St. Domingo.

SEIBOUSE, a river of Algiers, which runs into the Mediterranean, near Bona.

SEICHES, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Marmande; six miles N.E. of Marmande. The place contains 1,351, and the canton 13,546 inhabitants, on a territory of 230,000 square kilometres, in 20 communes.—Also, a town of France, in the department of the Maine and Loire, and chief place of a canton, in the district of Baugé; nine miles W. of Baugé. The place contains 1,364, and the canton 996 inhabitants, on a territory of 245,000 square kilometres, in 13 communes.

SEIDEN, a town of Períia, in the province of Laris; 25 miles N. of Lar.

SEIDE. See Saida.

SEIDENBACH, a town of Germany, in the principality of Coblenz; 9 miles W.S.W. of Bayreuth.

SEIDENBERG, a town of Lutich, in which are manufactories of cloth and knit stockings; 8 miles S.S.E. of Gorlitz.

SEIDENSCHWANZ, a town of Bohemia, in the circle of Boleflau; 8 miles N. of Turnau.

SEIDENSTETTEN, or SEITENSTETTEN, a town of Austria; 9 miles N.W. of Waidhoven.

SEIFERSDORF, a town of Bohemia, in the circle of Boleflau; 5 miles S. of Krottan.

SEIG, a town of Hindoustan, in Bahar; 15 miles S. of Bahar.

SEIGNH, a town of Hindoustan, in Bahar; 31 miles N. of Hdyppour.

SEIGN, a fortress of Dalmatia, in the territory of Spalatro; 16 miles N.E. of Spalatro.

SEIGNELAY, a town of France, in the department of the Yonne; 6 miles N. of Auxerre.

SEIGNEUR, or SEIGNIORS, Lord. See SIRE, SIEUR, MONSIEUR, LIGORD, &c.

SEIGNORY, DOMINION, in our Law, is used for a manor or lordship.

SEIGNORAGE, or SEIGNORAGE, a right or duty belonging to a seigneur, or lord.

SEIGNORAGE is particularly used for a duty belonging to the prince for the coining of money, called aloceineage, (which see), and in the bale Latin monetaodium. See RE-

MEDY FOR THE MASTERS OF THE MINT.

This duty is not always the same, but changes according to the pleasure of the prince, and the occasions of state. It is in some measure for the discharge of this duty that alloy was invented; that is, the mixture of other metals with gold and silver.

Under our ancient kings, for every pound of gold brought in the masts to be coined, the king’s duty was five shillings; one shilling, and sometimes eighteen pence, of which went to the matter of the mint. Under Edward III. the feignorage of every pound weight of silver was eighteen pennyweight, which was then equivalent to a shilling. Under Henry V. the king’s feignorage for every pound of silver was fifteen pence. At present, the king claims no feignorage at all, but the subject has his money coined at the public expense; nor has the king any advantage from it, but what he has by the alloy.

In France, under Philip Augustus, the feignorage was one-third of the profit made by the mint; St. Louis fixed it at one-sixteenth part of the value of the money coined; king John, at three livres the mark of gold; Charles VII. by reason of the distempered state of his finances, raised it to three-fourths of the value; Louis XIII. fixed it at six livres the mark, or eight ounces of gold, and ten fols the mark of silver. Louis XIV. took away the right of feignorage in 1679, though it was re-established in 1689, on the foot of seven livres ten fols the mark of gold, and twelve fols fix deniers the mark of silver.
SEI

It must be observed, that for the levying of this duty of feignorage, the just value of the money is augmented by the value of the duty.

SEIHAN Dag, in Geography, a mountain of Turkish Armenia; 36 miles S.S.E. of Erzurum.

SEIHOUN, a river of Caramania, which runs into the Adana, at Pedendo.

SEIJAT, a town of Asiatic Turkey, in the province of Diarbekir; 6 miles N.E. of Diarbekir.

SEIKS. See Siks.

SEIL, a small island near the coast of Scotland. N. lat. 56 16'; W. long. 5 37'.

SEILA. See Zeila.

SEILAND, a small island in the North sea, near the coast of Norway. N. lat. 70 20'.

SEILHAC, a town of France, in the department of the Corrèze, and chief place of a canton, in the district of Tulles; 6 miles N.W. of Tulles. The place contains 1,271, and the canton 11,355 inhabitants, on a territory of 237½ kilometres, in 9 communes.

SEILLAN, a town of France, in the department of the Var; 10 miles N.E. of Draguignan.

SEILLE, a river of France, which runs into the Saône, 4 miles S.W. of Cluny, in the department of the Saône and Loire.—Allo, a river of France, which runs into the Scheldt, above Valenciennes.

SEIM, in Agriculture, a term used by the farmers of Cornwall to express a certain determinate quantity of seaweed, which they use as manure to their lands.

They dredge this up on the sea-coasts, and carry it as far towards the lands where it is to be used, as they can by water. At the landing-place the farmers bring a train of horses to receive it; each horse carrying a team, that is, a team consisting of thirteen gallons. The land-carriage of this kind, in Cornwall alone, is supposed to cost thirty-two thousand pounds annually; and yet the farmers find abundant encouragement to continue the use of it, because it is so rich a manure.

SEIMAN, in Geography, a town of Asiatic Turkey, in Natalia; 48 miles N.N.E. of Alah Sehr.

SEIMARIEH, a town of the Arabian Iрак, on the Euphrates; 42 miles W. of Korna.

SEIME, a town of Nubia, which affords good water. N. lat. 22 15'; E. long. 30 12'.

SEIMOUR, a river of Hindooftan, which runs into the Jamna, 70 miles below Etawah.

SEIN, a small island near the coast of France, in the department of the Finisterre, the coasts of which are dangerous on account of its rocks and shallows; 28 miles S.S.E. of Ulhant. N. lat. 48 2'; W. long. 42 2'.

SEINE, a river of France, which rises about two leagues S. of Aignay-le-Duc, in the department of the Côte d'Or, and runs into the English Channel at Havre de Grace.

SEINE, a town of France, in the department of the Var, situated on a tongue of land, which runs into the sea; 3 miles S. of Toulon.

SEINE, a department of the northern region of France, formed of the line of France, situated in 48° 50' N. lat., containing 24 square leagues, on 452½ kilometres, and 629,763 inhabitants, and divided into three circles or districts, 20 cantons, and 79 communes. The circles are St. Denis, including 36 communes, and 42,984 inhabitants; Sceaux, with 24 communes, and 39,923 inhabitants; and Paris, comprising 12 cantons, in one commune, and 546,856 inhabitants. The contributions in the 11th year of the French era, were 22,499,486 francs, and the expenses charged upon it 1,819,941 francs 34 cents. The capital is Paris. According to Halleinfratz, its length is six and breadth five French leagues. Its circles are eight, cantons 17; and population 947,472. This department is diversified with plains and eminences; its soil is of various qualities, and in some parts moderately fertile. It abounds with fowls of all kinds, especially in the vicinity of Paris.

SEINE, Lower, a department of the northern region of France, formed of Roumois and the territories of Caux and Bray, and bounded on the N.W. by the English Channel, on the E. by the departments of the Somme and the Oise, and on the S. by the departments of the Eure and the Calvados, from both which it is mostly separated by the river Seine. It is situated in 49° N. lat., and contains 67,473½ kilometres, or 207 square leagues, and 642,773 inhabitants. It is divided into five circles, 50 cantons, and 987 communes. The circles are, La Havre, containing 117,733 inhabitants, in 125 communes; Yvetot, with 120,222 inhabitants, in 202 communes; Dieppe, having 166,082 inhabitants, in 222 communes; Neufchatel, with 82,506 inhabitants, in 200 communes; and Rouen, with 207,228 inhabitants, in 200 communes. Its contributions in the year 11, were 9,105,417 fr. and expenses 575,526 fr. 33 cents. Its capital is Rouen. According to Halleinfratz, its length is 35 and breadth 50 leagues; its number of circles is seven; and of cantons 64; and its population comprehends 559,400 inhabitants. This department affords abundance of grain, fruits, and pastures.

SEINE and MARNE, a department of the same region of France with the former, formed of a portion of French Gatois, and of Upper and Lower Brie, and bounded on the N. by the departments of the Oise and the Aisne, on the E. by the departments of the Marne and the Aube, on the S.E. by the department of the Yonne, on the S. by that of the Loiret, and on the W. by the departments of the Loiret, and of the Seine and Oise. It contains 617,258 kilometres, or 306 square leagues, and 298,515 inhabitants. It is situated in 48° 45' N. lat., and is divided into five circles, and 561 communes. The circles are Melun, comprising 55,830 inhabitants, in 107 communes; Coulommiers, with 49,420 inhabitants, in 80 communes; Mâcon, having 88,441 inhabitants, in 164 communes; Fontainbleau, with 15,964 inhabitants, in 104 communes; and Provins, having 47,190 inhabitants, in 106 communes. Its contributions in the 11th year of the French era, were 5,126,616 fr. and expenses 507,648 fr. 33 cents. The capital is Melun. According to Halleinfratz, the length of this department is 32, and its breadth 16 French leagues; its number of circles is five; and of cantons 37; and its population is 296,497. This department is diversified with forests, cultivated tracts, and pastures.

SEINE and OISE, a department of the same region of France, confining of a portion of Vexin-François, of Hurepoix, de Mantois, &c. and bounded on the N. by the department of the Oise, on the E. by the department of the Seine and Marne, on the S. by that of the Loiret, and on the W. by the departments of the Eure, and of the Eure and Loire. It contains 588,030 kilometres, or 286 square leagues, and 529,523 inhabitants. It is situated in 48° 30' N. lat., and is divided into five circles, and 566 communes. The circles are Mantes, including 59,279 inhabitants, in 127 communes; Pontoise, with 91,088 inhabitants, in 165 communes; Ver-Salles, having 163,349 inhabitants, in 195 communes; Corbeil, with 56,507 inhabitants, in 56 communes; and Etampes, with 58,860 inhabitants, in 111 communes. Its contributions in the year 11, were 7,312,659 fr. and its expenses 448,928 fr. 62 cents. The capital is Ver-Salles. According to Halleinfratz, the length of this department is 24, and its breadth 16 French leagues.
It is plain, from Avicenna, that this fetum, or setum, is no other than that species of acacia, which, from its producing our gum arabic, is called the gum arabic 

It is plain, from Avicenna, that this fetum, or setum, is no other than that species of acacia, which, from its producing our gum arabic, is called the gum arabic tree.

SEITIL, in Commerce, a wine measure at Vienna; 168 feet = 70 kopfen = 40 maass = 4 viertels = an eimer; and 30 eimers = a dreckling, and 32 eimers = a fuder of wine. The contents of a maass is 71/2 French cubic inches, or 86 English ditto, or 3 English pints nearly; to that one eimer = 15 English gallons.

SEIT'SAARI, in Geography, an island of the Baltic, five versts long, and about half as much in breadth, distant 95 versts from St. Petersburg, and 75 from Vyborg. The land-boats here reach as far as to the Peterburg channel, and, being invisible from their lying under water, are liable to dangers in dark nights, that in this place alone not fewer vessels have been lost than in all other parts of the gulf of Fland together. The land is everywhere unfruitful; though in some of the marshes there is a slight crop of hay. Great numbers of eels and eel parrch are caught here. The herring and seal fisheries are also considerable. The inhabitants compose about 20 families. Here is a little

SEITLENHOFF, a town of the duchy of Carniola; 3 miles N. of Weixelburg.

SEITZ, a town of the duchy of Stiria; 6 miles N.E. of Gilley.

SEJUR, a river of Syria, that rises a little N. of Antab, and after a course of about 30 miles through a plain deriving its name from it, loses itself in the earth.—Alfo, a town of Syria; 15 miles S. of Antab.

SEIX, a town of France, in the department of the Arriage; 7 miles S. of St. Giens.

SEIZE, SEIZE, or Seije, Ty, in Sea Language, is to join two ropes, or the two ends of one rope, together, &c. by several clove turns of small rope, line, or linen-yarn, round them, with two or more cross-turns.

Throat-feising, is the first feizing clapt on where a rope or ropes cross each other; see RIGGINS, Plate No. 11. fig. 16, at 5.

Middle-feising, is a feizing between a throat and end-feising, as at 6.

End-feising, is a round feizing near the end of a rope, as at 7, on the same plate.

Eye-feising, is a round feizing next the eye of a throud, &c. RIGGINS, Plate II. fig. 15, at 9.

The feizing, seizing, or seafen of a boat, is a rope tied to a ring or little chain in the fore-part of the boat, by which means it is fastened to the side of the ship.

SEIZING, in Falconry, is when an hawk grips her prey, or any thing else, fast between her claws.

SEIZURE, in Commerce, an arrest of some merchandise, unmoveable, or other matter, either in consequence of some law, or by some express order of the sovereign.

Contraband goods, those fraudulently entered, or landed without entering at all, or landed at wrong places, are subject to seizure.

In seizes among us, one half goes to the seizor, or informer, and the other half to the king. In France, half the painted linen, &c. seized, used to be burnt; and the other half sent abroad; but in 1715, by an arret of council, the whole was ordered to be burnt.

SEKI, in Geography, a town of Japan, in the island of Nippon; 20 miles S.S.W. of 1 xo.

SEKIALLE, a town of Japan, in the province of Nedsjed; 300 miles E. of Median.

SEKIS, a town of Arabia, in the province of Gold Coast, in the district of Agoune, which has an English factory.

SEKIN,
SEKIN, a town of Asiatic Turkey, in Caramania, 30
miles S.W. of Seodickeh.
SEKARA, a town of Africa, in the kingdom of
Wangara, on the Niger; 640 miles E. of Oama. N. lat.
45° 30'. E. long. 18°.
SEKOOBOOM, a small island in the Soooloo Archipel-
lago. N. lat. 5° 2'. E. long. 120° 20'.
SEL, Le, a town of France, in the department of
the 11e and Vilaine, and chief place of a canton, in the dis-
trict of Redon; 7 miles N.N.E. of Bain. The place con-
tains 3477, and the canton 4971 inhabitants, on a territory
of 1329 square miles, in 7 communes.
Sel, in the Materia Medica of the Ancients, a name given
to the fruit of an Indian plant, resembling the cucumber
in its manner of growth, but bearing a fruit like a pita-
chia-nut.

There are three of these fruits mentioned by the Arabian
writers, the 

cel, fel, and fel.

They tell us expressly that the bel and fel, as also the fruit
fel, were not the fruit of a tree, but of a plant, and that
of the creeping kind. It is very probable, that the other
fel of Avicenna is the root of the nymphia indica, which
he mentions in the chapter of nauph, as possessing the same
virtues which he attributes to this sort of fel, or the same
with those of mandrake.

SELA, in Ancient Geography, a town of Palestine, in the
tribe of Benjamin, according to Joshua. Here Saul was
interred in the tomb of his father Cic.—Afe, a river of
Peloponnesus, the mouth of which is placed by Ptolomy on
the coast of Melfenis, between the promontory Cyprinum
and the town of Pybus.

SELABINA, in Geography, a town of Hungary, 4
miles S.W. of Kobenhof.

SELACHLEA, a town of Abyfinia; 20 miles E. of
Sire.

SELAGEREH, a town of Affam, on the Burram-
pooter; 60 miles N.W. of Ghergon.

SELAGNOIDES, in Botany, the name of a genus of
mofles in the arrangement of Dillenius, a species of lyco-
podium; the characters of which are these: the capsules
are produced in the ax of the leaves, in the manner of those
in the felago, but they are of a different form, being trico-
ceous, and sometimes quadricepsceous, and opening, when
mature, into so many valves.

Of this genus of mosses we have only one known species,
which is the prickly Selagno, commonly called feeding
mountain moss. This is found in the mountainous parts
of Yorkshire, and in Wales, and loves rocky and moil
places.

SALAGO, an ancient generic name in the works of
Philo, who observes that the plant so called was in great
repute among the Celtic nations; its juice being expressed
and used by the Druids as a remedy for many disorders,
especially for diseases in the eyes. The name indeed (fays
De Theis) is expressive of this latter quality, being derived
from the Celtic words fel, light, and jack, good or balmy.
The celebrated hall of Fingal, recorded in Ollin's poems,
ought its appellation to the fame source, Selina meaning
beautiful to behold, belle-ce. Selago has also been thought to
be derived from felago, to choose; the Druids having gathered
or selected it both for medicinal and religious purposes. It
is impossible to make out the reasons which induced Linneus
to apply this name to the genus under consideration, which
appears to have nothing in common with the celebrated luc-
and sometimes on all of them, and an orange spot at the mouth of the tube. *Braétona alternata*, ovate, large. It is valuable not so much on account of its beauty as its fragrance. Linnaeus described it under the name of *Lippia ovata* from a dried specimen, which may account for his laying the flowers are of a dark-violet colour. M. L'Her
tier first referred it to *Selago*; in doing which, Mr. Curtis observes, it would have been better to change the specific name to *bracteata*, its floral leaves or bracteas constituting the most prominent feature of the plant.

*Selago*, in Gardening, furnishes plants of the shrubby and under-shrubby kinds, of which the species cultivated are; the five-leaved selago (*S. corymbosa*); the linear-leaved selago (*S. purpurea*); and the ovate-headed selago (*S. ovata*).

**Method of Culture.**—These plants may be increased by cuttings and layers. The cuttings should be made from the young under-stems, and be planted out during the summer months in a bed of fresh earth, covering them close with a bell or hand-glass, shading them from the sun, and refreshing them now and then with water. They should be gradually hardened, and then transplanted into small pots, placing them in the thickest till they have taken root. The layers may be laid down in the autumn or spring, and when well rooted be taken off and planted out in pots, as above.

The plants should afterwards be placed out with other hardy greenhouse plants, and about the end of October removed into the dry house. They only require protection from frost, being treated in the same manner with the harder fort of greenhouse plants.

They afford much ornament and variety in greenhouse collections, among other similar plants.

**Selah**, in Scripture Criticism, a word which occurs no less than seventy times in the Hebrew text in the Psalms, and which has occasioned great difficulty to the critics. The Septuagint renders it ἀκρόστιον, q. d. a psalm in fingling; and this, it must be owned, was greatly wanted before the Psalms were divided into verses.

**Selam** in Geography, a town of Egypt, on the left bank of the Nile; 6 miles N. of Siut.—Also, a town of Mexico, in the province of Yucatan, near the coast; 45 miles N.W. of Merida.

**Selame** is an island, or rather cluster of small islands, near the coast of Arabia, at the entrance into the gulf of Perisha, near Cape Mogandum.

**Selamum**, a town of Egypt, on the W. branch of the Nile; 48 miles N.N.W. of Cairo.

**Selanieh** or **Zelanieh**, a town of Egypt, on the E. branch of the Nile, opposite to Damietta.

**Selanieh**, in Botany, a name by which some authors have called the common *crocus vernus*, or the garden spring-flower, which we call the crocus.

**Selb**, in Geography, a town of Germany, in the principality of Culmbach; 14 miles S.E. of Hof.

**Selbe**, a river of the 1st of May, which runs into Ramsey harbour.

**Selbergh**, a mountain of Austrian Swabia; 4 miles W.N.W. of Schonau.

**Selbst**, a small town of Persia, in the province of Faridit, at the distance of 18 farsangs from the capital of the province, containing about 4000 inhabitants, situated at the foot of a hill, on the banks of a small stream, which is mostly absorbed in the irrigation of the gardens and fields adjoining the town.

**Selbitz**, a town of Germany, in the principality of Culmbach; 3 miles S.S.E. of Lichtenberg.—Also, a river of Germany, which rises in the principality of Culmbach, and runs into the Saal, 2 miles N.E. of Lichtenberg.

**Selboe**, a town of Norway, in the diocese of Drontheim, where a copper-mine was discovered in the year 1712; 40 miles S.E. of Drontheim.

**Selboese**, a town of Norway, in the province of Drontheim; 16 miles S.S.E. of Drontheim.

**Selby**, a market-town partly within the liberty of St. Peter of York, and partly in the lower division of the wapentake of Barkston Ash, Wellingborough, and county of York, England, is situated on the fourth bank of the river Ouse, at the distance of 14 miles S. by E. from York, and 181 miles N. by W. from London. This town is of great antiquity, having been known in Saxan times by the name of Selbea. In the year 1070, William the Conqueror erected a monastery at Selby; and having shortly after visited his new foundation, along with his queen, the latter was here delivered of a son, who succeeded to the throne by the title of Henry I. From these circumstances this place derived considerable celebrity; and was endowed with various privileges. Many of these, however, are now lost, but it still retains a market, held on Monday weekly, and three annual fairs, held on Easter Monday, the 22d of June, and the 15th of October. Here also are held the petty feoffments for the wapentake of Barkston Ash.

Selby abbey stood on the west side of the town. It was dedicated to the honour of St. Mary and St. German; and was filled with monks of the Benedictine order. King William Rufus gave the patronage of it to the archbishop of York and his successors, in lieu of the claim they had to some part of Lincolnshire. Previous to the dissolution its revenues were valued at 720l. 12s. 10d. per annum, according to Dugdale; and at 819l. 2s. 6d. according to Speed; which, with the abbey itself, were granted by king Henry VIII. to Sir Ralph Sadler. Since that period the buildings of this monastery have been appropriated to various uses; and most of them are now demolished, except the church, which appears to have been a very spacious and elegant pile. From the various styles of its architecture, no doubt can be entertained of its having been erected at different periods. The oldest divisions are the body and nave, which evince an early Norman origin, and are probably coeval with the foundation of the abbey. The western front, though extremely irregular, is exceedingly curious, both with respect to structure and ornaments. The entrance on this side, and likewise the northern porch, are particularly worthy of observation. The form of this church is that of a cross, the shaft of which measures 267 feet in length, and its transept 100 feet. From the centre of the whole pile rises a massive tower, which was rebuilt in 1702. On each side of the choir are twelve ancient stalls, similar in form and workmanship to the prebendal stalls in York cathedral. In the windows are considerable remains of stained glass, representing the armorial bearings of Thomas, earl of Lancaster, and other distinguished characters of the fourteenth and fifteenth centuries. Here are likewise several ancient monuments, and a great variety of modern date, i.e. ecclesiastic, since the church became the parochial place of worship about the year 1600.

According to the parliamentary returns of 1811, Selby parish contains 742 houses, and 3363 inhabitants. The principal trade of the town consists in ship-building, and in the manufacture of leather, sail-cloth, and iron articles.

Five miles to the northward of Selby is the village of Cawood, remarkable for the ruins of its ancient castle, which is said to have been ereeted by king Athelstane in the year 920, and which afterwards became a palace of the archbishops.
archbishops of York. The lately entrance or gateway is still remaining, on the summit of which cardinal Wolsey used to fit, and enjoy the view of the surrounding country. Cistwood castle continued in all its splendour till the commencement of the civil war in 1641, when it was seized upon, and garrisoned for the parliament. It subsequently, however, fell into the hands of the king's party, and sustained a siege of ten months before it was retaken by the parliamentary troops, when it was ordered to be demolished.

Selch Skernie, one of the smaller Orkney islands, a little N. of North Ronaldsha.

Selcha, or Selcha, in Ancient Geography, a town of Judea, situated in the half tribe of Manasseh, on the other side of Jordan, according to Joshua.

Selden, John, in Biography, a very distinguished scholar, and an eminent political character, called by Gros- tius "the glory of England," was born at Salvington, in Sussex, in 1584. He was educated at the free-school at Chichester, where he was sent to Hart-hall, Oxford, where he resided about four years. He then removed to London, for the study of the law, and with this view entered himself in Clifford's Inn, and about two years after he removed to the Inner Temple, where he soon acquired great reputation by his learning. He had already made himself known by some works of great merit, and this year he wrote verses in Latin, Greek, and English, upon Mr. William Browne's Britannia's Pastorals.

Having been called to the bar, he occasionally pleaded, but was much more employed as a chamber counsellor. The first object of his private studies was the history and antiquities of his own country, and in 1607 he drew up a work, entitled "Analeton Anglo-Britannicon," which was a chronological summary of English history down to the Norman conquest. This work was followed, in 1610, by "England's Epinomis," and "Janii Anglorum Facies altera," a Latin and English treatise on the origin and progress of English law. By these compositions he became known as an eminent enquirer into the early history and constitution of his own country, and acquired the esteem of several eminent literary characters, amongst whom were Camden, Spelman, and Sir Robert Cuffin. He was also on familiar terms with Ben Jonson, Drayton, Browne, and other poets of that period, who seem to have regarded his learning and talents with great respect, though his genius appears to have been inclined to poetry. In 1614 he published his largest English work, a treatise on "Titles of Honour," in which he displayed a vast extent of reading, directed by sound judgment. It became a standard authority with regard to all that concerns the degrees of nobility and gentility in this kingdom, in which light it is still revered; and it abounds in historical information concerning the origin of such distinctions as he traced through other countries. In the year 1617 he entered upon a wider field of literature, and made himself known to the learned throughout Europe, by a celebrated work "De Dis Syrius." The chief or leading object of this performance was to treat on the heathen deities mentioned in the Old Testament, but he extended it to an inquiry into Syrian idolatry in general, with occasional illustrations of the theology of other nations. This work was received with great applause by the learned world, and a new and improved edition of it was printed at Leyden, under the care of Daniel Heinius.

Hitherto Selden had passed his life in the tranquillity of a man of letters, engaged in subjects not liable to debate; but his next publication, being "A History of Tythes," printed in 1618, subjected him to much angry opposition, and brought upon him, says his biographer, "a storm from a quarter which has always proved dangerous to free enquirers." In the work alluded to, he had considered the question of the divine right to that impost, advanced by the clergy, and now beginning to be maintained by the English church, and though he only treated of it as a matter of his history, without arguing for or against the right, yet as the sum of his authorities manifestly inclined the balance to the negative side of the question, some of the clergy took offence at his freedom, and made an accusation against him before king James. That sovereign, who was fond of interfering in philosophical disputes, and who was always defirous of keeping on good terms with the church, set for Mr. Selden, and gave him a lecture on the subject, and being afterwards called before the archbishop of Canterbury, and some other members of the high commission court, he was induced to do to degrade himself, as to sign a declaration of his sorrow for what he had done. He, however, cautiously avoided retracting his opinion, or contradicting the facts which he had produced. Several answers to Selden's work were published, to which he was not permitted publicly to reply, though he circulated some remarks upon them among his friends. This incident unquestionably confirmed him in that hostility to civil and ecclesiastical tyranny which ever after marked his conduct. Selden was next to shine in the character of an advocate for constitutional liberty, with which his name is now so closely allied. The parliament which James's necessities had obliged him to convene in 1621, was soon at strife with him on the point of their powers and privileges, all of which the king affect to have been granted from his predecessors and himself, while they maintained them to be an inheritance from their ancestors. Selden being referred to by the parliament as the ablest legal antiquarian of his time, for information relative to the ancient privileges of that body, spoke to freely before them against the practices of the court, and was so instrumental in drawing up their spirited protestations, that he was selected as one of the victims to the yale of impeachment, and committed to custody. His imprisonment was not rigorous, and he was soon discharged upon his own petition. Refusing now his antiquarian studies, he edited, in 1723, the historical work of Edward Eadmer, a monk of Canterbury, with learned notes relating to the laws and customs established by William the Conqueror. In the following year he was elected to the new parliament, as one of the representatives for Lancashire, but nothing occurred to call forth his exertions during that session. He was again a member in the two first parliaments of king Charles, in the second of which he was appointed to support some articles of impeachment of the duke of Buckingham. He afterwards took up the cause of Sir Edward Hampden, who had been imprisoned for refusing to contribute to a forced loan; and in 1628 he was the perfon whom the house of commons employed to produce matter of record to justify its resolutions in favour of the subject's right to his liberty and property. These useful and very honourable labours did not so entirely engross his attention, but that he found time, in 1629, to draw up his learned treatise, entitled "Marmora Arundeliana," the occasion of which was the importation by the earl of Arundel of some very ancient Greek marbles, containing inscriptions of great value in the study of history and chronology. This was another obligation conferred by Selden on the learned world, which was received with due gratitude.

On the dissolution of the parliament, on account of its vigorous proceedings against the measures of the court, Sel-
Selden was one of the eight members of the house of commons who were thrown into the prison of the Tower, on a charge of sedition. Their application to be released on bail was only attended to by the judges on condition of giving security for future good behaviour, which they refused to do, as repugnant to the dignity of parliament, and the rights of Englishmen. Being brought up by virtue of the habeas corpus act to Westminster-hall, the like condition was again proposed, and again rejected, and both parties seemed to persist in their determination; of course the term of imprisonment was indefinitely protracted. Its rigour was, however, softened, and shortly after became very lenient. Selden being removed, first to the Marshalsea prison, and then to the Gatehouse, was at length suffered to go at large on bail, as were the others likewise, till the beginning of 1634, when bail was no longer required, and they were fully liberated.

Their fame was much applauded by the parliament, and Selden was distinguished among them as being their spokesman, when the point was argued before the judges. During the imprisonment of Selden, his mind was not inactive; his studies were turned to Jewish history and antiquities, and the first fruits of them were thrown in a work entitled "De successionibus in hona defuncti ad leges Ebrorum," which was published in 1631, and reprinted in 1636, with the addition of a treatise "De successione in Pontificatum Ebrorum." Selden had long employed his great talents in a work which was intended to afford and justify the maritime prerogatives of this country, in opposition to the principles advanced by Grotius in his work entitled "Mare Liberum." Selden's treatise was, after it had long lain on the shelf in MS., read and approved by king James; and the subject, in 1635, having become very interesting in consequence of some disputes with the Dutch, his majesty commanded its publication. It was therefore fitted by him for the press, and appeared in that year under the title of "Mare Claustrum, seu Dominio Maris." In this performance, the author first attempts to prove, by reasoning and example, that the sea is capable of dominion: and then to establish historically the British right over the circumjacent, or, as they have been denominated by others, the narrow seas. (See Campbell's Lives of the Admirals, vols. i. ii.)

This author, speaking of Mr. Selden and his Mare Claustrum, says in which, "he has effectually demonstrated, from the principles of the law of nature and nations, that a dominion over the sea may be acquired, and from the most authentic histories, that such a dominion has been claimed and enjoyed by several nations, and submitted to by others for their common benefit: that this was, in fact, the case of the inhabitants of this island, who, at all times, and under every kind of government, had claimed, exercised, and contently enjoyed such a dominion, which had been confessed by their neighbours frequently, and in the most solemn manner. All which, with learning, industry, and judgment superior to praise, this great man hath fully and unquestionably made out to the satisfaction of foreigners, as it is the design of this work to impress the same sentiment on the minds of all sensible Britons, viz., that they have an hereditary, uninterruped right to the sovereignty of their seas, conveyed to them from their earliest ancestors, in trust for their latest posterity."

Selden's work was, in truth, acceptable to all parties, and the king in council ordered copies of it to be kept in the council chamber, the court of exchequer, and the court of admiralty, as faithful and strong evidence to the dominion of the British seas. Several following years of Selden's life seem to have been chiefly occupied in Hebrew studies, of which one of the principal products appeared in 1640, under the title "De Jure Naturali et Gentium juxta disciplinam Ebbrorum." Lib. septem. This work is a copious digest of Jewish laws and institutions, as well from the rabbinical writers, as from the writings of the Old Testament, which is generally esteemed a valuable repertory of all the matters afforded by history or tradition relative to the subject.

This year, 1640, the long parliament met, and Selden was chosen one of the representatives for the university of Oxford. His name appears in several committees appointed for the correcting of the abuses, and reforming the oppressions of the reign, which parliament was, at this period, resolved to pursue. One of its strong measures, viz. the imprisonment of lord Strafford, he did not concur in, not considering that this measure was warranted by the law of the land. Nor did he seem willing to proceed further in the reformation of religion, than to check the usurpations of ecclesiastical power, to which he was a most decided enemy; and he had no wish to abrogate the episcopal form of church government, which he preferred to the presbyterian. So well affected was he, upon the whole, to the existing constitution in church and state, that after the king had withdrawn to York, there was a design of appointing him keeper of the great seal. When the differences between the king and parliament were manifestly tending to an open rupture, Selden opposed the attempts of both parties to gain possession of the power of the sword, hoping that the strong arm of the law might prove sufficient to settle the contending parties, and when his efforts had proved fruitless, he withdrew, as much as he was able, from public business. He remained, however, in parliament, and was one of the synod which met at Westminster for the establishment of church government. In 1643 he was appointed by the house of commons keeper of the records in the Tower, and in the next year he subscribed the Solemn League and Covenant. It is mentioned to his honour, that he constantly employed his influence, in those contentious times, for the service and protection of learning and learned men; and the university of Oxford, on different occasions, expressed its gratitude for the good offices which he performed for it in times of its distress. He likewise befriended the literary university, in which he was regarded with so much veneration, that he was elected to the mastership of Trinity-hall, though he thought it right to decline the office. His learned labours were still uninterred, and new works were occasionally issuing from his pen. Of these, the most considerable were, "Eutychius /Egyptii Origines Ecclesiae fux," translated from the Arabic; "De Anno Civili Veteris Ecclesiae?" "Uxor Ebraica," which contained an account of all the Jewish rites and institutions relative to marriage; an edition of the ancient work entitled "Fleta;" "De Synodis Veterum Ebrorum," being a copious account of the juridical courts of the Jews. His concluding work was "Vindiciae de Scriptione Maris Claustr," the object of which was to controvert a malignant libel of a Dutch author, that he had composed his Mare Claustrum in order to please king Charles, and obtain his liberation from imprisonment. Selden died in November 1654, having completed his seventieth year. He was interred with great solemnity in the Temple church, and on this occasion the learned Usher pronounced a funeral discourse. Selden was always in affluent circumstances, and had intended, at his death, to bequeath his valuable library and museum to the university of Oxford, but owing to some offence given to him, he left it to his executors, who, however, restored them to their first estimation, and they now make part of the Bodleian library. After his death, his amanuensis printed a collection of Selden's sayings, entitled "Table Talk,"
Talk," which contains much curious matter, and became popular.

"Selden," says Dr. Aikin, to whose lives of Selden and Usher our readers are referred for much curious and interesting matter, "was one of the most learned men of his time, and though the nature of his subjects, and a harsh and difficult style, have thrown his works out of the ordinary course of reading, yet he has been a considerable benefactor to literature, and his merit, as such, has been freely acknowledged by the most eminent scholars at home and abroad.

Grotius, Salmasius, Bochart, Gerard Vossius, Gronovius, Daniel Heinsius, and many other writers of great celebrity, have mentioned him with high encomium, and in England he was looked up to as at the head of a literary body. He was liberal in his patronage of men of letters, and appears to have been free from the jealousy and arrogance too frequently accompanying the learned character. "Lord Clarendon, though widely different from him in political sentiments, has, in his own life, spoken of him in terms of profound respect and admiration; and from personal knowledge, has testified to the amiable qualities of his heart, and urbanity of his manners, as well as to the powers of his understanding." Another author observes that he was a man of uncommon gravity and greatness of soul, averse from flattery, liberal to scholars, and charitable to the poor. His works were published collectively in three vols. folio, by Dr. David Wilkins, in 1726, with a Latin life of the author.

Selden is celebrated in German musical dictionaries, as a musical writer, for his notes on the Arundelian Marbles, concerning Hyagnis, the inventor of the flute, the Ambabak, Terpander, and the Names of the ancients.

**SELENA, in Ancient Geography, a town of Asia, in the interior of Susiana. Ptolemy.

SELE, in Geography, a river of Naples, which runs into the gulf of Salerno, N. lat. 43° 28'. E. long. 13°.—Also, a town of Nuba; 83 miles W. of Arkiko.

SELEBAR, a river on the W. coast of Sumatra, which runs into the sea, S. lat. 4° 2'. E. long. 102° 15'.

SELECTI JUDICES, in the Roman Republic, were persons appointed by the praetor with the mutual consent of contending parties, and bearing in many respects a remarkable resemblance to our juries; for they were first returned by the praetor, then their names were drawn by lot, till a certain number was completed; then the parties were allowed their challenges; next they trucck what we call a tales; and, lastly, the judges, like our jury, were sworn.

SELEFK, or terrace, in Geography, a town of Asiatic Turkey, in the province of Carmania, feasted on a river which soon after passing the town discharges itself into the Mediterranean, opposite to the island of Cyprus; anciently called Seleucia. It is now the residence of a fanatics, under the government of Cyprus. N. lat. 36° 45'. E. long. 33° 56'.

SELEMEUS, in Ancient Geography, a river of Achaia, N.W. and E. of the river Charadris, which discharges itself into the gulf of Corinth.

SELEMIE, in Geography, a town of Egypt, on the E. branch of the Nile; 43 miles N. of Cairo.

SELEN, or moon, in Antiquity, a kind of cakes used in sacrifices, and so called from their being broad and horned, in imitation of the new moon.

SELENERS, in the Magazine, are chops or manly fores in the bending of a horse's hough, as the malanders are in the knees.

SELENEUSIACA TERRA, Earth of Seleneusia, in the Materia Medica of the Ancients, a light scious earth, called by later naturalists agarricus mineralis, and when found in form of powder, or in a discontinuous state, lac luna.

It is an earth common enough, wherever there are stone quarries, all over the world; but the finest ever met with is that from Sicily, the place where the ancient Seleneusia, or Selenus Fod, and from whence the ancient physicians had it. Some of them have called it the creta Seleneusia; but all their descriptions agree in proving it to be this very earth now found there. Dioscorides and Galen mention its remarkable diffusibility in water, and Pliny mentions its melting in a kind of juice, or smooth homogenea fusiblance with it; properties so very applicable to this earth, and so little to any other, as to leave no doubt of their having been originally applied to the very same fusiblance.

The ancients gave it internally as an astringent; but its principal use was external, as a cosmetic among the ladies. And Dr. Plot recommends our lac luna, on personal experience, for the same purpofes.

SELENGA, in Geography, a river which rises in Chinefe Tartary, and traversing the confines of Russia, runs into the Baikal lake, 363 miles W.N.W. of Verchnei Udzin.

SELENGINSK, a town of Russia, in the government of Irkutsk, at the confluence of the Selenga and Chilok. It was made an offrog in the year 1666, and about 20 years afterwards, the fort, which is now standing, was built, and to this the place owes its prosperity. The town lies parallel to the river, and contains two churches, and about 150 houses, inclosed within the fortification. This is defended by five pieces of brass cannon, and as many iron guns; and the garrison consists of a regiment of felds. The inhabitants are nicknamed "Perothnikii," from the great quantities of sand found in these parts. The whole adjacent country is mountainous and barren, but a few miles below it there is good arable land. The country about Selenginsk yields a great quantity of rhubarb, inomuch that the rhubarb exported from Russia grows in these parts; 84 miles S.E. of Irkutsk. N. lat. 51°. E. long. 166° 44'.

SELENIACON, a name for a kind of amulet worn for the epilepsy.

SELENITE, in Mineralogy, crystallized gypsum. See Gypsum, and Sulphate of Lime.

SELENI, in Geography, a mountain of Carinthia; 10 miles S. of Cadenfurt.

SELENOGRAPHY, formed from σφαιρα, moon, and γραφειν, description, a branch of cartography, which describes the moon, and all the parts and appearances of it, as geography does those of the earth.

Since the invention of the telescope, selenography is very much improved.

We have now distinct names for most of the regions, mountains, &c. visible in the moon's body. The first who attempted, but in a very rude manner, to make a map of the moon's surface, was Riccioli. Hevelius, a celebrated astronomer, who was a burgler-marter of Danzic, and who published his selenography, represented the appearance of the moon in its different states from the new to the full, and from the full to the new; and named the several places of the moon from those of the earth, which figures Mayer prefers; but Langenus and Riccioli named them afterwards, from the names of the celebrated astronomers and philosophers, assigning the largest spots to those of the most celebrated characters, which distinction is now generally followed. Thus, what the one calls mons Parohypites, the other calls Ariflarebus. What the one calls Aenis, Sinai, Athens, Aequinum, &c. the other calls Copernicus, Poedonius, Tycho, Guiffenus, &c. A map of the moon, as it appears when full, was drawn by Cellini, who published a work entitled
entitled "Instructions Seleniques." The late Mr. Ruffel, a painter of eminence, made excellent drawings of the moon; but the most accurate and complete that have yet been published, are those of the celebrated Schroeter, who has given highly magnified views of most parts of the moon's surface. Dr. Brewster, in his improved edition of Ferguson's Astronomy, has given several tables of the lunar spots. The first of these tables is formed from the observations of Lambert, and contains the longitude and latitude of 207 spots, with the names given them by Riccioli and Hevelius, together with remarks on their position, appearance, and structure. The second table contains the longitude and latitude of 89 lunar spots, as determined by Tobias Mayer, with general remarks. The third table exhibits the new names which have been given to the anonymous lunar spots by J. Schreiber, with their positions, as determined by the editor, from a comparison of Schroeter's plates with Mayer's engraving of the moon, and his table of the lunar spots. Our limits will not allow of our insertion of either of these tables, and they are incapable of abridgment.

SELENTI, in Geography, a town of Asiatic Turkey, in Caramania, at the mouth of the river Selenti, which here runs into the Mediterranean; 45 miles E. of Alaniah. N. lat. 39° 3'. E. long. 29° 18'.

SELERNES, one of the smaller Shetland islands. N. lat. 60° 46'. W. long. 1° 22'.

SELESTRIA, a town of Asiatic Turkey, in Caramania; 50 miles S.W. of Tarbus.

SELETZKIA, a town of Russia, in the government of Archangel; 80 miles S. of Archangel.

SELEUCIA, in Ancient Geography, a famous city of Asia, built by Seleucus, one of Alexander's generals, and situated on the western bank of the Tigris, about 45 miles N. of ancient Babylon, was the capital of the Macedonian conquests in Upper Asia, and is said to have been the first and principal cause of the destruction of Babylon. Pliny reports, that the intention of the first of the Seleucidæ was to raise, in opposition to Babylon, a Greek city, with the privilege of being free. The ramparts and foles of this Grecian city are said to be nearly opposite to the ruins of Ctesiphon (which see); and in process of time Seleucia and Ctesiphon became united and identified, under the name of Al Modain (which see), or the two cities. For the precise situation of Babylon, Seleucia, Ctesiphon, Modain, and Bagdad, cities often confounded with each other, we refer with Gibbon, to an excellent geographical tract of M. d'Anville, in Mem. de l'Academie, tom. xxx. Many ages after the fall of the Macedonian empire, Seleucia retained the genuine characters of a Grecian colony, arts, military virtue, and the love of freedom. The independent republic was governed by a senate of 300 nobles; the population consisted of 600,000 citizens; the walls were strong; and as long as concord prevailed among the several orders of the state, they viewed with contempt the power of the Parthians; but the madness of faction was sometimes provoked to implore the dangerous aid of the common enemy, who was posted almost at the gates of the colony. The Parthian monarchs, like the Mogul sovereigns of Hindoostan, delighted in the pastoral life of their Scythian ancestors; and the imperial camp was frequently pitched in the plain of Ctesiphon, on the eastern bank of the Tigris, at the distance of only three miles from Seleucia. (See Strabo, lib. xvi. p. 743.) By the influx of the innumerable attendants on luxury and deftpotism, who retired to the court, the little village of Ctesiphon insensibly swelled into a great city. Under the reign of Marcus, A.D. 169, the Roman generals penetrated as far as Ctesiphon and Seleucia. They were received as friends by the Greek colony; they attacked as enemies the rest of the Parthian kings; and yet both experienced the same treatment. The lack and conflagration of Seleucia, with the massacre of 300,000 of the inhabitants, tarnished the glory of the Roman triumph; though it has been alleged in their favour, that the citizens of Seleucia had first violated their faith. Seleucia, already exhausted by the neighbourhood of a too powerful rival, sunk under the fatal blow; but Ctesiphon, in about 33 years, had sufficiently recovered its strength to maintain an obdurate siege against the emperor Severus.

Browne (Travels in Africa, p. 391.) identifies Seleucia with Susada, the port of Antioch, about four hours distant from it. Its former pollellers, he says, took immense pains to render it convenient for traffic; but it is now rendered useless, by the negligence of its present masters. A large gate, says this traveller, yet remains entire; it approaches to the Doric order. The rock near it has been excavated into various apartments. A part of the thick and substantial wall which defended Seleucia towards the sea. The port must have been commodious and secure, though small, as it was formed by a mole of very large stones. Although it be at present dry, the land in the bottom appears no higher than the surface of the sea. A little to the north is a remarkable passage, cut in the rock, leading, by a gentle descent, from the summit of the mountain towards the water. It is about 650 common paces long, from 50 to 50 feet high, and above 20 broad. In the middle of it is a covered way, arched through the rock, but both the ends are open. A channel for water runs along the side, conveying the pure element down from the mountain to Seleucia. The whole rock above is full of artificial caverns, formed for former people now unknown. A Greek inscription of five lines is visible on the S. side of the cavern. Towards the sea are some catacombs, ornamented with pilasters, cornices, and mouldings. Jackon, in his "Journey from India," considers Bagdad as the site of the ancient Seleucia; and he says that several of the coins of Seleucia are found in Bagdad. The gold coin is worth about two guineas; it bears as strong an impression of the head as the ancient Roman coins, but has a long beard.

SELEUCIA, a town of Asia Minor, which was anciently in Cilicia; but in the 4th century of the Chirilian era, the province of Isauria was made to constitute a part of Cilicia; and this city became the metropolis of the country. The Notitia of Hierocles represents Seleucia as founded by Seleucus Nicanor, and as being one of the largest and richest towns of the East. The river Calycadnus was navigable near this city, and facilitated the commerce of the country. In the year 115, Seleucia threw off the Roman yoke; but Trajan sent hither a body of troops in the beginning of the year 117, who reduced it to subjection. However it again recovered its liberty, as we learn from a medal of Gordian and another of Philip, on which it is denominated clesbura, or free.

SELEUCIA, a large town of the Perfide, in the territory of Elymais, on the river Edyphonte, according to Strabo. It was also named Salae.—Alfo, a town of Asia, in Phididia, according to the Notitia of Hierocles. Appian relates that it was one of the nine towns built by Seleucus Nicanor, who gave it his own name.—Alfo, the name given to the town of Trallis, in Lydia. Pliny.—Alfo, an episcopal town of Asia, in Pamphylia.

SELEUCIA PISIAEA, a town of Asia, in Syria, situated on the coast of the Mediterranean sea, N.W. of the river Orontes,
Selucia, the name which Seleucus gave to a town of Gadara, situated to the E. and beyond the sea of Tiberias. -Also, a town of Judea, in the half-tribe of Manassheh, on the other side of Jordan.

Seleucians, Seleucia, in Ecclesiastical History, a seat of ancient heretics, called also Hermians.

Seleucus and Hermias taught, that God was corporeal; that the elementary matter was co-eternal with him; and that the human soul was formed by the angels of fire and air. They also denied, that Jesus Christ sat at the right hand of God; alleging that he had quitted the right, and had removed his throne into the sun.

Seleucidae, in Chronology; era of the Seleucidae, or the Syro-Macedonian era, is a computation of time, commencing from the establishment of the Seleucidae, a race of Greek kings, who reigned as successors of Alexander the Great, in Syria, as the Ptolemies did in Egypt.

This era we find expressed in the book of Maccabees, and on a great number of Greek medals struck by the cities of Syria, &c.

The rabbins and Jews call it the era of contrails, because, being then subject to the kings of Syria, they were obliged to follow their method of computing in all contracts.

The Arabs call it therick dilemarain, era of two horns, which some say signify the era of Alexander the Great; because that prince bore two rams' horns on medals, in imitation of Jupiter Ammon, whose horn he would needs be; but others understand it much better of the two kingdoms of Syria and Egypt, which were now cloven or divided, and of one single empire parted into two monarchies.

The grand point is to know the year in which the separation was made; or, which is the same thing, when Seleucus Nicanor, one of Alexander's captains, and the first of the Seleucidae, established his throne in Syria.

Without detailing the various sentiments of various authors, it may suffice to observe, that, according to the best accounts, the first year of this era falls in the year 311 or 312 before Christ, which was twelve years after Alexander's death. See Epocha.

Seleucis, in Ancient Geography, a country of Asia, in Syria, which took its name from the city of Seleucia. It was also called Tetrapolis, on account of four celebrated towns contained in it, according to Strabo. This country extended southwards as far as Phoenicia.

Seleuco Belus, a town of Asia, in Syria; situated towards the river Orontes, W. of mount Belus, about N. lat. 35° 40'.

Seleucus, a town of Asia, in Syria, in the vicinity of Apamea.

Seleucus I., in Biography, fumamed Nicanor, king of Syria, was son of a Macedonian named Antiochus, a captain under king Philip. Seleucus entered, when young, into the service of Alexander the Great, by whom he was raised to an important command, and after the death of that conqueror, he was placed by Perdiccas at the head of the cavalry. On the division of the provinces made by Antipater, the government of that of Babylon was entrusted to Seleucus, in which situation he opposed the advance of Eumenes against Antigonus. When, however, that leader, after the death of Eumenes, marched to Babylon, he shewed such a hostile disposition towards Seleucus, that the latter thought it necessary to take refuge with Ptolemy, king of Egypt. Upon the defeat of Demetrius, the son of Antigonus, by Ptolemy, Seleucus recovered his government of Babylon, and added to it Media and Susiana, which he wrested from Nicanor, the governor, for Antigonus. Demetrius afterwards expelled Seleucus from Babylon, but he soon returned, and durably established his authority.

He then proceeded with a powerful army to the East, conquered and slew Nicanor, and marching through Parthia, Bactria, and Hyrcania, subdued those countries, and the other provinces which had formed part of Alexander's empire on this side the Indus. From these important victories he assumed the name of Nicator; and the other successful captains of Alexander taking the title of kings in the year 306 B.C., he followed their example.

The historical era of the Seleucid, however, commenced six years earlier than this, viz. in the year 312 B.C., when he recovered Babylon. He now marched to regain the district of India Proper, conquered by Alexander, but he was opposed by a large force, that he thought it expedient to leave him in possession, on condition of being supplied by him with 500 elephants. One reason of his making this treaty was the necessity of joining with Caius, Lysimachus, and Ptolemy, in order to reduce the overgrown power of Antigonus, which menaced the independence of them all. This purpose was effected by the great battle of Ipsus, in which Antigonus lost his life.

His dominions were shared by the four confederate monarchs, previously to which Seleucus had seized the province of Upper Syria, and founded the famous city of Antioch.

He also built other cities in the same province, to which he gave family names, as Seleucia, from himself; Apamea, from his wife; and Laodicea, from his mother; and as he was a great founder of cities in all his territories, he filled Asia with places bearing the names of his family. After this, he built Seleucia on the Tigris, which became one of the most famous cities in the East, and was the caufe of the detraction and ruin of Babylon. In many of his new cities he settled colonies of the Jews, whom he endowed with ample privileges, and to him was owing their establishment in the Asiatic provinces to the west of the Euphrates.

When he was advanced in years, he is said to have resigned to his son Antiochus, his wife Stratonice, and with her he resigned to the prince all the provinces of Upper Asia. Seleucus and Lysimachus were now the only survivors of Alexander's captains, and a domestic tragedy having taken place in the family of the latter, some of its members took refuge in the court of Seleucus, whom they urged to make war upon Lysimachus. He accordingly invaded, with a very powerful army, the territories of Lysimachus in Asia Minor. That prince crossed the Hellespont to protect them, and a most bloody battle was fought between the rivals in Phrygia, in which Lysimachus was slain, in the year B.C. 281. Seleucus took possession of his dominions, but did not long enjoy the fruits of victory, for as he was marching into Macedonia, eleven months after, he was treacherously murdered by Ptolemy Ceraunus, one of the fugitives from the court of Lysimachus. Seleucus died in the 43d year from the death of Alexander, and in the 73d year of his age.

He was a prince of splendid qualities, mild and equitable in his government, and a patron of letters and learned men. Unier, Hill.

Seleucus II., fumamed Callinicus, succeeded his father Antiochus Theos, in the year 246 B.C. His mother Laodice having cruelly put to death Berenice, the second wife of Antiochus, and her son, Ptolemy Euergetes, the brother of Berenice, marched into Syria, slew Laodice, and took possession of great part of the Syrian empire. After his return to Egypt, Seleucus recovered part of his lost dominions; but being defeated by Ptolemy, he applied for aid to his brother. This union brought about a truce with Ptolemy, but the two brothers then quarrelled, and Seleucus was defeated.
feated by Antiochus in a great battle at Ancyra. The war between them was carried on with great inveteracy, while the empire was invaded on one side by Eumenes and Attalus, kings of Pergamus; and on the other, Arsaces, founder of the Parthian monarchy, was making a progress in Hyrcania. Seleucus was at length delivered from the hostility of his brother, who was detained captive in Egypt, whither he had fled, and he then turned his arms against Arsaces, but in a great battle that was fought he was defeated and taken prisoner. He died in Parthia, in consequence of a fall from his horse, in the year 226 B.C.

Seleucus III., furnamed Ceraunus, eldest son of the preceding, succeeded him on the throne. He was a weak and incapable prince, and after a reign of three years he was poisoned by two of his chief officers, while engaged in an expedition against Attalus.

Seleucus IV., furnamed Philopator, succeeded his father Antiochus the Great, in the year 187 B.C. He was favourable to the Jews during the greatest part of his reign, but near the close of it he employed Heliodorus to carry off the treasuries of the temple at Jerusalem, as is mentioned in the second book of Maccabees. He was afterwards poisoned by Heliodorus, who usurped his throne. This event occurred in the year 176 B.C. There were several other kings of the name of Seleucus, but they did nothing worthy of notice.

Selezneva, in Geography, a town of Russia, in the government of Irkutsk, on the Ilim; 28 miles S. of Irkutsk.

Self-Abuse. See Self-Pollution.

Self-Defence, in Law. With regard to the defence of one's self, or the mutual and reciprocal defence of such as stand in the relations of husband and wife, parent and child, master and servant, it is observed, that, in these cases, if the party himself, or any of these his relations, be forcibly attacked in his person or property, it is lawful for him to repel force by force; and the breach of the peace, which happens, is chargeable upon him only who began the affair.

Self-defence, therefore, as it is justly called the primary law of nature, so it is not, nor can it be in fact, taken away by the law of society.

In the English law, particularly, it is held an excuse for breaches of the peace, nay, even for homicide itself; but care must be taken, that the retrenchment does not exceed the bounds of mere defence and prevention, for then the defender would himself become an aggressor. Blackft. Com. vol. iii.

Self-Examination. See Examination.

Self-Heal, in Botany. See Prunella.

Self-Heal, in the Materia Medica. The greater self-heal, with an undivided leaf, grows wild in pasturage grounds, and flowers in June and July. It has been reckoned among the vulnerary plants, and is accounted serviceable in all sorts of wounds and putrid ulcers. It is retstringent, and good for inward bleedings, and making bloody water; and has been much used in gargles, for ulcers in the mouth, throat, or gums, either in juice, or in a strong decoction.

Its virtues do not appear to be very great; its astringent or bitterish taste is more serviceable in the flower tops than in the leaves; though the latter are generally directed for medicinal use.

Self-heal is also a name given to officinal.

Self-Love, in Ethics, is that principle, or passion, which leads a man to desire and pursue his own happiness. It is contradistinquisht from benevolence. See Mental Philosophy.

Self-Opens, a term used by the miners in the north of England to express certain natural caverns, or chambers, which are frequently met with, some near the surface, some at very great depths, some small, and others very large.

These are of various figures, and often run into straddle fissures. Dr. Lillie, in accounting for the origin of earthquakes, supposes the whole crust of the earth to be more or less hollowed in this manner; which he also argues for, from the streams of waters which arise in large quantities from the sides of mountains, and must have communication with these self-opens, and supplies from them. These natural hollows the doctor thinks to be the means of continuing, and propagating earthquakes; the first cause of which he ascribes to the breath of the pyrites, which he also says is the pyrites itself tota subflantium. This he observes takes fire of itself, on being exposed to the air in our sight, and may be, from various other causes underground. The sulphurous smell of the air and waters before and after earthquakes, in the places where they happen, seems a proof that they owe their origin to some such fulphurous matter as this stone; and the rolling and defultory noise of an earthquake seems also to have that it is not expanded every way at once, but is propagated through a chain of these subterraneous hollows.

It is not necessary that we should suppose a continued chain of them, from the place where the earthquake begins to be felt to the spot where it ends; but if there are many of them irregularly scattered about the earth, the force of the explosion will be sufficient to burst through the solid parts between, and open a passage from one to the other, which may continue open no longer than the force continues, and after the shock is over, close together again, so as to leave no trace where it was.

Our miners not only find the natural caverns, but they also find them often full of what they call fire dams, which are inflammable vapours, of the very nature of those which he supposes to occasion earthquakes; and when fired make the flame explosions, and cause the same effects in a certain degree. These sometimes require a candle, or other actual fire, to come in contact, in order to kindle them; but sometimes they are found kindled of themselves, and flaming on the surface of the waters, in the bottoms of the pits, or at the fissures of the coal. Phil. Trans. No. 157.

Selga, or Selge, in Ancient Geography, a considerable and well-peopled town of Asia, in Phrygia. It was colonized from Lacedemon.

Selgenthal, in Geography, a town of Prussia, in the circle of the Natangen; 3 miles S. of Konigsberg.

Selgenthal, a town of Germany, in the circle of the Lower Rhine; 3 miles N.W. of Burken.

Selgovæ, in Ancient Geography, a people of Britain, seated to the west of the Gaden, in the countries now called Elgæ, Annandale, and Nithdale, lying along the shores of the Solway Frith, which is believed to have derived its name from that of this ancient British nation. Mr. Baxter supposes that the name of these people was compounded of the two British words Sal Giu, which signify salt waves, alluding to the Solway Frith, with which the coasts of their country were washed. But Dr. Macpherson thinks it more probable, that the name was derived from the British word Saeg, which literally signifies hunting, and metaphorically thief. The Selgovæ became first acquainted with the Romans, when Agricola marched his army through their country into Caledonia, in the second or third year of his government in Britain; at which time they made their submission to that victorious general. From that period they were alternately under the dominion of the Romans, or enjoyed freedom, as that people extended or contracted the limits of their empire in this island. The Romans had several stations and camps in the country of
of the Seljuk, of which some vestiges are still remaining.

SELL, in Botany, a word formed by an abbreviation of the word jeffel, signifying the same plant.

SELIA, in Ancient Geography, a town of Hifpania, in the interior of Bética. It belonged to the Turduli, according to Ptolemy.

SELIKINSKO, in Geography, an offshoot of Russia, in the government of Tobolsk, on the Enfiei; 260 miles N.N.W. of Turuchansk. N. lat. 69° 35'. E. long. 85° 14'.

SELICA, a name given by the Arabians to a kind of cinnamon.

SELCIO, or SELUCO, in Geography, a town of Africa, on the north side of the Gambia, in Mandingo.

SELIGENSTADT, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz, formerly imperial, on the Maine; 12 miles E.S.E. of Frankfort on the Maine. N. lat. 49° 59'. E. long. 8° 46'.

SELEGENTHAL, a town of Germany, in the county of Henneberg; 3 miles N. of Smalkalden.

SELIGER, a lake of Russia, in the government of Tver; 80 miles W.N.W. of Tver.

SELIGONTON, in Botany, a name by which some authors have called piony.

SELM, in Ancient Geography, a town of Palestine, in the tribe of Judah, on the southern side along the frontiers of Edom, according to Joshua. This was afterwards captured in the tribe of Simeon. See Silem.

Selin I., in Biography, a Turkish emperor, was the second son of Bajazet II. In 1511, being governor of Trebizond, he rebelled against his father, and marched to Constantinople, where he was defeated and obliged to seek his safety in a precipitate flight. The janizaries, however, favouring him, Bajazet was forced to resign his crown to him, and soon after died, probably by poison. Selim ascended the throne in 1512, being at that time about 46 years of age. His first step was to proceed against his eldest brother Achmet, who was at the head of some troops in Asia. He defeated and put him to death, which was soon after the fate of another brother. Selim then invaded Perisa with a numerous army, and defeating Shah Hamael in a great battle, entered the city of Tauris. He afterwards annexed Diarbekir to the Turkish empire; and one of his officers recovered Bosnia, which had been conquered by the Hungarians. In 1517 Selim turned his arms against the sultan of Egypt, and obtained a victory over him near Aleppo, the sultan being slain in the engagement. Aleppo and Damascus submitted to Selim after this event, and he prepared to march into Egypt. Arriving in the neighbourhood of Cairo, a very bloody battle ensued between him and Tuman Bey, which terminated in a total defeat of the Mamelukes. Cairo, after a desperate resistance, was taken, and all Egypt submitted. Selim returned to Constantinople, and, elated with his successes, made a vow that he would not lay down his arms till he had put an end to the Perisan empire. His career was, however, stopped by disease, which terminated in his death at a village in Thrace, in 1520. Selim was one of the most able and vigorous of the Ottoman sovereigns, and made greater additions to the Turkish empire than any one of his predecessors. He was, at the same time, unprincipled in his projects of ambition, and had all the ferocious cruelty of an eastern despot.

Selim II., Turkish emperor, son of Solymon I., succeeded his father in 1566. Being an indolent disposition, and extremely intemperate, the actions of his reign are those of his viziers and generals. Of these the principal was the capture of Cyprus, then belonging to the Venetians, which, after a vigorous refutation, was reduced in 1571. The European powers, who had combined for its relief, gained, in the same year, the famous naval battle of Lepanto, which nearly ruined the Turkish marine. Notwithstanding this success, the Venetians were obliged to make peace with the Turks in 1574, upon very disadvantageous terms. During the remainder of Selim's reign, the affairs of the Ottoman empire were prosperous. Selim died at the age of 52, probably of intermence. He had many good qualities, but was slothful and featural.

SELMABAD, in Geography, a town of Hindoostan, in Bengal; 12 miles S.S.E. of Burdwan. N. lat. 23° 5'. E. long. 87° 48'.

SELIMBRIA. See Selliura.

SELMIE, a village of Nubia, on the route of the Soudan caravan from Afia to Darfur; 42 miles S. of Sheb.

SELMPOUR, a town of Bengal; 24 miles N.W. of Burdwan. N. lat. 23° 23'. E. long. 87° 35'.

SELIN, a town of Africa, in the kingdom of Galam; 15 miles S. of Galam.

SELENA, in Ancient Geography, Illan-Adaifi, or Ille Serpents, an island of the Euxine sea, near the mouth of the Danube; called Parstatus, or Paraladum. Some authors have denominated it Meladita.

SELINGAGUR, in Geography, a town of Hindoostan, in Oude, on the Ganges, opposite to Furruckabad.

SELINCOURT, a town of France, in the department of Maine; 18 miles W. of Amiens.

SELINE, a river of Sileia, which runs N.W. into the Loh, 7 miles S. of Breflan.

SE-LING, a town of China, of the second rank, in the province of Cheung-fu. N. lat. 21° 55'. E. long. 106° 29'.

SELINGUE. See Selenga.

SELENO, a province of the island of Crete, south of that of Kilamos, which takes its name from that of a small town, built on the south coast of the island, in the situation formerly occupied by Lithia or Lirius, a place of small importance, mentioned by Ptolemy. It is entirely mountainous, but very fertile. It furnishes a little flax, honey, wax, and a tolerably large quantity of fruits, such as cherries, apricots, peaches, pears, and oranges. This is the only province in which the chestnut-tree is cultivated, and it thrives well on the schisto-dolmen hills and mountains of this country. The chestnuts are carried to Canea, Retimo, and Candia. A quantity is also annually exported to Syria. Oil, however, is the principal commodity of Selino; and it is reckoned better than any other in the island. The merchants of Canea generally establish their speculations on the quality and quantity of the oils of Selino. Wine, wheat, and barley, are not plentiful. The population of the Turks is estimated at a fourth or fifth of the inhabitants. Olivier.

SEL

Gen. Ch. General umbel of numerous, flatly-spaying rays; partial familiar. General involucrum of many, lanceolate, linear, reflexed leaves; partial familiar, spreading, the length of the flower. Perianth scarcely discernible. Cor. univerpal uniform; all the flowers fertile; partial of five, heart-shaped, equal petals. Stam. Filaments five, capillary; anthers roundish. Pfr. Gemen inferior; fyles two, reflexed; fragmas simple. Peric. Fruit comprefed or flat, oval, oblong, frigated on each fide in the middle, separable into two parts. Seeds two, oval-oblong, flat on both fides, frigated in the middle, their fides membraneous.

Obf. The form of the seeds is liable to variation, and fo is the number of leaves in the involucrum.

3. S. auffricum. Austrian Selinus. Wildl. n. 5. Jacq. Alur. v. 1. t. 71.-Stem frigated. Leaves of the involucrum wedge-shaped, much divided. - Native of Austria and the south of Europe, flowering in July. Root perennial, containing a yellowiy-white milk. Stem frigated, smooth. Radical leaf divided by a round ftalk into three branches, which are again frigated. Leaves dark green above, paler beneath. Flowers yellowiy-white, forming a compound umbel, which is usually made up of about twenty partial ones.

4. S. flbricum. Siberian Selinus. Wildl. n. 4. Retz. Obs. fcel. 2. 16.-Leaves tripily pinnate. Involuteums faded, of nine leaves. - Native of Siberia. Root biennial, fpindle-shaped. Stem erect, three feet high, hollow, frigated, glaucous. Leaves tripily pinnate; leaflets acute, on comprefed ftalks which are channeled on the upper fide. Flowers white; the general umbel composed of twenty or thirty partial ones. Its root smells like that of Daucus Carota.

gul. Root perennial, fibrous, both falted and feentlefs. Stem almost three feet in height, pale green, fimple, occasionally with one branch. Leaves pinnate in a compound manner, terminating in a white point. Flowers white, with a tinge of red on the under fide; the general umbel compact, conflating of about twenty partial ones.

6. S. Chabrei. Carrot-leaved Selinus. Wildl. n. 6. (S. carumifolia Chabrei; Jacq. Alur. v. 1. t. 72.) - Stem round, frigated. General involucrum none. Sheaths of the leaves loofe. Leaflets thread-shaped, linear.-Native of Switzerland and Germany. Firdl introduced at Kew by E. Daval, efl., in 1791, where it flowers in July and Augulf. Stems about a foot high, smooth, conflated. Radical leaves refting those of the laft species; lem-leafes tripily pinnate. Flowers white, fairly purplish on the outside. Partial umbels unequal in size, much smaller than in the laft species, generally about ten in number. Villars has observed that this species is as it were intermedium between Paeoncuma and Selinus.

white, forming a clofe compact general umbel.

10. "S. canadenfe. Canadian Selinus. Pursh v. 1. 192. (Apium bipinnatum; Walt. Fl. Carn. 115.) - Herb very smooth, shining, Leaves bipinnate. Leaflets much divided; segments lanceolate. Fruit oval.-On the mouths of large rivers from Canada to Carolina, flowering in July. Flowers white." This species is adopted on the authority of Mr. Purh, who has reffered it from Apium to the pre-
ent genus.

Selinus, in Ancient Geography, a town of Egypt, in the Thebaid, on the other fide of the Nile, between Panum and Anten, according to the Itinerary of Autonine.

SELINUS, or SELLINUM, a town of Sicily, south-east of Mazara, on the southern coast. It was founded by a colony from Hybla, another town of Sicily, 100 years before the defeution of that city by Gelo. In its vicinity were many palm-trees, whence arose the epithet of palmata, given to it by Virgil. It was destroyed, a little before Himera, by Hannibal, who took it by ftem and treated the inhabitants with great barbarity, maffeacring a great number, and carrying the relic into captivity. The inhabitants had confecrated to the Olympic Jupiter a trea-
ure, in which, among other rarities, was a flature of Bacchus, the face, hands, and feet of which were made of ivory. It appears to have been destroyed in the year of Rome.

Selixus,

his captain havinjr a quarrel,

L

and

ball, forae trifling

implements, and a few books, with
and nautical inftruments. Tims left
fole monarch of the ifland, with plenty of the neceflaries of
life, he found himfelf at firft in a Ctuation fcarcely fupportable ; and fuch was his melancholy, that he frequently
determined to put an end to his exiitcnce.
It was full
eighteen months, according to his own account, before he
could reconcile himfelf to his lot.
At length his mind became calm, and fully reconciled to his fituation he grew
happy, employed his time in building and decorating his
certain mathematical

:

huts, chafing the goats,

whom

he foon equalled in fpeed,

and fcarcely ever failed of catching them. He alfo tamed
young kids, and other animals, to be his companions.
When his garments were worn out, he made others from
the fltins of the goats, whofe flefti ferved him as food.
His
only liquor was water.
He computed that he had caught,
during his abode in the ifland, about 1000 goats, half of
which he had fuffered to go at large, having firit marked
them with a flit in the ear. Commodore Anfon, who
went there 30 years after, found the firil goat, which they
fhot, had been thus marked ; and hence they concluded
that it had been under the power of Selkirk.
Though he
conftantly performed his devotions at ftated hours, and read
aloud, yet when he was taken from the ifland, his language, from difufe of converfation, had become fcarceljr
intelligible.
In this folitude he remained four years and
four months, during which only two incidents occurred
which he thought worthy of record. The firft was, that
purfuing a goat eagerly, he caught at the edge of a precipice, of which he was not aware, and he fell over to the
bottom, where he lay fome time fenfelefs ; but of the exaft
fpace of time in which he was bereaved of his aftive powers
he could not form an accurate eftimate. When, however,
he came to himfelf, he found tke goat lying under him dead.
It was with difficulty that he could crawl to his habitation,
and it was not till after a confiderable time that he entirely
recovered from his bruifes.
The other event was the arrival
of a fliip, which he at firft fuppofed to be French, but
upon the crew's landing, lie found them to be Spaniards,
of whom he had too great a dread to truil himfelf in their
hands.
They, however, had feen him, and he found it extremely difficult to make his efcape.
In this folitude Selkirk remained until the 2d of February 1709, when he fav»
two fliips come to the bay, and knew them to be Englifli,
He immediately lighted a fire as a fignal, and he found,
upon the landing of the men, that they wore two privateers from Briltol,

commanded by

captains Rogers and

Courtney. Thefe, after a fortnight's ftay at Juan Fernandez, embarked, taking Selkirk with them, and returned
by way of the Eaft Indies to England, where they arrived
on the ift of Oftober 17
Selkirk having been abfent
;
eight years.
The public curiolity being much excited, he,
alter his return, drew up fome account of what had oc
curred during his folitary exile, which he put into the handt
of Defoe, who made it the foundation of his well-known
work, entitled Robinfon Crufoe. The time and place of
Selkirk's death are not on record.
It is faid, tliat fo late
as the year 1798, the cheft and miWket, which Selkirk had
with him on the ifland, were in poflcflion of a grand nephew,
John Selkirk, a weaver in Largo, North Britain. The
circumftaiicea of Selkirk's feclufion from human fociety,
during his llay on the defolate ifland, hare given birth to a

Eight poem by Mr. Cowper, with which all our readers are no doubt well acquainted. Brit. (This appears to be a foreign text, possibly in French, and the rest of the text seems to be a mix of English and Latin. This might be a page from a historical or literary document.)

**SELKIRKSHIRE**

Selkirk, in Geography, a royal borough town, and a parish, in the county of Selkirk, Scotland. It derived its name from the Celtic word Schelcikgreich, which signifies the kirk in the wood; expressing thus one word the situation of the place itself, and the flate of the surrounding country, which in former times was one continued forest. From the vicinity of its being placed on the summit of a considerable eminence, Selkirk enjoys an extensive prospect in all directions, especially up and down the river Ettrick. The inhabitants boast greatly of the spirit displayed by their ancestors at the celebrated battle of Flodden. Of a hundred citizens of Selkirk, who followed the fortune of their prince on that occasion, it appears that several survived the conflict, and even carried off some spoils and trophies. The English, in resentment, reduced their town to ashes. But, on the other hand, King James V. granted to them a thousand acres of the forest; the trees for rebuilding their houses; and the property as the reward of their heroism. These borough lands are now worth about 150l. per annum, and are divided into a great number of small properties; a circumstance which tends to damp that spirit for commerce and manufactures, by which the inhabitants of towns are in general distinguished. On the day on which the magistrates annually survey this tract, a standard, taken from the English in the field of Flodden, is carried before the corporation of weavers, a member of which was the captor. It may be added, that the sword of William Bryan, the town clerk, who led the citizens to the battle, and who is said to have been knighted for his valour, is still in the possession of a citizen of Selkirk, his lineal descendant.

Selkirk has a weekly market held on Tuesday, and six annual fairs; two in March, and one in July, August, October, and December. As a royal borough, it unites with Lanark, Linlithgow, and Peebles, in sending one member to parliament. The corporation consists of two bailies, a dean of guild, treasurer, and ten councillors, and possesses a revenue of about 300l. per annum, drawn from that portion of the borough lands which has not been alienated in fee to private individuals. The parish, which is about ten miles square in extent, lies partly in Selkirkshire and partly in Roxburghshire; and, according to the parliamentary return of 1811, contains 440 houses, and a population of 2466 persons, of whom about 1000 are resident within the borough.

The principal object of interest in this vicinity is Newark castle, situated on a peninsula, formed by the stream of Yarrow, which has here cut its turbid course through a deep gulf of rugged rocks, enveloped in wood, and presenting a most "fantastically wild scene of grandeur and beauty." The castle is now a ruin, but enough of it yet remains to evince its ancient strength and importance. It is generally supposed to have been the birthplace of Mary Scott, the Flora of Yarrow. Beauties of Scotland, vol. ii. 8vo. 1805. Statistical Account of Scotland, by Sir John Sinclair, vol. ii. 1762.

**SELKIRKSHIRE**

One of the southern counties of Scotland, is situated between 55° 22' and 55° 43' N. lat. and between 2° 50' and 2° 30' W. long. from the meridian of Greenwich. It is bounded on the W. by the county of Dumfries; on the E. by Mid-Lothian and Roxburghshire; on the S. by the county of Berwick; and on the N. by that of Peebles. Its greatest length, from the source of Ettrick water to the junction of Gala and Tweed, is 27 miles, and its greatest breadth from Borthwick brae to Glenfaxburn, about 17 miles. Taking, at a medium, 20 miles for its length, and 12 for its breadth, its contents may be calculated at about 240 square miles, or 153,600 acres. The proportion of arable land actually occupied in husbandry may be computed at about 6886 Scotch acres.

**General Aspect of the County.**—With the exception of a few valleys, the whole of Selkirkshire is mountainous, and presents elevations of considerable height, Meads, in the parish of Galashiels, being 1480 feet above the level of the sea. In the parish of Ettrick, the most remarkable hills are the Ward Law and Ettrick Penn: the former rises 1000 feet above the level of the sea, the latter 2200. In the parish of Yarrow, the hills are in general steep and towering; the most remarkable is the Blackhouse, 2370 feet. The highest point of elevation above the level of the sea measures 3370 feet. For the most part, the mountains exhibit a green appearance; though upon some few there is a considerable quantity of heath. Toward the source of the waters of this county, that is, on its western extremity, the hills are more green, and are covered with long coarse grass. Towards their junction with the Tweed they have a greater mixture of heath, and the grass is shorter. On the north side of the Tweed, some of the hills are covered with loose stones, but none of them are very rugged or barren of herbage, or interrupted by moors. Bordering on Minnoch, over which was the old road from Peebles to Selkirk, their aspect is bleak and barren, and forms a striking contrast with the green hills on the opposite sides of the Yarrow and the Tweed.

**Rivers and Lakes.**—The Tweed, Ettrick, and Yarrow, flow through this county. The Tweed enters it near the ancient seat of Elibank, and flows through it for nearly ten miles, along a well-cultivated and fertile but narrow valley. At the eastern corner of the county it receives the Gala, a small water, which rises in Mid-Lothian, and which forms the boundary of Selkirkshire for five miles. Yarrow water rises near the western extremity of the county, and flowing through the Loch of Lows, and St. Mary's Loch, augmented by many smaller waters, joins the Ettrick about a mile above Selkirk. From the nature of its source, lochs, and from the circumstance of its receiving in its course many additional streams from the hills, the Yarrow, in time of high winds and rain, is rapidly flooded, and rendered impassable; but, from its rapid descent, it rapidly subsides.

The Ettrick also takes its rise in the western angle of the forest, and running in an almost parallel direction with the Yarrow, unites with it about a mile above; they fall into the Tweed three miles below Selkirk, after a course of 30 miles. These waters, as they pass through this county, form many beautiful windings. Near their source they are hemmed in on each side by high towering hills; but as they approach their confluence with the Tweed, the expanse between the hills becomes wider and more open; and they flow through fertile valleys, in a broader channel, with a less rapid stream. For a considerable way above their junction, they are finely fringed with natural and artificial wood; but the extensive forests which once beautified and adorned their banks, and from which the country obtained the appellation of Ettrick fair, are now almost entirely deforested. Every stream abounds with trout; and for a considerable way up the Ettrick and Yarrow, salmon are caught in large quantities. Ale water takes its rise from the Kingmoor loch, but only runs in this county for a short way; in some places passing out of it into the Teviotdale, and in others forming its boundary. Borthwick water also constitutes part of its boundary. The hills are everywhere intersected by small streams.
When frosts frequently others might, though, the rather, on some Selkirk extensive and sharp, small very the numerous and gravel, the weather, to the heep in this pastoral district, and produce richer graps than the exposed sides of the hills. When the country was covered with wood, these glens must have afforded much beautiful scenery. In the south-west district of the county are a number of small lakes, not however worthy of description. The two already mentioned, viz., the Loch of the Lowes, and St. Mary's Loch, lie contiguous, being separated only by a narrow neck of land. The soil is very small, but the latter extends six miles in circumference, and one mile in breadth. Both of them are surrounded by high and steep hills, and abound with pine and pearch.

Soil.—The soil of the sheep-walks, with some exceptions, is found and dry, generally from its lying on a bottom of gravel, granite, or windstone; and even a good deal of it either inclining towards clay, or incumbent on clay or till, is prevented from retaining a hurtfull quantity of water, by its steepness, and the firm consistence of its surface. There is very little pure clay in the whole country; and most of the land where a mixture of it appears, or where it forms part of the sublustrum, lies on the sides of the hills, nearly at an equal distance from their summits and the valleys below. There are some, though very few, marshy spots near the sides of rivers, and on the tops of high mountains. There is, indeed, an extensive flat, in an elevated situation, between the waters of Ettrick and Borthwick, of a soft and impregnly nature, and full of morasses, but this may be confidered as the only exception to the general alleration that devers to be noticed. Heath grows vigorously on dry soil, but becomes rare and flunted, according to the wetness of the land, and in very wet land disappears altogether. Detached portions of it are found in every corner. It is only on the higher grounds, towards the sources of the waters, that the moffy soil prevails; sometimes appearing in its native dark and fertile hue, but more frequently presenting a thin fward of beautiful and tender graps, through which the feet of cattle sink more or less, according to the depth of the moffy sublustrum, and the quantity of rain it has had. It is in such places, chiefly, that the plant abounds which is called mofs, of whose leaves and root sheep are extremely fond early in spring, when other food is scarce. The soil of the small part in tillage is light, dry, and easily managed. Even the few places which lie on till have so much deadlift, that a little care in laying out and ploughing the ridges, carries off both the springs and the surface-water. Very little of it is sufficiently deep and strong for producing wheat. But nearly the whole of it is admirably adapted for turnips, clover, barley, and oats: peas, too, succeed very well; the white graps, though not large, have thin hulls, are plump, and of an admirable quality. Turnips seldom fail, and clover is frequently raised in very weighty crops. Theseth facts give the best idea of a sharp, warm, and kindly soil, which is rather, on the whole, however, deficient in depth. White clover appears, in every field that is surranded to pasture, without having been town, and indeed is found in all parts of the county where the soil is dry.

Climate.—In the lower part of the county there is not so much humidity as might be expected, from its elevation, and the numerous mountains with which it is surranded. Lefs rain falls at Selkirk than at Wool, about five miles nearly due south of it; and only about half an inch more than at Hawkhill, near Leith. According to the Statistical Account of Scotland, (vol. ii. p. 478.) the mean quantity of rain which fell yearly in Wool parish was found to be 31 inches; the medium height of the barometer 29.7; the medium of heat 43 degrees. Bransholm or Wool may be taken as a pretty just standard of the climate, about six or eight miles above Selkirk, on the waters of the Ettrick and Yarrow. There are few places, even in the highest part of the country, so very moist as Langholm; though, in proportion as it rises, there is a greater quantity of rain; the air becomes colder and more penetrating; frosts are more early and severely felt, and snow lies deeper and longer.

The rays of the sun, reflected by the surrounding mountains on some valleys 600 feet above the ocean, excite a degree of heat that brings the crop very quickly to maturity. The number of springs that are obstructed in their course, forms marshes more or less deep and extensive. There are many morasses, some of them of an unknown depth; a good deal of moffy land; and several lakes. The moisture exhaled from the vast quantity of water collected in these, greatly increases the dampness of the atmosphere, and produces frequent mists and showers. Nor can this inconvenience be effectually obviated by the numerous drains which are daily making, though these mult duplicat contribute to moderate the climate. The general course of the weather and feaons is much the same as in Roxburghshire.

See ROXBURGHSHIRE.

Mineralogy.—There are no metals, coal, lime, or freestone, in any part of this county. But there is abundance of windstone and granite. Moffs, formed of decayed wood and other vegetables, are made into peat for fuel. Some of them are of considerable extent and depth; though towards the south-east, in the parishes of Selkirk, Robertson, and a corner of Yarrow and Alhickir, cover large beds of excellent till-marle. In the rills by which some of them are fed, many small ftones are found; some of them overspread with a glutinous substance, others incrusted with matter very similar to that of which the shells are composed; others again with fthers in every progressive state of formation; and a few with the animals alive, in shells completely formed, but of different degrees of consistence and hardness.

To account for this incrutation of fstones with calcareous earth, in a county where no lime is known to exist, and to determine whether it comes from some rock as yet unexplored, from loose fragments or particles scattered among other substances, and wafted away by freams, or from pulverized fthers, or from any other matter found in the neighbourhood, would require a scientific and accurate examination of the surrounding mountains, and the different strata of which they are formed. On the supposition of the incrutation proceeding from a rock, or detached pieces of lime, it may become a question how far this substance is necessary or useful to the animals in rearing their fthers, and on the other supposition, of its being occasioned by pulverized fthers, it is of equal importance to ascertain the materials from which these fthers are constructed.

Agriculture.—The agriculture of such a county as this, cannot be a very intersting subject. In the lower parts of the county, the best practices in agriculture are successfully pursued, as in Roxburghshire and Berwickshire; but in the upper part of the county, or forest, as it is called, where the arable land is not fenced off, and the disadvantages of an unfavourable soil and climate occur, little can be done. In this situation, the small portion of arable land on the flirks of the hills is chiefly cropped with oats, which are the grain best adapted to the nature of the climate, and the wants of its inhabitants, both as a part of their food, and for the support of their horses. In these situations, the principal improvement that can be adopted, consists in rendering the arable land subservient to the support of sheep, which form
the great object of the farmer’s attention. Accordingly, green crops, such as turnips and hay, &c. are raised on many of the farms, from which very great advantages are derived, being food to the sheep in storms. Little wheat is produced in the county. Both barley and bear or bigg are sown. The return from barley is, at an average, from seven to eleven-fold. The return from bear is nearly the same, but the weight and market price are greatly inferior. Artificial grazes are very generally sown. Pease are less cultivated than formerly, the preference being given to turnips.

Live Stock.—Sheep are the staple animal of this county, and their number is estimated at 118,200. There are two forts, viz. the original breed, which are black-faced, and the white-faced, which are generally of the Cheviot breed. The former, being about one-third of the whole number, are to be found in the upper or western part of the county, and the latter mostly in the lower districts of the shire. The different qualities and value of these two breeds should seem nearly balanced, for though, of late years, a preference has been given to the Cheviot sheep, on account of their superior fleece, and even the opinion of their being less hardy than the black-faced sheep has been disputed, yet it is admitted that the white-faced lambs, when young, are much barer in wool, and therefore less protected from the weather, than the black-faced; and in an inclement lambing season, nearly four times more of them die than of the black-faced kind.

The mutton of the latter is likewise accounted more delicate. The practice of making ewe-milk cheese is nearly abandoned, from an opinion that it weakens the ewe. The few hories requisite for cultivating the arable districts, are of the Lanarkshire and Northumberland breed. Swine are reared only by a few gentlemen for their tables, and by millers for the market. Vat quantities of poultry are raised by the farmers, who fend cart-loads of eggs to Berwick, which are bought by “egglers,” who sell them again for the London market.

Inclufures.—Inclufures are not very generally used, unless round gentlemen’s seats, and on the farms in their own poffeffion. The reader is referred to what is mentioned in the account of Roxburghshire, as to the kind of inclufures used.

Towns, Villages, Roads, Fairs, and Manufactures.—Selkirk is the capital of the county. (See SELKIRK.) Galloway, so called from its being situated on the banks of the water Gala, is a thriving village. It has been long known for its manufactures of woollen cloth, which was at first coarse, and of a grey colour, and was called “Galloway’s grey;” but the cloths recently manufactured are of various kinds and colours. In consequence of an act of parliament obtained in 1764, a road of twelve miles was made from Croftlee toll-bar, on the confines of Mid-Lothian, through Selkirk, to Harrow’s toll-bar, with a branch of three miles to Galloway. Part of the road from Kelso to Peebles, of about six or seven miles long, also runs through this county from Galloway’s bridge to Cockhope burn, beyond Holillie toll-bar. The expense of these roads, and of a substantial bridge over the Tweed, was £560l. There are two considerable fairs held at Selkirk; four lesser fairs are likewise held there, and three at Galloway for various purposes. The chief manufactures are woollen cloth, stockings, tanned leather, and different implements of husbandry, or wood blocked out for making them.

Antiquities.—There are but few remains in this shire of British or Roman antiquities. There are the remains of some British strengths in the eastern division of the shire, which were erected upon heights, and were constructed generally in a form between the circular and the oval. There is also a Roman camp in the midit of several of these strengths, in the parish of Robertson. But the most remarkable remains of the Britons in this shire, is the “Catrain,” or battle fence, consisting of a large fole, with a rampart on either side. Its length is 28 miles. This wall or fence can only be referred, for its construction, to the Romanized Britons, who, after the abdication of the Roman government, had this country to defend against the intrusion of the Saxons on the eall, during the fifth century, the darkest period of our history. The modern antiquities of Selkirkshire consist chiefly of ruined castles and mofs-grown towers, erected, some of them, in the twelfth century, but the greater number of them in subsequent ages of foreign hollitories or domestic feuds.

Historical Events.—Like other counties of Scotland, Selkirkshire has its share of family feuds, fanatical conflicts, wars, and battles, which would occupy too large a portion of our pages to recount. Selkirk became a royal burgh on an occasion that reflects high honour on the loyalty and spirit of this ancient town. When James IV. was marching forward to his fate at Flodden field, a hundred townsmen joined him under the town clerk. They fought stoutly; they almost all fell in the field rather than flee. On the 13th of September 1515, was fought the decisive battle of Philiphaugh. This is one of the least civil conflicts which stained the forefathers of Selkirkshire with human gore.

Eminent Natives.—This shire puts forth a fair claim to rank in its annals many characters of celebrity. The Douglas, the Scott, the Murrays, and Patrick Ruthven, who had learned the art of war under the great Gustavus, and was created lord Eterick, are names conspicuous in history. Andrew Pringle, who was placed in the senate house on the 14th of June 1759, by the title of lord Alemuir, as a lawyer was distinguished by his modesty and eloquence, and as a judge for his dignity and knowledge. It produced an eminent soldier in colonel William Ruffel, of Athelney, who distinguished himself amongst the warriors of India. Mary Scott, the flower of Tarow, is still remembered by the “cold-blooded ministers of Eterick forest.” She is celebrated by Ramsay in amorous rant:

“With succces crown’d, I’ll not envy
The folks, who dwell above the sky;
When Mary Scott’s become my marrow,
We’ll make a paradise on Yarrow.”

Population.—This county has seven parishes, and a portion of two others, containing a population of 5,889 persons.

Selkirkshire, as a county, sends one representative to the united parliament. Beauties of Scotland, vol. ii. 8vo. 1805. Chalmers’ Caledonia, vol. ii. 4to. 1810.

SELL, in Building, is of two kinds, viz. ground-fell, which denotes the lowest piece of timber in a timber building, and that on which the whole superstructure is raised. See Ground-Plates.

SELL, Window, called also window-foil, is the bottom piece in a window-frame.

SELL-Bed, in Mining, a term used in some parts of England to express some particularly rich parts of the vein of ore.

In Cornwall they sometimes find the tin-ore so pure, that it requires but little refining to drefs it, without the washing and separation by grates, launderers, and the like means: they call these collections of ore the fell-beds of tin; and it is observed, that these never have any filings illuing from them, as the other lands have. Philof. Transf. No 60.

SELLA, in Ancient Geography, a river of Melitian, N. of the isle of Oenufa.

SELLA, in Geography, a town of Africa, in Benguela.
SELLA, among the Romans, a chair in which the old and infirm are carried byervants through the city, and in journeys. Sometimes the physicians prescribed it as an exer- 

icis. See Lectica.

SELLA Curulis, among the Romans. See Curule chair.

SELLA Equisina, Turrica, or Spheonicus, in Anatomy, is a name given to the four apophyses of the sp sphenoides, or cuneiforme, in the brain; in regard of their forming a re-

semblance of a faddle, which the Lattins call fella.

They are sometimes also called by the Greek name cliomide. In it is contained the pituitary gland, and in 

some beasts, the rete mirabile.

SELLARE, in Geography, a town of Naples, in 
Calabria Ultra; 16 miles N.E. of Bova.

SELLASIA, in Ancient Geography, a town of Laconia, S.W. of Glympsea, on the river Oenus. It was destroyed in the time of Pausanias. When T. Quintus Flamininus passed into the Peloponnesus, 195 years B. C., to deliver Greece from the yoke of the tyrants who opprissed it, he fo-

journed near this place; but a little after this time, it was destroyed by Aratus, the conqueror of the Lacedaemonians. Towards the N.W. was a mountain, which bore the name of Mount Olympus. The famous battle of Sellasia, in the year 122 B. C., was fought between this mountain and Eva. Antigonus, king of Macedonia, was at the head of the Achaeans, and Cleomenes, king of Sparta, commanded the Lacedaemonians. This last, having been entirely defeated, returned into Egypt to king Ptolemy Philadephus.

SELLAY, in Geography, a small island of the Hebrides, in the district of Harris and county of Inverness, Scotland. It is about a mile in circumference, and yields excellent fur-

ure for sheep.

SELL, a town of France, in the department of the Ca-

tal; 6 miles S. of Aurillac.—Alfo, a river of France, which runs into the Scheldt, about six miles above Valenciennes.

SELLA-Bird, La, a town of France, in the department of the Loiret; 7 miles N.E. of Montargis.

SELLA, a town of Hindooostan, in Guzerat; 25 miles S.E. of Mahomoodabad.

SELL, a town of Persia, in the province of Iran; 

110 miles E. of Ipahan.

SELLAS, in Ancient Geography, a river of the Pelo-

ponnesus, in Sicily. Strabo places the place Ephrya on the bank of this river.—Alfo, a river of Aetolia, in 

Agra, according to Strabo.—Alfo, a river of Astia Minor, in the Troade, which watered the town of Aribza, according to Homer, cited by Strabo.

SELLEMPUR, in Geography, a town of Hindooostan, in Oude; 42 miles S.E. of Goracpur. N. lat. 26° 15'. E. long. 84° 1'.

SELLAS, in Ancient Geography, a people who, accord-

ing to Homer, fixed their seat, together with the Perissab, in the environs of Dodona; but he must be understood to mean that they were rather mimerants of the temple than a 

distinct people. Strabo, however, says, that a barbarous 

people of this denomination inhabited the environs of 

Dodona.

SELLAS-fur-Cher, in Geography, a town of France, in the 

department of the Loire and Cher, and chief place of a 

canton, in the district of Romorantin; 14 miles S.W. of 

Romarantin. The place contains 3,400, and the canton 

67,145 inhabitants, on a territory of 325 kilometres, in 9 

communes.

SELL, in Ancient Geography, a people of Asia, in the 

Troade.

SELL, in Antiquity, an appellation given to those 

who first delivered oracles. These, according to Strabo

and Euthathius, were men, and the name felli is said to come from Selle, a town in Epirus, or from the river called by 

Homer Selleis.

SELLA, in Geography, a town of Naples, in Calabria 

Ultra; 4 miles N.E. of St. Severina.

SELLIERA, in Botany, a genus dedicated by Cava-

nillos to a Parian engraver, Natalis Sellei, who executed 

the plates of the first and second volume of Cava-

nillus' Icones, and also of his Mondelphia.—Cavan. Ic. v. 5. 

De Thisius, 427.—Clafs and order, Pentadendra Monogynia. 

Nat. Ord. . . .

Gen. Ch. Cal. Periandri superior, permanent, deeply 

five-cleft. Cor. of one petal, irregular; tube cloven lon-

gitudinally to the base; limb ascending, cloven into five, 

lanceolate segments. Stam. Filaments five, placed in an 

erect manner on the germin, surrounding the style; 

antlers ovate, erecti. Pfl. Germen inferior, ovate, turgid-shaped; 

style simple, incurved, longer than the filaments; 

uguina globular, truncated. Peric. Berry ovate-turbinate, crowned 

by the calyx, of one cell and many seeds. Seed ovate, 

compressled, roughish.

Eff. Ch. Calyx superior, five-cleft. Tube cloven lon-

gitudinally to its base. Berry of one cell and many seeds.

1. S. radicans. Cavan. Ic. v. 5. 1474. f. 2.—Native of 

the moist maritime parts of Chili, flowering between 

February and May.—Stem prostrate, hairy, a foot high, 

sending out fibrous roots. Branches scarcely more than an 

inch long. Leaves alternate, spatulate, entire, cluttered 

at the axis. Flowers blue and white, either terminating the 

branches, or axillary, on solitary stalks, which have two 

awl-shaped bracteae in the middle.—Cavalliles described 

this elegant little plant from a dried specimen only. He 

says that it differs from Scena in its fruit, which he sup-

pects is not to be succulent, as in Paflisera; for after immers-

ing the berry in warm water, he found it swelled with little 

moist cavities containing a glutinous fluid.

SELLIERA, in Geography, a town of France, in the 

department of the Jura; 9 miles W. of Poligny.

SELLAS, in the Materia Medica, a name by which some authors have called the narda Celta, or Celtic 

spikehead of the thors.

SELLINAGUR, in Geography, a town of Hindooostan, in Oude, on the left bank of the Ganges; 60 miles W. of 

Kaisabad.

SELLING of Land, in Rural Practises, the business of 

dispersing or transferring it from one to another for a cer-

tain stipulated sum. There are different modes of effecting 

this, according to Mr. Marshall, as by public biddings, 

and private contract or agreement, in each of which a pro-

per degree of precaution is requisite. In the former, as 

the conditions are fixed, an accurate valuation affords 

the greatest safety; and in the latter, with upright intentions, 

little more is necessary. In particular cases, however, 

where a landed estate has fallen into bad hands, more caution 

may be required; and it may be occasionally necessary to 

call in the professional aid of those who, from the nature of 

their employment, are upon their guard against all sorts of 

trick and cunning. It is suggested as highly improper to 

make use of the person who is to examine the title and 

adjut the deed of conveyance, to carry on the business of 

purchasing an estate;—of whose value and uses he is profes-

sionally ignorant; as the irrefutation, want of decision, the 

consequent mistakes, and the necessary delays, that will 

always attend the negociations of men who are conscious 

of a want of knowledge in the subject they are employed to 

treat on, must ever tend to the disadvantage of their 

employers. The above writer has known so many instances of
of disadvantage arising from suffering more men of the law to intermeddle in the purchases of lands, before the preliminaries of agreement have been adjusted, that no apology is due to the profession for the observances which he has thrown out in the above cases.

But in purchasing by private contract, the particulars which may be required to be furnished by a feller, are, he says, the quantities of the several pieces of lands on sale, together with the maps, or rough draughts of the same; the tenure under which they are held; some assurance as to the title of the feller, and his right of alienation; the tenancy under which the several farms are let; and, if on lives, the ages of the nominees; if for a term of years, the number unexpired; if at will, the notices (if any) which the tenants have had; and an abstract of the covenants under which they are let; particularly those which relate to taxes and repairs, to the execution of produce, to the ploughing of grass-lands, &c.; the existing rents and profits receivable; whether for tenanted lands, appurtenances, or abstract rights; and the estimated value of the demesne, and the wood-lands, in hand; together with the estimated value of the timber growing upon the estate on fable, as well as of the mineral and foils which it may contain; the outgoings to which the estate is liable; the proposed time of the delivery of possession; the price and the mode of payment expected for the same. And in the next place, he considers it as proper to set down the particulars of instructions to be given to a surveyor, or other valuer, of an estate to be purchased. But it will be right, however, he thinks, to premise, that much, in this respect, depends on the probability of purchasing; and on the time allowed for making the estimate. In cases of sale by public auction, where there can be no certainty as to purchase, and where the time for valuation is limited, a rough estimate of each farm, and a general idea of the value of the timber and other appurtenances, may be all that can be prudently ascertained. While in a sale by private contract, where the refusal of an estate is granted, and time allowed for deliberate survey, a more minute investigation may be proper, especially when there is every reason to believe that a bargain will take place. For the former report will not only serve as a guide to the purchase, but will become a valuable foundation on which to ground the future management of the estate. And he suggests, that for these and other reasons, a purchase by private contract is most to be desired by a gentleman, who is not in the habit of personally attending public sales, and is unacquainted with the business of auction rooms. But, he says, it does not follow that a sale by auction is equally ineligible for a feller; who may gain the advantage by this mode of disposing; provided he can frustrate the combinations of public fables. The auction duty, however, and the heavy expenses of public sales, are objections to this method of making a bargain; as the money thus expended must necessarily come out of the pocket of the buyer or the feller.

And in regard to the particulars to be required from a surveyor or valuer, they are principally these. The rental value of each field or parcel of land, with the fable in which it lies, as to arable, meadow, pasture, or wood-land, the value of the timber, and other appurtenances. The characteristic, and the fale of management, of each farm or tenement; with the eligibility of its occupier; together with the fale of repair of buildings, gates, fences, water-courses, and roads; the amount of the incumbrances and outgoings; and, lastly, the probable value of the improvements of which the estate may appear to be capable, in different ways. And it is also added, that these several particulars of information being procured, the subjects of treaty are few. The two statements having been duly compared, so that no misunderstanding can take place between the parties, the price, with the times and mode of payment, are the principal matters of agreement. A clear understanding respecting the custody of title deeds, and the expenses of conveyance, require, however, to be enumerated among the preliminaries of the purchase before any thing is finally settled.

But in what relates to the business of the negotiation, it is belted carried on by letters; which become vouchers of facts. Whatever is done by interview requires to be reduced to writing, and to be read by or to the parties before they separate, that no possibility of misconception may arise. And in addition to these precautions, it is proper, in large purchases, and when abstractions of intricate title deeds are to be made out, and examined, that a legal contract, or memorandum of agreement, should be entered into for the mutual satisfaction and security of the parties. This contract, and the deed of conveyance, (namely, the instrument which is legally to transfer the property from the feller to the purchaser,) may be paid to conclude and ratify the business of the purchase, and in this part of it, legal affiancy is essentially necessary; to examine existing deeds, and see that the feller has a legal right and clear title to the land, and a legal power to dispose of it; as well as to draw up, or examine, the fresh deed of conveyance, and see that it is sufficient to transfer the property, legally and adequately, to the purchaser of such landed estate or property.

See Valuation of Land.

SELLUM, in Ancient Geography, a town of Spain, in Lausitania, S.E. of Callipo and N.E. of Scalabis.

SELM, a town of Pernia, in the province of Adarbizzan or Azerbijan, situated in the most picturesque, and at the same time, the most flourishing division of the province, lying along the N. and W. border of the lake of Urmia, from Tabruz or Tabris, to the confines of Armenia. The town contains about 2000 inhabitants, principally Neftorian Christians, and is famed for its lofty poplars and delightful gardens; 75 miles W.S.W. of Tabres. N. lat. 37° 45'. E. long. 45° 30'.

SELMNITZ, a town of Bohemia, in the circle of Chrudim; 16 miles N.W. of Chrudim.

SELO, a river of Naples, which runs into the Mediterranean, near Petti.

SELOMOR, a town of Austrian Poland, in Galicia; 40 miles E. of Lemberg.

SELOGOOR, a town of Hindooftan, in Berar; 20 miles N. of Nottcheegong.

SELOKOI, a town of Russia, in the government of Tobolsk. N. lat. 64° 8'. E. long. 76° 14'.

SELOMME, a town of France, in the department of the Loire and Cher, and chief place of a canton, in the district of Vendome; 6 miles S.E. of Vendome. The place contains 625, and the canton 4395 inhabitants, on a territory of 215,000 square miles, in 16 communes.

SEQN, a town of Hindooftan, in the Carnatic; 10 miles S.W. of Tigrar.

SELONDA, a small island in the East Indian sea, near the N. coast of Cumbaya. S. lat. 8° 5'. E. long. 117° 34'.

SELONGEY, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Dijon; 4 miles N. of Isfur Tille. The place contains

1878,
SEL

1878, and the canton 5801 inhabitants, on a territory of 200 kilometres, in 11 communes.

SELORICO. See Selorico.

SELOWITZ, a town of Moravia, in the circle of Brun; 12 miles S. of Brunn.

SELRAIN, a town of Tyrol; 7 miles W.S.W. of Innsbruck.

SELSEA BILL, a cape on the S. coast of England, in the county of Suffolk, which takes its name from a village, situated on a peninsula formed by an inlet of the sea, called "Selsey harbour;" 8 miles S. of Chichester. N. lat. 50° 41'. W. long. 0° 50'.

SELSTEN, a town of the duchy of Bremen; 8 miles S.S.E. of Bremervord.

SELTERS, or Nieder Selters, a town of Germany, in the episcopalric of Treves, situated on the Embach near which is a celebrated medicinal spring; 21 miles N. of Mentz. See Seltzer-Water. Allo, a village of the principality of Nassau, on the Lahn, with a medicinal spring; 2 miles N. of Weilburg.

SELTSCAN, or Sedlezany, a town of Bohemia, in the circle of Moldau; 22 miles S.E. of Brama. N. lat. 49° 42'. E. long. 14° 25'.

SELTZ, a river of Germany, which runs into the Rhine, 3 miles N. of Ingelheim.

SELTZ, or Selz Benheim, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the district of Willemsburg, seated on the Rhine; 22 miles N.N.E. of Strasburg. The place contains 1307, and the canton 10,110 inhabitants, on a territory of 155 kilometres, in 18 communes.

SELTZBACH, a town of France, in the department of the Upper Rhine; 6 miles S.W. of Colmar.

SELZTER-WATER, the name of a mineral water of Germany, which arises near Neider Selters, or Lower Seltz, about ten miles from Francfort on the Mayne, and which is now used in England and many other countries.

This water issues forth at the spring with great rapidity, is remarkably clear and bright, and on pouring it from one bottle into another, discharges abundance of air-bubbles.

That which is imported at London is brought over in stone bottles, closely corked and cemented, containing about three English pints each, by which means this water, as long as the common air is excluded, will retain many of its excellent qualities for several months; but this caution is so necessary, that if too large an empty space be left even in the neck of a bottle, it soon looses in a great degree the brisk, sprit, pungent taste, which principally characterizes its excellence, and is more liable to be injured by keeping than any other mineral water.

Hoffman, in consequence of an analysis of this water, observes, that an immediate effervescence ensues on mixing any acid with it, and especially with Rhineh wine and sugar, in which case the emotion is attended with a noise, and the liquid becomes milky; but mixed with Rhineh wine alone, it becomes turbid, and acquires a brown colour with a reddish cast; that the taste of this water is not so penetrating and subacid as that of most other mineral waters, but has a flavour resembling that of a diluted solution of a lixivial salt; that, with an addition of powder of galls, it does not become purple, nor blacken the floors of those who drink it; that, on adding oil of tartar, it becomes milky without any precipitation: that a quart of this water, gently evaporated, yields a drachm and twelve grains of a saline matter, which, dissolved and filtrated, yields, on a second evaporation, two scruples of a pure alkaline salt; and that this salt dissolved in water, and added to a solution of corrosive sublimate, precipitates a yellow powder or turbid mineral, and mixed with an infusion of rhubarb, gives it a reddish colour, and mixed with sal ammoniac, emits a pungent smell; that a quart of this water, satured with spirit of vitriol, and gently evaporated, affords a drachm and a half of salt, not distinguishable from vitriolated tartar; that no medicinal water is so apt to spoil and be corrupted by keeping, and that if it be set for a day or two in an open vessel, it wholly loses its natural flavour, and tastes only like water in which oil of tartar had been mixed.

From all these observations he infers, that this water abounds with an alkaline salt in a much greater quantity than any of the other known mineral waters, without seeming to contain any particles of the ferruginous earth and bitter purging salt, which are the common ingredients of the other mineral waters: on this account, he adds, that it does not purge, but generally goes off by urine. Hoffman recommends it as one of the mildest and most innocent of all the mineral waters, and observes that it may be taken by persons of the weakest constitution.

From the experiments of Dr. Brockleby on Seltzer-water, we learn, that upon dropping twelve drops of very highly coloured syrup of violets into a wine-glass of it, the syrup seemed first to manifest a purple hue, but upon their intimate union, the whole changed into a beautiful green; that the same quantity of oil of tartar per deliquium dropped into a glass of sparkling, fresh, clear water, quickly turned the whole milky, and after standing, a fine pearl-coloured powder fell to the sides and bottom of the glass; on adding an equal number of drops of pure phlegmated spirit of vitriol to a glass of this water, a light cloud was seen suspended towards the middle of the glass, and numerous air-bubbles rose from all parts of the water, and the sparkling might be renewed by adding one or more drops of the acid, and shaking the glass; and the like ebullition was more readily produced by a solution of sugar and Rhineh wine, or vinegar with the same: and the same appearances were exhibited by dropping any vegetable or mineral acids into this water, as are observed when alkalies and acids are mixed together: a volatile caustic alkali, in half an hour after it had been dropped into this water, produced at first a cloud and afterwards a precipitation. Lixivium saponarium fo far decomposed a glass of Seltzer-water, that a cloud instantly appeared in the middle of it, and the air-bubbles emerging from the lower part of it were greedily absorbed by the caustic alkali, which is known to imbibe fixed air, whenever it comes into contact with it. This water, says Dr. Brockleby, poured into a glass, separates more air-bubbles than any other water which he had tried, and continues longer to do so in the open air, but its sparkling may be renewed by adding any sub acid vegetable, and a little sugar, as sharp cider and Rhineh wine and sugar; but, he adds, that the best Seltzer-water here will not perfectly curdle milk, nor lather with soap, and that with powder of gall nuts no further change of colour appeared than in pure water. By evaporating twenty-four ounces of the best Seltzer-water, he obtained thirty-six grains of a saline residuum; and the greatest quantity he could ever get from a pint, wine measure, was less than thirty grains.

Ten drops of strong spirits of vitriol, poured on as many grains of salt of Seltzer-water, caused great and instant ebullition, and suffocating fumes, which tinged blackish a silver spoon held in them, and gave to its polished surface a bitter tinge.

Having dissolved sixty-six grains of pure white salt, ob-
SALT.

prepared about with 15 and terri,

194, 121 to Botany. E.

e has be to land heat it London is miles the a and and gouty brilk

experienced in into incompatible with fuch nation much he found that this seems to have let go much the greatest part of its fixed air, and probably thereby loft most of the virtues inherent in the pure fresh water itself.

From such experiments Dr. Brockleby infers, that Seltzer mineral water contains, besides the mere elementary water, a very small quantity of calcareous earth, and a much greater portion of a native mineral alkali, together with some acid retained a while within the water, but which either evaporates into the open air, or else is soon combined with the mineral alkali: and he thinks it probable, that the active virtues of this water depend more on this elastic matter, or fixed air, which it contains in such uncommon abundance beyond other mineral waters, than in any combination of its saline and earthy contents, which are found in such small quantities, as to be incapable of any material service, though this water is known to be exceedingly beneficial.

This account of the analysis of Seltzer-water is closed with the history of some medical cafes, in which the use of this water completed a cure, after a great variety of other remedies had proved insufficient.

The operation of this water, as Hoffman observes, is chiefly by urine, for it has no purgative virtues. It corrects acidities, renders the blood and juices more fluid, and promotes a brisk and free circulation; and, therefore, it is good in obstructions of the glands, and against gout and viscid humours. It is of great use in the gravel and stone, and other disorders of the kidneys and bladder.

It is also excellent in gouty and rheumatic complaints, especially when mixed with milk, or improved by the addition of Rhinfiil wine and a little sugar. It is drunk with great success in scorbatic, cutaneous, and putrid disorders. It relieves the heart-burn, and is an excellent stomachic. On account of its diuretic quality, it is serviceable in dropsical complaints; and mixed with all's milk, it is much recommended in consumptive cafes, and in disorders of the lungs; with or without milk, it is in great esteem in nervous disorders, and also in hypochondriacal and hysterical complaints, and in obstructions of the menphis, accompanying the use of it with proper exercise.

It is also administered with success in purging and fluxes arising from acidity in the bowels; and it is said, if drunk by nurses, to render their milk more wholesome and nourishing, and to prevent it from turning sour on the stomach of children. See on the subject of this article Hoffman, Oper. vol. v. p. 144. London Med. Observ. iv. p. 7, &c. Elliot's Account of the Principal Mineral Waters, p. 194. &c.

Seltzer-Water, Artificial, may be prepared by adding one scruple of magnesia alba, six scruples of foifal alkali, and four scruples of common salt to each gallon of water, and saturating the water with fixed air, in the manner directed under Pyrmont-Water.

SELVA, in Geography, a town of Spain, in Catalonia, on the coast of the Mediterranean, 35 miles N.E. of Gerona. N. lat. 42° 20'. E. long. 3° 2'.

SELVA, a small illand in the gulf of Venice, separated from Ulbo by a narrow channel; it is rocky, and the soil so poor, that the olives feldom come to perfection: the vines produce bad grapes, and the corn is still worse. The fone that abounds there is chiefly hard whitish marble. N. lat. 44° 38'. E. long. 14° 5'.

SELVAGE, in Sea Language, a fort of hank or flecin of rope-yarn tied together at several distances. It is used to fatten round any rope, as a throud or flay, so that a tackle may be hooked in it, to extend the said throud or flay, which is called setting it up.

SELUCHUSA, in Ancient Geography, an illand near the Peloponnesus, being one of those which were situated on the coast of the promontory of Spiræum. Pliny.

SELUCIA, in Geography, a town of the Arabian Inark, 160 miles N.W. of Ballora.

SELVE, la, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Rodes or Rhodex; 14 miles S. of Rhodex. The place contains 840, and the canton 6738 inhabitants, on a territory of 24,250 kilometres, in 15 communes.

SELVG, a town of Denmark, on the W. coast of the illand of Samfco. N. lat. 55° 52'. E. long. 10° 30'.

SELUNE, a river of France, which runs into the sea, near mont St. Michel.

SELU, in Ancient Geography, a town of India, on this side of the Ganges, in the interior of the country of the Carzéns, according to Ptolemy.

SELYMBRIA, SELYRVA, called also by Suidas Olybria, a town of Thrace, on the coast of the Propontide, between the mouth of the river Athras and Perinthus, or Heraclea. Its name signifies the town of Selys, bria signifying town in the language of the Thracians. See Selyrva.

SELZBACH, in Geography, a river of France, which runs into the Rhine, 7 miles below Fort Vanban.

SEM, a river of Russia, which rises in the E. part of the government of Kurk, and falling by Kurk, unites with the Dena, near Sofinitza, in the government of Novgorod Sieverliko.

SEMAMPLEXICAULE LEAF, in Botany. See Leaf.

SEMANA, in Geography, a town of Hindooftan, in the subah of Delhi; 35 miles S. of Sirhind. N. lat. 29° 25'. E. long. 75° 33'.—Alfo, a town of Japan, in the island of Niphon; 125 miles W. of Meaco.

SEMAM, an illand of the East Indian sea, about 24 miles long from N. to S., and from fix to ten broad; separated
SEM

rated from the S.W. end of the island of Timor by a narrow channel, called the "Strait of Seno," S. lat. 10° 15', E. long. 123° 45'.

SEMARI, a river which rises in mount Cenis, and after forming a boundary by its course between Savoy and Piedmont, falls into the Doria at Sufa.

SEMARILLARIA, in Botany, a term applied to seeds which are surrounded half way down by an arillus, or any other similar covering.

SEMATAI, in Geography, a town of China, of the third rank, in Pe-te-chi; 35 miles N.E. of Pekin.

SEMELA, or SEMAAT, a town of the Arabian Irak, on the Euphrates, where a toll is collected; 115 miles S.E. of Bagdad.

SEMBAKE, or SEMAUSER, an island in the Red sea, near the coast of Arabia. N. lat. 25° 12'.

SEMBELLA, among the Romans, a small silver coin, equal in value and weight to half the libella.

SEMBEYE, or SEMAWE, a town of the Arabian Irak, on the Euphrates, where a toll is collected; 30 miles S. of Paghm Mew.

SEMBIANI, SEMBIANS, in Ecclesiastical History, a sect of ancient heretics, denominated from their leader, Sembas, or Sembianus, who condemned all use of wine, as evil of itself; permitted his followers, that the wine was a production of Satan and the earth, denied the resurrection of the dead, and rejected most of the books of the Old Testament.

SEMBRACENA, in Ancient Geography, a town of Arabia Felix, near the sea, in the kingdom of the Sabzacs, according to Ptolemy.

SEMBRADOR, an engine, invented by Don Jose de Lucatello, for the even fowling of feeds, described in the Philosophical Transactions under the title of the Spanish Sembrador.

The perfection of agriculture is allowed to consist much in setting plants at proportionable distances, and giving sufficient depth to the roots, that they may spread, and receive their necessary nourishment; yet there is very little care taken in the practice of this important part of husbandry, but all sorts of grains are sown by hands in the best way, by which means four parts in five of the feed are lost. To remedy this inconvenience, the sembrador, or fower, is invented, which being fastened to the plough, the whole bundles of ploughing, sowing, and harrowing, is done at once; the seedman's trouble is saved, and the grain spread at equal distances, and equally deep at the bottom of the furrow.

An experiment to this purpose was made before the emperor Leopold in the fields of Luxembourg in Austria, where the land usually yields four or five-fold; but the crop from the ground sown by this instrument was fifty-fold, as appears by a certificate of the emperor's officer appointed to see the experiment; signed, Vienna, Aug. 1, 1663.

We have a figure of the sembrador, in the Transactions, No. 60, by the earl of Callemain. See Plough.

SEMBACHON, or Sibachon, in Ancient Geography, a lake of Palestina.

SEMEL, or SEMEL. See Seam.

SEMACARUS, in Botany, derived from semes, to mark, and carus, a fruit; a name evidently derived from the use that is made of its nut, in the East Indies, to mark table linen and articles of apparel. If these are put over the nut, and pricked, the juice exuding will make an indelible mark, which serves as an excellent natural marking ink.—Linn. Suppl. 25. Schreb. 196. Willd. Sp. Pl. v. 1. 1476. Mart. Mill. Dict. v. 4. (Anacardium; Jaff. Gen. 368. Lamarck Illufr., t. 208. Gzrtin. t. 40.)—Clas. and order, Pentandria Trigynia. Nat. Ord. Terricinaceae, Jaff.

Gen. Ch. Cal. Persanith inferior, of one leaf, bell-shaped, cloven half way down into five, heart-shaped, acute segments. Cor. Petals five, lacinolate, bordered, obtuse, larger than the segments of the calyx. Stam. Filaments five, awl-shaped, shorter than the corolla, inserted into the receptacle; anthers oblong, small. Fil. Germen superior, globular, flattened; styles three, recurved, situated on the germen and shorter than it; stigma club-shaped, retuse. Peric. none, except the receptacle, which is erect, flabby, pear-shaped, smooth. Seed, a nut resting upon the receptacle, heart-shaped, flattened on both sides, smooth and shining.

Ob. Dr. Roxburgh has observed some trees of Semecarpus with male flowers only, on which account professor Martyn has described the genus as belonging to the clafs and order of Polygama Dioecia.

1. S. Anacardium. Marking-nut tree. Linn. Suppl. 182. Roxb. Curvam. v. 1. 13. t. 12. — Native of mountainous, dry woods throughout the East Indies, flowering in July and August, but ripening its seed in January and February. A handsome lofty tree, whole bark is rough, ash-coloured and glittinous within. Branches numerous, spreading, rather hairy. Leaves alternate, on shortifl salt, wedge-shaped, rounded at the tip, entire, firm, nearly smooth above, whitish and a little rough beneath. Flowers in large terminal, erect panicles, composed of numerous, small spikes, of a dirty-greenish-yellow colour. Bracteas numerous, small, deciduous. Receptacle yellow, as large as the nut, which is black, containing a corrosive resinous juice, at first of a pale milk colour, but turning black.

The wood of this tree is soft, containing an acrid juice. The flabby receptacles when wetted have the flavour of apples, and are eaten by the natives. The green fruit, pouted into a pulp, makes good bird-lime; when ripe, its black acid juice is highly esteemed by the Telinga physicians, as a remedy for various disorders.

SEMEGONDA, in Geography, a town of Africa, in the kingdom of Wangara, on the Niger, near a lake called by Ptolemy Libya Palus. N. lat. 15° 22'. E. long. 22° 30'.

SEMEIOTICA, SIGNS, or symptoms, that part of medicine which considers the signs or appearances of diseases, which are the sole guides to the physician, by which he can ascertain the seat and nature of diseases, and their probable termination. It includes, therefore, the art of diagnosis and prognosis, and nosology, or the art of arranging diseases in methodical order. See thes words respectively.

SEMELA, in Geography, a town of Africa, in Tripoli; 145 miles S. of Mefurada.

SEMELE, in Mythology, the mother of Bacchus.

SEMEDITANI, in Ancient Geography, a people who inhabited the interior of Sicily, according to Pliny.

SEMELE, in Botany. See Seed.

SEMELE, in Physiology, an animal fluid secreted by the male, the contact of which is necessary to render the germ formed by the female prolific. See Generation.

SEMECCAN, in Geography, a town of Grand Bucuria; 100 miles S.E. of Balk. 1
SEMENDERY, a town on the S. coast of the island of Java. S. lat. 7° 1'. E. long. 106° 50'.

SEMENDRIA, a town and fortress of Servia, on the S. 620 of the Danube; 20 miles S.E. of Belgrade. N. lat. 44° 52'. E. long. 20° 41'.

SEMENG, in Music, an instrument used in Arabia by those wandering musicians who accompany the dancing women. It is a sort of bad violin, joined with a drum. The body is commonly a cocoa-nut shell, with a piece of skin extended upon it; three strings of catgut, and sometimes of horsehair, are fitted to it; and it is played with a bow, not less awkward in its form than the Greek lyre.

SEMENIAN, in Geography, a town of Peria, in the province of Segellan; 132 miles S. of Kia.

SEMENJAN, a town of Grand Bucaria; 70 miles W. of Andarab. N. lat. 36° 22'. E. long. 66° 50'.

SEMENNAD, a town of Egypt, on the E. branch of the Nile; 8 miles S.S.W. of Manzora.

SEMEOV, a town of Russia, in the government of Niznai-Novgorod; 36 miles N. of Niznai-Novgorod. N. lat. 55° 30'. E. long. 44° 14'.

SEMEPOSOVSKOY, a town of Russia, in the government of Vologda; 44 miles N.N.W. of Vologda.

SEMENTINE, in Antiquity, a place held annually among the Romans, to obtain of the gods a plentiful harvest.

They were celebrated in the temple of Tellus, or the Earth, where solemn sacrifices were offered to Tellus and Ceres.

The time of the celebration was about midsummer, usually in the month of January; for Macrobius observes, they were movable feasts. They had their name from semen, seed.

SEMERON, in Ancient Geography, a royal town of Judea, in the tribe of Zebulon, according to the book of Joshua, whither, it is said, Jabin sent a messenger to demand succour of the king of the city, and which he accordingly obtained, together with that of several other kings, to attack the Israelites; but they were all defeated and slain in the combat.---Alfo, a mountain of Judea, in the tribe of Ephraim, E. of Sichem; called also the mountain of Samaria.

SEMETS, SUMMETS, or SUMNITE, in Botany, are used by Dr. Grew and others, for the apices of the stamens of plants.

SEMI, a word borrowed from the Latin, signifying half; but only used in composition with other words, as in the following articles.

The French, instead of feni, frequently use demi, the Greeks bemi.

In music, feni has three several usages; first, when prefixed to the name of a note, it expresses a diminution of half its value, as in demi-breve, &c.

Secondly, when added to the name of an interval, it expresses a diminution, not of half, but of a lesser feni-tone, or four commas, in the whole compass, as in feni-diapente, &c.

Thirdly, in old music to the end of the 16th century, it implies imperfection in the value of notes, as a demi-circle, or circolo mezzato; the whole circle then implying perfection, or triple-time. Three breves, or three times three semibreves, without a point. Common time, or, as it was then called, imperfect, or dual measure. See Musical Characters, and the first Time-Table.

SEMI-ARIANS, in Ecclesiastical History, a branch of the ancient Arians, consisting, according to Epiphanius, of such as, in appearance, condemned the errors of that heresy, but yet acquiesced in some of his principles, only palliating and hiding them under softer and more moderate terms. See Arians.

It is true, they separated from the Arian faction; but yet could never be brought to acknowledge that the Son was homoeousios, that is, confubstantial, or of the same substance with the Father; they would only allow him to be homoeousios, that is, of a like substance with the Father, or similar to the Father in his essence, not by nature, but by a peculiar privilege. See Homoeousios, &c.

Though, as to expression, they only differed from the orthodox by a single letter, yet were they, in effect, of the opinion of the Arians, as they placed the Son in the rank of creatures. It did not avail their teaching, that there was no other creature of the same class with him, since by denying him consubstantial with God, they effectually precluded him from being truly God.

Yet some, even among the orthodox, use the word homoeousios, in speaking of the Son; applying such an idea to it as it seems consistent with orthodoxy.

But the name Semi-Arians is also given, by the second general council, to another branch of Arians, who believed orthodoxly of the Father and Son, but denied the deity of the Holy Ghost; thus rejecting that part of the Arian system relating to the Son, but still retaining that which related to the Holy Ghost.

As the zeal of the Arians was chiefly directed against the second person in the Trinity, that of the Semi-Arians was bent against the third; whereas, as the former were sometimes called Χίλουμιασιοι, the latter were denominated Πιστοιοι.

Macedonius, bishop of Constantinople, made an innovation in this sect in 360, and gave rise to a new branch of Macedonian Semi-Arians, or Pneumatomachi; who allowed the Son not to be homoeousios, of the same substance, but homoeos, of like substance with the Father; and at the same time openly affirmed the Holy Ghost to be a creature. This heresy was condemned by the eleventh general council held at Constantinople in the year 381. See Macedonians.

SEMBRE, in Music, half a breve, See the Time-Tables.

SEMICIRCLE, in Geometry, a figure comprehended between the diameter of a circle, and half the circumference. Two semicircles can only cut each other in one point.

SEMICIRCLE is also an instrument in Surveying, sometimes called the grophometer.

It consists of a semicircular limb, as F, I, G (Plate VII. Surveying, fig. 5) divided into one hundred and eighty degrees, and sometimes subdivided diagonally or otherwise into minutes. This limb is subtended by a diameter FG, at the extremities of which are erected two sights. In the centre of the semicircle, or the middle of the diameter, is fixed a box and needle. On the same centre is fitted an alidade, or moveable index, carrying two other sights, as H, I. And the whole is mounted on a staff, with a ball and socket.

The semicircle, then, is nothing else but half a theodolite; with this only difference, that whereas the limb of the theodolite, being an entire circle, takes in all the 360° successively; in the semicircle the degrees only going from 1 to 180, it is usual to have the remaining 180°, or those from 180° to 360°, graduated in another line on the limb within the former.

To take an Angle with a Semicircle. Place the instrument in such manner, as that the radius CG may hang over one leg
SEM

leg of the angle to be measured, and the centre C over the vertex of the same. The first is done, by looking through the lights F and G at the extremities of the diameter to a mark fixed up in one extremity of the leg; the latter is had by letting fall a plummet from the centre of the instrument. This done, turn the moveable index H I on its centre towards the other leg of the angle, till through the lights fixed in it, you see a mark in the extremity of the leg. Then the degree, which the index cuts on the limb, is the quantity of the angle.

For farther uses of the semicircle, they are the same with those of the absciss.

SEMICIRCULAR ARCHES. See Arch.

SEMICIRCULAR Canals, in Anatomy, three small membranous tubes, inclosed in excavations of the bone, and composing part of the labyrinth of the ear. See Ear.

SEMICIRCULARIS TENDIN, a part of the brain. See Brain.

SEMICIRCULARIS Palpebrarum Musculus, a name given by Spigelius, and some others, to one of the muscles of the face, called by Albinus and Winslow the mucusmus orbicularis palpebrarum.

SEMICOLON, in Grammar, one of the points or stops, used to distinguish the several members of a sentence from each other.

The mark or character of the semicolon is (;). It has its name, as having somewhat less effect than a colon, or as demanding a shorter pause.

The use of the semicolon, the grammarians generally say, is to mark a fenerless complete than the colon, and more complete than the comma; but this only conveys a very obscure idea. In effect, the precise office of the semicolon, or that office which distinguishes it from the colon, is a thing very little known to the world. Our best authors seem to use them profusely. See Colon.

Dr. Ward, formerly professor at Gresham, is perhaps the first who settled a just use of the semicolon. His position is, that the semicolon is properly used to distinguish the conjunct members of sentences. Now by a conjunct member of a sentence, he means, such as one, as contains at least two simple members.

Whenever, then, a sentence can be divided into several members of the same degree, which are again divisible into other simple members, the former are to be separated by a semicolon.

E.g. If Fortune bear a great sway over him, who has nicely flatted and concerted every circumstance of an affair; we must not commit every thing, without reserve, to Fortune, lest she should have too great a hold of us.

But though the proper use of the semicolon be to distinguish conjunct members, it is not necessary that all the members divided by it be conjunct. For upon dividing a sentence into great and equal parts, if one of them be conjunct, all those other parts of the same degree are to be distinguished by a semicolon. Thus, whoever is overtaken with poverty; the same will find, that coldheifs, contempt, injuries, &c. are not far behind. Hither likewise may be referred such sentences, where the whole going before, the parts follow: as, the parts of rhetoric are four; invention, disposition, elocution, and pronunciation.

According to bishop Lowth, a member of a sentence, whether simple or compounded, that requires a greater pause than a comma, yet does not of itself make a complete sentence, but is followed by something closely depending on it, may be distinguished by a semicolon. E. g. But as this passion for admiration, when it works according to reason, improves the beautiful part of our species in every thing that is laudable; so nothing is more destructive to them, when it is governed by vanity and folly. Here the whole sentence is divided into two parts by the semicolon; each of which parts is a compounded member, divided into its simple members by the comma; which see.

SEMICOLON, a musical instrument among the Greeks, which had thirty-five strings.

SEMICROMA, Sextuple of. See Sextuple.

SEMICUBLICAL PARABOLA, a curve of the second order, in which the cubes of the ordinates are as the squares of the abscissals. Its equation is \( ax^2 = y^3 \).

SEMICUPIDUM, a half bath, in which the patient is only placed up to the navel. See Insessus.

SEMDIAMETER, a right line drawn from the centre of a circle or sphere, to its circumference; the same with what we otherwise call a radius.

The distances, diameters, &c. of the heavenly bodies, are usually estimated by astronomers in semidiameters of the earth.

For the proportions and values of the semidiameters of the planets, see Planets. For their apparent semidiameters, see Diameter.

SEMI-DIAMASON, in Music, a defective octave; or an octave diminished by a lefser semitone, or four commas. See Diapason.

SEMI-DIVAPENTE, a defective fifth, called usually by the Italians falsa quinta, and by us a falsé fifth.

SEMI-DIATESSARON, a defective fourth, called properly, a falsé fourth.

SEMI-DITONE, Diapason. See Diapason.

SEMI-DITONE, Dit-diapason. See Diapason.

SEMI-DITONUSUS, is used by some writers, as Salinas, for the third minor.

SEMI-DOUBLE, in the Roman Breviary, a term applied to such offices and festivals as are celebrated with less solemnity than the double ones; but yet with more than the single ones.

The semi-double office has double vespers, and nine lessons at matins; but the anthems are not redoubled. It is performed on Sundays, on the octaves, and on the feasts marked for semi-double in the calendar.

SEMFLOSCULOUS, a term used to express the flowers of a certain class of plants, of which the dandilion, hawkweed, and the like, are kinds.

This sort of flower consists of a number of semifloresculi, which are disposed into one or more circles, and all comprehended in the same cup, which often becomes inverted as the flower ripens. These semifloresculi are petals, hollow in their lower part, but in their upper half are flat, and continued in the shape of a tongue. These are often separated from each other by intermediate leaves, and are placed upon the embryo fruit, from which there stand out a slender calyx, divided at the end into two parts; often carried beyond the vagina, supported by five proper. The embryos are placed in the thalamus, or bottom of the cup, and finally become seeds, sometimes winged with down, sometimes naked, sometimes coronated, and sometimes foliated.

SEMIGALLIA, Duchy of, in Geography, a division of Courland, about 110 miles in length, and from 10 to 25 in breadth, bounded on the north by Ruffia, from which it is separated by the Dwina, and elsewhere by Courland. It is subject to Ruffia. Its capital is Mītaw.

SEMIGERMANÆ GENTES, in Ancient Geography, the name of a people who inhabited the Pennine Alps, according to Ptolemy.
SEMIJA, in Geography, one of the Fox islands, in the North Pacific ocean. N. lat. 53° 5'. E. long. 175° 14'.

SEMI-INTEROSSEUS INDICIS, in Anatomy, a small, short, flat, flexous muscle, very like the antihenar, or internal interfossus of the thumb. It is situated obliquely on one side of that of the thumb, between the first phalanx of it and the first metacarpal bone. It is fixed by one end to the outside of the head of the first phalanx of the thumb, and a little to that bone of the carpus, by which this phalanx is supported; and by the other end it is fixed near the head of the first phalanx of the index, on that side next the thumb. It lies almost parallel to the antihenar, crossing it a little; this muscle lying on the convex side of the hand, and the antihenar on the concave. Winslow.

SEMI-JUDAIZERS, in Ecclesiastical History, a sect of Socinians, consisting of the disciples and friends of Francis Davides, superintendent of the Socinian churches in Transylvania; who, in consequence of his adherence to the opinions he had adopted, was thrown into prison by Christopher Bathori, prince of Transylvania, where he died, in the year 1579, in an advanced age. The most eminent of his followers were Jacob Polelogoys, of the isle of Chio, who was burnt at Rome in the year 1485; Chrillian Franccken, who had disputed in person with Socinians; and John Somer, who was master of the academy of Cluflenburg. The followers of Davides were called Semi-Judaizers by the Socinian writers, according to Moreism, by way of reproach; but others maintain, that it was grounded on their sentiments, and that it was designed to express the partial preference they gave to the Law of Moses above the Gospel of Chrift. The words of Chrift, as Davides affirms, and those of his apostles, are to be tried by the doctrine of Moses and the prophets, which ought to be to us the sole rule of life and religious worship. He also maintains, that there is no difference between the old covenant established by Moses, and the new confirmed by Chrift, in doctrine or in promises; and that they differ merely in this circumstance, that under the former there was the ministry of the letter, and under the latter that of the spirit; and, therefore, the one has not abrogated or changed the other: so far from it, that the new covenant exiled only till the destruction of Jerusalem, and will have no farther influence till the time of Chrift's worldly government over Israel in the city of Jerusalem, which is to be rebuilt. In the mean time, Chrift is not really the Chrift or king of God's people, but only by designation; the Chrift predicted by the prophet, and promisèd by God, having no other than an earthly kingdom, which Jesus was appointed to take possession of; but being slain by the Jews, contrary to the divine purpose, he was translated into a secure and quickset flate. In this flate he is not any more to be called God, as he was by virtue of his office during his abode on earth, because his office had ceased; nor is he entitled to any adoration and worship, as Socinians thought, nor to any other kind of reverence, except obedience to his precepts, and faith in his doctrine; nor is he employed under the distinguishing appellation of priest and intercessor, both which offices terminated at his death. See the propositions drawn up by Paulus Socinus, and presented to C. Bathori, in Socin. Op. tom. ii. p. 801.-803, or Toulmin's Life of Socinus, p. 453, &c.

SEMI., in Geography, a river of Cabulistan, which joins the Dilen at Kerdiz, to form the Cow.

SEMI LUNAR, SEMILUNAR, in Anatomy, an epithep, applied, in consequence of their figure, to various parts of the body.

SEMI LUNAR CARTILAGES of the Knee-joint, are two small portions of cartilage situated in that articulation. See EXTRREMITIES.

SEMI LUNAR PORTION or EDGE of the Fascia Lata. See FASCIA.

SEMI LUNAR VALVES of the Aorta and pulmonary Artery, the three valves placed at the entrance of each of these vesels. See HEART.

SEMI LUNARES COCHLEAE, in Natural History, the name of a genus of sea-shells, so called, from their having semilunar mouths. See Conchology.

The characters of the genus are these. They are univalve shells of a compact body, with a flat semilunar, and often dentated mouth; the columnella, or inner lip, running diametrically across it in a straight line. Some of the species have exerted apses, and some depressed: these are nearly globose shells, and the turban is never much produced, but lies flat or level with the bottom.

There are many distinctive and specific characters in the several species of this genus, which arrange together considerable numbers of the species under each. Thus the nerite, which are of this genus, are some of them umbi- culated, and others have teeth and a kind of gums. The shell kinds, diffïntly so called, that fall under this genus, are very different from the nerites, in that they have no teeth, no gum, and no palate. The term semilunares cochlea was invented by Rumphius to express their mouths, being of the shape of half a circle.

All the species of the semilunar shells have few convolutions, and have the extremity of the voluta small, and usually standing a little out.

The species of the semilunar cochlea are thefe, as arranged under the two general divisions of dentated nerite, and umbilicate cochlea, viz. the dentated nerite, com- monly called the gum-shell; the bloody-tooth nerite; the ox-palate nerite; the triturated and punctuated nerite; the canalicate, the furrowed, the thrilling, and the partridge nerite.

Of the nerite which have no teeth, we have ten species; viz. the Jasper with a long beak; the Jasper with an operculum; the lemon-coloured pea; the yellow pea; the prickly; the reticulated; that variegated with black spots; the red and white falcated; the lightly triturated green; and the undulated nerite.

Of the umbilicate shells we have nine species; viz. the long umbilicate; that with an exerted apex; that with a depreffed apex; tefficated; the hermit; the umbonated; the small nipple; the heavy white; and the orange-coloured cochlea. Hist. Natural. Eclair. part ii. p. 256.

SEMI LUNARIS LIMEN, in the abdomen, is the line following the outer edge of the rectus abdominis muscle. See OBLIGUUS.

SEMI MEMBRANOSUS, (iichio-fous-tibien; demiamionévtique) ; a muscle of the thigh, situated on the posterior part of the limb, elongated, and extending from the tuberosity of the ischium to the upper and back edge of the tibia. It commences from the tuberosity of the ischium, in front of the ischium, and behind the quadratus femoris, by a strong flat tendon, which soon expands into a broad aponeurosis, thicker at its external than at its inner edge, and giving origin successively by the latter to the muscular fibres. The latter are all parallel, short, and placed obliquely, and form a thick
2 thick masts, which is largest at its middle, and smaller at the two ends. They defend obliquely inwards, and terminate in an aponeurosis, which, beginning opposite to the end of the superior one, receives the fibres successively, and ends below in a thick tendon, which passes behind the knee-joint, and divides into three portions. The external is narrow and slender, ascends obliquely upwards towards the joint, and is fixed above the external condyle of the thigh, confluent with the external head of the gastrocnemius. The middle, which is broad and continuous with the preceding, is fixed to the back of the internal tubercle of the tibia, and sends an expansion over the popliteus. The internal, more considerable and rounded, seems to be the continuation of the tendon; it turns round the tuberosity, and is attached in front of it, contained in a fibrous sheath, lined by a synovial membrane, which must be opened to gain a clear view of it.

It is covered by the femorodinosus, the biceps, and the vastus lata; it lies on the quadratus, the adducto magnus, the popliteal artery, the knee-joint, and the inner head of the gastrocnemius, between which and its tendon there is a synovial membrane.

It bends the leg on the thigh, or the thigh on the leg; and it extends the thigh on the pelvis, or carries the pelvis backwards on the thigh.

SEMI-METALS, a term formerly applied in Chemistry, to those metals not possessing ductility or malleability; these properties being then considered as the principal characters of a metal. In a mechanical point of view this is doubtless the cafe, but the chemical properties of these numerous classes of bodies are so striking, as to render the above distinction useless. See Metals.

SEMINA, in Ancient Geography, a town of Afia, in Parthia. Ptolemy.

SEMINAGUR, in Geography, a town of Hindoostan, in Oude; 36 miles N. of Kairabad.

SEMINAL, SEMINALIS, in Medicine, spermatic, or something belonging to the semen or seed.

SEMINAL Leaves, those soft, plain, and undivided leaves, that first shoot forth from the greatest part of all fawn seeds, and are different from those of the succeeding plant in figure, texture, and all other respects. See Seed and Vegetation.

SEMINAL Varieties of Plants, such as are produced from seeds, which, in many instances, is invariably the cafe, as in the potato, &c.

SEMINAL Root, in Natural History, a name given by Grew to that part of the seeds of plants, which may otherwise be called the inner body of the seed; this is distributed through the parenchyma of the seed, but is wholly different from it; and distinguished by Dr. Grew from the radicle, which becomes the plant-root in its future growth. The parenchyma of the seed is, in some degree, that to the seminal-root, which is the mould or earth is to the plant-root, or radicle; and the seminal-root is to the plant-root, what the plant roots is to the trunk.

SEMINALIS, in Botany, a name by which some authors have called herfetal.

SEMINARA, in Geography, a town of Naples, in Calabria Ultra; destroyed by an earthquake in 1783, though the inhabitants escaped; 17 miles N.N.E. of Reggio.

SEMINARY, a place appointed for the instruction of young persons destined for the ministry, in its duties, ceremonies, and offices; first instituted, as Thomasin tells us, by St. Augustine.

Of these seminaries there are many abroad, furnished with halls for the assemblies of the exorcizants, and little chambers, or cells, where each person retires, studies, and prays, apart. Such is the seminary of St. Sulpius, at Paris.

The council of Trent decrees, that children exceeding twelve years of age be taken, brought up, and instructed in common, to qualify them for the ecclesiastical state; and that there be a seminary of each belonging to each cathedral, under the direction of the bishop.

In France, the establishment of seminaries was somewhat different from the decree of the council; none are taken in but young people ready to study theology, and to be ordained: so that the seminaries were a kind of houses of probation, where the vocation of clerks is examined, and they are prepared to receive orders. And by an edict of 1749, no seminary could be established without letters patent from the king.

For the subsistence of these seminaries, there are several unions of benefices, or else the clergy of the diocese are obliged to contribute to maintain them.

Pope Pius IV. having established a seminary at Rome, in consequence of the decree of the council of Trent, by advice of the cardinals, it was given to the Jesuits, who have made very good use of it.

SEMINARY, among the canons of St. Augustine, is used for a kind of college, or school, where pensioners are kept, and instructed in classical and other learning; and this among us is the popular tenet of the word.

The houses of the society de propaganda fide, established for the preparing of ecclesiastics for millions among infidels and heretics, are also called seminaries. The principal of which is that at Rome, called the apostolical college, apostolical seminary, pastoral seminary; seminary of the propaganda, &c. See Pistoia.

SEMINARY is now used among us in the same sense with school; which feem.

SEMINARY, in Gardening, the term used for the feed-plot, or place allotted for raising plants from seed, and keeping them till they are fit to be removed into the garden, or nursery.

When the seminary is intended for trees, it must be proportioned to the quantity of seeds fown, and of a soil adapted to the generality of the trees intended to be raised in it. The land should be good, and the situation warm, and well defended, and as near the nursery as possible. A fertile mead, or rich pasture, lowly situated, will be very proper for the purpose. In preparing the seminary, let the ground be double dug, working the soil to the bottom, which operation may be performed in winter. In the spring, the weeds must be constantly kept down; and about Midsummer, if the soil is not naturally very rich, some rotten dung should be spread over the surface of the ground, which should be then trenched, or double dug afresh. From Midsummer till September, the ground must be kept clean from weeds, and just before the seeds are committed to it, it should be double dug afresh; at which time the parts must be wholly incorporated. When this is done, the ground must be levelled, and the beds laid out for the different purposes wanted; reserving such a portion of it as will be wanted for the reception of those seeds which are to be sown in the spring.

The seminary must be divided into different apartments, for the different sorts of seeds, according to their nature; those seeds that are sown in autumn being sown in a part by themselves; those in the spring in another. Those seeds, which remain till the second spring before they come up, should be all sown in beds contiguous to each other; and those, which often continue three years, must be sown by themselves. When the plants produced in any of the apartments
apartments are taken off for the nursery, the ground should be double dug, and lie fallow the following summer, manuring it with rotten dung, and double-digging it about Midsummer, as before. In autumn it will be ready to be fown afresh, which should be done with seeds of a different nature from those by which it was before occupied. The fernary should be well fenced and guarded. The fernary which is most in use is for the supply of the flower-garden, and this is the place where flowers are to be raised from their seeds, to procure varieties, or, as the florists express it, new flowers; as also for the fowing of all the biennial plants, to succeed those which decay in the flower-garden. The fernary should always be situated at some distance from the house, and be walled or paved round, and kept under lock and key, to keep out dogs, &c. and to prevent a great deal of damage that is frequently done by those who are not acquainted with gardening before they are aware of it. The several directions for the management of the fernary are to be seen under the names of the several plants intended to be raised in it.

SEMINATION, in Agriculture, the act of sowing grain or other sorts of feed. It is of much consequence to have this performed in as equal and regular a manner as possible; the crops being thereby much better, and more productive. See Sowing.

SEMINERVOSUS, in Anatomy. See Semitendinosus.

SEMINIFEROUS Tubes or Ducts, the innumerable fine canals composing the body of the testis, into which the seminal fluid is secreted. See Generation.

SEMINIUM, a term used by the writers on fossils to express a sort of first principle, from which the several figured stones, or, as they are more usually called, the extraneous fossils, are supposed to have their origin. The generality of the learned world, at this time, supposed these to be the remains of real shells, &c. brought from the sea to the places where they are now found, at the time of the universal deluge. See Formed Stones, and Adventitious Fossils.

But those who differ from this system pretend, that these fossil shells, though they exactly repreffent shells, &c. yet never were in the sea at all, but that their minute first principles, or, to use their own term, their feminia, have been carried from the sea, through subterranean passages, to the places where we now find the complete shells, &c. into which they have grown. Langius, who has written expressly on this subject, though he has candidly collected all that has been said in favour of the diluvian system, by the adherents of it, yet is not convinced by these arguments, but rather inclines to the other side of the question, or the rise of such fossils from feminia.

These fossil shells are usually found throughout one and the same substance, and that the most different imaginations from the substance of the living creatures which they represent; and often, though found in pairs, and perfectly closed on all sides, yet when broken, they are found full of the substance of the stone in which they lie; and the armature of several kinds of them, particularly of many of the cornea ammonis, is supposed to plead greatly in favour of this hypothesis; as it is not of the nature of or at all owing to the substance of the matrix in which they lie, or of the matter of which they are formed, and is therefore to arise solely from the nature of the feminia from which they are formed.

The immense number of the sea-shells, as they are called, thus found fossil, is also thought to argue much on this side of the question; as the favourers of this hypothesis suppose that the sea could not, at any one time, have given up such numbers as the earth is stocked with, though there are no limits to the numbers supposed to be raised from feminia; and the immense columns of black marble found in Ireland, and found of such regular joints, are brought as a proof of the possibility of such a formation of fossils as this from feminia, which they suppose must have given origin to those pillars.

SEMINOLES, in Geography, a division of the Creek nation of Indians, who inhabit the flat level country on the rivers Apalachicola and Flint.

SEMIORBICULARES Oris, Superior and Inferior, in Anatomy, the names under which Winslow describes the orbicularis oris. See Declination.

SEMI-ORDINATES, in Geometry, the halves of the ordinates or applicates. See Ordinate and Conic Sections.

SEMI-PARABOLA, a curve defined by the equation, \( ax^{n-1} = y \); as \( a x^2 = y \), \( a x^3 = y \).

In semi-parabolas \( y^2 = ax^{1/2} \); as \( y^2 = 2x \); \( z^2 = ax \); or the powers of the semi-ordinates are as the powers of the abscissae, one degree lower; \( e.g. \), in cubical semi-parabolas, the cubes of the ordinates \( y \) and \( z \) are as the squares of the abscissae \( x \) and \( z \). See Parabola.

SEMI-PELAGIANS, in Ecclesiastical History, a name anciently, and even to this day, given to such as retain some tincture of Pelagianism.

St. Prosper, in a letter to St. Augustine, calls them religiosi Pelagii.

Many learned men, principally among the Gauls, who could not come into St. Augustine's doctrine of grace, &c. were accused of Semi-pelagianism; they were also called Maffians, or priests of Marseilles, in regard their opinions had their first rife in that city.

Caffian, who had been a deacon of Constantinople, and was afterwards a priest at Marseilles, was the chief of these Semi-pelagians. And about the year 450, several other persons embarked in the undertaking of fixing upon a kind of mean between the opinions of Pelagius and those of Augustine, and formed this new sect.

The leading principles of the Semi-pelagians were the five following. 1. That God did not dispenfe his grace to one more than another in consequence of predestination, \( i.e. \) an eternal and absolute decree, but was willing to fave all men, if they complied with the terms of his gospel. 2. That Christ died for all men. 3. That the grace purchafed by Christ, and necessary for salvation, was offered to all men. 4. That man, before he received grace, was capable of faith and holy defires. 5. That man was born free, and was consequently capable of refifting the influences of grace, or of complying with its fuggation. The Semi-pelagians were very numerous; and the doctrine of Caffian, though variously explained, was received in the greatest part of the monaflic schools in Gaul, from whence it spread itself far and wide through the European provinces. As to the Greeks, and other ancient Chriflians, they had embraced the Semi-pelagian doctrine before Caffian, and still adhere firmly to it. In the sixth century, the controversy between the Semi-pelagians and the disciples of Augustine, prevailed much, and continued to divide the Western churches. Molheim's Eccl. Hist. vol. i.

SEMI-PERIOD, in Grammar, a mark of diftinction recommended by Dr. Ward, but not admitted by other grammarians. It is greater than the colon, and supposed to answer the fame purpose between the colon and period as the semicolon does between the comma and colon. It is used to terminate a perfect sentence, when a new sentence arising out of
of the preceding is annexed to it; and he distinguishes it by beginning the new sentence with a small letter. But the colon and fermicron, differently applied, supercedes the necessity of his new division.

SEMPOLATNOI, or SEMPLAT, in Geography, a fortress of Ruffia, in the government of Kolivan, on the Irritich, first built in the year 1714, on the bank of the Irritich; but afterwards taken down and erected in several different situations. It now stands in its fourth situation, and is easily commanded from the mountains that lie to the east of it; and the adjacent country is very pleasant and fertile, but remains uncultivated. The gardens at Semplat yield a very fine species of melons. The fort derives its name from Semplata, a ruinous town, distant from it about 16 versts on the river Irritich, where are seen some remains of old stone buildings. The Ruffian settlers found here seven houfes, as the name of the place imports. Some learned men are of opinion, that certain interlopers found among the ruins, relate to the mythology of the Kalmucks; and that this place was deferted by these people, in conformity to a maxim of their religion, that when any consecrated place is profaned by war, it should be for ever relinquished; 148 miles S. of Kolivan. N. lat. 50° 25'. E. long. 80° 14'.

SEMI-PORCELANÆ, in the History of Shells. See SHELLS.

SEMPREBEND. See PREBEND.

SEMPI-proof, an imperfect proof.

In the French law, the deposition of a single evidence only makes a semiproof.

The testament of a person deceased is deemed a semi-proof.

In enormous cases, the semiproof frequently determined them to try the torture.

SEMIQUARTILE, or SEMIQUADRATÄ, is an aspect of the planets, when distant from each other 45 degrees, or one sign and a half.

SEMIQUAVER, in Music. See QUAVER.

SEMIQUINTILE is an aspect of the planets, when at the distance of 36 degrees from one another.

SEMIRA, in Geography. See SAFIRA.

SEMIRAMIS, in Biography, queen of Assyria, a very distinguished personage in ancient history, lived at a period so remote, that little can be known with certainty of her actions. It appears, however, that Semiramis was a female of obscure origin, but of great beauty and a superior understanding, and that she became the wife of Menon, an officer of high rank under king Ninus; that following her husband to the army, she engaged in the invasion of Babâra, and attracted the king’s notice, whom he afterwards married, her former husband, through jealousy or despair, having put an end to his life. After the death of Ninus, who left her regent and guardian of their infant son, she assumed the reins of empire, and governed with great glory. She founded the famous city of Babylon; then purifying her husband’s plan of conquest, and marching through Media and Peria, every where, it is said, leaving traces of her splendour, in works of magnificence and utility, penetrated to the banks of the Indus. She there encountered the king of the country, at the head of a vast army, and underwent a total defeat, which obliged her to return to Babâra with scarcely a third part of her forces. A conspiracy being then formed to affaile her, at the instigation of her own son, the either fell under it, or was obliged to resign her crown after wearing it upwards of 40 years.

SEMIIMREVÉBERATORY Fire, in Chemistry, a term used to express such a reverberatory fire, in which the flame is only beaten back upon the bottom of the vessel.

SEMIRHOMBUS, in Surgery, a sort of bandage.

SEMIRUS, in Ancient Geography, a navigable river of Italy, in Brutium, the country of the Locri, according to Pliny.

SÉMIS, among the Romans, the half of the as.

SEMISAT, in Geography. See SAMISAT.

SÉMIESEXTILE, or SEMIESEXUS, or S.S. an aspect of two planets, wherein they are distant from each other one-twelfth part of a circle, or 30 degrees.

The semiextile was added to the ancient aspects by Kepler; and, as he says, from meteorological observations.

SEMINICILICUS, a word used by some pharmacutic writers to express a drachm.

SEMINOSERATUS, a word used by some for a perfon struck with a hemiplegia.

SEMISOPHROLO, in the Italian Myth, a little paufe, or the eighth part of a bar in common tune.

SEMISPINALIS DORSI, in Anatomy, a portion of the muscular mass, which fills the hollow of the spine between the transversa and the spinous processes. It arises from the transversa processes of four, five, six, or seven of the inferior dorsal vertebrae, beginning with the second from the lains, and is covered in the spinous processes of the two lowest cervical, and of the two, three, or four first dorsal vertebrae. It lies on the multifidus fponge, with which it is much connected; and it is covered by the longissimus and complexus. It is described as a distinct muscle by Albinus and Soemmerring; Boyer and Bichat include it with the multifidus sponge under the name of transversa fagineus. See MULTIFIDUS, under which article its action is described.

SEMITA LUMINOÃ, a name given to a kind of lucid tract in the heavens, which a little before the vernal equinox, or after the autumnal, may be seen about six o’clock at night, extending from the western edge of the horizon, up towards the Pleiades.

The phenomenon has been taken notice of by Caffini and Fatio, who both evince, that this light comes diffused from both sides of the sun. Its brightness is much the same with that of the via lactea, or the tail of a comet: it is seen plainest with us about the beginning of October, or the latter part of February.

Fatio conjectures, that the bodies, or rather the congeries or aggregate of bodies, which occasion this light, conforms to the fun like a lens, and takes it to have ever been the same; but Caffini thinks it arises from a vast number of small planets, which compass the sun, and give this light by reflection; effecting it also not to have existed long before he observed it. See ZODIAL LIGHT.

SEMITALAE, among the Romans, a name given to the gods who were the protectors of roads.

SEMITENTINS. See TRANTS.

SEMITEENSUS, feminervous; ifchio-pre-tibien, in Anatomy, a long muscle at the back of the thigh, thicker above and very flender below, extending from the tuberosity of the ischium to the tibia. It arises from the ischium by a tendon, which, for the space of three inches, is common to it with the long head of the biceps flexor erulis. The muscular fibres arising from this tendon form a fasciculus, which is first flender, then larger, and then again diminished, and interfected in its middle by an aponeurosis very obliquely directed. The femitendinosus passes along the inner and posterior edge of the thigh, and terminates below in a tendon, which first constitutes...
constitutes the sharp edge of the inner ham-string, then goes behind the internal condyle and the knee-joint, fends off an expansion, which contributes to the formation of the aponeuroles of the leg, turns round the head of the tibia, and spreads into a flat form to terminate on the anterior surface of that bone, a little below the knee, behind the tendon of the fasci- torius, and in company with that of the gracili. Between this tendon, and the internal lateral ligament of the knee-joint, there is a bursa mucofa. The mufcle is covered by the fascia of the thigh, and at its origin by the gluteus magnus: it covers the feminembranous and the adductor longus. The feminendentous acts on the knee, the hip, and the pelvis, in the fame way as the feminembranous does. See the description of that mufcle.

**SEMITERTIAN FEVER.** See Fever, Semiterian.

**SEMITONE,** in Music, one of the degrees, or concinuous intervals, of concords.

There are three degrees, or lefs intervals, by which a sound can move upwards and downwards successively from one extreme of any concord to the other, and yet produce true melody; and by means of which, feveral voices and instruments are capable of the neceffary variety in passing from concord to concord. These degrees are the greater and lefis tone, and the femitone. The ratio of the firft is 8 : 9; that of the feeond 9 : 10.

The ratio of the femitone is 15 : 16; its compafs is five comans; which interval is called a femitone, not that it is geometrically the half of either of the tones, for it is more; but becaufe it comes somewhat near it. It is also called the natural femitone, and the greater femitone, becaufe greater than the part it leaves behind, or its complement to a tone, which is four comans. The Italians also call it seconda minore, or a leffer second.

There are feveral fpecies of femitones; but thofe that usually occur in practice are of two kinds, diftinguifhod by the addition of greater and lefs. The firft is expreffed by the ratio of 16 to 15, or 100/9; and the fecond by 25 to 24, or 25/24. The octave contains ten femitones major, and two dieses, nearly; for the meafeure of the octave being expreffed by the logarithm 1.000000, the femitone major will be meafeured by 0.0931909; and the octave contains seventeen femi- tones minor, nearly. If the meafeure of the octave be the logarithm 1.000000, the meafeure of the femitone minor will be 0.058894. These two differ by a whole harmonic diefs, which is an interval practicable by the voice, and was much in use among the ancients, and not unknown even among the modern practitioners. Euler, Tent. Nov. Theor. Muf. p. 107. See Interval.

These femitones are called fictitious notes; and with refeft to the natural tones, are expreffed by characters called flats and sharps.

Their ufe is to remedy the defects of instruments, which, having their sounds fixed, cannot always be made to answer to the diatonic fcale.

By means of these we have a new kind of fcale, called the Semitonic Scale; which fee.

In practical music, on keyed and fretted instruments, it is a nominal half-tone; though mathematicians, in theory, find it imposfible to divide a tone into halves. Rouffeau, after explaining the scientific and nominal difference between the major and minor femitone; the major changing its place, as to f, and b to e; and the minor remaining on the fame line, as f♯, f♭, b♭, b♭; observes, that though the imaginary change of tone is expreffed by the accident of a sharp or a flat, yet there is no difference in the found of E♭ and F♭, or in A♭ and D♭, on the organ or harpichord, the fame tones being sometimes major and sometimes minor, sometimes diatonic and sometimes chromatic, according to the key we are in.

For the importance of the femitone in music, fee Mattheson's Organiftn-preb. or Treatife on Thorough-bafe, where he has bfeftowed many pages on this interval. Zarlinho calls it il fale, the falt, or lefioning of music.

The ufe of femitones has been much abused of late, by the now too common trick of running up and down the piano forte in half-notes. Our flow chromatic is fundament- al, and productive of modulation; but the quick chiefly confifts of appoggiaturas, and mere notes of taille, unnoticed in the bafe and the accompaniments. See Modern Chromatic.

For the fober ufe of thefelfe femitones with good taife and effect, see Mozart's Theme, No. 5. Var. 4. fefian thraim.

**SEMITONIC Scale,** or the Scale of Semitones; a fcale or fystem of music, confifting of 12 degrees, or 13 notes, in the octave, being an improvement on the natural or diatonic fcale, by inferting between each two notes of it another note, which divides the interval or tone into two unequal parts, called femitone.

The ufe of this fcale is for instruments that have fixed founds, as the organ, harpichord, &c. which are exceedingly defective on the foot of the natural or diatonic fcale. For the degrees of the fcale being equal, from every note to its octave, there is a different order of degrees; fo that from any note we cannot find any interval in a feries of fixed founds; which yet is neceffary, that all the notes of a piece of music, carried through feveral keys, may be found in their just tone, or that the fame fong may be begun indifferently at any note, as may be neceffary for accommodating some instrument to others, or to the human voice, when they are to accompany each other in unison.

The diatonic fcale, beginning at the lowest note, being firft fettled on an instrument, and the notes thereof diftinguifhed by their names, a, b, c, d, f, g; the inferted notes, or femitones, are called fictitious notes, and take the name or letter below, with e, as c♯, called c sharp; signifying that it is a femitone higher than the found of c in the natural feries; or this mark ♯, called a flat, with the name of the note above, signifying it to be a femitone lower.

Now 15, and 16 being the two femitones the greater tone is divided into; and 15 and 16, the femitones the lefs tone is divided into, the whole octave will fland as in the following scheme, where the ratios of each term to the next are written fraction-wise between them below.

**Scale of Semitones.**

For the names of the intervals in this fcale, it may be confidered, that as the notes added to the natural fcale are not designed to alter the fpecies of melody, but to alter it to a greater and lefs, the fixing and limiting the founds; we fee the reafeon why the names of the natural fcale are continued, only making a diftinution of each into a greater and lefs. Thus an interval of one femitone is called a left fecond; of two femitones, a greater fecond; of three femitones, a left third; of four, a greater third, &c.

A fefion kind of femitone fcale we have from another division of the octave into femitones which is performed by taking an harmonical mean between the extremes of the greater
greater and less tone of the natural scale, which divides it into two femitones nearly equal. Thus, the greater tone
8 : 9 is divided into two femitones, which are 16 : 17, and
17 : 18; where 16 : 17 : 18, is an arithmetical division, the
numbers representing the lengths of the chords; but if
they represent the vibrations, the lengths of the chords are
reciprocals, viz. as 2 : 3; which puts the greater femi-
tone 16 next the lower part of the tone, and the lesser 17
next the upper, which is the property of the harmonical
division.
And after the same manner the less tone 9 : 10 is divided
into the two femitones 18 : 19, and 19 : 20; and the whole octave
flats thus:
\[ e^\# e^\# d^\# f^\# g^\# a^b^c^d^e^f^g^h^i^j^k^l^m^n^o^p^q^r^s^t^u^v^w^x^y^z
\]
This scale, Mr. Salmon tells us, in the Philosophical
Transactions, he made an experiment of, before the Royal
Society, on chords, exactly in these proportions, which
yielded a perfect concert with other instruments, touched by
the bell hands. Mr. Malcolm adds, that, having calculated
the ratios thereof, for his own satisfaction, he found more
of them false than in the preceding scale; but then their
errors were considerably less, which made amendments.
Malcolm's Music, chap. x. § 2.

SEMIWOWELS, in Grammar. See CONSONANTS.

SEMIULPA, in Zoology, a name by which Gesner,
and some others, have called the opolium.

SEMIUS, in Ancient Geography, a town of Lefter Ar-
menia, in Melitene. Ptolomy.

SEMILIN, in Geography. See ZELMIN.

SEMILYO, a town of Hungary; 12 miles W.N.W. of
Stuhl Weissenburg.

SEMMARA, a town of Naples, in Calabria Ultra; 10
miles W. of Oppido.

SEMMYA, a town of Hindoostan, in Bahar; 14 miles
N. of Bahar.

SEMNAN, a town of Persia, in the province of Comis;
40 miles S.W. of Damagan.

SEMLEON, in Ancient Geography, a town and episco-
pal see of Asia, in Pamphylia.

SEMNI, a race of philosophers in India.

SENO, in Geography, a river of Albania, which runs
into the Adriatic; 4 miles W. of Canovia.

SEMONES, a people of Germany, who, according to
Tacitus, boasted of being the most noble among the Suevi.

SEMIDOMUS, among the Romans, a measure equal to
half the modus, or the fifth part of the amphora.

SEMONES, among the Ancients, a clas of gods that
were of a middle nature between the celestial and terrestri-
al gods. Justin Martyr has mistaken one of these for Simon

SEMOVNIE, in Geography, a town of European Tur-
key, in Bulgaria; 12 miles W. of Nicopol.

SEMOMY, a town of France, in the department of the
Forelts; 5 miles N.W. of Chiny.

SEMOMY, a river of France, which rises near Arlon, and
enters the Meuse near Chateau Renard, in the department of
the Ardennes.

SEMPACH, a town of Switzerland, and capital of a
bailiwick, situated on a lake to which it gives name; 7
miles N.W. of Lucern.-Alfo, a lake of Switzerland, in
the canton of Lucerne, six miles long and two wide; 8 miles
N.W. of Lucerne.

SEMPERVIVAE, in Botany, a natural order of plants,
so termed from one of the principal genera; as also per-
haps, more especially, in allusion to the tenaciousness of the
living principle, common to the whole order, and to which
the said genus owes its name. See SEMPERVIVUM.

Vol. XXXII.

This is the 83d of Jullieu's orders, the first of his 14th
clafs, whose characters may be found at length under the
article Ficoidae. The Sempervivae are defined as follows.

Calyx inferior, divided deeply into a definite number of
segments. Petals inserted into the bottom of the calyx,
alternate with its segments, and agreeing with them in
number, or more rarely the corolla is monocotyledonous, either
rubular, or deeply divided. Stamens either as many as the petals,
and alternate therewith; or twice as numerous, inserted alter-
nately into the claws of the petals, and the bottom of the
segments of the calyx; anthers roundish. Germinse se-
veral, equal in number to the petals, joined together by
the internal angle of their base, glandular at the opposite part,
their glands, in some instances, assuming the form of scales;
styles and ligmas as many as the germins. Caffulae as many,
of one cell, with many seeds, separating at the inner margin
into two valves, whole edges bear the seeds. Caruncle in-
curved, surrounding a farinaceous mass. Stem herbaceous,
or somewhat shrubby. Leaves opposite or alternate, fuculent.

The genera are Tilia, Craflula, Cagyledon, Rodhia, Se-
dum, Semperivivum, and Septis; to which Penthorus is sub-
joined, as akin to the rest, but differing in habit, (as being
not fuculent,) and in the mode in which the capsule bursts;
see PENTHORUS, where Jullieu's mistake is recti-
tified, and this genus referred to the order in question, with-
out any exception or doubt.

SEMPERVIVUM, a name which immediately beseak
its own derivation, jnper vivum, ever-living, or evergreen;
the plants which compose this genus being from their very
fuculent nature so extremely tenacious of life.—Linn. Gen.
mareck Illustrator. t. 413. Garthn. t. 65.—Clafs and order,
Sempervivae, Jull.

Gen. Ch. Cal. Perianth inferior, permanent, deeply
cloven into about twelve, concave, acute segments. Cor.
Petals twelve, oblong, lanceolate, acute, concave, a little
larger than the calyx. Neftaries usuallu wanting. Stam.
Filaments twelve, slenderly awl-shaped; anthers roundish.
Pfl. Germins twelve, superior, placed in a circle, erect,
terminating in the same number of spreading stiles; ligmas
acute. Peric. Capsules twelve, oblong, compressed, short,
ranged circularly, pointed outwardly, opening inwardly.
Seeds numerous, roundish, small.

Eff. Ch. Calyx inferior, in twelve deep segments. Petals
twelve. Capsules twelve, with many seeds.

Ofb. Linnaeus in a remark under the natural character
in his Gen. Pl. makes the greater number of petals the
essential distinction between this genus and Sedum, but in the
Syfl. Veg. the nectariferous scales are properly made charac-
teristic of the latter. According to this principle, Sem-
perivum sedifolium, of Jacquin, has been referred by sir J. E.
Smith, in Tr. of Linn. Soc. v. 10. 6, to Sedum, with which
it accords also in habit, differing altogether from Semper-
ivum, except in number of petals, &c. a circumstance
known, in this case, to be uncertain. Nevertheless, there
being in Semperivum hirtum, according to Schmidel's figure
at left, a minute indication of a scale, or tooth, at the bafe
of each germin, the learned editor of Hort. Kew, was in-
duced, on that ground alone, to prefer the character de-
duced from number, in the above plant of Jacquin. Both
Willdenow and Martyn enumerate fourteen species of this
handsome genus, including Sedifolium; many of these are
beautifully figured by Jacquin and Curtis. The following,
beginning with the only British species, may serve as an
epitome of the whole.
S. tectorum. Common Houseleek. Linn. Sp. Pl. 664. f. 3. 1720. Curt. Lond. f. 3. 29. Fl. Dan. t. 681. — Leaves fringed. Offsets spreading. Common on old walls and decayed thatched roofs, where it forms large, dense tufts, flowering, though sparingly, in July. — Roots perennial, fibrous, throwing out numerous, roseaceous, leafy runners. Stems erect, nearly a foot high, round, flabby, downy, leafy, corymbose at the top, many-flowered. Leaves extremely succulent, carinated, acute; the radical ones obovate; those of the stem alternate, lanceolate, more flender, reddish. Flowers pale pink, or flesh-coloured, downy.—“The bruised leaves are by rustic surgeons used as a cooling external application, but their virtues are inconsiderable.”

S. arachnoidea. Cobweb Houseleek. Linn. Sp. Pl. 665. Curt. Mag. t. 68. Jacq. Ann. v. 5. t. 42. App. — Leaves interwoven with hairs. Offsets globular. — Native of the Alps of Italy and Switzerland, flowering in the summer. — This very elegant species, commonly known by the name of Cobweb Sceum, reffembles all the other species in habit, but is exceedingly remarkable for a woolly fubftance on the top of its globular offsets, which, as the leaves expand, is extended with them, and affumes the appearance of a cobweb, whence the specific name. Flower-flafts about six inches high, of a bright pink colour, like the flem-leaves. Flowers terminal, corymbose, pink or reddish.

The remaining species are S. arboresum, canarijea, glutinum, glandulorum, villosum, flaccidum, and hiermum.

Semperivium, in Gardening, contains plants of the fuculent, hardy, herbaceous, evergreen, and flabby perennial kinds, of which the species cultivated are; the common houseleek (S. tectorum); the globular houseleek (S. globiferum); the cobweb houseleek (S. arachnoidea); the mountain houseleek (S. montanum); the tree houseleek (S. arboresum); and the Canary houseleek (S. canarijea).

In the sixth fort a variety with variegated leaves was obtained from a branch accidentally broken by a plant of the plain fort, at Badminton, the seat of the duke of Beaufort.

Method of Culture.—The different herbaceous:forts are all capable of being increased without difficulty, by planting their off-fet heads, which should be flipped with a few root-fibres to them, and planted in the spring seafon on rubbish, rock-works, or other places, or in pots for variety; and the tender greenhouse forts may be raised from cuttings of the branches and from seeds; but the first is the better method. The cuttings should be made from the smaller branches in the early summer months, and be planted out in pots, or a bed of fine earth, in a warm shaded situation: where the cuttings are succulent, they should be laid in a dry place for a few days to heal over the cut part; they should be shaded from the sun; and those in pots lightly watered in dry weather: when they are become well rooted, they should be carefully removed into separate pots of a middle size, being placed in the greenhouse. Some forward these plants by means of bark hot-beds.

The feeds of the Canary kind should be found in the autumn or early spring in pots of hot mould, placing them in a garden-frame to protect them from frost, having the air freely admitted in mild weather: when the plants are come up, and have a little strength, they should be removed into small pots and placed in the greenhouse.

The first forts are ornamental on walls, buildings, and rock-works, as well as in pots; and the last two kinds among other potted greenhouse plants.

Semphiropolis, in Geography, a town of Ruffia, in the province of Tauris; 60 miles S. of Perekop. N. lat. 45° 8'. E. long. 34° 10'.

Semphoris, in Ancient Geography, a town situated in the environs of Galilee, according to Josephus.

Sempronius, in Geography, a port-town of New York, nearly in the centre of the county of Onondago, within the jurisdiction of the township of Scipio, 20 miles S.E. from the ferry on Cayuga lake, and 457 miles from Washington.

Sempt, a river of Bavaria, which runs into the Ifer, 5 miles above Landhut.

Semrah, a town of Hindooftan, in Bahar; 38 miles N. of Chuprah. N. lat. 26° 45'. E. long. 84° 51'.

Semsat. See Samisat.

Semshin, or Sempcshin, a town of Little Bucharia; 18 miles E.S.E. of Tourfan. N. lat. 44° 50'. E. long. 80° 40'.

Sempciarsko, a fortrefs of Ruffia, on the Itfich. N. lat. 51°. E. long. 73° 10'.

Semur, or Semur en Auvergne, a town of France, and principal place of a district, in the department of the Côte d'Or, feated on a rock, near the river Armançon; 10 miles N.W. of Dijon. The place contains 4205; and the canton 14,852 inhabitants, on a territory of 277 square kilometres, in 28 communes. Its principal commerce consists in woollen cloth of its own manufacture. N. lat. 47° 29'. E. long. 4° 25'.

Semur en Brionne, a town of France, in the department of the Saône et Loire, and chief place of a canton, in the district of Charolles; 12 miles S. of Charolles. The place contains 598, and the canton 11,106 inhabitants, on a territory of 182 square kilometres, in 16 communes. N. lat. 46° 16'. E. long. 4° 10'.

Seminssyr, one of the Kurlitko Islands, 30 versts from Ketai, another of the same islands. Its length is 150 versts, and its breadth not more than 10. This island has four mountains, one of which exhibits effident traces of
its having been formerly burnt; in other respects it has the fame properties with those of Ketosterin.; which see. The passage from this island to Thirrio O is 200 versts.

SEMYDA, in Botany, the name of a tree, mentioned by Theophrastus, and by some supposed to be the same with the betula, or birch-tree, but very erroneously.

SEMYSTA, in Ancient Geography, an island of the British ocean, near the coast of the Offinini, in which the Gauls had a celebrated oracle, according to Pomponius Mela.

SEMZA, in Geography, a town of Ruffia, in the government of Archangel; 16 miles N.E. of Mezen.

SENA, or Marzali, a town of Africa, in the country of Mocaranga, on the river Zambeza, where the Portuguese have a factory. S. lat. 17° 35'. E. long. 35° 20'.

SENA, or Egyptian Caffia, in the Materia Medica, a purgative leaf much used in draughts and compositions of that intention.

The thyrus which bears it is a species of caffia; which see. There is also a kind of fena growing about Florence; but it is inferior to that of the Levant, as is owned by the Italians themselves. Father Plumer mentions also a third kind growing in the Antilles islands.

M. Lemery distinguishes three sorts of fena of the Levant: the first brought from Seyda, called fena of apolo, that is, cyfum fena, by reason of the custom paid the grand signor, for the privilege of exporting it; the second comes from Tripoli; the third is called fena of Mocha.

Sena is a native of Egypt, the belt of which is laid to grow in the valley of Baiabras, or of Nubia: it also grows in some parts of Arabia, especially about Mocha; but as Alexandria has ever been the great mart from which it has been exported into Europe, it has long been distinguished by the name of Alexandrian fena or fenna.

The belt fena, named in Nubia "gubbelly," grows wild, and yields two crops of leaves, the abundance of which depends on the periodical rains. The first crop is collected after the first rains, about the middle of September; the second in the following March. The plants are cut down, and exposed on the rocks to dry in the sun. The leaves are then picked, packed up in bales, and sent down to Alexandria, where they are mixed with two other species of caffia: the one the C. fena of Forkkal, with obtuse leaves; the other probably the C. angulifolia of Wildenow, the leaves of which are longer, narrower, and sharper pointed than those of the proper fena, and come from Mocha. There is reason also for thinking that it is further adulterated with the leaves of colutea, bladder-fena, and of box. The fena, after being thus mixed, is repacked in bales at Alexandria, whence it is exported to Europe.

M. Blondel, who was French consul at several sea-ports of the Levant, informs us, that the true fena grows only in the woods of Ethiopia, and in Arabia; and that the fena, which was brought from Saïde and Tripoli, was carried there by the caravans; and this opinion is strengthened by the negative testimony of Alpinus, who, in his book "De Plantis Aegypti," does not notice fena. But as Hallequin found this plant growing spontaneously in Upper Egypt, Blondel's assertion is not to be implicitly received. Sena appears to have been cultivated in England in the time of Parkinson, A.D. 1640.

The colour of fena leaves is faint, rather disagreeable, and sickly; the taste slightly bitter, sweetish, and nauseous. Boiling water extracts about one-third of the weight of the leaves employed: the infusion has a deep reddish-brown colour, with the odour and taste of the leaves. This infusion, when exposed to the atmosphere, deposits a lemon yellow-coloured insuble matter; and a similar precipitate is produced by oxyymuriatic acid, and several other substanstes. Alcohol and sulphuric ether, digested on the powdered leaves, acquire a deep olive-green colour. When the ethereal tincture is poured on the surface of pure water, a dark olive pellicle remains after the evaporation of the ether, which is almost inipid, and has all the properties of resin; and a golden colour is communicated to the water. This colour may be produced by some extractive being taken up by the ether, closely united to the resin. The alcoholic tincture is rendered only slightly milky by the addition of water, and scarcely any precipitate is produced; but a copious one is thrown down by oxyymuriatic acid. The active principle of fena appears to be a very oxidizable extractive, resin, and a peculiar volatile matter; and it contains also mucus, and some tallow ingredients. According to Buillon Lagrange, the residue of the watery infusion evaporated to dryness, and burnt, yields potas, sulphate of potas, carbonate of lime, magnesia, and fihra.

It is in common use as a purgative, generally operating under four hours after it is taken; and is well adapted for all cafes, in which the bowels require certain, but moderate, evacuation (see Cassia Sena); and though it be not easily accounted for, its bitternes aids its operation. To this purpose Dr. Cullen remarks, that when fena was infused in the infusion amarum, a lefs quantity of the fena was necessary for the dose than the simple infusion of it. Sena, however, when infused in a large proportion of water, as a draehm of the leaves to four ounces of water, rarely occasioned much pain of the bowels; and to those who do not object to the bulkiness of the dose, may be found to answer all the purposes of a common cathartic, its operation being aided by plentiful draughts of weak broths or gruel. The dose, in substance, is from a scruple to a draehm; in infusion, from one draehm to three or four. It gives out its virtue both to watery and spirtuous menstrua; communicating to water and proof spirit a brownish colour, and to rectified spirit, a fine green. The two inconveniences attending the use of this medicine, are its being liable, in most confections, to occasion gripes, and its being accompanied with an ill flavour, which is apt to nauseate the stomach and palate. The gripping fena to be occasioned by the refining matter, as the infusion made with cold water does not grip, although it purges. The fira may be greatly obviated by dilution; the latter by aromatic and other additions; x. gr. cinnamon, or a draehm or two of its distilled water, or carraway, or cardamon seeds. The decoction is a bad form in which to administer this drug, as its activity is much impaired by boiling; owing, according to Grew, to the total dissipation of the NSA and volatile principles; but, as Thomson conceives, to the oxydement of the extractive, which also accounts for the severe gripings occasioned by the decoction.

Several compositions of this kind are prepared in the shops, sufficiently palatable, and which operate for the most part with ease and mildness. Such are the following: viz. confecition of fena, the electuary of fena of the Londo. Ph. of 1787, and the leventic eleuctuary of P. L. 1745 and 1750. (See Electuary of Sena.) The Dublin pharmacopeia directs the electuary of fena to be prepared by taking of fena leaves, in very fine powder, 4 ounces; pulp of prunes, 1 pound; pulp of tamarinds, 2 ounces; molasses, 1/8 pint; and cinnamal oil of carraway, 2 drachms. Boil the pulps with the syrup, to the thickness of honey, then add the powder; and when the mixture is nearly cold, the oil is finally mixed, the whole thoroughly together.

These electuaries furnish a mild and pleasant purgative, and well adapted for those who are afflicted with habitual colic, and also for pregnant women. The dose is from 1/2 to 3/4, or more, taken at bedtime.
**Extract of Sena.** See Cassia.

As the activity of fena is impaired by the preparation of it in the form of a decoction, it must necessarily suffer much more in this preparation. The extract is black, shining, and tenacious, and has an odour similar to that of mord, and a bitterish tinge. It is almost inert as a purgative, and might properly be altogether rejected.

However, some have highly extolled M. Geoffroy's dry extract, which is made of a very strong infusion, evaporated to a dry and pulverizable substance. This, they say, is easily taken, of no ill taste, and operates in a very small quantity, one-third part containing the virtue of the whole, or nearly so; the next calculations showing, that 24 grains of the extract, some part of which may be supposed to be earth, or other accidental or unfledged matter, polish the virtues of a drachm in infusione. Mem. de l'Acad. des Scienc. Paris, 1738.

**Infusion of Sena.** See Cassia.

The Dublin pharmacopeia directs this infusion to be prepared by taking 3 drachms of fenam leaves, half a drachm of lefser cardamom seeds, freed from the capsules and bruised, and boiling water, as much as will yield, when strained, 6 ounces by measure. Digest for an hour, and when the liquor is cold, strain it. These infusions will spoil in warm weather in 48 hours; and by simple exposure to the air, attract oxygen, which occasions a yellowish precipitate of oxized extractive, that griplens violently, but is not purgative; on which account they should be preferred in a well-closeted vessel, and made only when wanted. They are also precipitated by the stronger acids, the alkaline carbonates, lime-water, solutions of nitre of silver, oxymurcate of mercury, superacetate of lead, tartarized antimony, and infusion of yellow cinchona bark, which are consequently incompatible in formula with these infusions. The infusions now mentioned contain all the purgative principles of the plant, and the aromatics correct its griping properties. They are given alone, or more generally combined with neutral herbs and manna. The dose of the infusions will be from f 3/ij to f 1/iv; and will g of the farr of potas, or 3/ij of the fulphate of magnesia, which are the usual adjuncts, f 5/9 are sufficient.

**Infusion of Tamarind and Sena is prepared, according to the Edinburgh Ph., by taking of preferred tamarinds, 1 ounce; fenam leaves, 1 drachm; coriander seeds, bruised, half a drachm; raw sugar, half an ounce; and boiling water, 8 ounces. Macerate in a covered earthen vessel, which is not glazed with lead, shaking frequently, and after 4 hours strain. It may be made with double or triple the proportion of fenam. This infusion is made, according to the directions of the Dublin Ph., in the same manner as the infusion of fenam, except that 5/9 of tamarinds is added, before straining the liquor.

In these infusions, the nauseous taint is covered by the sugar and the acid of the tamarinds; but in other respects they agree both in their properties, and in the effects of the incompatible substances; to which, however, must be added all faults having potas for their base.

**Compound Powder of Sena.** See Cassia, and Powder of Sena.

**Tincture of Sena** is prepared, according to the London Ph. of 1809, by taking of fenam leaves, 3, oz., caraway seeds bruised, 1/2 oz., cardamom seeds bruised, 1 dr., raisins stoned, 4 oz., and proof spirit, 2 pints. Macerate for 14 days and filter. The Dubl. Ph. directs to take of fenam leaves 1 lb., caraway seeds bruised, 1/2 oz., lefser cardamom seeds hulked and bruised, 1/2 oz., and proof spirit, a gallon. Digest for 14 days, then filter.

**Compound Tincture of Sena, formerly called Elixir salutaris, or Elixir of health, is prepared by taking of the leaves of fenam, 2 oz., jalap root bruised, 1 oz., coriander seeds bruised, 1/2 oz., proof spirit, 33 lb. Digest for 7 days, and to the filtered tincture add of refined sugar, 4 oz.**

These tinctures are efficacious and purgative; they are very efficacious in flatulent colic, atonic gout, and as an opening medicine for those whose bowels have been weakened by intemperance. The dose is from 5/ij to 5/ij in any appropriate vehicle.

**Syrup of Sena**, according to the London Ph., is prepared by taking of fenam leaves, 1 oz., fennel seeds bruised, 1 dr., manna, refined sugar, of each 1 lb., and boiling water, a pint. Macerate the fenam leaves and the fennel seeds in the water for 12 hours; strain the liquor and mix with it the manna and the fugar. The Dubl. Ph. directs to take of manna, refined sugar, of each 1 lb., fenam leaves, 1/2 oz., and boiling water, a pint. Let the fenam leaves be macerated in the water in a covered vessel for 12 hours; then disolve the manna and the fugar in the strained liquor.

This syrup contains the purgative properties of the fenam, and is chiefly intended for children; but the fimple infusion of fenam, sweetened with fugar, and with the addition of a little milk, given in the form of tea, is more willingly taken by children, and operates with greater certainty. Lewis Woodville. Thom. Sena, Safflard, in Botany. See Cassia.

**Sena, Bladder.** See Colutea.

**Sena, Puddled.** See Cornuilla.

**Sena, Scorpius, Eimurus, a species of cornuilla; which see.** The leaves of this plant are used, but Boerhaave has unacquainted with any medicinal virtue in them. Rupinus writes, that the common people substitute the leaves instead of those of fenam; and Buxbaum tells us, that old women who pretend to medicine, call it fenes blater, and use it instead of fenam leaves.

**Sena, in Ancient Geography, a river of Italy, in Umbria, between the Metaurus and the Mius, according to Silius Italicus.**

**Sena Gallica, Senagaglia, a town of Italy, in Umbria, of Gaulish origin, as its name indicates.** When the Romans had put the Gauls to flight, they established a colony in this city, towards the year 339. Sena, of which was vanquished Marcus in this place and destroyed it. Ptolemy assigns it to the Senones, from whom it derived its name.

**Sena Infusa, an island, according to Mela, in the British ocean, on the coast of the Sifilin. It is now the Isle of Sein or of Saints, on the coast of Bretagne.**

**Sena Julia, Sienne, a town of Italy, in Etruria, E. of Volaterra, from which it is separated by mountains. Different accounts have been given of its origin, from which we may infer, that it is not one of the ancient towns of Etruria. The Romans established a colony in this place in the year of Rome 466, or as others say, 471. A new colony was established in this place in the time of Julius Caesar, who gave it the name of Julia. In 1730 it was subject to Charles IV.; it suffered much in the wars of the Guelfs and Gibelines. Charles V. gave the墅titude of it to Philip II. his son, who sold it to Cofino, duke of Florence, in 1558.**

**SENABA, in Geography, a town of Egypt, on the left bank of the Nile; 13 miles S. of Melauti.**

**SENAC, John, in Biography, a distinguished French physician, was born in Gafo, about the close of the 15th century. Little is recorded respecting the progress of his education and life; but he is stated to have been a doctor of the faculty of physic of Rheims, and a bachelor of that of Paris; which last degree he obtained in the year 1724 or 1725. He was a man of profound erudition, united**
united with great modelly, and becamepossess'd, by hisindustry in the practice of his profession, of muchfound medical knowledge. His merits obtained for him thefavour of the court, and he was appointed consultingphysician to Louis XV.; and subsequently succeeded Chevonnay in the office of first physician to that monarch. He was also a member of the Royal Academy of Sciences at Paris, and of the Royal Society of Nancy. He died in December, 1770, at the age of about 77 years, and theking appointed no physician as his successor, as long as he lived.

This able physician left some works, which will probablymaintain a reputation as long as medicine is studied. Weallude more especially to his treatise on the heart and itsdiseases, "Traité de la Structure du Coeur, de fon Action,et de fes Maladies," Paris, 1740, in two volumes, 4to,which is still a standard work upon this interesting subject.An essay "De reconditâ febrorum intermittentium et remitentiumnaturâ," Amst. 1759, is generally ascribed to Senac. Healso published, when young, an edition of Heister's Anatomy, with some interesting comments andobservations of his own, entitled, "Anatomie d’Heister,avec des Élairs de Phystique fur l'Ufage des Parties duCorps Humain," Paris 1724, and afterwards "Difcour furla Méthode du Françoîs, et fur celle de M. Rau touchant l'Opération de la Taille," 1727. "Traité des Caufes, desAccidents, et de la Cure de la Pelle," 1744. A workunder the affumed name of Julien Morillon, entitled "Letteres fur la Choisie des Saignées," 1730, was from his pen; aswell as a paper in the Memoirs of the Academy ofSciences for 1725, on the title of "Reflexions fur lesNoyâes," in which he combatted some erroneous opinionsrespecting the cause of death by drowning, and thetreatment founded upon them. A work, entitled "NouveauCours de Chymie suivant les Principes de Newton et deStahl," Paris, 1722 and 1723, has been attributed bymit-take to Senac; it was in fact a compilation of notes takenat the lectures of Geoffroy by some students, and isunworthy of his pen. See Eloy, Dict. Hilt de la Médecine.

SENACIA, in Botany, a genus of Commeron's,apparently named by him in honour of the French physician Senac, (see the preceding article,) who might perhapshave patronized the expedition of Commeron, but of wholebotanical merits we find nothing recorded. Vulcain, Gen. Pl.378, merely mentions this genus under Celastrus, as differingfrom that in having a longer style, oblong anthers, and a fruitwith generally two cells, two valves, and six seeds. Ourpredecessor, the Rev. Mr. Wood, seems to have intended toadopt Senacia; see Celastrus, at the end. We do nothowever find that any other writer has done so, nor do weknow of what species the genus in question ought toconsist, except those mentioned in the place just cited. Theprecise structure of the capsule, and the number of the seeds,are so little ascertained in some reputed species of Celastrus, andthe variable forms of these characters, in others, is so wellknown, that while Gartner himself has even doubted the distinctionbetween Euonymus, (see that article,) and Celastrus itself, wefeel some inclination to subdivide the latter. The comparativelength of the styles in these plants, variable in differentstates of the flowers, can afford no certain mark of genericdistinction.

SENAILLEE, John Baptisté, in Biography, aFrench musician, born about 1688. He was a greatperformer on the violin for his time. Having travelled intoItaly, the manager of the Opera at Modena engaged himtoperform in his orchestra, and did him the honour to preparefor his reception a feast more elevated than what was allowedto the rest of the band. The duke desired him to play somefolks between the acts of the opera, and he obeyed hisferene highness, to the great joy of the whole audience. Heset five books of folks, which had great reputation, till those of Le Claire appeared; which are now as littleknown as those of Senaillee, though infinitely superior tothem. What a fluctuating art is music, and how transfigurethe fame of its professors! since we may be certain, thatthe works of him who now enjoys the highest reputation,will be for ever plunged into oblivion, at the latest, in aperiod of 25 years; or appear as ridiculous to our children,as our ancient music now does to us!

SENAMARIBO, in Geography, a river of Guiana,which runs into the Atlantic, N. lat. 5° 30'. W. long. 54° 6'.

SE-NAN, a city of China, of the first rank, in the provinceof Koei-tcheou, surrounded on all sides by mountains; 845 miles S.S.W. of Peking. N. lat. 27° 56'. E. long. 107°.

SEAN, a town of Algiers; 20 miles S. of Oran.

SEANLUS, a town of Alifat Turkey, in Caramania;30 miles N.W. of Seleckhe.

SENAPE, a town of Egypt, on the left bank of the Nile; 17 miles W. of Dendera.

SEANPONT, a town of France, in the department of the Somme; 22 miles W. of Amiens.

SENEAT, Senatus, an assembly or council of senatort hat is, of the principal inhabitants of a state, whohave a share in the government.

Such were the senates of Rome, of Carthage, &c. amongthe ancients; and such are the senates of Venice, of Genoa, &c. among the moderns.

The senate of ancient Rome was, of all senates, themost celebrated, during the splendor of the republic. Cicero in his oration for Milo, defines it, tempum junctissitatem, amplitudinis, potestatis, civilisque publici Romani, caput orbis, arius fociarum, portuque omnium gentium. The Roman senate exercised no contentious jurisdiction; it appointed judges either out of the senate, or among the knights; but itnever bowed to judge any proceedings in a body. The senateconcer ted matters of war, appointed who should commandthe armies, sent governors into the provinces, took order,and dispensed of the revenues of the commonwealth. Yetdid not the whole sovereign power reside in the senate; itcould not alone elect magistrates, make laws, nor decree ofwar and peace; but in all these cases, the senators wereto consult the people. Under the emperors, when the senatebecame despoiled of most of its other offices, they began tohear causes. For those of less consequence theyappointed particular judges; the rest, principally criminalcauses, they referred for their own cognizance, to be judgedby them in a body, and that frequently in the emperor'spresence. This was put in their way to keep their headsfrom litigant affairs. Nero farther committed to the senatethe judgment of all appeals; but this did not hold long;nor do we find any footsteps of it anywhere but in thesixty-second Novel.

With regard to the jurisdiction of the senate, Dr. Middle ton observes, that the supreme power at home was in thecollective body of the people; yet where haife, perhaps, orsecrecy was required, and where the determinations of thesenate were so just and equitable, that the consent of thepeople might be presumed, and granted for granted, thesenate would naturally omit the trouble of calling themfrom their private affairs to an unnecessary attendance on thepublic; till by repeated omissions of this kind, begun atfirst in trivial matters, and proceeding insensibly to moreserious,
fensive, they acquired a special jurisdiction and cognizance
in many points of great importance, to the exclusion even
of the people; who yet, by the laws and constitution of
the government, had the absolute dominion over all. For
example:

1. They assumed to themselves the guardianship and
superintendence of the public religion; so that no new god
could be introduced, nor altar erected, nor the Sibylline
books consulted, without their express order.

2. They held it as their prerogative, to settle the number
and condition of the foreign provinces, that were an-
ually assigned to the magistrates, and to declare which of
them should be confarlar, and which praetorian provinces.

3. They had the distribution of the public treafure, and
all the expences of the government; the appointment of
tribunes to their generals, with the number of their lieu-
tenants and their troops, and the provisions and clothing
of their armies.

4. They nominated all ambassadors sent from Rome, out
of their own body, and received and discharged all who came
from foreign states, with such answers as they thought
proper.

5. They had the right of decreeing all supplications, or
public thanksgiving, for victories obtained, and of con-
ferring the honour of an ovation, or triumph, with the title
of emperor, on their victorious generals.

6. It was their province to inquire into public crimes or
treason, either in Rome, or the other parts of Italy; and to
hear and determine all disputes among the allied and de-
pendent cities.

7. They exercized a power, not only of interpreting the
laws, but abolishing men from the obligation of them, and
even of abrogating them.

8. In the case of civil divisions, or dangerous tumults
within the city, they could arm the confuls by a vote with
absolute power, to destroy and put to death, without the
formality of trial, all such citizens as were concerned in ex-
iting them.

9. They had a power to prorogue, or postpone the assem-
yblies of the people; to decree the title of king to any prince
whom they pleased; thanks and praise to those who had de-
ferred them; pardon and reward to enemies, or the di-
coverers of any treason; to declare any one an enemy by a
vote; and to prescribe a general change of habit to the city,
in cases of any imminent danger or calamity.

The tribunes soon snatched from them that original right,
which they had enjoyed from the very foundation of the
city, of being the authors, or first movers of every thing,
which was to be enacted by the people, and excluded them
from any share or influence in the assemblies of their tribes;
and though in the other assemblies of the curiæ and the cen-
turies, they seemed to have referred to them their ancient
right, yet it was reduced to a mere form, without any real
force; for instead of being what they had always been, the
authors of each particular act that was to be proposed to the
people's deliberation, they were obliged, by a special law,
to authorize every assembly of the people, and whatever
should be determined in it, even before they had proceeded
to any vote. And C. Gracchus afterwards, in his famous
tribunate, used to boast that he had dissolved the senate at
once, by transferring to the equilibrar order the right of
judicature in all criminal causes, which the senate had pos-
fessed from the time of the kings.

It has been a question among the learned, how sena-
tors were created, and how the vacancies of the senate in old
Rome were supplied.

Dr. Middleton is of opinion, that the constant and regular
supply of the senate was from the annual magistrates; who,
by virtue of their several offices, acquired an immediate right
to sit and vote in that assembly. The usual gradation of
these offices was that of questor, tribune of the people, adile,
praetor, and consul; which every candidate, in the ordinary
forms of the constitution, was obliged to take in their order,
with this exception only, that he might forego either the tri-
bundle, or the edileship, at his own choice, without a neces-
osity of passing through them both. See Questor, Tri-
burse, &c.

But though these offices gave both an immediate right,
and actual entrance into the senate, yet the senatorial cha-
acter was not esteemed complete, till the new senators had
been enrolled by the cenfers at the next bullrum, or general
review of all the orders of the city, which was generally held
every five years. Yet this enrolment was but a matter of
form, which could not be denied to any of them, except for
some legal incapacity, or the necessity of some crime, or in-
famy upon their characters; for which the same cenfers
could expel, or deprive any other senator, of what rank or
standing ever. See Censor.

It has been the opinion of some, that under the kings of
Rome the choice and nomination of all the senators depended
wholly on the will of the prince, without any right in the
people, either direct or indirect; and that the confuls, who
succeeded to the kingly power, enjoyed the same pre-
rogative, till the creation of the cenfers, who ever after pos-
fessed the sole and absolute right of making and unmaking
senators. But Dr. Middleton is of opinion, that the kings,
the confuls, and the cenfers, acted in this affair but min-
isterially and subordinately to the supreme will of the people,
in whom the proper and absolute power of creating senators
always relied. And the doctor assures us, upon the strictest
search into the state of the present question, as it stood under
the kingly government, he cannot but conclude, from the
express testimony of the bellic historians, the concurrence
of similar facts, and the probability of the thing itself, that
the right ofchoosing senators was originally and constitutionally

But lord Hervey, who seems to have studied the Roman
history with care and attention, is of a different opinion.
The senate, at its first establishment (notwithstanding the
judicial and legislative power it afterwards acquired) was
nothing more than the king's council. In this light not
only Feltus, Eutropius, and Livy, represent the senate, but
even Dionysius himself. It is therefore highly probable, his
lordhip says, that each member of this council was merely,
as Livy and Plutarch relate, the choice of the king, and not,
as Dionysius reports, elected by the people. Nor is there
the least ground to imagine, he tells us, from any author
whatever, except Dionysius, that during the whole regal
government, the people had, directly or indirectly, actu-
ally, or virtually, any share or concern at all in the choice of
the senators. The first institution, in a word, every augmenta-
tion, and every supply on vacancies, he supposes to have
depended entirely on the will and authority of the kings.
Nor does he, like Monfieur Vertot, imagine the reason why
Dionysius had reported otherwise, proceeded from his repub-
lican spirit, but from what every body who reads him must
find in his manner of describing every institution, law, or
custom, among the Romans, viz. an affectation of tracing
its origin from some familiar practice in the Grecian states,
in order, from his partiality to that country, to give Greece
the honour of having furnished the sketch of every plan, on
which the Roman government was framed, and the Roman
greatness raised.

Soon after the expulsion of Tarquin, and the establishment
of the confular government, the senate, which, by many
condemnations to death, or exile, the last king had reduced
to less than half its complement, was filled up to its former
number of three hundred; this supply, according to every
historian, was made out of the plebeians; and in all pro-
bability, his lordship says, by the sole power of the confuls,
since no author relates otherwise, and all authors agree that
the confular power at first differed from the regal powers
in no particulars but that of being annual, instead of per-
petual, and divided between two persons, instead of being
veiled in a single one.

Till the time of the cenfors then, lord Hervey tells us,
there is not the least reason to imagine, that the people had
any hand in promoting any man to the senatorial rank.
From the time that the people were allowed to choose the
annual magistrates out of their own body, till the time the
commonwealth fell into confusion, which ended, as con-
fusion generally does, with a total loss of liberty, the only
difficulty in accounting for the filling up of the senate, his
lordship says, is to reconcile the right of the annual magis-
trates to enter the senate, with the power of the cenfors.
And this, he thinks, may be done by distinguishing between
a right to vote in the senate, and being a senator, which were
two different privileges, and quite distinct honours.
The first was obtained by virtue of exercising any public office,
from the quaeftorship to the confullship; and was con-
sequently conveyed by the people; whereas the last was a digi-
nity conferrable only by the cenfors. Feltus says, that those
who held any public office in the state, and by virtue of that
office voted in the senate, were nevertheless no senators till
made so by the cenfors. And Aulus Gellius, in his chapter
upon the "Pedarii Senators," says the same thing.

These two offices were always distinguished even in the
edict that convoked the senate; the form of the edict, as
may be seen in many writers, being to convene the cenfors,
and all those who had a right to vote in the senate.

Nor was the difference, according to Aulus Gellius, bet-
tween the voters in the senate, and the confirmed cenfors, so
uneffential, as it may at first appear; for, those, who had only
a right to vote in the senate, and were not enrolled cen-
sors, had no right to speak there, and could only pass in
silence to one side or the other, when a division was made on
the point in debate. Whereas an enrolled senator had a
right, when he gave his vote, to speak as long as he pleased,
and on what he thought fit; a privilege, which amounted to
a power of stopping all proceedings for that day, and was
often so used.

From the story of Fabius Maximus and Craflus, relat-
ed by Valerius Maximus, book ii. chap. 2. there appears to
have been another very effential difference between a cen-
sor, and a voter in the senate; for by that Rome one muft imagine
that those who were enrolled cenfors, had not only the sole
right of debating any question that came into the senate, but
were like a secret committee, or cabinet council, who pre-
viously weighed every proposal that was to be made in a
general senate, and determined whether it should be brought
in or not.

The power of taking cognizance of the manners of every
Roman citizen, was first annexed to the cenforship, when
the office itself was disjoined from that of the confullship,
in the three hundred and eleventh year of Rome, as may be
seen in Livy, book iv. chap. 8. But the power of choosing
the new cenfors was not transferred from the confuls to the
censores till near a hundred years afterwards, in the tribune-
ship of Ovainius; and it was then given to the cenfors by the
people, to revenge the breach of the Licinian law (which
law ordained that one of the cenfors should always be chosen
out of the plebeians) for both the cenfors being that year
patricians, and one of the cenfors that year, for the first time,
being a plebeian, the tribune Ovainius put the people upon
this expedient to do themselves justice, and mortify the
nobility.

When the annual magistrates were not sufficient to supply
the vacancies in the senate, the cenfors chose whom they
pleased. And that the annual magistrates were seldom
enough to supply the vacancies, may easily be concluded,
when one considers how few they were, and how many va-
cancies must be made in to large a body as three hundred
men, by natural deaths, the change of perpetual war, and
the purging made by the reforming authority of the cenfors.

The filling up of the senate then from the Ovainius tribune-
ship till the time of the Gracchi, lord Hervey thinks, de-
dpended entirely on the cenfors; for though he allows that
the annual magistrates, at the expiration of their office, had
a fort of claim and pretension to be put on the roll of fe-
nators, by the cenfors; yet as the cenfors, under the pre-
tence of reformation, had an uncontrollable power to re-
move senators already enrolled, so on the same pretence they
could, if they pleased, refuse to enroll, and even without
giving any reason; since their manner both of expelling or
admitting senators was merely by omitting or inferting a
name in the ceremony of calling over the roll.

Though the cenforship, therefore, at its original institu-
tion by Servius Tullius, was nothing more than the offi-
ce of numbering the people, and taking the valuation of their
estates and an office annexed first to the royal authority,
and afterwards to the confular power; yet when it was
detached from the confular power, and erected into a sepa-
rate office, with the power of filling up the senate
annexed; from that time, as the cognizance of the manners
of every citizen of Rome was also in their department, his
lordship looks upon the cenfors to have been full as aboul-
te in the city and the civil government, with regard to all pro-
motions and degradations, from the senate down to the
lower tribe, curia, or century, as the confuls were in the
camp and the military government.

Ever after the time of the Gracchi, the state was either
in such confusion, or such absolute slavery, that his lord-
ship thinks there was no regular method at all observed in
filling up the senate, or any justice in purging it. Who-
ever had the sovereign power in his hand, under what title
soever he feized or possessed it, modelled the senate by the
introduction of new members, or the expulsion of old ones,
just as he thought fit.

Dr. Middleton politely acknowledges, that the hypo-
thetical of lord Hervey has the advantage of his own,
and will be thought the more solid or plausible by the gene-
rality of readers. See Letters between Lord Hervey and
Dr. Middleton, concerning the Roman Senate; published
by Dr. Knowles, quarto, 1778.

The magistrates who had the power of assembling the
senate were the dictator, the consuls, the praetors, the tribunes
of the commons, and the interrex. Yet upon
extraordinary occasions the same privilege was allowed to
the tribuni militum, invested with confular power, and to
the decemviri, created for regulating the laws; and to
other magistrates chosen upon some unusual occasion.

In the early ages of the republic, when the precepts of
the city were small, the cenfors were perfonally summoned
by an appanator; and sometimes by a public crier, when
their affairs required immediate dispatch; but the usual
way of calling them, in later days, was by an edict ap-
pointing the time and place, and published several days
before,
before, that the notice might be more public. These edicts were commonly understood to reach no farther than to those who were resident in Rome, or near it; yet when any extraordinary affair was in agitation, they seem to have been published also in the other cities of Italy. If any senator refused, or neglected to obey this summons, the consul could oblige him to give surety for the payment of a certain fine, if the reasons of his absence should not be allowed. But from sixty years of age they were not liable to that penalty, nor obliged to any attendance but what was voluntary.

The senate could not regularly be assembled in a private or profane place, but always in one seat apart, and solemnly consecrated to that use by the rites of augury.

The senate frequently met in certain curiae. See CURIA.

But their meetings were more commonly held in certain temples, dedicated to particular deities; as in that of Jupiter, Apollo, Mars, Vulcan, Cæsart, Bellona; of Concord, Faith, Virtue, the Earth, &c. These temples, on account of the use which the senate made of them, were called likewise curiae; as well as the proper curiae, or senate-houses, on account of their solemn dedication, are frequently called temples.

On two special occasions the senate was always held without the gates of Rome, either in the temple of Belona, or of Apollo. 1st. For the reception of foreign ambassadors, and especially of those who came from enemies, who were not permitted to enter the city. 2dly. To give audience, and transact business with their own generals, who were never allowed to come within the walls as long as their commission subsisted, and they had the actual command of an army.

The senate met always, of course, on the 1st of January, for the inauguration of the new consuls, who entered into their office on that day.

The month of February, generally speaking, was reserved entirely to the orders of business which were of the most importance. In all months, universally, there were three days, which seem to have been more especially defined to the senate, the kalends, new moons, and ides, from the frequent examples found in history, of its being convened on those days. But Augustus enacted afterwards, that the senate should not meet regularly, or of course, except on two days only of each month, the kalends, and ides.

On their days of meeting, they could not enter upon any business before the sun was risen, nor finish any after it was set; every thing transacted by them, before or after that time, was null and void, and the author of it liable to censure. Whence it became a standing rule, that nothing new should be moved after four o'clock in the afternoon. The senate, as has been shewn above, was composed of all the principal magistrates of the city, and of all who had borne the same offices before them: and consisted therefore of several degrees and orders of men, who had each a different rank in it, according to the dignity of the character which he sustained in the republic. At the head of the senate sat the dictator and consuls, in chairs of flax. Manutius thinks that the other magistrates sat next to the consular chair, each according to his rank; the praetors, censors, ædiles, tribunes, quaestors. But Dr. Middleton rather thinks that the consular senators, who, in all ages of the republic, were the leaders and first speakers in the senate, used to sit next in order to the consuls; and after them the praetors, and all who were of praetorian dignity, or had been praetors; then the ædiles, the tribunes, and the quaestors, on distinct benches; and on the same bench with each, all who had borne the same offices; but the eunuch magistrates, as the praetors and ædiles, were perhaps distinguished, at the head of their several benches, by seats some what raised, or separated at least from the rest, in the form of our fettees, or of that longa cathedra, which Juvenal mentions, to denote the eunuch dignity.

All the private senators sat on different benches, and in a different order of precedence, according to the dignity of the magistrates which they had severally borne. First the consular, then the praetors, ædilships, tribunions, and quaestions; in which order, and by which titles, they are all enumerated by Cicero. And as this was their order in fitting, so it was the same also in delivering their opinions when it came to their turn. Cic. Phil. 14, 14.

The senate being assembled, the consuls, or the magistrates, by whose authority they were summoned, having first taken the auspices, and performed the usual office of religion, by sacrifice and prayer, used to open them to the reasons of their being called together, and propose the subject of that day’s deliberation; in which all things divine, or relating to the worship of the gods, were dispatched preferably to any other business. When the consul had moved any point, with intent to have it debated and carried into a decree, and had spoken upon it himself as long as he thought proper, he proceeded to ask the opinions of the other senators, severally in their name, and in their proper order, beginning always with the consuls, and going on to the praetors, &c.

It was the practice originally to ask the prince of the senate the first; but that was soon laid aside, and the compliment transferred to any other ancient consul, distinguished by his integrity and superior abilities; till, in the later ages of the republic, it became an established custom to pay that respect to relations, or particular friends, or to those who were likely to give an opinion the most favourable to their own views and sentiments on the question proposed. But whatever order the consuls observed in asking opinions on the 1st of January, when they entered into their office, they generally purified the same through the recess of the year.

Julius Cæsar, indeed, broke through this rule; for though he had asked Cæcilius the first, from the beginning of his consulship; yet, upon the marriage of his daughter with Pompey, he gave that priority to his son-in-law, for which, however, he made an apology to the senate.

This honour of being asked in an extraordinary manner, and preferably to all others of the same rank, though of superior age or nobility, seems to have been seldom carried farther than to four or five distinguished persons of consular dignity; and the rest were afterwards asked according to their seniority. And this method, as has been said, was observed generally throughout the year, till the election of the future consuls, which was commonly held about the month of August; from which time, it was the constant custom to ask the opinions of the consuls elect, preferably to all others, till they entered into their office, on the 1st day of January following.

As the consuls elect had this preference given in speaking before all the consuls, so the praetors, and tribunes elect, seem to have had the same, before the recess of their particular orders.

None were allowed to speak till it came to their turn, excepting the magistrates, who seem to have had a right of speaking on all occasions, whenever they thought fit; and for that reason, perhaps, were not particularly asked, or called upon by the consuls.

If in the debate several different opinions had been offered, and each supported by a number of senators, the consul,
The decrees of the senate were usually published, and openly read to the people soon after they were passed; and an authentic copy of them was always deposited in the public treasury of the city, or otherwise they were not considered as legal or valid.

As to the force of these decrees, it is difficult to define precisely what it was. It is certain that they were not considered as laws, but seem to have been designed originally as the ground-work, or preparatory step to a law, with a sort of provisional force, till a law of the same tenor should be enacted in form by the people; for in all ages of the republic, no law was ever made, but by the general suffrage of the people.

Even under the kings, the collective body of the people was the real soveraign of Rome, and the dernier resort in all cases. But their power, though supreme and final, was yet qualified by this check, that they could not regularly enact any thing, which had not been previously considered and approved of by the senate. This indeed continued to be the general way of proceeding in all quiet and regular times, from the beginning of the republic to the end of it; and the constant style of the old writers, in their accounts of the public transactions, is, that the senate voted or decreed, and the people commanded such and such an act. Middleton, ubi supra, and the authorities cited by him.

Before the accession of Augustus the senate had lost its power, and also its dignity. Many of the most noble families were extinct; the republicans of spirit and ability had perished in the field of battle, or in the prostration. The door of the assembly had been designedly left open for a mixed multitude of more than a thousand persons, who reflected disgrace upon their rank, instead of deriving honour from it. Julius Cæsar introduced soldiers, strangers, and half-barbarians into the senate; and this abuse, recorded by Sue- tonius, became still more scandalous after his death. Augustus, soon after his accession, set about the reformation of it. He was elected censor; and in concurrence with his faithful Agrippa, he examined the list of the senate, expelled a few members whose vices or whole obliquity required a public example; persuaded near two hundred to prevent the flame of an expulsian by a voluntary retreat; raised the qualification of a senator to above ten thousand pounds; created a sufficient number of patrician families; and accepted for himself the honourable title of prince of the senate, which had always been bellowed, by the censors, on the citizen most eminent for his honours and services. But in thus renewing the dignity, he destroyed the independence of the senate, the principles of a free constitution being irrecoverably lost, when the legislative power is nominated by the executive. How he was afterwards recompened by the flattery of the senate is well known. (See Augustus, Proconsul, and Imperator.) It was, however, on the dignity of the senate, that Augustus and his successors founded their new empire; and in the administration of their own powers, they frequently consulted the great national council, and semed to refer to its decision the most important concerns of peace and war. Rome, Italy, and the internal provinces, were subject to the immediate jurisdiction of the senate. With regard to civil objects, it was the supreme court of appeal; with regard to criminal matters, a tribunal, constituted for the trial of all offences that were committed by men in any public station, or that affected the peace and majesty of the Roman people. The exercice of the judicial power became the most frequent and serious occupation of the senate; and the important causes that were pleaded before them afforded a lait refuge to the spirit of ancient eloquence. As a council of state, and as a court of justice, the senate protected
senate.

feiled very considerable prerogatives; but in its legislative capacity, in which it was supposed virtually to represent the people, the rights of sovereignty were acknowledged to reside in that assembly. Every power was derived from their authority; every law was ratified by their function. Their regular meetings were held, as we have already said, on three fated days in every month; their debates were conducted with decet freedom; and the emperors themselves, who gloried in the name of senators, sat, voted, and divided with their equals.

Augustus found by experience, what he had previously expected, that the senate and people would submit to slavery, provided they were respectuefully assured, that they still enjoyed their ancient freedom; a feeble senate and an enervated people cheerfully acquiesced in the pleasing illusion, as long as it was supported by the virtue, or even by the prudence of the successors of Augustus. It was a motive of self-prevention, not a principle of liberty, that animated the conspirators against Caligula, Nero, and Domitian. After seventy years of patience, the senate made an ineffectual attempt to realize its long-forgotten rights. When the throne was vacated by the murder of Caligula, the confuls convoked the assembly in the Capitol, and during forty-eight hours acted as the independent chiefs of the commonwealth. But while they deliberated, the praetorian guards had resolved: the dream of liberty was at an end; and the senate awoke to all the horrors of inevitable servitude. Defeated by the people, and threatened by a military force, that feeble assembly was compelled to ratify the choice of the praetorians, and to embrace the benefit of an armistice, which Claudius had the prudence to offer, and the generosity to observe. To censure, to deplore, or to punish with death the first magistrate of the republic, who had abused his delegated trust, was the eminent and undoubted prerogative of the Roman senate; accordingly they condemned Nero to be put to death, as Suetonius observes, *more majorum*; but on the death of Commodus, that feeble assembly was obliged to content itself with inflicting on a fallen tyrant that public justice from which, during his life and reign, he had been shielded by the strong arm of military despotism. Till the reign of Severus, the virtue and even the good sense of the emperors, had been distinguished by their real or affected reverence for the senate, and by a tender regard to the nice frame of civil policy instituted by Augustus. But Severus, trained from his youth to the despotic of military command, disdain'd to profess himself the servant of an assembly that detected his perfons, and trembled at his power: he assumed the conduct and style of a sovereign and a conqueror, and exercised, without disguise, the whole legislative as well as executive power. Hence the senate, neither elected by the people, nor guarded by military force, nor animated by public spirit, refted its declining authority on the frail and crumbling bafts of ancient opinion. The fine theory of a republic inenfibly vanished, and made way for the more natural and substantial feelings of monarchy. The pulished and eloquent slaves from the eastern provinces, by whom the senate was filled, justified personal flattery by speculative principles of servitude. The lawyers and the historians concurred in teaching, that the imperial authority was held, not by the delegated commission, but by the irrevocable renunciation of the Senate; that the emperor was freed from the restraint of civil laws, could command by his arbitrary will the lives and fortunes of his subjects, and might dispose of the empire as of his private patrimony. Popularity, who experienced the fatal effects of the maxims and example of Severus, justly considered him as the principal author of the decline of the Roman empire. Such was the timid ingratitude of Gallienus, that, unmindful of his obligations to the senate and people for repulsing the Alemanni from Rome, he published an edict, prohibiting the senators from exercising any military employ; and even from approaching the camps of the legions. Tacitus was chosen emperor by the senate; and the judgment of this assembly was confirmed by the consent of the Roman people, and of the praetorian guards. By this election the senate regained several important prerogatives, the principal of which were the following: 1. To invite one of their body, under the title of emperor, with the general command of the armies and the government of the frontier provinces. 2. To determine the lift, or as it was then styled, the college of confuls. 3. To appoint the praefults and presidents of the provinces, and to confer on all the magistrates their civil jurisdiction. 4. To receive appeals through the immediate office of the prefect of the city from all the tribunals of the emperor. 5. To give force and validity by their decrees to such as they should approve of the emperor's edicts. 6. To those several branches of authority, we may add some inspection of the finances, since even in the former reign of Aureliian, it was in their power to divert a part of the revenue from the public service. Diocletian expressed his dislike of Rome and Roman freedom, by framing a new system of imperial government, which was afterwards completed by the family of Constantine; and as the image of the old constitution was religiously preferred in the senate, he resolved to deprive that order of its small remains of power and consideration. The name of the senate was continued with honour till the last period of the empire; the vanity of its members was still flattered with honorary distinctions; and the assembly which had been so long the source, and so long the instrument of power, was respectfully suffered to fall into oblivion. The senate of Rome losing all connection with the imperial court and the actual constitution, was left a venerable but useless monument of antiquity on the Capitoline hill. During the Gothic war, and in consequence of the conquest of Rome by Narses, the institution of Romulus, after a period of thirteen centuries, expired; and if the nobles of Rome still assumed the title of senators, few subsequent traces can be discovered of a public council, or constitutional order. Ascend one hundred and contem plate the kings of the earth soliciting an audience, as the slaves or freemen of the Roman senate. From the year 1144 the senate was restored, and its establishment is dated as a glorious era in the acts of the city. After its revival, the conscript fathers, if the expression may be used, were inviolate with the legislative and executive power; but their views seldom reached beyond the present day, and that day was most frequently disturbed by violence and tumult. In its utmost plentitude, the order or assembly consisted of fifty-six senators, the most eminent of whom were distinguished by the title of counsellors; they were nominated, perhaps annually, by the people; and a previous choice of their electors, ten persons in each region or parish, might afford a basis for a free and permanent constitution. The popes confirmed by treaty the establishment and privileges of the senate, and expected from time, peace, and religion, the restoration of their government. The motives of public and private interest might sometimes draw from the Romans an occasional and temporary sacrifice of their claims; and they renewed their oaths of allegiance to the successors of St. Peter and Constantine, the lawful head of the church and republic. At length the union and vigour of a public council were dissolved in a lawless city; and the Roman fee adopted a more strong and simple mode of administration. They changed the name and authority of the senate in a single magistrate, or two colleagues; and as they were changed at the end of a year,
a year, or six months, the greatness of the senator was compensated by the shortness of the term. The senators of Rome indulged their avarice and ambition; their justice was perverted by the interest of their families and faction; and as they punished only their enemies, they were obeyed only by their adherents. In this state of anarchy, most of the Italian republics chose, in some foreign but friendly city, an impartial magistrate of noble birth and unblemished character, a soldier and a statesman, recommended by the voice of the Senate and his country, to whom they delegated for a time the supreme administration of peace and war. See Gibbon's Hist. of the Decline and Fall of the Roman Empire.

**Senate of four hundred,** an ancient senate of Athens, when the city was divided into four tribes, each of which chose a hundred men. This lasted till Solon instituted the senate of five hundred, after the city was divided into five tribes.

**Senate of Venice.** See PREGADI.

**SENIOR,** a member of a senate.

There were two orders, or degrees, among the Roman nobility: that of the senators, and that of the knights; after these two, came the people. The first hundred senators were appointed by Romulus, and called *patres,* fathers. Upon the union with the Sabines, Romulus, or as others say, Tullius, added a second hundred, called *patres majorum gentium:* this distinguished them from a third hundred, added by the elder Tarquin, and called *patres minorum gentium,* fathers of the lower rank.

In ancient Rome, the number of senators is commonly supposed to have been limited to three hundred, from the time of the kings to that of the Gracchi. But this must not be taken too strictly. The senate generally had that number, or thereabout, and upon any remarkable deficiency, was filled up again to that complement by an extraordinary creation. But as the number of the public magistrates increased with the increase of their conquests and dominions, so the number of the senate, which was supplied of course by those magistrates, must be liable also to some variation. To what number Sylla increased them is not absolutely certain; but in Cicero's time they were not less than four hundred and fifteen, as appears by his letter to Atticus, lib. i. ep. 14.

In the time of Gracchus they were fix hundred; during the civil wars they were reduced to three hundred. Julius Caesar augmented that number to nine hundred; the triumvirs added a thousand; and Augustus reduced them to six hundred, according to Dion Cassius; and to three hundred, according to Suetonius. For the choice of senators belonged at first to the kings, then to the consuls, then to the censors, who in their census or survey every fifth year, appointed new senators in lieu of those dead or degraded; but at length it fell to the emperors. See SENATE.

Though, for a long time, none were raised to the dignity of senators, but those most conspicuous for their prudence, &c., yet some regard was afterwards had to their eftate, left their dignity should become debased by poverty. To hold the senatorial dignity, a yearly revenue of eight hundred thousand pounds was required, which amounts to between six and seven thousand pounds of our money. Half as much was required for the qualification of the knights. The senators who sunk below this revenue, were disinherited, and expelled out of the city by the censors; and this was increased by Augustus to twelve hundred thousand.

This qualification must not be taken, as it is borne, for an annual income, but the whole estate of a senator, real and personal, as estimated by the survey and valuation of the censors.

This proportion of wealth may seem perhaps too low, and unequal to the high rank and dignity of a Roman senator, but it must be considered only as the lowest to which they could be reduced; for whenever they sunk below it, they forfeited their seats in the senate.

In ancient Rome, a certain age was required for a senator, as is often intimated by the old writers, though none of them have expressly signified what it was. The legal age for entering into the military service was fifteen, by Servius Tullius, at seventeen years; and they were obliged, as Polybius tells us, to serve ten years in the wars, before they could pretend to any civil magistracy. This fixes the proper age of being for the senatorship, or the first step of honour, to the twenty-eighth year; and as this office gave an admission into the senate, so the generality of the learned seem to have been the same date to the senatorial age. Some writers, indeed, on the authority of Dion Cassius, have imagined it to be twenty-five years, not reflecting that Dion mentions it there as a regulation only proposed to Augustus by his favourite Macenas. Dr. Middleton takes the senatorial age, which was the same with the senatorial, to have been thirty years complete.

The laws concerning the age of magistrates were not very ancient: and were made to check the forward ambition of the nobles, and to put all the citizens upon a level in the pursuit of honours. And Livy tells us, that L. Villius, a tribune of the people, was the first who introduced them, A.U. 573; and acquired by it the surname of Annalian. Middlet. of Rom. Sen. p. 99.

The senators were ordinarily chosen from among the knights, or from among such as had borne the principal offices. At first the magistrates were taken wholly from among the senators; whence Tacitus calls the senate the *feminary of all dignities:* but after the people had been admitted to magistratures, senators were taken from among such as had discharged those offices, though before plebeians.

There was some law subsisting from the earliest times, concerning the extraction and descent of senators, enjoining that it should always be ingenuous; and as their morals were to be clear from all vice, to be born with a face from any stain of base blood. In consequence of which, when Appius Claudius, in his censorship, attempted to introduce the grandsons of freed slaves into the senate, they were all immediately turned out again.

These are some of the laws by which the censors were obliged to act, in the enrolment of the new, or the omission of old senators; and when we read of any left out, without any intimation of their crime, it might probably be for the want of one or other of these legal, or customary qualifications:

It was from the senatorial order alone, that all ambassadors were chosen and sent to foreign states; and when they had occasion to travel abroad, even on their private affairs, they usually obtained from the senate the privilege of a free legation, as it was called; which gave them a right to be treated every where where with the honours of an ambassador, and to be furnished on the road with a certain proportion of provisions and necessaries, for themselves and their attendants; and as long as they resided in the Roman provinces, the governors used to assign them a number of lifers, or messengers, to march before them in state, before the magistrates in Rome. And if they had any law-suit, or cause of property depending in those provinces, they seem to have had a right to require it to be remitted to Rome.

At home, likewise, they were distinguished by peculiar honours and privileges; for at the public shows and plays, they had particular seats set apart, and appropriated to them.
in the most commodious part of the theatre; and on all festival days, when sacrifices were offered to Jupiter by the magistrates, they had the full right of feasting publicly in the Capitol, in habits of ceremony, or such as were proper to the offices which they had borne in the city.

The peculiar ornament of the senatorian tunic was the latus clavus (see Latitia vium), as it was called, being a broad stripe of purple sewed upon the fore part of it, and running down the middle of the breast, which was the proper distinction between them and the knights, who wore a much narrower stripe of the same colour, and in the same manner. The fashion also of their shoes was peculiar, and different from that of the rest of the city: this difference appeared in the colour, shape, and ornament of the shoes. The colour of them was black, while others wore them of any colour perhaps, agreeable to their several fancies; the form of them was somewhat like to a short boot, reaching up to the middle of the leg, as they were sometimes seen in ancient statues and bas-reliefs; and the proper ornament of them was a half moon sewed, or fastened upon the forepart of them, near the ankle.

Confins, praetors, ædiles, tribunes, &c. during the year of their magistracy, always wore the praetexta, or a gown bordered round with a stripe of purple. In which habit also, as has been signified above, all the rest of the senate, who had already borne those offices, used to appear at the public festivals and solemnities.

The senators carried their children with them to the senate, to inform them betimes of affairs of state; though their children had not admittance till seventeen years of age. Some make a distinction among the senators, and say, that besides the senators who were allowed to speak, and were asked their opinions, there were others, who, without speaking, or being ever asked their judgment; were only to follow the opinion of those they thought the most reasonable, and were hence called pedarii. A. Gallus gives us another notion of the pedarii, and fays, those were thus called, who, having never borne the office of curule magistrate, were obliged to go to the senate on foot.

They had the name senator, qa. d. old men, given them in imitation of the Greeks, who called their senate ἂγεμενος. So when the Athenians assembled the people to consult about the affairs of the public, the officers summoned none but such as were at least fifty years old.

The Egyptians and Persians followed the same example, after the Hebrews; and the Lacedæmonians and Carthaginians received none but such as were sixty years of age. See SUN.

As to other matters relating to Roman senators, see the article SENATE, supra.

SENATUS ACTORITAS. See Senate.

SENATUS-CONSULTUM. A vote, or resolution, of the Roman senate, pronounced on some question, or point of law, proposed to it. See Senate.

The senatus-consultum made a part of the Roman law: when passed, they were deposited in the temple of Ceres, under the custody of the ædiles; and at last they were carried, by the censor, to the temple of Liberty, and put up in an armory called tabularia.

Julius Capitolinus speaks of a sort of senatus-consulta ta- tua, which, he says, were made in reference to affairs of great moment and secrecy, by the senators themselves, without the privity of the public officers, under an oath of se- crecy, till their designs should be effected.

The narrative of the famous senatus-consultum, or rather decree, against the musician Timotheus, at Sparta, for augmenting the number of strings on his lyre, is confirmed by Paufanius and Suidas.

This curious piece of antiquity is preserved at full length by Boethius (De Music, cap. i.) Mr. Stillingfleet (Prin. and Power of Harm. § 135.) has given an extract from it, in proof of the simplicity of the ancient Spartan music. The fact is mentioned in Athenæus and Cæsennius, in his notes on that author (Animad. in Athen. p. 386.), has interpolated the original text from Boethius, with corrections, to which we refer the learned reader. We shall here, however, give a faithful translation of this extraordinary Spartan Act of Parliament—

"Whereas Timotheus the Mileian, coming to our city, has dishonoured our ancient music, and, despoiling the lyre of seven strings, has, by the introduction of a greater variety of notes, corrupted the ears of our youth; and by the number of his strings, and the novelty of his melody, has given to our music an effeminate and artificial dress, instead of the plain and orderly one in which it has hitherto appeared; rendering melody infamous, by composing in the chromatic, instead of the enharmonic; — The kings and the ephori have, therefore, resolved to pass censure upon Timotheus for these things: and, further, to oblige him to cut all the superfluous strings of his lyre, leaving only the seven tones; and to banish him from our city, that men may be warned for the future, not to introduce into Sparta any unbecoming customs."

The same story, as related in Athenæus, has this additional circumstance, that when the public executioner was on the point of fulfilling the sentence, by cutting off the new strings, Timotheus, perceiving a little flax in the same place, with a lyre in his hand, of as many strings as that which had given the offence, and shewing it to the judges, was acquitted.

Indeed the decree only informs us, that the use of a lyre, with more than seven strings, was not allowed at this time by the Lacedæmonians; but does not prove that the rest of Greece had confined their music within the compass of seven notes: nor, consequently, ascertain how many of the eleven strings were additions peculiar to Timotheus. That the outcry against the novelties of this musician was, however, not confined to Sparta, appears from a passage in Plutarch's Life of Ajax, where he gives a list of the innovators who had corrupted and enervated the good old melody, by additional notes both upon the flute and lyre.

"Latus of Hermione," says he, "by changing musical rhythms to the dithyrambic irregularity of movement, and, at the same time, emulating the compass and variety of the flute, occasioned a great revolution in the ancient music. Melanippides, who succeeded him, in like manner, would not confine himself to the old music, any more than his fellow Philocles, or Timotheus."

The same thing also appears from the bitter invectives to which the comic poets at Athens, especially Pherecrates and Aristophanes, gave a loofe; not, perhaps, from underlining music, or being at all sensible of its effects, but from that envy which the great reputation of the musician had excited. An exalted character is a shooting butt, at which farriors, and witted wits, constantly point their arrows; and the rage at all times wages war against whatever calls off the public attention from itself.

The abuse, therefore, of this musician, which abounds in ancient authors, is, perhaps, as great a proof of his superiority as the praise. A Greek epigram, preferred in Macrobius, informs us, that the Ephesians gave him a thousand pieces of gold for composing a poem in honour of Diana, at the dedication of the temple of that goddess; and
SEN

and was not that a sufficient reason for hungry authors to rail?

Plutarch tells us, that the comic poet Pherecrates introduced Music on the stage, under the figure of a woman, whose body was terribly torn and mangled. She is asked by Justus, under the figure of another woman, the cause of her ill-treatment? when she relates her story in the following words: "The first source of all my misfortunes was Melanippides, who began to enrave and debilitate me by his twelve songs. However, this would not have reduced me to the deplorable condition in which I now appear, if Cineas, that cursed Athenian, had not contributed to ruin and disguise me in his diithyrambic frolics, by his falfe and untameable inflexions of voice. In short, his cruelty to me was beyond all description; and next to him, Phrynis took it into his head to abuse me by these divisions and flourishes, as if I were ever thought of before, making me subservient to all his whims, twirling and turning me a thousand ways, in order to produce from five songs, the twelve different modes. But still, the freaks of such a man would not have been sufficient to complete my ruin, for he was able to make me some amends. Nothing was now wanting but the cruelty of one Timotheus to send me to the grave, after maiming and mangling me in the most inhuman manner."

"Who is this Timotheus?" says Justus.

Music.

"O o'ers that vile Midian blade:
Who treats me like an arrant jade:
Rob me of all my former fame;
And lends me with contempt and shame:
Contriving tell, where'er he goes,
New ways to multiply my woes:
Nay more, the wretch I never meet,
De it in palace, house, or street,
But straight he tries to clip my wings,
And ties me with a dozen strings."

SENAURA, in Geography, a town of Hindooftan, in the circuit of Bickaneer; 5 miles E. of Jellemere.

SENCE, a river of England, which rises in Leicetershire, and runs into the Anker, near Atherstone, in Warwickshire.

SEND, is used by seamen, when a ship, either at anchor, or under sail, falls with her head, or stern, deep into the trough of the sea, i.e. into a hollow made between two waves, or billows. They say the sends much that way, whether it be a-head or a-stern.

SENDAL, in our Old Writers, a kind of thin fine silk, mentioned in the flat. 2 Rich. II. cap. 1.

SENDEBAS, in Geography, a town of Egypt, on the east branch of the Nile; 13 miles S. of Smemund.

SENDELBACH, Langen, a town of Germany, in the bishopric of Bamberg; 5 miles S. E. of Forchem.

SENDEN, a town of Germany, in the bishopric of Munster; 7 miles S. W. of Munster.

SENDENHORST, a town of Germany, in the bishopric of Munster; 10 miles S. E. of Paderborn.

SENDSE, a town of Egypt, on the Kalis il Menh; 3 miles N. of Behene.

SENDGEAN, a town of Asiatic Turkey, in Natolia; 13 miles S. E. of Balikefri.

SENDGISCHOW, a town of Poland, in the palatinate of Sandomir; 36 miles S. S. W. of Sandomir.

SENDI, or Sindi, in Ancient Geography, a people of Scythia, in the country called Sendica, in the vicinity of the country of the Tauro-Scythians. Purtyn.

SENDA, in Geography, a town of New Mexico, on the Bravo; 50 miles S. of Santa Fé.

SENDUARY, a town of Hindooftan, in Bahar; 45 miles S. S. W. of Patna.

SENEBLERIA, in Botany, a genus of Decandolle's, dedicated to Mr. John Senebie, a Genevan naturalist, who published a work upon Vegetable Physiology, in 1791.

SENICA, Lucius Annæus, in Biography, a celebrated philosopher, was born at Corduba, near the commencement of the Christian era. His father was a man of eques- trian rank, and an eminent orator, of whom some declamations and controversies are extant. His mother was Helvia, a Spanish lady of distinction. Being educated at Rome, he was early initiated in the study of eloquence by his father, and other masters; but his own propensity led him to devote his talents to the study of philosophy. He first joined the Pythagoreans, whom he soon left for the Stoics; he, however, confided himself to no sect, but extended his inquiries to all the syllems of Grecian philosophy. In conformity to the wishes of his father, he pleaded some time in the courts of justice, and acquired by the practice a considerable reputation; but it is thought he relinquished the bar, through fear of the jealousy of Caligula, who was ambitious of oratorical fame. Entering into public life, he obtained the office of queller, and had riven to some consequence in the court of Claudius, when, at the instigation of Menalina, he was accused of an adulterous commerce with Julia, the daughter of Germanicus, and was banished to the island of Corfu. In that island he remained in exile eight years, confounding himself with the maxims of philosophy, though never refrained to the severity of his lot, as may be inferred from his complaints, and his abject application to the emperor for pardon.

Upon the marriage of Claudius to his second wife Agrippina, Seneca was, through her influence, recalled, and, after being raised to the praetorship, was appointed preceptor to her son, the afterwards most infamous Nero; while Burrhus was made his governor and military instructor. They are said to have acted with the most perfect unanimity in restraining him from those vices, to which his situation and inclination prompted him; and obtained an ascendancy over him, to which is attributed the flattering promise of the first years of his reign.

When Nero began to display his real character, his quarrels with his mother, who was as violent and wicked as her son, laid his governors under great difficulties. Once they were the means of reconciling them, but at length the breach was irreparable, and Nero determined to free himself from one whom he regarded as a dangerous competitor, by the horrid crime of matricide. Seneca and Burrhus were apprized of his intention, and did not oppose it, as they ought to have done; and after the deed was perpetrated, Seneca wrote to the senate, in the name of the emperor, to justify it. Burrhus died very soon, and the influence of Seneca over his pupil was entirely lost; nevertheless the tyrant leaped upon his preceptor unbounded wealth, which not only exalted the character of the philosopher to severe cenure, but was in the end the principal caufe of his destruction. Finding that he was an object of envy to the favourites of the prince, he requested permission to retire from court, and refund all that he had received from the imperial liberality. Nero allured him of his continued regard, and would not hear of the professed restitution of rewards, which he had so well merited. Seneca, however, knew him too well to place any confidence in his declarations,
tions, and kept himself out of fight as much as possible. Notwithstanding his prudence, it is said that the tyrant engaged one of his freedmen to poison him, and that Seneca by good fortune escaped the snare. It was not long, however, before an occasion was given to the emperor to gratify his hatred against one, whom he felt as a secret cenfor of his vices. Under the pretence of Seneca's connection with a conspiracy, a military tribune was sent with a band of soldiers to Seneca's house, where he was at supper with his wife Paulina, and two friends. He was, without much ceremony, commanded to put an end to himself. The philosopher heard the sentence with equanimity, and only asked for time sufficient to make his will. This was refused, and turning to his friends, he said, that since he was not allowed to shew his gratitude to them in any other way, he would leave them the image of his life, as the bell memorial of their friendship. He then exhorted them to moderate their grief. He embraced Paulina, and endeavoured to comfort her; but she refused any other consolation than that of dying with him. The death which he chose was that by opening his veins, and he expired in the year 65, and in the 12th year of Nero's reign. The emperor would not suffer Paulina to die with her husband; but she never recovered the loss of blood which she had experienced, before the imperial decree arrived.

The character of Nero has been greatly extolled by some writers, and not least deprecated by others; but Tacitus, without pretending to conceal his faults, inclines to a favourable opinion of him; and it is completely ascertained, that while Nero followed the precepts of his master, he appeared a good prince; and that all virtue was banished from the court, when Seneca left it.

"If," says one of the philosopher's biographers, "a writer could be estimated by his works, a purer moralist could not easily be found; for their constant tenor is that of solid virtue, tempered with humanity, and exalted by the noblest principles of theirm. They are indeed marked with the timid pride inculcated by the Stoical sect, to which he chiefly adhered; though he freely adopted what he found good in others." Of his writings which have come down to us, the greater part are moral, consisting of epitaphs, 124 in number, and of distinct treatises on Anger, Contemplation, Providence, &c. There are, moreover, seven books on physical topics, entitled "Natural Questions," in which are to be found the rudiments of some notions regarded as fundamental in modern physics.

A number of tragedies are extant, under the name of Seneca, but they are probably not his; nor is it at all known to whom they ought to be ascribed. The editions of Seneca's works are very numerous. Of the works, not including the tragedies, the most esteemed are those of Lipsius; the Variorum, 3 vols. 8vo.; the Leipziger, 2 vols. 8vo.; and the Bipontine. Of the tragedies, are the Variorum; that by Heinius, with notes by Scaliger; and the quarto Delphin.

Seneca, in Geography, a town of America, in the county of Onondago, in New York, laid out in streets and squares, on the north side of Seneca Falls. The inhabitants have erected, at a great expense, flour and saw-mills, of the best kind in this place, and also a bridge across Seneca river; and as the place is central, and accessible from the eastern and western countries, it promises a rapid increase.

Seneca Creek, a creek in Maryland, which has two branches; one called Little Seneca. It empties into Potomac river, about 15 miles N.W. of the mouth of Rock creek, which separates George-town from Washington city.
of a canton, in the district of Chalons sur Saône; 8 miles S. of Chalons sur Saône. The place contains 2345, and the canton 13,612 inhabitants, on a territory of 222½ kilometres, in 18 communes.

Gen. Ch. Commum calyx calyptrate, conical, truncated; scales awl-shaped, numerous, parallel and contracted into a cylinder at the upper part, contiguous, equal; not so numerous at the base, but imbricated, withering at the tip. Core, compound, higher than the calyx; florets of the distinct perfect, tubular, numerous, funnel-shaped, with five-lobed, reflexed limb; those of the radius, if any, female, ligulate, oblong, slightly three-toothed. Stem, (in the perfect florets) Filaments five, capillary, very small; anthers cylindrical, tubular. Petal, (in all the florets) Germen ovate; fyle thread-shaped, the length of the filaments; stigmas two, oblong, revolute. Pericarp, none, except the conical, converging calyx. Seeds in both kinds of florets alike, follicular, ovate, crowned with capillary long down. Receptacle, naked, flat.

Obf. Senece of Tournefert and others, is delivered of a common radius to the corolla, whereas their Jacobea is furnished with one. This, however, is by no means a sufficient generic distinction. Mott authors have accordingly united them into one genus.

Eff. Ch. Receptacle naked. Down simple. Calyx cylindrical, many-leaved, falcate at the base; scales dead at the tip.

In the Species Plantarum of Linnaeus we meet with only forty species of Senece, (to which however many others are added in his Supplementum Plantarum,) whereas Willdenow enumerates one hundred and twenty-two. These are divided into the four following sections, from each of which we shall select a few species in order to give as clear and concise an account of this extensive genus as we are able.

S. purpurascens. Purple Groundsel. Linn. Sp. Pl. 1215. Willd. n. 6. (Cacilia villosa; Jacq. t. 1. Rar. v. 3. t. 586.)—Corolla naked. Leaves lyrate, hairy; the upper ones lanceolate, toothed. Native of the Cape, and flowering from June to September. Root perennial, thick. Stems numerous, erect, a foot high, foliariated. Leaves alternate, lyrate, obtuse, thickish; the lower ones on long flanks; all beautifully veined. Flowers terminal, corymbose, purple, rather small.

A common weed, flowering throughout the year, in any kind of soil or situation. Seeds annual, fibrous. Stem erect, branched, leafy, somewhat panicked, round, angular, either smooth or clothed with a cottony down like the back of the foliage. Leaves alternate, bright green; radical ones stalked, those of the stem feeble, auriculate. Flowers terminal, panicked or panicked, yellow. Seeds furred, pubescent. Seed-down fefile, rough. The great peculiarity of Senece in having the scales of the calyx withered, and black at the tip, is a very conspicuous in the present species, whole flower-buds and young tops are the food of many small birds, and especially domestic Canary-birds. In several parts of England it is called Simson, apparently a corruption of the generic name, perhaps through the medium of the French Senson.

The remaining species of this section, described by Wildenow, are S. angustifolius, mucronatis, nivios, bicaulis, cerudeis, perpendiculatus, llyratus, paniculatus, bilacinus, scalaris, wightii, vittatus, davisianus, colour, japonicus, paulificus, arabicus, and herbicribus.

Sec. 2. Floribus radialis, radio flaum revolventes. Flowers with a revolute radius.

S. villosus. Stinking Groundsel. Linn. Sp. Pl. 1217. Engl. Bot. t. 32.—Radius revolute. Leaves pinnatifid, viscid. Scales of the calyx lax, and nearly as long as the calyx itself, which is hairy. Not uncommon in many parts of Britain, in a chalky or sandy soil; flowering from July to October. The whole herb is hairy and viscid, with a very fetid smell. Root annual. Stem a foot high, much branched, spreading, furrowed, leafy. Leaves alternate, falcate, very finely embracing the stem, pinnatifid, somewhat toothed. Flower-flalks solitary, terminal, each bearing a flower of a bright gold colour.

ton, &q. in Yorkshire. It flowers in October. “This new British species,” says the author of English Botany, “is most like S. involucrata, but the essential and all-sufficient marks of distinction are the dilated base of the leaves which embrace
SENECIO.

embrace the stem, and the taper-pointed scales at the base of
the calyx, which are not blackened and abrupt at the tip, as
in perhaps every other Senecio.” This species varies much
in the depth of the segments of its leaves. The florets of
the radius are not at first revolute, but gradually become so.

tate. Leaves pinnatifid, lobed, toothed. Scales of the
calyx short. Stem erect, bright, corymbose. —Common
in bushy spots upon gravely or sandy heaths, flower-
ing in July. Root annual. Stem three feet high, leafy, fur-
rowed, rather hairy, many-flowered.

Leaves numerous, scattered, with an unpleasing smell, and slightly viscid.
Flowers yellow, but paler and smaller than in falcatus, of
which some authors have considered this as a variety, but
from which it is perfectly distinct.

The remaining species of Willdenow in this section are,
S. triflorus, egojmus, angulata, latus, crysifolius, humitus, leu-
canthemifolius, auritns, giganteus, telepholius, trilobus, cimicif-
cens, javanicus, Coronopus, multiflorus, nebrodenius, subvirgus,
and variojus.

Sect. 3. Floribus radiatis, radice patente; foliis pinnati-
fatis. Flowers with a spreading radius and pinnatifid leaves.
(Jacobaea atra Peterm. viscosa.) Lutea, aplenis foliis; Dill.
Ethl. 183. t. 152. f. 184.) —Radius spreading. Leaf-
stalks embracing the stem. Flower-stalk thrice as long as
the leaf. Leaves hialate, serrate. —Native of the Cape of
Good Hope, flowering most part of the summer. Stem
herbaceous, perennial, about two feet high, branched at the
bottom. Leaves stalked, narrow, seven or eight inches
long, very gluttonous. Flowers terminal, yellow, two or
three on each stalk.

S. elegans. Elegant Groundsel, or Purple Jacobaea.
Radius spreading. Leaves hairy, viscid, pinnatifid, equal,
much-spreading. Common stalk narrow below. Calyx
hairy. —Native also of the Cape, flowering from June to
autumn. Linn. designated this annual the name of elegans,
because of the beauty of its flowers, their being a lot
of most brilliant purple, and their disk bright yellow; colours
peculiar to this and S. venetus. Willd. n. 57. —The stem
is about eighteen inches high, erect, branched, furrowed.

Leaves at the stem-joints, bright green. The figure of
Curtis exhibits a beautiful variety of this species, with double
flowers, whose colours are equally brilliant as when single.
It occasionally produces white flowers.

Engl. Bot. t. 660.—Radius spreading, longer than the
calyx; its florets elliptical and entire. Leaves pinnatifid;
their segments distant, somewhat linear. Plentiful on almost
every wall in and about Oxford, flowering from June to
October. Root annual or biennial. Stem erect, branched,
much spreading, sometimes a little hairy. Leaves subfoli
deeply pinnatifid, narrow, smooth, flat, rather fleshy, often
purplish beneath. Flowers solitary, of a bright golden
yellow, on terminal, solitary, bracteated, corymbose stalks.
The whole herb has a peculiar smell, somewhat like Tansy
or Mugwort.

S. obnexitus. Southern-wood-leaved Groundsel.
Leaves pinnatifid, jagged; leaves linear, naked, acute.
Stalks mostly two-flowered. —Native of the Auffrian Alps,
flowering from July to October. Root perennial, com-
posed of many, long, slender fibres, striking deep, and
spreading on all sides. Stem from one to two feet high,
the base, smooth above, paler and downy beneath. *Flowers*
above an inch in diameter, bright yellow; in a kind of ter-
mary corolla, the lowermost petals arising from the bo-
oms of the upper leaves.

Native of Austria and Switzerland; flowering in July and Aug.

*Root* perennial, fibrous, not creeping. *Stems* gen-
erally single, two or three feet high, erect, slightly an-
gular or grooved towards the top, pale green, pubescent here and there. *Leaves* alternate or scattered, five or fix inches long, pointed, smooth above, hairy beneath. *Flowers* very numerous, yellow, in terminal compound corymbs.

*Root* perennial, creeping. *Stems* erect, from three to five feet high, angular, leafy, smooth, corymbose at the top. *Leaves* alternate, sessile, lanceolate, slightly downy. *Flowers* bright yellow, in a large, terminal corymb, with narrow, lanceolate, pointed bracts, and rather downy flanks. —This is one of our rarest British plants. The specific name alludes to its being used by the Saracens as a vulnerary. Its qualities are astringent, with considerable acrimony.

*Root* perennial, caespitose, bitter, with long white fibres. *Stems* from two to five feet in height, much branched upwards, flattened. *Leaves* alternate, lower ones flaked; upper sessile; all of them extremely glaucescent and ribbed. *Flowers* rather small, numerous, palish yellow, in terminal, compound corymbs.

*Root* perennial, fibrous. *Stems* perfectly simple, hairy. *Radical leaves* flaked, thickish, plain or hispid on either side of the mid-rib; *stem-leaves* small, lanceolate, nearly awl-shaped. *Flowers* large, terminal, mostly solitary, of a deep yellow or orange-colour, on longish, thick, hairy flanks.

*Root* perennial, fibrous. *Stems* numerous, annual, round, smooth; from four to six feet high, branched with purple. *Leaves* alternate, somewhat leathery, smooth, glaucescent, pointed, veined with purple. *Flowers* in terminal, thick, compound corymbs, bright yellow; the *dijk* turning brown.

The remaining species of this last and fourth section described by Willdenow are the following.—*S. linifolius*, juniperinus, rofmarinifolius, aper,niestus, cruciatus, rigefens, pinnaetus, hadniius, ovatus, coriaceus, orientalis, Barrellieri, arenarius, glabifolius, epianus, longifolius, undulatus, byzan-
tinus, heterophyllum, balanifolius, marginatus, lanatus, mollis, quercifolius, ilicifolius, crispus, crenatus, angustus, cardifolius, repandus, rigidus, and foliadosinodes.

*Senecio*, in Gardening, contains plants of the herbaceous, annual, and perennial kinds, of which the species cultivated are; the hieracium-leaved groundsel (*S. hieraciifolius*); the Chinese groundsel (*S. pseudo-china*); the spleenwort-leaved groundsel (*S. haftatus*); and the elegant groundsel, or purple Jacobean (*S. elegans*).

In the fourth species there are varieties with very double purple, and with equally double white flowers. The former is now chiefly cultivated.

And there are other species that may be cultivated for variety.

**Method of Culture.**—The first and two last sorts are readily increased by planting cuttings of the branches in pots filled with fine mould in the summer season, shading them till they have taken root; and, as the winter approaches, removing them under the protection of the greenhouse, where they should remain till May, when they may be planted out in the borders or clumps. They may likewise be raised from seed, which should be sown in the spring in pots, and placed in a gentle hot-bed.

The second sort should be more carefully attended to, being raised from offsets, which should be planted in pots in the spring season, and be plunged in the hot-bed of the flower, where the plants should be constantly kept.

The first and two last sorts afford variety in the borders, and among potted plants; and the second in flower collections.

**SENECTA Anguium**, the exuviae, or sloughs of ser-
pents. The snakes cast their whole skin, and with it were supposed to call off their age, and be born anew; while the name of the call skins. A decoction, or infusion of these, is recommended by medical writers against pains of the ears and eyes, and some superstitious people recommended it to women to tie about their waists, to prevent miscarriages, and about their thighs, in time of labour to hasten delivery.

**SENEFFE**, in Geography, a town of France, in the department of Jemappe, and chief place of a canton, in the district of Charleroy; 13 miles N.W. of Charleroy. The place contains 2,531, and the canton 12,063 inhabitants, on a territory of 167 ½ square miles, in 18 communes.

**SENEGA.** See *Gum Senega*.

**SENEGAL** or *SENEGAMBA*, in Geography, a country of Africa, situated between the rivers Senegal and Gambia, and including many kingdoms and states. It derives the former name from the river Senegal, and the latter from that of Gambia. According to Bruns, all the coast extending from Cape Blanco to the mountains to the N. of Senegal, has been called Upper Senegambia. It is frequented by the Moors, wandering shepherds in the desert of Zaara or Sahara. They acknowledge the supremacy of the emperor of Morocco; but only obey him as they find it to be their interest. The Europeans trade with these people in gum; and the establishment of Portenbeek, formed by the Dutch, and that of Arguin, have been disputed by several European nations, with inconceivable eagerness. The dreadful portrait which Mungo Park has given us of the foolhardy pride, perfidy, and barbarity of the Moors of the environs of Tombuctoo, perfectly agrees with that given by Brillon of those who inhabit the coasts. The whole country watered by the rivers of Senegal and Gambia has been called Senegambia, and extends, according to Bruns, from the northern shores of Senegal to the northern shores of Sierra Leone.
SENEGAL.

Senegal, a river of Africa, which rises in the interior of the country, and runs, after a winding course, into the Atlantic. It takes its rise by various streams in a chain of mountains, situated, according to Mr. Park's discoveries, between the 6th and 9th degrees of west longitude, and directs its course towards the N.W. Within the same space are the sources of the Gambia, which runs to the W.N.W., and thence the Joliba or Niger flowing towards the E.N.E. A large portion of the tract bounding on the northern foot of the mountains, whence the branches of the Senegal river issue, is covered with thick forests. One part of this tract is denominated the Jallonka wilderness, in which no habitations are to be seen during nine days of forced marching. The head of the principal branch of the Senegal is about 80 geographical miles W. of that of the Joliba; and the head of the Gambia is about 100 miles W. of the Senegal. The branches of the latter are very numerous, and intersect the country for about 200 miles from E. to W., in the line of the caravan route. In Mr. Park's judgment, the Senegal river, below the falls of F'low, or Fflee, as Labat calls it, was about the bulk of the Tweed at Melrose in summer; but this was in the dry season, or Christmastide; and as the river does not swell periodically, till many months after that, Mr. Park did not fee it at its lowest pitch. And yet this was the Allamblage of all the rivers, the Falemé excepted, which was itself about three feet deep at the same feason. But the Senegal is even fordable in some places before the confluent of the Falemé, according to Labat; for the Moors cross it in the dry season, and commit depredations on some of the lands to the south. However, almost all the towns and villages are placed on the south side, with a view of being in security for the longest possible time. The Senegal river is then by no means a very capital stream, except in the rainy season; when, like all the other tropical rivers, its bed is filled, and it very commonly overflows. Mr. Park observed, by the mark of the highest point of swelling of the river Kokaro, or eastern branch of the Senegal, that it had been twenty feet higher than when he crossed it, in the line of the southern route. The main branch of this river, the Ba-fing, or Black river, was not fordable, and was crossed over a temporary bridge of a very singular construction. Alligators and crocodiles are found in all these rivers, at the height at which Mr. Park passed them. The Falemé river has a remote source, and drains a great extent of country. The great body of the river Senegal is precipitated from the upper level, containing the political divisions of Manding, Jallonkadda, Foulaadu, Kallon, Gadon, and some other smaller stems, to the intermediate one; thus forming the falls of Gouvina. The intermediate level contains Bambouk, Konkado, Satalado, Dentilla, and some others, and is bounded on the S.W. by the great slope of country at Kerwanney, when the waters first begin to flow towards the W. On the N.W. it is bounded by the great defcent which forms the second or lower fall of the Senegal river, named F'low. This fall is about 30 miles below Gouvina, 48 above fort St. Joseph; and here the river, being arrived at the lowest level of the country, continues navigable, with little interruption, to the sea. The Falemé river, of course, must run on a far lower level than the other heads of the Senegal river. The distance between Koonia-karry in Kallon, lat. 14° 34', and the Senegal river, 13 miles, points to a W.N.W. course, or reabounds, of the river between the falls; not much different from its general course, lower down. But as the Ba-fing, or principal arm of the river, must run almost directly to the N. from the place where Mr. Park crossed it, in Jallonkadda, it is highly probable that the two great branches unite at no great distance above the upper fall; the same ridge of mountains that occasion the fall, may, perhaps, occasion a junction of the different streams above it. These falls are said by Labat to be from 30 to 40 toises perpendicular, or 180 to 240 French feet. The Senegal, in its course, separates the two countries of Kajaaga and Kallon.

Within six miles of the sea, the river in its course takes a sudden turn to the south, and for the remainder of its passage is divided from the sea only by a natural ridge of sand, sometimes not 100 toises over. By this curve it prolongs its course for 75 miles farther, from north to south, till at length it discharges itself into the ocean, in N. lat. 15° 50'. This great river separates the country of the Negroes from the Moors of Sahara, or the Defert, stretching by a number of windings to a prodigious length, from east to west. The extreme rapidity of this river is attributed to the spae passed through by fo large a body of water, confined within so narrow a channel; the mouth of it being no more than a mile and a half over, and that chocked up with sand, called a bar, which renders the passage exceedingly difficult and dangerous. This bar is doubly dangerous, on account not only of the shallowest of the water at all times, but the shifting of the bar, and the change of its situation after floods and heavy rains, by which the channels are lost, and new foundings requisite to discover them; indeed the Senegal would be quite shut up, but for one channel of 200 toises in breadth, and two fathoms depth, which has long kept its situation immovable, amidst the floods and overflows of the river. This bar prevents ships of 500 tons from entering the river, and mooring under the fort; an inconvenience that obliged the French company to keep a vellest constantly at anchor in the channel, for no other purpose than to keep an account of the foundings. The most commodious time of the year for crossing the bar, is from the month of January till August, the winds being then variable, the river smooth, and the bar fixed till the ensuing rainy season, when the prodigious swell of the river, and south-west winds, opposed to its rapid course, raise waves of fo prodigious height at the bar, that their clashing resembles the shock of mountains, and so furious, as to dash in pieces the stoutest ship. After crossing the bar, it becomes a beautiful, smooth, and gently gliding river, at four fathoms depth. In advancing three miles higher, the country on the south side is clothed with a beautiful verdure, the trees in perpetual bloom, than which nothing can form a more agreeable contrast to the dry, sandy, and barren points of land, that frith present themselves to the shipping. All around it lie a great number of islands, pleasantly flopped with trees, fruits, herbage, and birds, but appropriated to no ufe, except the island of Senegal.

Fort St. Louis, at the mouth of the Senegal river, according to the observations and refuits of M. D'Anville and M. Fleurius, is placed in lat. 16° 5' (by D'Anville), long. 16° 8' by Fleurius: and Cape Verd in lat. 14° 48', long. 17° 34', W. of Greenwich. By the treaty of 1783, the river of Senegal and its dependencies were left in the possession of the French, who had extended their factories above 500 miles from the shore. In 1784 was founded the company of the gum of Senegal, which obtained an exclusive privilege of trading in gum, slaves, gold-dust, ivory, wax, and other products of the river Senegal, and dependencies, from Cape Blanco to Cape Verde. Goree was chosen as the residence of the adminiftrators. In 1791 this company was suppressed by the national assembly, and the trade with Senegal was declared free.

The Moors chiefly gather the gum in the three forests of 10 Sokel,
Senegal, an island of Africa, in the river so called, about one mile and a quarter in length, from north to south, and almost half a mile in breadth, from east to west. It is composed of a bed of loose sand, productive of nothing but what is forced by art and the richest manure, notwithstanding which it contains 3000 inhabitants, whose principal food is fish and maize. This fort of corn grows in great plenty all over the whole country. It may seem surprising, that a part of the world so very unhealthy as this, should yet be so populous, but the wonder will cease when we come to understand, that the greatest pride among the men consists in the number of their wives; so that every one takes as many as he is able to maintain; some fix, others eight, and others twelve at a time. In the year 1758, this island was taken from the French by the British troops, and by the peace of 1763 it was ceded to Great Britain. N. lat. 16° 5'.

SENEKAL, or SENEGALLUS, in Ornithology, the Loxia orif. See Loxia. See also Fringilla Senega. SENEKA, RATTLESNAKE ROOT. This is a root lately brought into use among us, and which seems to deserve very great regard. It is the root of a species of polygala, or milk-wort, (see Polygala Senega,) distinguished by Gronovius, in his Flora Virginica, under the name of the erect polygala, with a fimple tattle, with oval leaves, pointed at the end, and with an erect cluster of flowers. We generally call it the rattlesnake-root, and the French, from the place whence it comes, Seneka. The plant is a native of Virginia, Pennsylvania, and Maryland, and is cultivated in some of our gardens.

The root is perennial; the thickness of it is generally about that of a man's little finger. It is four or five inches, or more, in length, and is variously contorted and twisted, and divides into many branches, furnished with fine fibres, and with a membranaceous rim running all along it. It is yellowish on the outside, and white within, very acid, and somewhat bitter to the taste, and has somewhat of an aromatic flavour. From this root arise numerous tattles, all simple, and without branches; some lie on the ground, others stand erect. There are ten or twelve inches high, when fully grown. The leaves stand alternately on the tattles, and the flowers are white, and perfectly like those of our own kinds of polygala. This root, which is brought from Virginia in bales, each containing from two to four hundred weight, is of no remarkable smell, but has a peculiar kind of subtile, pungent, penetrating tattle. Its virtue is extracted both by water and spirit.

Dr. Tennent, who brought over a large quantity of this root from America some years ago, and took great pains to introduce it into practice, prais'd it very largely as a diuretic, a diaphoretic, and an alexipharmic, and a very powerful attenuant and resolvent. He says it will sometimes vomit and purge.

The Senegaw Indians first taught the use of it to the Europeans; they esteem it a sovereign remedy against the bite of the rattle-snake; and Dr. Tennent assures us, that he saw two persons, who had been bitten by this creature in the month of July, when its poison is most fatal, perfectly restored to health by it. The powder, or a decoction of the root, is taken internally; and either the powder or cataplasm made with it applied to the wound.

He afterwards gave it in pleurises and peripneumonia with great success, and in all other cases where the blood is inflamed. The effect of this medicine was found to be, that it made the fizzly fluid, (which is contradicted by a strong fact adduced by De Haen,) procure a plentiful spitting, increased perspiration and urine, and sometimes purged or vomited. If the first doses of it provoke a vomiting, it is not at all the worse, except in cases in which the patient is very weak; and in such this effect is easily prevented, by giving some of the tattleaceous powders with it.

In pleurises it is best to take away ten ounces of blood, before the entering on the use of the medicine; in other cases no precaution is required, but it is to be given in powder, or tincture, in white wine, particularly Madeira wine; and the ordinary drink, during the use of it, should be marshmallow tea. Its good effects in pleurises have been attested by several of the French academicians and others. But repeated bleeding is not to be neglected.

This medicine may be given either in powder or decoction, and combined with aromatics, opium, or camphor, which check its nauseating qualities; but Dr. Tennent prefers the decoction, having observed it to give relief sooner than the powder does. The dose of the powder is thirty-five grains, and he gives at once three spoonfuls of the decoction, prepared by boiling three ounces of the root bruised in a quart of water to nearly the half. The dose is repeated every six hours. He is also fond of this root in the rheumatism, dropsy, and gout, in which last disease, he says, he has given it with success. See his Letter concerning the Seneca, or rattlesnake-root. The extract of it in combination with carbonate of ammonia has been found by Mr. Brandreth, of Liverpool, to be efficacious in some cases of lethargy; and in America the decoction given in divided doses, at short intervals till it vomits or purges, has been employed with benefit and success in group; it has also been lately used as a stimulating gargle in the same disease.

The usual dose, says Woodville, is from one scruple to two of the powder, or two or three spoonfuls of a decoction prepared by boiling an ounce of the root in a pint and a half of water till it is reduced to a pint.

SENEMBI, in Zoology, a name given by Maregrave to the Lacerta iguana. See Lizard.

SENECHAL, SENEGALLUS, a name anciently used for a flavel or majordomo; formed from the German, Land, house, or family, and saddle, servant.

Thus the fenechal of a lord, or a baron, is his steward or bailiff, who holds his courts, and manages his demesne lands; and the sub-fnechal, his under-steward.

High fenechal of England is the high-steward of England; high fenechal del hotel du roi, is the fenechal of the king's household.

The office of fenechal was at all times a great office; but the jurisdiction it increased much, when the grand
The ancients used the term *fenecaffus* indifferently with that of *dapipef*; whence we are sure it signifies household.

*Seneschallo et marechallo quod non tenant placita de libero tenemento,* in Lex, a writ directed to the freedherd and marshall of England, inhibiting them to take cognizance of an action in their court that concerns freehold.

*Senesino,* Francesco Bernardo, Detto, in Biography, called Seneafino, from being a native of Siena, one of the greatest fingers and the best actor who performed in Handel's operas during the Royal Academy of Music, established in the year 1720, and dissolved in 1729. He continued singing in England till the year 1735; but in an opera established by the nobility and gentry in opposition to Handel.

We have conveyed with several good judges of music, who had been frequent in their attendance at the operas of those times, who always spoke of Seneafino's voice, style of singing, figure, and action, in the highest terms of admiration. In early youth his voice had been a sopranino, but it had descended into the fullfet, most melodious, and most flexible contralto, that was ever heard in this country. He had not more than five or seven notes in his compass; but these were so mellow and powerful, and his execution of divisions to *granito,* or distinct, that, without the rapidity of a bravura finger, he seemed possessed of every solid and faulting charm of a great performer. Quantz, who heard him at Dresden in 1719, gives him the following character: "Francesco Bernardo, called Seneafino, had a powerful, clear, equal, and sweet *contralto* voice, with a perfect intonation, and an excellent shake; his manner of singing was mellowly, and his eloquence unrivalled; though he never loaded *adagios* with too many ornaments, yet he delivered the original and effential notes with the utmost refinement. He sung *allegros* with great fire, and marked rapid divisions, from the chief, in an articulate and pleasing manner; his countenance was well calculated for the illustration, and his action was natural and noble: to thefe he joined a figure that was truly majestic, but more suited to the part of a hero than a lover."

When he returned to his own country, he sung no more on a stage; but retired to Siena, the place of his nativity, where he built himself a magnificent manfion, called there a palazzo, and ended his days in splendid tranquility.

*Senetoso,* in Geography, a cape on the S.W. coast of the island of Corfica; 35 miles W. of Sarcena.

*Senex,* a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Cattellane, before the revolution the seat of a bishop, suffragan of Embrun; 6 miles N.W. of Caftellane. The place contains 758, and the canton 2681 inhabitants, on a territory of 180 kilometres, in 4 communes.

*Senentenberg,* a town of Mullria; 3 miles N. of Staia.—Allo, a town of Bohemia, in the circle of Koniggratz; 3 miles N. of Geyerberg.—Allo, a town of Saxony, in the margravate of Meiffen, containing about 300 houses, surrounded with ramparts and ditches; 32 miles N.E. of Meiffen. N. lat. 51° 31'. E. long. 14° 1'.

*Sengana,* a town of Hindoostan, in the Mewat country; 95 miles S.W. of Delhi.

*Sengbost,* a town of Perfsia, in the province of Khorasan; 25 miles S.E. of Meffghid.

*Sengen,* or *Sens,* a river of Switzerland, which joins the Sanen river, near Laufen, in the canton of Berne.

*Sengen,* or *Sengen,* a city of China, of the first rank, in Quang-fu; N. lat. 23° 24'. E. long. 107° 34'.

*Sengershasara,* a town of Perfsia, in the province of Ghilan; 69 miles N.W. of Rehfd.

*Sengin,* or *Sengen,* a town of China, of the third rank, in Quang-fo; 25 miles N.W. of King-yuen.

*Senglea,* a town of the island of Malta, divided by a channel from Vittoriofa; and containing about 4200 inhabitants.

*Sengma,* a town of Africa, in the country of Cal-bari; 5 miles N. of Cape Formosa.

*Sengo,* a town of Perfsia, in the province of Adribiztan or Azerbeijan; 48 miles S.E. of Tauris or Tifftet.

*Sengreen,* in Botany. See *Sanifraga.*

*Sengwarden,* in Geography, a town of Germany, in the lordship of Kniphausen; 6 miles E. of Jever.

*Senz,* a small island in the North sea, near the coast of Norway. N. lat. 60° 15'.

*Senigaglia.* See *Sangaglia.*

*Seningham,* a town of France, in the department of the Straits of Calais; 9 miles W. of St. Omer.

*Senitenitz,* a town of Bohemia, in the circle of Konigingratz; 6 miles N. of Konigingratz.

*Senore,* a town of Algiers; 22 miles W. of Tifftet.

*Senito,* a river of Naples, which runs into the Sibari.

*Senitz,* a town of Hungary; 25 miles W. of Toppolttan.

*Senke,* a town of Tibet; 46 miles E. of Toudfong.

*Senlis,* a town of France, and principal place of a district, in the department of the Oise, before the revolution the seat of a bishop, suffragan of Rheims; 55' N. E. of Paris. The place contains 4312, and the canton 11690 inhabitants, on a territory of 2225 kilometres, in 18 communes. N. lat. 49° 12'. E. long. 2° 40'.

*Senne,* a town of Asiatic Turkey, in the government of Moful, on the Tigris; 80 miles S.S.E. of Moful.

*Senra,* or *Senra,* a most romantic and flourishing little town of Perfsia, in the province of Ardelen, seceded in the bosom of a deep valley, well cultivated and inhabited with orchards of peach, apricot, pear, apple, and cherry trees. Its population amounts to about 6000 perons, of which number 2000 are Jews, Armenians, and Neltrians, who trade to Moful, Baghdad, and Ifpahan. The Walles, who seldom quits this place, resides in a magnificent palace, built on the top of a small hill in the centre of the town, where he maintains a degree of ftele and splendour superior to any thing in Perfsia, except at court. His house is ever open for the entertainmef of strangers, and he always retails about his person a body of horfe. The mountains to the W. of Senra are covered with fores of oak, which produce fine timber and abundance of gall-nuts. The former is made into rafts and floated down the Tigris to the Tigris; the latter is an article of trade, and exported to India. A small river of the fame name flows about one mile and a half or two miles from it. The route from Tabezze by way of Maraga to Senna is 223 miles; that from Senna by Kermez to Baghdad is 303 miles; and that from Senna to Hamadan is 89 miles.
SENNAAR, in Geography, a kingdom of Africa, in the country of Nubia, situated on the banks of the Nile, between Egypt and Abyssinia. At the beginning of the 16th century, the whole country from the sources of Egypt to those of Abyssinia, though nominally subject to Egypt for the sake of trade, had its own prince of the race of Beni Koré, whose title was Wëlëd Ageob, son of the good; and he was also called Ali, or Mahomet Wëlëd Ageob. This prince was, nevertheless, only the sheik of all the Arabs, to whom they paid a tribute for the support of his dignity and authority. The residence of this Arab prince was at Geri, a town situated on the ferry which leads across the Nile to the desert of Bakiyouda, and the road to Dongola and Egypt, joining the great desert of Selima. In the year 1504, a black nation, hitherto unknown, inhabiting the western banks of the Bahar El Abiad, in about lat. 13°, made a descent, in a multitude of canoes or boats, upon the Arab provinces, and in a battle near Herbag, defeated Wëlëd Ageob, and forced him to a capitulation, in consequence of which the Arabs became tributaries to their conquerors, and Wëlëd Ageob was allowed to retain his place and dignity, on condition that he should be always ready to use coercion in favour of the victors, in case any of the Arabs, who were to enjoy their former privileges unmolested, refused payment; and thus he became, as it were, their lieutenant. This race of Negroes are called in their own country Shillook. It was in the year 1564 that Amru, son of Adlän, the first of their sovereigns on the E. side of the Nile, founded this monarchy, and built Sennaar, which has ever since been the capital. From this period to that in which Bruce visited the country, 266 years had elapsed, and 20 kings had reigned, that is, from Amru the first to Ilman, who was king at the time of Bruce's being at Sennaar. At the establishment of this monarchy, the king, and the whole nation of Shillook, were Pagans. But they were soon after converted to Mahometanism, for the sake of trading with Cairo, and took the name of Funge, which they interpret sometimes lords, or conquerors, and at other times, free citizens; though Bruce says, that titles and dignities are under-valued, and that slavery in Sennaar is the only true nobility. Mr. Bruce has given a list of the kings, with their names and the years of their reign, from 1564 to 1772. Upon the death of a king of Sennaar, his eldest son succeeds by right; and immediately afterwards, as many of the brothers of the reigning prince as can be apprehended are put to death. This practice of murdering all the collaterals of the royal family is similar to that which prevails in Abyssinia, of confining the princes all their lives upon a mountain. In Sennaar, as is also the case in Abyssinia, women do not succeed to sovereignty. The royal family were originally Negroes, and remain so still, when their mothers have been black like themselves; but when the king has happened to marry an Arab woman, as he often does, the black colour of the father cedes to the white of the mother, and the child is white. In and near the metropolis of Sennaar there is a conflagrant mortality among the children, so that the people would probably be extinct, if they were not supplied by a number of slaves, brought from all the different countries to the southward. Hence it is concluded, that the climate must have undergone a strange revolution, as Sennaar is but a small distance from the territory where the ancients placed the Macrobis, so called from the remarkable length of their lives. Although these people are Mahometans, they are so brutal with regard to their women, that they sell their slaves after having lived with them, and even after having had children by them. The king himself, it is said, is often guilty of this unnatural practice, utterly unknown in any other Mahometan country. Once in his reign the king is obliged, with his own hand, to plow and sow a piece of land. From this operation he is called Baady, the countryman or peasant; and this name is common to the whole race of kings, as Cesar was among the Romans.

No horde, mule, ass, or any beast of burden, will breed or ever live at Sennaar, or many miles about it. Poultry does not live there. Neither dog nor cat, fowc or bullock, can be preferred there for a fea lion. All of them must be removed every half-year to the sands. Though all possible care be taken of them, they die in every place where the fat earth is about the town during the first season of the rains. Hence, it appears that the soil of Sennaar is very unfavourable both to man and beast, and particularly adverse to their propagation. This circumstance is ascribed by Bruce to some noxious quality of the fat earth; for this noxious quality is not known in the sands. Aira, between three and four miles from Sennaar, which has no water near it but the Nile, surrounded with white barren land, agrees perfectly with all animals. Nevertheless, this soil contributes very abundantly to the nourishment of man and beast. It is said to render 350 for 1: though this must be an exaggeration; it is town with dora or millet, which is the principal food of the natives. The falt used at Sennaar is wholly extracted from the earth about it, especially at Halfaia, in lat. 15° 45' 54". E.long. 32° 45' 15", is strongly is the soil impregnated with this useful folli. Halfaia is a large, handsome, and pleasant town, though built with clay. The houses are terraced at the tops. This town is the limit of the rains, and is situated upon a large circular peninsula, surrounded by the Nile from S.W. to N.W. about half a mile from the river. It consists of about 300 houses, and derives its principal gain from a manufacture of very coarse cotton cloth, called Dernour, which serves for small money through all the lower parts of Atbara. The people here eat cats, and also the river-horse and the crocodile, which are very plentiful.

About twelve miles from Sennaar, nearly to the N.W. is a collection of villages called Shaddly, from a great fawn, who in his time directed large pits to be dug, and plaited closely within with clay, into which a quantity of grain was put when it was at the cheapest, and tliee were covered up, and plaited again at the top, which they call felling, and the hole itself matamore. These matamas are in great number all over the plain, and, on any prospect of corn growing dearer, they are opened, and corn sold at a low price both to the town and country.

To the north of Shaddly, about twenty-four miles, is another foundation of this fort, called Web Abond, still greater than Shaddly. Upon these two charities the chief subsistence of the Arabs depends; for as there is continual war among these people, and their violence being always directed against the crops rather than the persons of their enemies, the destruction of each tribe would follow the loss of its harvest, was it not for the extraordinary supplies furnished at such times by these granaries.

The small villages of foldiers are scattered up and down through this immense plain to watch the grain that is tourn, which is dora only, and it is said that here the ground will produce no other grain. Prodigious excavations are made at proper distances, which fill with water in the rainy season, and are a great relief to the Arabs in their passage be-
between the cultivated country and the sands. The fly, that inexorable peræcutor of the Arabs, never pursues them to the north of Shaddly. The knowledge of this circumstance was what, perhaps, determined the first builders of Sennaar to place their capital here; this too, probably, induced the two saints, Shaddly and Wed Aboud, to make here their vast excavations for corn and water. This is the first resting-place the Arabs find, where, having all things necessary for subsistence, they can at leisure transact their affairs with government.

To the westward of Shaddly and Aboud, as far as the river Abiad, or El-ace, the country is full of trees, which make it a favourite station for camels. As Shaddly is not above three hours ride on horseback from Sennaar, there could not be chosen a situation more convenient for levying the tribute; for though Gerri, from the favourable situation of the ground, being mountainous and rocky, and just on the extremity of the rains, was a place properly chosen for this purpose by the Arab prince before the conquest of the Funge, (for his troops there cut them off, either from the sands, or the fertile country, as he pleased), yet many of them might have remained behind at Shaddly, and to the westward, free from the terror of the fly, and consequently without any necessity of advancing so far north as Gerri, and there subjecting themselves to contribution.

In this extensive plain, near Shaddly, arise two mountainous districts, the one called Jebel Moia, or the Mountain of Water, which is a ridge of considerable hills nearly of the same height, closely united; and the other Jebel Segou, or the Golden Mountain, a broken ridge composed of parts, some high and some low, without any regular form. Both these enjoy a fine climate, and are full of inhabitants, but of no considerable extent. They serve for a protection to the Dabaera, or farms of Shaddly and Wed Aboud. They are also fortresses in the way of the Arabs, to detain and force them to payment in their flight from the cultivated country and rains to the dry lands of Athara. Each of these districts is governed by the descendant of their ancient and native princes, who long refilled all the power of the Arabs, having both horse and foot. They continued to be Pagans till the conquest of the Funge. Bloody and unnatural sacrifices were said to have been in use in these mountainous states, with horrid circumstances of cruelty, till Abdelcader, son of Amru, the third of the kings of Sennaar, about the year 1554, befiegéd Shaddly and then the other of these princes in their mountain, and forced them to surrender; and, having fastened a chain of gold to each of their ears, he expoed them in the public market-place at Sennaar in that situation, and sold them to the highest bidder, at the vile price of something like a farthing each. After this degradation, being circumcised, and converted to the Mahometan religion, they were restored each to their government, as slaves of Sennaar, upon very easy conditions of tribute, and have been faithful ever since.

Nothing is more pleasant than the country around Sennaar, in the end of August and beginning of September, I mean (says Bruce) for as the eye is concerned; instead of that barren, bare, walls, which it appeared on our arrival in May, the corn now sprang up, and covering the ground, made the whole of this immense plain appear a level, green land, interpersed with great lakes of water, and ornamented at certain intervals with groups of villages, the conical tops of the houses present, at a distance, the appearance of small encampments. Through this immense, extensive plain, winds the Nile, a delightful river there, above a mile broad, full to the very brim, but never overflowing. Everywhere on these banks are seen numerous herds of the most beautiful cattle of various kinds, the tribute recently extorted from the Arabs, who, freed from all their vexations, return home with the remainder of their flocks in peace, as at great a distance from the town, country, and their oppressors, as they possibly can.

The banks of the Nile about Sennaar resemble the pleasant parts of Holland in the summer season; but soon after, when the rains cease, and the sun exerts its utmost influence, the dora begins to ripen, the leaves to turn yellow and to rot, the lakes to putrefy, smell, and be full of vermin, all this beauty suddenly disappears; bare, scorched Nabia returns, and all its terrors of poisonous winds and moving sands, glowing and rentinated with fultry blasts, which are followed by a troop of terrible attendants, epileptics, appoxelles, violent fevers, obtinate aces, and lingering, painful dysenteries, still more obtinate and mortal. War and treafon seem to be the only employment of this horrid people, whom heaven has separated, by almost impassable deserts, from the rest of mankind, confining them to an accursed spot, seemingly to give them earneft in time (as Mr. Bruce forebodes) of the only other worfe which he has referred to them for an eternal hereafter.

The drefs of Sennaar is very simple. It consists of a long skirt of blue Surat cloth called Marouty, which covers them from the lower part of the neck down to their feet, but does not conceal the neck itself; and this is the only difference between the men's and the women's dress; that of the women covers their neck altogether, being buttoned like ours. The men have sometimes a fah tied about their middle; and both men and women go bare-footed in the house, even those of the better sort of people. Their floors are covered with Perlian carpets, especially the women's apartments. In fair weather, they wear sandals; and without doors they use a kind of wooden patten, very neatly ornamented with shells. In the great heat at noon, they order buckets of water to be thrown upon them instead of bathing. Both men and women anoint themselves, at least once a day, with camels' grease mixed with ivy, which they imagine softens their skin, and preserves them from cutaneous eruptions, of which they are too fearful, that the smallest pimple in any visible part of their body keeps them in the house till it disappears; for the same reason, though they have a clean shirt every day, they use one dipt in grease to lie in all night, as they have no covering but this, and lie upon a bull's hide, tanned, and very much fastened by this constant greasing, and at the same time very cool, though it occasions a smell that no washing can free them from.

The principal diet of the poorer is millet, made into bread or flour. The rich make a pudding of this, toasting the flour before the fire, and pouring milk and butter into it; besides which, they eat beef, partly roasted and partly raw. Their horned cattle are the largest and fattest in the world, and are exceedingly fine; but the common meat sold in the market is camel's flesh. The liver of the animal, and the spare rib, are always eaten raw through the whole country. Bruce never saw one instance where it was dressed with fire; it is not then true that eating raw flesh is peculiar to Abyssinia; it is practiced in this instance of camels' flesh in all the black countries to the westward. Hogs' flesh is not sold in the market; but all the people of Sennaar eat it publicly: men in office, who pretend to be Mahometans, eat theirs in secret.

There are three principal governments in the kingdom of Sennaar. The first is at El-ace, the capital of that country, from which the Shillook came. The Bahar el Abiad spreads...
fpreads itself all over the territory, and, divided into a quantity of small channels, (whether by art or nature we know not,) surrounds a number of little islands, upon each of which is a village, and this collection of villages is called the town of El-aiace. The inhabitants are all fishermen, and have a number of boats, like canoes, in which they sail up and down to the cataracts. With incredible fleets of these their invasion was made when they undertook the conquest of the Arabs, who had not the smallest warning of the attempt. They had, at that time, no weapons of iron; their swords and lances were of a hard wood called Denguis-Sibber. It must be a relation of the Mek of Sennaar that commands at El-aiace; and he is never suffered to leave that post, or come to Sennaar.

The second government, next to this in importance, is Kordofan. The revenue consists chiefly in slaves procured from Dyre and Tegla. It feems this situation is the most convenient for invading those mountains, either from its having water in the way, or from some other circumstance that is not known. Mahomet Abou Kalee had this government, and with him about 1000 black horse, armed with coats of mail, with whom he maintained himself at this time independent of the king. It is a frontier nearest to Dar-Fowr, a black state still more barbarous, if possible, than Sennaar, and by them it often has been taken from Sennaar, and again retaken.

The third government is Fazuelo, bounded by the river El-aiace on the west, and the Nile on the east, and the mountains of Fazuelo, where are the great cataracts, on the south. These are part of the large chain of mountains of Dyre and Tegla, which reach so far westward into the continent, from whence comes the chief supply both of gold and slaves which constitute the riches of this country; for the greatest part of the revenue of Fazuelo is gold; and the person that commands it is not a Funge, but the same native prince from whom the army of Sennaar conquered it. This feems to be a very remarkable piece of policy in this barbarous nation, which must have succeeded, as they constantly adhere to it, of making the prince of the state they have conquered their lieutenant in the government of his own country afterwards. Such was the case with Dongola, whose Mek they continue; also with Wed Ageeb, prince of the Arabs, whom they subdued; and such was the case with Fazuelo, Wed Abood, Jibbel Moia, and other petty states, all of which they conquered, but did not change their prince.

The forces at Sennaar, immediately around the capital, consist of about 14,000 Nuba, who light naked, having no other armour but a short javelin and a round shield, very bad troops, as Bruce lappees; about 1800 horse, all black, mounted by black slaves, armed with coats of mail, and without any other weapon but a broad Sclavonian sword. These, he lappees, by the weight and power of man and horse, would bear down, or break through double the number of any other troops in the world: nobody, that has not seen this cavalry, can have any idea to what perfection the horse rides here. The Mek has not one mulek in his whole army. Besides these horse, there is a great, but uncertain number of Arabs, who pay their tribute immediately to the Mek and to the great men in government, and live under their protection close by the town, and thereby have the advantage of trading with it, of supplying it with provisions, and, no doubt, must contribute in part to its strength and defence in time of need.

The diseases of Sennaar are the dyentery, or bloody flux, fatal in proportion as it begins with the first of the rains, or the end of them, and return of the fair weather. Intermittent fevers accompany this complaint very frequently, which often ends in them. Bark is a sovereign remedy in this country, and seems to be by so much the furer, that it purges on taking the first dose, and this it does almost without exception. Epilepsies and feverish livers are likewise very frequent, owing, as is supposed, to their defeating or diminishing perspiration, oroppersing the pores by constant unctun, as also by the quantity of water they deluge themselves with at the time it they are hottest.

The elephantiasis, so common in Abyssinia, is not known here. The small-pox is a disease not endemic in the country of Sennaar. It is sometimes twelve or fifteen years without its being known, notwithstanding the constant intercourse they have with, and merchandizes they bring from Arabia. It is likewise said this disease never broke out in Sennaar, unless in the rainy season. However, when it comes, it sweeps away a vast proportion of those that are infected: the women, both blacks and Arabs, those of the former that live in plains, like the Shillook, or inhabitants of El-aiace, those of the Nuba and Guha, that live in mountains, all the various species of slaves that come from Dyre and Tegla, and from time immemorial have known a species of inoculation which they call Tiftberee el Jidderee, or, "the buying of the small-pox." The women are the conductors of this operation in the fairest and driest season of the year, but never at other times. Upon the first hearing of the small-pox any where, these people go to the infected place, and, wrapping a fillet of cotton cloth about the arm of the person infected, they let it remain there till they bargain with the mother how many the is to tell them. It is necessary that the terms be discussed judicially, and that the bargain be not made collusively or gratuitously, but that one piece of silver, or more, be paid for the number. This being concluded, they go home, and tie the fillet about their own child's arm; certain, as they say, from long experience, that the child infected is to do well, and not to have one more than the number of pulules that were agreed and paid for. There is no example, as far as Bruce could learn, either here or in Abyssinia, of this disease returning, that is, attacking any one person more than once.

The trade of Sennaar is not great; they have no manufactures, but the principal article of consumption is blue cotton cloth from Surat. Formerly, when the ways were open, and merchants went in caravans with safety, Indian goods were brought in quantities to Sennaar from Jidda, and then dispersed over the black country. The return was made in gold, in powder called Tibbar, civet, rhinoceros's horns, ivory, ostritch feathers, and, above all, in slaves or glads, more of which was exported from Sennaar than all the sail of Africa together. But this trade is almost destroyed, so is that of the gold and ivory. However, the gold still keeps up its reputation of being the purest and finest in Africa, and therefore bought at Mocha to be carried to India, where it all at half centers. If the wakea of Abyssinian gold falls at 16 patakas, the Sennaar gold falls at the same price for 22 patakas. The ivory falls at 15 oz. per rotol at Cairo, which is about 25 per cent. lighter than the rotol of Mocha. Men-slaves, at a medium, may be about a wakea per head at Sennaar. There are women, however, who sell for 15 or 14 wakeas. What their peculiar excellencies may be, which so far alters the price, Bruce could not tell, only they are preferred by rich people, both Turks and Moors, to the Arab, Circassian, and Georgian women, during the warm months in summer.

The Daveina Arabs, who are great hunters, carry the ivory to Abyssinia, where they are not in fear. But no caravan
caravan comes now from Sudan (Nigritia) to Sennaar, nor from Abyfimia or Cairo. The violence of the Arabs, and the faithless deeds of the government of Sennaar, have hurl them up on every side but that of Jidda, whether they go once a-year by Suakem.

The wakas of Sennaar, by which they fell gold, civet, scented o ils, &c. consigns of 10 drachms; 10 of these wakas make a Rotol. This waka at Sennaar is accounted the fame as that of Mafuah and Cairo. It is equal to 7 drachms 57 grains troy weight.

1 Rotol = 10 Wakeas.
1 Wakea = 10 Drachms.

But there is another waka used by the merchants called the Atareyas.

1 Rotol = 12 Wakeas.
1 Wakea = 12 Drachms.

But this is only used for coarse goods. There is but one long measure in Sennaar, called the Draa, which is the peck, or cubit, and is measured from the centre of the elbow-joint to the point of the middle finger. This is probably the ancient cubit of Egypt, and of the holy scripture.

Bruce's Travels, vol. iv.

Sennaar, a city of Africa, and capital of the kingdom of the fame name, situated on the W. side of the Nile, and close upon its banks. The ground on which it stands rises just enough to prevent the river from entering the town, even in the height of the inundation, when it comes to be even with the street. Ponset says, that when he was at this city, his companion, father Brevedent, a Jesuit, an able mathematician, on the 21st of March 1699, determined the latitude of Sennaar to be 13° 4' N. the difference therefore will be about half a degree. The reader however may implicitly rely upon the situation given it by Ponset, being the mean result of above fifty observations, made both night and day, on the most favourable occasions, by a quadrant of three feet radius, and telescopes of two, and sometimes of three feet focal length, both reflectors and refractors made by the best masters.

The town of Sennaar is very populous, there being in it many good houses after the fashion of the country. Ponset says, in his time they were all of one story high; but now the great officers have all houses of two. They have parapet roofs, which is a singular construction; for in other places, within the rains, the roofs are all conical. The houses are all built of clay, with very little straw mixed with it, which sufficiently shews the rains here must be less violent than to the southward, probably from the distance of the mountains. However, when Ponset was there, a week of conflagrant rain happened, and on the 30th of July the Nile increased violently, after loud thunder, and a great darkens to the south. The whole stream was covered with wrecks of houses, canoes, wooden bowls, and platters, living camels and cattle, and several dead ones pulled Sennaar, hurried along by the current with great velocity. A hymen, endeavouring to cross before the town, was surrounded and killed by the inhabitants. The water got into the houses that stand upon its banks, and, by riving several feet high, the walls melted, being clay, which occasioned several of them to fall. It seemed, by the floating wreck of houses that appeared in the stream, to have destroyed a great many villages to the southward towards Fazuola.

It will not be thought surprising, considering the latitude of Sennaar, that the heats should be excessive. The thermometer rises in the shade to 119°. Nevertheless, from 70° to 78° Fahrenheit's thermometer, the air is cool; from 79° to 92° temperate; at 92° it begins to be warm. N. lat. 13° 34' 50'. E. long. 33° 20' 30". For further particulars relating to this city see the preceding article.

SENNERAT, an island near the W. coast of West Greeneland. N. lat. 61° 28'. W. long. 47° 35'.

SENNERUS, Daniel, in Biography, an able and learned physician, was born at Breilaw, in Silefia, on the 25th of November, 1572, where his father was a shoemaker, and died in his childhood. He received his early education in his native city, under the direction of his mother, and was then sent to the university of Wittemberg, in the year 1593, where he exhibited such proofs of acuteness of mind and solidity of judgment, that every opportunity was afforded him, by visiting the other celebrated universities of Germany, especially those of Leipzic, Jena, Francfort on the Oder, and Berlin, of cultivating his talents. He returned to Wittemberg in 1601, and received the degree of doctor in September of that year, and in the same month of the following year was appointed to a professorship of medicine. In this office his eloquence and knowledge were calculated to raise him to a high reputation, and his luminous method of teaching brought crowds of pupils to his lectures. He also endeavoured, by means of various publications with which he enriched the profession among his contemporaries, to affirn it in cultivating the science of medicine. By these means his reputation became so extensive, that patients came to him from all parts of the world, and he refused his assistance to nobody. He took what was offered for his trouble, but demanded nothing, and even returned to the poor what they gave him. The plague prevailed seven times at Wittemberg, while he was professor there; but he never retired, nor was ever known to refuse to visit the poor sick. George I., elector of Saxony, whom he had cured of a dangerous illness in 1626, appointed him one of his physicians in ordinary; but with the permission to remain at Wittemberg, that the world might continue to derive the benefit of his public instructions. He was three times married, and had seven children by his first wife, three of whom survived him. He was at length carried off by an attack of the plague, which was raging in Wittemberg, in the month of July 1637, in the sixty-fifth year of his age.

Sennertus was a voluminous writer, and has been characterized, by some critics, as a mere compiler from the works of the ancients. It is true that his writings contain an epitome, but, it must be added, a most comprehensive, clear, and judicious epitome, of the learning of the Greeks and Arabs, which renders them, even at this day, of considerable value as books of reference, and which are highly creditable, considering the age in which they were composed, to his learning and discrimination. The freedom, indeed, with which he impugned many of the doctrines of the ancients, called up many opponents, and led him into much controversy. He was the first to introduce the study of chemistry into the university of Wittemberg, and demonstrated his freedom from the shackles of ancient opinion, by combining much of the chemical with the Galenicai doctrines; an union which the mere advocates of antiquity strongly deprecated, as well as the introduction of chemical medicines. His treatise "De Consequenti et Diffusii Galenicorum et Peripeteticorum cum Chymicis," 1619, may be said to have introduced a new field into Germany by this union. His various works have been collected together, and published at different times and places, under the title of "Opera omnia;"

SENNIT, (of senn and spin,) a sort of flat, braided corset, formed by plaiting five or seven rope-yarns together. This is beaten smooth and flat with a hammer, and serves to keep the ropes to which it is applied from getting out.

SENNONE, in Geography, a small island in the Mediterranean, near the coast of Naples. N. lat. 41° 3'. E. long. 11°.

SENO, a river which rises in the N. part of Etruria, crosses the department of the Amone, in Italy, and runs into the S. branch of the Po, between Ferrara and the Adriatic.

SENOGU, a town of New Navarre; 270 miles S.S.E. of Cama Grande.

SENONALY, a town of Bohemia, in the circle of Rakonitz; 5 miles W.S.W. of Rakonitz.

SENONCA, a town of Naples, in Lavora; 43 miles W. of Cuma.

SENONCHES, a town of France, in the department of the Eure and Loire, and chief place of a canton, in the district of Dreux; 9 miles W. of Chateauneuf. The place contains 1856, and the canton 7541 inhabitants, on a territory of 205 kilometres, in 12 communes.

SENONE, a river of France, which runs into the Meuret, 5 miles S.E. of Nancy.

SENOVES, a town of France, in the department of the Voges, and chief place of a canton, in the district of St. Die; 9 miles S.W. of Salem. The place contains 1589, and the canton 10997 inhabitants, on a territory of 215 kilometres, in 19 communes.

SENOSES, in Ancient Geography, a people of Gallia Celica, who occupied nearly the whole extent of the diocese of Sens and that of Auxerre, according to the ancient divisions of France. According to Caesar, they were confined to Belgica. This author lays of them: "eit civitas in primis firma, et magne apud Gallos autoritatis."—Alfo, a people of Italy, in Gallia Cispadana, upon the borders of the Adriatic sea. Their arrival in Italy may be fixed in the year before the vulgar era 397. Having joined a leader named Aruns, who wished to avenge himself of one of the Leuconeans in Etruria, they passed the Alps in a numerous body, and traversed the plains watered by the Po, where other Gauls were already established, and arrived on the other side of the river, in Umbria, still occupied by its ancient inhabitants. They established themselves from the Utii as far as the Ætii, having the Adriatic sea to the N.E. and the Apennines to the S.W. After having spent about six years in forming their establishments, Aruns conducted them to Clusium, to besiege that place, where his wife and her relations were. The Romans, whose mediation was refused, took part with the inhabitants of Clusium, and joined the troops of that city. The Senones were indignant, and determined to do themselves justice. Accordingly they marched towards Rome, and penetrated into the city, in defiance of the army that was opposed to them. The Capitol made a vigorous resistance; till at length Camillus arrived, defeated the Senones, and rescued Rome. About 100 years after this expedition they engaged in a war, and were overpowered in the year 485 B.C., by M. Curios Gentialis and P. Cornelius Rufinus. They were afterwards driven from the whole country which they occupied, from the Ætii to the Rubicon. A colony was sent into their country, which affirmed the name of "Sena Gallia." Seven years afterwards they were almost entirely exterminated by Dola-bella.

SENOPOLE. See SinoPole.

SENONAE, in Geography. See Sona.

SENONIAE, in Botany, a name by which some authors have called the banana-tree, or mufa frutus brevire.

SENOSEZ, in Geography, a town of Bohemia, in the circle of Czaffau; 20 miles S.S.W. of Czaffau.

SENOSECZ, or Sennoesch, a town of Carniola; 8 miles S.W. of Cirkuitz.

SENRa:A, SENRæA, or Serra, in Botany, a genus of Cavanilles, upon which different authors have bestowed the above appellations. None of these, however, seem satisfactory, for it has been suggested, that SERRA would be a preferable name to any of the foregoing. We are ignorant of its derivation.—Cavan. Diff. 2. 83. "Wild. Sp. Pl. v. 3. 695. Juff. 274.—Clafis and order, Monandphilia Decandria. Nat. Ord. Malvaceae, Juff."

Described by Cavanilles from a dried specimen, which was communicated to him by Sir Joseph Banks. It appears to be allied both to Malva and Gephyrum.

SENS, in Geography, a town of France, and principal place of a district, in the department of the Yonne, situate on the Yonne. Before the revolution it was the seat of an archbishop, and contained 16 parish churches, and 14 abbeys and convents. In the reign of Edward III. and Henry V. Sens was taken by the English; 24 pofts N.N.W. of Dijon. The place contains 16,500, and the canton 21,847 inhabitants, on a territory of 2573 kilometres, in 33 communes. N. lat. 48° 1'. E. long. 4° 28'.—Alfo, a town of France, in the department of the Ile and Vilaine; 14 miles N.E. of Rennes.—Alfo, a town of France, in the department of the Saone and Loire; 7 miles N.N.E. of Loutham.

SENSABARY, a town of Bengal; 20 miles N. of Nulli.

SENSAON,
SENSAON, a town of Africa, in the kingdom of Fez, near a mountain of the same name; 25 miles S. of Tetuan.

SENSATION, in Physiology, a general term denoting the effect produced in the mind by the impressions of external bodies on our organs of sense, by various changes in the internal organs, and by affections of any parts of the body which poises nerves. The appropriate external objects, being presented to the eyes, ears, nose, tongue, or skin, give us the sensations of those parts respectively the organs: hunger and thirst, nausea and sickness, griping, fainting, agitation, &c. are the results of particular states of internal organs; fatigue is caused by exertion of the muscular system; mechanical or chemical applications to any points poising nerves cause pains of all kinds and degrees. Thus seeing, hearing, smelling, tasting, and touching; hunger and thirst, sickness, feeling, &c.; and all the agreeable or disagreeable effects produced by external objects acting on our frame, are so many modes of sensation, so many states of existence, accompanied each with a peculiar feeling or act of consciousness.

In the five senses, sensation requires a healthy condition of the external organs of the brain, and of the nerves which pass between the organs and the brain. The absence of either of these conditions destroys sensations: if the optic nerve be divided there is no seeing, although the eye and brain be healthy; if the brain be compressed, the nerve and the eye remaining unaffected; or if the eye be diseased, the nerve and the brain being found, vision is destroyed. The same is the case with the general feeling of the frame: if the nerves of a limb be divided, or the brain be compressed, there is no sensation; a pin might be thrust into the part without being felt. The dependance of the internal feelings on the brain is not so clearly made out in every instance. On the whole, however, physiologists consider it as established, that sensation is the function of the nervous system. On this subject, as well as on the phenomena of sensation exhibited by the brain and nerves, we refer to Brain, Physiology of the, Life, and Nervous System.

As there are so many different phenomena included under the common term of sensation, what is the point in which they agree? What is the character by which they are all recognized as sensations? It is the feeling excited, the conceptions of a new mode of existence, the modification which the sentient being experiences. Sensation in short is feeling.

This is the only point in which the various sensations agree; independently of this there is little resemblance, or even analogy between them. Hearing is no more like seeing, and either of these is no more like hunger or thirst, than a muscle is to a nerve or the skin.

Sensations may be reproduced without any external objects, by an active state of the brain; thus in dreams we pass through scenes, and experience feelings, which are not distinguishable from real occurrences.

Sensation, according to Dr. Reid, is a name given by philosophers to an act of mind, which may be distinguished from all others by this, that it hath no object distinct from the act itself. Pain of every kind is an uneasy sensation. The pain and the feeling, he says, are one and the same thing; and cannot be disjoined even in imagination. Pain, when it is not felt, has no existence. The same observation may be applied to every other sensation. This author adds, that when we have acquired a distinct notion of that simple act of the mind called sensation, we shall be able the more easily to distinguish it from every external object that accompanies it, and from every other act of the mind that may be conjoined with it. Hence it is of importance, that the name of sensation should, in philosophical writings, be appropriated to signify this simple act of the mind, without including any thing more in its signification, or being applied to other purposes. The word feeling, which signifies the perceptions we have of external objects by the sense of touch, is also used to denote the same thing as sensation; in which sense it has no object, the feeling and the thing felt being one and the same. He acknowledges, however, that the word feeling, taken in this last sense, and sensation, there may be this small difference; that sensation is most commonly used to signify those feelings which result from our external senses, and bodily appetites, and all our bodily pains and pleasures. But there are feelings of a nobler nature, accompanying our affections, our moral judgments, and our determinations in matters of taste, to which the word sensation is least properly applied.

Dr. Reid, in another place, observes, that almost all our sensations have corresponding sensations, which constantly accompany them, and, on that account, are very apt to be confounded with them. Hence the names of most of our sensations become ambiguous, and this ambiguity hath very much perplexed philosophers. He alleges several facts that serve to illustrate and evince this ambiguity, in reference to the names we have for smells, tastes, sounds, and for the various degrees of heat and cold, which names denote both a sensation, and a quality perceived by means of that sensation. The cause is the same with respect to many operations of mind to which we give one name, and which we always consider as one thing; and yet they are complex in their nature, and made up of several more simple ingredients; of which ingredients sensation very often reckons one. Indeed, the number of our sensations and feelings is prodigious; and the most general and important division of them is into the agreeable, the disagreeable, and the indifferent.

The preceding remarks serve to evince the importance of distinguishing carefully between our sensations, and that perception of external objects, which is constantly conjunct with them. Sensation, says this author, to itself implies neither the conception nor belief of any external object. It supposes a sentient being, and a certain manner in which that being is affected, but it supposes no more. But perception, in his view of it, implies an immediate conviction and belief of something external; something different both from the mind that perceives and from the act of perception. Things so different in their nature ought to be distinguished; but by our constitution they are always united. Every different perception is accompanied with a sensation that is proper to it. The one is the sign, the other the thing signified. They coalesce in our imagination; they are signified by one name, and are considered as one simple operation. To the philosopher it belongs to distinguish between them.

Our author elsewhere observes, that when certain impressions are made upon our organs, nerves, and brain, certain corresponding sensations are felt, and certain objects are both conceived and believed to exist. But we can neither discover the cause of any one of these operations, nor any necessary connection of one with another.

On the subject of this article, in its connection with metaphysics, or the philosophy of the human mind, we refer to Ideas, Perception, Mental Philosophy, Vibration, and other terms of a similar import, or in any degree connected with them, occurring in various parts of the Cyclopaedia.

SENSBURG, in Geography, a town of Prussia, in the province of Bartenland; 14 miles S. of Raftenburg. N. lat. 52° 44'. E. long. 21° 23'.

SENSE. Senses, in Physiology and Anatomy, the or-
SIE.

gons by which we become acquainted with surrounding objects, by which external bodies impress our frame, so as to communicate to us a knowledge of their properties. They are five in number, viz. the eyes, ears, nose, tongue, and skin; for the anatomical and physiological account of which, we refer to these articles. These are often called the external senses; while the internal organs, the parts of the brain which are concerned in knowing and reflecting, have sometimes been called the internal senses. See Mental Philosophy.

Dr. Hutcheson gives us a more extensive and philosophical notion of sense. On his principle, sense is defined, a power of perception, or a power of perceiving ideas; at least if what is absolutely passive may be properly called a power.

On some occasions, instead of power, he chooses to call it a determination of the mind to receive ideas; and the ideas thus perceived, or raised in the mind, he calls sensations.

Senses, he considers, either as natural or moral; and the natural, either as external or internal: though the distribution is chiefly founded on the common ways of conceiving; for, in reality, they appear to be all natural and necessary. Some reasons, however, for the distinction, will be shewn under the several articles of it.

External senses, then, are powers of perceiving ideas, upon the presence of external objects. On such occasions, we find the mind is merely passive, and has not power directly to prevent the perception, or idea, or to vary it at its reception; as long as the body is continued in a state fit to be acted upon by the external object.

When two perceptions are entirely different from each other, or agree in nothing but the general idea of sensation, the powers of receiving those different perceptions are called different senses. Thus, feeling and hearing denote the different powers of receiving the ideas of colours and sounds. And though colours, as well as sounds, have vast differences amongst themselves; yet is there a greater agreement among the most opposite colours, than between any colour and a sound; and hence all colours are deemed perceptions of the same sense.

All the several senses seem to have their distinct organs, except feeling, which is, in some degree, diffused over the whole body. Inquiry into the Original of our Ideas of Beauty and Virtue, p. 2. 8vo. 1726.

In another place, the same writer defines the external senses to be those determinations of nature, by which certain perceptions constantly arise in the mind, when certain impressions are made upon the organs of the body, or motions raised in them. Some of these perceptions are received solely by one sense; others may be received by two or more. Of the former classes are these five forts: viz. colours, sounds, tastes, smells, cold, or heat. Some ingenuous authors reckon more: these we may call the proper ideas of sensation. System of Moral Philosophy, vol. 1. p. 4.

Internal senses are powers or determinations of the mind to be pleased with certain forms and ideas, which occur to our observation, in objects perceived by the external senses. Of these there are two different species, distinguished by the different objects of pleasure, viz. pleasant or beautiful forms of natural things, and pleasant or beautiful actions, or characters of rational agents: whence the internal senses become divisible into natural and moral; though what others call the internal natural sense, our author calls simply, and by way of eminence, the internal sense.

In reflecting on our external senses, we plainly see, that our perceptions of pleasure and pain do not depend directly on our will. Objects do not please us, according as we imagine they should; the presence of some objects necessarily pleases us, and the presence of others as necessarily displeases us; nor can we by our will any otherwise procure pleasure, or avoid pain, than by procuring the former kind of objects, and avoiding the latter. By the very frame of our nature, the one is made the occasion of delight, and the other of dissatisfaction. In effect, our sensitive perceptions are pleasant, and painful, immediately, and without any knowledge of the cause of this pleasure and pain, or of the manner how they arise, or of the circumstances of it, or without our seeing to what farther advantage, or detriment, the use of such objects might tend. Nor would the most accurate knowledge of these things vary either the pleasure, or the pain, of the perception; however it might give a rational pleasure, distinct from the sensible; or might raise a distinct joy, from prospect of farther advantage in the object, or another aversion, from apprehension of evil. There is scarcely any object which our minds are employed about, but is conjoined the necessary occasion of some pleasure or pain. Thus, we shall find ourselves pleased with a regular form, a piece of architecture, or painting, a composition of notes, a theorem, an action, an affection, a character; and we are conscious, that this pleasure naturally arises from the contemplation of the idea then present to the mind, with all its circumstances, though some of those ideas have nothing of what we call sensible perception in them; and in those which have, the pleasure arises from some uniformity, order, arrangement, and imitation; and not from the simple ideas of colour, sound, or mode of extension, separately considered.

It seems hence to follow, that when instruction, education, or prejudice of any kind, raise any desire or aversion towards an object; this desire, or aversion, is founded on an opinion of some perfection, or deficiency, in those qualities, for perception of which we have the proper senses. Thus, if beauty be defined by one who has not the sense of sight; the desire must be raised by some apprehended regularity of figure, sweetness of voice, smoothness, softness, or some other quality, perceivable by the other senses, without relation to the ideas of colour.

The only pleasure of sense, which our philosophers seem to consider, is that which accompanies the simple ideas of sensation; but there are vastly greater pleasures in those complex ideas of objects, which obtain the names of beautiful and harmonious. The power, then, by which we receive ideas of beauty and harmony, has all the characters of a sense. It is no matter, whether we call these ideas of beauty and harmony, perceptions of the external senses of seeing and hearing; or not: we should rather choose to call these ideas an internal sense, were it not for the convenience of distinguishing them from other sensations of seeing and hearing, which men may have without perception of beauty and harmony. Huchefon's Inquiry, &c. Preface, and P. 3. &c.

For the general manner in which our senses act, or, more properly, the manner in which we become sensible, that is, perceive external objects, see Sensation.

For the particular senses, or, more properly, the particular manner in which we become sensible, by the particular organs of sense, see Hearing, Seeing, Smelling, &c.

For the several organs of sense, miniflering to the several manners of sensation, see Eye, Ear, Nose, &c.

Pliny observes, that of all the senses, feeling and tasting are those which man enjoys in the greatest perfection. As to seeing, he says, he is excelled by the eagle, &c.; as to smelling, by the vulture, &c.; and as to hearing, by the mole, even when hid under ground.
The senses have been sometimes found greatly sharpened and improved by diseases. Mr. Boyle mentions a gentleman, who, during a distemper he had in his eyes, had his organs of sight brought to be so sensible, that when he waked in the night, he could, for a while, plainly see and distinguish colours, and other objects; and the same author gives an instance of another person, who, after getting half-fuddled with claret, if he waked in the night, could see for some time to read a moderate print.

Grimaldi tells us, that some women of Megara were able by their eyes alone to distinguish between eggs laid by black hens, and those by white ones. Grimald. de Lum. & Col.

In the Philosophical Transactions, No. 312, we have an account of Dan. Frazer, who continued deaf and dumb from his birth to the seventeenth year of his age; when, upon recovering from a fever, he perceived an uneasy motion in his brain, after which he began to hear, and by degrees to speak.

Dr. Reid, in his second Essay, suggests a variety of methods, by which our senses may be improved, as they give us information of things that concern us. Our original powers of perceiving objects by our senses admit of great improvement by use and habit; but, besides, there are various ways in which our senses may be improved, or their defects remedied by art; as by a due care of the organs of sense, that they be in a sound and natural state; by accurate attention to the objects of sense; by additional organs or instruments contrived by art; and by discovering the connection which nature has established between the sensible qualities of objects, and their more latent qualities.

Dr. Reid suggests, that the fallacy of the senses has been a common complaint among philosophers, both ancient and modern; and this, he thinks, is founded on a common error, to which another has been added, that our use of reason is to detect the fallacies of sense. In his opinion, there is no more reason to account our senses fallacious, than our reason, our memory, or any other faculty of judging which nature hath given us. They are all limited and imperfect, but wisely suited to the present condition of man. We are liable to error and wrong judgment in the use of them all, but as little in the information of sense as in the deductions of reasoning; and the errors we fall into, with regard to objects of sense, are not corrected by reason, but by more accurate attention to the information we may receive by our senses themselves.

Sense, Moral, is a determination of the mind to be pleased with the contemplation of those affections, actions, or characters, of rational agents, which we call good or virtuous.

This moral sense of beauty in actions and affections, may appear strange at first view; some of our moralists themselves are offended at it in Lord Shaftesbury, as being accustomed to deduce every approbation, or aversion, from rational views of interest. Our gentlemen of good taste can tell us of a great many senses, tastes, and relishes for beauty, harmony, imitation in painting and poetry; and yet we do not find, too, in mankind a relish for a beauty in characters, in manners? The truth is, human nature does not seem to have been left quite indifferent in the affair of virtues, to form to itself observations concerning the advantage of each, and disadvantage of actions, and accordingly to regulate its conduct. The weakness of our reason, and the avocations arising from the infirmities and neceties of our nature, are so great, that very few of mankind could have framed those long deductions of reason, which may shew some actions to be, in the whole, advantageous, and their contraries pernicious.

The Author of nature has much better furnished us for a virtuous conduct than our moralists seem to imagine; by almost as quick and powerful instructions, as we have for the preservation of our bodies; he has made virtue a lovely form, to excite our pursuit of it; and has given us strong affections, to be the springs of each virtuous action. Hutcheron's Inquiry, &c. See Mental and Moral Philosophy, and also Virtue.

Sense, Public, is defined by the same author to be our determination to be pleased with the happiness of others, and to be uneasy at their miseries. Thus, he says, is found in some degree in all men, and was sometimes called san- vero, or sensus communis, by some of the ancients.

Sense, Common, is a term that has been variously used both by ancient and modern writers. With sense it has been synonymous with public sense; with others it has denoted prudence; in certain instances it has been confounded with some of the powers of taste; and, accordingly, those who commit egregious blunders with regard to decorum, laying and doing what is offensive to their company, and ineffectual with their own character, have been charged with a defect in common sense. Some men are distinguished by an uncommon acuteness in discovering the characters of others; and this talent has been sometimes called common sense; similar to which is that use of the term, which makes it to signify that experience and knowledge of life which is acquired by living in society. Hor. lib. i. sat. 3. lin. 66. To this meaning Quintilian refers, speaking of the advantages of a public education: "Senfum ipsum qui communis dicitur, ubi dicit, etiam, qui non hominibus folum, fed mutis quoque animulis naturalis est, segregat?" Lib. i. cap. 1.

Dr. Reid observes, in his 6th Essay, "of Common Sense," that, in common language, sense always implies judgment, nor is the popular meaning of the word sense peculiar to the English language: the corresponding words in Greek, Latin, and probably in all the European languages, have the same latitude. The Latin words sensere, sententia, sensus, sensus, from the fall of which the English word sense is borrowed, express judgment or opinion, and are applied indiscriminately to objects of external sense, of taste, of morals, and of understanding.

Thus is the meaning which Mr. Pope has given to it; and in his epistle to the Earl of Burlington he has thus delicately upon it:

"'Tis sense that feeth, in its most common, and therefore most proper meaning, signifies judgment, our author infers that common sense should mean common judgment; as it really does.

Lord Shaftesbury has given to one of his treatises the title of "Sensus Communis," and he has introduced some criticism upon this word in Juvenal, Horace, and Seneca; after shewing in his facetious manner, that the fundamental principles of morals, of politics, of criticism, and of every branch of knowledge, are the dictates of common sense, he sums up the whole in these words: "that some moral and philosophical truths are so evident in themselves, that it
would be easier to imagine half mankind run mad, and joined
precisely in the same species of folly, than to admit any
thing as truth, which should be advanced against such natural
knowledge, fundamental reason, and common sense; and
on taking leave he adds; "and now, my friend, should you
find I had moralised in any tolerable manner, according to
common sense, and without caution, I shall be satisfied with
my performance." After citing other numerous testimonies
in vindication of common sense, as a principle of knowledge,
our author concludes with observing, that it is absurd to
conceive that there can be any opposition between reason
and common sense. To reason we ascribe two offices, or
two degrees. The first is to judge of things self-evident; the
second to draw conclusions that are not self-evident from
those that are; the first of these is the province, and the
sole province, of common sense; and therefore it coincides
with reason in its whole extent, and is only another name for
one branch or degree of reason. The first is purely the gift
of heaven; the second is learned by practice and rules, when
the first is not wanting.

Our author further observes, that the province of com-
mon sense is more extensive in refutation than in confirmation.
A conclusion drawn by a train of full reasoning from true
principles, cannot possibly contradict any decision of com-
mon sense, because truth will always be consistent with itself.
Neither can such a conclusion receive any confirmation from
common sense, because it is not within its jurisdiction.
But it is possible that, by setting out from false principles, or by
an error in reasoning, a man may be led to a conclusion that
contradicts the decisions of common sense. In this case, the
conclusion is within the jurisdiction of common sense, though
the reasoning on which it was grounded be not; and a man
of common sense may fairly reject the conclusion, without
being able to shew the error of the reasoning that led to it.

After these preliminary remarks, we observe that the term
common sense hath in modern times been used to signify
that power of the mind which perceives truth, or com-
mans belief, not by progressive argumentation, but by an
instantaneous, intuitive, and irresistible impulse; derived
neither from education nor from habit, but from nature;
acting independently of our will, whenever its object is pre-
fented, according to an established law, and, therefore,
called sense; and acting in a similar manner upon all, or at
least upon a great majority of mankind, and, therefore,
called common sense. The first among the moderns who took
notice of this principle as one of the springs of our know-
ledge, was Buffier, a French philosopher of the last cen-
tury, in a book entitled "Traité des Premières Vertez,"
and this doctrine hath lately, in our own country, been illus-
trated and maintained by Drs. Reid, Beattie, Olufuald,
and Campbell.

In order to evince that there is a real and essential
difference between this faculty and that of reason, it is ob-
erved, that we are conscious, from internal feelings, that the
energy of understanding, which perceives intuitive truth,
is different from that other energy which unites a conclu-
sion with a first principle, by a gradual chain of intermediate
relations; that we cannot discern any necessary connection
between reason and common sense; that the one is more in
our power than the other; the faculty of reasoning being
improvable by culture, whereas common sense, like other
influences, arrives at maturity with almost no care of ours,
and it is impossible to teach common sense to one who wants
it; though this, like other influences, may languish for want
of exercise; and that a distinction, similar to that which is
here maintained, is acknowledged by the vulgar, who speak
of mother-wit as something different from the deductions of
reason, and the refinements of science. All sound reasonings,
it is said, must ultimately rely on the principles of com-
mon sense; that is, on principles intuitively certain, or intuitively
probable; and, consequently, common sense is the ultimate
judge of truth, to which reason must continually act in
subordination. Thus the advocates for this faculty, as an
original and distinct power of the human mind, align to it
a very extensive empire, and an authority that is suprême and
absolute. And they have proceeded so far as to sublimate,
in the room of Mr. Locke's abstraction, this faculty as the
characteristic of rationality. To this they refer the evidence
of mathematical truth, of external and internal sense, of
memory, of reasoning from the effect to the cause, of prob-
able or experimental reasoning, of analogical reasoning,
of faith in testimony, and, indeed, of all primary truths.

To common sense, therefore, all truth must be conformable;
this, they say, is its fixed and invariable standard. And
whatever contradicts common sense, or is inconsistent with
that standard, though supported by arguments that are
deemed unanswerable, and by names that are celebrated by
all the critics, academics, and potentates on earth, is not
truth, but falsehood. In a word, the dictates of common
sense are, in respect to human knowledge in general, what
the axioms of geometry are in respect to mathematics: on
the supposition that these axioms are false or dubious, all
mathematical reasoning falls to the ground; and on the
supposition that the dictates of common sense are erroneous
or deceitful, all truth, virtue, and science, are vain.

And hence it appears, that, according to this system, common
sense is not only the test of truth, but the standard of moral
obligation.

Dr. Priestley, in his attack upon this system, has charged
the abettors of it with an unnecessary innovation in the re-
ceived use of a term; as no person ever denied that there are
self-evident truths, and that these must be assumed as the
foundation of all reasoning. But they also recommend par-
ticular positions as axioms, not as being founded on the per-
ception of the agreement or disaffection of any ideas,
which is the great doctrine of Mr. Locke, and which makes
truth to depend upon the necessary nature of things, to be
absolute, unchangeable, and everlasting; but merely some
unaccountable instinctive persuasions, depending upon the
arbitrary constitution of our nature, which makes all truth
to be a thing that is relative to ourselves only, and conse-
quentially to be infinitely vague and precarious. This system,
he says, admits of no appeal to reason, properly considered,
which any person might be at liberty to examine and dispro-
but, on the contrary, every man is taught to think himself
authorized to pronounce decisively upon every question,
according to his present feeling and persuation; under the
notion of its being something original, instinctive, ultimate,
and incontrovertible, though, if freely analyzed, it might
appear to be a mere prejudice, the offspring of mistake.
Some of the maxims which they have adopted as self-evident
truths, and which they have multiplied without necessity,
are so far from being self-evident, that, in the judgment of
many sober and candid enquirers after truth, they are not
true, but capable of a satisfactory refutation.

At the same time, since no man can pretend to any natural
right to fix the principles of faith for another, they teach un-
believers, and by their example authorize them, to reject
the principles of religion by the same summary and super-
ficial processes, as what appear to them to be, at first sight,
too absurd and ridiculous to be admitted as true and divine.

Dr. Priestley apprehends, that the inconveniences above-
mentioned, may attend even the calling of that faculty by
which we discern truth by the name of sense. By this term,
philosophers
philosophers in general have denominated those faculties, in
consequence of which we are liable to feelings relatively to
ourselves only, and from which they have not pretended to
draw any conclusions concerning the nature of things;
whereas truth is a thing not relative, but absolute, and real,
independent of any relation to this or that particular being,
or this or that order of beings. Besides, if the determi-
nations of this new principle of common sense be fo instanta-
neous, irresistible, and infallible, as Dr. Reid, Dr. Beattie, and
Dr. Ofwald represent, how can we account for all the
error there is in the world? Not to add, that this syllem,
in its practical influence, tends to prevent the exercise of
free and unrestricted enquiry, with regard either to truth or
duty; and to promote, in many cases, the extravaganties of
credulity, enthusiasm, and mysticism. Dr. Priestley also
observes, that Dr. Price (in his Review of the Principal
Questions and Difficulties in Morals, 8vo.) though un-
noticed by the writers above cited, by maintaining that the
understanding is the source of many of our most important
fimple ideas (see IDEA), has secured all the flattering ad-
vantages of the new doctrine of common sense, without the
capital inconveniences attending it. Like this syllem, his
scheme cuts off, if it be admitted, all objections to primary
moral truths, refting them on a simple appeal to the faculty
of intuition; and refusing to reason upon a fubjeft, which is
maintained to be as evident as the truth of the geometrical
axioms, that if equal things be taken from equal things, the
remainders will be equal.

If the ideas of moral right and wrong, &c. be perceived
by a feme, it depends upon our arbitrary constitution, that
we conceive of them as we do, or whether we perceive them
at all; and we have no method whatever of investigating,
whether they have any foundation in the absolute nature of
things; whereas by making moral ideas the object of the
understanding as fuch, the principles of morality become
part of this fyllem of neceflary, eternal, and unalterable
truth, perceived by the divine Being as by ourselves, but
altogether independent of his will, as well as of all other
beings and things whatever; as much fo as the truth of the
axiom above-mentioned, or of the proposition, that two
and two make four.

It is added, that thefe writers feem even to have bor-
rowed their language, as well as their ideas, from Dr. Price,
who also ufed the term common feme, though applied in a
different manner. Reid's Enquiry into the Human Mind
on the Principles of Common Senfe, 8vo. ed. 2. 1765.
Reid's Eflays, above cited. Beattie's Eflay on the Nature
and Immortality of Truth, 8vo. ed. 2. 1771. Ofwald's
Appeal to Common Senfe in behalf of Religion, 8vo. ed. 2.
1768. Campbell's Philosophy of Rhetoric, 8vo. 1776,
vol. i. p. 109. &c. Priestley's Examination of Reid,
Beattie, and Ofwald, &c. 8vo. 1774. For a farther ac-
count of this fyllem, see ABSTRACTION and IDEA.

SENSE, in Geography. See SENSE.

SENSIBILITY, in Phvsiology, the power of receiving
an impression, and transmitting it to the brain, fo as to cause
fenfation or feeling. The queftion whether any part be fen-
sible is, therefore, whether by acting on it in any way, feel-
ing can be excited. Sensibility in this, its common accepta-
ton, obviously refers to the internal feeling or act of con-
ciounfefs resulting from its exercise. Some physiologists
have ufed the word in a more extenfive fense, to denote all
impressions produced on our organ, even thofe which are not
felt; as that of the blood on the heart, the food on the
alimentary canal, &c. They call the former animal sen-
sibility, becaufe it is peculiar to living beings; and they dif-
tinguifh the latter by the name organic, as it belongs to thofe
parts where motions are involuntary, and which confiftute
the automatic or organic life. See LIFE.

Roufseau has given the word fenfibibility a place among
French medical feiences. The foul of the companion fhould
furnifh ideas, the performer fhould be gifted with feeling in
their expr effion, and the audience fhould be capable of being
impressed with the beauties and defcfs of the music which is
executed for their amufement.

SENSIBLE Horizon, Point, and Qualities. See the
Subfubtatives.

SENSIBLE Note. See Note, Sensible.

SENSIBLE Fluid. Some have imagined a fensitive
fluid as the principle that ferves animals from corruption,
and to which we owe our fenfation and motion. This animal
fluid paffes in the proper nervous tubes to the organs of
motion; but is contained in the fibrous coats of the nerves to
become an organ of fenfation. This fenfitive fluid is,
according to M. Le Cat, capable of thinking, and is so mo-
dified by the ganglions, that what is lodged in each part, is
capable of being impressed by the object proper to each
organ. And from the doctrine concerning this animal fluid,
he endeavours to account for moft operations, which are
Abridg. vol. ii. p. 481.) But all thefe attempts to account
for fenfation and thought, from the properties of matter,
feem to be very desperate undertakings, not to fay absurd.

SENSITIVE Plant, in Botany. See Mimoso.

The fensitive plant is sufficiently known to the world for
its remarkable property of refting from the touch, and
giving signs, as it were, of animal life. Philosophers in
general have, however, contented themselves with admiring
the fact, without giving themselves any trouble about the
caufe. See LEAF.

Mr. Hook, indeed, has made fome conjectures about it;
but the greateft light that has been given into the thing, is
from the inquiries which Meffrs. Du Fay and Du Hamel,
gentlemen of the Academy of Sciences at Paris, concerted
and afterwards made separately on different plants, or at diftrent times, that each might be able to correct the
errors of the other.

Botanic writers mention many kinds of fensitive plants,
some of which contract at a touch, others with heat, others
with cold. The truth is, many, if not moft, vegetables ex-
and their flowers, down, &c. in warm fun-thiny weather,
and again clofe them towards evening, or in rain, &c. espe-
cially at the beginning of flowering, or after the flowers
are fallen, whilst the seed is yet young and tender; as is very
evident in the doun of dandelion, &c. and in the fower of
the pimpernel, the opening and fluttering of which are the
countryman's weather-wifer; by which, Gerard fays, he
foretels what weather shall follow the next day; for if the
flowers be clofe shut up, it betokens rain and foul weather;
if they be spread abroad, fair weather.

The structure of the fensitive plant is this; from the large
leaves, or main branches of the whole, there part off several
other leafer ones, and from these there go off others ftilf lefs,
which, by way of dilinition, may be called the ribs of the
leaves, as they serve to support a number of leaves arranged
on each fide, and fanding on fhort pedicles in pairs, over
againft one another. Several other plants have this fort of
compound leaves, as the caflia, colutea, and the like; and
all these fliut their leaves together at night, and open them
again in the morning, in the fame manner as the fensitive
plant does. This periodical opening and futting of the
leaves are therefore common to many plants, not peculiar to
the fensitive plant; but the wonder in this is, that behind
having this motion periodical and regular, it is to be brought
on
on at other times, and by accidents, there requiring no more
than the touching of the plant to make it close its leaves at any
time of the day, which it soon afterwards naturally opens
again. This is peculiar to this plant, and resembles the
action of an animal which had been injured or frightened. A
close observation of the manner in which this is per-
formed, will give many hints towards the finding of its cause.

It is a very difficult thing to touch the leaf of a vigorous
sensitive plant so lightly, as not to make it close; its sensa-
tion is extremely delicate, and its large rib or nerve, which runs
along its middle, turns it into a hinge, on which the two
halves of the leaf move when they turn upon being touched,
till they stand erect, and by that means meet one another.

The slightest touch imaginable gives this motion to the
side of the leaf which is touched, which is communicated
immediately to the other side, or half, and the leaves to-
gether; and if the touch has been a very little rougher, the
opposite leaf on the same rib receives the impulsion, and
closes up in the same manner with that which was actually
touched.

Nor is this all, for when the two sides of each of these
leaves move upwards, the pedicle of each half moves up-
wards at the same time, and by this means they, in some
manner, approach towards each other, and make the angles
of their pedicles with the main rib, or stalk of the composite
leaf, less than before; and the total motion of each leaf is
composed of these two motions.

If the touch be still rougher, the whole arrangement of
leaves on the same rib feels its influence on each side, and all
close in the same manner with the single pair in the preceding
instance: and if the touch be yet stronger than this, the rib
itself feels it, and attempts to close in its way; moving itself
upwards towards the branch from which it is produced, just
as the single pedicles of the leaves did towards it: and if the
leaf be yet more hard and rough, the very branches have the
sensation propagated to them, and apply themselves to the
main stem, or trunk of the throb, as the simple leaves did
before to their rib, and that rib to the branch; so that the
whole plant in this state forms itself from a very complexly
branched figure, into a sort of straight cylindrical one. That
motion which has, of all others, the greatest effect upon this
plant, is a shaking one.

These three motions of the plant are performed by means
of three distinct and sensible articulations; the first that of
the single leaf to its pedicle, the second that of the pedicel to
its branch, the third that of the branch to the trunk. The
primary motion of all which, is the closing of the two halves
of the leaf upon their rib, which ought also to be per-
formed in a similar manner, and by a similar articulation;
this, however, is much less visible than the others.

These motions are wholly independent of another, as
may be proved by experiment. It should appear, that if the
stalks are moved, and the plant towards the branches, or
these towards the trunk, that the leaf's whole motion is
usually primary to these; it should be affected also: yet ex-
periment proves, that it is possible to touch the branches in
such a manner, as to affect them only, and make them apply
themselves to the trunk, while the leaves feel nothing of the
touch; but this cannot be, unless the branches are so dis-
pposed, as that they can fall to the trunk without suffering
their leaves to touch any other part of the plant in their
passage, because, if they do, they immediately become affected.

Winds and heavy rains cause the sensitive plants to shut
up their leaves, while easy showers do not at all affect them;
it is plain hence, that the agitation of the plant by the wind,
and the frosts given by the large and heavy drops of rain,
are what cause the contraction.

By whatever accident the plant has been made to close its
leaves, it always regularly opens them again afterwards.
This, however, requires different times, according to several
circumstances, as the time of the day, the season of the year,
and the manner and degree of its vigor and healthy state of the
plant; sometimes this is done in ten minutes, sometimes it requires
half an hour; and the manner is not less different than the
time, for sometimes the leaves unfold themselves first, and
sometimes the branches, whereas sometimes all is done at
once, and the whole plant seems in motion at a time.

In endeavouring to account for the motions of this plant,
the gentlemen above named have conjectured that they are
performed by means of a figure of very nice and fine hinges,
which communicate one with another by means of very
minute and slender cords, which occasion them to act as we
see when the plant is sufficiently disturbed, and these cords
shaken; and what gives a strong probability to this con-
jecture is, that the decayed and drying leaves of the plant
perform this motion as regularly and vigorously, as those
which are fresh and full of juice.

It seems plain, that while the juices are evaporating, and
the parenchymatous substance of the leaves drying up, these
more solid parts, the lines and cordages, retain their figure;
and consequently, if it is by means of these that the motion
is always performed, it will be as well performed in these
as in the former leaves, which could not be the case were it
owing to the juices.

The natural opening and shutting of the leaves of this plant
at night and morning, are not so fixed but that they are
variable also, according to circumstances of place, tempera-
ture, &c.

In the month of August, a sensitive plant was carried in
a pot out of its usual place into a dark cave, the motion that
it received in the carriage shut up its leaves, and they did not
open till twenty-four hours afterwards; at this time they be-
came moderately open, but were afterwards subject to no
changes at night or morning, but remained three days and
nights with their leaves in the same moderately open state.
At the end of this time they were brought out again in the
air, and then recovered their natural periodical motions, shut-
ing every night and opening every morning, as naturally
and as strongly, as if it had not been in this forced state; and
while in the cave, it was observed to be very little affected
with the touch that when abroad in the open air.

Repeated experiments have proved, lay these philosophers,
that it is not the light of the day that opens these leaves of this
plant, nor the darkenss of the night that closes them: neither
is it the alternate warmth and cold of the day, nor the heat
on the night, that have this effect, since it fluts in nights which are much
warmer than the days, or in days which are much colder than the
nights; and the increasing heat of the plant in which it is kept, and
marking the increase or decrease of the thermometer, have been
found to have not the least effect, as to its sooner or later
opening or shutting of its leaves.

The most probable conjecture seems, that it is not great
heat, or great cold, such as it can bear, that bring on this
effect, but the sudden change from one to the other, and
this is confirmed by this experiment, that if one of these
plants be raised under a glass bell, or cage, and the bell or
covering be taken off, it immediately closes, even though it
be in the middle of the day; and this is also observed, that
the more open or exposed the plant stands, the more strong
and lively are its shutting and opening; and that they are
more observable in summer, and much less so when it is kept
in a close close in winter.

The great heats of summer, when there is open sunshine at
noon, affect the plant in some degree like cold, causing it to

But
Mr. Ellis has described a sensitive plant, which is a native of the swamps in North Carolina, called Dionaea muscipula, or Venus's fly-trap, (see Dionaea,) and which, from his account of it, appears to be the most animated of the whole sensible tribe of vegetables. Its sensibility exists in its leaves, each of which exhibits, in miniature, the figure of a rat-trap with teeth closing on every fly or other insect that is tempted to taste the sweet liquor which is supposed to be secreted in certain minute red glands that cover its inner surface; but before it has had time to taste it, the leaves rise up, and incline and grasp the invader, and he is soon deprived of his life by the action of three small erect spines, fixed near the middle of each lobe; nor do the leaves open again while the dead animal continues there. The same effect is produced by a blow or pin.

Mr. Ellis conjectures, that in the construction and modes of powers of this plant, nature may have had some view to its nourishment, by forming the upper joint of each leaf like a machine to catch food, and by having laid a bait upon the middle of it, to entice the unhappy insect that becomes its prey. But, perhaps, it may be equally probable, that nature has armed and animated this plant for the preservation of its juices against the depredations of insects. Ellis's Directions for bringing over Seeds and Plants, &c. 1770.

**Sensitive Plant, Biflard:** See Eschynomene.

**Sensitive Power.** See Mental Philosophy.

**Sensitive or Sensible Soul,** the soul of brutes, or that, which man is supposed to have in common with brutes. See Brute.

It is thus called, either as intimating its utmost faculty to be that of sensibility; or, perhaps, because it is supposed to be material, and to come under our senses.

Lord Bacon affirms, that the sensible or brute soul is plainly no more than a corporeal substance, attenuated by heat, and thus rendered indivisible; or a kind of aura or vapour, partly of an aerial, and partly of a fiery nature, endowed with the softness of air, to be fit to receive impressions, and with the vigour of fire to communicate its action; fed partly with oily matters, and partly with aqueous ones inclosed in the body, and, in the more perfect animals, principally in the head, moving along the nerves, and restored and repaired by the spirituous blood of the arteries. Bac. de Augment. Scient. lib. v. See Life.

**SENSKOWA,** in Geography, a town of Prussia, in the palatinate of Culm; 15 miles N.E. of Thorn.

**SENSORIUM,** in Physics, the part which feels and perceives, the common centre, to which sensations are conveyed, and from which volition emanates; in other words, the brain. In medical and physiological writings, this expression is used as synonymous with brain; thus we read of affections of the sensorium; of sensorial power and influence, &c. Sensoria commune, is the imaginary point of the brain, the residence of the metaphysical soul, to which every sensation is brought, and from which all determinations of the will proceed. The speculations on this subject have been founded in the asumed unity of the soul. Physiologically speaking, there is not the slightest ground for supposing such a part to exist in the brain. Our remarks on the functions of the brain and parts connected with it, will be found under the articles Brain, Life, and Nervous System. See also Mental Philosophy.

Sir Isaac Newton considers the universe as the fenforium of the godhead.

**SENTELIUS, LUDOVICUS,** in Biography, a disciple of Henry Isaac, and in 1530 appointed chapel-matuer to the duke of Bavaria. Many of his compositions are inserted in the Dodecachordon of Glareanus, with great encomiums.
He was in high favour with Martin Luther, a good judge of music; and Sebaldus Hayden, in 1540, calls him the prince of German musicians.

**SENTENCE**, in Law, a judgment passed in court by the judge upon some proofs either civil or criminal.

Sentences are either **definitive**, which put an end to the suit and controversy, and regard the principal matter in question; or **interlocutory**, which determine only some incidental matter; **contradictory**, &c.

There are sentences of abolition, excommunication, &c. Superior judges may either confirm or annul the sentences of inferior ones.

Every sentence must be in writing, on a seal, and it must be pronounced in the presence of both parties; other wise sentence given in absence of one of the parties is void.

**Sentences.** Three conformable, tres sententiae conformes. In the Roman *Ecclesiastical Law*, it is allowed to appeal three times; so that there must be three conformable sentences before the decisions of the judges can take effect. The first degree of jurisdiction is in the bishop's official; from him an appeal lies to the metropolitan, from the metropolitan to the primate, or immediately to the pope. If the appeal come from the metropolitan to the pope, the pope is obliged to delegate judges in *partibus*; and then if the three sentences palled in these three stages be conformable, there is no farther appeal; but if one of them annull another, new judges are to be required of the pope for a fourth sentence; and thus they sometimes proceed to a sixth or seventh sentence.

This number of jurisdictions is found infinitely prejudicial to the public, and vexatious to private persons.

**Sentence.** In Grammar, denotes a period, or a set of words expressing some perfect sense or sentiment of mind.

Every sentence comprehends at least two words.

Mr. Harris, in his Hermes, p. 17, &c., considering that the leading powers of the soul are those of perception and volition, observes, that every sentence, in reference to those powers, will be either a sentence of assertion, or a sentence of volition: and he describes it as a compound quantity of found significant, of which certain parts are themselves also significant. Thus he distinguishes a sentence from a word, which is a found significant, of which no part is of itself significant.

The business of pointing is, to distinguish the several parts and members of sentences, so as to render the sense of it the clearest, aptest, and fullest possible. See **Punctuation**.

In every sentence there are two parts necessarily required; a noun for the subject, and a definite verb; whatever is found more than these two, affects one of them, either immediately, or by the intervention of some other, by which the subject is affected.

Again, every sentence is either simple or conjunct; a simple sentence is that consisting of one single subject, and one finite verb. A conjunct, or compounded sentence, contains several subjects, and finite verbs, either expressly or implicitly; or it consists of two or more simple sentences connected together.

A simple sentence needs no point or division, only a period to close it; as, *A good man loves virtue; for itself*. In such a sentence, the several adjuncts affect either the subject, or the verb, in a different manner. Thus the word good expresses the quality of the subject, virtue the object of the action, and, for itself, the end of it. Now none of these adjuncts can be separated from the rest of the sentence; for if one be, why should not all the rest? And if all be, the sentence will be minced into almost as many parts as there are words.

But if several adjuncts be attributed in the same manner either to the subject, or the verb; the sentence becomes conjunct, and is to be divided into parts.

In every conjunct sentence, as many subjects, or as many finite verbs as there are, either expressed or implied, so many distinctions may there be. Thus, *My hopes, fears, joys, pains, all centre in you;* and thus *Cicero, Catilina, abitis, exceptis, egoquis, crate. The reason of which pointing is obvious*; for as many subjects or finite verbs as there are in a sentence, so many members does it really contain; whenever, therefore, there occur more nouns than verbs, or contrariwise, they are to be conceived as equal; hence, as every subject requires its verb, so every verb requires its subject, with which it may agree, excepting, perhaps, in some figurative expressions.

Indeed there are some other kinds of sentences which may be ranked amongst the conjunct kind, particularly the absolute ablative, as it is called. Thus, *Physicians, the diseafe once discovered, think the cure half wrought;* where the words, diseafe once discovered, are equivalent to, *when the cause of the diseafe is discovered.*—So also in nouns added by apposition, as, *The Scots, an hardy people, endured it all;* to also in vocative cafes and interjections, as, *This, my friend, you must allow me;* and, *What, for heaven's sake! would it be at?*

The case is much the same when several adjuncts affect either the subject of the sentence or the verb in the same manner, or at least something by which one of them is affected, as, *A good, wise, learned man is an ornament to the commonwealth;* where the several adjectives, denoting so many qualities of the subject, are to be separated from one another. Again, when I say, *Your voice, countenance, gesture, terrified him,* the several nominative cases do not many modes of the verb, which are likewise to be distinguished from each other. The case is the same in adverbs, as, *He behaved himself modestly, prudently, virtuously.* In the first example, the adjuncts immediately affect the subject; in the third, the verb; in the following one, another adject, as, *I saw a man loaded with age, sicknels, wounds.*

Now, as many such adjuncts as there are, so many several members does the sentence contain; which are to be distinguished from each other, as much as several subjects or finite verbs; and that this is the case in all conjunct sentences, appears hence, that all these adjuncts, whether they be verbs or nouns, &c., will admit of a conjunction copulative, by which they may be joined together. And wherever there is a copulative, or room for it, there a new member of a sentence begins. For the other partitions, &c., of sentences, see Colon, Semicolon, and Period.

**Sentence** is also used, in Rhetoric and Poetry, for a short pithy remark, or reflection, containing some sentiment of use in the conduct of life.

Such are *Diffeito jutitiam monitit, & non tamere divos*; or, *A teuisa affigisere multum si, &c.*

Sentences, father Bolitó observes, render poems useful; and, besides, add I know not what luflre and spirit, which pleases. But there is no virtue which is not accompanied with some dangerous vice. Too many sentences give a poem too philosophical an air, and sink it into a kind of gravity; this is less fit for the majesty of a poem than the study of a learned man, and the quaintness of a dogmatist. Such thoughts not only contain, but inspire a certain calm wisdom, which is directly opposite to the passions, and cools.
them both in the hearers and in the speaker. Lastly, the affection of speaking sentences leads a person to trifling and impertinent ones, inferences of which we have an abundance in Seneca's tragedies. Petronius recommends it to authors to disguise their sentences, that they may not fland glaring above the thread or ground of the discourse.

SE T E R N A R B A U R, in Geography, a cove in the N.W. part of lake Winnipiccogee.

S E N T H E N H E I M, a town of France, in the department of the Upper Rhine; 10 miles N.E. of Befort.

S E N T I C A, in Ancient Geography, a town of Spain, in the Tarragonensis, assigned by Ptolemy to the Vescavens.

S E N T I C E, a country of Macedonia, according to Livy.

S E N T I I, a people of the Maritime Alps, S.E. of the Bodanetc, mentioned by Ptolemy, who assigns to them the town of Dina.

S E N T I M E N T S, in Poetry, and particularly dramatic, are the thoughts which the several perors express, whether they relate to matters of opinion, passion, buffeur, or the like.

The manners form the tragic action, and the sentiments explain it, discovering its causes, motives, &c. The sentiments are to the manners, what those are to the fable. In the sentiments, regard is to be had to nature and probability; a madman, for instance, must speak as a madman; a lover, as a lover; a hero, as a hero. The sentiments, in great measure, are to fulfill the character. The word sentiment, in its true and old English sense, signifies a formed opinion, notion, or principle; but of late years it has been much used by some writers to denote an internal impulse of passion, affection, fancy, or intellect, which is to be considered rather as the cause or occasion of our forming an opinion, than as the real opinion itself.

S E N T I N E L, G R E AT, in Geography, an island in the Eait Indian sea, about 10 miles in circumference; 20 miles S.W. from the Greater Andaman. N. lat. 11° 36'. E. long. 92° 40'.

S E N T I N E L, L I T T L E, a small island in the Eait Indian sea, about 8 miles from the Little Andaman. N. lat. 10° 59'. E. long. 92° 23'.

S E N T I N E L, C E N T R Y, or S E N T R Y, in War, a private solder placed in some post to watch any approach of the enemy, to prevent surprizes, and to stop such as would pass without orders, or without discovering who they are. They are placed before the arms of all guards, at the tents and doors of generals officers, colonels of regiments, &c.

The word is modern; it is not long since they said, To be on the scout, in the same sense as we now say, To stand sentry, &c. Menage derives the word a fentieudo, from perceiving.

S e n t i e d pe r d u s, is a sentinel placed at some very advanced and dangerous post, whence it is odds that he never returns.

S e t i n s, in Ancient Geography, a river of Italy, in Umbria, according to Strabo and Ptolemy. Alto, a town of Italy, belonging to the Senones, S.W. of Suafa.

S E N T I N U S, a river of Italy, in Picenum.

S E N T O, in Geography, a river of Naples, which runs into the Adriatic; 3 miles S.E. of Lanciano.

S E N T O U, a town of China, of the third rank, in Se-chuen, on the river Kincha; 22 miles N.E. of Pei.

S E N T U R, a town of Egypt; 9 miles N.W. of Fayoum.

S E N U R I S, a town of Egypt, near the Birket il Kerum; 9 miles N.W. of Fayoum.

S E N U S, in Ancient Geography, a river of Hibernia, according to Ptolemy, who places its mouth on the western coast, between the mouths of the Asina and of the Dar.-Allo, a river of India, in the country of the Sinus, according to Ptolemy, who says, that it was connected with the Cetaria, at a great distance from its mouth.

S E N Z A, an Italian preposition, implying, in Music, without; as in Handel's organ concertos, when passages are to be wholly left to the violins, fensa organo implies, without the organ; fenza viola, without the tenor; fenza buffo, without the bafe, &c.

S E N Z A R S K A I , in Geography, a fortress of Russia, in the government of Tobolsk; 80 miles S. of Yalutorovsk.

S E O D A, a sea-port of Japan, on the S. coast of the island of Nippon; 105 miles E. of Mexico. N. lat. 35° 20'. E. long. 139° 10'.

S E O N, in Ancient Geography, a town of Palestine, in the tribe of Issachar, according to Joshua. Euebflus says, that in his time there was a place of this name at the foot of mount Tabor.

S E O N St. Henry, in Geography, a town of France, in the department of the Mouths of the Rhone; 4 miles N. of Narrelles.

S E Q U I I K I A N E S, a poft of Chinese Tartary, in the country of the Mongols; 23 miles S.W. of Kara Hotun.

S E P A R A B L E M O D E S. See Mode.

S E P A R A T E A F F E C T I O N. See Affection.

S E P A R A T E, Penultimate of the. See Penultimate.

S E P A R A T E I S L A N D, in Geography, a small island in the Chinise sea. N. lat. 3° 6'. E. long. 107° 45'.

S E P A R A T E D F L O W E R S, in Botany, are so called when the flumes and pistils are situated in different flowers of the same species. Hence it appears that separated flowers are conjoined to such plants as are either monocious, dioecious, or polygamous. They are termed by Luninus, Diclines. S E P A R A T O R S, among Horsethe, the teeth usually called incisors, by which the animal separates or bites off a portion of his food for chewing. See Teeth.

S E P E R A T I O N, in Navigation, the fame with what we more usually call departure.

S E P E R A T I O N, of Man and Wife. See Divorce.

S E P E R A T I O N, Waters of. See Water.

S E P E R A T I O N B a y, in Geography, a bay in the Straits of Magellan, on the coast of Terra del Fuego; 10 miles S.E. of Cape Pillar.

S E P E R A T I S T S, in Ecclesiastical History, a religious sect in England, so denominated from their setting up a separate church, different from that established by law. See Dissenters, &c.

At present, Separatists is rather the name of a collection of sects than of any particular one; but nearer their original, there was that agreement among them, that one name served them all.

Their division into Presbyterians, Anabaptists, Independents, &c. is a more modern thing.

The Separatists, Horns us tells us, Hift. Eccl. are such as under Edward VI. Elizabeth, and James I. refused to conform to the church of England, and who were called Puritans, then Separatists, and latterly, Nonconformists.

The first leader of the Separatists was Bolton, who, upon quitting the party he had formed, was succeeded by Robert Browne, from whom the Separatists were called Brownists.

S E P E R A T O R I U M, the name of a surgical instrument used for separating the pericranium from the skull.

S E P E R A T R A X I S, in Arithmetics, denotes the point, or comma, which separates and distinguishes decimals from integers; thus, 465.32 or 465.32.
SEPAPRI, in Ancient Geography, a people who inhabited an island on the coast of Liburnia, according to Pliny.

SEPAUNAGUR, in Geography, a town of Hindoo-istan, in the circc of Bopal; 30 miles W. of Hufingabad.

SEPAUX, a town of France, in the department of the Yonne; 9 miles W. of Joigny.

SEPHELACUS, in Ancient Geography, a place of Spain, upon the route from Tarragon to Carthage, between Idlau and Saguntum, according to the Itinerary of Antoninus.

SEPHAAT, or SEPHA, a town of Palestine, in the tribe of Simeon, according to the book of Judges.

SEPHALITES. See MATZALITES.

SEPHAMA, in Ancient Geography, a town of Asia, in Syria, which served as a limit to the land of promisc, according to the book of Numbers.

SEPHAR, a mountain of the East, probably about Armenia. (See Gen. x. 30.) This mountain seems to have been the habituation of the Sepharvain and of the Suftipus, mentioned by geographers.

SEPHARVAIN, a people were brought by Shalmaneser into Palestine, to supply the place of the Israelites, whom he carried away from Samaria to a country beyond the Euphrates (2 Kings, xvii. 24. 31.) A.M. 3283. B. C. 1731. Their former habitations seem to be on the mountains of Sephar, and the Suftipus or Suftipus, who, according to Herodotus (lib. i. iii. vii.) were the only people that inhabited between the Cohelians and the Medes, were probably the Sepharvains. The Scripture speaks (Ifalal, xxxvii. 13. 2 Kings, xix. 13.) of the city of Sepharvain, which was probably the capital of these people, and the king of Sepharvain was the god of these people. See 2 Kings, xviii. 34. If. xxxvii. 13. 2 Kings, xix. 13.

SEPHIROIS, a word used by Paracelus and his followers, to express a sort of dry and hard hippomethne, or kind of fpurious ficirrhus.

SEPHIROTH, a Hebrew word signifying brightenues ; and the cabalists give the name of sephirot to the most secret parts of their science.

SEPHORIS, in Ancient Geography, a famous city of Zebulon, and the capital of Galilee; afterwards named Dioecetara; 18 according to some, and according to others 19 miles from Tiberias. It was not far from Tabor and the great plain. Josephus represents it as the largest and bett city in Judea, and states, that it became the capital of it, after Nero had given Galilee to the younger Agrippa. The first city of Galilee in going from Ptolemais was Sephoris. Joseph. de Bello, 1. ii. c. 23. i. iii. c. 1.

SEPHOURY, or SAPPURE, in Geography, a town or village of Palestine, anciently Sephor or Sephoris, which was once the strongest town of the country, and capital of Galilee, before Tiberias; called also Dioceetaraa. Here was held one of the five judicature of Palestine. It was fortified by Herod, and destroyed in the time of Constanin, on an infurrection of the Jews. It was once much venerated as the habitation of Joachim and Anna, parents of the blessed Virgin; 12 miles N.W. of Tabarion.

SEPUL, in Ancient Geography, a mountain of the Peloponnesus, in Arcadia, to the left of mount Geronte, near a place called Tricene, upon which Egyptus, the son of Elatus, died from the sting of a serpent, and where he was buried, according to Paulainius.

SEPUL, in Natural History, the Cuttle-fish, a genus of the Vermes-Mollufica clafs and order, of which the generic charaer is as follows; the body is fvelvy, receiving the breath in a sheath, with a tubular aperture at its base; it has eight arms, fetet with numerous warts or fuckers, and in molt species two pedunculated tentacula; the head is short; the eyes large; the mouth resembling a parrot's beak.

These animals inhabit various seas, and in hot climates some of them grow to an enormous size; they are armed with a dreadful apparatus of holders furnished with suckers, by which they fasten upon and convey their prey to the mouth; they have the power of squirting out a black fluid resembling ink, and which is said to be an ingredient in the composition of Indian ink; the bone in the back is converted into pouche; the eggs are deposited upon sea-weed, and exactly resemble a bunch of grapes; at the moment the female deposits them they are white, but the males pass over them to impregnate them, and then become black; they are round, with a little point at the end, and in each of them is enclosed a living cuttle-fish, surrounded by a gela- tinous fluid. There are eight species, of which five are natives of this country.

Species.

* OCTOPUS. The specific character of this species is, that the body has no tail or appendage; it has no pedunculated tentacula, or longer arms. It is found in the Mediterranean and Indian seas, in the latter of which it sometimes grows to a vast size; the arms are said to be eight or nine fathoms long. In these seas the Indians never venture out without hatchets in their boats, to cut off the arms, should it attempt to fallen upon them under water. This species is characterized by the shortness of the body, which is rounded behind; the arms taper to a point, joined at the base by a membrane or web, and covered within with two rows of alternate suckers. When opened this animal is said to exhibit so brilliant a light as to illuminate a large room.

* OFFICINALIS. Body without tail or appendage, and surrounded by a ring; it has two tentacula, or longer arms. This is found on our own coasts, and also in other oceans, and is frequently the prey of the whale tribe, and of plaice; its arms are frequently eaten by the conger-ee, and are reproduced; the body scale on the back is that which is folded in the shops; and the black matter which it squirts out to darken the waters round it, and elude the pursuit of its enemies, is sometimes used as ink. The body was eaten by the ancients, and it is even now used as food by the Italians. The body of this species is ovate, the margin crenate, and interrupted at the bottom; eight of the arms are short and pointed; the two tentacula are four times as long as the others; they are rounded, and the tips are very broad, and furnished within with numerous suckers.

UNGUCUTA. The body of this is without a tail or appendage; the arms are furnished with hooks, and it is found in the Pacific ocean. The body is rounded behind; the arms are furnished with hooks, which are retractile within their proper sheaths instead of suckers.

HISAPUS. The body of this is tailed, four or five-pointed; arms only fix in number. This also is found in the Pacific ocean. The body is about half a foot long, and the thickens of a finger; arms furnished with very minute suckers, whichlick fall to whatever it fixes on.

* MEDIA. Body long, slender, cylindrical; the tail is finned, pointed, and carinate on each side; it has two long arms. It inhabits the ocean, and in some respects it resembles the S. officinalis. The body ends in a point, and is furnished with a membrane on each side, commencing about the middle of the body.

* LICIUS; the Calamary. The body of this is subcy- lindrical, fubulate, and furnished with a flat broad-edged rhombic membrane at the tail on each side. This is found in divers parts of the ocean, and is from nine to twelve inches.
inches long. The body is of a reddish-brown, with two
longer arms or tentacula; the eyes are of a fine blue; the
cartilaginous plate or bone in the back is long, lance-shaped,
and transparent; it has sometimes been placed as a species of
the pennatula.

*SEPIOLA.* The body of this species has two rounded
wings or procces behind. It is found in the Mediterranean
and European seas, and is very small. The body is short,
rounded behind, with a round membrane or fin at the lower
extremity; it has two long arms.

**Tunicata.** The body of this species is entirely enclosed
in a black pellucid membrane, with two semicircular wings
or procces behind. This is an inhabitant of the Pacific
Ocean. The body is very large, and is said sometimes to
weigh one hundred and fifty pounds, and is convertible into
palatable and pleasant food.

SEPIACE, in Italian Muse, signifies that the part it is
joined to may be repeated or not, at pleasure.

SEPIAS, in Ancient Geography, a promontory of Thes-
faly, in Magnesia, at the entrance of the Pelasgic gulf,
according to Ptolemy. Cape Sepias is now the promontory
of St. George's.

SEPIUSSA, an island situated on the coast of Asia
Minor, in the Ceramic gulf, according to Pliny.

SEPOORY, in Geography, a fortress of Hindoostan,
in the circle of Gohud; 18 miles S.W. of Narwa.

SEPOU, a town of Hindoostan; 12 miles S.W. of
Agra.

SEPR, or Sippa, a river of Hindoostan, which rises
near Indore, joins the Callilind in the circle of Kitchwara,
and, united with other streams, forms the Chumbul.

SEPRIO, a town of Italy, in the department of the
Onona; 20 miles N.W. of Milan.

SEPS, in Zoology, the name of a very peculiar animal of
the lizard or lacerta kind, but seeming as if of a middle
nature between that genus and the snakes, and appearing
rather a serpent with feet than a lizard.

It is a small species; its body is rounded, and its back
variegated with longitudinal lines of black; its eyes are
black; it has ears, and a small and very slender tail. What
appears most singular in it is, that it has four legs, with four
divided into toes; the first pair are placed very near the
head, the other by the anus; the scales are laid in a reticu-
lated manner, they are of an oblong figure, approaching to
a rhomboid, and laid longitudinally; its belly is white,
with a flight of blue, and it has no nostrils near the end of
the snout. Colonna took five living young ones out of
the body of one of this species, some of which were in-
cluded in membranes, and others loose, as is the case in the
viviparous viviparous of the whole body.

SEPT MONCEZ, in Geography, a town of France, in
the department of the Jura; 2 miles E. of St. Claude.

SEPTA, in Antiquity, were inclosures, or rails made of
boards, through which persons went in to give their votes in
the assemblies of the Romans.

The word also signifies divisions, and, in that sense, is
used to express the plates of spar, which separate or divide
the tali of the ludus Helmontii, thence called by Dr. Hill,
septaria; which see.

SEPTALIUS, or SETTALA, Louis, in Biography, an
Italian physician of celebrity, was born at Milan, in Feb-
brary, 1552. He evinced from his early childhood, a
strong inclination to the pursuits of literature, and at the
age of sixteen defended some theses on the subject of natural

philosophy with an acuteness of reasoning far above his
years, and which excited the surprise of the audience, among
whom was the archbishop of Milan. It was now supposing
that he would follow the steps of his ancestors, both ma-
ternal and paternal, who had been much distinguished at
the bar; but his inclination led him to the medical profes-
sion, and he accordingly repaired to Pavia, for the purpose
of commencing the study of it. Here he proceeded with
the same success, and obtained the degree of doctor in his
twenty-first year, and was even appointed to a chair in this
celebrated university in his 23d year. In his professorial
capacity, though so young, he gave so many demonstrations
of his talents and acquirements, that he soon became known
to the most distinguished men of his time. Nevertheless,
at the end of four years from the time of his appointment,
he determined to relinquish the professorial dignity, for
the purpose of exercising his medical skill in his native city.
While he was engaged in the practice of his art at Milan,
Philip III., king of Spain, selected him for his historiogra-
pher. But though fully sensible of the value of this
compliment, yet neither this, nor many other more con-
genial honours, that were offered to him, could induce him
to quit his native city, to which he was ardently attached.
He was invited by the elector of Bavaria to a professorship
in the university of Ingolstadt; by the grand duke of Pisa,
to a chair at that place; and by the city of Bologna to
a similar appointment in their schools; and the senate of
Venice, by still more considerable offers of both honour and
reward, laboured assiduously to bring him to the university
of Padua. But he declined all these opportunities of eleva-
tion, content with the esteem and affection of his fellow-
citizens, which he amply obtained; and with the domestic
felicity, which the society and education of his family,
consisting of seven sons and five daughters, constantly afforded
him. The only honour which he accepted was the ap-
pointment of chief physician to the state of Milan, which
Philip IV. conferred upon him in 1627, as a reward for
his virtues and talents. In the year 1628, the plague visited
Milan. Septalis gave all the aid in his power to his fellow-
citizens, and in the midst of his labours to alleviate the
difficulties occasioned by this fatal calamity, he was himself
feized with the disease. He had fearfully recovered from
this attack, when he was suddenly surprized by a fit of
apoplexy, which left him speechless, and paralytic on one
side. From this, however, he in a great measure recovered,
and lived several years afterwards, but in a state of feeble-
ness and imperfect health. He died in September 1633, in
consequence of an attack of dysentery, at the age of 81.
Septalis was a man of acute powers, and solid judgment,
and he was esteemed extremely successful in his practice.
He was warmly attached to the doctrines of Hippocrates, whose
works he never ceased to study. He was author of the fol-
lowing works: "In Librum Hippocratis Cui, de Aeribus,
Aquis, et Locis, Commentari quinque," 1590; "In
Arietotellis Problematum Commentaria Latina," tom. i.
1602, ii. 1607; "De Neivis Liber," 1606. In this work Sep-
talus has not displayed his usual judgment; for he accuses
the navi, or mother-sports, to the imagination of the preg-
nant mother, and deduces from their appearances many
practical inferences, which are as unfounded as the notion
of their origin. "Animadversionum et Cautiornm Medi-
carum Libri duo, septem aliis additis," 1629. This is
a valuable work, the result of 40 years of practice, and
equal to any of its contemporaries of the 17th century.
"De Marginatis Judicio," 1618; "De Pelle et Peteliers Af-
fectibus Libri V.," 1622; "Analyticarum et Animali-
carum Differtationum Libri II.," 1626; "De Morbis ex
mucronata
SEPTANA, a word used by the ancient physicians for a febrile fever, or one that performs its regular period in seven days.

SEPTARIÆ, in Natural History, the name of a large class of fossils, called by some Ludus Helmontii, and by others the _waxen veins_. They are defined to be fossil bodies not inflammable, nor soluble in water, naturally found in loose detached malleys of a moderately firm texture and dusky hue, divided by several septa, or thin partitions, and composed of a sappy matter greatly debased by earth, not giving fire with fuel, fermenting with acids, and in great part dissolved by them, and calcined in a moderate fire.

Of these there are two distinct orders of bodies, and under those fix genera. The septarian of the first order are those which are usually found in large masses of simple uniform construction, but divided by large septa, either into larger or more irregular portions, or into smaller and more equal ones, called _talis_.

Those of the second order are such as are usually found in smaller masses of a curriated structure, formed by various incrustations round a central nucleus, and divided by very thin septa.

The peculiarity of character in Septas, with regard to the prevalence of the number seven, in the parts of fructification, is not so constant as Linnaeus seems to have imagined; hence Thunberg was induced to refer this genus to _Cras-fula_.

Loucreio has given the name of Septas to a plant in _Dich-nania Angiopteris_, which, according to professor Martyn, is allied to _Thuernbergia_.

SEPTA, in Ancient Geography, a town of Asia Minor, in Phrygia, according to Ptolemy.

SEPTEM APER, a town of the Sabines, situated on an eminence, and commanding the Rura rorea, or the fine Rolean valley. It is suppofed by the abbe Chauzi to be the present Pont Grifpoli.

SEPTEM, _Areus_, Arronches, a place of Hifpania, between Matufarum and Budia, according to Antonine's Itinerary. It was situated towards the N.W. of Emerita Angarra.

SEPTEM Fraires, a mountain of Africa, in Mauritania Tingitana. Ptolemy calls it Heptadelphus Mons, and places it on the Northern coast, between Exiliia and Abyla.

SEPTEM Maria, a name given, according to Herodian, to the marshes which were formed by the seven branches of the Eridanus, before its discharge into the Adriatic sea.

SEPTEM Pagus, the name of a plain of Italy, on the banks of the Tiber, in the country of the Veians, according to Dionysius of Halicarnassus.

SEPTEM Pada, a town of Italy, in the Picenum, according to Strabo. Frontinus makes it a Roman colony, and gives it the title of Oppidum.

SEPTEMBER, the ninth month of the year, reckoned from January, and the seventh from March, whence its name, _vix._ from _septimus_, seventh.

The Roman senate would have given this month the name of Tiberius, but that emperor opposed it; the emperor Domitian gave it his own name Germanicus; the senate under Antoninus Pius gave it that of Antoninus; Commodus gave it his surname Herculeus, and the emperor Tacitus his own name Tacitus. But these appellations are all gone into disuse.

SEPTEMES, in Geography, a town of France, in the department of the _Ile_; 9 miles E. of Vienne.

SEPTEMVIR, in Antiquity. See Quinqueviri.

The Germans sometimes use the word _septemviratus_, for the seven electors of the empire. See _Elector_.

SEPTENA, in Ancient Geography, a town of Asia Minor, in Lydia.

SEPTENTRIO, or SEPTENTRIONES, in Astronomy, a northern constellation of stars, more usually called _Urfa Minor_, or the Little Bear; and by the people, _Charles's Wain_: though the seven stars in the Great Bear have been of late fo denominated.

The word is formed from the Latin _septem_, seven; and _triones_, bullocks, which, in the ancient constellation, were yoked to the plough.

SEPTENTRIO, in Cosmography, the fame with _north_; thus called from the ancient constellation Septentrio, one of whose stars is the pôle-star. Hence also,

SEPTENTRIONAL, _Septentronics_ something belonging to the north; as _septentrionalis_, _septentrionalis_, &c. are those on the northern side of the equator.

SEPTEORION, _Septoerion_, in Antiquity, a Delphic festival, celebrated every ninth year, in memory of Apollo's victory over Python. The chief part of the solemnity was a representation of Python pursued by Apollo.

SEPTEUILL, in Geography, a town of France, in the department of the Seine and Oise; 9 miles N.W. of Montfort.

SEPTEOIL, in Botany. See _Tormentil_.

SEPTEOAINS, in Geography, a town of France, in the department of the _Lot_; 16 miles N.E. of Montauban.

SEPTEOILS, in Ancient Geography, a name, or rather an epithet, given to the city of Rome.

SEPTICS, among Physicians, an appellation given to all such substances as promote putrefaction.

From the many curious experiments made by Dr. Pringle to ascertain the leptic and antileptic virtues of natural bodies, it appears that there are very few substances of a truly leptic nature. Those commonly reputed such by authors, as the alkaline and volatile salts, he found to be no wise leptic. However, he discovered some, where it seemed
leat likely to find any such quality: these were chalk, common salt, and teftaceous powders. He mixed twenty grains of crab's eyes, prepared with six drachms of ox's gall, and an equal quantity of water. Into another phial he put an equal quantity of gall and water, but no crab's eyes. Both these mixtures being placed in the furnace, the putrefaction began much sooner where the powder was, than in the other phial. On making a like experiment with chalk, its teptic virtue was found to be much greater than that of the crab's eyes: nay, what the doctor had never met with before, in a mixture of two drachms of flesh, with two ounces of water and thirty grains of prepared chalk, the flesh was resolved into a perfect mucus in a few days.

To try whether the teftaceous powders would also diffuse vegetable substances, the doctor mixed them with barley and water, and compared this mixture with another of barley and water alone. After a long maceration by a fire, the plain water was found to swell the barley, and turn mucilaginous and four; but that with the powder kept the grain to its natural size, and though it softened it, yet made no mucilage, and remained sweet.

Nothing could be more unexpected, than to find tea-falt a halfaller of putrefaction; but the fact is this: one drachm of salt prefers two drachms of fresh beef in two ounces of water, above thirty hours uncorrupted, in a heat equal to that of the human body; or, which is the same thing, this quantity of salt keeps flesh sweet twenty hours longer than pure water; but then half a drachm of salt does not preserve it above two hours longer. Twenty-five grains have little or no antifeptic virtue, and ten, fifteen, or even twenty grains, manifestly both halen and heighten the corruption. The quantity which had the most putrefying quality, was found to be about ten grains to the above proportion of flesh and water.

Many inferences might be drawn from this experiment: one is, that since salt is never taken in aliment beyond the proportion of the corrupting qualities, it would appear that it is subservient to digestion, chiefly by its teptic virtue, that is, by softening and resolving meats; an action very different from what is commonly believed.

It is to be observed, that the above experiments were made with the salt kept for domestic uses. See Pringle's Observ. on the Difeases of the Army, p. 348, seq. See Salt and Scurvy.

From some experiments of Mr. Canton, it appears like-wise, that the quantity of salt contained in sea-water hafens putrefaction; but since that precise quantity of salt which promotes putrefaction the most, is less than that which is found in sea-water, he concludes it probable, that if the sea were less salt, it would be more luminous. See Luminousness of the Sea.

SEPTIEME. Fr. Septima, Lat. Setima, Ital. the seventh.

Broffard has been the guide of all subsequent musical lexicographers. He has been very awkwardly translated by Graffen鸢; Graffen鸢 has been followed in the last folio edition of Chambers; and Roufseau, who writes clearly and elegantly, has retained the mixture of theory, ratios, and the rules of jargon of major and minor tones and semi-tones, in practice, so much, as to render the useful knowledge of this important interval totally unintelligible to young students in harmony; to whom we shall address all we have to offer on the subject of the present article, referring scientific enquirers to Harmonics, Ratios, and the definitions of major and minor tones and semi-tones.

The 7th in music, is one of the principal discords; some say the only original discord, as all the rest are derived from it. The 2d and the 9th are only inversions of the 7th. The 4th in itself is a concord, and only made a discord by another discord being struck upon it; but the 2d and the 9th, however derived from inversion, are discords to the ear at all times and in all places.

There are three kinds of 7ths used in practical harmony; the minor, or flat 7th, ten semi-tones, or half notes, above the base; the major, or sharp 7th, eleven semitones above the base; and the extreme flat 7th, only nine half notes above the base or lowest note, as B b, B, and F. b, F.

In counterpoint and thorough-bass, the 7th is accompanied by the ♯, or common chord, from which its harmony only differs by the addition of that single found from the triad. And as a base, in practice, is called fundamental, by being accompanied only with the common chord, the addition of the 7th to this common chord does not rob the base figured with a 7th of its title of fundamental.

The 7th in binding notes is prepared in the 3d, 5th, 6th, and 8th, and resolved on the 6th, 3d, and 5th.

Dr. Pepusch has given an excellent chapter on 7ths prepared and resolved in the treble; but to his instructions for 7ths prepared and resolved in the base, p. 37 of the text, we cannot subscribe. See PEPSUCH, and Analyſis of his Treatise on Harmony.

The 7th is the only discord which need not be always prepared.

The sharp 7th, which the French call la note sensible, till about the middle of the last century, was only used in recitative; but since that time it has been rapidly increasing in favour; first in German symphonies, and afterwards in songs, and every species of elegant music. Its chord is frequently indicated by a ♯, a sharp 7th; but different masters frequently use the following numerical expressions of this chord; ♯, ♯, ♯, ♯, and ♯. Its origin is an appoggiatura organized.

The extreme flat 7th gives what has been termed by Rousseau the enharmonic chord, consisting entirely of flat 3ds, whence twelve modulations may be acquired, by making each note of the chord the sharp 7th, or leading note to a new key; by which means these three chords ♯ ♯ ♯, ♯ ♯ ♯, B ♯ ♯ give 36 modulations. See Music Plates, and Inter vals, Chords, Modulation, and Counterpoint.

SEPTIEME, or SETTIER, a French measure, differing according to the species of the things measured. For dry measure, the septier is very different in different places and different commodities; as not being any vell of measure, but only an estimation of several other measures. At Paris, the septier of wheat consists of two mines, the mine of two minots, and the minot of three bushels or boiffeaux, and 12 feptiers are a muid. The boiffeau contains 16 liters. A muid of wheat weighs about 2880 lbs. poids de marc; and a septier, 3240 lbs. But a muid of oats contains 24 septiers. The boiffeau is a cylinder 8 inches 2½ lines in height, and 10 inches in diameter; its contents are, therefore, 4.44 French cubic inches, or 780 English ditto; hence 11 septiers of Paris are = 6 English quarters, and 11 boiffeaux = 4 English bushels. A muid of salt contains also 12 septiers, and a septier, 4 minots, 16 boiffeaux, 256 liters, or 4096 meunetres, weighing about 4000 lbs. poids de marc, or 432 lbs. avoirdupois. At Abbeville 18.87 septiers are equal to 10 English quarters, and each septier is 9564 cubic inches.
SEP

inches. At Amiens, 85.79 septiers = 10 English quarters, and each septier = 2005 cubic inches. At Arles, 47.40 septiers = 10 English quarters, and each septier = 5628 cubic inches. At Boulogne, 16.52 septiers = 10 English quarters, and each septier = 10,535 cubic inches. At Calais, 16.95 septiers = 10 English quarters, and each septier = 10,144 cubic inches. At Cette, 42.98 septiers = 10 English quarters, and each septier = 4002 cubic inches. At Lige, 9.14 septiers = 10 English quarters, and each septier = 1827 cubic inches. At Montpellier, 53.21 septiers = 10 English quarters, and each septier = 3232 cubic inches. At Nantes, 19.68 septiers = 10 English quarters, and each septier = 8739 cubic inches. At Paris, 18.38 septiers = 10 English quarters, and each septier = 9350 cubic inches. At Rouen, 15.75 septiers = 10 English quarters, and each septier = 10,920 cubic inches. At St. Valery, 18.38 septiers = 10 English quarters, and each septier = 9350 cubic inches.

The septier is also a liquid measure at Paris and in other parts of France, and at Geneva. A muid of wine at Paris and in some other parts of France, contains 35 septiers, 144 quarts or pots, or 288 pints, and 280 pints without the lees. The pinte contains 2 chopes, 4 demi-septiers, or 8 poillons, in all 47½ French cubic inches, or 573 English ditto; so that a French pinte is nearly equal to an English quart; and a muid of wine contains 7½ English gallons.

At Geneva, the char, wine measure, contains 12 septiers; the septier, 24 quarters, or 48 pots; and the septier is = about 12 English gallons; 8.37 septiers are = 100 English gallons wine measure, and each septier = 2769 cubic inches.

SEPTIMANCA, SIMANCAS, in Ancient Geography, a town in the interior of Hispании Citerior, belonging to the Vassalions. In the Itinerary of Antonine it is marked on the route from Emerita to Saragossa, between Almaboba and Nivaria. It was situated on the Durias, S. of Pallentia.

SEPTIMENI. See SEPTUMI.

SEPTIMINicia, a town of Africa Propria, upon the route from Thence to Allure, between Madalama and Tabalta, according to the Itinerary of Antonine.

SEPTIMONTIUM, among the Romans, a festival celebrated in December, on all the seven hills of Rome; whence also it had this name, being otherwise called Agonalia.

SEPTIZON, SEPTIZONIUM, in the Ancient Architecture, a term almost appropriated to a famous mausoleum of the family of the Antonines, which, Aur. Victor tells us, was built in the tenth region of the city of Rome, being a large insulated building, with seven stages or stories of columns. The plan was square, and the upper stories of columns falling back much, rendered the pile of a pyramidal form, terminated at top with the statue of the emperor Septimius Severus, who built it. It had its name Septizon, Septizonium, from septem and zona, q. d. seven zones or girdles, by reason of its being girt with seven rows of columns. Historians make mention of another Septizon, more ancient than that of Severus, built near the Thermes of Antoninus.

SEPTUAGESIMA, in the Calendar, denotes the third Sunday before Lent, or before quadragesima; and quinquagesima is the next before quadragesima, then vexagesima and septuagesima: these were all days appropriated by the church to acts of penance and mortification, by way of preparing for the devotion of the Lent ensuing. It is supposed by some to take its name from its being about seventy days before Easter: pope Telephorus first made it a feast day, and appointed Lent to commence from it.

The laws of king Canutus ordained a vacation from justice, from septuagesima to quinquagesima. (See Quinquagesima.) From septuagesima to the octaves after Easter, marriage is forbidden by the canon law.

SEPTUAGINT, LXX, or the Seventy, a term famous among divines and critics, for a version of the Old Testament out of Hebrew into Greek, said to have been performed by seventy-two Jewish interpreters, in obedience to an order of Ptolemy Philadephus.

The ancients, till Jerom's time, univerally believed, that the Seventy were inspired persons, not mere translaters, grounding their belief on a fabulous history of this version given by Arittea; who tells us, that the high-priest Eleazar chose six doctors out of each tribe for this office, which made the number of seventy-two; and that these being six up each in his several cell, each translated the whole; and without seeing what any of the rest had done, they were found to agree to a letter.

The learned Dr. Hody, "De Bibliorum Textibus Originalibus, " &c. who seems to have studied the origin of the Greek version more accurately than any critic before him, has laboured very successfully in detecting the false story of Arittea; and he has likewise proved, that this version was made by the Jews living at Alexandria, for the use of themselves and many thousands of their brethren, who were then settled in Egypt, and who, living among the Greeks, generally used the Greek language. And he has also proved, that the whole Hebrew bible was not translated into Greek at once, but that different parts were translated at different times: that the Pentateuch was translated first, about 285 years before Christ; that only the Pentateuch was read in the synagogues till about 170 years before Christ, when Antiochus Epiphanes, their cruel persecutor, forbade them to recite any part of the law; that soon after this prohibition, the Jews translated into Greek Isiah, and the following prophets, for the use of the temple at Heliopolis and the Alexandrian synagogues; and that the other books were translated afterwards, with different degrees of skill and care, at various times, and by various persons. See also on this subject Prideaux's Connex. vol. iii. p. 38, &c. Brett's Dissertation on the ancient Version of the Bible, published in Bishop Watson's Collection of Tracts; Dupin's Canon, Walton's Prolegomena, &c. &c. See ALEXANDRIAN COPY, and GREEK BIBLE.

SEPTUAGINT, Chronology of the, or Seventy, is an account of the years of the world, very different from what is found in the Hebrew text, and the Vulgate; making the world 1466 years older than it is found in the latter.

The critics are much divided as to the point of preference. Baronius prefers the account of the Seventy; and If. Vossius makes an apology for it. The two late and most intelligent advocates in this dispute, are father Pezron, a Bernardine, and father Le Quien, a Dominican; the first of whom defends the chronology of the Septuagint, and the latter that of the Hebrew text. See SACRED CHRONOLOGY.

SEPTUM, in Anatomy, a name applied to various parts of the body; generally such as separate contiguous cavities.

The Septum Auricularum in the heart is placed between the two auricles. See HEART.

SEPTUM Cerebri and Cerebelli, the falciform processes of the dura mater. See BRAIN.
SEPTUM Cordis or Ventricleorum, the partition between the ventricles of the heart. See Heart.

SEPTUM Lucidum, the part interposed between the two lateral ventricles of the brain. See Brain.

SEPTUM Narii, the partition between the nostrils. See Nose.

SEPTUM Penesforma Penis. See the description of the penis under Generation.

SEPTUM Serotii. See Generation.

SEPTUM Thoracis, the mediastinum, which forms the partition between the two sides of the chest. See Lung.

SEPTUM Transversum, or Musculares, the diaphragm. See Diaphragm.

SEPTUMANI, in Ancient Geography, a people of Gallia Narbonenis, who inhabited the town of Bitera, according to Pliny. In process of time a province of their territory was denominated Septimania.

SEPU, in Geography, a town of Asiatic Turkey, in the government of Sivas; 40 miles S. E. of Sivas.

SEPULCHRAL, SEPULCHRALS, something belonging to sepulchres or tombs.

SEPULCHRAL Columna. See Column.

SEPULCHRAL Inscriptions, are the funereal monuments we have of antiquity.

SEPULCHRAL Lamps. See Lamp.

SEPULCHRAL, or SEPULCHRALS, is also the appellation of a sect; thus called from their supposed principal error, which was, that by the word hell, whither the Scripture tells us Jesus Chri$t descended after his death, they understood no more than his grave or sepulchre. See Hell.

SEPULCHRALS Pecunia. See Pecunia.

SEPULCHRE, SEPULCHRAM, a tomb, or place, defined for the interment of the dead.

The term is chiefly used in speaking of the burying-places of the ancients; those of the moderns we usually call tombs.

Besides the usual sepulchres for the interment, either of the whole body, or of the ashes of the burnt, the ancients had a peculiar kind, called cenotaphia, being empty sepulchres made in honour of some persons, who, perhaps, had no burial at all; from a superstitious opinion, that the souls of those who wanted burial wandered a hundred years before they were admitted to pass into the Elysian fields. See Burial and Cenotaph.

The pyramids are supposed to have been built as sepulchres for the kings of Egypt. And the obelisks had generally the same intended use.

Sepulchres were held sacred and inviolable, and the care taken of them was deemed a religious duty, grounded on the fear of God, and the belief of the soul's immortality. Those who searched or violated them, have been odious to all nations, and always severely punished.

The Egyptians call their sepulchres eternal houses, in contradistinction to their houses and palaces, which they called inner; by reason of the short sojourn we have in the one, in comparison of our long stay in the other. The Eastern pilgrimages are all made with design to visit the holy sepulchre, that is, the tomb of Jesus Christ. Nobody enters here but bare-footed, and with abundance of ceremonies. The Turks exact twenty-four crowns of each pilgrim, whom devotion carries to the holy sepulchre.

SEPULCHRE, St., or the Holy Sepulchre, gives the denomination to an order of regular canons, anciently instituted in Jerusalem, in honour of the holy sepulchre.

They ascribe their institution to Godfrey of Boulogne, who, they say, upon his taking Jerusalem in the year 1099, placed canons in the patriarchal church of the Holy Sepulchre, which indeed is true, but then they were not regulars.

In effect, it was Arnoul, who, of archdeacon of the church of Jerusalem, got himself elected patriarch of that, in 1114, first obliged his canons to live in community, and to follow the rule of St. Augustine.

From the Holy Land numbers of these canons were brought into Europe, particularly into France by Louis the Younger; into England by king Henry; into Poland by John, a Polish gentleman; and into Flanders by its counts.

But the order was afterwards suppressed by Innocent VIII., and its effects given to that of Our Lady of Bethlehem, which itself sealing, they were bellowed, in 1484, on that of the knights of St. John of Jerusalem; but the suppression did not take place in Poland, nor in several provinces of Germany, where they still subsist; their general is in Poland; their habit, rather Heliot observes, has been different in different places.

SEPULCHRE, St., or the Holy Sepulchre, is also the name of a military order, established in Palestine, as some say, by Godfrey of Boulogne, but according to others by his successor, Baldwin.

However, it is certain there were none but canons in the church of St. Sepulchre till the year 1114; and it is no more than probable, the knights were only instituted upon the ruins of the canons, four hundred years after, and that by pope Alexander VI. in order to excite rich and noble persons to visit the holy places, by giving them the title of knights of the Holy Sepulchre, and to this end, instituting an order under that name, of which he reserved the quality of master to himself and his successors.

Leo X. and Clement VII. granted to the guardian of the religious of St. Francis, in the Holy Land, the power of making these knights; which power, first granted vivae voce, was afterwards confirmed by a bull of Pius IV. In 1558, the knights of this order in Flanders, chose Philip II. king of Spain, their master, and afterwards his son; but the grand master of the order of Malta prevailed on him to resign; and when afterwards the duke Nevers assumed the same quality in France, the same grand master, by his interest and credit, procured a like renunciation of him, and a confirmation of the union of this order to that of Malta.

SEPULCHRI Pretium. See Pretium.

SEPULVEDA, JOHN GESMUS, in Biography, an eminent Spanish divine, born in the diocese of Cordova in 1491. He became distinguished for his knowledge of law, philosophy, and divinity, and was, on account of his great learning, nominated by the emperor Charles V. historiographer and theologian. His name was chiefly owing to his version of Aristotle into the Latin language. When in the height of his reputation, he was engaged in a controversy from which he derived no honour. It is thus related:

At the time that the celebrated Las Cafas, bishop of Chiapa, was pleading the cause of the oppressed Indians before the court of Spain, Sepulveda, induced by some Spaniards who had tyrannized over that people, wrote a book in the Latin language, by way of dialogue, in which he undertook to prove, that the wars of the Spaniards in the Indies were just, and founded on their right to subdue the people of that new world; that it was the duty of the Indians to submit to be governed by the Spaniards, on account of their own inferiority in knowledge and wisdom; and that if they would not voluntarily acquiesce in the Spanish dominion, they might and ought to be compelled by force of arms. Sepulveda, to add weight to his argument, declared that his whole object was to establish the right of the kings of Castile and Leon to take possession of their domain in the
the Indies. He presented his work to the royal council, and earnestly requested permission to print it. He was refused, and applied to some friends in the emperor's court. Las Cafas, who was returned from the Indies, persuaded that the book would encourage the cruelties of which he complained, opposed the printing. The royal council, regarding the subject as of a theological rather than as of a political nature, referred it to the universities of Alcalá and Salamanca, both of which pronounced that it ought not to be committed to the press. The author, determined if possible to carry his point, sent his book to Rome, where it was printed. The emperor, informed of his intention, sent express orders to prohibit its circulation, and caused the copies to be seized: some of them, however, had already reached Spain. Las Cafas thought it necessary to make a reply in defence of the poor Indians. The emperor at length cited the parties before the council of the Indies, and sent Domínic Soto to arbitrate between them. He heard the arguments on both sides, and made a report in favour of Las Cafas. The matter, however, remained undecided: and the good bishop had not the satisfaction to see the Indians freed from their tyrants. Sepulveda died at Salamanca, of which he was a canon, in 1572. Besides the works above-mentioned, he was author of various tracts, theological and controversial, which were printed collectively at Cologne in 1602.

Sepulveda, in Geography, a town of Spain, in Old Calilé, on the river Duraton; 28 miles N. E. of Seviglia.

Sepyra, in Ancient Geography, a town of Syria, upon mount Ammonus, of which Cicero made himself master.

SEQUANA, a river which separated the country of the Gauls from that of the Belgae, according to Caesar. It is the present Seine.

Sequani, a people of Gaul. In the time of Caesar they were in Celta, but Augustus places them in Belgica.

SEQUATUR sub suo periculo, in Lawo, a writ that lies, when a summam ad warrantzandum is awarded, and the sheriff returns that the party hath nothing by which he may be summoned; then goes forth an alias and a pluries; and if he comes not on the pluries, this writ shall issue.

SEQUANG, in Geography, a town of Pegu, on the Irrawaddy, 20 miles N. of Rangoon.

Sequel, Sequela, in Logic, a consequence drawn from some preceding proposition.

As if I say, The human soul is immaterial, and therefore immortal; the last member of the sentence is a sequel of the first.

Sequence, French, from sequor, I follow, in Gaming, a series or set of cards immediately following each other in the same suit or colour.

We say, a sequence of four cards, of five, &c. At piquet, there are called tierces, quarts, quintets, &c.

Sequestration, Sequestratio, in Common Law, the act of separating a thing in controversy, from the possession of both parties, till the right be determined by course of law.

This is of two sorts, voluntary and necessary: voluntary, when it is done by consent of both parties; and necessary, being that which the judge doth by his authority, whether the parties will or not.

Sequestration, in the Civil Law, is the act of the ordinary, disposing of the goods and chattels of one deceased, whose estate no man will meddle with.

A widow is also said to sequestrate, when she disclaims having any thing to do with the estate of her deceased husband.

Among the Romanists, in questions of marriage, where the wife complains of impotency in the husband, she is to be sequestrated into a convent, or into the hands of matrons, till the process be determined.

Sequestration is also used for the act of gathering the fruits of a benefice void, to the use of the next incumbent.

Sometimes a benefice is kept under sequestration for many years, when it is of so small value, that no clergyman fit to serve the cure, will be at the charge of taking it by incumbrance; in which case the sequestration is committed either to the cure alone, or to the curate and churchwardens jointly. Sometimes the profits of a living in controversy, either by the consent of the parties, or the judge's authority, are sequestrated and placed for safety in a third hand, till the suit is determined, a minister being appointed by the judge to serve the cure, and allowed a certain salary out of the profits. Sometimes the profits of a living are sequestrated for neglect of duty, for dilapidations, or for satisfying the debts of the incumbent. And this is, where a judgment hath been obtained against a clergyman, and upon a fieri facias directed to the sheriff to deny the debt and damages, he returns, that the defendant is a clerk benefited having no lay fee. Whereupon a levari facias (see Levari) is directed to the bishop to levy the fame of his ecclesiastical goods, and by virtue thereof the tithes shall be sequestrated. (Watson, c. 15.) In this case the bishop may name the sequestrators himself, or grant the sequestration to such persons as shall be named by the party who obtained the writ. If the sequestration be laid and executed before the day of the return of the writ, the mean profits may be taken by virtue of the sequestration after the writ is made returnable, otherwise not. If an appeal be made against a sentence of sequestration, and lawfully preferred, the party sequestrated shall enjoy the profits pending the appeal. (Lind. 104.) It is usual for the ecclesiastical judge to take bond of the sequestrators, well and truly to gather and receive the tithes, fruits, and other profits, and to render a just account (Watson, c. 30.); and those to whom the sequestration is committed are to cause the fame to be published in the respective churches, in the time of divine service.

The sequestrators cannot maintain an action for tithes in their own name at the common law, nor in any of the king's courts; but only in the spiritual court, or before the justices of the peace where they have power by law to take cognizance. When the sequestrators have performed the duty required, the sequestration is to be taken off, and the profits applied according to the direction of the ordinary, and they shall be allowed out of the profits a recompense for their trouble, and also for the supply of the cure, and also for the maintenance of the incumbent and his family, if they need it. Sequestrators refusing to deliver up their charge, may be compelled to do it by the ecclesiastical judge. If the incumbent be not satisfied with the conduct of the sequestrators in the execution of their charge, his proper remedy is by application to the spiritual judge; and if he be not satisfied with his determination, he may appeal to a superior jurisdiction.

In the time of the civil wars, sequestration was used for a seizing of the estates of delinquents, for the use of the commonwealth.

Sequestration, in Chancery, is a commissio usual directed to seven persons therein named, empowering them to seize the defendant's personal estate and the profits of his
his real, and to detain them, subject to the order of the court. It illus on the return of the serjeant at arms, in which it was certified that the defendant had sequestred himself.

Sequestrations were first introduced by Sir Nicholas Bacon, lord keeper, in the reign of queen Elizabeth; before which the court found some difficulty in enforcing its precedents and decrees: and they do not seem to be in the nature of proceed to bring in the defendant, but only intended to enforce the performance of the court’s decree.

Sequestration, in London, is made upon an action of debt: in which case, the action being entered, the officer goes to the shop or warehouse of the defendant, when there is no body within, and puts a padlock upon the door, &c. using these words, “I do sequestrate this warehouse, and the goods and merchandises therein of the defendant in the action, to the use of the plaintiff,” &c. and having put on his seal, makes return of it to the compter; and after four court days, the plaintiff may have judgment to open the doors, and appraise the goods by a serjeant, who takes a bill of appraisement, having two freemen to appraise them, for which they are to be sworn at the next court helden for that compter; and then the officer puts his hand to the bill of appraisement, and the court giveth judgment. However, the defendant in the action may put in bail before satisfaction, and so dissolve the sequestration; and after satisfaction may put in bail ad difprobandum debitum, &c.

Sequestro, Sequestri, in Civitatis, a term used by some writers to express separation.

Sequestro Harenzo, In Lucr., a writ judicial for the discharging a sequestration of the profits of a church-benefice, granted by the bishop at the king’s commandment, in order to compel the parson to appear at the suit of another. The parson, upon his appearance, may have this writ for the release of the sequestration.

Sequin, Zecchin, Zecchino, a gold coin struck at Venice, Genoa, Rome, Milan, Piedmont, and Tuscany, and in several parts of the grand signor’s states.

Abalancourt derives the word from Cicium, or Ciceni-um; as supposing the sequin first struck at Cicium: Menna, from the Italian zecchino, of zeca, the name of the mint at Venice. At Florence, pieces of 3 sequins are called Rupioni (see Rupioni); zecchini or sequins, called Giglanti, weigh 2 dinta 23 grains, and are worth 13 lire or 20 paoli. The Roman and Genoa sequins circulated here are valued at 13 lire; Venetian sequins at 13 lire. The sequin Gigliato weighs 53/2 English grains, and the gold is 23/2 carats fine: it is therefore worth 91. 6d. sterling. At Rome 100 francene, or 50 sequins, are exchanged for 100 fudni Romani, more or less. At Genoa, the sequins are valued at 13 lire 10 foldi. In 1807 the Roman sequins were valued here at 142, and the Venetian at 143 102. The weight of the sequin at Genoa is 76 grams of gold 23/2 carats fine, and its value is 91. 5d. At Leghorn the sequin is current for 13 lire 6 foldi 8 denari, of moneta buona, and for 13 lire 18 foldi 3 denari of moneta langa. At Lucera in Italy the sequins pass for 14 lire 4 sgrs.; Venetian sequins are taken at the same as other Italian sequins, and German ducats at 14 lire 6 foldi. In the island of Malta, Venetian sequins pass for 6 fudni; the fenuo current money being worth 20 d. sterling. At Marseilles, Italian sequins pass for 11 livres 2 sous 4 marcs. At Milan, sequins, weighing 2 denari 20 sgrs., are valued at 15 lire 4 foldi. At Parma the sequin is valued at 45 lire, the lira being worth 23/4 d. nearly.

At Rome, the zecchini or sequins are current at 21½ paoli, with their doubles and halves in proportion. The sequin is to weigh 2 denari 21 sgrs. or 52% English grains, and the gold is 23% carats fine: so that it contains little more than 52 grains of pure gold, and is therefore worth 91. 3d. sterling. At Tunis, a Venetian sequin passes for 2½ piastres, 32 alpers, more or less. At Venice, the gold coins of the old republic are zecchini or sequins, with halves and quarters. The sequin is commonly reckoned at 22 lire, but it bears a fluctuating agio, which in the year 1805 was 37 per cent.: 68½ zecchini or sequins are to contain a Venetian mark of fine gold; and are said to have no alloy; the quantity of alloy, however, is small and uncertain. The Venetian sequin weighs 54 English grains nearly, and it is therefore worth 91. 6d. sterling.

The alloy of the Genoa sequin is better than the English standard of 22 carats, and its value, &c. according to the mint price of gold in England, viz. 31. 17s. 10½d. per oz. to weight 2 dwts. 5½ grs., contains in pure gold 53½ grs., and value in sterling 91. 5½d. The sequin of Milan is better than the English standard; its assay is 1 car. 3 grs., its weight 2 dwts. 5½ grs., its contents in pure gold 53½ grs., and its sterling value is 91. 5½d. The sequin, or two-ducat piece of Naples, of 1762, is worse than Engl. stand.; its assay is 1 car. 2½ grs., weight 1 dwt. 20½ grs., contents in pure gold 37.4 grs., and 7½d. sterling value 73½d. The sequin of Piedmont (and half sequin in proportion) is better than Engl. stand.; its assay is 1 car. 2½ grs., weight 2 dwts. 5½ grs., contents in pure gold 52½ grs., and value 91. 4½d. The sequin of Rome, coined before 1700, is better than Engl. stand.; its assay is 1 car. 2 grs., weight 2 dwts. 4½ grs., contents in pure gold 51.4 grs., and value 91. 1¼d. The assay of the sequin coined since 1700 is 1 car. 3½ grs., weight 2 dwts. 4½ grs., contents in pure gold 52.2 grs., and value 91. 3d.

The zecchino, or sequin of Tuscany, is better than the English standard; its assay is 1 car. 3½ grs., its weight 2 dwts. 5½ grs., its contents in pure gold 53.6 grs., and its value 91. 5½d. The zecchino or sequin (the half and quarter in proportion) of Venice is better than the English standard; its assay is 1 car. 3½ grs., its weight 2 dwts. 6 grs., its contents in pure gold 53.6 grs., and its value 91. 5½d.

The impressions on the Italian sequins are as follow: on that of Genoa, St. John the Baptist holding a croz; legend, NON SUSCRIT MAJOR, i. e. a greater has not arisen, and the date; reverse, the arms of Genoa with a crown; legend, Dux et Gub. Reg. Gen. i. e. doge and governor of the republic of Genoa. On that of Milan, the head of the reigning emperor of Germany, with name and title thus; JOSEP H. D. G. R. IMP. S. AUG. G. H. ET B. REX. A. A. i. e. Joseph the second, by the grace of God, emperor of Rome, ever august, king of Germany, Hungary, and Bohemia, archduke of Austria; reverse, arms of Milan; legend, MEDIDIANI ET MANTUE DUX, duke of Milan and Mantua. On that of Venice, a man holding a croz, and another kneeling before him with the doge’s name, as ALOY. MOC. (Aloyius Mocengo,) and the letters s. m. v. e. n. e. one above the other near the edge of the piece; i. e. Sandwier Marcus Venetus; also the letters d. v. x. Dux, duke or doge, placed in the same manner above the kneeling figure; reverse, a whole length figure of St. Mark, holding a book, and surrounded with stars; legend, SIT T. XBE. DAT. Q. TU REGIS ISTE DUCA, suppoed by Muratori in his Antiquitates Italicae Medii AEVI, to denote, Sit edit Chriflile datum, quod (vel quia) tu regis ifte ducatum, i. e. To thee, O Chrift,
O Chrift, be it (this coin) given, because thou governest (universally). He, St. Mark, governs the duchy. Muratori doubts this interpretation, and supposes that "e" might have been originally "te". The legend, however, is curious, as being both an hexameter verse and a monikih rhyme. The half and quarter sequins bear the same impressions, but the legend on the reverse is, Ego sum lux mundi, i.e. I am the light of the world.

At Cochin, on the Malabar coast, Venetian sequins are worth 72 fanams, of which 20 are reckoned for a rupee. At Goa, Venetian sequins are worth 16 pagodas, each of which is worth about 7/12d. florins. At Surat, the weight of a Venetian sequin is reckoned at 92.012, of which 82/7 make 1 oz. troy.

The gold coins of Turkey are the sequin or chequen, called the sequin funduc, coined in the year 1764; 100 of these weigh 110 Turkish drachma, or 54.15 English grains, and they are about 23 carats fine. The sequin funduc of Constaninople passed at first for 3/12 piastres, or 400 apers; but its price was gradually raised to 4 piastres.

In 1769 most of them were called in for a new coinage. There is another sequin, called madhub, or zamahub, and the roubib, or one-third ditto: 100 madhubs, 200 nissi, or 300 roubibs, were to weigh 82/7 Turkish drachma, or 46.61 English grains: they were at first 22 carats fine, but in 1781 were reduced to 19.4/12 carats; and in subsequent coinages they have been still more debased. Venetian sequins pass at present for 94 piastres. At Alexandria in Egypt the sequin, called funduc, is worth 146 medini; that called zumahub is valued at 120 medini, 40 medini being a piastre.

At Grand Cairo in Egypt, contracts are made in funduc and madhub sequins; the former are reckoned at 146 medini, and 3 madhubs are equal to 4 patacca, so that the madhub is worth 120 medini. The only coins allowed by the Turkish government to be struck at Cairo are the madhub (or zamahub) sequins, and medini: 40 medini are valued at 193/12 florins, so that the madhub is worth 41.9/12 florins. Madhubs, however, of inferior value, are coined by the Beys in Egypt, and generally pass for 110 medini. The Turkish coins are current at Patras in the Morea. Some European gold ducats and sequins circulate in Períssa. The sequin funduc of Constaninople of 1773 is worse than the English standard: its afay is 2 car. 23/12 gr.; its weight 2 dwt. 53/12 gr.; its contents in pure gold 43.4 gr., and its Florin value 72.83d. The sequin funduc of 1789 is also worse than the English standard: its afay is 2 car. 33/12 gr.; its weight 2 dwt. 53/12 gr.; its contents in pure gold 42.9 gr., and its value 72.74d. The double sequin madhub of Constaninople of 1773 is better than the English standard: its afay is 1 car.; its weight 3 dwt. 42/12 gr.; its contents in pure gold 73.1 gr., and its value 12r. 113/12d. The sequin madhub of 1789 is worse than the English standard: its afay is 2 car. 5 gr.; its weight 1 dwt. 12 gr.; its contents in pure gold 28.9 gr., and its value 5s. 1d. The sequin of Cairo of 1773 is also worse than the English standard: its afay is 3 car. 1/2 gr.; its weight 1 dwt. 15/12 gr.; its contents in pure gold 31 gr., and its value 5s. 5d. The sequin of Cairo of 1789 is also worse than the English standard: its afay is 5 car. 21/2 gr.; its weight 1 dwt. 15/12 gr.; its contents in pure gold 26.9 gr., and its value 4s. 93/12d.

As the representation of men and animals is forbidden by the Mahometan law, the Turkish coins have no other impressions than inscriptions stating the names, titles, defcent, &c., of their sultans, with the date of the legisra, or Mahometan era. They are in the Arabic language, and the following translations from the principal coins of sultan Selim (1789) may serve as a specimen, as there is but little variety in the form or style of these compositions.

The sequin madhub has on one side, "Sultan Selim, fon of Mustafa Khan," and on the reverse, "Sultan of the two lands, and sovereign of the two seas, sultan by inheritance, fon of a sultan." The words, "May he be victorious, and his value be blest, struck at Constaninople in the year 1203," and on the reverse, "Sultan of the two lands, and soverign of the two seas, sultan by inheritance, son of a sultan." The words, "May he be victorious, and his value be blest," are occasionally used by the Turks at the end of their prayers. By the "two lands," are meant Europe and Asia; and by the "two seas," the Black sea and the Archipelago. The latter is also called here the White sea.

The sequin funduc has on one side, "Sultan Selim, son of Mustafa Khan," and on the reverse, "Struck at Constaninople in the year 1203.

The impressions of sequins of different periods modify answer to either of the foregoing descriptions; but the sequins cast at Cairo, under sultan Abdulhamid in 1773, have their inscriptions as follows: "Sultan Abdulhamid, son of Ahmed Khan, may his value be blest, struck in Egypt in the year 1187," and on the reverse, the titles as on the sequin madhub of Selim.

The pieces of two, three, four, and five sequins bear the same inscriptions as the single sequin, and they are sometimes also encircled with ornaments.

The sequins of the Barby flates are coined in the name of the grand sigior, and are only distinguished by the words, "Struck at Tunis, Tripoli," &c. They bear on the reverse the titles as on the sequin madhub of Selim.

Kelly's Un. Cambiat.

SERA, in Ancient Geography, a town of Serica, which had the title of metropolis, according to Ptolemy.

SERA, in Geography, a town of Hinduotan, and capital of a district, once a confederate sultan, conquered by Hyder Ali; taken from the dominions of his son Tipoo, and given to the Nizam in the year 1800; 58 miles N.W. of Bangalore. N. lat. 13° 28'. E. long. 75° 54'.-Also, a town of Hindostan, in Guzarat; 24 miles S. of Dungarpur.

SERA Capriola, a town of Naples, in the province of Capitanata; 14 miles S.S.E. of Ternola.

SERA, a district of Adirbeiztan, or Azerbaijan, and a town, 15 miles E. of Tabriz.

SERAIS, in Ancient Geography, a river of Hiþpania, in the Tarragonenses. Ptolemy.

SEARACH, in the Turkish Military Orders, an officer who holds the stagg of the cities of the janizaries in charge, attends him when he goes out on horseback, and serves him as a messenger on all occasions. After this office he has the title of chouv; and after he has passed through this, he has the same office under the age of the janizaries. Pococke's Egypt, p. 168.

SERA COYNA, in Geography, a town of Bengal; 38 miles E.S.E. of Calamabad.

SERA CORRO, a town of Africa, in Bambarra; 80 miles W.N.W. of Segu.

SERAES, or SERKAS, a town of Periza, in the province of Khorasan; 180 miles N.N.W. of Herat. The Tedzian has its source near this place.

SERA FISSINI, in Biography, an Italian singer with a fecable soprano voice, but so good an actor, that in 1754, when Metaltafio's "Attilio Regolo," set by Haffe, was performed in London, in the last scene of this opera, which ends with an accompanied recitative, without an air, he was constantly encored: but perhaps it was the poet who
was encored; for the addio of Regulus, returning to Carthage to certain torture and death, in spite of the prayers and intertreaties of his family and all Rome, is so characteristic and truly Roman, that it must have struck every one who had the least knowledge of the Italian language, and the inflexible virtue of Regulus.

SERAGANORE, in Geography, a town of Hindooflan, in the Carnatic; 5 miles S.S.W. of Ottotare.

SERAGE, in Ornithology, an English name for a bird of the larus, or gull-kind, more usually called the _sea-swallow_, and by authors _fervus_.

SERAGIO, in Geography, a town of the illand of Corsica; 6 miles S. of Corve.

SERAGLIO, a district of Italy, south of Mantua, in which Augustus had some poiffessions; called also "Virginian Fields.”

SERAGLIO, formed of the Turkish word _servis_, which is borrowed from the Persian _قار_ signifies a _house_ among the Levantines denotes the palace of a prince or lord. At Constantinople they fay, the seraglio of the ambassador of England, of France, &c.

The seraglio is used, by way of eminence, for the palace of the grand feignor at Constantinople, where he keeps his court, and where his concubines are lodged, and where the youth are trained up for the chief poiffors of the empire.

It is a triangle about three Italian miles round, wholly within the city, at the end of the promontory Chryfoceras, now called the Seraglio Point. The buildings run back to the top of the hill, and from thence are gardens that reach to the edge of the sea. It is inclosed with a very high and strong wall, upon which there are several watch towers: and it has many gates, some of which open towards the sea-side, and the rest into the city; but the chief gate is one of the latter, which is constantly guarded by a company of paffonees, or potters; and in the night it is well guarded towards the sea.

The outward appearance, du Loir tells us, is not beautiful, in regard the architecture is irregular, being cantoned out into separate edifices and apartments, in manner of pavilions and domes. No stranger, it is faid, has ever yet been admitted to the innomt parts of the seraglio. See _Sultana_.

The old seraglio is the place where the emperor’s old military, who have died or who have been depofed, and the fultanas that have belonged to the defeased grand feignors, are kept.

They are here fed and maintained with some luxury, and served with much attention, but they can no longer go out of this place of reftoration; for it would not be decent, in the estimation of the Maffulmans, that a flaw, fuppofed to have enjoyed the favours of a fultan, should pafs into the arms of another man.

The harem is that quartar of the seraglio in which the females are kept. This is soon repleniied, because traders come from all parts to offer young slaves, and the puchaf and great men are eager to prefent beauties capable of fixing the attention of the sovereign; thus hoping to obtain iniately his good graces, and place about his perfon the women who at fome future time may be ufeful to them.

It is very difficult, and perhaps impoffible, to learn exactly the manner in which the female slaves are treated in the harem of the grand feignor: never has the eye of the obfervor penetrated into this abode of hatred, jealousy, and pride; into this abode where pleafure and love have fo seldom refided. But, according to the account of the women, whose profession calls them thither, the reader may repreffent to himself three or four hundred black eunuchs, malicious, peevifh, tormented by their impotence, curving their nullity, endeavouring to counteract the female slaves intruded to their charge; then a confiderable number of young women, whose hearts would willingly expand, whose fenses are moved by the idea of the pleasures which they wish in vain to know, jealous of the happiness which they are perfuaded that their rivals enjoy, curving the overfeers who perplex them, folely taken up with their toilet, with their drefs, and with all the nonefe which idlenefs and ignorance can fuggeft to them; racking, rather from vanity than from love, every means of pleafing a matter, too frequently difdaining. We may repreffent to ourselves, in short, a fultan young or old, fuffered by ridiculous prejudices, without delicacy, often whimifical or capricious, alone in the midst of five or fix hundred women, all equally beautiful, in whom he gives birth to defires which he is unable to gratify, who enjoys with them no pleasures but fuch as are too eafy and without prelude, in which the heart has no share, and we fhall have a true idea of what paffes in the harem of the grand feignor.

The charge of the women is intruded only to black eunuchs, whose mutilation is fuch, that there remains no trace of their fex. Oriental jealousy has very rightly judged, that fuch creatures were rather capable of infpiring sentiments of hatred and contempt, than thofe of affection and friendship, which would not have failed to take birth, if the charge of the harem had been intruded to women. It was not enough to condemn these unfortunate females to long privations, never to let them know of love only what was to excite in them defires, it was even necffary to deprive them of the conftillation of opening their heart in the bofom of friendship.

The chief of the black eunuchs, called _kiflar-aga_, is one of the great pois of the empire: he is who carries to the female slaves the will of his master; he is who announces to them the fatisfactions which they have to please him. Independently of the authority which he exercises in the harem, he has the fuperintendance of all the imperial mofques; he is charged with the general administration of all the pious foundations which relate to them; he has the pre-eminence over the chief of the white eunuchs, and what is more flattering to a flaw, he more frequently approaches his master; and more commonly enjoys his confidence. His income is very confiderable.

The _khatun-sekili_ is the second eunuch of the seraglio: he replaces the _kiflar-aga_ when he dies, or is turned out of office. He has the general administration of the interior imperial mofque, which must be dilinguished from the private treafure of the grand feignor, adminiftered by the _khatun-adora-aga_, one of the pages of confidence. There are some other eunuchs raised in dignity, fuch as he who belongs to the queen-mother, he to whom the care of the princes is intruded, whofe converse is fentiment, whofe who ferve the royal moifque of the fultana Valide, whether the flavés of the grand feignor go to pay their prayers; he who has the particular fuperintendance of the apartment of the _bâbée_; and a few others whose functions are less important.

The white eunuchs do not approach the women: they are employed out of the harem, and in the particular fervice of the fultan. They have the charge of the gates of the seraglio; they fuperintend and intruft the pages. Their chief is called _kapou-aga_. (See _Capi-aga_.) For an account of other officers of the seraglio, fee _Bostangi-baschi, Ichoglans, and Catog_.

Balzac obferves, that the seraglio at Constantinople is only a copy of that which Solomon anciently built at Jerusalem, for his wives and concubines. For a particular description

SERAI, in Geography, a town of Asiatic Turkey, in Natolia; 24 miles E. of Cai'tamena.—Allo, a town of the defect of Syria; 30 miles E. of Aleppo.—Allo, a town of Hindoostan, in the cirec of Naderbar; 20 miles S.S.W. of Naderbar.

SEARING, a town of France, in the department of the Ourte, and chief place of a canton, in the district of Liege. The place contains 2503, and the canton 6400 inhabitants, on a territory of 92½ square miles, in 7 communes.

SERAGO, or SOSSA SERAGO, a town of European Turkey, in Bofnia, situated on the river Bofna, and the residence of a faniqaj. It is large, rich, and commercial, and the fee of a Catholic bishop, appointed by the king of Hungary; 118 miles W. of Belgrade. N. lat. 44° 26'. E. long. 18°.

SEAKINO, a small Greek island, which, together with Drini, afford a place of shelter to navigators.

SEAMICA, a river of Surnam, which runs into the Atlantic, N. lat. 5° 54'. W. long. 55° 38'.

SEAMPUR, a town of Hindoostan, near the river Hooquy; 12 miles N. of Calcutta.—Allo, a town of Hindoostan, in the country of Bahar; 75 miles S.E. of Bahar.—Allo, a town of Bengal; 40 miles S. of Dacca. N. lat. 23° 4'. E. long. 90° 40'.—Allo, a town of Bengal; 20 miles S.E. of Curvackdeo. N. lat. 24° 0'. E. long. 86° 28'.—Allo, a town of Bengal; 37 miles N.W. of Burdwan.

SEANGAN, a cluffter of three small islands in the East Indian Sea; one of them about 15 miles long and 3 broad, and the other two smaller. N. lat. 5° 25'. E. long. 125° 26'.

SEANGODES, a word used originally as an epithet for the pumice-flone, and exprressing cavernous, spungy, or full of holes. It has been hence applied to finest ulcers, and to all sorts of things that are cavernous, or of a spungy texture.

SEAPGUNGE, in Geography, a town of Bengal; 28 miles N. of Maidulah.

SESAPH, or SERAPHIM, in the Hierarchy of Angels, a spirit supposed to be of the firit or highest rank.

The seraphs, or rather seraphim, make that clafs of angels, supposed to be the most inflamed with divine love, by their nearer and more immediate attendance on the throne, and to communicate their heat to the inferior and remoter orders: hence their name, which is formed from the Hebrew root הַרַּפִּים, to burn, inflame.

Seraph is also said to be the name of a Turkiff gold coin, worth about 5½ florins.

Seraph's Head, in Heraldry, is used to denote a child's head, with three pair of wings, viz. two in chief, two in fette, and two in bafe.

SERAPHIC, something belonging to the seraphim.

Mr. Boyle has a treatife of seraphic love, i.e. of divine love, or the love of God.

In the schools, St. Bonaventure is called the Seraphic Doctor, from his abundant zeal and fervour.

St. Francis, founder of the Cordeliers and Franciscans, is called the Seraphic Father, in memory of a vision he faw on mount Alverna.

SERAPHIM. See SERAPH.

SERAPHIM, Order of, in Heraldry, otherwise furnamed of Jfus, was instituted in Sweden, in 1334, by Magnus II. king of Sweden, in memory of the fiege of the metropolis of Upfal; and not, as some authors say, by Eric the Great, called Sneek; nor by Gullavan I., as others ima-
gine. Upon the change of religion which happened in Sweden, under Charles IX., this order was abolished; but it was revived, February the 11th, in the year 1748, by Frederic I., king of Sweden. The habit of the order is a white fattin jacket, trimmed with black lace, and lined with black; with white breeches, shoes, and stockings, trimmed with black, and black ribbons; a black fattin short cloak, lined with white, the cape being white, trimmed with black lace; a hat of black fattin, bound with white, having on the left side four white orffich feathers, and in the middle of them one black feather. Upon the left breast of the cloak is a star of eight points, embroidered in silver; and upon the jacket, on the same fide, is the like star, but somewhat less in fize. The collar of the order is composed of eleven golden heads of seraphs, with wings expanded, and eleven blue patriarchal crosses, enamelled on gold, all joined with chains of the latt. To the collar is fupended the ensign of the order, viz. a star of eight points, enamelled white, the centre blue, with the arms of Sweden, and the initial letters, I.H.S.; over the H. a crofs; the arms inclosed with four seraphs' heads, as in the collar; in the arms, under the bottom crown, the paffion-nails. N.B. The seraphs' heads are between the double points of the star; and over the upward points is the royal crown of Sweden, by which it is pendant to the collar. The ensign alfo is pendant to a broad sky-blue watered ribbon, worn scarlet, and brought over the right shoulder, and under the left arm.

SERAPIAS, in Botany, one of the poetic names, derived from Serapis, the Egyptian idol. The Serapis of Pliny was evidently, from his description, a plant of the Orchis tribe, with globular roots, and supposed to have an aphrodisiacal quality. Hence Linnaeus retains the above name for a genus of the fame natural order, which, according to his characters and idea, was more ample than botanists at present make it, including many species of our Epidactylus. (See that article.)—Linn. Gen. 462. Schreb. 603. Wild. Sp. Pl. v. 4. 70. Mart. Mill. Dict. v. 4. Swartz Act. Holm. for 1800. 225. t. 3. f. H. Schrad. New Journ. v. 1. 47. t. 1. f. H. Jull. 65. Brown in Ait. Hort. Kew. v. 5. 194. Sm. Prodr. Fl. Graec. Sibth. v. 2. 218.—Clafs and order, Gynandria Monandria. Nat. Ord. Orchidace.

Gen. Ch. Cal. Perianth superior, of three ovate, pointed, concave, converging, equal leaves. Cor. Petals two, lanceolate, acute, smaller than the calyx, and concealed within it. Nercty a lip, without a spur; concave at the bafe; its terminal bome large, undivided, pointed, dependent. Stamina none; anther oblong, erect, attached in a parallel manner to the fore part of the style, of two cells, opening in front; the nucells of pollen club-shaped, attached themselves, each by its taper bafe, to a gland by the stigma, in one and the fame pouch; Brown. Pfl. Gemmen inferior, obovate, furrowed; style elongated, erect, with a taper point extended above the anther; stigma in front, below the anther, concave. Peric. Capsule obovate, of one cell, with three ribs, curviting longitudinally between the ribs. Seeds very numerous, minute, roundish, each with a chaffy tuft.

Eff. Calyx converging. Nercty a lip without a spur; concave at the bafe; its terminal bome very large, dependent, undivided. Anther parallel to the style, fur-mounted by a point.

Serapions

Rudb. Elyf. v. 2. 204. Orchidæ Etrurie; Petiv. Gaz. t. 128. f. 1—3? Tellucrii species tertia; Matth. Valgr. v. 2. 233. f. 1. Dalech. Hist. 1531.—Lateral segments of the lip erect; middle one ovate, smooth.—Native of open mountainous situations in the south of Europe. Dr. Sibthorp gathered it in Zante, as well as in Greece, and we readily affirm to the opinion of a learned German writer, in the Allgemeine Literatur-Zeitung, for June 1807, n. 133. 1060, that this plant, and not Iris tectoria, is probably the true Aegyptis of Dioscorides. The root consists of two flatted, roundish knobs, like others of this tribe, but rather smaller. Stem a foot high, clothed on the lower part with laciniolate, sheathing, smooth leaves. Spike of from two to eight flowers, with a large, concave, purplish-grey bractea to each. Calyx ribbed, of the same colour as the bractea, and pointed like them, three quarters of an inch long. Lip twice that length; its disk whitish, with a dark red, oblong, undivided elevation at the base, and two rounded, erect, lateral lobes, of the same colour; the central lobe dependent, ovate, pointed, undulated, purplish, wavy, smooth. Haller justly refers both the above synonyms of Rudbeck to this species.

2. S. cordigera. Heart-lipped Serapion. Linnae., Sp. Pl. 1835. Wildl. n. 2. Ait. n. 2. Sm. Fl. Grec. Sibth. t. 932, unpublished. Andr. Rep. t. 475. (Orchis montana italic, flore ferrugineo, lingua oblonga; Rudb. Elyf. v. 2. 204. f. 18. O. Elyric, lingua ferruginea pilosa; Petiv. Gaz. t. 128. f. 4.)—Lateral segments of the lip erect; middle one heart-shaped, hairy.—More frequent than the foregoing in the south of Europe, and north of Africa, in the same kind of situations. We gathered it in July 1787, in pastures at St. Orsélie, near Genoa. The whole plant, especially the bulbs and flowers, are larger than in S. lingua, and the whole spike is of a more dingy hue. The colour, however, of the different parts is variable in both. The broad hairy lip of cordigera, with a divided glandular elevation at its base, is sufficiently characteristic. We trust we are right in the citation of Rudbeck, and that he misquotes Matthioli.

Wildenow's S. oxyglossa, founded solely on Petiver's t. 128. f. 5 & 6, appears to us too uncertain to be adopted, though we doubt not that some distinct species of this order, and perhaps of this genus, are still latent in Italy. SERAPIONS, in the Materia Medica, the official name of the dried root, called falep.

SERAPION, of Alexandria, in Biography, lived about the year 280 before Christ, or in the 125th Olympiad, and is affirmed by Celsus to have been the founder of the empire of phthisicians, and accused by Galen of vaunting himself, and of maltreating the character of Hippocrates. (See EMPEROR.) He was probably a contemporary of Philinus, to whom also the origin of the same sect has been attributed. See Celsus, Pref.

SERAPION, John, or John, the Son of Serapion, an Arabian physician, lived during the time of Meucc and Rhazes, and was probably the first writer on phthisic in the Arabic language; for it appears that Meucc, like his predecessor Aaron, or Ahron, wrote in the Syracague tongue. Haly Abbas, when giving an account of the works of his countrymen, describes the writings of Serapion, as containing only an account of the cure of diseases, without any precepts concerning the preservation of health, or relating to surgery; and he makes many critical observations, which, Dr. Freind observes, are sufficient proofs of the genuine existence of the works ascribed to Serapion, from their truth and correctness. Rhazes also quotes them frequently in his "Continent." Serapion must have lived towards the middle of the ninth century, and not in the reign of Leo Iaurus, about the year 730, as some have stated. One circumstance remarkable in Serapion, Dr. Freind observes, is, that he often transcribes the writings of Alexander Trallian, an author with whom few of the other Arabians appear to be much acquainted.

This work of Serapion has been published, in translations, by Gerard of Cremona, under the title of "Practica. Dicta Breviarum," and by Torinus, under that of "Therapeutica Methodus." See Freind's History of Phythe, and Sprengel Geschiche der Arzneykunde, n. 355.

Some confusion appears to exist respecting another Serapion, whom Sprengel calls the younger, and places 180 years later than the former, and who was probably the author of a work on the materia medica, entitled "De Medicamentis tam simplicibus, quam compostis." This work bears intrinsic evidence of being produced at a much later period, since authors are quoted who lived much posterior to Rhazes. It is probable that this work, which must obviously have been composed in the latter part of the eleventh century, (for Avenzoar, who wrote in that century, is quoted in it,) is the same with that which is often cited by Constantine, the African, under the name of Joannes Danacenus, a name which some authors erroneously given to the elder Serapion, instead of the subject of the present article; and some to Melus; to the latter of whom Freind has shown that it could not belong. See Freind and Sprengel, as above quoted.

SERAPIONS Portus et Promontorium, in Ancient Geography, a port and promontory of Ethiopia, between Ellinna emporium and Tomis emporium, according to Ptolemy.

SERAPIS, in Mythology, an Egyptian deity, who was worshipped under various names and attributes, as the tutelary god of Egypt in general, and as the patron of several of their principal cities.

It is impossible for us, that was worshipped as a kind of universal deity that represented Eculapius, O'iris, Jupiter, and Pluto; and he was sometimes taken for Jupiter Ammon, the Sun, and Neptune; and the honours that were rendered to him at Alexandria were more solemn and extraordinary than those of any other place.

Learned writers have differed in opinion as to the time of the introduction of this deity into Egypt; some have supposed that he was known and worshipped in this country long before the time of the First Ptolemy, and that he was the same with their Apis; Serapis being no other than Apis to Lacon, i.e. Apis in his coffin. Accordingly, they say, that while the sacred bull, which the Egyptians worshipped for their great god, was alive, he was called Apis; and that when he was dead and buried in his coffin, he was called Serapis, that is, Apis in feto, and thus they derive his name by corruption from saropis; and some have even imagined that the patriarch Joseph was worshipped under this title; but to this etymology it has been objected, that as the Ptolemies first brought the Greek language into Egypt, if Serapis had been an ancient god worshipped in that country before the Ptolemies reigned there, his name could not have had a Greek etymology.

According to the learned Mr. Bryant, sar signifies any thing noble; and O'iris, the great husbandman, who had been exposed in an ark, was styled sar-apis, which signifies illustris genitor., the great father of mankind. But, he observes, that there was likewise the term sar, from whence came the σαρός of the Greeks, which signified a scar or coffin, and also a place of interment. Hence the temple where the dead Apis was deposited, had the name of Sar-apis, rendered inaccurately sarapis.

Plutarch,
Plutarch, who did not know this dilution, fancied that some people in Egypt would not allow forapis to have been a god; the dispute was about the found of a word; no Egyptian could deny the divinity of the god Serapis, but Ser-apis had another meaning; and this was the term in debate. Upon the whole he concludes, that the demon, or deified man, was Sar-apis, and that for-apis was the tomb of Apis. Analyis of Ancient Mythology, vol. ii. p. 428.

Others have maintained, that Serapis was not originally an Egyptian deity, anciently worshipped in that country, but an adventitious god brought thither from abroad. The ancient place of his institution, according to Polybius, was on the coast of the Propontis, on the Thracian side, over against Hieras; and there Jason, when he went on the Argo- nautic expedition, sacrificed to him. Thence his image was brought to Sinope in Pontus; and from Sinope, Ptolemy, the first of that name, in obedience, as it is said, to a supernatural direction, brought it to Alexandria, and set it up in one of the suburbs of that city, called Rhacotis, where it was worshipped by the name of Serapis; and this new god had in that place, soon after, a very famous temple erected to him, called the Serapeum. This temple, says Ammianus Marcellinus, did, in the magnificence and ornaments of its buildings, exceed all other edifices in the world, next to that of the Capitol at Rome. Hence Serapis became the god of the court, and led the Egyptians almost to forget their ancient gods. The provinces vied with each other in building temples to him, and burning incense on his altar. The most ancient temple, according to Paufanias, was that at Memphis.

And this, say the advocates of this opinion, was the first time that this deity was either worshipped or known in Egypt.

Ptolemy found great difficulty in obtaining this image; but the inhabitants of Sinope, being oppressed with a grievous famine, were relieved by Ptolemy with a fleet of corn, and in return they consented to part with the image of their god.

The statue of Serapis, according to Macrobius, was of a human form, with a basket or bunchel on his head, resembling plenty, and referring, as some say, to the history of Jophiel's supplying the Egyptians with corn; or, according to others, to the relief of Sinope by Ptolemy: his right hand leaned on the head of a serpent, whose body was wound round a figure with three heads of a dog, a lion, and a wolf; in his left he held a measure of a cubit length, as it were, to take the height of the waters of the Nile.

Those who maintain that Serapis was a foreign god, unknown to the Egyptians before the time of the Ptolemies, argue, that Herodotus, who dilates in his account of the Egyptian gods, makes no mention of Serapis: which he probably would have done, if he had been one of the great gods of that people. Moreover, the Icasis table, upon which so many Egyptian deities appear, presents us with nothing that resembles Serapis. Besides, Tacitus relates, that Serapis appeared in a dream to Ptolemy, under the figure of an exquisitely beautiful young man, and ordered him to send two of his most faithful friends to Sinope, a city of Pontus, where he was worshipped, and to bring his statue from thence. Ptolemy, having communicated this vision, deputed a seer of embassied to Sinope, and from thence the statue of that god was brought. Hence it is concluded that he was unknown in Egypt before this event.

On the other hand, those who contend that Serapis was one of the great gods of Egypt, where he was worshipped before the time of the Ptolemies, allege, that before the testimony of Tacitus can be admitted, it must be proved that Serapis was the deity actually worshipped at Sinope, whereas, they say, that the god to whom that city paid adoration was Pluto; and that the name Serapis was not given to him till his statue was brought into Egypt. Plutarch testifies, that he had not that name when he came into Egypt; but upon his arrival at Alexandria, he took the name which the Egyptians gave to Pluto, which was Serapis. When Paufanias relates, that the Alexandrians received from Ptolemy the worship of Serapis, he says, at the same time, that there was already at Alexandria a very magnificent temple of that god; and another, not so grand, but of great antiquity, in the city of Memphis. Tacitus himself, when he says that Ptolemy, after Serapis was brought into Egypt, built a flatly temple to him in the place named Rhacotis, affirms also, that there was another smaller one, consecrated to the same god, and to Isis; which proves, not that Serapis was not worshipped in Egypt till the time of the embassy to Sinope, but only that the worship of that god, perhaps neglected for a long time, was re-established there with solemnity. The silence of Herodotus, and the omission in the Icasis table, may be accounted for by the following considerations. Though it is true that Herodotus set apart his second book for the history of the Egyptian religion, yet we cannot be sure that he has omitted none of their gods. Besides, having spoken fully of Osiris, who was perhaps the same face with Serapis, he might think it needful to say any thing particularly of the latter. The fame observia is applicable to the Icasis table. Although a great number of the Egyptian gods may be found there, yet it cannot be affirmed that they are all there, and much less that they can all be distinguished by their particular symbols. The proof drawn from the diversity of representations is yet less conclusive. The Egyptians varied exceedingly with respect to the figures of their gods, and the symbols annexed to them. The figures frequently bore a vast number of attributes, which could not agree to a single divinity. These are what have been called the Pantheon figures, which represented several deities; as any one may be convinced by viewing some of those of Isis, of Harpocrates, and others. From these and some other considerations, many learned men have inferred that Serapis was an Egyptian god, known and worshipped by that people long before the time of the Ptolemies; and that he was the same with Pluto; and though the testimonies of Tacitus and Plutarch, above cited, were less conclusive than they are, yet one of the finest statues of that god, at whose feet we see the three-headed Cerberus, would leave no room to doubt. See a print of this figure in Montfaucon's Antiquity s, tom. ii. p. 185. Antiquarians have furnished us with several other figures, always known to be those of Serapis by the calathus, or a kind of bonnet which he wore upon his head. Sometimes he is joined with Isis, and represented like a young man, and then he is taken for Osiris or the Sun; frequently like a bearded old man, very much resembling Jupiter, whose name he also bore; at last, from the time that the Greeks became masters of Egypt, Varro says, that there was a law which forbade saying, under pain of death, that Serapis had been a mortal man. We shall here add, that Osiris was variously represented, sometimes by a sceptre and eye, to express his power and providence; at other times, by the image of a hawk, because of its sharp fight, swiftness, and other qualities; and in later times, in a human form, in a posture not very decent, signifying his generative and nutritive faculty; but the greatest adoration was paid to his living image, the bull.

The image of Isis was usually in the form of a woman, with cow's horns on her head, representing the appearance
of the moon in her increase and decrease, and holding the sistra (a kind of cymbal) in her right hand, and a pitcher in her left; the former signifying the perpetual motion there is in nature, and the other the fecundity of the Nile. But sometimes she was represented as Cybele, having her body full of breasts, to express her prolificall of all things.

It is observed, that when Serapis was introduced into Egypt, at the period above-mentioned, as writers have inferred from the silence of Herodotus, and of other authors who wrote before the times of the Ptolemies, he brought in with him among the Egyptians, a new way of worshipping: for till the time of the Ptolemies, the Egyptians never offered any bloody sacrifice to their gods, but worshipped them merely with their prayers and frugality; but the tyranny of these princes having forced upon them the worship of two foreign gods, viz. Saturn and Serapis, they in this worship first introduced the use of bloody sacrifices among that people. And to avert these were the Egyptians to this mode of worshipping, that they would never suffer any temple to be built to either of these gods within any of the walls of their cities, but they were always erected in their suburbs: and they seem to be only Egyptians of the Greek original who conformed to this practice, and not those of the old race. See Exod. viii. 26, 27. Prid. Conv. vol. iii. p. 15, &c.

The famous temple of Serapis at Alexandria was destroyed by order of Theodotus; and the celebrated statue of this deity was broken in pieces, and its limbs carried in triumph by the Christians throughout the city, and then thrown into a fierce fire, kindled for that purpose in the amphitheatre. As the Egyptians ascribed the overflowing of the Nile, to which was owing the fertility of that country, to the benign influence of their god Serapis, they concluded, that, now he was destroyed, the river would no longer overflow, and that a general famine would ensue; but when they observed, on the contrary, that the Nile swelled to a greater height than had been known in the memory of man, and thereby produced an immense plenty of all kinds of provisions, many of the pagans, renouncing the worship of idols, adored the God of the Christians. Ancient Univ. Hist. vol. vi. p. 417.

The figure of Serapis is found on many ancient medals.

SERAPIS, in Ancient Geography, a place of Egypt, beyond the Nile, between Heracleopolis and Chifino, according to the Itinerary of Antonine.

SERAQUINO, in Geography, an island in the Grecian Archipelago; 8 miles N.E. of Scopelo.

SERARIUS, Nicholas, in Biography, a learned Jew, was born at Ramberwille, in Lorraine, in 1555. He studied at Cologne, where he entered into the society of the Jesuits, and afterwards was for twenty-four years a professor of the languages of philosophy and theology at Wurtzburg. He died at Mentz in 1609, having, besides his employment in teaching, occupied himself in the composition of a vast number of works, which were printed collectively at Mentz, in 3 vols. folio. Of these, the most esteemed were "Commentaries on several Books of Scripture." "Prolegomena on the Holy Scriptures;" "Trilingual, feu de ceberebrum tribus, apud Judaeos, Phari
daeos, Sadduceos, et Elenorum Secetis." This last work was afterwards printed at Delft, with the addition of the treatises of Drufius and Scaliger on the same subject. Serarius was a strenuous defender of the church of Rome against the reformers, and wrote several works against Luther and his followers. Cardinal Baronius gives him the title of "the luminary of the Germanic church." Dupin says, that the Prolegomena of Serarius have a great deal of unction, but that he handles his quellions in too scholastic a manner, and mixes up too much controversy in them; he thus sums up the literary character of this author: "Serarius," says he, "was very learned, and well versified in the languages, and in topics relating to the Holy Scriptures: he is not equally exact in ecclesiastical history, nor equally powerful in controversy. He wrote with ease, but withoutPoliticka. In treating on a subject, he often defends to impertinent and tedious tripping, and sometimes wanders from the point to attack the Protestants, and discuss controversal questions."

SERASAPOUR, in Geography, a town of Hindoostan, in Bahar; 18 miles W. of Bahar.

SERASKER, a Turkish word, composed of fer, which in Persian signifies head, and after, i.e. soldiers. This is a military degree, that admits of no superior, somewhat like generalissimo, and is a title given to those who command on the frontiers, or are detached with a considerable body of troops.

SERASPARLE, in Ancient Geography, a town of Aina, in the Lesser Armenia, and in the prefecture of Rhanca, according to Ptolemy.

SERAS, in Ornithology, a bird of the same genus with the Colum, which comes yearly to Surat in the Eal Indies, from Mount Cauecous, and distinguished by a plication of the aspera arteria; which is designed to answer similar purposes with that of the colum.

SERAT, SERED, or SERED, in Geography, a town of Hungary, on the river Waag; 27 miles E. of Protburg.

SERATZ, a town of Selavonia; 28 miles N.W. of Polzega.

SERAVAN, in Ornithology, the name given by Buffon to the Loxia Aetrid, which is.

SERAUCOURT, in Geography, a town of France, in the department of the Aifne; 6 miles S. of St. Quinten.

SERAVI, a town of Egypt, on the E. branch of the Nile; 21 miles N. of Cairo.

SERAUSTEH, a town of Candahar; 30 miles S.W. of Cabul.

SERAY, a town of Hindooftan, in Bahar; 12 miles N. of Chuprah. N. lat. 25° 18'. E. long. 84° 53'.—Allo, a town of Hindooftan, in Boggitund; 20 miles W. of Rewah.

SERAYA, a town of Hindooftan, on the right bank of the Jumna; 42 miles S.E. of Agra.—Allo, a town of Hindooftan, in Bahar; 20 miles S. of Bettiah. N. lat. 26° 28'. E. long. 84° 53'.

SERBADJE, a town of Egypt, on the E. bank of the Nile; 20 miles N. of Cairo.

SERBAJEE, in the Eastern Military Orders, is a captain in the horse in the service of the grand feignoor.

SERBAR, in Geography, a town of Peria, in the province of Meckan; 50 miles N.W. of Kidge.

SERBATIS, Yisser, in Ancient Geography, a river of Africa, in the eastern part of Mauritania Caofarien, which discharged itself into the Mediterranean, to the E. of Ruf
guinio colonia. Ptolemy places its mouth between Modunga and Ciffa.

SERBI, a people of Asian Sarmatia, who dwelled with the Orinxi and Vali, between the Ceraunian mountains and the river Rha, according to Ptolemy.—Allo, a people called likewise Scythians, who inhabited a territory towards Dalmatia.

SERBINUM, a town of Lower Pannonia, along the Danube.

SERBONIS LACUS, or Serbonis lake, a lake which was situated between Egypt and Palestine, near mount Ca
dius;
and eight from the hills, and the town consists of 250 huts, defended by a mud fort.

SEREGIPPE. See Seregipe.

SEREGNAN, a town of Tyrol; 8 miles N.N.E. of Trent.

SEREGNO, a town of Italy, in the duchy of Milan; 10 miles N. of Milan.

SUIIIL, Feather of a Hawk, the name which answers to pinions in any other fowls.

SERELON, in Geography, a town of Spain, in the province of Elbaramada; 30 miles S. of Palencia.

SERENA, a, town of Spain, in the province of Elbaramada; 18 miles E.S.E. of Merida.

SERENA, a river of Chili, which runs into the South Pacific ocean, near Coguimbo; which lake.

SERNA, in Geography, the name of a mushroom.

SERNADE, an evening concert, given by a lady under the window of his mistress. It generally consists of instrumental music; sometimes, however, vocal is added. These pieces in Italy are also called serenate. The mode of serenading, says Rouleau, has been long discontinued, unless by the common people; and its discontinuance is to be lamented. The silence of the night, which banishes all distraction, gives music additional charms, and renders it more delicious. In the summer of 1770, this was not the case at Venice, six years after Rouleau's Dictionary was written; as we find in our journal, during the month of August of that year, the following memoranda. "The people here (at Venice) during summer, seem to begin to live only at midnight. Then the canals are crowded with gondolas, and St. Mark's square with company; the banks too of the canals are all crowded, and harmony prevails in every part. If two of the common people walk together arm in arm, they seem to converse in loud; if there is company on the water, in a gondola, it is the fame; a mere melody, unaccompanied with a second part, is not to be heard in the city; all the ballads in the streets are fung in dou. Luckily for us, this night, August 7th, a barge, in which there was an excellent band of music, consisting of violins, flutes, horns, bagpipes, and a kettle-drum, with a pretty good tenor voice, was on the great canal, and floated very near the house where we lodged; it was a piece of gallantry, at the expense of an innovero in order to serenade his mistress. Shakspere says of nocturnal music,

"Methinks it sounds much sweeter than by day.
Silence beffows the virtue on it—"I think
The nightingale, if she should sing by day,
When every goose is cackling, would be thought
No better a musician than the wren."

Whether the time, place, and manner of performing this music, gave it adventitious and collateral charms, we will not pretend to say; but all we know is, that the symphonies formed to us, to be admirable, full of fancy, full of fire; the ballads well contrived; sometimes the graceful, sometimes the pathetic prevailed; and sometimes, however strange it may be thought, even noise and fury had their effect.

SERENE, SERENITY, a quality or title of honour given to certain princes, and chief magistrates of republics.

The king of England is styled, the most serene; the same term is also applied to the doge of Venice. The pope and the sacred college, writing to the emperor, to kings, or the doge, give them no other title but that of most serene. Indeed the Venetians let the title of serenity above that of highness.

In 1646, Wicquefort observes, there was a clashing between the courts of France and Vienna, because the emperor refuted
SER

refused the king of France any other title than that of
serene. Bishops also were anciently addressed under the title
of serene.

The kings of France, of the first and second race, speaking
of themselves, use no other quality but notre sérenité.
The emperor gives no other title to the king of England,
nor even to any other king, excepting the king of France.
The king of Poland, and other kings, give it to the electors.
The emperor, writing to the electors, or other princes of the
empire, only uses the term dition; but in treating with
them he uses électoral sérenité to the electors, and dueal sérenité
to the other princes.

SERENE, in Geography, a small island in the Red sea.

N. lat. 19° 30' E. long. 39° 50'.

SERENT, a town of France, in the department of the
Morbihan; 13 miles N.E. of Vannes.

SERENUS, Samonicus, Quintus, in Biography, a
Roman physician in the reigns of Severus and Caracalla,
who was attached at a banquet by the order of the last
mentioned emperor. He left an immense library, said to
contain twenty thousand volumes, to his son, who was pre-
ceptor to the younger Gordian, to whom he presented this
valuable bequest. Serenus was the author of several works
on history and the products of nature; and also of a medical
work in verse, which has passed through a multitude of
editions, under the title of "Carmen de Medicina." He
was superstitious in the choice of his remedies, and especially
in that which he professed for the Semiticiis feve, which
confisted in wearing about the neck, suspended by a linen
thread, a piece of paper, on which was written the word
de la Méd.

SERENZ, in Geography, a town of Hungary; 9 miles
W. of Tokay.

SERERES, a people of Africa, in the vicinity of Cape
Verd, differing into several small republics, which unite
into one body against a common enemy. Their laws are
merely those of nature. They wear no clothing, and they
have little or no idea of a Supreme Being or future life;
nevertheless they seem to be indifferent, unacquainted with
strong liquors, inoffensive, and hospitable to strangers.

SERES, in Ancient Geography, a name given to those
people who were situated to the call of India, and who,
by the investigations and discoveries of the moderns, are sup-
poited to have inhabited Serica. They were renowned for
their justice, according to Melis, and for their longevity of
200 years, according to Strabo. They had an infect which
produced silk, says Paulus. (See Serica.) People of
the same name were also established in the northern part
of Taprobana.

SERET, in Geography. See Sibet.

SERETIUM, in Ancient Geography, a town of Dalma-
tia. Dion Cassius reports, that Tiberius was obliged to raise
the siege of this town, but that it was afterwards taken by
the Romans.

SERETKINA, in Geography, a town of Russia, in the
government of Irkutsk, on the Angara; 24 miles E.S.E.
of Balgaansko.

SERGA, a town of Russia, on the Volga; 40 miles S. of
Astrakan.

SERGAG, a town of Russia, in the government of
Nizni Novgorod; 48 miles S. of Nizni Novgorod. N.
latt. 56° 51', E. long. 45° 20'.

SERGE, in Commerce, a woollen quilted stuff, manu-
factured on a loom with four treadles, after the manner of
ra-
teens, and other fluffs that have the whale.
The goodness of serges is known by the quilting, as that
of cloths by the spinning.

SERGE, Manufacture of London. For wool, the longest
is chosen for the warp, and the shortest for the woof. Be-
fore either kind is used, it is first scour'd, by putting it in
a copper of liquor, somewhat more than lukewarm, com-
posed of three parts of fair water and one of urine. After
having laid long enough therein for the liquor to disolve,
and take off the geache, &c., it is dried briskly about
with a wooden peel; taken out of the liquor, drained, and
washed in a running water, dried in the flode, beaten with ficks
on a wooden rack, to drive out the couler dirt and filth, and
then picked clean with the hands. Thus carefully prepared, it
is greased with oil of olives, and the longest part, destined
for the warp, is combed with large combs, heated in a little
urn for the purpose. To clear off the oil again, the wool
is put in a liquor composed of hot water, with soap
melted in it: whence being taken out, wrung, and dried,
it is spun on the wheel.

As to the shorter wool, intended for the woof, it is only
carded on the knee with small cards, and then spun on the
wheel, without being scour'd of its oil. Note, the thread
for the warp is always to be spun much finer, and better
twisted than that of the woof.

The wool both for the warp and the woof being spun, and
the thread divided into skeins, that of the woof is put
on poools (unless it have been spun upon them) fit for the
cavity or eye of the shuttle; and that for the warp is
wound on a kind of wooden bobbins to fit it for warping.
When warped it is fuffed with a kind of size, of which that made
of the threads of parchment is held the best; and when dry
is put on the loom.

When mounted on the loom, the workman raising and
falling the threads (which are passed through a reel), by
means of four treads placed under the loom, which
he makes to act transversely, equally and alternately, one
after another, with his feet, in proportion as the threads are
raised and lowered, throws the shuttle across from one side
to the other; and each time that the shuttle is thrown, and
the thread of the woof is croset between those of the warp,
strikes it with the frame to which the reed is fastened,
through whole teets the threads of the warp pass; and this
stroke he repeats twice or thrice, or even more, till he
judges the croset of the ferge sufficiently close; thus he
proceeds till the warp is all filled with woof.

The ferge now taken off the loom is carried to the fuller,
who fulls, or scour's it in the trough of his mill, with a kind
of fat earth, called fullers-earth, first purged of all bones
and filth. After three or four hours scouring, the fullers-
earth is washed out in fair water, brought by little and little
into the trough, out of which it is taken when all the earth
is cleared; then, with a kind of iron pincers, or pryers, they
pull off all the knots, ends, straws, &c. flicking out on the
surface on either side; and then returning it to the fulling
trough, where it is worked with water somewhat more
than lukewarm, with soap dissolved therein for near two
hours: it is then washed out till such time as the water be-
comes quite clear, and there be no suds of soap left; then
it is taken out of the trough, the knots, &c. again pulled
off, and then put on the tenter to dry, taking care as fast as
it dries to stretch it out both in length and breadth till it be
brought to its just dimensions. When well dried, it is taken
off the tenter, and dyed, thorned, and press'd.

SERGEANT. See SERJEANT.
SERGENTIUM, in Ancient Geography, a town situated in the interior of Sicily. Ptolemy.

Sergiev, in Geography, a town of Russia, in the government of Tobolsk, on the Enisei; 72 miles N. of Eniseiik.

Sergievsk, a town of Russia, in the government of Ufa; 80 miles W. of Ufa. N. lat. 54°. E. long. 54' 44'.

Sergievskaja Nova, a fortress of Russia, in the government of Ufa, on the Samara; 56 miles N.W. of Orenburg.

Sergievskoi, a town of Russia, in the province of Uftug, on the Vim; 52 miles N.E. of Yaroslavl.—Alfo, a town of Russia, in the province of Ekaterinburg; 48 miles S.W. of Ekaterinburg.

Sergilus, in Botany, a genus formed by Gartner, v. 2. 409. t. 174. f. 6, of the Linnaean Calea fepartia, Chrysecoma n. 2. Browne Jan. 316. t. 34. f. 4, by the following character. Calyx somewhat turbinate, imbriicately or clove-prelled, unequal, slightly membranous scales. Flowers all perfect and fertile, five-cleft. Receptacle naked. Down capillary, tufted at the summit.

The above author remarks that this plant "differs in its receptacle, as well as head-down, from Calea, but from Chrysecoma in the foot-down only, so that it is nearer akin to the latter. The leaves seem to be sometimes opposite, but are generally very remote, as well as extremely minute." The only species known is 1. S. fepartia. Native of the coldest mountains of Jamaica. Browne says it has the habit of our European broom, being the only tree of the fame appearance, observed by him in that country. Swartz has not noticed this plant. See Calea and Chrysecoma.

Sergines, in Geography, a town of France, in the department of the Yonne, and chief place of a canton, in the district of Sens; 9 miles N. of Sens. The place contains 1484, and the canton 10,094 inhabitants, on a territory of 260 kilometres, in 18 communes.

Sergipe do Conde, a river of Brazil, which runs into the bay of All Saints.

Sergipe, or Sergippe, a captaincy or province of Brazil, which chiefly produces cattle, grain, and tobacco, for which last Brazil is particularly celebrated.—Alfo, the capital of the district, situated near the coast of the Atlantic, on a river of the same name, which runs into the Atlantic, S. lat. 1° 32'. The town is distant 140 miles from St. Salvador. S. lat. 11° 42'. W. long. 38° 36'.

Sergius I., pope, in Biography, was descended from a family at Antioch, but was himself born, and brought up at Palermo. He came to Rome in the time of pope Adeodatus, and entering among the clergy of that capital, was ordained priest by Leo II. On the death of Conon, in the year 687, there was a great schism respecting his successor, one party espousing the cause of Theodore the archpriest, and the other that of Paschal the archdeacon. The principal persons of Rome, not being able to bring them to an agreement, concurred in the choice of Sergius, and put him in possession by force. Theodore infantly renounced his claim, but Paschal did not give up his pretensions for a considerable time. He at length, however, submitted. The second year of the pontificate of Sergius was rendered memorable by the arrival at Rome of Cedwalla, king of the West-Saxons, who came to receive baptism from his hands, and who died soon after he had submitted to that rite. In 691 the emperor Justinian II. assembled a council at Constantinople, in which a number of canons were passed. Five of these were opposed by the pope, among which was one condemning a former canon of the church, that forbade ecclesiastical persons to have any connection with their wives after ordina-

tion. Sergius not only rejected these canons, but on their account invalidated all the proceedings of this council, which on much exasperated the emperor, that he sent his sword-bearer with an order to apprehend the pope, and bring him to Constantinople. The boldness in Italy, however, standing in so much awe of his holiness, not only refused to suffer violence to be offered to him, but intimidated the sword-bearer, that he dared not execute his commission, and was glad to quit Rome in safety. In 696 Sergius consecrated Willibrord bishop of the Frisians, recommended to him by Pepin the elder, as a person every way adapted to undertake the conversion of that heathen people. Sergius died in the year 701, in the 14th year of his pontificate. He had the reputation of much learning and virtue, and is said to have repaired and enriched several churches, which added, in those times, very much to his celebrity.

Sergius II., pope, a Roman, was elected in 844, on the death of Gregory IV. He had a competitor in John, deacon of the Roman church, who took possession of the Lateran, but was expelled by the nobility. Sergius was consecrated immediately after his election, without waiting for the imperial confirmation. Lothaire, the emperor, so much repressed this seeming hostility, that he sent into Italy his son Lewis, whom he had declared king of Lombardy, with a powerful army, attended by his uncle Drogo, archbishop of Metz. This prince, after cruelly ravaging the ecclesiastical state, marched to Rome, and entered the city amidst the acclamations of the people. He proceeded to the Vatican church, in great solemnity, with the pope, and was afterwards crowned by the latter as king of Italy. Sergius now gladly took the accustomed oath of allegiance to the emperor, and received a confirmation of his election. This pontificate, short as it was, is marked by the predatory incursions of the Saracens, who falling upon the Tiber, burnt the suburbs of Rome, and pillaged the churches of St. Peter and St. Paul without the walls. Sergius died in 847. The famous scala-famula, or holy stairs, at Rome, was erected during the pontificate of Sergius II.

Sergius III., pope, a prebendary of the church, though elected by a party, in 898, after the death of Theodore II., was not able to enter upon the duties of his office. A more powerful party supported John IX., and Sergius was glad to seek his safety by flight from the city. He lay in concealment for seven years, during which he contrived to engage in his interest his relation Adelbert, marquis of Tuscany, by whose alliance he was enabled to expel Christoffer, who had forcibly intruded into the pontifical seat, and placed himself there in the year 904. Sergius, who is termed by Baronius, and apparently with good reason, "one of the most wicked of men," had a scandalous connection with the infamous Marozia, who with her mother Theodora, and her sister of the same name, at that time almost entirely governed Rome, and disposed of the holy see. Marozia, who had already been mistres of the marquis Adelbert, bore a son to the pope, who was afterwards raised to the papal throne under the name of John XI., and is the purity of the holy bishops of the Roman church. Sergius received a solemn embassy from Leo, emperor of the East, on account of the refusal of the patriarch Nicholas to confirm the fourth marriage of Leo, as forbidden by the Greek church. Sergius, as there was no limitation to the number of successive marriages in the Roman church, not only approved the marriage of Leo, but sent legates to Constantinople to confirm it. The patriarch, however, could not be prevailed upon to admit its legality. Sergius died in 911. He rebuilt the Lateran church.

Sergius IV., pope, a native of Rome, whose family name is said to have been Peter Buccapori, or in English, Hosp.
Hog's-nout, was bishop of Albano at the time of his election to the papal see in 1009, after the death of John xviii. Little is recorded of the transactions of this pontiff. He sent a legate into France to consecrate a monastic in the diocese of Tours, which the archbishop of that see regarded as an encroachment upon his jurisdiction; he also determined a dispute between the archbishop of Hamburg and the bishop of Verden. He was greatly respected for the mildness of his disposition, and his liberality to the poor. He died in 112.

Sergius 1. patriarch of Constantinople, is well known in ecclesiastical history for the support which he gave to the doctrine of the Monothelites. He was a Syrian by birth, and the son of parents who adhered to the heresy, as it was denominated, of the Monophysites. He was raised to the patriarchal dignity in the year 610. The emperor Heraclius, being disposed of re-uniting the perfected Nestorius to the Greek church, and having held conferences with persons of influence in that sect, was assured by them, that there would be no difficulty in terminating the controversy, provided the Greeks would assent to the following proposition, 'that in Jesus Christ there was, after the union of the two natures, but one will, and one operation.' Sergius thought this proposition might be adopted without the slightest injury to the truth; and without derogating from the authority of the council of Chalcedon, which had condemned the doctrine of a single nature, in consequence of this decision, the emperor issued an edict in the year 639, in favour of the doctrine of the single-will. This hope of concord was soon frustrated, by the violent opposition of Sophronius, a monk, and patriarch of the see of Jerusalem, who also endeavored to gain pope Honorius to his party, but Sergius was beforehand with him, and had persuaded his holiness to approve the doctrine in question. In order to quiet the commotions in the church, Heraclius, in 659, issued an edict composed by Sergius, which was entitled 'Euchesis,' or an exposition of the faith in which all controversies on the question 'whether in Christ there were one or two operations,' were prohibited, though the edict plainly inculcated the doctrine of one will. Sergius died in the same year, and his memory was afterwards anthomized in several councils.

Serinde, in Geography, a town of Hindooftan, in Bednore; 8 miles S.W. of Sacrapatam.

Serk, a town of Hindooftan, in Baglana; 25 miles N. of Baffien.

Serkov, a town of Hindooftan, in Bednore; 25 miles W. of Sacrapatam.

Serjan. See Srian and Kerman.

Sirana, in Botany, could hardly be supposed to have been designed to commemorate a person of the name of Sergeant; yet such was the intention of Plumier. "The Rev. father Philip Sergeant, a native of Calais, of the order of Minims, in Provence, an able botanist, but more able physician, practiced medicine at Rome for 25 years, with so much success, as to gain the high esteem of all ranks of people. His departure from that city caused the deepest regret, but he was welcomed at Paris with no less exultation." Plumier, from whom we take this account, named the genus Serjanja; but Linnaus, who united it to Paulina, by accident, as it seems, altered the word, as he adopted it for a specific name, to Seriana. So it now remains, the genus having been restored by recent authors: nor do the botanical claims of the reverend father appear sufficiently great, to make us solicitous about the precise mode of spelling the name of his plant. — Pl. Gen. 34. t. 35. "Schumacher in Act. Hist. Nat. Hafn. v. 3. p. 2." Willd. Sp. Pl. v. 2. 404. (Paulinia; Lamarck Illust.)

SER

SER

t. 318. f. 1. 2. 3.) — Claps and order, Olandaria Trigynis, Nat. Ord. Tribulata, Linn. Sapindi, Juf.

Gen. Ch. Cal. Perissanth inferior, of five ovate, concave, spreading, permanent, unequal leaves. Car. Petals four, obovate-oblong, twice the length of the calyx, furnished with claws; two of them more dilated than the rest. Nectaries two; one of four oblong scales, inserted into the claws of the petals; the other of four glands at the base of the petals. Stam. Filaments eight, simple, shortish; anthers small, ovate, two-lobed. Pist. Germination superior, filiform, obovate, with three furrows; styles three, combined at the base, recurved; fligmas simple, obtuse. Peric. Capsules three, globose, combined longitudinally, each of one cell, not furrowing, dilated at the base into a half-ovate membranous wing. Seeds solitary, ovate.

Eff. Ch. Calyx of five unequal leaves. Petals four, Nectaries of four fleses and four glands. Capsules three, globose, combined, not furrowing, each with a dilated wing at the base. Seeds solitary.

Obf. The fruit sufficiently distinguishes this genus from Paulinia; see that article, however similar the flowers, and habits of the plants.

1. S. foxta. Willd. f. 1. "Schumacher, as above, t. 12. f. 1." (S. scandens, triphylles et racemosa; Plun. Gen. 34. t. 113. f. 2. Paulinia Seriana; Linn. Sp. Pl. 524. Jacq. Offic. f. 5. t. 61. f. 2.) — Wings of the capsules dilated below their inferior. Leaves ternate; leaflets ovato-lanceolate, furnished and toothed.—Native of South America. Neither this, nor any other of the genus, is known in our gardens. The stem is angular, furrowed and downy, climbing by means of tendrils. Leaves alternate, filiform; leaflets about two inches long, very, tapering at the base; roughly to the touch, though somewhat shining, above; paler beneath. Flowers small, in compound downy clusters. Wing of each capsule about an inch long.

2. S. Flueringa. Willd. f. 2. "Schumacher, t. 12. f. 2." (Paulinia dwaria; Swartz Ind. Occ. v. 2. 484.) — Leaves twice ternate; leaflets ovate, acute, entire, filiform, shining. Common footstalks without wings. — Native of the woods of Jamaica. Stem climbing to a great height, zigzag, with a few distinct flageolet prickles, an angular, smooth. Footstalks two inches long, furrowed, smooth. Leaflets filiform, the flake of the middle one winged. Tendrils axillary, divided at the extremity. Panicles from the same point, on long flake, their branches racemose, alternate, spreading. Flowers white.

3. S. racemosa. Willd. f. 2. (Paulinia caracatala; Jacq. Hort. Schonbr. v. 12. t. 99.) — Wings of the capsules not dilated below their inferior. Leaves twice ternate, leaflets oblong, acute at each end, distinctly toothed. Common flages without wings. — Native of the Caracas, from whence we presume it was sent by Dr. Merer to the Flowes at Vienna, where it flowers in the summer. The numerous stems climb by tendrils to a great height. Leaves smooth; leaflets elliptico-oblong, two or three inches in length. Flowers white, in compound cylindrical clusters, each cluster on a long flake, accompanied by two strong revolute tendrils at the top of the flake.

5. S. speculabulis. Willd. f. 5. "Schumacher, t. 12. f. 4." —Wings of the capsules dilated below their base. Leaves twice ternate; leaflets obovate; the terminal one abrupt.
Footstalks winged.—Native of the West Indies. Communicated by Sir J. Banks, from Miller's herbarium. This has much of the habit of S. caracolina, but the winged footstalks, and obtuse leaves, distinguish it essentially. We do not find any tendrils under the flowers, as Schumacher describes them, nor are the leaves, as Wildenow says, quite entire.

6. S. mexicana. Willd. n. 6. (Paulinia mexicana; Linn. Sp. Pl. 525; excluding Plummer's and Hernandez synonyms.)—"Schumach. t. 11. f. 3."—Leaves twice ternate; leaflets obovate, entire, all marginate. Footstalks winged. Clusters aggregate.—Native of Mexico. Akin to the last, but the entire leaflets, and compound inflorescence distinguish it. The clusters, each of which is simple, are ranged alternately, in one large panicle. Wildenow says Schumacher's figure is taken from the specimen in the Linnaean herbarium. With this Linnaeus at one time confounded the true Paulinia eurostis, to which the figure of Henderson better answers. The Linnaean speciments wants fruit, and yet its habit, colour, and leading characters, are so near the Seriana we have just been describing, that there can scarcely be a doubt of its belonging to this genus.

7. S. angustifolia. Willd. n. 7. (S. scandens, enneaphylla et racemosa; Plum. Gen. 34., t. 1. 112, f. i.)—Leaves twice ternate; leaflets linear-lanceolate, acute, entire. Footstalks winged.—Native of South America. Nothing can be left like the last, with which Linnaeus confounds this narrow-leaved species, whole clusters moreover are solitary. We know it only from Plummer's figure.

8. S. lapulina. Willd. n. 8. "Schumach. t. 12. f. 5."—Wings of the capsules half-oval. Leaves twice ternate, crenate, rufly toothed; the terminal leaflets nearly rhombid; the lateral ones ovate. Footstalks winged.—Native of South America. Clusters almost simple, the length of the leaves, and accompanied by two tendrils. Schumacher.

9. S. lucida. Soland, MSS. Willd. n. 9. "Schumach. as above, p. 128."—Wings of the capsules half-oval. Leaves twice ternate; leaflets ovate, acute, serrate. Footstalks scarcely winged.—Native of Santa Cruz. The upper surface of the leaves is highly polished, and strongly vened. Clusters in some measure compound, accompanied by two spiral tendrils. Communicated by Sir J. Banks, to the younger Linnaeus.

10. S. interiusata. Willd. n. 10. (S. scandens, polyphylla et racemosa; Plum. Gen. 34., t. 1. 112, Paulinia interiusata; Linn. Mant. 236., Jacq. Obs. f. 3. 11. t. 62. f. 11? Amer. 110. t. 1. 122. f. 52? P. polyphylla; Jacq. Obs. ibid. t. 61. f. 10.)—Leaves thrice ternate; leaflets ovate, obtuse, wavy. Footstalks winged. Clusters aggregate.—Native of South America, or the West Indies. The clusters are not accompanied by tendrils, but form a sort of panicles, as in S. mexicana. See PAULINIA, n. 8.

There seem to be more species, of which incomplete specimens or description exist, but with which we are not sufficiently acquainted to reduce them to order. Nor is the genus, in every case, to be ascertained, for want of the fruit, or essential in differentiating Seriana and Paulinia.

SERIANE, SRIKH, or ESRICH, in Ancient Geography, a town of Asia; in Syria, situated in the mountains S.E. of Chaldea, about the 43rd degree of latitude. It appears by its rains to have been formerly a large town.

SERRIE, or Striae, in Ancient Geography, a town of Italy, in the department of the Serio; 5 miles E.S.E. of Bergamo.

SERICA, in Ancient Geography, an oriental country, the position of which was indicated very vaguely by the writers of antiquity, but which has been, it must be acknowledged, more precisely ascertained by Ptolemy. Its situation and history, however, have been more accurately delineated by M. d'Anville, in an interesting memoir entitled "Recherches Géographiques et Historiques sur la Sérique des Anciens." M. d'Anville refutes the opinion of those who apprehended that the Serica described by Ptolemy corresponded to the northern part of China; and he adopts the opinion of M. de Guignes, in his History of the Huns, that it belonged to the conquests of the Chines towards the west. M. d'Anville adds, that with the exception of a small angular territory at the extremity of the province of Chen-fi, towards the N.W., China formed no part of Serica. In speaking of Scythia, on the other side of the Imaus, Ptolemy mentions a passage in this mountain, which was the habitation of merchants that traded with the Seres. Contiguous to this station, according to Ptolemy, is a country called Cafa, which M. d'Anville supposes to be the same with Calgarh, called by the Chinese Kin-tse. In proof of their identity it may be alleged that the tables of Nafr-Uddin and Ulugh-beigh assign to Calgarh 41° of latitude, and that Ptolemy makes the latitude of Cafa 42°, differing only by one degree. Ptolemy mentions the river Oechareds, which M. d'Anville supposes to be the Yerghien. Another river near the limits of Serica, mentioned by Ptolemy, is that called Bautes, which, in its course towards the N., is joined by the lateral branch of another river pursuing the same direction; and these circumstances correspond with those of the present Etzine. The Bautes, as M. d'Anville apprehends, is the old Serica, mentioned by Ptolemy, the metropolis of Serica. For according to the ancient geographers, this town is very near the point where the last branch of the Bautes separates from it, and a town is actually found at the eastern branch of the Etzine, towards its source. This town must therefore correspond to the Sera of Ptolemy, and bear the name of Can-techeou. It is the first considerable town that occurs at the entrance of the Chine province of Chen-fi. This town belongs to a particular country known to the Orientals under the name of Tangu. Tangu may therefore probably be the country anciently inhabited by the Seres, of which Sera was the capital. Another decisive proof that Can-techeou is the Sera metropolis of Ptolemy, is deduced from the circumstance that this town, according to the Greek geographer, is 38° 35' of latitude, and that the latitude of Can-techeou, according to the Jesuit astronomers, is 39°, the difference being only 25'. Ptolemy places the Elfedones in Serica. But Elfedon or Elfeo, signifying a chariot, and some of the Scythians, called by the Greeks Hamaxobites, or persons living in chariots, it has been inferred, that the people who bore the name of Elfedones, in the Serica of Ptolemy, were merely those whose habitation was in chariots, and it is also added, that a part of the country of the Seres had borne the name of Eygyar, and that the nation who occupied a part of this country is called by the Chinese Kao-tech, a word which signifies high chariots.

Sera, according to Ptolemy, is bounded to the W. by Scythia; on the other side of the Imaus; to the S. by unknown territories; and by a part of India beyond the Ganges and the Sines; the other boundaries are unknown. Its principal mountains are the Annib, which encompasses the Seres to the N.; the Auxaces, which extend to the Seres by their eastern parts; the Aimirs in the country; the eastern part of the Caffian mountains; mount Thagurus, called also Thagarius; the mountains Emodi and Sericus. The chief rivers are the Oechards or Oecharde, which rises in the Auxeian mountains, and the Bautes, which springs from Mount Carlaus. The north of Serica was inhabited by Anthro-
throphophagi; below these were the Annibi, bearing the name of these mountains; the Axacii and the Sizyges, below whom were the Danmae; the Piddax extended themselves to the river Oecarhes. The Garumae and the Nabbanze lay more to the east than the Annibi. To the S. was the country called Almira, where were the mountains of the same name; the Iffidones, or Effedones, were situated to the S. and extended themselves to mount Caffius; and these formed a powerful nation; the Throama lay to the E., and below them the Ithaguri; the Aspacerae lay to the S. of the Iffedones, and below them the Batæ; the Ottorochorrae were situated to the S. The principal towns were the Danmae, Pidax, Almira, or Almira, Tharrana or Throama, Iffedon, Sarice, Aspacerae, Drofache, Paliana, Ablagana, Thiegara, Daxata, Orofana, Ottorochorrae or Ottorocorras, Solana, and Sera Metropolis. It appears from the article Little Bocchia, to which we refer the reader, that no region but this correspond to Ptolemys Serica.

SERICH, the name of a feed used in the food of the Egyptian Coptics. It is produced by an herb called frangula, and is pounded and put into oil. In this they dip their bread, which is always new, being baked as often as they eat, in small flat cakes; these they eat dipped in this oil with raw onions, or else they break the cakes to pieces, and put them into a syrup of sugar, made when the canes are green. Percosse's Egypt, p. 182.

SERICORA, in Geography, a town of Persia, in the province of Mazanderan; 15 miles N.E. of Aftarabat.

SERICUM, Silk. See Silk.

Sericium is also a name given by several chemical writers to the flowers of zinc reduced by sublimation in an inclined open crucible. These flowers are not reducible into zinc again, and are of a fibrous texture, and a beautiful white colour. This has made them be called also the philosophic cotton, and others have named them the aqua fissa philosophorum.

SERIDIA, in Botany, a generic name given by Jussieu to those species of Centaurea which are included under the sixth section (Stabe) of that genus. Juss. 173. See Centaurea.

SERJEANT, or SERGEANT, a term in our Law, applied to fundry offices. Serjeant at law, or of the coif, is the highest degree taken in the common law, as that of doctor is in the civil law.

The first mention which judge Blackstone has met with of serjeants, or countours, is in the Stat. of Wett. 13 Edw. I. c. 29. But M. Paris, in his life of John II. abbot of St. Alban's, which he wrote in 1255, 39 Hen. III. speaks of advocates at the common law, or countours (quos banc narratres vulgariter appellamus) as of an order of men well known; and the antiquity of the coif appears from the fame author's Hist. of England, A.D. 1259. Serjeants were anciently called servientes ad legem, and servientes narratres.

Mr. Selden adds, that they were also called doctores legis; though others are of opinion that the judges are more properly the doctores legis, and serjeants, the bachelors of law.

Spelman observes, that however a serjeant may be richer than all the doctors of the Commons, yet a doctor is inferior in degree to a serjeant, for the very name of a doctor is magisterial, but that of a serjeant ministerial. Hence, the doctors are seated and covered when they plead, but the serjeants stand uncovered at the bar, excepting for their coif.

As there are supposed the most learned and experienced, there is one court appropriated for them to plead in by themselves, which is the Common Pleas, where the common law of England is most strictly observed; but they are not prohibited pleading in other courts; and all judges, who, by custom, must first be serjeants, call them brothers.

Serjeants at law are bound by a solemn oath to do their duty to their clients; and by custom the judges of the courts of Welleminor are always admitted into this venerable order, before they are advanced to the bench; the original of which was probably to qualify the public barons of the exchequer to become justices of assize, according to the exigence of the statute of 14 Edw. III. c. 16.

They are called by the king's mandate, or writ, directed to them, commanding them to take upon them that degree, by a day assigned. See Barrister.

Out of these, some are made the king's serjeants to plead for him in all causes, especially in causes of treason; and one is usually appointed, called premier serjeant. See Counsel and Precedence.

SERJEANTS at ARMS, are officers appointed to attend the perfou of the king, to arrest traitors, and perfons of quality offending, and to attend the lord high steward when he sits in judgment on any traitor, &c.

The duty of these serjeants originally was to watch round the king's tent in complete armour, with a mace, a bow, arrows, and a sword, and occasionally to arrest traitors, and other offenders, about the court, for which the mace was deemed a sufficient authority. They were called the valourous force of the king's errand, in the execution of justice; they held their places for life; their number was originally twenty-four, all persons of approved worth, and not under the degree of the son of a knight; but afterwards the sons of gentlemen were admitted into the body. In the reign of Edward I. the serjeants at arms were allowed two marks for winter, and the same for summer robes; their pay in that of Edward II. was 12d per diem, when they attended on horseback, and 8d. when they attended without a horse. Their allowance, when absent from court, on the king's affairs, was 12d. each by the day; and under another head they appear charged at 26s. 8d. each for winter, and 20s. for summer. They were besides entitled to certain fees from persons arrested, in proportion to their rank and degree. According to the orders given by Thomas of Lancaster, constable at the siege of Caen, Sept. 3d. 1417, a serjeant at arms was to appear in the king's presence, with his head bare, his body armed to the feet with the arms of a knight riding, wearing a gold chain with a medal, bearing all the king's coats, with a peon royal, or mace of silver, in his right hand, and in his left hand a truncheon. In the 7th of Hen. VII. they were ordered to attend the army. The number of this corps has varied exceedingly. In the reign of Edw. IV. they were reduced to four; in that of Edw. VI. they were increased to twenty-two, and in the succeeding reign to twenty-three; but by king James I. retrenched to sixteen, and afterwards to eight.

Such is the number now at court, at 100l. per annum salary each; they are called the king's serjeants at arms, to distinguish them from others; they are created with great ceremony, the person kneeling before the king, his majesty lays the mace on his right shoulder, and says, Rite up serjeant at arms, and esquire for ever. They have, besides, a patent for the office, which they hold for life.

They have their attendance in the presence-chamber, where the band of gentlemen-pensioners wait; and receiving the king at the door, they carry the maces before him to the chapel door, whilst the band of pensioners stand foremost, and make a lane for the king, as they also do when the king goes to the house of lords.
They have a considerable share of the fees of honour, and travelling charges allowed them when in waiting, viz. five shillings per day when the court is within ten miles of London, and ten shillings when twenty miles from London. The places are in the lord chamberlain's gift.

There are four other serjeants at arms, created in the same manner; one who attends the lord chancellor; a second, the lord treasurer; a third, the speaker of the house of commons; and a fourth, the lord mayor of London on solemn occasions.

There are also serjeants of the mace of an inferior kind, who attend the mayor, or other head officer of a corporation.

**Serjeant, Common,** an officer in the city of London, who attends the lord mayor and court of aldermen on court days, and is in council with them on all occasions, within and without the precincts, or liberties of the city. He was to take care of orphans' elates, either by taking account of them, or by signing their indentures, before their passing the lord mayor and court of aldermen; and he was likewise to let and manage the orphans' elates, according to his judgment to their best advantage. See **Recorder.**

**Serjeants of the Hooihood,** are officers who execute several functions within the king's household, mentioned in the Stat. 33 Hen. VIII. c. 12.

**Serjeant, or Serjeants, in War,** is a non-commissioned or inferior officer in a company of foot, or troop of dragoons; armed with a halberd, and appointed to see discipline observed, to teach the soldiers their exercise and other duty. He receives the orders from the adjutant, which he communicates to his officers.

Each company has generally two serjeants.

**Serjeant, Covering,** a non-commissioned officer, who, during the exercise of a battalion, regularly stands or moves behind each officer, commanding or acting with a platoon or company. When the ranks take open order, and the officers move in front, the covering serjeants replace their leaders; and when the ranks are closed they fall back in their rear.

**Serjeant, Drill,** an expert and active non-commissioned officer, who, under the immediate direction of the serjeant-major, instructs the raw recruits of a regiment in the first principles of military exercise. When awkward or ill-behaved men are sent to drill, they are usually placed under the care of the drill-serjeant.

**Serjeant, Lance,** a corporal who acts as serjeant in a company, but only receives the pay of corporal.

**Serjeant-Major.** See **Major.**

**Serjeant, Pay,** an honest, steady, non-commissioned officer, who is a good accountant, and writes well, that is selected by the captain of a company in the infantry to pay the men twice a-week, and to account weekly to him, or to his subalterns, for all disbursements. He likewise keeps a regular statement of the necessaries of the men, and affists in making up the monthly abridgment for pay, allowances, &c.

**Serjeant, Quarter-Master,** a non-commissioned officer, who acts under the quarter-master of a regiment; he ought to be steady, a good accountant, and well acquainted with the resources of a country town or village.

**SERJEANTY, or SERGEANTY,** in Law, a service anciently due to the king for lands held of him, and which could not be due to any other lord.

It is divided into grand and petit serjeanty.

**Serjeanty, Grand,** is where one holds lands of the king by serjeanty which he ought to do in his own person, as to bear the king's banner or spear, affit at his coronation, or do some office in his court.

It was in most other respects like knight-service, only he was not bound to pay aid or escheate; and when tenant by knight-service paid five pounds for a relief on every knight's fee, tenant by grand-serjeanty paid one year's value of his land, whether it were much or little. Tenure by cornage was a species of grand-serjeanty. See Cornage. Litt. § 153. 158. 2Init. 233.

**SERJEANTY, Petit,** is where a man holds land of the king to yield him yearly some small thing towards his wars, as a sword, dagger, bow, fprus, &c. in the manner of rent.

Coke, on Littleton, tells us, that Sir Richard Rockefly held lands at Seaton, by grand-serjeanty, to be vantarius regis, i.e. the king's footman, when he went into Gascony, till he had worn out a pair of shoes of the price of four-pence.

By the Statute 12 Car. II. all tenures of any honors, manors, lands, &c. are turned into free and common foggage; but the honorary services of grand-serjeanty are thereby continued.

**SERIES,** a continual succession of things in the same order, and which have some relation or connection with each other.

Medals are formed into suites or serjeanties, both with regard to the metal and to the subject. The different metals of medals constitute three different serjeanties in the cabinets of the curious, we mean, as to the order and arrangement of the several metals.

The gold series, for instance, of imperials, amounts to about 5000; that of silver may amount to 10,000; and that of brass to 30,000. See **Medals.**

With regard to the subject, the series of medals are usually formed from the side called the head; in the first class, is dispossessed the serjeanties of kings; in the second, that of Greek and Latin critics; in the third, the Roman consular families; in the fourth, the imperial; in the fifth, the deities; and to these may be added a sixth serjeanty, consisting of medals of illustrious peripius. See **Medals.**

There are also serjeanties of modern medals; that of the popes only commences from Martin V. in 1430. From that time we have a series of papal medals, tolerably complete, to the number of five or fix hundred.

We might likewise have a series of emperors from Charlemagne, provided the current coins were admitted; but in practice they commonly commence with Frederic II. in 1465.

The series of the kings of France is most numerous and most considerable of all the modern kings. See **Medals.**

**SERIES,** in **Analysis,** is a succession of terms, or progression of quantities, connected together by the signs plus and minus, and proceeding according to some law or determinate relation. Such are the following.

\[ 1 + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \frac{1}{9} + \ldots \]

\[ 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{8} + \frac{1}{16} + \ldots \]

The former being the reciprocals of the odd numbers, and the terms of the latter a geometrical progression, of which the ratio is \(\frac{1}{2} \).

Series are of various forms, and arise in many different ways, as from the expansion of functions, the inverse method of fluxions, &c. But they very frequently arise independent of any general derivation, and the object of enquiry is then to determine that function to which they are equivalent, and from the expansion of which they may be reproduced, or the numeral value of a certain of an infinite number of their terms.

Thus, 

---

**SER**
Thus, of the former kind, we have
\[
\frac{1}{a + b} = (a + b)^{-1} = \frac{1}{a} - \frac{b}{a^2} + \frac{b^2}{a^3} - \frac{b^3}{a^4} + \&c.
\]
\[
\frac{1}{a - b} = (a - b)^{-1} = \frac{1}{a} + \frac{b}{a^2} + \frac{b^2}{a^3} + \frac{b^3}{a^4} + \&c.
\]
and a variety of others. And of the latter,
\[
\frac{1}{a^n} + \frac{1}{a^{n+1}} + \frac{1}{a^{n+2}} + \frac{1}{a^{n+3}} + \&c.
\]
\[
\frac{1}{3^2} + \frac{1}{3^3} + \frac{1}{3^4} + \frac{1}{3^5} + \&c.
\]
\[
\frac{1}{3^n} + \frac{1}{3^{n+1}} + \frac{1}{3^{n+2}} + \frac{1}{3^{n+3}} + \&c.
\]
Many of these are still irreducible to any equivalent finite function.

Series also receive several different denominations according to certain circumstances attending their formation, the law which they follow, the function of the form to which they are reducible, &c. &c. as arithmetical, geometrical, converging, diverging, reciprocal, &c. series.

Series, Converging, are those in which the terms decrease, or become successively less and less; as
\[
1 + \frac{1}{5} + \frac{1}{5^2} + \frac{1}{5^3} + \&c.
\]
Series, Diverging, are those in which the terms continually increase; as
\[
1 + 2 + 2^2 + 2^3 + 2^4 + \&c.
\]
Series, Neutral, are those in which all the terms are equal to each other; as
\[
1 + 1 + 1 + 1 + 1 + \&c.
\]
This arises from the division of 1 by 1, and is therefore equal to 1.

Series, Indeterminate, is sometimes used to denote a series, whose terms proceed according to the powers of some indeterminate letter or quantity; as
\[
x + \frac{1}{2} x^2 + \frac{1}{3} x^3 + \frac{1}{4} x^4 + \&c.
\]
Other writers, however, mean by this denomination those series whose sums are indeterminate in any finite form.

Series are again either ascending or descending.

Series, Ascending, are those in which the powers of the indeterminate quantity continually increase; as
\[
1 + ax + bx^2 + cx^3 + dx^4 + \&c.
\]
Series, Descending, are those in which the powers decrease in the numerator, or increase in the denominator; as
\[
1 + ax^{-1} + bx^{-2} + cx^{-3} + dx^{-4} + \&c.
\]
or
\[
1 + \frac{a}{x} + \frac{b}{x^2} + \frac{c}{x^3} + \frac{d}{x^4} + \&c.
\]
Series, Circular, are those whose sums depend upon the quadrature of the circle; thus,
\[
1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} + \&c.
\]
\[
1 + \frac{1}{3^2} + \frac{1}{3^3} + \frac{1}{3^4} + \frac{1}{3^5} + \&c.
\]
are circular series; the former being equal to one-eighth of the circumference of a circle whose radius is 1; and the latter equal to one-sixth of the square of the semi-circumference to the same radius.

Series, Logarithmic, are those which express, or whose sums depend upon the logarithms of numbers; as
\[
(a - 1) - \frac{1}{2} (a - 1)^2 + \frac{1}{3} (a - 1)^3 - \frac{1}{4} (a - 1)^4 + \&c.
\]
which is equal to the hyperbolic logarithm of a.

Series, Arithmetical, are those whose successive terms differ from each other by a certain and determinate quantity; as
\[
a + (a + d) + (a + 2d) + (a + 3d) + \&c.
\]
\[
a + (a - d) + (a - 2d) + (a - 3d) + \&c.
\]
Series, Geometrical, are those whose successive terms are some multiple or submultiple of those immediately preceding them; as
\[
a + ra + r^2a + r^3a + r^4a + \&c.
\]
\[
a + a \frac{r}{r - 1} + \frac{a r^2}{r - 1} + \&c.
\]
Series, Fractional, are those whose terms are all fractional; as
\[
\frac{a}{b + c} + \frac{a}{(b + c)(b + 2c)} + \frac{a}{(b + 2c)(b + 3c)} + \&c.
\]
Series, Trigonometrical, are those which relate to trigonometrical lines or quantities; as
\[
\sin a + \frac{\sin 3a}{3} + \frac{\sin 5a}{5} + \frac{\sin 7a}{7} + \&c.
\]
\[
\tan a - \frac{\tan 3a}{3} + \frac{\tan 5a}{5} - \frac{\tan 7a}{7} + \&c.
\]
which are each expreisons for the length of a circular arc, the former in terms of the sine, and the latter in terms of the tangent.

Series, Exponential, are those which arise from the expansion of, or whose sums depend upon exponential quantities; as
\[
1 + \frac{x}{1} + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \&c.
\]
which is equal to e^x, e being the number whose hyperbolic logarithm is 1.

Series, Recurring, are those in which each term has a constant relation to a certain number of the preceding terms. See Recurring Series.

Series, Law of a, is used to denote that relation which subsists between the successive terms of a series, and by which their general term may be denoted: thus the series
\[
1 + 2 + \frac{8}{3} + \frac{16}{5} + \frac{32}{15} + \&c.
\]
may be put under the form
\[
1 + \frac{2}{3} x + \frac{2.4}{3.5} x^2 + \frac{2.4.6}{3.5.7} x^3 + \frac{2.4.6.8}{3.5.7.9} x^4 + \&c.
\]
where the law by which it may be indefinitely continued is manifest; and from which we draw the general term, viz.
\[
\frac{2.4.6 \ldots (2n - 1)}{3.5.7 \ldots (2n - 3)} x^{n-1}.
\]
Series, Interpolation of. See INTERPOLATION.

Series, Recursion of. See REVERSION.

Series, Summation of, is the finding the sum of a series, whether the number of its terms be finite or infinite; the various methods of performing which is treated of in the subsequent part of this article.

Method
**Series.**

Method of series is used in a general sense to denote the principle upon which different authors have treated this subject, as well with reference to the inversion and interpolation of series, as to the finite and approximate summation of them.

The doctrine of series is certainly one of the most important subjects of mathematical investigation, and has been very appropriately denominated by James Bernoulli the chief anchor of analysis; being our only hope and last resort, in a variety of difficult problems, which bid defiance to every other method of computation.

The summation of series, and the quadrature of a curvilinear space, are intimately connected with each other, as well in their origin as in their subsequent progress. We have stated under the article Quadrature, that Archimedes was the first who found the area of a curvilinear space, which he effected by means of the summation of an infinite series upon geometrical principles, and which is the first instance on record of such an operation; from which time, for nearly two thousand years, little or nothing was attempted relative to this subject; but about the middle and latter end of the 17th century, it began to attract the general attention of mathematicians, and has since that time been pursued with a degree of perseverance and success commensurate with its great importance, and the general progress of analysis during the same period.

Wallis, in his Arithmetical of Infinites, seems to have been the first amongst the moderns who drew the attention of mathematicians to the doctrine of series. Lord Brouncker, Sir Christopher Wren, Mercator, and James Gregory, also pursued the subject with considerable success, exhibiting the quadrature and rectification of different curves under the form of infinite series.

In 1682, Leibnitz published in the Leipsic Acta a memoir entitled "De proportionibus ad quadraturn circumferentiam, in numeris rationalibus," in which he gave several numerical series of a very novel kind, whose sums were expressible in finite terms, without, however, accompanying them with their demonstrations; amongest the most curious of which we may reckon the following: viz.

\[
\frac{1}{3} + \frac{1}{8} + \frac{1}{15} + \frac{1}{24} + \frac{1}{35} + \frac{1}{48} + \&c. \text{ or}
\]

\[
\frac{1}{2^2} + \frac{1}{3} + \frac{1}{4} - \frac{1}{5} + \&c.
\]

The sum of an infinite number of terms of which is equal to $\frac{3}{4}$; the sum of its odd terms being equal to $\frac{1}{2}$, and the sum of its even terms equal to $\frac{1}{2}$: that is

\[
\frac{1}{3} + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \frac{1}{9} + \frac{1}{11} + \&c. = \frac{1}{2},
\]

\[
\frac{1}{2^4} + \frac{1}{4} + \frac{1}{6} + \frac{1}{8} + \frac{1}{10} + \&c. = \frac{1}{4}.
\]

The sum of an infinite number of terms of the same series, omitting every three terms after the 1st, the 5th, the 9th, &c. as

\[
\frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \frac{1}{13} + \frac{1}{15} + \frac{1}{17} + \frac{1}{19},
\]

is equal to the area of a circle of which the inscribed square is $\frac{1}{4}$.

But if we begin at the second term, and thence omit every three terms, as above, we shall have

\[
\frac{1}{2^4} + \frac{1}{6} + \frac{1}{8} + \frac{1}{10} + \frac{1}{12} + \&c.
\]

Vol. XXXII.

which is equal to the area or space included between the curve and asymptote of an equilateral hyperbola, or $\frac{1}{2}$ of the hyp. log. 2.

Leibnitz also gave in the same work for 1683, the summation of several other series of a more difficult kind, as

\[
1 - \frac{1}{2} + \frac{1}{2} - \frac{1}{2} + \frac{1}{2} - \frac{1}{2} + \&c. = \frac{1}{2}
\]

\[
1 - \frac{2}{2} + \frac{3}{2} - \frac{4}{2} + \frac{5}{2} - \&c. = \frac{2}{2}
\]

\[
1 - \frac{3}{2} + \frac{6}{2} - \frac{10}{2} + \frac{15}{2} - \&c. = \frac{2}{2}
\]

These, as we have before observed, were not demonstrated by Leibnitz, but this was soon after done, and many other series investigated, by the brothers John and James Bernoulli; the latter in a small tract "De Seriebus Infinitis," published with the "Ars Conjectandi;" and the former in vol. iv. of his "Opera Omnia."

From the preface to the former tract we learn, that James, having turned his attention to the doctrine of series, had discovered a few which were summable, and which he propounded to his brother; who having quickly demonstrated them, proposed others to James; this led to other propositions, and so on, till in a short time they were not only able to demonstrate all Leibnitz's series, but had discovered two general principles, which applied with great facility to a variety of new cases; the one of which was the resolution of an infinite series into an infinite number of other series; and the other, the method commonly called the summation by subtraction. We see here that spirit of emulation and rivalry with which these two brothers were constantly actuated, and to which they each probably owe many of their finest discoveries. It is only to be regretted that it terminated in a manner so unworthy of their talents and character; particularly with regard to John, who was doubtless at first much indebted to his brother's instruction, but who, notwithstanding, indulged his resentment against him for many years after his death, seeking every opportunity of alarming his methods, and of lessening his reputation.

The Bernoulli's Method of Series.—The principal difference between the methods of these two celebrated mathematicians consists in this, that James, in his "Trajectus de Seriesbus Infinitis," proceeds synthetically; and John, in his "Opera Omnia," analytically; but the series in both cases are nearly of the same kind, and the summation of them depends upon the same principles; we shall, therefore, by way of illustration, abstrait one or two propositions from the former work, which will be sufficient for giving the reader an idea of the spirit of the two methods above alluded to.

Prop.—To find the sum of an infinite number of fractions, whose denominators increase in any geometrical progression, but whose numerators proceed according to the natural numbers, or polygonal or figurate numbers, of any denomination.

Case 1.—When the numerators proceed according to the natural numbers, that is, when they form an arithmetical progression.

Let the proposed series, whose sum is required, be

\[
\frac{a}{b} + \frac{a+e}{b+d} + \frac{a+2e}{b+d^2} + \frac{a+3e}{b+d^3} + \&c.
\]

This
This is obviously equal to
\[
\frac{a}{b} + \frac{a}{b^2} + \frac{a}{b^3} + \frac{a}{b^4} + \&c. = \frac{ad}{b^2 - b} + \frac{c}{b^3 - b} + \frac{c}{b^3 - b^2} + \frac{c}{b^4 - b^2} + \&c.
\]

Each of which series being geometrical, are found by the known rules for such progressions; and it is obvious that the sums, except the first, are also in geometrical progression; the sum of which, viz. of
\[
\frac{cd}{b - b} + \frac{cd}{b^2 - b^1} + \frac{cd}{b^3 - b} + \frac{cd}{b^4 - b^2} + \&c. = \frac{c}{b - 1}
\]

which therefore adding \(\frac{a}{b} + \frac{a}{b^2} + \frac{a}{b^3} + \frac{a}{b^4} + \&c. = \frac{ad}{b^2 - b}\) to, we have \(\frac{ad}{b} + \frac{cd}{b - 1}\) for the sum of the proposed series.

Case 2.—When the numerators of the fractions proceed according to the triangular numbers. Let
\[
\frac{e}{b} + \frac{3e}{b^2} + \frac{6e}{b^3} + \frac{10e}{b^4} + \&c.
\]

be the proposed series. This may be resolved as follows: viz.
\[
\frac{e}{b} + \frac{3e}{b^2} + \frac{6e}{b^3} + \frac{10e}{b^4} + \&c. = \frac{cd}{b - b}
\]

which sums, with the exception of the first, constitute a series agreeing in form with that solved above, and from which we derive \(\frac{cd}{b - 1}\) for the sum required.

Cor.—If we make \(a\) in the first series \(= 0\), the sum of that series will be to the sum of the latter, as \(d - 1: d\); that is, as \(d - 1: d^2\) \(b - (d - 1)\) \(= \frac{cd}{b - 1}\). And when the numerators proceed according to the figurate numbers of the first order, viz. 1, 4, 10, 20, 35, then the sum of this series will be to that of the latter, as \(d : d - 1\); that is, as \(d - 1: d^2\) \(b - 1: (d - 1)\) \(= \frac{cd}{b - 1}\) = the sum of the series
\[
\frac{e}{b} + \frac{4e}{b^2} + \frac{10e}{b^3} + \frac{20e}{b^4} + \frac{35e}{b^5} + \&c.
\]

In a similar manner is found the sum of the series, when the numerators are squares, cubes, &c. from which the author draws the following results; viz.

<table>

</table>

As an illustration of the second method, that is, of summation by subtraction, we shall give an abstract of James Bernoulli's fourteenth proposition, which is as follows.

Prop.—To find the sum of an infinite series of fractions, whose numerators constitute a series of equal numbers, and denominators, a series of triangular numbers, or of their multiples.

From the series \(\frac{a}{c} + \frac{a}{2c} + \frac{a}{3c} + \frac{a}{4c} + \frac{a}{5c} + \&c. = S\)

Subtract \(\frac{a}{c} + \frac{a}{3c} + \frac{a}{4c} + \frac{a}{5c} + \&c. = S - \frac{a}{c}\)

we have \(\frac{a}{2c} + \frac{a}{2c} + \frac{a}{2c} + \frac{a}{2c} + \&c. = 2\frac{a}{c}\)

which last is a series of fractions of the form proposed, their denominators forming the series of triangular numbers, multiplied by the constant quantity \(c\). Thus in numbers; if the series
\[
1 \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \&c. = S
\]

(without regard that what may be the value of \(S\)), we take
\[
\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \&c. = S - 1
\]

we shall have
\[
\frac{1}{1} \frac{1}{2} + \frac{1}{2} \frac{1}{3} + \frac{1}{3} \frac{1}{4} + \frac{1}{4} \frac{1}{5} + \&c. = S - 1
\]

In the same way we find
\[
\frac{1}{1} \frac{1}{3} + \frac{1}{2} \frac{1}{4} + \frac{1}{3} \frac{1}{5} + \frac{1}{4} \frac{1}{6} + \&c. = 3\frac{1}{4}
\]

On the same principle, John Bernoulli demonstrated, that the sum of the reciprocals of the natural numbers is infinite. Let
\[
\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \&c.
\]

be changed into the equivalent form
\[
\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \&c.
\]
SERIES.

and let this last be resolved into the infinite series
\[
\frac{1}{2} + \frac{1}{6} + \frac{1}{12} + \frac{1}{20} + \frac{1}{30} + \text{&c.} = 1
\]
\[
\cdots + \frac{1}{6} + \frac{1}{12} + \frac{1}{20} + \frac{1}{30} + \text{&c.} = \frac{1}{2}
\]
\[
\cdots + \frac{1}{12} + \frac{1}{20} + \frac{1}{30} + \text{&c.} = \frac{1}{3}
\]
\[
\cdots + \frac{1}{30} + \text{&c.} = \frac{1}{4}
\]
\[
\cdots + \frac{1}{20} + \frac{1}{30} + \text{&c.} = \frac{1}{5}
\]
\[
\cdots + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \text{&c. ad infinitum}
\]

Whence it follows, that the sum of
\[
\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \text{&c. ad infinitum} = \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \text{&c. ad infinitum}
\]

which equality can only have place when the first sum is infinite.

John Bernoulli afterwards found the sum of the series of the reciprocals of the natural squares, a problem mentioned by his brother, in his scholiarm to proposition 17, in which he declared that the solution of it had evaded his industry; and that whoever solved it should receive his warmest thanks.

It should be observed, however, that though James had failed in finding the true sum, he had discovered several curious properties of this series; viz. that the sum of the odd terms, \(1 + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \cdots\), as 3 to 1. And generally, if we have a series of the reciprocals of any powers whatever, as \(\frac{1}{1^n} + \frac{1}{2^n} + \frac{1}{3^n} + \cdots\), the sum of the terms in the odd places beginning at unity, is to the sum of the terms in the even places, as \(n - 1\) is to 1. Hence,
\[
1 + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \text{&c. : } \frac{1}{2} + \frac{1}{4} + \frac{1}{6} + \text{&c. :: 7 : 1.}
\]

John Bernoulli's solution of the above problem depends upon the expression for the sine of an arc in terms of the arc, the same as that of Landen, of which we shall speak in the subsequeent part of this article, and shall, therefore, only give here the results that Bernoulli drew from his solution; viz. he proved that
\[
1 + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \frac{1}{5^2} + \text{&c.} = \frac{\pi^2}{6}
\]
\[
1 + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \frac{1}{5^2} + \text{&c.} = \frac{\pi^2}{6}
\]
\[
1 + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \frac{1}{5^2} + \text{&c.} = \frac{\pi^2}{6}
\]
\[
1 + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \frac{1}{5^2} + \text{&c.} = \frac{\pi^2}{6}
\]
\[
&c. &c. &c.
\]
where \(\pi\) denotes the semi-circumference of a circle whose radius is 1. Montucla has, by mistake, attributed the first summation of this series to Euler, see page 209, tom. iii. "Histoire des Mathematiques."

We shall only further observe with regard to these authors, that we here find the first notice of continued expressions of the form
\[
\sqrt{a} + \sqrt{a} + \sqrt{a} + \cdots + \text{&c.}
\]
\[
\sqrt{a} + b \sqrt{a} + b \sqrt{a} + b \sqrt{a} + \cdots + \text{&c.}
\]

with the method of summing them by means of quadratic, cubic, and biquadratic equations. See our articles QUADRATIC, and SURDS.

3. Montmort's Method of Series.—The two methods above illustrated, by means of which the Bernoullis arrived at the summation of various series, are both indirect, and are better suited to finding summable series, than to the summation of any series proposed; they are moreover only applicable to such series as continually decrease ad infinitum.

In 1712 another interesting correspondence took place on series of a different kind, between M. Montmort, John Bernoulli, and his nephew Nicholas Bernoulli. They were led to these considerations, in consequence of certain problems relating to the doctrine of probabilities, which at that time began to excite great interest amongst both the English and French mathematicians. The subject here was not the determination of the sum of an infinite number of decreasing terms, but the summation of any finite number of terms, either increasing or decreasing; and the formula of M. Montmort, given at page 65 of his "Eloge d'Analyse fur les Jeux de Hazard," second edition, for this purpose, is as follows.

Let \(a + b + c + d + e + f + \cdots\) be the proposed series, and \(n\) the number of terms whose sum is required; also, let \(D', D'', D''', D''''\), &c. be the first terms of the first, second, third, fourth, &c. differences; then will the sum of the \(n\) terms be expressed by
\[
a + b + c + d + e + f + \cdots + n\text{ th term of the series: } D' + \frac{n}{1} \cdot \frac{n-1}{2} \cdot \frac{n-2}{3} \cdot D''
\]
\[
+ \frac{n}{1} \cdot \frac{n-1}{2} \cdot \frac{n-2}{3} \cdot \frac{n-3}{4} \cdot D'''
\]

which series will terminate in all cases, wherever any of the order of differences become zero; but in others it will only give an approximation.

Let it be required, for example, to find the sum of the natural series of the squares
\[
1 + 2^2 + 3^2 + 4^2 + 5 \cdots \cdot n^2
\]

Here \(a = 1, D' = 3, D'' = 2, D''' = 0\);

therefore
\[
n + \frac{n}{3} \cdot \frac{n-1}{2} \cdot \frac{n-2}{3} \cdot \frac{n-3}{4} \cdot \cdots \cdot \frac{n-\text{th}}{\text{number of terms}}
\]

is the sum required.

If it were the series of triangular numbers,
\[
1 + 3 + 6 + 10 \cdots \cdot n \cdot \frac{n+1}{2}
\]

then we should have
\[
a = 1, D' = 2, D'' = 1, D''' = 0;
\]

therefore the sum of \(n\) terms will be expressed by
\[
\frac{n}{1} \cdot \frac{n-1}{2} \cdot \frac{n-2}{3} \cdot \frac{n-3}{4} \cdot \cdots \cdot \frac{n-\text{th}}{\text{number of terms}}
\]

\[
\text{From.}
\]
From this general formula are readily drawn the following particular expressions for the sums of the different orders of polygonal and figurate numbers; as also for the squares, cubes, and higher powers.

### Figurate Numbers

<table>
<thead>
<tr>
<th>Series</th>

</tr>
</tbody>
</table>

A variety of other series fall under the above general formula of M. Montmort; viz. series of which the sum may be exhibited in a finite form; and in all cases where the successive differences decrease, an approximation may be obtained by it, and that with a considerable degree of facility, when the terms are alternately + and −, but when they are all plus, or all minus, except the first, little, if any, advantage is gained by it.

The above method of summation is commonly called the differential method, and was first used for interpolation by Briggs, in the construction of his table of logarithms. Newton also applied it to a variety of interesting problems in his "Methodus Differentialis," but Montmort, as far as we have been able to trace, was the first who employed it in the summation of series.

The following formulae, all relating to the differential method, will not be unacceptable to the reader.

Let \( a + b + c + d + e + f + &c. \) be any series; make

\[ D' = b - a \]
\[ D'' = a - 2b + c \]
\[ D''' = a - 3b + 3c - d \]
\[ D'' = a - 4b + 6c - 4d + e \]
\[ \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \]
\[ D^{(n)} = a - nb + \frac{n(n-1)}{1 \cdot 2} c - \frac{(n-1)(n-2)}{1 \cdot 2 \cdot 3} d + &c. \]

From which last general formula the first term of any order of differences may be found independent of all those which precede it.
Again, let \( N \) represent the \( n \)th term, and \( S \) the sum of \( n \) terms; then will
\[
N = a + \frac{\binom{n-1}{1}}{1} \text{D'} + \frac{\binom{n-1}{2}}{1 \cdot 2} \text{D''} + \frac{\binom{n-1}{3}}{1 \cdot 2 \cdot 3} \text{D'''} + \&c.
\]
\[
S = n a + \frac{n(n-1)}{1 \cdot 2} \text{D'} + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} \text{D''} + \frac{n(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3 \cdot 4} \text{D'''} + \&c.
\]
which latter expression for the sum is, as we have above observed, due to M. Montuort. The same author also published in the Philosophical Transactions for 1718, some other formulae for the summation of series; but as these are nothing more than particular cases of the method of increments, we shall not notice them in this place; but refer the reader to the article INTEGRALS, for an illustration of the method of summation as depending upon those principles, first published by Dr. Brooke Taylor, in his “Methodus Incrementorum,” 1715.

4. De Moivre’s Method of Series. The next author who made any considerable improvement in this theory was De Moivre, to whom we owe the doctrine of RECURRING SERIES, on the principles of which we have spoken at some length under that article of the present work; we shall not therefore enter again upon the subject in this place, but confine ourselves to an illustration of his method for finding summable series, which is not referred to in the article above mentioned; it was first given by him in his “Miscellanea Analytica,” 1730.

Let there be assumed any series, and let this be multiplied by any binomial or trinomial factor, such that the resulting series shall have its powers of \( x \) recurring again in the same order; then, by equating the resulting series to \( c_0 \), and transposing the negative terms, a new numerical series will arise, the sum of which will be given.

Thus, let there be taken the series
\[
1 + \frac{1}{2} x + \frac{1}{3} x^2 + \frac{1}{4} x^3 + \frac{1}{5} x^4 + \&c. = S.
\]
Multiplying this by \( x - 1 \), we have
\[
-1 + \frac{1}{1 \cdot 2} x^2 + \frac{1}{2 \cdot 3} x^3 + \frac{1}{3 \cdot 4} x^4 + \&c. = (x - 1) S.
\]
Whence, making \( x - 1 = c_0 \), or \( x = 1 \), we have
\[
\frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \frac{1}{4 \cdot 5} + \&c. = 1.
\]
Again, assume
\[
1 + \frac{1}{2} x + \frac{1}{3} x^2 + \frac{1}{4} x^3 + \&c. = S.
\]
Multiplying by \( x^3 - 1 \), we have
\[
-1 + \frac{1}{1 \cdot 3} x^2 + \frac{2}{2 \cdot 4} x^3 + \frac{2}{3 \cdot 5} x^4 + \&c. = (x^3 - 1) S
\]
where making again \( x = 1 \), we have
\[
\frac{2}{1 \cdot 3} + \frac{2}{2 \cdot 4} + \frac{2}{3 \cdot 5} + \frac{2}{4 \cdot 6} + \frac{2}{5 \cdot 7} + \&c. = \frac{2}{3},
\]
\[
\frac{1}{1 \cdot 3} + \frac{1}{2 \cdot 4} + \frac{1}{3 \cdot 5} + \frac{1}{4 \cdot 6} + \frac{1}{5 \cdot 7} + \&c. = \frac{3}{4}.
\]
As another example, let the same series
\[
1 + \frac{1}{2} x + \frac{1}{3} x^2 + \frac{1}{4} x^3 + \frac{1}{5} x^4 + \&c. = S
\]
be multiplied by
\[
(2 x - 1) (3 x - 1) = 6 x^3 - 5 x + 1,
\]

and we have
\[
1 - \frac{9}{1 \cdot 2} x + \frac{23}{1 \cdot 2 \cdot 3} x^2 + \frac{38}{2 \cdot 3 \cdot 4} x^3 + \frac{57}{3 \cdot 4 \cdot 5} = (2 x - 1) (3 x - 1) S
\]
where, by making \( x = \frac{1}{2} \), and \( x = \frac{1}{3} \), we have the two following series:
\[
1. \quad \frac{23}{1 \cdot 2 \cdot 3} + \frac{38}{2 \cdot 3 \cdot 4} + \frac{57}{3 \cdot 4 \cdot 5} + \&c. = \frac{5}{4}
\]
\[
2. \quad \frac{23}{1 \cdot 2 \cdot 3} + \frac{38}{2 \cdot 3 \cdot 4} + \frac{57}{3 \cdot 4 \cdot 5} + \&c. = \frac{1}{2}
\]
The law of both which series is obvious, the numerators being in arithmetical progression. This method is not much different in principle from the second method of Bernoulli above explained.

5. Stirling’s Method of Series. In the recurring series of De Moivre, each term is connected with a certain number of the preceding terms, by a constant and invariable law, but in the series considered by Stirling, in his “Methodus Differentialis,” 1730, each term is a certain function of the number of terms from the beginning, or from some determinate term of the series; which function may therefore be considered as the general term, and the method of summation depends on the following principles.

Having first determined the general term of the series in some function of \( x \), its distance from the beginning, or some determinate term of the series; it follows, that the sum of all the terms to that place will also be some function of \( x \). Therefore, if \( x^t \) is made to denote the distance of any other term from the same point, the sum to that term will be the same function of \( x^t \), as the other sum is of \( x \); and each term of the series may be considered to represent the difference between two consecutive sums, or the difference between two similar functions, viz. of \( x - 1 \) and \( x \); and the object of the author is to determine what those sums or functions are from the difference between them being given.

To be a little more explicit, if there be any series of quantities
\[
a, b, c, \ldots, \&c., t, t', \&c.
\]
proceeding from the first \( a \), by any uniform law, either increasing or decreasing; and if \( x \) be taken to represent the distance of any term, as \( t \), from the beginning of the series, or from any term in the same, then will \( t \) be expressible by some function of \( x \); \( t' \) by the same function of \( x + 1 \); \( t'' \) by the same function of \( x + 2 \), &c.; by denoting therefore this function by \( f(x) \), we shall have
\[
t^0 = f(x - 1), \ t^1 = f(x), \ t'^1 = f(x + 1), \ &c.
\]
Also if \( f^0, f^1, f'^1, \&c. \) denote the sums of all the terms from the beginning to the terms \( t^0, t^1, \&c. \) respectively, these several sums will also be some function of \( x - 1, \ x, \ x + 1, \ x + 2, \ &c. \) which we may denote by
\[
f^0 = \phi(x - 1), \ f^1 = \phi(x), \ f'^1 = \phi(x + 1) \&c.
\]
whence we draw immediately
\[
f - f^0 = t, \text{ or } \phi(x) - \phi(x - 1) = f(x).
\]
SERIES.

Now the function \( f(x) \) is given, being the general term of the series, and the object of enquiry is, from this given function to determine the two functions \( \zeta(x) \) and \( \zeta(x-1) \), of which it is the difference; for the former of these, \( \zeta(x) \), will then be the sum of the series to the term \( n \) inclusive.

To illustrate this by a familiar example; let the proposed series be

\[
1 + 3 + 5 + 7 + 9, \quad \&c.
\]

the general term of which is \( 2x-1 \); therefore,

\[
\zeta(x) = \zeta(x-1) = 2x-1;
\]

whence we have obviously \( \zeta(x) = x^3 \), for

\[
x^3 = (x-1)^2 = 2x-1;
\]

therefore \( x^3 \) is the sum of \( n \) terms of the above series.

Again, let it be required to find the sum of \( n \) terms of the series

\[
1, 7, 19, 37, \quad \&c.
\]

of which the general term

\[
f(x) = 3x^2 - 3x + 1,
\]

therefore,

\[
\zeta(x - \zeta(x-1)) = 3x^2 - 3x + 1;
\]

consequently \( \zeta(x) = x^3 \), the sum of the terms of the series.

In these two examples, finding the sum \( \zeta(x) \) from the difference is extremely simple; but in the generality of cases it is far from being so obvious, and even in some, it is impossible to exhibit the sum of the series in any other manner than by another series; but as in the latter case the transformed series may be made to poise almost any degree of convergence we please, this method of summation is still attended with important advantages, and even more perhaps in the latter case, than in any other; because, although not all, summable series, may be summed on some other principles; viz. by the method of recurring series, or by the differential method, or by increments, while the transformation of a slowly converging series, into another of rapid convergence, is frequently extremely difficult to effect on any other principle than that of Stirling's, or some other tantamount to it.

From what is stated above it appears, that the principal object of enquiry is, in what manner we are to determine a function from two laws of it being given. In the examples we have chosen for illustration, the function whose difference is derived is extremely obvious; but this in many cases is, as we have before observed, attended with some difficulty. In this respect the summation of series resembles a great degree the inverse method of fluxions. There is little or no difficulty in any case in finding the fluxions of any proposed quantity; but the finding of the fluent of any given fluxion is far from poising the same facility. So also in the present case, if the question was to find the difference between two different states of a given function, we should find the operation direct and simple; but the converse, or the finding the function from the difference being known, is indirect, and frequently difficult to be determined.

It is obvious also, that two different functions, which differ from each other only by some constant quantity, will give the same difference, and consequently, a given difference may give rife to different functions, the same as happen in finding fluents, and it will therefore be necessary in this case, as in that, to have recourse to a correction, which will be found in the same manner as is practised in that calculus, viz. by finding the value of the series, when the variable quantity is made equal to zero, or some determined magnitude.

Of the general Term of a Series.—With regard to the general term of a series, it is difficult, particularly within our limits, to lay down any fixed or constant rule for its determination; it is besides seldom necessary, as the law of the series is commonly presented in the terms of the series itself; we shall therefore leave this determination, as in fact it must be in most cases, to the ingenuity of the analyst, and shall proceed immediately to the other subjects of investigation.

It may not, however, be amiss to state, that in such series as have any order of their differences vanish, the general term is always of the form

\[
A n^m + B n^{m-1} + C n^{m-2} + D m^{m-2} + &c.
\]

where \( m \) denotes the order of the differences that vanish, and \( n \) the number of terms from the beginning. The values of \( A, B, C, D, \&c. \) being found by making \( n \) successively equal to 1, 2, 3, \&c., and equating the results with the 1st, 2nd, 3rd, \&c. terms of the series.

Of the Transformation of a given Function to an equivalent one of a different Form.—Since we shall confine our investigation only to those series whose terms are either integers or rational fractions, it is obvious that the general term must also be some rational function either of the form,

\[
a + bx + cx^2 + dx + &c. \quad \text{or}
\]

\[
a + bx + cx^2 + dx^3 + &c.
\]

and our object is to transform either of those general forms into others, whereas the general function from which they have been derived may be the more readily determined. Different transformations may be employed for this purpose; but the most general, and that, in fact, to which Stirling principally confines himself, is to transform the above general terms into other equivalent ones of the form

\[
A + B x + C x(x-1) + D x(x-2) + &c.
\]

\[
A \left( \frac{x(x+1)}{x(x+1)+x(x+1)(x-2)} + \frac{x(x+1)(x+2)}{x(x+1)(x+2)(x+3)} \right)
\]

from either of which the general function whence they have been derived may be readily determined. For it is obvious that the first is equal to the difference between the two similar functions

\[
A x + \frac{1}{4} B (x+1) x + \frac{1}{4} C (x+1) x(x-1) + \frac{1}{4} D (x+1) x(x-1)(x-2) + &c.
\]

and

\[
A (x-1) + \frac{1}{4} B x(x-1) + \frac{1}{4} C x(x-1)(x-2) + \frac{1}{4} D x(x-3)(x-4) + &c.
\]

For by subtracting these one from the other, we have

\[
A + B x + C x(x-1) + D x(x-2) + &c.
\]

And therefore, from what has been stated, the first of the above formulae will be the general sum of those series of which the general term is

\[
A + B x + C x(x-1) + D x(x-2) + &c.
\]

And in a similar manner it may be shown, that the second general form is equal to the difference between the two similar functions.
SERIES.

\[ \frac{A}{x} + \frac{B}{2x(x+1)} + \frac{C}{3x(x+1)(x+2)} + \frac{D}{4x(x+1)(x+2)(x+3)} + \&c. \]

and

\[ \frac{A}{1+x} + \frac{B}{2(x+1)(x+2)} + \frac{C}{3(x+1)(x+2)(x+3)} + \frac{D}{4(x+1)\cdots(x+4)} + \&c. \]

For by subtracting these one from the other, we have

\[ \frac{A}{x(x+1)} + \frac{B}{x(x+1)(x+2)} + \frac{C}{x(x+1)(x+2)(x+3)} + \&c. \]

and consequently the former is the sum of that series whose general term is

\[ \frac{A}{x(x+1)} + \frac{B}{x(x+1)(x+2)} + \frac{C}{x(x+1)(x+2)(x+3)} + \&c. \]

So that the whole difficulty is now reduced to that of transforming any proposed function, expressing the general term of a series into an equivalent function of one or other of the above forms.

To transform a quantity of the form

\[ a + bx + cx^2 + dx^3 + ex^4 + \&c. \]

into another of the form

\[ A + Bx + Cx(x-1) + Dx(x-1)(x-z) + \&c. \]

By the actual multiplication of the latter formula, we have

\[ A = A \]
\[ B = Bx \]
\[ Cx(x-1) = -Cx + Cx^2 \]
\[ Dx(x-1)(x-z) = Dx - 3Dx^2 + Dx^3 \]

And equating the co-efficients of the like powers of \( x \) in this and the original series, we obtain

\[ d = D \]
\[ e = C - 3D \]
\[ b = B - C + D \]
\[ a = A \]

Whence the values of \( A, B, C, D, \&c. \) are determined by means of the known co-efficients \( a, b, c, d, \&c. \). And the same method may obviously be employed in any other similar case. The following table, however, will facilitate the operation; \( \&c. \)

\[ x = x \]
\[ x^2 = x + x(x-1) \]

Now

\[ \frac{1}{x} = \frac{1}{x(x+1)} + \frac{1}{x(x+1)(x+2)} + \frac{2}{x(x+1)(x+2)(x+3)} + \frac{6}{x(x+1)\cdots(x+4)} + \&c. \]

\[ \frac{1}{x^3} = \frac{1}{x(x+1)(x+2)} + \frac{3}{x(x+1)(x+2)(x+3)} + \frac{11}{x(x+1)\cdots(x+4)} + \&c. \]

\[ \frac{1}{x^4} = \frac{1}{x(x+1)(x+2)(x+3)} + \&c. \&c. \]

Or by making

\[ A = \alpha \]
\[ B = \alpha + \gamma \]
\[ C = 2\alpha + 3\beta + \gamma \]
\[ D = 6\alpha + 11\beta + 6\gamma + \gamma \]
\[ E = 24\alpha + 50\beta + 35\gamma + 10\beta + \gamma \]
\[ F = 120\alpha + 274\beta + 225\gamma + 85\beta + 15\gamma + \gamma \]

which
which values substituted for $A$, $B$, $C$, &c. will give the transformation sought, and which will terminate by one of those expressions becoming zero, when the series is summable, but when it is not the expression itself will become an infinite series, but such that we may give it almost any degree of convergency at pleasure.

Let us now illustrate what has been said by a few examples, remembering that the sum of a series, whose general term is

$$A + Bx + Cx(x - 1) + Dx(x - 1)(x - 2), =$$

$$A + \frac{1}{2}B(x + 1)x + \frac{1}{3}C(x + 1)x(x - 1) + &c.$$

Let it be proposed to sum the series of odd numbers,

$$1 + 3 + 5 + 7 + &c.$$

Here the general term is $2.\pi - 1$, or $-1 + 2n$; so that

$$a = -1 \text{ and } b = 2; \text{ whence } A = -1, \text{ and } B = 2,$$

and

$$C = 0; \text{ whence } A + \frac{1}{2}B (x + 1)x = x + x^2 - 1 = x^3, \text{ which is the known expression for the sum of } n \text{ terms of the above series.}$$

Again, require the sum of the series,

$$1 + 2 + 3 + 4 + 5 + &c.$$

Here the general term is $n(x + 1)$, or $x^3 + x^2 + 1$; by the preceding table,

$$x = n$$

$$x^2 = n + x(x - 1) = 2x + x(x - 1).$$

Therefore $A = 0$, $B = 2$, and $C = 1$; whence we have

$$\frac{1}{2}B (x + 1)x + \frac{1}{3}C (x + 1)x(x - 1) =$$

$$\frac{1}{3}(x^3 + 3x^2 + 2x), \text{ the sum of } n \text{ terms, as required.}$$

But as there is no advantage gained by the application of this method to series of the above kind, nor indeed to any summable series, as these are commonly more readily resolved by some one of the preceding methods than by this, we shall pass immediately to series of the second kind, in which it possesses a facility of application, which is perhaps unattainable by any other principle at present known.

Here we must observe, that after the general term of any series is reduced to the form,

$$A + B + C$$

$$x(x + 1) + x(x + 1)(x + 2) + x(x + 1)(x + 2)(x + 3) + &c.$$

the sum of that series is expressed by

$$A + \frac{B}{2x(x + 1)} + \frac{C}{3x(x + 1)(x + 2)} + &c.$$

1. Let it be proposed to find the sum of the infinite series,

$$\frac{1}{1} + \frac{1}{4 \cdot 7} + \frac{1}{4 \cdot 7 \cdot 10} + \frac{1}{7 \cdot 10 \cdot 13} + &c.$$  

where the general term is

$$\frac{1}{3x(x + 3)(x + 6)} = \frac{1}{27}x(x + 1)(x + 2)^3$$

$x$ being successively $\frac{1}{2}$, $\frac{1}{3}$, $\frac{2}{3}$, &c.

Now this is of the required form, $A = 0$, and

$$B = \frac{1}{27}; \text{ therefore the required sum is }$$

$$\frac{1}{54} \frac{(x + 1)}{x},$$

by taking $x = \frac{1}{3}$, its first value. If we took $x = \frac{1}{2}$,

we should have the sum of all the terms of the series, except the first; if $x = 2$, we should have the sum of all but the two first terms, and so on: and it is by this means that we are enabled to give to a great degree of convergency in those series that are not summable; for we may assume any one of the values of $x$, and by that means give almost any magnitude to the denominators of our converging fractions; observing only, that such of the leading terms of the series as are not included must be summed by themselves, and added to the approximation found as above. As this is the great characteristic of Stirling's method, we shall confine our future remarks to one or two examples, which are not summable, in order to illustrate the nature of his approximations.

Let there be proposed the series,

$$\frac{1}{1 \cdot 2} + \frac{1}{3 \cdot 4} + \frac{1}{5 \cdot 6} + \frac{1}{7 \cdot 8} + &c.;$$

which is that found by lord Brontimer, for the quadrature of the hyperbola.

Here the general term is

$$\frac{1}{2x(2x + 1)} \text{, or } \frac{1}{4x(x + \frac{1}{2})} = \frac{1}{4x^2 + 2x};$$

taking $x = \frac{1}{3}$, $\frac{1}{3}$, $\frac{2}{3}$, &c. Now

$$\frac{1}{4x^2 + 2x} = \frac{1}{4x^2} - \frac{1}{8x^3} + \frac{3}{16x^4} - \frac{1 \cdot 3 \cdot 5}{32x^5} + &c.;$$

that is,

$$A = \frac{1}{4}, B = \frac{1}{8}, C = \frac{3}{16}, D = \frac{1 \cdot 3 \cdot 5}{32}, &c.;$$

whence

$$\frac{1}{4x^2 + 2x}, \text{ when converted into the required form, is,}$$

$$\frac{1}{4x^2 + 2x} + \frac{1 \cdot 3 \cdot 5}{32x(x + 1)(x + 2)(x + 3) + &c.;}$$

where the law of continuation is obvious, and the sum will be expressed by

$$\frac{1}{4x} + \frac{1}{16x(x + 1)} + \frac{1 \cdot 3}{48x(x + 1)(x + 2)} + \frac{1 \cdot 3 \cdot 5}{128x(x + 1)(x + 2)(x + 3) + &c.;}$$

The original series has, therefore, been converted into another infinite series, but with this advantage attending the latter, that we may give it almost any degree of convergency at pleasure, according to the value we give to $x$. If we assume $x = 13\frac{1}{2}$, which is its value in the 14th term, then the preceding series will exhibit the sum of the original series.
SERIES.

Series from that term, to which adding the sum of the first 13 terms, we have, for the whole sum,

\[
\begin{align*}
13 & \text{ first terms} = .674285961 \\
9 & \text{ first terms of the new series} = .018861219 \\
\text{Whole sum} & = .693147180
\end{align*}
\]

This is true to nine places of decimals, which, if we had used the original series, would have required the summation of at least one hundred million of its terms.

Hence the advantage of this transformation, which consists in our being able, by the summation of a few of the leading terms of the original series, to give any degree of convergency to our transformed series, and thereby to perform the same upon a few terms, as would require the labour of ages to effect upon the series in its original form.

As another example, let the series,

\[
\frac{1}{x} = \frac{1}{x(x + 1)} + \frac{1}{x(x + 1)(x + 2)} + \frac{1}{x(x + 1)(x + 2)(x + 3)} + \frac{1}{x(x + 1)(x + 2)(x + 3)(x + 4)} + \&c.;
\]

be proposed, in which the general term is \( \frac{1}{x} \).

Now, from what has been said, it appears that

\[
\frac{1}{x} = \frac{1}{x(x + 1)} + \frac{1}{2 x(x + 1)} + \frac{1}{3 x(x + 1)(x + 2)} + \frac{1}{4 x(x + 1)(x + 2)(x + 3)} + \frac{1}{5 x(x + 1)(x + 2)(x + 3)(x + 4)} + \&c.;
\]

and consequently the sum will be

\[
\frac{1}{x} - \frac{1}{x(x + 1)} \frac{1}{2 x} \frac{1}{(x + 1)(x + 2)} \frac{1}{3 x} \frac{1}{(x + 1)(x + 2)} \frac{1}{4 x} \frac{1}{(x + 1)(x + 2)(x + 3)} + \&c.;
\]

in which substituting 13 for \( x \), viz. its 14th value, we find, by summation 13 terms of the new series, and adding that sum = .6742857427, to the sum of the first 12 terms of the original series, viz. 1.5619766653, we have 1.6419345065 for the whole approximate sum, true to nine places of decimals.

Our limits will not allow of our entering farther upon this method, and we shall therefore conclude our illustration of it, by merely giving the author's formula for the summation of those series, in which the successive powers of an indeterminate quantity enter; all those which we have at present considered, having been wholly numerical. The formula for this purpose is as follows.

If the terms of any series be formed by writing any number, differing by unity, for \( z \) in the quantity

\[
x + \frac{a}{(1-x)z} + \frac{b}{(1-x)z(z+1)} + \frac{c}{(1-x)z(z+1)(z+2)} + \&c.;
\]

then the sum will be expressed by

\[
x^{n+1} \times \left\{ \frac{a}{(1-x)z} + \frac{b}{(1-x)z(z+1)} + \frac{c}{(1-x)z(z+1)(z+2)} + \&c. \right\};
\]

where \( A, B, C, \&c. \) represent the terms immediately preceding those in which they are found.

This latter expression, like those in the preceding propositions, will terminate when the series is summable; in other cases, it will be itself an infinite series, but such that we may give it to any degree of convergency required.

Simpson's Method of Series.—In 1743 Simpson published his "Mathematical Dissertations on a variety of Physical and Analytical Subjects," and amongst other interesting researches in that work, there is one relating to the summation of series, which is perhaps as general and complete as any we have yet noticed; at least, if we except (with regard to approximations) that of Stirling's, above explained. This method consists in deriving the sum of one series from that of another being given or known; which former sum is expressed by a finite or infinite formula, according as the successive differences of certain parts of its terms are of definite or indefinitely extent; thus, if

\[
a^n + b a^{n-1} x + c a^{n-2} x^2 + d a^{n-3} x^3 + \&c.,
\]

be any power (\( n \)) of the binomial \( a + x \), \( n \) being either integral, fractional, positive, or negative; and the terms of it be respectively multiplied by any series of quantities, \( p, q, r, s, \&c. \); and we make \( q - p = D, r - q + p = D', r - 2 q + p = D'', \&c. \), viz.

\[
D', D'', D''', \&c. \],
\]

being the first terms of the successive orders of differences, then the sum will be

\[
D' b a^{n-1} x + D'' c a^{n-2} x^2 + D''' d a^{n-3} x^3 + \&c.;
\]

be expressed by

\[
(p + a x)^n + D' b x (a + x)^{n-1} + D'' c x^2 (a + x)^{n-2} + D''' d x^3 (a + x)^{n-3} + \&c.;
\]

which formula will obviously be finite, if any order of the

Vol. XXXII.

From which general formula a great variety of particular cases may be drawn, according to the different values that are given to \( a, x, \) and \( n \).

Again, let the sum of the series

\[
a x^2 + b x^{n+1} + c x^{n+1} + d x^{n+2} + \&c. = \Lambda
\]

and the terms be respectively multiplied by the terms of the arithmetical progression \( r, r + n, r + 2 n, \&c. \), then will the sum of the series hence arising (B), viz.

\[
r a x^2 + (r + n) b x^{n+1} + (r + 2 n) c x^{n+2} + \&c.
\]

be
be expressed by the fluxional formula

\[(r - p) A + \frac{x \dot{A}}{x} = B;\]

where, because it is given in finite terms, \( \dot{A} \) will always
likewise be had in finite terms, and consequently, also, the
value of \( B \). And in the same manner as we have

\[a x^r + b x^{r+n} + c x^{r+n} + \&c. = A\]

\[r a x^r + (r + n) b x^{r+n} + (r + 2 n) c x^{r+n} + \&c. =\]

\[(r - p) A + \frac{x \ddot{A}}{x} = B;\]

so also

\[r \Delta x^r + (r + n) \Delta x^{r+n} + (r + 2 n) \Delta x^{r+n} + \&c. =\]

\[(r - p) B + \frac{x \dddot{B}}{x} = C \&c. \&c.\]

The three preceding cases are the first, second, and third
propositions in the author's chapter on series, which contains
four other propositions equally general and important; but
for these we must refer the reader to the tract itself.

Since the publication of Simpson's work above referred to,
a variety of other treatises have appeared either wholly or in
part devoted to this subject, besides numerous memoirs in all
the principal academies and learned societies in Europe. It
will be impossible to enter upon these at any considerable
length within the limits of this article, and we shall therefore
merely select two or three of the principal authors
whose methods are the most eligible for the purposes of
general fumination.

Euler, in this, as in every other branch of analysis, has
distinguished himself by the many new lights he has thrown
upon this theory, and the general and elegant investigations
that he has given of many very interesting problems relating
to this doctrine. These investigations are found in various
memoirs in the Acta Petrop. and in his "Institutiones calculi
differentialis," as also in the first volume of his "Introduction
in Analyzin Infinitorum;" many of these, however, may be
referred to the Method of Increments and Recurring
Series, which have been already treated of under those
articles; the theory of circular series is also handled in his
usually masterly manner, but for our purpose we shall prefer
adopting the method employed by Landen in his "Mathematical
Lucubrations," and shall therefore, in this place, limit our
observations to Euler's differential method.

Euler's Differential Method of Euler.—Let there be
proposed the general series

\[S = a x + b x^2 + c x^3 + d x^4 + \&c.\]

in which \( a, b, c, d, \&c. \) are constant and positive quantities,
\( x \) being indeterminate. This series Euler transforms into
the following equivalent series, viz.

\[S = \frac{x \Delta a}{1 - x} + \frac{x^2 \Delta^2 a}{(1 - x)^2} + \frac{x^3 \Delta^3 a}{(1 - x)^3} + \&c.\]

in which \( \Delta a, \Delta^2 a, \Delta^3 a \) denote the first terms of the
first, second, third, \&c. differences of \( a, b, c, \&c. \) observing
that the leading term is always supposed to be taken from
the following, so that when the terms diminish, this
difference will be negative. It is obvious here, as in the other
differential series, we have had occasion to notice, that when
any order of differences vanishes, the transformed series will be
finite, but in other cases infinite, the same as that whence it is
derived.

Let, for example, the series

\[S = x^2 + 2 x^3 + 3 x^4 + 4 x^5 + \&c.\]

be the one proposed. Here the first differences are 1, 1, 1,
\&c. and, consequently, the second differences are zero; that
is, we have \( a = 1 \), and \( \Delta a = 1 \); so that we have

\[S = \frac{x}{1 - x} + \frac{x^2}{(1 - x)^2} + \frac{x^3}{(1 - x)^3} + \&c.\]

Hence, by substituting \( x = 1, \frac{1}{2}, \frac{1}{3}, \&c. \) we obtain

\[x = 1; S = 1 + 2 + 3 + 4 + \&c. = \frac{1}{1 - 1} = \infty\]

\[x = \frac{1}{2}; S = \frac{1}{2} + \frac{2}{4} + \frac{3}{8} + \frac{4}{16} + \&c. = \frac{1}{1 - \frac{1}{2}} = 2\]

\[x = \frac{1}{3}; S = \frac{1}{3} + \frac{2}{9} + \frac{3}{27} + \frac{4}{81} + \&c. = \frac{1}{1 - \frac{1}{3}} = \frac{3}{2}\]

Again, let the proposed series be

\[S = x + 3 x^2 + 5 x^3 + 7 x^4 + \&c.\]

Here \( a = 1, \Delta a = 2, \Delta^2 a = 0 \); therefore

\[S = \frac{x}{1 - x} + \frac{x^2}{(1 - x)^2} + \frac{x^3}{(1 - x)^3} + \&c.\]

Making therefore, as before, \( x = 1, \frac{1}{2}, \frac{1}{3}, \&c. \)
we have

\[x = 1; S = 1 + 2 + 3 + 4 + \&c. = 1 + \frac{1}{1 - 1} = \infty\]

\[x = \frac{1}{2}; S = \frac{1}{2} + \frac{2}{4} + \frac{3}{8} + \frac{4}{16} + \&c. = \frac{1}{2} + \frac{1}{1 - \frac{1}{2}} = 3\]

\[x = \frac{1}{3}; S = \frac{1}{3} + \frac{2}{9} + \frac{3}{27} + \frac{4}{81} + \&c. = \frac{1}{2} + \frac{1}{1 - \frac{1}{3}} = 1\]

Without further examples, it is obvious, that a most ex-
tensive class of converging series may be drawn from this one
simple principle, by merely changing the values of \( x \); and
those of \( a, b, c, d, \&c. \) being supposed, that a certain
order of their differences may vanish, which will always hap-pen, if they be made to represent any order of polygonal or
figurate numbers, or any order of powers whatever. This
method, however, is not limited to finding converging series,
it may frequently be employed to great advantage in approxi-mating towards the real value of slowly converging series
that are not convergent in any finite form, as for example,
the series

\[1 = \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \&c. = \text{hyp. log. 2} \]

putting this under the form

\[S = x + \frac{1}{2} x^2 + \frac{1}{3} x^3 + \frac{1}{4} x^4 + \&c.\]

we have \( a = 1, \Delta a = -\frac{1}{2}, \Delta^2 a = \frac{1}{2}, \Delta^3 a = -\frac{1}{2} \&c. \)
whence

\[S = \frac{x}{1 - x} + \frac{x^2}{(1 - x)^2} + \frac{x^3}{(1 - x)^3} + \&c.\]

will
will become, by making \( x = -1 \),
\[
S = \frac{1}{2} - \frac{1}{3} + \frac{1}{4} - \frac{1}{5} + \frac{1}{6} - \frac{1}{7} + \frac{1}{8} - \frac{1}{9} + \cdots &= \text{etc.}
\]
whence, by changing signs, we have
\[
1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5} - \cdots = \text{hyp. log. 2}
\]
\[
= \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \cdots = \text{etc.}
\]
which latter series, though indefinite like the first, is so much more converging, that 25 terms of it will give a result as true as 10,000 terms of the original series.

The same formula is also applicable to certain diverging series, but we can only give some of the most remarkable results, as
\[
1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots = \frac{1}{2}
\]
\[
1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5} - \frac{1}{6} = \frac{1}{4}
\]
\[
1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5} = \frac{1}{2}
\]
\[
1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5} + \frac{1}{6} = \frac{1}{2}
\]
\[
= 0.57493562137
\]
euler also employed other methods for summing series which we have not referred to either in the above article, or in the articles \textit{Increments or Recurring Series}, one of the most general of which is by means of certain fluxional operations; but as this has been carried to a greater extent by lorgna, in his tract "de seriebus convergentibus," we shall defer any further mention of it till we come to an explanation of lorgna's method.

We ought to give here some account of the differential method of Maclaurin and hutton, but our article having already been carried to a greater extent than usual for mathematical subjects, we must limit ourselves to giving merely the theorem, and leave the application of them to the ingenuity of the reader.

8. Maclaurin's differential Formula for slowly converging Series.

Let
\[
a + bx + cx^2 + dx^3 + \cdots
\]
represent any series, and \( D, D', D'', \text{etc.} \), the first terms of the successive order of differences of the coefficients \( a, b, c, d, \text{etc.} \), which are supposed continually to diminish, then will the sum of the above series be expressed by the differential series
\[
a + bx + cx^2 + dx^3 + \cdots = \frac{D}{1 + x} - \frac{D'}{1 + x}^2 - \frac{D''}{1 + x}^3 - \cdots
\]
which is necessarily converging, provided \( x \) be equal to, or greater than unity. By means of this series, the author finds the circumference of the circle from the series
\[
1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \cdots = \text{etc.}
\]
true to seven places of decimals, by the summation of ten terms, whereas, in its original form, 10,000 of its terms will only give two decimals correct. For a further illustration of this method, the reader is referred to the Phil. Trans. for 1775, or to the author's treatise on Converging Series.

9. Hutton's Method for slowly converging Series.—This method applies only to those series whose terms are alternately plus and minus, as \( a - b + c - d + \cdots \), the total sum of which series is given alternately in excess and defect, by the successive quantities
\[
\begin{align*}
\frac{a}{2}, & \quad \frac{3a - b}{4}, & \quad \frac{7a - 4b + c}{8}, \\
\frac{15a - 11b + 3c - d}{16}, & \quad \frac{31a - 26b + 16c - 6d + e}{32}, & \quad \cdots
\end{align*}
\]
and each of these quantities, as we have stated above, is an approximation towards the whole sum; the first in excess, the second in defect, the third in excess, and so on; but each is a nearer approximation than the preceding. The general formula for \( n \) terms is
\[
\frac{1}{2^n} \left\{ (2^n - 1) a - (A - n) b - (B - \frac{n(n - 1)}{1 \cdot 2} \cdots) c \right\}
\]
The method of applying this formula to computation, however, is such, that we must refer the reader for an explanation of it to the author's Miscellaneous Tracts, published in 1778, or to the new edition of the same in 3 vols. 8vo. published in 1812.

10. Lorgna's Method of Series.—This consists in multiplying the terms of the proposed series by such powers of an indeterminate quantity, that the fluxion of the whole series being taken, and then divided by \( x \), there shall result a known series, from which the sum of the original one may be readily derived. Thus, let there be proposed the series
\[
\frac{1}{p + q} + \frac{1}{p + 2q} + \frac{1}{p + 3q} + \text{etc.}
\]
Multiply each term successively by
\[
x^{p+1}, x^{p+2}, x^{p+3}, \text{etc.}
\]
and there results
\[
x^{p+1} + x^{p+2} + x^{p+3} + \text{etc.}
\]
\[
\frac{x^{p+1}}{p + q} + \frac{x^{p+2}}{p + 2q} + \frac{x^{p+3}}{p + 3q} + \text{etc.}
\]
Make the sum of this series \( S \), and then taking the fluxion on both sides, we have
\[
\frac{q}{x} \frac{dS}{dx} = x^{p+1} + x^{p+2} + x^{p+3} + \text{etc.}
\]
or
\[
\frac{q}{x} = 1 + x + x^2 + x^3 + \text{etc.}
\]
whence
\[
S = \frac{x^{p+1}}{q(1 - x)}
\]
which, by making \( x = 1 \), becomes the same as the series originally proposed, viz.
\[
\frac{1}{p + q} + \frac{1}{p + 2q} + \frac{1}{p + 3q} + \frac{1}{p + 4q} + \text{etc.}
\]
It must be observed, however, that in all such expressions, the fluxion must be so taken, as to vanish when \( x = 0 \), and to be perfectly integral when \( x = 1 \).

By a similar process, the author finds the sum of the series,
\[
\frac{1}{p + q} + \frac{1}{p + 2q} + \frac{1}{p + 3q} + \frac{1}{p + 4q} + \text{etc.}
\]

O 0 2
to be equal to \( \frac{1}{q} \int \frac{p}{x^2 + \frac{x}{1 + x}} \); the fluent being taken under
the same restrictions as before. And in nearly the same way
he finds the sum of \( n \) terms of the former to be
\[
\Sigma = \frac{1}{q} \left\{ \int \frac{x}{x^2 + \frac{x}{1 + x}} - \int \frac{x + 2}{1 - x} \right\}
\]
and the latter,
\[
\Sigma = \frac{1}{q} \left\{ \int \frac{x}{x^2 + \frac{x}{1 + x}} - \int \frac{x + n}{1 - x} \right\}
\]
In a similar manner, M. Lorgna finds for the infinite sum of
\[
\frac{1}{(p + q)m} + \frac{1}{(p + 2q)m^2} + \frac{1}{(p + 3q)m^3} + \cdots
\]
\[
S = \frac{1}{q} \int \frac{x}{m \pm x}; \text{ and the sum of } n \text{ terms,}
\]
\[
\Sigma = \frac{1}{q} \int \frac{(m^n - x^n) x}{m^n (m - x)} \text{, when the signs are all plus;}
\]
and \( \Sigma = \frac{1}{q} \int \frac{(m^{2n} - x^{2n}) x}{m^{2n} (m + x)} \) when alternately plus and minus.

For a farther illustration of this method, we refer the reader to Clarke's translation of Lorgna's treatise, "De Seriesbus Convergentibus," 4th. ed., 1779.

11. Circular Series. — We have stated, when illustrating the methods of summation employed by the Bernoullis, that James, although he had discovered several curious properties of the series,
\[
\frac{1}{1} + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \cdots
\]
had not been able to find its sum; but this his brother John afterwards effected, and the solution of it is published in the 4th volume of his "Opera Omnia." Bernoulli found this sum to depend upon the rectification of the circle, shewing that it is equal to one-sixth of the square of the semi-circumference of a circle, whose radius = 1. This result he drew from the known series, which expresses the sine of an arc in terms of the arc, viz.

\[
f \sin \, x = x - \frac{x^3}{2 \cdot 3} + \frac{x^5}{2 \cdot 3 \cdot 4 \cdot 5} - \frac{x^7}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} + \cdots
\]
which, when \( \sin \, x = 0 \), becomes, after dividing by \( x \),
\[
o = 1 - \frac{1}{2 \cdot 3} x^3 + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} - \frac{1}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} + \cdots
\]
Or writing \( x = \frac{1}{z} \);
\[
o = 1 - \frac{1}{2 \cdot 3} \frac{z^3}{2 \cdot 3 \cdot 4 \cdot 5} - \frac{1}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} + \cdots
\]
Again, multiplying by \( z^n \),
\[
o = z^{3n} - \frac{1}{2 \cdot 3} z^{5n-1} + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} z^{7n-4} + \cdots
\]
Now the sum of the roots of every equation of this form
being equal to the co-efficient of the second term with its sign changed, we have
\[
z^2 + z^3 + z^4 + \cdots + \&c.,
\]
and in nearly the same way he finds the sum of the roots of the above equation.

But we know that the values of \( x \), answering to the case of
\( \sin \, x = 0 \), arc \( x \), \( \frac{x^3}{2} \), \( \frac{x^5}{2 \cdot 3} \), \( \frac{x^7}{2 \cdot 3 \cdot 4} \), \&c.; = denoting the semi-circumference; substituting, therefore, these succeessive values of \( x \), we have
\[
\frac{1}{x^2} + \frac{1}{x^3} + \frac{1}{x^4} + \cdots + \frac{1}{x^n} + \&c. = \frac{1}{q} i
\]
denoting by \( x^\frac{1}{2}, x^\frac{3}{4}, x^\frac{5}{6}, \&c., \) or \( \frac{1}{x^\frac{1}{2}}, \frac{1}{x^\frac{3}{4}}, \frac{1}{x^\frac{5}{6}}, \&c. \) the
succeessive roots of the above equation.

And Landen's method depends upon exactly the same principles; but he has rendered it more general, and exhibits several very remarkable series of this kind. He first deduces the formulae for expressing the sums of the several powers of the roots, \( a, b, c, \&c. \) of any equation
\[
x^n + A x^{n-1} + B x^{n-2} + C x^{n-3} + \&c. = 0;
\]
\( viz. \) if \( S' = a + b + c + \&c. \)
\( S'' = a^2 + b^2 + c^2 + \&c. \)
\( S''' = a^3 + b^3 + c^3 + \&c. \)
then
\( S' = - A \)
\( S'' = - 2 B - A S' \)
\( S''' = - 3 C - B S' - A S'' \)
\( S' = - 4 D - C S' - B S'' - A S''' \)
\&c. \&c.

Then from the two series for the sine and cosine of any
arc \( x \), viz.
\[
\sin \, x = x - \frac{x^3}{2 \cdot 3} + \frac{x^5}{2 \cdot 3 \cdot 4 \cdot 5} - \frac{x^7}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} + \cdots
\]
\[
\cos \, x = 1 - \frac{x^2}{2} + \frac{x^4}{2 \cdot 3} - \frac{x^6}{2 \cdot 3 \cdot 4} + \cdots
\]
he derives the sum of their squares, when \( \sin \, x = 0 \), and \( \cos \, x = 0 \); and, from the preceding formula for the sums of the squares, cubes, \&c. of the roots of an equation, draws the values of the several powers of those quantities.

Thus in the series for the cosine, when \( \cos \, x = 0, \) we
have for the several roots, (denoting the quadrant or \( \frac{\pi}{2} \) by \( \varphi \)),
\[
\frac{1}{\varphi} + \frac{1}{3 \varphi} + \frac{1}{5 \varphi} + \frac{1}{7 \varphi} + \cdots
\]
there being no second term, but the sum of these squared, \( \cos^2 \),
\[
\frac{1}{\varphi^2} + \frac{1}{3 \varphi^2} + \frac{1}{5 \varphi^2} + \frac{1}{7 \varphi^2} + \cdots
\]
SERIES.

\[ \frac{2}{\varphi} + \frac{2}{2^2 \varphi} + \frac{2}{5^2 \varphi} + \frac{2}{7^2 \varphi} = S'' = \frac{1}{6^3} \]

\[ \frac{1}{1^2} + \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} = \frac{\pi^2}{2}. \]

In a similar manner we have

\[ \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} + \&c. \]

and on the same principle, the sum of the series,

\[ \frac{1}{1^2} + \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} + &c. \]

may be found, a being any positive number whatever.

Euler's method is still more general than Landen's, but it depends upon principles of very nearly the same origin: we must, however, limit ourselves to giving a few of the principal results. Representing by \( \pi \) the semi-circumference to radius 1, he shews that

\[ 1 + \frac{1}{2^2} + \frac{1}{4^2} + \&c. = \frac{\pi^2}{6} \]

\[ 1 + \frac{1}{3^2} + \frac{1}{5^2} + \&c. = \frac{\pi^2}{12} \]

\[ 1 + \frac{1}{6^2} + \frac{1}{8^2} + \&c. = \frac{\pi^2}{24} \]

\[ \&c. \]

where the law of the first multiplier is obvious, but the coefficients of \( \pi^2, \pi, \&c. \) are not so easily seen: those for the following powers are

\[ \frac{\pi^3}{3}, \frac{\pi^5}{5}, \frac{\pi^7}{7}, \frac{601}{105}, \&c. \]

If each of these series be multiplied by their first fraction, they give

\[ \frac{1}{2^2} + \frac{1}{4^2} + \frac{1}{6^2} + \&c. = \frac{1}{2^2} \cdot \frac{\pi^2}{6} \]

\[ \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} + \&c. = \frac{1}{3^2} \cdot \frac{\pi^2}{12} \]

\[ \&c. \] and subtracting the first from the latter, we have

\[ \frac{1}{3^2} + \frac{1}{5^2} + \&c. = \frac{\pi^2}{2^2} \]

\[ \frac{1}{3^2} + \frac{1}{5^2} + \&c. = \frac{\pi^2}{3^2} \]

\[ \&c. \]

Again, subtracting the first from these last, we find the sum of the powers under the alternate signs plus and minus, and so on, almost in endless variety.

Other series, whose sums are found in nearly the same manner, are as follows, viz.

\[ \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \&c. = \frac{\pi}{4} \]

\[ \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \&c. = \frac{\pi}{8} \]

\[ \frac{1}{3} - \frac{1}{5} - \frac{1}{7} + \&c. = \frac{\pi}{32} \]

\[ \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \&c. = \frac{\pi}{96} \]

\[ \&c. \]

For a great variety of other series of this kind, see Euler's "Introductio in Analytin Infinitorum," and his "Institutiones Calculi Differentialis." See also Spence's "Effay on the Theory of the various Orders of Logarithmic Transcendents," 4th. 1809; in which several series, somewhat similar to the above, but which were not fumenable by Euler's method, are treated of, and investigated in a very able manner.

We ought perhaps to apologize to such of our readers who are not interred in mathematical enquiries, for the length to which we have extended this article; but those who are, will not, we presume, be displeased to find in a condensed form a general view of the first introduction, and successive improvements, which have been made in this important branch of analysis. We have, of course, been obliged to pass over silence many authors who have written on this subject; but we have endeavoured to include all those who have introduced into the doctrine any methods distinctly different from those who preceded them, at least, if we except Mr. Spence's method, published in his "Logarithmic Transcendents," and that of M. Arbogast, given in his "Calcul des Derivatives." We had indeed, in the first instance, intended to give an illustration of the principles of these two authors; but the length to which the article has already extended, and the nature of their notation, which render necessary a considerable degree of previous explanation, put it out of our power to execute this part of our plan, and we can therefore do nothing more than refer the reader for information to the works themselves; we refer him also to the "Calcul des Differences Fines," by La Croix, and to an ingenious memoir by professor Vince, in the 72d volume of the Philosophical Transactions.

As the preceding article is arranged wholly with reference to the historical order of the subject, we intend, in conclusion, to furnish the reader with a general synopsis of the doctrine of series for the advantages of practical operations.

12. General Synopsis for the Summation of Series.—In the following table, \( S \) denotes the sum of a finite number of terms \( n \), and \( S \) the sum of an infinite number.

1. To find whether the sum of any proposed series be finite or infinite, let \( p, q, r, s \) be any three equidistant terms; then, if \( p (q-r) > r (p-q) \), the sum is finite, but if \( p (q-r) < r (p-q) \), it is infinite.

2. The general form of a series, when any order of \( m \) of its differences vanish, is of the form

\[ T = A_n + B n^{-1} + C n^{-2} + \&c. \]

and its sum of the form

\[ S = A' n^{m+1} + B' n^m + C' n^{m-1} + \&c. \]

the values \( A, B, C, \&c. \) being found as indicated in art. 5, and those of \( A', B', C', \&c. \) in a similar manner.

3. Simple arithmetical Series.

\[ a + (a+d) + (a+2d) + (a+3d) + \cdots + (a+(n-1)d) \]

\[ (S) \] Infinite (\( S = \frac{n}{2} (2a + (n-1)d) \).

If the series decrease, then \( d \) is negative, and

\[ (S) = \frac{n}{2} (2a - (n-1)d). \]

4. Simple geometrical Series.

\[ a + ra + r^2a + r^3a + \cdots + r^{n-1}a \]

\[ (S) = \frac{a}{1-r} \]

\[ (S) = \frac{r^n - 1}{r - 1} \]

5. Powers
5. **Powers of Arithmeticals.**

\[(m + p)^r + (m + 2p)^r + (m + 3p)^r + \cdots + (m + np)^r\]

\[S = \frac{np^{r+1}}{(r+1)p} + \frac{n^r}{2} + \frac{np^r}{3} + \frac{np^{r+1}}{4} \cdot \cdots \cdot \frac{np^r}{6} + \frac{r(r-1)}{2} \cdot \frac{r(r-2)}{3} \cdot \frac{r(r-3)}{4} \cdot \frac{r(r-4)}{5} \cdot \frac{r(r-6)}{6} \cdot \frac{r(r-8)}{7}, \cdots \]

\[= \frac{1}{3} \cdot \frac{r(r-1)}{2} \cdot \frac{r(r-2)}{3} \cdot \frac{r(r-3)}{4} \cdot \frac{r(r-4)}{5} \cdot \frac{r(r-6)}{6} \cdot \frac{r(r-8)}{7}, \cdots \]

continued till they terminate. The co-efficients are the same as \(\frac{1}{A^e}, \frac{1}{B^e}, \&c.\) \(N^3 11.\)

This form includes all the powers of the natural series, of which we have given the particular forms to the fifth power, under art. 3.

6. **Series of figurate Numbers.**

\[1 + m + \frac{m(m+1)}{1 \cdot 2} + \frac{m(m+1)(m+2)}{1 \cdot 2 \cdot 3} + \frac{m(m+1)(m+2)(m+3)}{1 \cdot 2 \cdot 3 \cdot 4} + \&c\]

\[S = \frac{n(n+1)(n+2)(n+3)}{1 \cdot 2 \cdot 3 \cdot 4} \text{ to } m \text{ terms,}\]

See particular results, art. 3.

7. **Series of compound Arithmeticals.**

\[(m + e) \cdot (p + e) + (m + 2e) \cdot (p + 2e) + \cdots \cdot (m + ne) \cdot (p + ne)\]

\[S = np^e + \frac{n+1}{2} \cdot (m + p) \cdot e + \frac{(n+1)(2n+1)}{6} \cdot e^2\]

8. **Series of compound geometrical Numbers.**

\[(b - m) \cdot (c - p) \cdot e^1 + (b - 2m) \cdot (c - 2p) \cdot e^{1+e} + (b - 3m) \cdot (c - 3p) \cdot e^{1+2e} + \&c.\]

\[S = e^e \cdot \left\{ \frac{b}{1 - e^e} + \frac{b \cdot p \cdot c}{1 - e^e} + \frac{m \cdot p \cdot (1 + e^e)}{(1 - e^e)^2} \right\}\]

9. **Series of compound figurate Numbers.**

\[1 + \frac{m}{1 \cdot 2} + \frac{m(m+1)}{1 \cdot 2 \cdot 3} \cdot \frac{m(m+1)(m+2)}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.\]

\[S = \frac{1}{(1 - x)^m}\]

10. **Series of the Reciprocals of figurate Numbers.**

\[1 + \frac{1}{m} + \frac{1}{m(m+1)} + \frac{1 \cdot 2 \cdot 3}{m(m+1)(m+2)} + \frac{1 \cdot 2 \cdot 3 \cdot 4}{m(m+1)(m+2)(m+3)} + \&c.\]

\[S = \frac{m - 1}{m - 2}\]

11. **Reciprocals of the Powers of Arithmeticals.**

\[\frac{1}{a^n} + \frac{1}{a^{n+1}} + \frac{1}{a^{n+2}} + \cdots \cdot \frac{1}{a^{n+1}}\]

\[S = \frac{n}{a^n} - \frac{1}{a^{n+1}} - \frac{1}{a^{n+2}} - \cdots \cdot \frac{1}{a^{n+1}}\]

where
SERIES.

where the law of continuation is obvious, \( p \) being \( \frac{a}{a+nA} \) and the values of \( \frac{1}{A}, \frac{1}{B}, \frac{1}{C}, \&c \) being derived as follows,

viz. denoting these respectively by \( \frac{1}{a}, \frac{1}{b}, \frac{1}{c}, \&c. \)

\[
\begin{align*}
\phi &= \frac{1}{6} \\
\psi &= \frac{3}{10} - 2.5 \\
\phi &= \frac{5}{14} - 3.5 - 5\psi \\
\end{align*}
\]

\( \psi = \&c. \&c. \) and generally

\[
\begin{align*}
\psi &= \frac{n}{2n+4} - \frac{n+1}{2}\psi - \frac{(n+1)n(n-1)}{2 \cdot 3 \cdot 4}\psi - \frac{(n+1)n(n-1)(n-2)(n-3)}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6}\psi \&c.
\end{align*}
\]

12. Fractional Series of the following Form.

\[
\begin{align*}
(1) & \frac{m}{\beta} + \frac{m(m+p)}{\beta(\beta+p)} + \frac{m(m+p)(m+2p)}{\beta(\beta+p)(\beta+2p)} + \ldots \frac{m(m+p)\ldots (m+(n-1)p)}{\beta(\beta+p)\ldots (\beta+(n-1)p)} \\
(\Sigma) &= \frac{m}{\beta-p-m} \\
(2) & \frac{1}{(p+q)(m+r)} \pm \frac{1}{(p+2q)(m+2r)} + \frac{1}{(p+3q)(m+3r)} \pm \&c. \frac{1}{(p+qn)(m+nr)} \\
(\Sigma) &= \frac{1}{p+q} \times \int \frac{(x^q-x^r)}{1+x} \\
(3) & \frac{1}{(p+q)\beta} \pm \frac{1}{(p+2q)\beta^2} + \frac{1}{(p+3q)\beta^3} \pm \&c. \ldots \frac{1}{(p+qn)\beta^n} \\
(\Sigma) &= \frac{1}{q} \int \frac{(\beta^n-x^n)}{\beta^n-x^n} \\
\end{align*}
\]

where \( \beta \) must be affirmative, and not less than unity.

\[
\begin{align*}
(4) & \frac{a}{b(b+c)} + \frac{a}{(b+c)(b+2c)} + \frac{a}{(b+2c)(b+3c)} + \&c. \ldots \frac{a}{(b+(n+1)c)(b+nc)} \\
(\Sigma) &= \frac{n}{a} \frac{b}{b+nc} \cdot (\Sigma) = \frac{a}{bc} \\
(5) & \frac{a}{b(b+c)} + \frac{a}{(b+c)(b+2c)} + \frac{a}{(b+2c)(b+3c)} + \frac{a+2c}{(b+3c)(b+4c)} \\
&+ \&c. \ldots \frac{a+(n+1)c}{b+(n+1)c} \\
(\Sigma) &= \frac{2abc+ace-bce}{2b(b+c)} \frac{n}{b+(n+1)c} + \frac{(ace+bc)e}{b+(n+1)c} n^2 \\
(6) & \frac{a}{a+1} + \frac{a+b}{(a+1)(a+1+b)} + \frac{a+2b}{(a+1)(a+1+b)(a+1+2b)} \\
&+ \&c. \ldots \frac{a+(n-1)b}{(a+1)(a+1+b)\ldots (a+1+(n-1)b)} \\
(\Sigma) &= 1 - \frac{1}{(a+1)(a+1+b)\ldots (a+1+(n-1)b)} \\
(7) & a \cdot c + (a+b)ce + (a+2b)ce + (a+3b)ce + \&c. \\
(\Sigma) &= \frac{ace(q^n-1) + nbcq^2 - bce(q^n-1)}{q-1} \\
\end{align*}
\]
For a great variety of other fractional series, see Clarke's translation of Lograna's Series; for the several differential formulae, our articles 3, 6, 7, 8, and 9; for the summation of Recurring Series, see that article; for the most useful logarithmic series, see Logarithms; and for various trigonometrical series, see the articles Sines, and Trigonometry.

SERIGNAC, in Geography, a town of France, in the department of the Finiliferre; 10 miles N. of Carhaix.

SERIGNAN, a town of France, in the department of the Herault; 6 miles S. of Beziers.

SERIGNI, a sea-port town of the island of Java, in the straits of Sunda, belonging to the king of Bantam.

SERIGO, See Cerigo.

SERIGO, a town of Italy, on the lake Como; 27 miles N. of Como.

SERIJHEYODOUC, a town of Chinese Tartary, in the country of the Mongols. N. lat. 42° 15'. E. long. 102° 34'.

SERIKOTCHE, a town of Persia, in the province of Choralan or Khorassan; 195 miles N. of Herat.

SERIMSAH, a town of Egypt; 16 miles S. of Damietta.

SERIN, or SERAIN, a river of France, which runs into the Yonne, between Auxerre and Joigny.

SERIN, or SERINUS, in Ornithology, the name of a small bird; a species of the Fringilla in the Lusitan fynum, common in Germany and Italy, and called by theAUTHORS haemogn, or hirangryl. Its back is of a reddish-brown, and its head a little black; the colour being deeper in the male, and paler in the female; the rump is of a beautiful yellowish-green, as is also the breast; the belly is white, and the sides have some oblong blackish spots; the tail, and long feathers of the wings, are black, and a little greenish at their extremities; the beak is very thick, strong, and short. and is very sharp at the point. It is kept in cages, and sings very sweetly.

SERIN of Serinam. See PIPRA Crippata.

SERIN of the Canaries. See Fringilla Canaria.

SERIN of Jamaica. See Fringilla Canaria.

SERINDA, in Ancient Geography, a town of India, on this side of the Ganges, the inhabitants of which paid great respect to the emperor Julian.

SERINE, in Geography, a town of European Turkey, in the province of Macedon; 44 miles S.E. of Salomik.

SERINEAH, a town of Bengal, 18 miles S. of Pur- neah.

SERINETTE, a bird organ, said to be the Encyclopédie to be an invention of Barbary. The pitch is very high, being in unison with the largest flut in French organs, and with our 15th. It is used to teach birds little tunes, by those unable to play on the flageolet. Its compass is only an octave, or 13 pipes, as no base is ever wanted.

SERINGAPATAM, in Geography, a city of Hindostan, and capital of Myro, situated on an island in the Cauvery, which is here about five feet deep, and runs over a rocky channel, about 290 or 300 miles from Madras. The length of this isle is about four miles, and its breadth about four and a half miles; the western side being allotted to the forts, which occupied 2000 yards, distinguished by regular out- works, magnificent palaces, and lofty mofiefs; for Tippoo and his father were both Mahometans, nor were they averse from the persecution of the Hindoos and Christians. The environs were decorated with noble gardens; and among other means of defence was the "bound hedge," as it was called, consisting of every thorny tree and caustic plant of the climate, planted to the breadth of from 30 to 50 feet. Covered on the north and south by the river, this fortress was defended till the peace of 1792 by a single rampart; the east and west faces being much weaker, were strengthened by double walls and ditches, by outworks before the gates, by a circular work upon the south-east angle, and by several formidable cavaliers within and upon the southern rampart. The rampart, which is thick and strong, varies in height from 20 to 35 feet and upwards: the whole of the revet- ment, except the north-west bastion, is composed of granite cut in large oblong pieces, laid in cement, transversely in the walls. The ditches are cut out of the solid rock; a stone glacis extends along the north face. But the inte- rior of the fort has few good buildings, and the town in general is mean. The old Mysore palace being in a ruined state, has been converted into a military headquarters. The sultan's palace is a magnificent edifice, in the Asiatic style, but much disfigured by a high wall, and a number of unfin ished buildings round it. The great mole is covered with the finest chunam (or polished cement), and ornamented with lofty minarets. In the year 1792, Lord Cornwallis laid siege to this city, and compelled Tippoo, king of Myro, to a peace, by which he made a cession of great part of his dominions, and agreed to pay three crores and thirty-five lakhs of rupees towards the expenses of the war. In the year 1799, the British troops, after a short siege of a few days, took it by assault. The lots of the besiegers amounted to 22 officers killed, and 45 wounded, 181 Europeans rank and file killed, 622 wounded, and 22 missing; 119 natives killed, 420 wounded, and 100 missing. There were in the fort 13,739 regular infantry; and without the fort and in the intrenchments of the island 800. The lots must have been very great, as in the assault only, 214 principal officers were killed, and 740 wounded, besides Tippoo himself, who received a shot in his head. There were founders in the forts 323 brass guns, 60 mortars, 11 howitzers, 466 iron guns, and 12 mortars, 424,400 round shot, 520,000 lbs. of gunpowder, and 99,000 muskets, carabines, &c. Within the fort there were 11 large powder magazines, 72. experience magazines, 17 armories, 2 cannon foundries, three buildings with magazines for boring guns and muskets, four large arquebuses, and 17 other foureleeves, containing accoutrements, swords, and other articles, besides many granaries abundantly stored with provisions of all kinds. Of treasure and jewels the total value was 2,533,804 rupas pagodas, or 1,143,261 sterling. The fall of this city put the whole kingdom of Mysore, with all its resources, into the power of the British government. Tippoo's sons surrendered on the fall of Seringapatam. When the strength of the fortifications of all kinds of this place, and the number of Tippoo's troops and artillery are considered, our repeated successees afford a convincing proof that no climate or fortresses can overcome British courage, conduct, and perseverance. N. lat. 12° 31' 45''. E. long. 76° 46' 45''.

SERINGHAM, an island of Hindoostan, in the river Cauvery, on which are two pagodas, much venerated by the Hindoos, and one particularly the object of devotion. In 1751 the French took possession of this pagoda, and in the following year it was taken by the English under major Lawrence; 4 miles N.E. of Trichinopoly.
SERINHAEM, a river of Brazil, which runs into the Atlantic, S. lat. 1° 50'.

SERINO, a town of Naples, in Principato Ultra; 19 miles S. of Benevento.

SERINPALLE, a town of Africa, in the country of Cayor, on the left bank of the Senegal. N. lat. 16° 50'. W. long. 15° 50'.

SERINPETTA, an island in the river Senegal, where the canoes of the country are contracraet.

SERIO, a river of Italy, which runs into the Adda, at Pizzighitone.—Allo, a department of Italy, composed of part of the Bergamaco: it contains 195,803 inhabitants, who elect 15 deputies. Its capital is Bergamo.

Gen.Ch. Common calyx simple, composed of linear, nearly equal, erect leaves. Cor. compound, imbricated, uniform, composed of numerous, equal, perfect flowers; proper of one ligulate, linear, truncated, five-toothed petal. Stam. Filaments five, capillary, very short; anthers cylindrical, tubular. Pist. Germen ovate; style thread-shaped, the length of the flaments; stigmas two, reflexed. Peric. none, except the unchanged calyx. Seeds oblong, the length of the calyx. Down capillary, feathered, with ten rays hairy at the recept. Recept. chaffy, deciduous, as long as the calyx.

3. S. criptes. Cretan Seriola. Linn. Sp. Pl. 1139. ("Achiloplos serisus, dentis leonis folio leviter dentato; Vaill. Act. 740.")—Hardy rough with hairs. Leaves runcinate.—Native of the island of Candia or Crete. We know not of any figure or description of this species. It is kept on the above quoted authorities.

Vol. XXXII.

SERIPALA, in Ancient Geography, a town of India, on this side of the Ganges, in the number of those which were situated to the east of the river Nosudus, according to Ptolemy.

SERIPHUS, in Botany, a plant applied to this genus on account of the analogy, in its habit and foliage, with Artemisia pontica of Pliny, called by the Greeks Seriphe. The origin of this name may be traced to Seriphion, or, as it is now called, Serphi, an island in the Aegean sea, where a fish is used to feed the nature, as only to abound in plants of this rough kind. "This island," says De Theis, "covered with rocks and mountains, has always been regarded as a melancholy retreat. A Greek once demanded of one of its inhabitants, what crime they punished with banishment? Perjury, was the answer. Why then, says the Greek, don't you always perjure yourselves, in order that you may escape from such a horrible residence?" The French name Armee, from Arnoifi, Wornwood, is expressive of its natural affinity to that genus.—Linn. Gen. 454. Schreb. 594. Martt. Mill. Dict. v. 4. Juff. 180. Lamarck Hith. t. 722. Gaertn. t. 157.—Clas and order. Synonemia Polygama Segregata. Nat. Ord. Composite Nuemcanteae. Linn. Cimbrabae, Juff.

Obf. Wilkendow and the editor of Hortus Kewensis have not adopted this genus. They refer the several species of it to Artemisia and Stachy.

Gen. Ch. Cal. Peranth double; outer of five, roundish, imbricated, downy leaves; inner of five, erect, acuminate, awl-flowered, smooth, feamy leaves, which are twice as long as the outer ones, single-flowered. Cor. of one petal, funnel-flowered, shorter than the inner calyx; limb five-toothed. Stam. Filaments five, capillary; anthers cylindrical. Pist. Germen between the calyx and the flower; style thread-flowered; stigma rather slender. Cor. none, except the unchanged, closed calyx. Seed solitary, oblong.

The food-down of this species being feathered at the tip, induced Linnaeus to make it a Seriphium.

SERIPIUS, or Seriphion, in Ancient Geography, an island in the Archipelago, and one of the Cyclades, ac-
acording to Herodotus, the inhabitants of which took the part of the Greeks against Xerxes. Some authors, however, place Scythus in the rank of the Sporades. It is situated west of Paros, and south of Cythnos. It presents the appearance of a rock, but is inhabited. The Romans fent several certain criminals.

SERIPO, a town of Hifpania, in Bética. Pliny.

SERI SOMTOUT, in Geography, a district of Tibet, situated between E. long. 95° and 96°, and between N. lat. 30° and 31°.

Gen. Ch. Cal. Perianth superior, divided into five, awl-shaped, erect segments. Cor. of one petal, funnel-shaped; tube short; limb broad, reflexed, five-leaf; segments trifid, acute. Stam. Filaments five, very short, below the mouth of the tube; anthers oblong, incumbent. Pith. Germin inferior, rounded; style thread-shaped, the length of the corolla; stigma oblong, villous, reflexed. Peric. Berry roundish, small, of one cell. Seeds numerous, (according to L’Heritier and Brown only two), ovate, fmal.

El. Ch. Corolla funnel-shaped, fringed at the mouth. Segments of the limb mostly three-lobed. Berry inferior, with two seeds.

This elegant little shrub produces numerous white flowers, which have the appearance of those of Jasmine, but are without scent, as indeed is the whole plant, until it is squeezed or bruised, when it emits a highly disgusting smell. A variety with double flowers is not uncommon in the gardens about London.

SERIUM, in Ancient Geography, a town of European Sarmatia, in the vicinity of the Borytenees. Ptolomy.

SERKA, in Geography, a town of Nubia; 200 miles S. of Sennar.

SERKEISK, a town of Ruffia, in the government of Kaluga; 44 miles W.S.W. of Kaluga. N. lat. 54° 16'. E. long. 34° 34'.

SERKES. See Tserkesh.

SERKIS, a town of Afgan Turkey, in Caramania; 50 miles W. of Cogni.

SERLIO, Sebastiano, in Biography, an eminent architect, was a native of Bologna, who flourished in the early part of the sixteenth century at Venice, in the character of an architect. He afterwards travelled through Italy, and refided a considerable time at Rome, where he studied the fine arts, and made many drawings of edifices, ancient and modern, and he is said to have been the first who examined, with the eye of a man of science, the remains of ancient architecture. The knowledge which he acquired was given to the public in a complete treatise of architecture, of which he planned several books, and the first that appeared was the fourth in order, comprehending the general rules of architecture, which he printed at Venice in 1537, dedicated to Hercules II, duke of Ferrara. The other six books appeared successively at different intervals, and the different editions made of them prove their popularity. Serlio, in 1541, was invited to France by Francis I, and was by that sovereign employed in the elections at Fontainebleau, where he thenceforth resided, and where he died, at an advanced age, in 1578. Though as an author he was much attached to the principles of Vitruvius in his designs as an artist, he very much neglected them. His school of St. Roch, and palace Griman at Venice, are built in a grand and magnificent style. Gen. Bion.

SERMAISE, in Geography, a town of France, in the department of the Marne; 10 miles S. of Menehould.

SERMAIS, a town of France, in the department of the Loiret; 7 miles N. of Pithiers.

SERMAK, a town of Sweden, in the province of Tavalland; 170 miles N. of Tavallus.

SERMANICOMAGUS, in Ancient Geography, a town of Gaul, which, according to the tabular of Peutinger, was situated in Aquitania secunda. It was on the right of the Varus, at some distance N. of Icullina, according to M. d’Anville; it is the present Chermes.

SERMATIA, in Geography, a town of Hindostan, in the sbah of Agra; 25 miles N.E. of Kerowly.

SERMATTIA, an island in the East Indian sea, about 22 miles long, and six broad. S. lat. 8° 9'. E. long. 129° 13'.

SERMESOK, an island near the W. coast of Greenland. N. lat. 61° 50'. W. long. 47° 43'.

SERMIA, a river which rises near Montegio, in the state of Genoa, and after passing by Serravalle, Tortona, &c. runs into the Tanaro.

SERMIN, a town of Ilria; 2 miles N.E. of Capo d’Itria.

SERMIONE, a town and castle of Italy, in the Veronese, on a neck of land running into lake Gorda, the harbour of which may be shut by means of chains, defended by a castle. This was the native place of the poet Catullus; 16 miles W. of Verona.

SERMOCINATION, SERMOCINATIO, in Rhetoric, denotes discourse in general, whether held by a perfon alone, or in company, and is the same with what is otherwife called dialogism.

SERMOLOGUS, SERMOLOGUE, an ecclesiastical book composed of sermons, or homilies of popes, and other persons of eminence and finuity, formerly read at the feafts of the Confessors, the Purification, All Saints, and on every day from Christmas to the octave of the Epiphany. See HOMILY.

SERMON, a discourse delivered in public, for the pur- pose of religious instruction and improvement; or a per- fusive oration.

As to the choice of subjects for a sermon, they should be such as in the judgment of the preacher seem to be the moft useful, and the best accommodated to the circumstances of his audience. The unmeaning applause which the ignorant give to what is above their capacity, common sense and common probity must teach every man to despife. Usefulness and true eloquence are insepable, nor can any man be justly deemed a good preacher, who is not an useful one. A sermon, considered as a peculiar species of composition, the first object of attention is its unity; by which we mean, that there should be some one main point, to which the whole strain of a sermon should refer. This unity, however, does not require that there should be no separate heads or divisions in the discourse, or that one thought should again and again be presented to the hearer in different lights. Separate divi-
sions or distinct heads, provided that they are not too numerous
numerous and too minute, serve to aid the composer and the
hearer of a sermon. In order to render sermons more
shining, and consequently more useful, the subject of
them should be precise and particular. General subjets, though
often chosen by young preachers, because they offer a more
ample supply of matter, without much labour of thought,
and a wider scope for the display of flowry talents, are by
no means the most favorable for producing the highest effects
of preaching. These subjets, often recur to, admit of
little diversify and variety. The attention of the hearer
is more certainly engaged and fixed, by fixing some particular
view of a great subjet, some fingle interlacing topic, and
directing to that point the whole force of argument and
elegance. Here indeed the execution is more difficult,
but the merit and the effect are higher. Moreover, the com-
poser of a sermon should never fludy to lay all that can be
said upon a subjet: no error can be greater than this. On the other hand,
the preacher should select the most useful, flring, and
perfeftive topics which the text suggests; and with this view
he should confider, that difcourses for the pulpit are intended
lest for information than perfuafion, and that nothing is
more opposite to perfuafion than an unneceffary and tedious fulnefs.
Again, in fludyng a sermon, the preacher ought to place
himself in the situation of a ferial hearer; and derive his
principal materials from those views of a subjet, and those
arguments and reflections which would operate moft favour-
ably and moft effectually on his own mind. Above all things,
the preacher should fludy to render his instructions interlacing
to the hearers. In this refpect, much depends on the delivery
of a difcourse, but much will also depend on the composition
of it. Correct language and elegant defcription are but
the secondary instruments of preaching in an interlacing
manner. The great fecret lies, in bringing home all that is
faid to the hearts of the hearers, fo that every man may be
led to think that the preacher is addreffing him in particular.
It is hardly neceffary to fubjoin a caution here, that perfon-
ality should be avoided. For the attainment of the end now
firmed, the preacher should avoid all intricate reafonings,
and expriffing himfelf in general speculative propofitions,
and laying down abstract truths in an abstract metaphypfical
manner. As much as poifible, the difcourse ought to be
caflly on the plan of direct adfrefs to the audience;
not in the strain of one writing to felf, but of one speaking
to a multitude, and fludyng to mix what is called application,
or what has an immediate reference to practice,
with the doctrinal and didactic parts of the sermon.
In this connexion we may add, that the preacher fhow
adapt his difcourses, with a view of making them inter-
lacing, to the different ages, characters, and conditions of
men, and that he fhould avail himfelf of any personal or
domestic occurrence, for imparting either inftruction or confo-
lation. Some of the moft imprefive difcourses are thoje
that delineate and exhibit examples founded on historical
facts, and drawn from real life. Many of these may be
found in scripture, which, when they are well chosen, command
a high degree of attention. Bishop Butler's fermo{i of the
"character of Balaam," affords a fpecimen of this kind of
preaching. It is of importance to obferve, farther, that
the preacher fhould be cautious not to take his model from
particular fashions that chance to have the voige. It is the
universal taflie of mankind, which is fubjecf to no changing
modes, that alone is entitled to poiffefs any authority: and
this will never give its fanaion to any strain of preaching
that is not founded in human nature, connected with ufe-
fulnefs, adapted to the proper idea of a fermo{i, as a ferial
persuasive oration, delivered to a multitude, in order to make
them better men. Let the preacher fowmelf him upon this
standard, and he will attain reputation and succces much
more than by a fervile compliance with any popular taste, or
tranfient furoeur of his hearers.
As to the fyle of sermons, it fhould in the firth place be
very perficuous. Plainnefs and simplicity fhould prevail;
and of course all unusual, fowl, or high-founding words
fhould be avoided; and especially thoje that are merely poe-
tical, or merely philofophical. Dignity of expression is in-
deed indifpenfable; but this dignity is perfectly conffident
with fimplicity, and also with a lively and animated fyle,
dictated by the earneffnefs which a preacher ought really to
feel, and not merely to affect, and justified by the grandeur
and importance of his subjets. He not only may employ
metaphors and comparifons, but, on proper occasions, may
apologize the faint or the finner, may perfominate inanimate
objects, break out into bold exclamations, and, in general,
command the moft passionate figures of speech.
The language of scripture, properly employed, is a great
ornament to sermons; and it may be employed either in the
way of quotation or allusion. But the allusions which
the preacher ufe{hould be natural and fady, for if they fecm foorm,
they approach to the nature of conceits. In a fermo{i, no
points or conceits fhould appear, no affected furntteis and
quaintnefs of exprfion; which derogate much from the
dignity of the pulpit. It is a frong, expressive fyle, rather
than a sparkling one, that ought to be fludied. Epithets
have often great beauty and force, but it is a great error to
imagine, that we render it ftreng and expressive, by a
confant and multiplied ufe of epithets.
As to the quefion, whether it be moft proper to write
sermons fully, and commit them accurately to memory, or
to fludy only the matter and thoughts, and truff the exp-
reffion, in part at least, to the delivery, Dr. Blair is of
opinion that no univerfal rule can be given. Preachers
must adopt either of thefe methods, according to their diferent
genius, and we may add according to the situation where they
are fettled, and the rank or character of the assembly which
they addrefs. It is proper, however, to begin, at leaft, the pracife
of preaching, with writing as accurately as poifible. He thinks
it alfo proper to continue, so long as the habits of industry
falt, in the practice both of writing and committing to
memory. The practice of reading sermons is, as our author
fays, one of the greateft obficles to the eloquence of the
pulpit in Great Britain, where alone this practice prevails.
No difcourse which is designed to be perfuafive can have the
fame force when read as when spoken. We are of opinion,
however, that fermons from memory have little advantage,
in point of effect, above thoje that are read. An ex
temporary fermo{i has this advantage in an eminent degree; but
few excel, and many difcourses of this kind are fuch as
would dignify a judicious, though cau{u, hearer.
The French and English writers of sermons proceed upon
very different ideas of the eloquence of the pulpit. A
French fermo{i, for the moft part, is a warm animated
exhortation; an English one, a piece of cool inftuctive rea-
foning. The French preachers adfress themfelves chiefly to
the imagination and the passions; the English, almost solely
to the underftanding. The union of these two kinds of
compoftion, of the French earneffnefs and warmth with
the English accuracy and reafoning, would form,
in Dr. Blair's judgment, the model of a perfect fermo{i.
The ceufure which, in fact, the French critics
pass on the English preachers is, that they are philo-
ophefs and logicians, but not orators. Among the French
Protestant divines, Saurin is the moft dilligufhed; and the
late Mr. Robinfon of Cambridge has done a public fervice by
translating many of his difcourses into the English language.
Saurin is copious, eloquent, and devout, though, in his manner, too ornamental. Among the Roman Catholics, the two most eminent are Bourdaloue and Maffillon. The French critics differ in their opinion to which of these preachers the preference is due. To Bourdaloue they attribute more direct and close reasoning; to Maffillon, a more pleasing and engaging manner. The former, is a great reasoner, and inculcates his doctrines with much zeal, piety, and earnestness; but his style is verbose, and abounding with quotations from the fathers, and he wants imagination. Maffillon has more grace, more sentiment, and, as Dr. Blair thinks, may have more genius. He discovers much knowledge, both of the world and of the human heart; he is pathetic and persuasive, and is perhaps the most eloquent writer of sermons which modern times have produced. During the period that preceded the restoration of Charles II., the sermons of the English divines abounded with scholastic casuistical theology, but in their application they adopted more pathetic addresses to the consciences of the hearers. Upon the restoration, preaching assumed a more correct and polished form. Whatever was carnal and passionate, either in the composition or delivery of sermons, was reckoned enthusiastic and fanatical; and hence that argumentative manner, bordering on the dry and imperceptive, which is too generally the character of English sermons. Dr. Clark, who excels in a variety of respects, may be esteemed a very instructive compiler of sermons, but he is deficient in the power of interesting and feizing the heart. Tillet's manner is more free and warm, and he approaches nearer than most of the English divines to the character of popular speaking; and he is, even now, one of the best models for preaching. Dr. Barrow is admirable for the prodigious fecundity of his invention, and the concurrence, strength, and force of his conceptions; but less happy in execution, or composition. Atterbury deserves to be particularly mentioned as a model of correct and beautiful style, besides having the merit of a warmer and more eloquent strain of writing in some of his sermons, than is commonly met with. If Bullett had given us more sermons in the strain of those upon self-deceit and the character of Balaam, in the room of abstrat philosophical essays, he might have been distinguished for that species of characteristic sermons above recommended.

The parts of a sermon, discourse, or regular formed oration, are the following fix: 1. The exordium or introduction, the state and division of the subject, narration, and explication, reasoning, or arguments, the pathetic part, and the conclusion. (See each under its proper head.) The introduction of an English sermon is too often flail and formal, whereas those of the French preachers are very splendid and lively. Common-place topics should be avoided; variety should be studied; and in some cases the discourse may commence without an introduction. Explanatory introductions from the context are not uncommon, they are appropriate and instructive; but they should not be too long. An historical introduction has, generally, a happy effect in causing attention. To the proposition or enunciation of the subject generally succeeds the division; but it has been questioned, whether this method of laying down heads, as it is called, be the best method of preaching. Archbishop Cambroy declares strongly against it; alleging, that it is a modern invention, that it was never practised by the fathers of the church, and that it took its rise from the schoolmen. But we are of opinion, with Dr. Blair, that it serves useful purposes, and ought not to be laid aside. (See the preceding part of this article.) But in any discourse or sermon, there are certain rules which should be observed, e.g., the several parts into which the subject is divided should be really distinct from one another: the order of nature should be followed, beginning with the simplest points, or things that are most easily apprehended and necessary to be first discussed, and then proceeding to those which are built upon the former, and which suppose them to be known;—the several members of a division ought to exhaust the subject;—the terms in which the partitions are expressed should be as concise as possible;—and the number of heads should not be needlessly multiplied. Another part of a discourse or sermon is narration. This part must be concise, clear, and distinct, and in a style correct and elegant, rather than highly adorned. The argumentative part is succeeded by the pathetic, in which, if anywhere, eloquence reigns, and exerts its power. (See PATHETIC.) In sermons, inferences from what has been said make a common conclusion. With regard to these care should be taken, not only that they rise naturally, but that they should so much agree with the strain of sentiment throughout the discourse, as not to break the unity of the sermon. The precise time of concluding a discourse is an object of importance. It should be so adjusted that our discourse is brought to a point; neither ending abruptly and unexpectedly; nor disappointing the expectation of the hearers, when they look for the close; and continuing to hover round and round the conclusion, till they become heartily tired of us. We should endeavour to go off with a good grace; not to end with a languishing and wrinkling sentence; but to rise with dignity and spirit, that we may leave the minds of the hearers warm; and dismiff them with a favourable impression of the subject, and of the speaker. Blair's Lectures, vol. ii. See ELOCUTION OF THE PULPIT, AND PREACHING.

SERMON, FUNERAL. See Funeral.

SERMONES, the title which Horace gives his Satires. See SATIRE.

Critics are divided about the reason of the name; the opinion of father Boffu seems best grounded. A mere observance of feet and measure, such as we find in Terence, Plautus, and in Horace's Satires, he thinks is not sufficient to constitute verse, to determine the work to be poetical, or to distinguish it from prose; unless it have some farther air, or character of poetry; somewhat of the fable or the sublime.

Hence he judges it, that Horace calls his Satires prope, or sermons: his Odes have quite another air, and are therefore called poesia, carmina.

SERMONETTA, in Geography, a town of Italy, in the Campagna, situated on a mountain difficult of access. Some say that it occupies the site of the ancient Sora; but others say that it occupies the spot on which Sulmo stood; 13 miles S. of Veletri.

SERMONIUM, in Old Records, a kind of interlude or historical play, which the inferior orders of clergy, afflicted by boys, &c. used at times to act in the body of the church, suitable to the solemnity of some festival or high procession day.

This is supposed to have been the origin of the modern drama.

SERMOUNTAIN, in Botany, a species of the linnæan order, and, according to others, of the jefell, or wild fennel, which grows wild in some of the southern parts of Europe, is raised with us in gardens, and flowers in June.

The seeds of this plant are the part directed for use in our pharmacopoeia, and the roots appear to be useful aromatics, though not regarded in practice; of an agreeable smell, and a warm glowing sweetness; the roots have the greatest warmth and pungency; the seeds the greatest sweetnees, and the most pleasant flavour. A spirituous extract
tract of the seeds is a very elegant aromatic sweet. Lewis.

See Seneka Seed.

SERMUR, in Geography, a town of France, in the department of the Creuse; 6 miles S.S.W. of Auzance.

SERNA, La., a town of Spain, in the province of Leon; 24 miles N. of Palencia.

SERNANCELLA, a town of Portugal, in the province of Beira; 19 miles S.E. of Lamego.

SERNETTY, a town of Bengal; 30 miles E.S.E. of Calcutta.

SERNICUM, in Ancient Geography, a town of Italy, on the route from Milan to Colonne, in passing through Picenum, according to the Itinerary of Antonine, in which it is marked between Aufidiana Civit., and Bevianum Civit.

SERNON, in Geography, a town of France, in the department of the Var; 7 miles N.W. of Graffe.

SERNST, a town of Switzerland, in the canton of Glarins, near a river of the same name; 3 miles S. of Glaros. The river runs into the Sundbach at this place.

SEROGLAZOVSKAIA, a fortress of Ruffia, in the government of Caucausus, on the Volga; 24 miles N.W. of Astrachan.

SEROLZECHE, a town of the duchy of Warsaw, at the union of the rivers Narlaw and Bug; 20 miles N. of Warsaw.

SERON, a town of Spain, in the province of Grenada; 7 miles W. of Parchena.

SERON of Almonds, is the quantity of two hundred weight; of anle-feed, it is from three to four hundred; of Calilis soap, from two hundred and a half to three hundred and three quarters.

SERONGE, in Geography, a town of Hindooollan, in the Malwa country, celebrated for its manufacture of printed cottons and chintzes; 132 miles N.E. of Ougein. N. lat. 24° 5'. E. long. 78° 4'.

SEROR, a town of Hindooollan, in Dowlatabad; 24 miles S.S.W. of Amedagur.

SEROS, Los, a town of the island of Cuba; 38 miles N. of Trinidad.

SEROITY, the watery part of the blood, or serum.

See Blood.

SEROTA, in Ancient Geography, a town of Pannonia, between Lentuli and Marinhins.

SEROUGE, in Geography, a town of Asiatic Turkey, in the province of Diarbekir; 80 miles S.W. of Diarbekir.

SEROWRA, a town of Hindooollan, in Oude; 4 miles N. of Lucknow.

SERPA, a town on the E. coast of the island of Corfu; 8 miles N. of Corfu.—Alfo, a town of Portugal, in Alentejo, containing two churches, and about 4000 inhabitants; 12 miles S.W. of Mourao.

SERPA, in Ancient Geography, a town of Ilipiania, in Boetia, on the left of the river Anas, and nearly E. of Pax-Julia.

SERPEGEE, in the Manege, was used to denote the riding a horse in the serpentine way, or in a tred with waved turnings like the posture of a serpent's body; but is now become obsolete.

SERPENTARA, in Geography, a small island near the E. coast of Sardinia. N. lat. 39° 18'. E. long. 10° 2'.

SERPENTARIA, in Botany, a name applied by the older botanical and medical writers, to various plants, either on account of the serpent-like form of their roots, as in Polygonum Biflorna, their spotted stems, as in Arum Dracunculus, or some other fanciful resemblance. The same name has likewise been given to plants supposed to cure the bites of serpents, as Aristolochia Serpentaria, or Virginian Snake-root. For a similar reason certain species of Plantago have been denominated Serpentina.

SERPENTARIUS, in Astronomy, a constellation of the northern hemisphere, called also Ophiuchus, and Aniciently Aesopus.

The stars in the constellation Serpentarius, in Ptolemy's catalogue are 29; in Tycho's, 15; in Hevelius's, 40; in the Britannic catalogue, they are 74. See Constellation.

SERPENTES, Serpents, in Zoology, the second order in the Linnean class Amphibia, which are thus commonly characterized: they are footless; their eggs are connected in a chain; the penis is double, and mucrulate.

These animals are sufficiently distinguished from reptiles by their total want of feet, moving by the assistance of their scales, and their general powers of contortion. The distinction of species in this numerous tribe is, according to Dr. Shaw, frequently very difficult. Linnaeus thought that an infallible criterion might be found in the number of scaly plates on the abdomen, and beneath the tail; and accordingly attempted, in the Syllena Natura, to discriminate the species by this mark alone. This is now found to be, by much, too uncertain and variable for a specific test. The colour is indeed frequently variable, but the pattern, or general distribution of markings in each species, appears to be more constant; the relative size of the head, the length of the body and tail, the size, smoothness, or roughness of the scales, as well as their shape in different parts of the animal, often afford tolerably certain specific marks.

The distinction of serpents into poisonous and innocuous, can only be known by an accurate examination of their teeth; the fangs, or poioning teeth, being always of a tubular structure, and calculated for the conveyance or injection of the poisonous fluid from a peculiar reservoir, communicating with the fang on each side of the head; the fangs are always situated in the anterior and exterior part of the upper jaw, and are generally, but not always, of much larger size than the other teeth; they are also frequently accompanied by some smaller or subsidiary fangs, apparently defined to supply the principal ones, when lost either by age or accident. The fangs are situated in a peculiar bone, so articulated with the rest of the jaw, as to elevate or depress them at the pleasure of the animal. In a quiet state, they are recumbent, with their points directed inwards or backwards; but when the animal is inclined to use them as weapons of offence, their position is altered by the peculiar mechanism of the above-mentioned bone, in which they are rooted, and they become almost perpendicular.

A general rule for the determination of the existence or non-existence of these organs, in any species of serpent, was proposed by Dr. Gray, in the Transactions of the Royal Society for the year 1788. According to this author, the fangs may be distinguished with great ease, by the following simple method. When it is discovered that there is something like teeth in the anterior and exterior part of the upper jaw, which situation he considers as the only one in which venomous fangs are ever found, let a pin, or other hard body, be drawn from that part of the jaw to the angle of the mouth. If no more teeth be felt in that line, it may be fairly concluded that these first discovered are fangs, and that the serpent consequentlv is venomous; if, on the contrary, the teeth first discovered be observed not to stand alone, but to be only part of a complete row, it may as certainly be concluded that the serpent is not venomous. This rule, however, like most other general rules, may have its exceptions; and perhaps the most legitimate test of real fangs
fangs in a serpent is their tubular structure, which may always be easily detected by the allusion of a proper magnifier. It is to be observed, that all serpents, whether poisonous or not, have, besides the teeth, whether fangs or simple teeth, in the fides of the upper jaw, two additional or interior rows, which are generally much smaller than the rest, and frequently scarcely visible. The general rule, therefore, is, that all venomous serpents have only two rows of true or proper teeth in the upper jaw, and that all others have four.

A head entirely covered with small scales is, in some degree, a character, but by no means an universal one, of poisonous serpents; as are also carinated scales on the head and body, or such as are furnished with a prominent middle line. All serpents call their skins at certain periods: in the temperate regions, annually; in the warmer climates, perhaps more frequently. The serpents of the temperate and cold climate also conceal themselves, during winter, in cavities beneath the surface of the ground, or in some other convenient places of retirement, and pass the winter in a state more or less approaching, in the different species, to complete torpidity. Some serpents are viviparous, as the rattle-snake, the viper, and many other of the poisonous kind; while the common snake, and probably the greater part of the innoxious serpents, are oviparous, depositing, as have already observed, their eggs, in a kind of firing or chain, in any warm and close situation, where they are afterwards hatched. The broad undivided lамиa, or flat plates, on the bollsies of serpents, are termed fetsa; and the smaller or divided plates, beneath the tail, are called sub-caudal scales; and from these different kinds of lamiae, the Linnean genera of serpents are chiefly instituted. In the edition of the Systema Naturae by Gmelin, seven genera are enumerated and described, viz.

Acrochordus,
Amphibana,
Anguis,
Boa,
Cecilia,
Coluber,
Crotalus.

Having, in our alphabetical arrangement, omitted a description of some of the above genera, and referred to the species of others which have not yet been given, we shall take the opportunity which the order itself gives us, of making up for the defects that have escaped our notice, beginning with

Acrochordus, of which the generic character is, that it has tubercles covering the whole body. Gmelin gives but a single species, viz. the javanicus; but Dr. Shaw has described three

Species.

Javanicus; or Warded Snake. Brown, beneath paler; the fides obliquely variegated with whith.

This, as its specific name denotes, inhabits Java, chiefly among the pepper plantations; it grows sometimes to the length of seven or eight feet. The warts or prominences appear, by a magnifying glass, to be convex carinate scales, and the smaller ones are furnished with two smaller prominences, one on each side the larger. The head is somewhat flattened, hardly wider than the neck; the body is gradually thicker towards the middle, and suddenly contracting near the tail, which is short and slightly acuminate.

This remarkable snake, which gave rise to the institution of the genus, was first described by Mr. Hornstedt, in the Swedish Transacti ons for the year 1787. It was found in a large pepper-ground near Sangafan, in the year 1784, and measured eight feet in length. Its neck was six inches thick, that of the largest part of the body ten inches, and that of the tail an inch and a half; the colour of the upper part of the animal was blackish, and of the under part whitish; the fides are marked with dusky spots; the head is truncated, depressed, and scaly; the jaws equal, the superior being emarginated beneath, the inferior curved; the eyes lateral, on the fore part of the head, the irides livid; the nostrils circular, small, approximated, and situated above the tip of the snout; the body was entirely covered, as well as the tail, with rough tri-carinated warts; the vent is small, the body very suddenly tapering towards the tail. This animal was secured by a Chinfe, by means of a split bamboo passed over its neck, and thus carried to Batavia, where, on being skinned and opened, exclusive of a quantity of undigested fruit, were found completely formed five young, measuring nine inches each; the flesh of the animal was eaten by the Chinefe, who affirmed that it was excellent food, and the skin being preferred in Africa, was brought to Europe by Mr. Hornstedt, and deposited in the museum of the king of Sweden.

Dubius, or Brown Acrochordus, has a carinated abdomen, and its fides are spotted with black. In its general appearance and proportion, this very nearly resembles the javanicus just described; but the head of the dubius is covered with very minute rough or warty scales, differing in size alone from those on other parts of the animal. It is not more than about three feet in length; its colour is of an obscure brown, with some ill-defined clouds and patches of a darker colour, differing along the fides and abdomen. The specimen from which this description is taken, is in the British Museum; but its native place is not ascertained.

Fasciatus, or Fuliginus Acrochordus, called also the Hydrus granulatus, has a carinated abdomen, with whitish ascendant lateral bands. This is so much allied to the dubius, that it may be doubted whether it really differs in any other respect than age, figure, and in the cast of colours, measuring about eighteen inches in length, and being of a dusky brown colour, with several paler fasciae, which take their rise from the abdomen, and ascend on the fides; the abdomen is carinated as in the former. "This," says Dr. Shaw, "is certainly the Hydrus granulatus of Mr. Schneider, who, in his work on the Amphibia, describes it as a water-snake, though, seemingly, without any other foundation than that it has a carinated abdomen; its other characters by no means agreeing with those of the genuine Hydrus." Its native place is not known. A specimen is preferred in the British Museum.

Anguis, or Snake. This genus of serpents was noticed in its place, and the names of the species enumerated, with the intention of describing each species in the alphabetical order: after this the plan of the work was somewhat altered, and the species will now be given with their appropriae description. The generic character is, scales on the belly and scales under the tail.

Species.

Striatus. The scales of the belly are 179 in number; those of the tail seven; the body is surrounded with transverse lines.

Meleagris. The scales on the belly of this are 165; those of the tail 32. It inhabits South America and some parts of India. It resembles the Lacerta hips (see Lizard); it is glaucous, with numerous longitudinal rows of black dots. There are two varieties, one dotted, with brown, and one characterized by its long tail.

Columb us. Scales of the belly 180; of the tail 18. It inhabits Egypt; is varied with brown and pale ochre.

Miliaris. Scales of the belly 170; of the tail 52.
Found near the Caspian sea; it is 14 inches long, and is about as thick as one's finger; black, with numerous pale scales or dots on the sides, and grey ones on the back; the head is grey, sprinkled with black; the tail is two inches long, much thinner than the body, cylindrical, obtuse, varied with white.

**Jaculus.** The scales of the belly of this species are 186, those of the tail 23; it inhabits Egypt.

**Maculatus.** There are on this 200 abdominal scales; 12 subcaudal ones. It inhabits America; above it is yellow, with a brown dorsal stripe and linear bands. A variety is decollate with red bands dotted with black. It inhabits Asia.

**Reticulata.** Scales on the belly 177; of the tail 37. This is an American snake. The scales are brown with a white disk.

**Chryseus.** Abdominal scales 200; subcaudal 15. It is found in Egypt.

**Nasutus.** On the belly of this are 218 scales; on the tail 22. It is about a foot long; the colour is of a greenish-black; beneath, at the fides, on the tip of the head, a broad band on the tail, and dots on the tip, all yellow. The snout is prominent; it has no teeth; the eyes are on the top of the head, not lateral; the trunk is round with 20 rows of hexagonal scales; the tail not quite half an inch long, with minute scales, and obtuse, rigid at the tip.

**Lumbricalis.** In this the scales of the belly are 230; those of the tail seven; it inhabits America. In colour it is whitish, inclining to yellow.

**Laticauda.** The abdominal scales are 200; the subcaudal 50. This is found at Surinam; the tail is compressed, sharp, pale, with brown bands.

**Scyphus.** Scales of the belly 240; of the tail 13. As Dr. Shaw calls all the species of this genus by the English name shew-flow-worm, from its singular beauty; its general length is from eighteen inches to two feet, and its diameter in proportion; the ground colour is a rich yellowish-ferruginous or orange, on which are dispersed throughout the whole length of the animal, numerous, moderately broad, equidistant, jet-black transverse bands, not continued entirely round the body, but alternating with each other, and terminating in rounded extremities; the scales on the intermediate parts are generally tipped with brown, exhibiting more or less of a flecked appearance on the skin. When this animal has been preserved a considerable length of time in spirits, many of its fine colours fade into white, in consequence of which, the specimen usually seen in museum, appear variegated only with black and white; the head is small, and the tail is very short, being not more than the twentieth of the whole length, and terminating otherwise. This species is a native of South America, and one of the West Indian islands.

*Erucis; Aberdeen Snake. The scales on this species of the belly are 126; those on the tail 136. It inhabits America and England. Above it is cinereus, with black lines the whole length, beneath it is lead-colour, with white spots. It has been thought to be only a variety of the next species.

*Fragilis; Blind Worm. Scales of the belly 135, and the same number on the tail. This species is found in almost all parts of Europe, in our own islands, and in Siberia, in familiar situations with the common snake. It is a perfectly innoxious animal, living on worms and insects; its usual length is from ten to twelve inches, and sometimes even more; its colour is pale russet-brown above, with three narrow longitudinal dorsal streaks of a darker cast; and beneath a deep lead-colour. The head is rather small, and covered in front with large scales, as in most other innoxious serpents; the eyes are very small; the tail measures more than half the length of the animal, and terminates rather suddenly in a slightly acuminated tip. It is a viviparous animal, and sometimes produces a very numerous offspring; like other serpents, it varies in the intensity of its colours at different periods, and the young are commonly of a deeper cast than the parent; the general motions of this animal are either slow or otherwise, except when endeavouring to escape, and the young seem to move more slowly than those that are full-grown. Slow-worms can, however, exert a considerable degree of swiftness, and can readily penetrate the loose soil, in order to conceal themselves from pursuit; they are often found in considerable numbers, during the winter season, at some depth beneath the surface, retiring on the approach of winter, and lying in a state of torpidity, and again emerging from their concealments on the approach of spring, when they cast their skin and recover their former liveliness. It has been observed by some naturalists, that if the individuals of this species, and of some others likewise, be struck with any degree of violence, the body not only breaks abruptly on the struck part, but even frequently at different parts; the skin is remarkably strong, and the animal, when handled or irritated, has a mode of stiffening itself by stretching to its utmost length, in which state, it can, if any part of the skin be injured, the separation soon takes place in consequence of this rigidity. The fragments will live a long time after their separation.

**Ventralis.** Abdominal scales 127; subcaudal 223. This is an inhabitant of South Carolina. The body is of an ash-green, black, lateral hand black; belly short, and appearing as if annexed by a hollow future; the tail is verticillate, three times as long as the body. A small blow will cause the animal to break into several pieces, the muscles being articulated quite through the vertebrae.

**Platurus.** Tail compressed, obtuse. It is a native of the shores of Pine island, in the Pacific ocean. The body is a foot and a half long; above it is black, and beneath it is white; the scales are minute, sub-ornicular, not imbricate; head oblong; it is toothless, smooth; the back is subcarinate; the tail is variegated with black and white.

**Lineatus.** Blackish, but on the upper part it is white; a curved line runs down the whole body.

**Clivicus.** Cinereous-brown; the plate of the front is larger and heart-shaped. It is found in some parts of Germany.

**Annulatus.** White, with straight brown bands; beneath, tail tapering, beneath with a double row of imbricate scales.

**Scutatus.** This is a very slender species; waved with white and black bands; plates of the head broad; tail sharpish. This is found at Surinam. The belly and tail beneath with transverse broad scales, like the boa. Gmelin thinks it does not belong to this species.

**Corallinus.** This is named by Shaw the pale-red flow-worm, with blood-red variegations, and so, by Seba it is called the red Brazilian serpent, so named probably from its colour, it being red with paler bands; the scales are tipped with black. This is a very elegant species; it is about a foot and a half long, the thickness very considerable; the ground-colour is of a pale-red, with very broad, alternating facets, and variegations of a deep coral red; the scales are moderately large, and of a rounded form, and the head and tail are remarkably obtuse. This highly beautiful animal is a native of the warmer parts of South America, where it is said to be found in woods, and to derive its fullness from the larger
larger insects, as locopendrium, &c.; in colour it sometimes varies, a mixture of black in different proportions being blended with the red on the sides, and the bands are also more numerous in some specimens than in others.

AFTER. This, as its name denotes, is black with white bands; scales tipt with black. This is nearly allied in general appearance to the corallinus, but differing in colour; being white with black bands; the abdominal scales are dilated according to Seba’s figure, on the authority of which, a beautiful engraving of it is given by Shaw. It is a native of South America.

Rufus. Tawny, with tranverse but interrupted white lines; beneath it is variegated. This is found at Surinam.

HEPATICA. Line on the top of the back, and a waved line on each side, of liver-colour, the spaces between paler, with roundish whitish spots. It inhabits Surinam.

Tessellatus. This species is of a fawn-colour, with numerous bands, and three fringes: the head is white, and spotted with brown. It inhabits Paraguay.

ALBUS. The individuals of this species are entirely white; tapering towards each end.

Boa, another genus of the serpent race, has been generally described in the alphabetical arrangement, with reference to the species, which having been neglected in their places, must be noticed now. (See Boa.) The genus, according to Gmelin, includes ten species, but Shaw mentions others; we shall first mention those given by Gmelin.

Species.

Contortrix. Hog-nosed Boa. The plates of the belly are 150 in number, and those on the tail 40. It inhabits Carolina; it is broad, and its back is convex; it is emerise, with lateral round spots; it has a poisonous bag, but no fangs; the tail is about half the length of the body.

Canina. This species has 203 plates on the belly, and 77 on the tail. It inhabits America. By Shaw it is named the Green Boa, with tranverse, undulated, white dorsal bands. It is a highly beautiful snake, meauring, when full-grown, about four feet in length, and of a proportionable thickness; the head is large, and shaped like that of a dog; the colour of the whole animal on the upper parts is a molt beautiful Saxon green, with several short, undulating, tranverse white Saxon spots down the back, the edges of which are of a deeper or stronger green than the ground-colour of the body; the under or abdominal part is white. There is a specimen of this species in the British Museum.

A variety of this species is described by Seba; the ground-colour is of a bright orange, the dorsal bands are of a pale yellow, edged with red, and the abdomen is of a pale yellow. It is a native of the East Indies, differing merely in colour from the former.

Hipnale. The plates on the belly are 179; those on the tail 120. It is found at Siam, and is of a yellowish colour, with white oblate spots on the back.

Constrictor. This, by some naturalists, is denominated the yellowish-grey boa, with a large chestnut-coloured chain-like pattern down the back, and subtrigonal spots on the sides. Dr. Shaw gives the generic character thus: scuta, or undivided plates, both on the abdomen and beneath the tail. But by Gmelin it is characterized simply by the 240 plates on the belly, and 60 on the tail.

Of all the boa, the most conspicuous is the B. confolidus, which is at once pre-eminent, from superiority of size, and beauty of colours; in this respect it appears to be subject to considerable variation from age, sex, and climate, but may be distinguished in every state from the rest of its tribe by the peculiar pattern or disposition of its variegations.

The ground-colour of the whole animal in the younger specimens is a yellowish-grey, and sometimes even a bright yellow; on which is disposed along the whole length of the back, a series of large, chain-like, reddish-brown, and sometimes perfectly red variegations, leaving large, open, oval spaces of the ground-colour at regular intervals: the largest or principal marks composing the chain-like pattern above-mentioned are of a squarish form, accompanied on their exterior sides by large triangular spots, with their points directed downwards; between these larger marks are disposed many smaller ones of uncertain forms, and more or less numerous in different parts; the ground-colour itself is also scattered over by a great many small specks of the same colour with the variegations; the exterior edges of all the larger spots and markings are commonly blackish, or of a much deeper cast than the middle part, and the ground-colour immediately accompanying the outward edges of the spots is, on the contrary, lighter than on other parts, or even whitish, thus constituting a general richness of pattern, of which nothing but an actual view of a highly-coloured specimen of the animal itself can convey a complete idea. In the larger specimens, the yellow tinge is often lost in a uniform grey cast, and the red tinge of the variegations sinks into a deep chestnut; and in some the general regularity of the pattern before described is disturbed by a kind of confluent appearance: the head is always marked above by a large longitudinal dark band, and by a narrower lateral band passing across the eye towards the neck.

The boa constrictor is a native of Africa, India, the larger Indian islands, and South America, where it chiefly resides in the most retired situations in woody and marshy regions.

It was, in all probability, an enormous specimen of this very serpent that once diffused so violent a terror amongst the most valiant of mankind, and threw a whole Roman army into dismay. Historians relate this surprising event in terms of considerable luxuriance. Valerius Maximus mentions it from Livy, in one of the loft books of whose history it was related more at large, and the learned Friennhemus, in his Supplementa Liviana, has attempted a more ample and circumstantial narrative of the same event, of which the following is a quotation.

“In the mean time Regulus, every where victorious, led his army into a region watered by the river Bagrada, near which an unlooked-for misfortune awaited them, and at once affected the Roman camp with considerable loss, and with apprehensions still more terrible; for a serpent of prodigious size attacked the soldiers who were sent for water, and while they were overwhelmed with terror, and unequal to the conflict, engulphed several of them in its enormous mouth, and killed others by writhing round them with its fropes, and bruising them with the strokes of its tail; and some were even destroyed by the pestilential effluvia proceeding from its breath; it caused so much trouble to Regulus, that he found it necessary to contest the possession of the river with it, by employing the whole force of his army; during which a considerable number of soldiers were lost, while the serpent could neither be vanquished nor wounded; the strong armour of its scales easily repelling the force of all the weapons that were directed against it; upon which recourse was had to battering engines, with which the animal was attacked in the manner of a fortified tower, and was thus at length overpowered. Several discharges were made against it without success, till its back being broken by an immense stone, the formidable monstur began to lose its powers, and was yet with difficulty destroyed; after having diffused such a horror...
horror among the army, that they confessed they would rather attack Carthage itself than such another monster: nor could the camp continue any longer in the same situation, but was obliged to fly; the water and the whole adjacent region being tainted with the pestilential effluvia. A most mortifying humiliation to human pride! Here at least was an instance of a whole Roman army, under the command of Regulus, and universally victorious both by sea and land, opposed by a single snake, which conflicted with it when living, and even when dead obliged it to depart. The proconol, therefore, thought it no diminution to his dignity to fend the spoils of such an enemy to Rome, and to confcles at once the greatnes of his victory and his terror, by this public memorial: for he caused the skin of the snake to be taken off and sent to the city; which is said to have measured 120 feet: it was supfenced in a temple, and remained till the time of the Numantine war.

Cenchris, the Rufeceent Boa, with large dusky dorsal rings, and blackish kidney-shaped lateral spots with white centres; it has 265 plates on the belly, and 57 on the tail. It inhabits Surinam; it is greenish, with white occellate spots; the irids are grey.

Ophevas, or Brown Boa, has on its belly 281 plates, on the tail 84; the body is brown, and in appearance it resembles the B. confdictor.

Enydris, or Water Boa. This species is variegated with different shades of grey; the teeth in the lower jaw are longer than usual in this genus; the number of abdominal fecta is 270, and of those on the tail 105. It is very like the hortulanus, hereafter to be described.

Murina; Grey Boa. This species has 254 plates on the belly, and about 65 on the tail. It inhabits America. It is glaucous, with round black spots.

Scytalle; Spotted Boa. Cinereous, with large orbicular black dorsal spots, and annulated lateral ones, with white centres; it has 270 plates on the belly, and 70 on the tail.

This is farceally inferior in size to the B. confdictor, and is of inferior manners, deleasuring, like that animal, goats, sheep, deer, &c.; it is generally of a grey or glaucous colour, marked with large orbicular black spots on the back, and with smaller ones of a similar form, but with centres, on the fides; while on the abdomen are scattered several oblong spots, and marks interfused with smaller specks and variegations. It is a native of several parts of South America, and like other large snakes is occasionally eaten by the Indians.

Hortulana; Garden Boa. This is of a yellowish-grey, with brown variegations, thence on the head resembling face; the body sub-compresed, and the fides marked by wedge-shaped spots; it has 290 plates of the belly, of the tail 128.

This very elegant serpent, which is of a moderate size, measuring only a few feet in length, and being of a slender form, has obtained its specific name from the singular variegations on the head, which represent the form of a parterre in an old-fashioned garden; the variegations on the body are, like those on the head, of a blackish-brown, on a pale ferrorous or yellowish ground; they are disposed into large circular, and sometimes angular patches on the fides, the centres of fome being open, and of others marked by an oblong spot; besides these there are others interfused of smaller size and of different forms; the abdomen is commonly yellowish, with dusky specks and patches; the ground-colour of the whole snake is sometimes of a pale violet, and the variegations of a dark purplish-brown; but in all its varieties this species may be easily distinguished by the rich embroidered appearance of the pattern, and more particularly by that on the top of the head; the head is also broader, and the neck more fnder in proportion, than in most of the other boas, the body slightly compressed, and the tail slender. It is a native of South America.

Such are the Linnean species given by Gmelin; the following are additional ones, described by Dr. Shaw in his General Zoology.
