dom and good sense, is reported by Tacitus. His design of retiring from the capital, encouraged by selfish purporses by Sejanus, was put into execution A.D. 37. Accordingly he withdrew into the Isle of Capree, near the bay of Naples. Here he passed his remaining years, immersed in grofs and infamous debauchery, having mankind, fearfully known to exit but by his cruelties, and rendering himself, in direct opposition to his own maxims, "let them hate, provided they esteem me," no less contemptible than odious. It ought to be mentioned, however, that in a conflagration which consumed a large quarter of Rome, he displayed a very laudable and spontaneous munificence. For an account of his connection with Sejanus, and of the effects and termination of that connection, we refer to the article Sejanus.

The latter part of Tiberius's reign was marked by servility on one hand, and despotic ferocity on the other; and it appears by one of his letters to the Senate, that he suffered as much misery from the anguish of self-reproach and tumult of mind as he inflicted: "What shall I write to you, conscript fathers, or what I shall not write, or why I should write at all at this time, may the gods and godfiees plague me more than I feel daily that they are doing, if I can tell!" What mental torture must have been, says Tacitus, that could have exorted such a confession. Some few occasional acts of wildom and munificence brightened in a faint degree the black picture that was exhibited by his general conduct. Towards the close of life, and at an advanced age, the appointment of a successor engaged his attention. He had two alternatives; the one was the nomination of Caius, his grandson, the son of Germanicus, who was his adopted son; and the other, the appointment of Gemellus, the son of Drusus, who was his son by nature. The former was of mature age, being now twenty-five, and possessed of popular favour. The diffumulation of this aspirant to the empire had not eluded the penetration of Tiberius. See Caligula.

Tiberius, leaving Capree, frequently changed his abode, and at last settled at a country-house, which had belonged to Lucellas, near the promontory of Misenum. There, on March 16th, A.D. 57, he sunk into a fit, in which he appeared dead; upon which Caius, with indecorous precipitation, proceeded with a numerous efort to seize possession of the empire; but his revival threw them all into confusion. At this instant Macro, the preternior priest, caused him to be suffocated with pillows. He died in the seventeenth year of his age, and twenty-third of his reign, universally execrated; and his predominant vices were such, that they have almost effaced the records of his laudable qualities.

Tiberius Constantine, emperor of the East, was a Thracian by birth, and by office captain of the guards to Jullian II. By the recommendation of the empress Sophia, he was raised to the rank of Cæsar A.D. 574, and in 578, when Jullian died, succeeded to the imperial throne. Sophia, attached to his person, had flattered herself with the hope of his being her second husband; but on his accesion to the empire, it appeared that he had been previously married to Analecta, who was proclaimed Augusta. Sophia, thus disappointed, concurred in a conspiracy for raising to the purple Jullianus, commander of the eastern army; but the plot being discovered, Sophia was punished by losing the greatest part of her allowance. The government of Tiberius has been favourably represented. He was temperate, juf, and humane; economical in the disbursement of the revenue, yet liberal and beneficent, and ready to remit the dues of taxadon to sufferers under public calamity. The principal events of his reign were two victories over the Persians. Soon after the second victory, Tiberius fell into a dispaee, during which he declared Maurice, who had married his daughter Contantine, and who had been nominated Cæsar, his successor; and after a reign of four years, he closed his life in 582, with the general regret of his subjects. Anc. Un. Hist. Gibbon's Rom. Emp.

TIBESTI, in Geography, a town of Africa, on the route from Fezzan to Bornou, inhabited by the people called Tibbe (which fee); 150 miles S.E. of Mourzouk. The vales of Tibesti are fertile in corn, and paturage for cattle, of which they have numerous herds; and they are particularly celebrated for their breed of camels, which are esteemed the best in Africa. For this fertility they are indebted to the water of the innumerable springs, which amply compensate for the want of rain, which seldom, if ever, falls within the limits of Tibesti. Among the natives of Tibesti, different religions are professed; for some of them are Mahometans, and others continue attached to their ancient sytlem of idolatry. From the plain, which lies to the W. of the desert of Tibesti, a part of the mountains of Tibesti take their rise. These vast hills, the range of which is very extensive, are variously peopled; but such of them as are crossed on the route from Fezzan to the city of Bornou, are inhabited by a mixture of Muffulmen and idolaters, who employ themselves in breeding camels and ases, and other cattle, particularly horses of a small size.

TIBET. See THIBET.

TIBI, a town of Arabia, in the country of Oman; 8 miles N. of Kalhat.

TIBIA, in Anatomy, the large bone of the leg. See Extremities.

Tibia, Fractures of the. See Fracture.

Tibia Biceps. See Biceps.

Tibia, in Musics, was originally a flute, made of the shank or shin-bone of an animal; and when the art of boring flutes was discovered, they were made of box-tree, laurel, brash, silver, and even of gold. See Flute.

Tibia Articularis. See Bagpipe.

Dr. Burney (Hist. Mus. vol. i. p. 521.) apprehends that the union of this instrument with the syrinx suggested the first idea of an organ.

Tibia Pares et Impares, in the Dramatic Music of the Ancients. It has been long doubted, whether pares and impares meant double and single flutes, or equal and unequal in point of length and fize. But though in preferring either of these acceptations, some sense and meaning is acquired, yet we should incline to the latter. For in none of the representations in ancient painting or sculpture, which we have yet seen, does it appear that the tibiae, either at sacrifices or in the theatre, plays on a single flute, though we as often see double flutes of different lengths in his hands, as of the fame length; and as harmony, or music in different parts, does not appear to have been practiced by the ancients, the flutes of equal length may naturally be supposed to imply unisons; and unequal, such as are octaves to each other.

TIBIALIA, among the Romans, a kind of swaths with which they used to cover their legs.

TIBIALIS, in Anatomy, a name applied to various organs situated in the neighbourhood of the tibia. There is an anterior and a posterior tibial artery; an anterior and posterior tibial nerve (see Artery and Nerve), and the two following muscles.

Tibialis Anticus, jambier antérieur, tibio-fustarten; an elongated muscle, flattened at the fides, placed on the front of the leg, and extending from the upper end of the tibia to the first cuneiform bone. It is covered in front by
the aponeurosis of the leg, to which it adheres closely at the upper part: the anterior surface of the muscle forms the convexity on the outside of the tibia, which is more considerable in strong muscular subjects. The inner flat surface corresponds to the outer or concave surface of the tibia, and is attached to its upper half; the outer surface corresponds above to the extensor longus digitorum pedis, below, to the extensor longus pollicis pedis: the anterior tibial velifies and nerve being interposed. The posterior edge of the muscle is attached to the upper three-fourths of the interosseous ligament, then it lies on the front of the tibia, on the ankle joints, and on the upper and inner part of the tarus. The upper extremity of the muscle is fixed to the front of the external tuberosity of the tibia; thence it descends parallel to the tibia, first increasing in size, then diminishing again, and ending about the lower third of the leg in a thick and flat tendon, which descends over the front of the tibia, and of the ankle, confined by the superior annular ligament of the tarsus. (See Fascia.) Having passed this ligament, the tendon paffes forwards on the foot, then turns obliquely inwards, becoming a little broader, over the convexity of the first cuneiform bone, and divides into two portions. The posterior, which is the largest, is fixed to the inner and front part of the bases of that bone; the anterior and smaller is attached to the posterior extremity of the first metatarsal bone.

The lower part of the tibialis anticus consists of a strong tendon, which enters the substance of the muscle, and expands into an aponeurosis reaching nearly to the upper end of the muscle. The fibrous fibres arise from the falcum of the leg, from the external surface of the tibia, from the interosseous ligament, and from an aponeurotic feptom between it and the extensor longus digitorum. They pass obliquely to both surfaces of the tendon, like the bars on the shaft of a feather, and are continued much lower on its posterior than on the anterior surface.

It bends the foot on the leg, and turns the point inwards: it elevates at the same time the whole internal edge of the foot. It brings the leg forwards on the foot, and maintains it in that position.

TIBIALIS Posticus, jambeur postérieur, tibio-lous-tarden, is a long narrow muscle, thicker above than below, placed at the back of the leg, under the calf, and extending from the upper part of the tibia and fibula to the os navicular. It is covered behind by the soleus, by the flexor longus digitorum and pollicis pedis. In front it is attached to nearly the whole posterior surface of the interosseous ligament, and above, to the posterior surface of the tibia. On the outside it is fixed to the fibula. Its upper extremity is divided into two portions, an external and smaller attached to the fibula, an internal larger to the tibia and interosseous ligament; they are separated by an interval, through which the anterior tibial artery passes. The muscle descends parallel to the bones of the leg, and arcuated between them, becoming larger to its middle, from which it again diminishes; towards the lower part of the leg it forms a strong tendon, which runs in a groove hollowed in the external malleolus, and surrounded by a fibrous sheath, which separates it from the flexor longus digitorum. In this groove the tendon becomes broader: it passes below the head of the tibiagrus, swelling into a hard and nearly bony substance, and is attached to the lower and inner part of the os naviculare, and to the bases of the first cuneiform bone. The inferior tendon ascends into the muscle, expanding into an aponeurosis, in which the fibrous fibres are inserted obliquely on all sides from the fibula, the tibia, the interosseous ligament, and the aponeurosis, which covers it from the flexor longus digitorum. It extends the foot on the leg, turning the sole and point a little inwards. It will carry the leg backwards on the foot, when that is fixed.

TIBICEN, in Ancient Musici, a flut-player. TIBICEN, in Ichthyology, a fish of the trigla kind, called by many authors byrus, or the harp-fish; and in some parts of England, the piper.

The head of this fish runs out into two broad horns, which are ferrated, or bet with a fort of teeth, or small spines, all along their edges, which is its principal distinction from thehirundo or swallow-fish. Above the gill-fins it has on each side a long and sharp spine. The forehead is elevated into a sort of eye-brows over the eyes: and at the angles of these there are small and short spines, which are long and crooked. The side fins feel but very little rough to the touch, and the forehead between the eyes is not hollowed. The whole head is covered with a bony crust, which runs into two horns or spines behind. It has three fingers or filaments on each side, from the roots of the gill-fins; and its jaws are rough like files, but have no distinct teeth. The tail-fin, and the middle of the back, in this fish, are red. It is caught in the Mediterranean, and in some other seas. In our county of Cornwall it is not unfrequently caught about the shores, and from the noise it makes, when taken out of the water, is called the piper. Ray and Willughby.

TIBIGENSE OPPIUM, in Ancient Geography, a town of Africa Propria, according to Pliny; called Thigbya by Ptolemy.

TIBIGI, in Geography, one of the rivers of the Brazils, which flow into the Parana, rich in diamonds, as the few families that live in its vicinity have reason to remember with gratitude. West of this river and of Corrinita, it is dangerous to land, since in that direction are the Anthropophagi, who were driven from these boundaries at a very recent period. The country to the N. abounds with wood.

TIBILIS, in Ancient Geography, a place of Africa, distant 10 leagues S.W. from Hippo Regius, and 16 miles E. of Cirta: where are many ruins.

TIBISCA, a town of Lower Media. Ptol.

TIBISCU, one of the most considerable towns of Dacia. Ptol.

TIBISCU, a river of Dacia, which ran into the Danube.

TIBISIS, a large river, which rofe in mount Haemus, and pursuing a north course, discharged itself into the Ister.

TIBIUM, a mountain of Asia, in Phrygia.

TIBOELAELE, in Geography, a town on the S. coast of the island of Ceram. S. lat. 3° 19'. E. long. 128° 45'.

TIBOUCHINA, in Botany, an unexplained barbarous name, Aubl. Guian. 445. t. 177. Julf. 329. The shrub which bears it is suspected by Schreber to be a species of Melastoma. (See that article.) We fee no reason to question this, though Aublet describes the fruit as a dry capule; for the known Melastoma differ greatly in the degree of pulp in their berries, especially according to the period at which they are examined.

TIBOULEN, in Geography, a small island in the Mediterranean, near the coast of France. N. lat. 43° 15'. E. long. 6° 24'.

TIBOURBOU, in Botany, the Caribbean name of a fine tree of Guiana and Cayenne, called Apiaiba Tibo-bou in Aubl. Guian. 538. t. 213. See Aubletia and Sloanea.
TIBRACANA, in Ancient Geography, a town of Asia, in the interior of Media. Pol.

TIBULA, or Tibula, a town situated on the northern coast of the island of Sardinia. Pol. Iter. Anton.

TIBULLUS, Attics, in Biography, a Roman poet of the Augustan age, of the equestrian rank, whose native place and time of birth are not ascertained. His patrimony was much impaired, either by his own prodigality, or by the devastation of several wars; but yet he does not seem to have been distinguished by any tokens of the liberality of Augustus and Maecenas, the munificent patrons of literature at the period in which he lived; nor does he mention their names in any of his poems. M. Valerius Meffala Corvius, upon whom he composed a panegyric, was his particular friend and patron, whom he accompanied in his expeditions to Asia; but he preferred peace and retirement in the society of one of those objects of his affection whom he has celebrated in his elegies. Horace, with whom he was intimate, has addressed to him an ode and an epitaph, complimenting him as a candid judge of his writings, and describing him as possessed of every worldly advantage. It has been inferred, from an epigram of Domitian Marcus, that he died about the same time with Virgil, B.C. 19, in the flower of his age. Ovid lamented his death in a beautiful elegy, representing his mother and sister as mourners at his funeral, and speaking of him as a poet of the highest reputation.

The poems of Tibullus are elegies comprised in three books, and a panegyric of Meffala. His fame is founded on his elegies, which are described by one of his biographers as occupying, by the testimony of ancient and modern critics, the first class of such compositions with regard to the appropriate qualities of elegance, tenderness, and that beautiful simplicity, which is the character of real feeling. Their principal subjects are "love and rural life." With his description of a passion which is illicit, he has blended "more touches of a pure, and what may be termed a congenital affection, than almost any other Roman poet. His language is a true example of what the Latins call tenes, or neat and polished. He is easy and natural, with scarcely any mixture of learned allusion or figure." His works are usually printed with those of Catullus and Propertius; but of the separate editions, the most esteemed are those of Brookhufius, Amst. 1708, 4to.; of Vulcius, Patav. 1749, 4to.; and of Heyne, Lips. 1755, 1777, 8vo. Gen. Biog.

TIBUR, Tivoli, in Ancient Geography, a town of Italy, near the Anio, N.E. of Rome, in the country of the Sabines. Pliny refers its origin to the age which preceded the siege of Troy, and says that its founder was Tiburinus, one of the sons of Ampharius, affixed by his two brothers, Catellie and Corax. This Tiburinus was regarded after his death as a god; and was worshipped in a wood consecrated to him, and where a temple was erected to his honour. But Dionyfus Halicarnulensis pretends that it was built by the Siculi, before this epocha. For its situation, and some other circumstances attending it, we refer to the article Tivoli.

Horace has described in a few lines the beauties which he admired in contemplating this ancient city, Od. 7. 1. 4. "Nothing," says the poet, "draw me so much as the house of the refounding Albaneus, the lofty cedars of the Anio, the sacred wood of Tiburinus, and the gardens irrigated by unintermitting supplies of water." The "domus Albaneus resonantus" of the poet was the fofatara or sulphureous springs of the place, probably the crater of some ancient volcano, which perpetually discharged a kind of gas or mephitic vapour, that was thought to possess a fanatical quality, and to be a remedy for many disorders. Many persons resorted hither for relief; and Suetonius informs us, that Augustus also came for the benefit of the baths which the place afforded. These benefits were ascribed to imaginary deities, who were thought to preside over this privileged spot. Accordingly, a monument has been discovered, which indicated that Hygeia, the goddess of health, was worshipped here. The vapour possessed also a kind of inspiring quality, so that here was a temple of the Muses; and also, besides various other monuments, a temple in which was an oracle. Virgil informs us how this oracle was consulted. The "praecipes Anio" of Horace refers to the cascade of this river. The gardens and vineyards have to this day retained their celebrity; the wine of this canton being held in high estimation.

Tibur was also famous for its temple of Hercules, which had its college of priests and curators; a beautiful portico, where, according to Suetonius, Augustus administered justice when he resided here; and an excellent library of which Aulus Gallus speaks in his "Noches Atticas." Tibur had also a temple of the Sibyl, much admired for its elegance. This place was also famous for other monuments, now in ruins. Towards the end of the Roman republic, the adjoining territory was selected for superb buildings and houses of various kinds, all distinguished by their magnificence and beauty. Of these, the Tiburinus of Adrian was the most celebrated.

TIBURO, in Ichthology, a fish very badly and falsely described by several authors, and proving, on a strict inquiry, to be no other than the lamia or white shark.

The Tiburo of Linnaeus is a species of squalus, with a very broad and heart-shaped head, found in the American seas. Linnaeus queries, whether it is not a variety of the xynus, or hammer-headed shark.

TIBURON, in Geography, a town and bay on the S.W. coast of Hispaniola, near Cape Tiburum.—Also, a small island in the Pacific ocean, discovered by Megellan in 1520. It is variously laid down in maps. S. lat. 9°, 13°, 14°, 15°, 17°.

TIBURONES, or Main Cape Reef, two small islands, surrounded with rocks, near the coast of Honduras. N. lat. 15° 16′. W. long. 82° 8′.

TICADEE, a town of Hindostan, in the circuit of Ruttumpour; 15 miles N. of Dumah.

TICAL, in Commerce, a weight for gold and silver, and also a money of account in certain parts of the East Indies, particularly at Pegu and Siam. At Pegu, the weight of silver, under this denomination, is divided into 16 toises or touch. Gold and silver are here weighed by the tical, and their fineness is expressed by the parts called touch. The tical weighs 43 1/4 pagodas, or 237 7/8 English grains. The commercial weights are the vis of 100 ticals or tuals, and the candy of 100 vis. From the above weight of the tical, the candy should weigh 50 1/2 lbs.; nevertheless the English reckon it at 6 maunds 28 seers of the Bengal factory, or 500 lbs. avoid. dupo.

At Siam, the accounts are kept in catties, tales, ticals or tuals, maunds, fowanges, and cowries. The catty is = 20 tales, the tale = 4 ticals = 16 maunds = 32 fowanges; and the fowang is = 800 cowries. The coins are gold ticals, which pays for ten silver ticals; silver ticals, maunds, fowanges, and fumpeises, the latter being the fourth part of a fowang. The silver tical weighs 22 5/8 English grains, and being from 11 oz. 4 dwt. to 11 oz. 12 dwt. fine, is worth from 291 to 302 stiverling; but these coins are often adulterated; 1 tical pays commonly for 1 Spanish dollar, and 2 1/2 ticals for 1 Dutch
TIC

TICAO, in Geography, one of the Philippine islands, about 25 miles long, and from 3 to 8 broad. N. lat. 12° 39'. E. long. 123° 34'.

TICENA, in Ancient Geography, a town of Africa Propria, S. of Carthage, between the rivers Bagradas and Triton. Ptole.

TICENGIO, in Geography, a town of Italy, in the department of the Upper Po; 6 miles E. of Crema.

TICHASA, Te-GEWSE, in Ancient Geography, a town of Africa Propria, S. of Carthage, between the rivers Bagradas and Triton, 12 leagues S.W. of Capira; in which are some vestiges of the Romans. Ptole.

TICHENBRAY, in Geography. See Tinchebray.

TICHFIELD, a village of England, in the county of Hants, situated on a river which runs into the Southampton Water. Here Charles I. concealed himself, when he fled from Hampton-Court, in the year 1674, at a seat of the earl of Southampton. This seat had been an abbey, and is said to be the place where the marriage of Henry VI. with Margaret of Anjou was solemnized; 8 miles N.W. of Gosport.—Allo, a town of Jamaica, on the N. coast; 22 miles N.E. of Kingston. N. lat. 18° 12'. W. long. 75° 16'.

TICHIS, in Ancient Geography, a river which flowed from the Pyrenees, now Tich, in the department of the Eastern Pyrenees.

TICHITIUM, a town of Greece, in Eotia. Thucydides.

TICHOS, or TICHUS, a fortress of Achaia, in the eastern part to the S. of the promontory Arazum.

TICINDLO, or NAVIGIA GRANDE, in Geography, a canal made from the river Tefino to the city of Milan, by order of Francis I. king of France.

TICINUM, Pavia, in Ancient Geography, a town of Tranfpadane Gaul to the S.W. upon the river Ticinum, or near it. After the second Punic war, it attained the rank of municipal. Odoacer, king of the Heruli, destroyed it, and it was rebuilt under the name of Pavia, whence the name Pavia.

TICINUS, TESIN, a river of Tranfpadane Gaul, which commenced in the country of the Lepontini, traversed the lake Verbannus, and discharged itself into the Po, near Ticinum. It is celebrated for a battle of the same name, between the Romans, conducted by Cornelius Scipio, the father of Scipio Africanus, and the Carthaginians, conducted by Hamilcar, in the year of Rome 535, in which the Romans were defeated.

TICK, in Natural History, a nafty little animal of a livid colour, with a blunt and roundish tail, elevated antennae, a globo-ovate form, and full of blood; which infects cows, swine, goats, sheep, and dogs. The tick or ricinus is, in the Linnean sytem, a species of acarus in the opiliones order of infests.

In order to destroy and remove these noxious vermin, which spread very rapidly in sheep, it has been recommended to repare the wool, and to wash the diseased spots two or three times, or oftener, if necessary, with a liquid preparation, consisting of one ounce of cream of tartar, and a quarter of a pound of bay-falt, each finely powdered and sifted, and one ounce of corrosive sublimate, reduced into the same flate; the whole being well dissoled and mixed together in two quarts of soft water: or four pounds of soft soap, and two pounds of arsenic, may be steeped and dissolved in thirty gallons of water, and the animals be immersed in the infusion or solution, the heads of them being carefully kept above water, and the sheep being sheltered from rain for one or two days afterwards. The wool must be closely preffed, and the liquor that runs off be caught in a tub, or other vessel, for future use. The proportion above specified, is sufficient to bathe or wash forty lambs, or the same number of small sheep; and sometimes many more.

But the preparation which is in use at Holkham-Hall, in the county of Norfolk, for this purpose, consists of two pounds of tobacco, two pounds and a half of soft soap, and one pound of the white calx of mercury, well reduced into powder; the whole being boiled in eight gallons of water for an hour. This is a quantity sufficient for dressing fifty sheep, being applied by parting the wool down the shoulders and breast, and twice on each of the sides of the sheep, then pouring it very carefully so as to prevent its being wasted. It is said to be very effectual not only in destroying the vermin, but in removing the scabby fores that are produced.

It is stated in a paper in the third volume of the "Transactions of the Highland Society of Scotland," that the tick, or acarus redivivus, is a distinct or species or vermin of this kind from that of the kid, or hippobosca ovina, the former of which harraffes the lambs and trembling sheep in the spring season, while the latter molefts all forts and ages, but particularly hogs or young sheep, and chiefly such as are in a lean state. The former always adheres close to the bare spots of the shoulders, thighs, or ears, draining and drawing away the blood from them; and for the most part drops off about midsummer: but the latter harrours in the wool, bites the sheep, and sucks their blood. Smearing with tar, it is said, expels it from the skin, and it soon afterwards drops from the wool. Tobacco-juice is fatal to it almost instantaneously, and mercurial ointment destroys it. The former, or tick, is removed by the same remedies as the kid, and it is wholly prevented by having the young sheep in good condition. This distinction, in some cases, may be of considerable use to the sheep-farmer in the destruction and removal of such hurtful vermin.

Tick, in the Mange, a habit that some hores take of preffing their teeth against the manger, or all along the halter or collar, as if they would bite it.

Tick-Bean, or Ticks, in Agriculture, a term commonly applied to the small bean employed in the feeding of hores and other animals; of which there are several kinds, as the common ticks, the large flat ticks, the small or Effex ticks, and the French ticks. The first is a fort which is small and very commonly cultivated, but most generally by the farmers of Kent, where they are used for the fattening of hogs, and as food for hores, especially those of the team kind. The second is a larger fort than the common, and ripens somewhat earlier. They are very productive in some cafes; but from being larger in size, they are coarse and heavy, and consequently of rather less value the quarter or any other measure. They are sometimes called May beans. The Effex ticks are much smaller than the common, and of a rounder shape or form. They ripen a few days later, and are not so productive, but more valuable, as being heavier in proportion. The last fort, or small French ticks, are a still less kind, being only about as large as a middling-sized pea, and nearly circular. They ripen later than
than any of the other forts, but are the most valuable when dry, on account of their great weight.

Ticks are an important article of cultivation in most places, where the land is suited to their growth; and though they have been for a long time, and are at present, almost wholly confined to the counties of Essex and Kent, they may be raised in many other districts with equal success and advantage.

TICKERY, in Geography, a town of Hindoostan, in Bish; 15 miles N.W. of Gaya. N. lat. 24° 58'. E. long. 87°.

TICKELL, Thomas, in Biography, an English poet, was the son of a clergyman in Cumberland, and born at Bredkirk, near Carlisle, in the year 1686. He was admitted at Queen's college, Oxford, in 1701; and in 1707 he published a poem, entitled "Oxford," and inscribed it to Lord Lonsdale, expressing his gratitude to that university. In 1708 he took his degree of M.A., and two years after was elected a fellow of his college, under a dispensation from the crown against the statute which required him to be in orders. With a view of advancement by the exercise of his literary talents, he came to the metropolis, and ingratiated himself with Addison by an elegant copy of verses in praise of his opera of Rosamond. He contributed to the periodical publications of the "Spectator" and "Guardian," in the latter of which, all the papers on pastoral poetry, except one by Pope, are ascribed to him. During the negotiations which terminated in the peace of Utrecht, he published a very popular poem, entitled "The Prospect of Peace," which was highly commended by Addison, in return for which commendation he wrote his lines on the "Cato" of that author. On the accession of the Hanover family, to which he was attached, he prefented George I. on his arrival with a piece called "The Royal Progress," and he served the cause still more effectually by two satirical poems on the Jacobite party, viz. "An Imitation of the Prophecy of Nereus," and "An Epistle from a Lady in England to a Gentleman at Avignon." Tickell accompanied Addison to Ireland, and was there initiated in public buffoons with a view to future preferment. On occasion of Pope's publication of the first volume of his translation of Homer's Iliad, Tickell published a translation of the first book of that poem, which was patronised by Addison, so as to occasion an interruption of his friendship with Pope. When Addison was made secretary of state, Tickell was under-secretary, and continued in office under his successor Crayges. On the death of Addison, Tickell was entrusted with the charge of publishing his works, to which he prefixed a valuable life of the author. In 1725 he was appointed to the lucrative post of secretary to the lords-judges of Ireland, and retained it till his death, which happened at Bath in 1740. Tickell had been married and left a family.

Tickell is ranked by his biographers among English poets of the second order; equalled by few of his contemporaries in eloquence of diction and harmony of verification, and without lofty flights maintaining a decent elevation by a cultured style, and by just and ingenious thoughts. His funeral poem on Addison is pronounced by Dr. Johnson to be more sublime and elegant than any that is to be found in the whole compass of English literature. His "Ode to the Earl of Sunderland," and his "Colin and Lucy," are highly commended.

Richard Tickell, esq., a grandson of this poet, who was a commissioner of the stamp-office, has been known to the literary world by his "Wreath of Fashion," and especially by an effusion of political art and satire, entitled "Anticipations of the Debates of the House of Commons," 1778.

TICKELY, in Geography, a town of Hindoostan, in the circuit of Cicacole; 30 miles N.E. of Cicacole. N. lat. 18° 36'. E. long. 84° 34'.

TICKERA, a pattle which is prepared in Fezzan from dates and the meal of Indian corn, and which, whenever they travel, is in great request among the people of Fezzan.

TICKEREE, in Geography, a town of Hindoostan, in Oude; 48 miles N.E. of Manicopour.

TICKHILL, a market-town in the lower division of the wapentake of Strafford-and-Tickhill, in the West Riding of the county of York, England; is 4 miles W. from Bawtry, 7 miles S. from Doncaster, and 154 miles N. by W. from London. The houses are placed in a valley, and cover a large space of ground. Some of them are of brick, and others of stone; a few of them are respectable, but the more numerous have only a mean appearance. A market is held on Fridays, but is nearly fallen into disuse. A fair is kept annually for horses, horned cattle, and sheep. The population return of the year 1811, states that Tickhill contained 1508 inhabitants, who occupied 279 houses. The objects most worthy of attention are the church, and the remains of an ancient castle. The former is a spacious edifice, with a lofty and beautiful tower, and from its architecture seems to have been built in the reign of Henry III. The castle, of which nothing now remains but the lofty mound on which the keep formerly stood, with a ditch and part of the walls surrounding the fortresses, is situated on the south side of the town. An ancient gateway, forming the entrance on the western side, is the most curious part of the ruins. Part of these, with modern repairs and additions, is the seat of the honourable Frederick Lumley. A great part of the ground within the walls is converted into gardens and shrubberies. The steep declivity of the mound is formed into winding walks, leading by a gentle ascent to the summit.

The history of Tickhill prior to the Norman conquest is wholly unknown. It appears to have been one of the forty-nine manors given by the Conqueror to Roger de Bulf, who probably erected and resided in the castle. It was afterwards successively held by several noblemen, till Richard II. gave it to his uncle, John of Gaunt, duke of Lancaster, from whom it passed to the crown by the succession of Henry IV. In the year 1644 the castle was regarded as a very strong fortress, and was garrisoned for Charles I.; but being surrendered to the parliament, an order was issued that it should be dismantled and rendered untenable. The circular keep was in consequence demolished, but the foundations may still be traced by opening the ground. A royal free chapel or collegiate church was founded in the castle by queen Eleanor, wife of Henry II. It was given by king John to the prebends of the cathedral church of Rouen in Normandy. It was afterwards granted to the prior and convent of Lenton, Nottinghamshire; and in 1504 to the abbot and convent of St. Peter, Wellingtong. After the disolution it was given by Edward VI. to Francis, earl of Shrewsbury.

About two miles and a half from Tickhill is Sandbecks, the seat of the earl of Scarborough. The mansion, built by the late earl, is a large and commodious edifice, seated in a spacious park, which abounds with forest trees; and is adorned with an extensive lake. Near the western verge of the park, are the venerable and picturesque ruins of Roche abbey, which was founded in the year 1147, for monks of the Cistercian order. Here is a famous quarry, from which the
the stone for building the abbey, and for many other public edifices, was obtained.

About five miles nearly S. from Tickhill is Walding. Well, the seat of Sir Thomas White, bart. The house is a modern edifice, situated in a well-wooded park of considerable extent, and stands partly in Yorkshire and partly in Nottinghamshire; a small rivulet, which runs under a part of the out-buildings, forming the boundary between the two counties. In the park was formerly a priory of nuns, called St. Mary in the Park, founded by Ralph de Chevrolcourt. This religious house appears to have stood within the limits of Nottinghamshire. — Beauties of England and Wales, vol. xvi. Yorkshire; by J. Bigland.

TICKING, or TICING, in Hydrography, denotes the act of letting up turf in such a manner as they may be dried by the sun, and fit for being burnt into ashes on the land.

TICKLE HARBOUR, in Geography, a harbour on the E. coast of Newfoundland.

TICKLE me Quickly, a bay on the coast of Darien, near the Sambalas.

TICKISH, in the Mange. A horse is said to be ticklish that is too tender upon the spur, and too sensitive, that does not freely fly the spurs, but in some measure resists them, throwing himself up when they come near and prick his skin. A ticklish horse has somewhat of the ruminating, i.e. the kickers against the spurs; but with this difference, that the latter put back, leap, and kick, and yerk out behind, in disobeying the spurs; whereas a ticklish horse only resists for some time, and afterwards goes, and goes much better, through the fear of a vigorous hand, when he finds the horsemaster stretch his leg, than he does upon being actually pricked.

TICKSAH, in Geography, a river of America, in the Mississipi territory, which rises 10 miles N.E. of the forks of the Amite, and when it enters West Florida, is a creek of trivial size; it then becomes gradually augmented by several creeks, and after a S. course of 60 miles, falls into lake Maurepas, 4 miles N.E. of the mouth of Amite. Three miles above its mouth the Tickfah receives from the E. the united streams of the Natalbany and Pontchartrain, upon the latter of which stands Springfield, on the road from Madisonville to Natchez. Springfield is one of the landing places of travellers, who pass in schooners from New Orleans to Natchez. The above-mentioned Amite rises within the Mississipi territory, about 20 miles N. of the town of Liberty, in Amite county. The two streams that constitute the Amite, remain separate in their course through the Mississipi territory, but unite immediately upon entering West Florida, and then it joins the Iberville, and falls after a whole course of 100 miles into the lake Maurepas. Below the juncture of Amite and Iberville, the united streams form a navigable river, admitting vessels of six feet draught.

TICKSEED Sun-flower. See Coreopsis, and Sun-flower.

TICOLEA, in Geography, a town of Hindoostan, in Bahar; 7 miles N. of Bettiah. N. lat. 26° 55'. E. long. 84° 38'.

TICOLLOOSA, a town of the United States of America, in Tennessee; 38 miles S. of Knoxville.

TICONDEROGA, a township of Essex county, in the State of New York, erected in 1824. It is bounded N. by Crown Point, E. on lake Champlain, S. by Washington county, W. by Schroon, and includes the N. end of Lake George. Mount Defiance is in the S. part of this township. In 1830 it had about two hundred families, and thirty-five senatorial electors: seven saw-mills, three gramine-
mills, three forges, three carding-engines, and some other machines, and three school-houses. Here is also a steam machine, in which, by means of machinery moved with water, one man makes a hundred brooms a day. The inhabitants are mostly farmers.

In this township stands the fortresses of Ticonderoga, now a heap of ruins. It was built by the French in 1756, on a point of land formed by the junction of lake George, with lake Champlain, in N. lat. 43° 50', and 4° 14' E. long. from New York. It was, both by nature and art, a place of great strength. On three sites it is surrounded by water, and about half the other side is occupied by a deep swamp, and the line of defence was completed by the French with the erection of a break-work nine feet high, on the only accessible ground. In 1758, general Abercrombie with the British army unsuccessfully assaulted this fortress, and with the loss, as it is said, of 1944 men; but in July of the following year it was surrendered to general Amherst. It was the first fortress carried by the arms of America, in their contest for independence; being taken by surprise by general Allen, May 19, 1775, and retained till July 1777, when it was evacuated at the approach of general Burgoyne with the British army. This fort is never likely to be rebuilt; for the situation is very insecure, being commanded by the lofty hill called Mount Defiance. Mount Independence lies on the E. side of the lake, about two miles S.E. of the fort, between which two places there is a well-regulated ferry. The population of the township, in 1810, consisted of 985 persons.

TICOLO, a town on the W. coast of Sumatra, near the Line. E. long. 99° 21'.

TICOLO Island, a cluster of small islands near the W. coast of Sumatra. S. lat. 0° 2'. E. long. 99° 13'.

TICORANTE, a town of the island of Teneriffe.

TICOREA, in Botany, a name of Aublet's. — See Osphryllum.

TICOS, in Geography, a small island in the Pacific ocean, near the E. coast of the island of Luzon. N. lat. 14° 10'. E. long. 124'.

TICOUL HOUTIN, a town of Corea; 450 miles E.N.E. of Peking.

TICOUR, a town of France, in the department of the Mofelle; 6 miles N.W. of Morhange.

TICSAN, a town of Peru, in the jurisdiction of Cuenca.

TICUARIN, the name of the island of Goa, before the city was built.

TICUNAS, Poison, is an active poison prepared by the native Indians, on the borders of the river of the Amazons, in three or four degrees of south latitude, which, together with that of Lamas, Pesas, and Yameos, is extracted by fire from plants, called by the French lianes, and used in poisoning their arrows. See an account of the nature and effects of these poisons by M. Herrillant, in Phil. Trans. vol. xlvii. art. 12. and by M. Fontana, in Phil. Trans. vol. lxx. part i. Append. art. 2.; and also Fontana fur les Poisons, &c. Florence, 1806. See also Poison.

TIDE, or Tide, in Geography, a river of England, which passes by St. Germans, and runs into the Hanozae below Saltash.

TIDE, the name with time, or season. The word is originally Saxon, tid; which signifies the same. Tide, among Miners, denotes the space of twelve hours.

TIDE, Shrove. See Shrovet.

TIDE, Twelfth. See Twelfth.
TIDES.  

Tides, Whitson.  See Whitson-Tide.

Tides, two periodical motions of the waters of the sea; called also the flux and reflux, or the ebb and flow.

When the motion of the water is against the wind, it is called a windward-tide: when wind and tide go in the same direction, leeward-tide: when it runs very strong, it is called a tide-gate.

To tide it over or up into any place, is to go in with the tide, either ebb or flood, as long as that lasts; then to stay at anchor all the time of contrary tide; and thus to set in again with the return of the next tide.

It is said to flow-tide and half-tide, allowing fix hours to a tide, when the tide runs three hours in the ebb longer than it does by the shore; but, by longer, they do not mean its running more hours; but that, if it be high water a-shore at twelve, it will not be so in the ebbing till three. An hour and a half longer make tide and quarter-tide, three-fourths of an hour longer make tide and half-quarter tide, &c.

When the moon is in the first and third quarter, i.e. when she is new and full, the tides are high and swift, and are called spring-tides: when she is in the second and last quarter, the tides are lower and slower, and called neap-tides.

Tides, Phenomena of the.  The sea is observed to flow, for certain hours, from north towards south; in which motion, or flux, which lasts about six hours, the sea gradually swells: so that, entering the mouths of rivers, it drives back the river-waters toward their heads, or springs.

After a continual flux of six hours, the sea seems to rett for about a quarter of an hour; after which it begins to ebb or retire back again from north to south, for six hours more; in which time, the water sinking, the rivers return their natural course. Then, after a seeming pause of a quarter of an hour, the sea again begins to flow, as before; and thus alternately.

Thus does the sea ebb twice a day, and flow as often; but not in the same hours. The period of a flux and reflux is 12 hours 50½ minutes; so that the tides return later and later each day by 50½ minutes, which is the excess of a lunar day above a solar one, since 28½ lunar days are nearly equal to 29½ solar ones. So that the sea flows as often as the moon pales the meridian, both the arc above, and that below the horizon; and ebb as often as the pales the horizon, both the eastern and western point of it.

This farther agreement we observe between the moon and the sea, that the tides, though constant, are not equal; but are greatest, when the moon is in conjunction or opposition to the Sun, or at the time of new and full moon; and least, when in quadrature to it. This increase and diminution constitute the spring and neap tides: the augmentation becomes also still more observable when the moon is in its perigee, or nearest the earth. The lowest as well as the highest water is at the time of the spring-tides: the neap-tides neither rise so high nor fall so low.

Lastly, those tides are the greatest, which happen in the new and full moon, and the time of the equinoxes, while the moon is in its perigee. These tides are often still more increased by the equinoctial winds, which are sometimes so powerful as to produce a greater tide before or after the equinox than that which happens in the usual course, at the time of the equinox itself.

Add, that the same things are observed throughout most of the coasts of Europe; only that the tides are so much the less, and happen the later, as the coasts are the more northerly.

These phenomena of the tides are admirably accounted for, from the principle of gravitation. All we require to their solution is, that the earth and moon, and every particle of them, mutually gravitate towards each other: the reasonableness of which assumption, see under the article Gravity.

Indeed the sagacious Kepler, long ago, conjectured this to be the cause of the tides: "If," says he, "the earth ceased to attract its waters towards itself, all the water in the ocean would rise and flow into the moon: the sphere of the moon's attraction extends to our earth, and draws up the water." Thus thought Kepler, in his Introd. ad Theor. Mart. This surmise, for it was then no more, is now abundantly verified in the following theory, first amply deduced by Dr. Halley from the Newtonian principles.

However, we may observe with M. de la Lande (Astronomy, vol. iv. Paris, 1781.) that several of the ancients, and among others, Pliny, Ptolemy, and Macrobius, were acquainted with the influence of the sun and moon upon the tides. And Pliny says expressly, that the cause of the ebb and flow is in the sun, which attracts the waters of the ocean; and adds, that the waters rise in proportion to the proximity of the moon to the earth.

Tides, Theory of the.—It is obvious, that if the earth were entirely fluid, and quiescent, its particles, by their mutual gravity towards each other, would form themselves into the figure of an exact sphere.

Suppose, then, that some power acts on all the particles of this earth with an equal force, and in parallel directions, the whole mass will be moved by such a power, but its figure will suffer no alteration by it; because all the particles, being equally moved by this power in parallel lines, they will still keep the same situation with respect to each other, and still form a sphere, whose centre will have the same motion as each particle. Upon this supposition, if the motion of the earth round the common centre of gravity of the earth and moon were destroyed, and the earth were left to the influence of its gravitation toward the moon, the earth falling toward the moon would still retain its spheroidal figure; all the parts being equally carried on, and retaining therefore the same situation with respect to each other. But the effects of the moon's action, as well as the action itself, on different parts of the earth, are unequal, at all places within the angular distance of 79½ from the line passing through the attracting body, either in the nearer or in the remoter hemisphere: those parts, by the general law of gravity, being most attracted which are nearest the moon, and those being least attracted which are farthest from the moon; while the parts that are at a middle distance, are attracted by a mean degree of force; besides, all the parts are not acted on in parallel lines, but in lines directed towards the centre of the moon; and on these accounts the spheroidal figure of the earth must suffer some change from the moon's action.

Supposing the earth to fall towards the moon, and, abstracting from the mutual gravitation of its parts towards each other, and also from their cohesion; it will easily appear, that the parts nearest the moon would fall with the swiftest motion, being most attracted, and that they would leave the centre or greater bulk of the earth behind them in their fall, while the more remote parts would fall with the slowest motion, being least attracted than the rest, and be left a little behind the bulk of the earth, so as to be found at a greater distance from the centre of the earth than at the beginning of the motion. Whence it is manifest, that the earth would soon lose its spheroidal figure, and form itself into an oblong elliptic spheroid, whose longest diameter would point at the centre of the moon.
If the particles of the earth did not gravitate toward each other, but toward the moon only, the distances betwixt the parts of the earth that are supposed to be nearest the moon, and the central parts, would continually increase, because of their greater celerity in falling; and the distance betwixt the central parts, and the parts that are farthest from the moon, would increase continually at the same time; these being left behind by the central parts, which they would follow, but with a less velocity. Thus the figure of the earth would become more and more oblong, that diameter of it which pointed toward the moon continually increasing.

But there is another reason why the earth would soon assume an oblong spheroidal form, if its parts were allowed to fall freely by their gravity towards the moon's centre; for the lateral parts of the earth, or those which are at the distance of a quarter of a circle from the point which is directly below the moon, and the central parts depending with equal velocities toward the same point, viz. the centre of the moon, in approaching to it, would manifestly approach, at the same time, to each other; and their distance becoming less, the diameters of the earth passing through them would be diminished, so that the diameters of the earth that point toward the moon would increase, and those diameters of the earth that are perpendicular to the line joining the centres of the earth and moon, would decrease at the same time, and render the figure of the earth still more oblong for this reason.

Let us now allow the parts of the earth to gravitate towards its centre; and, as this gravitation far exceeds the action of the moon, and much more exceeds the differences of her actions on different parts of the earth, the effect resulting from the inequalities of these actions of the moon, will be only a small diminution of the gravity of those parts of the earth which it endeavoured in the former supposition to separate from its centre, and a small addition to the gravity of those parts which it endeavoured to bring nearer to its centre; that is, those parts of the earth which are nearest to the moon, and those which are farthest from her, will have their gravity toward the earth somewhat abated; whereas the lateral parts will have their gravity increased; so that if the earth be supposed fluid, the columns from the centre to the nearest, and from the farthest parts must rise, till, by their greater height, they be able to balance the other columns, whose gravity is either not so much diminished, or is increased by the inequalities of the action of the moon. And thus the figure of the earth must still be an oblong spheroid.

Let us now consider the earth, instead of falling toward the moon by its gravity, as projected in any direction, so as to move round the centre of gravity of the earth and moon; it is manifest, that the gravity of each particle toward the moon will endeavour to bring it as far from the tangent, in any small moment of time, as the earth were allowed to fall freely toward the moon; in the same manner as any projectile, at our earth, falls from the line of projection as far as it would fall by its gravity in the perpendicular in the same time. Consequentially the parts of the earth nearest to the moon will endeavour to fall farthest from the tangent, and those farthest from the moon will endeavour to fall least from the tangent, of all parts of the earth; and the earth will be the same as if the earth were free toward the moon; that is, the earth will still affect a spheroidal form, having its longest diameter directed toward the moon.

In order to understand this theory, it must be carefully considered, that it is not the action of the moon, but the inequalities in that action, that produce any variation from the spheroidal figure; and that if this action were the same in all the particles as in the central parts, and operating in the same direction, no such change would ensue.

For the farther illustration of the preceding observations, we must perceive that the waters at $Z$ (Plate 1, Geography, fig. 10.) on the side of the earth $ABCDEFGH$, next to the moon $M$, are more attracted than the central parts of the earth, $O$, by the moon, and the central parts are more attracted by her than the waters on the opposite side of the earth at $n$; and therefore the distance between the earth's centre and the waters on its surface, under and opposite to the moon, will be increased. For let $H_1, O$, and $D$ be three bodies, all equally attracted by the body $M$, and they will all move equally fast toward it, their mutual distances from each other continuing the same. If the attraction of $M$ is unequal, then that body which is most strongly attracted will move faster, and this will increase its distance from the other body. Consequentially, by the law of gravitation, $M$ will attract $H_1$ more strongly than it does $O$, by which the distance between $H_1$ and $O$ will be increased; and a spectator in $O$ will perceive $H_1$ rising higher toward $Z$. In like manner $O$, being more strongly attracted than $D$, will move farther toward $M$ than $D$ does; and therefore the distance between $O$ and $D$ will be increased; and a spectator in $O$, not perceiving his own motion, will see $D$ receding farther from him towards $n$; all effects and appearances being the same, whether $D$ recedes from $O$, or $O$ from $D$.

Suppose now there is a number of bodies, as $A$, $B$, $C$, $D$, $E$, $F$, $G$, $H$, placed round $O$, so as to form a flexible or fluid ring; then, as the whole is attracted toward $M$, the parts at $H$ and $D$ will have their distance from $O$ increased; whilst the parts at $B$ and $F$, being nearly at the same distance from $O$, will not recede from one another; but rather, by the oblique attraction of $M$, they will approach nearer to $O$. Hence the fluid ring will form itself into an ellipse $ZIBL n K F N Z$, whose longer axis $n O Z$ produced, will pass through $M$, and its shorter axis, $B O F$, will terminate in $B$ and $F$. Let the ring be filled with fluid particles, so as to form a sphere round $O$; then, as the whole moves toward $M$, the fluid sphere, being lengthened at $Z$ and $n$, will assume an oblong or oval form. If $M$ is the moon, $O$ the earth's centre, $ABCDEFGH$ the sea covering the earth's surface, it is evident that, whilst the earth by its gravity falls towards the moon, the water directly below her at $H$ will swell, and gradually rise toward her; and also the water at $D$ will recede from the centre, (or, fictionally speaking, the centre recedes from $D$,) and rise on the opposite side of the earth; whilst the water at $B$ and $F$ is deprefled, and falls below the former level. Hence, as the earth turns round its axis from the moon to the moon again in about 24½ hours, this oval of water must shift with it; and thus there will be two tides of flood and two of ebb in that time.

Some persons have found a difficulty in conceiving how, agreeably to the principles above stated, the earth can fall towards the moon by the power of gravity, when the moon is full, or in opposition to the sun; since the earth revolves about the sun, and must continually fall towards it; and if the earth is confluently falling towards the moon, they must at last come together. In order to obviate this difficulty, it has been suggested, that it is not the centre of the earth that describes the annual orbit round the sun, but the common centre of gravity of the earth and moon, the distance of which from the earth's centre, dividing 240,000 miles, the moon's distance from the earth, by 40, the excess of the earth's weight above that of the moon, is 6000 miles; and
TIDES.

that whilst the earth is moving round the sun, it also describes a circle round that centre of gravity, going as many times round it in one revolution about the sun as there are locations or courses of the moon round the fun in a year; and therefore the earth is constantly falling towards the moon from a tangent to the circle which it describes round the said common centre of gravity. Let \( M \) (fig. 11.) be the moon, \( T \) its orbit, and \( C \) the centre of gravity of the earth and moon; whilst the moon goes round her orbit, the centre of the earth describes the circle \( dqk \) round \( C \), to which circle \( guk \) is a tangent; and, therefore, when the moon has gone from \( M \) a little beyond \( W \), the earth has moved from \( q \) to \( e \), and in that time has fallen towards the moon, from the tangent at \( a \) to \( e \), and so on round the whole circle.

From the above reasoning it appears, that the parts of the earth directly under the moon, or that have the moon in their zenith, and also those in the nadir, or places diametrically opposite to each other, will have the flood, or highest water, at the same time. Moreover, those parts of the earth, where the moon appears in the horizon, or \( 90^\circ \) distant from the zenith and nadir, will have the ebb, or lowest waters.

It is evident that, by the motion of the earth on its axis, the most elevated part of the water is carried beyond the moon in the direction of the rotation. The water continues to rise after it has passed directly under the moon, though the immediate action of the moon there begins to decrease, and comes not to its greatest elevation till it has got half a quadrant farther. It continues also to descend after it has passed at \( 90^\circ \) distance from the point below the moon, though the force which the moon adds to its gravity begins to decrease there. For till the action of the moon adds to its gravity, and makes it descend till it has got half a quadrant farther; the greatest elevation, therefore, is not in the points which are in a line with the centres of the earth and moon, but about half a quadrant to the east of these points in the direction of the motion of rotation. Thus in open seas, where the water flows freely, the moon, \( M \), (fig. 10.) is generally past the north and fourth meridian, as at \( P \), when the high water is at \( Z \) and at \( J \); the reason of which is plain, because the moon acts with some force after it has passed the meridian, and thereby adds to the libration or waving motion, which the water acquired when the was in the meridian; and, therefore, the time of high water is not precisely at the time of her coming to the meridian, but some time after.

Besides, the tides answer not always to the same distance of the moon from the meridian at the same places; but are variously affected by the action of the sun, which brings them on sooner when the moon is in her first and third quarters, and keeps them back later when she is in her second and fourth; because, in the former case, the tide raised by the sun alone, would be earlier than the tide raised by the moon, and in the latter case later.

For the further illustration of the principle upon which lunar tides depend, we shall suppose, with Dr. Young, that the earth were wholly fluid, and the same part of its surface were always turned towards the moon; in which case, the pole of the spheroid being immediately under the moon, the lunar tide would remain stationary; the greatest elevation being at the points nearest to the moon and farthest from her, and the greatest depression in the circle equally distant from these points; the elevation, however, being twice as great as the depression, on account of the smaller surface to which it is confined. The actual height of this elevation would probably be about 40 inches, and the depression 20, making together a tide of five feet. If also the waters were capable of assuming instantly such a form as the equilibrium would require, the summit of a spheroid equally elevated would still be directed towards the moon, notwithstanding the earth's rotation. This may be called the primitive tide of the ocean; but on account of the perpetual change of place which is required for the accommodation of the surface to a similar position with respect to the moon, as the earth revolves, the form must be materially different from that of such a spheroid of equilibrium. The force employed in producing this accommodation, may be estimated by considering the actual surface of the sea as that of a wave moving on the spheroid of equilibrium, and producing in the water a sufficient velocity to preserve the actual form. We may deduce, says Dr. Young, from this mode of considering the subject, a theory of the tides which appears to be more simple and satisfactory than any which has yet been published; and by comparing the tides of narrower seas and lakes with the motions of pendulums suspended on vibrating centres, we may extend the theory to all possible cases.

If the centre of a pendulum be made to vibrate, the vibrations of the pendulum itself, when they have arrived at a state of permanence, will be performed in the same time with those of the centre; but the motion of the pendulum will be either in the same direction with that of the centre, or in a contrary direction, accordingly as the time of this forced vibration is longer or shorter than that of the natural vibration of the pendulum; and in the same manner it may be shown that the tides, either of an open ocean, or of a confined lake, may be either direct or inverted with respect to the primitive tide, which would be produced, if the waters always assumed the form of the spheroid of equilibrium, according to the depth of the ocean, and to the breadth as well as the depth of the lake. In the case of a direct tide, the time of the passage of the luminaries over the meridian must coincide with that of high water, and in the case of an inverted tide with that of low water.

In order that the lunar tides of an open ocean may be direct, or synchronous, its depth must be greater than 13 miles, and for the solar tides than 14. The less the depth exceeded these limits, the greater the tides would be, and in all cases they would be greater than the primitive tides. But in fact the height of the tides in the open ocean is always far short of that which would be produced in this manner; it is therefore improbable that the tides are ever direct in the open ocean, and that the depth of the sea is so great as 13 miles.

In order that the height of the inverted or remote lunar tides may be five feet, or equal to that of the primitive tides, the depth of the open sea must be 62 miles; and if the height is only two feet, which is perhaps not far from the truth, the depth must be 3\( \frac{1}{2} \) miles.

The tides of a lake or narrow sea differ materially from those of the open ocean, since the height of the water scarcely undergoes any variation in the middle of the lake; it must always be high water at the eastern extremity when it is low water at the western; and this must happen at the time when the places of high and low water, with respect to the primitive tides, are equally distant from the middle of the lake.

The tides may be direct in a lake 100 fathoms deep and less than 8\( \frac{1}{2} \) wide; but if it be much wider, they must be inverted. Supposing the depth a mile, they will be direct when the breadth is less than 25\( \frac{1}{2} \); but if a sea, like the Atlantic, were 50 or 60 degrees wide, it must be at least four miles deep, in order that the time of high water might coincide with that of the moon's rising.
TIDES.

free from all resistence; but where the tides are direct, they must be retarded by the effect of a resistence of any kind; and where they are inverted, they must be accelerated; a small resistence producing, in both cases, a considerable difference in the time of high water.

Where a considerable tide is observed in the middle of a limited portion of the sea, it must be derived from the effect of the elevation or depression of the ocean in its neighbourhood; and such derivative tides are probably combined in almost all cases with the oscillations belonging to each particular branch of the sea.

Lunar tides, the rise and progress of which are scientifically traced by Dr. Young, are subject, independently of the influence of the fun, to a variety of modifications, some of which we shall specify in the sequel of this article.

2. We have hitherto taken notice only of the action of the moon in producing tides; but it is manifest that, for the same reasons, the inequality of the fun's action on different parts of the earth would produce a like effect, and that this alone would cause a like variation from the exact spherical figure of a fluid earth. So that, in reality, there are two tides every natural day from the action of the sun, as there are in the lunar day from that of the moon, subject to the same laws; and the lunar tide, as we have observed, is somewhat changed by the action of the sun, and the change varies every day on account of the inequality between the natural and the lunar day. Indeed, the effect of the sun in producing tides, because of his immense distance, must be considerably less than that of the moon, though the gravity of the sun toward the earth be much greater, the solar tide being, as Dr. Young states it, only about two-fifths of the lunar.

For it is not the action of the sun or that of the moon, but the inequalities in the actions of each, which have any effect. The sun's distance is so great, that the diameter of the earth is as a point compared to it, and the difference between the action of the sun on the nearest and that on the farthest parts, becomes, on this account, vastly less than it would be if the sun were as near as the moon.

However, the immense bulk of the sun makes the effect still sensible, even at so great a distance; and, therefore, though the action of the moon has the greatest share in producing the tides, the action of the sun adds sensibly to it when they conpire together, as in the change and full of the moon, when they are nearly in the same line with the centre of the earth, and therefore unite their forces. Thus, in conjunction, or when the sun and moon are on the same side of the earth, they both conpire to raise the water in the zenith, and consequently in the nadir; and when they are in opposition, that is, when the earth is between them, whilst one makes high water in the zenith and nadir, the other does the same in the nadir and zenith. Consequently, in the syzygies, or at new and full moon, the tides are the greatest, and are what we call the spring-tides. Moreover, the action of the sun diminishes the effect of the moon's action in the first and last quarters, because the one raises the water in that case where the other depresses it; and therefore, in the quadratures the tides are the least, and are called neap-tides.

As the lunar tide is much larger than the solar tide, the former must always determine the time of high and low water, which, in the spring and neap-tides, remains unaltered by the effect of the sun; so that in the neap-tides the actual time of low water is that of the solar high water; but at the intermediate times, the lunar high water is more or less accelerated or retarded. The progress of this alteration may easily be traced by means of a simple construction. If we make a triangle, of which two of the sides are two feet and five feet in length, the external angle which they form being equal to twice the distance of the luminaries, the third side will show precisely the magnitude of the compound tide, and the halves of the two angles opposite to the first two sides the acceleration, or retardation, of the times of high water belonging to the separate tides respectively. Hence it appears that the greatest deviation of the joint tide from the lunar tide amounts to $11^\circ 48'$ in longitude, and the time corresponding to 47 minutes, supposing the proportion of the forces to remain always the same; but in fact the forces increase in proportion as the cubes of the distances of their respective luminaries diminish, as well as from other causes; and in order to determine their joint effects, the lengths of the sides of the triangle must be varied accordingly. In some ports, from a combination of circumstances in the channel, by which the tides reach them, or in the seas, in which they originate, the influence of the sun and moon may acquire a proportion somewhat different from that which naturally belongs to them; thus at Breth, the influence of the moon appears to be three times as great as that of the sun; when it is usually only twice as great.

Sir Isaac Newton has calculated the effects of the sun and moon respectively upon the tides from their attractive powers. The augmentation of the gravity of the lateral parts of the earth, produced by the action of the sun, is a similar effect to an augmentation, estimated by him on another occasion, that is made to the gravity of the moon toward the earth by the same action; and when the moon is in the quarters; only the addition made to the gravity of the lateral parts is about $66^\circ$ times less, because their distance from the earth's centre is so many times less than the distance of the moon from it. The gravity of these parts of the earth that are directly beneath the sun, and of those opposite to it, is diminished by a double quantity of what is added to the lateral parts; and as the diminution of gravity of the one, and augmentation of gravity of the other, confpire together in raising the water under the sun, and the parts opposite to it, above its height in the lateral parts; the whole force that produces this effect is to be considered as triple of what is added to the gravity of the lateral parts; and is hence found to be to the gravity of the particles as $1$ to $128085206$, and to the centrifugal force at the equator as $1$ to $44527$. The elevation of the waters by this force is considered by Newton as an effect similar to the elevation of the equatorial parts above the polar parts of the earth, arising from the centrifugal force at the equator; and, being $44527$ times less, is found to be $1$ foot and $11\frac{3}{4}$ inches, Paris measure. This is the elevation arising from the action of the sun upon the water.

Mr. Maclaurin makes this elevation to be $1$ foot $10\frac{2}{3}$ inches, of the same measure, which differs from the above estimate by the $\frac{1}{4}$ part of an inch; and the greatest elevation, when the sun is in the equinoctial, $1$ foot $11\frac{3}{4}$ inches.

In order to find the force of the moon upon the water, Newton compares the spring-tides, at the mouth of the river Avon, below Bristol, with the neap-tides there, and finds their proportion to be that of $9$ to $5$; whence, after several necessary corrections, he concludes, that the force of the moon is to that of the sun, in raising the waters of the ocean, as $4\cdot 4815$ to $1$; so that the force of the moon is, of itself, to produce an elevation of $8$ feet and $7\frac{3}{4}$ inches, and the sun and moon together may produce an elevation of about $10\frac{3}{4}$ feet, in their mean distances from the earth, and an elevation of about $12$ feet, when the moon
TIDES.

The height to which the water rises and falls, upon coasts of the open and deep ocean, is agreeable enough to this computation.

The greatest heat is not on the solstitial day, when the immediate action of the sun is greatest, but some time after.

Thus would for some time continue in an agitation like to that in which it is at present. The waves of the sea, that continue after a storm ceases, and every motion almost of a fluid, may illustrate this.

The refraction of fluids, in general, says Dr. Young, is as the square of the velocity, consequently it must be much greater for the lunar than for the solar tide, in proportion to the magnitude of the force; and the acceleration of the lunar tide produced by this cause must be greater than that of the solar; hence it may happen, that when the lunar tide occurs two or three hours after the transit of the moon, the solar tide may be three or four hours after that of the sun, so as to be about an hour later, at the times of conjunction and opposition, and the tides will be highest when the moon passes the meridian about an hour after the sun; while at the precise time of the new and full moon, the lunar tide will be retarded about a quarter of an hour by the effect of the solar tide.

The different distances of the moon from the earth produce a sensible variation in the tides. When the moon approaches the earth, her action on every part increases, and the differences of that action on which the tides depend, increase. For her action increases as the squares of the distances decrease; and though the differences of the distances themselves be equal, yet there is a greater disproportion between the squares of les than the squares of greater quantities; e. g. 3 exceeds 2, as much as 2 exceeds 1; but the square of 2 is quadruple of the square of 1, while the square of 3 (viz. 9) is little more than double the square of 2 (viz. 4).

Thus it appears, that by the moon's approach, her action on the nearest parts increases more quickly than her action on the remote parts; and the tides, therefore, increase in a higher proportion as the distances of the moon decrease.

Sir Isaac Newton shews, that the tides increase in proportion as the cubes of the distances decrease, so that the moon, one half her present distance, would produce a tide eight times greater.

The moon describes an ellipse about the earth, and in her nearest distance produces a tide sensibly greater than at her greatest distance from the earth; and hence it is, that two great spring-tides never succeed each other immediately; for if the moon be at her nearest distance from the earth at the change, the must be at her greatest distance at the full, having, in the intervening time, finished half a revolution; and, therefore, the spring-tide then will be much less than the tide at the change was: and for the same reason, if a great spring-tide happens at the time of full moon, the tide at the ensuing change will be less.

The spring-tides are greatest about the time of the equinoxes, i. e. about the latter end of March and September, and about the time of the solstices, i. e. toward the end of June and December; and the neap-tides are least at the equinoxes and greatest at the solstices; so that the difference between the spring and the neap-tides is much less considerable at the solstitial than at the equinoctial seasons. In order to illustrate and evince the truth of this observation, it is manifest, that if either the sun or moon were in the pole, they could have no effect on the tides, for their action would raise all the water at the equator to the same height, and any place of the earth, in describing its parallel to the equator, would not meet, in its course, with any part of the water more elevated than another, so that there could be no tide in any place.

The effect of the sun or moon is greatest when in the equinoctial; for then the axis of the spheroidal figure, arising from their action, moves in the greatest circle, and the water is put into the greatest agitation; and hence it is that the spring-tides produced, when the sun and moon are both in the equinoctial, are the greatest of any, and the neap-tides are the least of any, about that time.

But the tides produced when the sun is in either of the tropics, and the moon in either of her quarters, are greater than those produced when the sun is in the equinoctial, and the moon in her quarters, because, in the first case, the moon is in the equinoctial, and in the latter case, the moon is in one of the tropics; and the tide depends more on the action of the moon than of the sun, and is, therefore, greatest when the moon's action is greatest.

However, it is necessary to observe, that, because the sun is nearer the earth in winter than in summer, i. e. in February and October than in March and September, the greatest spring-tides are after the autumnal, and before the vernal equinox.

Since the greatest of the two tides happening in diurnal revolution of the moon, or lunar day, i. e. about 24h 50m, is that in which the moon is nearest the zenith, or nadir; for this reason, while the sun is in the northern signs, the greater of the two diurnal tides in our climates, is that arising from the moon above the horizon: when the sun is in the southern signs, the greater is that arising from the moon below the horizon.

In proof of this observation, let it be considered, that when the moon declines from the equator toward either pole, one of the greatest elevations of the water follows the moon, and describes nearly the parallel on the earth's surface which is under that which the moon, on account of the diurnal motion, seems to describe; and the opposite greatest elevation, being antipodal to that, must describe a parallel as far on the other side of the equator; so that while the one moves on the north side of the equator, the other moves on the south side of it, at the same distance.

Now the greatest elevation which moves on the same side of the equator, with any place, will come nearer to it than the opposite elevation, which moves in a parallel on the other side of the equator; and, therefore, if a place is on the same
side of the equator with the moon, the day-tide, or that which is produced while the moon is above the horizon of the place, will exceed the night-tide, or that which is produced while the moon is under the horizon of the place. It is the contrary if the moon is on one side, and the place on the other side of the equator; for then the elevation which is opposite to the moon, moves on the same side of the equator with the place, and, therefore, will come nearer to it than the other elevation. The difference will be greatest when the sun and moon both describe the tropics; because the two elevations in that case describe the opposite tropics, which are the farthest from each other of any two parallel circles they can describe. Thus it is found, by observation, that the evening tides in the summer exceed the morning tides, and the morning tides in winter exceed the evening tides. The difference is found at Bristol to amount to fifteen inches, and at Plymouth to one foot. It would be still greater, but that a fluid always retains an impressed motion for some time; so that the preceding tides affect always those that follow them. Upon the whole, while the moon has north declination, the greatest tides in the northern hemisphere are when she is above the horizon, and the reverse while her declination is south.

To illustrate this matter by figures; let $NESQ$ (fig. 12, 13, 14.) be the earth, $NCS$ its axis, $EQ$ the equator, $T\theta$ the tropic of Cancer, $t\varphi$ the tropic of Capricorn, $ab$ the arctic circle, $cd$ the antarctic, $N$ the north pole, $S$ the south pole, $M$ the moon, $F$ and $G$ the two eminences of water, whose lower parts are at $a$ and $d$ (fig. 12), at $N$ and $S$ (fig. 13.), and at $b$ and $e$ (fig. 14.), always $90^\circ$ from the highest.

Now, when the moon is in her greatest north declination at $M$ (fig. 12.), the highest elevation, $G$, under her is on the tropic of Cancer, $T\theta$, and the opposite elevation, $F$, on the tropic of Capricorn, $t\varphi$; and these two elevations describe the tides by the earth's diurnal rotation. All places in the northern hemisphere, $ENQ$, have the highest tides when they come into the position $b\equiv Q$, under the moon; and the lowest tides when the earth's diurnal rotation carries them into the position $a\equiv F$, on the side opposite to the moon: the reverse happens at the same time in the southern hemisphere $ESQ$, as is evident to sight. The axis of the tides $ac\equiv d$ has now its poles $a$ and $d$ (being always $90^\circ$ from the highest elevations) in the arctic and antarctic circles; and, therefore, it is plain, that at these circles there is but one tide of flood, and one of ebb, in the lunar day. For when the point $a$ revolves half round to $b$ in twelve lunar hours, it has a tide of flood; but when it comes to the same point $a$ again in twelve hours more, it has the lowest ebb. In seven days afterward, the moon $M$ (fig. 13.) comes to the equinoctial circle, and is over the equator $E\equiv Q$, when both elevations describe the equator; and in both hemispheres, at equal distances from the equator, the tides are equally high in both parts of the lunar day. All the phenomena being reversed, when the moon has south declination, to what they were when her declination was north, require no farther description, fig. 14.

From what has been said it appears, that as the tides are governed by the moon, they must turn on the axis of the moon's orbit, which is inclined $23\frac{1}{2}$ degrees to the earth's axis at a mean rate; and, therefore, the poles of the tides must be so many degrees from the poles of the earth, or in opposite points of the polar circles, going round these circles in every lunar day. It is true that, according to fig. 14., when the moon is vertical to the equator $EQ$, the poles of the tides seem to fall in with the poles of the world $N$ and $S$; but when we consider that $FGH$ is under the moon's orbit, it will appear that when the moon is over $H$, in the tropic of Capricorn, the north pole of the tides (which can be no more than $90^\circ$ from under the moon) must be at $C$ in the arctic circle, not at $P$, the north pole of the earth; and as the moon ascends from $H$ to $G$ in her orbit, the north pole of the tides must shift from $c$ to $a$ in the arctic circle, and the south pole as much in the antarctic.

It is not to be doubted, but that the earth's quick rotation brings the poles of the tides nearer to the poles of the world than they would be if the earth were at rest, and the moon revolved about it only once a month; for, otherwise, the tides would be more unequal in their heights, and times of their returns, than we find they are. But how near the earth's rotation may bring the poles of its axis and those of the tides together, or how far the preceding tides may affect those which follow, is to make them keep up nearly to the same heights, and times of ebbing and flowing, is a problem more fit to be solved by observation than by theory.

Those who have opportunity to make observations, and choose to satisfy themselves whether the tides are really affected in the above manner by the different positions of the moon, especially as to the unequal times of their returns, may take this general rule for knowing when they ought to be so affected. When the earth's axis inclines to the moon, the northern tides, if not retarded in their passage through shoals and channels, nor affected by the winds, ought to be greatest when the moon is above the horizon, least when she is below it; and quite the reverse when the earth's axis declines from her; but in both cases at equal intervals of time. When the earth's axis inclines sideways to the moon, both tides are equally high, but they happen at unequal intervals of time. In every vibration the earth's axis inclines once to the moon, once from her, and twice sideways to her, as it does to the sun every year; because the moon goes round the ecliptic every month, and the sun once in a year. In summer, the earth's axis inclines towards the moon when new; and, therefore, the dry-tides in the north ought to be highest, and night-tides lowest about the change; at the full the reverse. At the quarters they ought to be equally high, but unequal in their returns; because the earth's axis then inclines sidewise to the moon. In winter the phenomena are the same at full moon as in summer at new. In autumn the earth's axis inclines sidewise to the moon when new and full; therefore the tides ought to be equally high and unequal in their returns at these times. At the first quarter the tides of flood should be least when the moon is above the horizon, greatest when she is below it, and the reverse at her third quarter. In spring, the phenomena of the first quarter answer to those of the third quarter in autumn, and vice versa. The nearer any time is to either of these seasons, the more the tides partake of the phenomena of these seasons; and in the middle between any two of them, the tides are at a mean state between those of both.

8. Such would the tides regularly be, if the earth were all over covered with sea very deep, so that the water might follow the influence of the sun and moon; but, by reason of the shallowns of some places, and the narrowness of the straits in others, by which the tides are propagated, there arises a great diversity in the effect, not to be accounted for, without an exact knowledge of all the circumstances of the places; such as the position of the land, and the breadth and depth of the channels, direction of the winds, &c. For a very slow and imperceptible motion of the whole body of water,
TIDES.

The tide entering the Atlantic appears, says Dr. Young, to advance northwards at the rate of about 500 miles an hour, corresponding to a depth of about three miles, so as to reach Sierra Leone at the eighth hour after the moon's southing; this part of Africa being not very remote from the meridian of the middle of the South Atlantic ocean, and having little share in the primitive tides of that ocean. The southern tide seems to pass by Cape Blanco and Cape Bojador, to arrive at Gibraltar at the thirteenth hour, and to unite its effects with those of other tides at various parts of the coasts of Europe.

We may therefore consider the Atlantic as a detached sea, about 3500 miles broad, and three miles deep; and a sea of these dimensions is susceptible of tides considerably larger than those of the ocean, but how much larger we cannot determine without more accurate measures. These tides would happen on the European coasts, if there were no resistance, a little less than five hours after the moon's southing, and on the coast of America, a little more than seven hours after; but the resistance opposed to the motion of the tide may easily accelerate the time of high-water in both cases about two hours, so that it may be a little before the third hour on the western coasts of Europe and of Africa, and before the fifth on the most exposed parts of the eastern coast of America; and in the whole of the Atlantic, this tide may be combined more or less both with the general southern tide, and with the partial effects of local elevations or depressions of the bottom of the sea, which may cause irregularities of various kinds. The southern tide is, however, probably less considerable than has sometimes been supposed, for, in the latitudes in which it must originate, the extent of the elevation can only be half as great as at the equator; and the islands of Kerguelen's land and South Georgia, in the latitudes of about 50° and 55°, have their tides delayed till the tenth and eleventh hours, apparently because they received them principally from distant parts of the ocean, which are nearer to the equator.

On the western coasts of Europe, from Ireland to Cadiz; on those of Africa, from Cape Coast to the Cape of Good Hope; and on the coast of America, from California to the frontiers of Magellan, as well as in the neighbouring islands; it is usually high-water at some time between two and four hours after the moon's southing; on the eastern coast of South America, between four and six; on that of North America, between seven and eleven; and on the eastern coasts of Asia and New Holland, between four and eight. The Society Islands are perhaps too near the middle of the Pacific ocean to partake of the effects of its primitive tide, and their tide, being secondary, is probably for this reason a few hours later. At the Almirantaz, near the eastern coast of Africa, the tide is at the fifth hour; but there seem to be some irregularities in the tides of the neighbouring islands.

The progress of a tide may be very distinctly traced from its source in the ocean into the narrow and shallow branches of the sea which constitute our channels. Thus the tide is an hour or two later at the Seilly Islands than in the Atlantic, at Plymouth three, at Cork, Bristol, and Weymouth four, at Caen and Havre five, at Dublin and Bightelmestone seven, at Boulogne and Liverpool eight, at Dover near nine, at the Nore eleven, and at London-bridge twelve and a half. Another portion appears to proceed round Ireland and Scotland into the North sea; it arrives from the Atlantic at Londonderry in about three hours, at the Orkneys in fix, at Aberdeen in eleven, at Leith in fourteen, at Leoboffe in twenty, and at the Nore in about twenty-four, so as to meet there the subsequent tide coming from the south. From the time occupied by the tide in travelling from the mouth of the English Channel

water, where it is (for example) two miles deep, will suffice to raise its surface ten or twelve feet in a tide's time; whereas, if the same quantity of water were to be conveyed through a channel forty fathoms deep, it would require a very great stream to effect it in fo large inlets as are the channel of England and the German ocean; whence the tide is found to flow strongest in those places where the sea grows narrower, the same quantity of water being, in that case, to pass through a smaller passage.

This is most evident in the straits between Portland and Cape la Hogue in Normandy, where the tide runs like a gulf; and would be yet more between Dover and Calais, if the tide, coming round the island, did not check it.

This force, being once impressed upon the water, continues to carry it above the level of the ordinary height of the ocean, particularly where the water meets a direct obstacle, as it does in St. Malo's; and where it enters into a long channel, which running far into the land, grows very straight at its extremity, as it does into the Severn sea at Chepstow, where the tide rises to 40 feet, and Bridgol, where its height is 50 feet. At Brest, the height of the tides is about 20 feet; at St. Malo's, 50; at Annapolis, in the bay of Fundy, as much sometimes as 100 feet. In the Mediterranean, the tides are generally inconsiderable; nevertheless, they are perceptible: at Naples, they sometimes rise to a foot; at Venice, to more than two feet; and in the Euphrates, for a certain number of days in each lunation, they are very distinctly observable from the current which they occasion. In the West Indies, and also in the gulf of Mexico, the tides are less observable than in the neighbouring seas, perhaps on account of some combinations derived from the variations of the depth of the rivers, and from the different channels by which they are propagated.

The shallows of the sea, and the intercurrent continents, are the reasons that in the open ocean the tides rise but to very small heights in proportion to what they do in wide-mouthed rivers, opening in the direction of the stream of the tide; and that high-water is not at the time of the moon's appulse to the meridian, but always some hours after it, as it is observed upon all the western coasts of Europe and Africa, from Ireland to the Cape of Good Hope; in all which a south-west moon makes high water; and the same is reported to hold in the west of America.

So that tides happen at different places at all distances of the moon from the meridian, and consequently at all hours of the lunar day.

It is to be considered that, in order to allow the tides their full motion, the ocean, in which they are produced, ought to be extended from east to west 90° at least. Because the places, where the moon rises, molt, and most depresses the water, are at that distance from each other. Hence it appears, that it is only in the great oceans that such tides can be produced, and why in the larger Pacific ocean they exceed those in the Atlantic ocean. Hence also it is obvious, why the tides are not so great in the torrid zone, between Africa and America, where the ocean is narrower, as in the temperate zones on either side; and we may hence also understand, why the tides are so small in islands that are very far distant from the shores. It is manifest, that, in the Atlantic ocean, the water cannot rise on one shore but by defecding on the other; so that, at the intermediate distant islands, it must continue at a mean height between its elevation on one and on the other shore. But when tides pass over shoals, and through straits into bays of the sea, their motion becomes more various, and their height depends on many circumstances.
TIDES.

Channel to Boulogne, at the rate of about fifty miles an hour, we may calculate that the mean depth of the channel is about twenty-eight fathoms, independently of the magnitude of the refractions of various kinds to be overcome, which require us to suppose the depth from thirty to forty fathoms. In the great river of Amazons, the effects of the tides are still sensible at the estuaries of Pausias, 500 miles from the sea, after an interval of several days spent in their passage up: for the slower progressive motion of the water, no more impedes the progress of a wave against the stream, than the velocity of the wind prevents the transmission of sound in a contrary direction.

Dr. Young observes, that fearfully a single influence occurs that favours the supposition of high water in the open sea being within an hour of the moon's rising, as it must if the depth were very great; so that neither the height of the tide, nor the time of high-water, will allow us to suppose the sea at any place quite so deep as four miles.

The tide that is produced on the western coasts of Europe, in the Atlantic, corresponds to the situation of the moon already described. Thus it is high-water on the coasts of Spain, Portugal, and the west of Ireland, about the third hour after the moon has passed the meridian; from thence it flows into the adjacent channels, as it finds the ebbier passage. One current from it, e.g., runs up by the south of England, another comes in by the north of Scotland; they take a considerable time to move all this way, and it is high-water sooner in the places to which they first come, and it begins to fall at those places, while they are still going on to others that are farther in their course. As they return, they are not able to raise the tide, because the water runs faster off than it returns, till, by a new tide propagated from the open ocean, the return of the current is stopped, and the water begins to rise again. The tide, propagated by the moon in the German Ocean, when the sun is three hours past the meridian, takes about twelve hours to come from thence to London bridge; so that when it is high-water there, a new tide is already come to its height in the ocean; and, in some intermediate place, it must be low water at the same time.

Consequently, when the moon has north declination, and we should expect the tide at London to be the greatest when the moon is above the horizon, we find it is less; and the contrary when the sun has south declination.

At several places it is high-water three hours before the moon comes to the meridian; but that tide which the moon pulls, as it were, before her, is only the tide opposite to that which was raised by her when she was nine hours past the opposite meridian.

It would be endless to recount all the particular solutions which are easy corollaries from this doctrine: as why the lakes and seas, such as the Caspian sea and the Mediterranean sea, the Black sea and Baltic, have either small or no very sensible tides: for lakes are generally so small, that when the moon is vertical the affects every part of them alike, and therefore no part of the water can be raised higher than another; and having no communication with the ocean, it can neither increase nor diminish their water, in order to rise and fall; and seas that communicate by such narrow inlets, and are of so immense an extent, cannot, in a few hours time, receive and empty water enough to raise or sink their surface any thing sensibly.

To demonstrate the excellence of this doctrine, the example of the tides in the port of Bathy, in the kingdom of Tonquin, in the East Indies, 20° 50' N. lat. which are so extraordinary and different from all others we have yet heard of, may suffice.

The day in which the moon passes the equinoctial, the water flagonates there without any motion; as the moon removes from the equinoctial, the water begins to rise and fall once a day; and it is high-water at the setting of the moon, and low-water at her rising. This daily tide increases for about seven or eight days, and then decreases for as many days by the same degree, till this motion ceases, when the moon has returned to the equinoctial. When she has passed the equinoctial, and declines toward the south pole, the water rises and falls again as before; but it is high-water now at the rising, and low-water at the setting of the moon.

Sir Isaac Newton, in order to account for this extraordinary tide, considers that there are two inlets to this port of Bathy, one from the Chinese ocean, betwixt the continent and the Mainillas, the other from the Indian Ocean, betwixt the continent and Borneo. This leads him to propose, as a solution of this phenomenon, that a tide may arrive at Bathy, through one of these inlets, at the third hour of the moon, and another through the other inlet six hours after, at the ninth hour of the moon. For, while these tides are equal, the one flowing in as the other ebbs out, the water must flagonate; now they are equal when the moon is in the equinoctial; but as soon as the moon begins to decline on the same side of the equator with Bathia, it has been found that the diurnal tide must exceed the nocturnal, so that two greater and two lesser tides must arrive at Bathia by turns.

The difference of these will produce an agitation of the water, which will rise to its greatest height at the mean time betwixt the two greater tides, and fall lowest at a mean time betwixt the two lesser tides; so that it will be high-water about the sixth hour at the setting of the moon, and low-water at her rising. When the moon has got to the other side of the equinoctial, the nocturnal tide will exceed the diurnal; and, therefore, the high-water will be at the rising, and low-water at the setting of the moon.

The same principles will serve to account for other extraordinary tides, which, we are told, are observed in places whose situation exposeth them to such irregularities: and, as some think, for particular currents and winds. See Currents and Winds.

When the time of high-water at any place is, in general, mentioned, it is to be understood on the days of the fitness of the moon, or days of new and full moon; when the sun and moon pass the meridian of the place at the same time. Among pilots, it is customary to reckon the time of high, or high-water, by the point of the compass the moon bears on, allowing a quarter of an hour for each point, at that time: thus, on the full and change days, in places where it is flood at noon, the tide is said to flow N. and S., or at 12 o'clock; in other places, on the same days, where the moon bears S. or W. of the meridian, when it is high-water, the tide is said to flow on such point; thus, if the moon bears S. or W. of the meridian, that is, at 9 o'clock; if it bears S. or W. it flows S. or W. and S. or W. or at three hours after the meridian; and, in like manner for other points of the moon's bearing.

The times of high-water in any place fall about the same hours after a period of about fifteen days, or between one spring-tide and another; but during that period, the times of high-water fall each day later by about forty-eight minutes.

From the observations of many persons there have been collected the times when it is high-water on the days of the new and full moon, on most of the sea-coasts of Europe, and many other places; which are usually put in a table against the names of the places; a specimen of which is subjoined.

A Table
A Table of the Times of High-Water on the Days of the New and Full Moon, on most of the Sea-Coasts of Europe.

</table>

The following times serve for coasts of considerable extent, and nearly for the places on those coasts; viz. Finmark, or N.N.W. coast of Lapland, 1° 30'; Jutland iles, Øσ Øm; Friesland coast, 7° 30'; Zealand coast, 1° 30'; Flanders coast, øσ øm; Picardy and Normandy coasts, 1° 30'; Biscay, Gallician, and Portugal coasts, 2° 30'; Irish coast, 3° 30'; Irish south coast, 5° 15'; Africa west coast, 3° 30'; America east coast, 4° 30'.

The use of the preceding table is to find the time of high-water at any of the places contained in it: for this purpose, find the time of the moon's fourting on a given day (see Moon); and then add the time which the moon has passed the meridian on the full and change days, to make high-water at that place; and the sum gives the time of high-water on the given day.

Tide-Dial, the name of an instrument contrived by Mr. Ferguson, for exhibiting and determining the state of the tides. It is represented in Plate IV. Dialling, fig. 36., and the external parts of it consist of 1. An eight-sided box, on the top of which, at the corners, are shown the phases of the moon at the octants, quarters, and full. Within these is a circle of 20° equal parts, which are the days of the moon's age reckoned from the full to new moon, round to the full again. Within this circle is one of twenty-four hours, divided into their halves and quarters. 2. A moving elliptical plate, painted blue, to shew the rising of the tides under and opposite to the moon, with the words high-water, tide-falling, low-water, tide-rising, marked upon it. To one end of this plate is fixed the moon's position by the wire W, which goes along with it. 3. Above this elliptical plate is a round one, with the points of the compass upon it, and also the names of above two hundred places in the large machine (but only thirty-two in the figure, to avoid confusion) set over those points on which the moon bears when she raises the tides to the greatest heights at these places, twice in every lunar day; and to the north and south points of this plate are fixed two indices I and K, which shew the times of high-water, in the hour-circle, at all these places. 4. Below the elliptical plate are four small plates, two of which project from below at the ends at new and full moon; and by lengthening the ellipse, the four plates are adjustable, to shew the spring-tides: the other two of these small plates appear at low-water when the moon is in her quadratures, or at the sides of the elliptic plate, to shew the neap-tides. When any one of these small plates appear, the other two are hid; and when the moon is in her octants, they all disappear. Within the box are a few wheels for performing these motions by the handle H. Turn the handle till the moon, M, comes to any given day of her age in the circle of 20° equal parts, and the moon's wire W will intercept the time of her coming to the meridian on that day, in the hour-circle: the XII under the fun being mid-day, and the opposite XII mid-night: then looking for the name of any given place on the round plate (which makes 29° rotations, whilst the moon M makes only one revolution from the fun to the fun again) turn the handle till that place comes to the word high-water under the moon, and the index which falls among the forenoon hours will shew the time of high-water at that place in the forenoon of the given day; then turn the plate half round, till the same place comes to the opposite high-water mark, and the index will shew the time of high-water in the afternoon at that place. And thus, as all the different places come successively under and opposite to the moon, the indices shew the times of high-water at them in both parts of the day; and when the same places come to the low-water marks, the indices shew the times of low-water. For about three days before and after the times of new and full moon, the two small plates come out a little way from below the high-water marks on the elliptical plate, to shew that the tides rise still higher about these times: about the quarters, the other two plates come out a little from under the low-water
TID

tide-mark toward the fun, and on the oppofite fide, flour-
ishing that the tides of flood rise not fo high, nor do the
tides of ebb fall fo low, as at other times. For the defcrip-
tion of the inferior work of this machine, and the method of
conflruing it, fee Ferguson's Altron. p. 297.

TIDE-Gate. See Gate.

TIDE-Gates are the lower gates of a lock open to a tide-
way: there are also placed at the mouths of drains.

TIDE-Mill, in Rural Economy and Agriculture, an ufeful
form of mill, the moving power of which is formed by
running a dam across an inlet where tide-water comes in, so
as to leave a narrow passage open for placing it in on one
fide. It also furnifhes a mill for raffing and clearing lands
from tide-water in fen fituations, and where injury is
done by the overflcwing of the tides. See WATERING
of Land.

Tide-mills may mofi be formed without producing any
obftuction or hindrance to agriculture.

TIDE-Waiters, or Tide-Men, certain officers belonging
to the cullom-house, appointed to watch or attend on
fhips coming from abroad, to fee that nothing be landed till
the culloms be paid.

They are thus called, because they go aboard the ships at
their arrival in the mouth of the Thames, and come up with
the tide.

TIDENSDF, in Geography, a town of Pruffia, in
the province of Ermeland; 4 miles S. of Frauenburg.

TIDER, or Ner, a small ifland in the Atlantic, near the
coafl of Africa. N. lat. 10° 30'.

TIDESWELL, a small market-town in the hundred of
High Peak, and county of Derby, England; is fited in
a valley among bleak hills, 32 miles N.N.W. from the
county-town, and 160 miles N.W. by N. from London.
The town is reported to have received its name from an
ebbing and flowing well, now hardly remembered, as it has
long ceased to flow. The church, which was erected in
the fourteenth century, is a handfome edifice of the con-
ventual form, with a neat tower at the west end, terminated
by eight pinnacles; thofe at the angles rising from octa-
gonal bases, and being much higher than the intermediate
ones. In the chancel is a small flone commemorative of
John Fofjambe, who died in 1358, and is said to have con-
tributed much towards the building of the church. A
raifed tomb perpetuates the name of Sampfon Mevrill, who
died in 1462, and who, in the course of two years, was en-
geaged in eleven battles in France. Among other monu-
ments of ancient date, is one to the memory of a native of
this town, Robert Purfoglove, prior of Gifburn priory, who
obtained a penfion from Henry VIII. for his obfequious
compliance with that monarch's wishes, in not only fur-
rendering his own house, but alfo acting as a commif-
sioner to procure the surrender of others. In queen Mary's
reign he was appointed archdeacon of Nottingham, and
fulfragant bishop of Hull; but on the acceffion of Eliza-
beth, he was deprived of all his spiritualities, and retired to
Tidewell, where, having founded a grammar-school, and an
hospita1 for twelve poor people, he died in 1579. By the
population return of the year 1811, the inhabitants of this
parifh are flated to be 1219, who are chiefly supported by
the mining buinfefs; the number of houfes, which are mofi
fattered on the oppofite banks of a rivulet, was eimated at
283. A weekly market is held on Wednefdays; and
here are three annual fairs.

In the vicinity of Tidewell is the fequeftered retreat of
Monfal Dale, peculiarly eminent for picturesque beauty.
Near the head of the Dale, the rocks jut out on the south
side, like the immense towers of a strong fortrefs. Lower
down, the crags ftench into verdure, the dale expands, and
the eye dwells enraptured on the rich profpect that preffents
itfelf. The back-ground is formed by a steep precipice,
variegated by short herbage and briifwood, with occa-
flonally a ftrating rock breaking its continuity of furface.

On the hill-tum of an eminence called the Great Fin, was
about a large barrow, about 160 feet in circumference, chiefly com-
pofed of broken mafs of limeftone, to obtain which the
barrow was destroyed about the year 1795. Within this
firmus various fkeletons were discovered, two of them of
gigantic fize, with feveral urns, and other ancient memo-
rials; among which were two arrow-heads of flint, whence
the barrow is fuppofed to have been of very remote anti-
quity; for, as the learned author of "Nenia Britannica"
obferves, "flint arrow-heads are evidences of a people not
in the ufe of malleable metal; and it therefore implies,
wherever thofe arms are found in barrows, they are inco-
tellibly the relics of a primitive barbarous people, and pre-
ceding the era of thofe barrows in which bras or iron arms
are found." It is worthy of note, that, excepting on the
rode next the precipice, the fummit of the Great Fin is
furronded by a double ditch, with a vallum to each: the
diftance between the banks is 160 yards.

Near the hamlet of Wormhill, in this parish, is a romantic
and deep glen or dale, where the river Wye flows beneath
a tremendous mafs of rock, called Chee-Tor. This mafs of
freadfone rifes about 300 feet above the level of the river,
and confiftutes a moft imposing and fingular feature. At a
small hamlet called Tunstall, in the liberty of Wormhill,
was born James Brindley, juftly famed for his fuccefsful
efforts in planning and executing canals. See BRINDLEY.

— Beauties of England and Wales, vol. iii. Derbyshire; by
J. Britton and E. W. Braley. Davies's Hiftorical and
Decriptive Account of Derbyshire, 8vo. 1811.

TIDEWA, a town of Sweden, in Weft Gothland; 62
miles N.E. of Uddevalla.

TIDLA, a river of Sweden, which runs into the
Wenner lake, near Marietadt, in the province of Weft
Gothland.

TIDON, a town on the east coaft of the ifland of Celebes,
in the bay of Gunong Teltu. N. lat. 6° 2'. E. long.
120° 38'.

TIDOR, or Tidore, an ifland in the East Indian
sea, and one of thofe called Moluccas, fettuated near the
weft coaft of the ifland of Gilolo, between Ternate and
Timor; about ten leagues in circumference, and fof called
from its capital, though named Tadura, or Daco, by the
natives. It abounds in fpecies, efcpecially floves. The
Dutch have feveral forts, but the ifland is governed by a
king, who poiffefs likewife fome territory on the ifland of
Gilolo; 15 miles S.E. of Ternate. N. lat. 0° 42'.
E. long. 127° 19'.

TIDS, a river of Morocco, which difcharges itsfelf into
the ocean a few miles S. of the Tegrewelt, or Cape
Oifam.

TIEBAS, a town of Spain, in the province of Navarre;
5 miles S.E. of Pamplona.

TIEDEMAN, DIETERICH, in Biography, a philo-
 sophical writer, was born April 1748, at Bremenverde,
in the duchy of Bremen, and educated in the school of his
native place in the Greek and Latin languages, in which he
made very confiderable proficiency. Devoting himfelf to
the church, he removed to the school of Verden, and from
thence to the Athenem at Bremen, where he formed an
intimate friendship with Meiners, afterwards professor at
Göttingen.
GOTTINGEN. In 1767 he settled at Gottingen, and here he renounced the study of theology, because he disapproved the system there taught, and applied to mathematics, classical literature, and philosophy. In the winter of 1769 he fixed his residence in Livonia, as tutor to a nobleman of that country; and whilst he was there, he published at Riga, in 1772, his "Essay on the Origin of Language." After visiting his native place in the following year, he went to Gottingen, and formed an acquaintance with the celebrated Heyne, who wrote a preface to his "System of Stoic Philosophy," and persuaded him to publish it. By the recommendation of this learned friend, he was appointed professor of ancient literature in the Caroline college at Caffel, of which office he took possession in 1766. His intervals of leisure were employed in the study of philosophy and its history; and also in preparing for the press his "Investigation of Man," "The First Philosophers of Greece, & c.," and his "Spirit of Speculative Philosophy." Upon the dissolution of the Caroline college in 1786, he occupied the chair of philosophy at Marburg, and his lectures were very popular. He was an opponent of Kant's philosophy: and he indulged himself in ridiculing the extravagant pretensions and pious arrogance of the founders of sects. Although his constitution was robust, he was carried off by a fever and inflammation of the lungs, in May 1803, at the age of 55. As a literary character, he was intimately conversant with the literature of Greece and Rome, and with all the syslms of ancient and modern philosophy, as well as the manners and customs of ancient and modern times. His extensive erudition appears in his "Argumenta Platonis," annexed to the edition of Plato, printed at Deux-Ponts; in his prize essay, entitled "Dissertatio de Quaflione quae fuerit magicaus artium origo," and in various other dissertations. In philosophy he was in early life a dogmatist, and in the latter period of his life inclined to scepticism. His works, which, besides those already mentioned, were numerous, and relate chiefly to the history of philosophy, and its different systems, afford ample evidence of his affability and labour. Monthly Magazine. Gen. Biog.

TIEFENSEE, in Geography, a town of Prussia, on a lake of the same name; 20 miles S. of Brandenburg.

TIEFF, a town of Prussia, in the province of Bartenland; 7 miles S.E. of Angerburg.

TIEFFENAW, a town of Prussian Pomerelia; 15 miles S. of Marienburg.

TIELLEN-HEAD, a cape of the county of Donegal, on the west coast of Ireland. N. lat. 54° 41'. W. long. 8° 49'.

TIEM, a town of Aasia, in the kingdom of Laos, on the Mecom; 90 miles S.S.E. of Lastian.

TIEN, or LIEN, a city of China, of the second rank, in Quang-tong; 960 miles S. of Peking. N. lat. 24° 52'. E. long. 118° 49'.—Alfo, a town of Corea; 23 miles N.N.E. of King-ki-tao.—Alfo, a city of China, of the second rank, in Quang-hi, on the north side of the Pofoi; 1120 miles S.S.W. of Peking. N. lat. 23° 46'. E. long. 106° 19'.

TIEN-CHAN, a town of Corea; 53 miles W.N.W. of Han-tcheou.

TIENEN. See TIRLEMONT.

TIENGEN, or THIENEN, or THUNGEN, a town of Germany, in the principality of Klettgen, on the Wutach, formerly, with its district, constituting a lordship; 29 miles E. of Balo. N. lat. 47° 42'. E. long. 8° 17'.

TIENHOVEN, a town of Holland, on the Leek; 6 miles S. of Schoonhoven.—Alfo, a town of Utrecht; 7 miles N. of Utrecht.

TIEN-SING, a great port of China, on the river Pei-ho. Its Chinese name literally signifies "heavenly spot," and in the time of Marco Polo, when it is supposed to have been much larger than at present, it was called "Citla Celeste:" and it is said to have a claim on this appellation from its situation in a genial climate, fertile soil, dry air, and serene sky. It is the general emporium for the northern provinces of China, and is built at the confluence of two rivers, from which it rises in a gentle slope. The palace of the governer stands on a projecting point, commanding a broad bay, and expanse of water, produced by the union of the rivers, and almost covered with vessels of different sizes. These two rivers are the Pei-ho and the Yung-ling-ho, or grain-bearing river, from the quantities of wheat conveyed upon it from the province of Shan-fei, and sent up by the Pei-ho to the neighbourhood of Peking. Over these rivers, where they unite, is a bridge of boats: and along the quays were some temples and other handiome edifices, but the rest consisted chiefly of shops for the retail of goods, and also warehouses, together with yards, and magazines for maritime stores. The houses at Tien-fing are chiefly built of brick, of a leaden-blue colour. Few are red: the poorest are pale brown. Many of the houses are two stories high.

TIEN-TCHA, or NEW GIBRALTAR, a mountain of Cochin-china, which forms the harbour of Tenon; which see.

TIENTONG, a town of Siam; 350 miles N.N.W. of Jutia.

TIEN-TSANG, a town of Thibet; 268 miles E.S.E. of Hami.

TIEPOLO, GIOVANNI BATISTA, in Biography, was one of the laft of the eminent Venetian painters. He was born at Venice in 1697, and was a scholar of G. Lazza-riani; but he afterwards studied the works of P. Veronese. He possessed a quick invention, and great freedom of hand, and was admirably qualified for the execution of large fresco works upon ceilings, &c.; where great facility of handling, and richness of colouring, will often apologize for the want of higher qualities, particularly in allegoric or grotesque subjects. Tiepolo was employed in many of the palaces in Italy, but most honoured by the employment he received from the king of Spain, who engaged him to adorn his palace at Madrid. He died at Madrid in 1770, at the age of 73. He etched many of his own designs with great neatness and taste.

TIER, in Sea Language, the name of the several ranges of guns mounted on one side of a ship's deck; which, according as they are placed on the lower, middle, or upper decks, are called the lower, middle, or upper tier.

TIER of the Cable, denotes a range of the fakes or windings of the cable, which are laid within one another in an horizontal position, so that the last becomes the innermost.

TIER Cable, is the hollow space in the middle of a cable, when it is coiled.

TIER, in Organ-Building, is used to distinguish the different ranks or ranges of pipes (as a tier of guns in men of war) in the front of the instrument, and even the interior of the house, when the compound flutes have several ranks of pipes, as the fesquialter, turriton, and cornet.

TIERBY, in Geography, a town of Sweden, in the province of Halland; 6 miles S.E. of Helmsland.

TIERCE, a town of France, in the department of the Mayne and Loire; 3 miles S. of Chateauneuf.

TIERCE, or TIERE, in Commerce, a measure of liquid things,
things, as wine, oil, &c. containing the third part of a pipe, or forty-two gallons. See Measure.

The tierce is also a weight by which provisions are sold in Ireland. The tierces, barrels, and firkins are not tared, but the pieces in each cask must be of the following weight and number:

Tierce, in Music, a 3d. The highest stop in an organ, called the tierce, is a major 3d above the 15th, every found being a 17th above the diapason. See Third.

Tierce de Picardie, in French Music, and indeed all choral music of old masters in a minor key, is terminated with a sharp 3d, which the French now call tierce de Picardie, on account of the great number of cathedrals in that province, where it continues still in use.

Padre Martini (Saggio di Contrap. parte prima, 23.) recommends the terminating minor movements with a sharp 3d; a practice which Rouffeau (Dict. de Mus.) confines as Gothic, and a proof of bad taste. If the first of those excellent writers wish'd only to preserve its use in the church, and the second to banish it elsewhere, they were both right, however their opinions may seem to clash. The learned author of the Saggio di Contrappunto, who was so perfectly acquainted with all the beauties and effects of choral music, is certainly more to be relied on in whatever concerns it, than the animated author of the Dictionnaire de Musique; who, with the most refined taste and exalted views with respect to dramatic compositions, had neither time nor opportunity sufficiently to explore the mysteries of canto fermo, or to become a very profound contrapuntist. For our own part, though we never wish to hear a song or glee in a minor key, and with a sharp 3d; yet there is something so solemn and grateful in these terminations of ecclesiastical compositions, that we should be very sorry if the practice were not continued. And if we consider the relation and composition of the several stops in an organ, we shall find, that as every single key in the chorus of that instrument has a complete chord with a sharp 3d to it, when we dwell on a chord with a flat 3d, while the tierce, cornet, fesquialter, and sometimes the furniture, are founding the sharp 3d, it affords an additional reason for the origin and continuance of the practice, besides the peculiar properties of tonal modulation.

Tierce, in Gaming, a sequence of three cards of the same colour.

Tierce, in Fencing. See Guard and Thrust.

Tierce Order. See Third Order.

Tierce Point. See Third Point.

Tiercel, Tierce, in Heraldry, denotes the shield to be divided by any of the partition lines, party, coupy, tranchy, or tailly, into three equal parts, of different colours or metals.

If the chief and base be of the same colour when divided by a fesse, they blazon it by expressing the colour, and mentioning the fesse; otherwise, they say, it is tierce in fesse, and mention each of the colours, or tierce in pale, if so divided in pale.

Tiercel, in Falconry, a name given to a male hawk, as being a third part lesser in size than the female.

Tiercellet. See Tassel.

Tierdill, in Geography, a town of Hindostan, in Viftapur; 20 miles W. of Galgala.

Tierpied, a town of France, in the department of the Channel; 3 miles E. of Avaranches.

Tierra. See Terra.

Tierra Bamba, a small island near the coast of South America, at the entrance of the harbour of Carthagena; where, in 1741, the English erected a battery.

Tiery, a town of Sweden, in the province of Upland; 80 miles N. of Upsal.

Ties, aboard a ship, are those ropes by which the yards hang; and when the halyards are strained to hoist the yards, these ties carry them up.

Tiessarbach, in Geography, a river of Wurttemberg, which runs into the Neckar, near Nurningen.

Tiétar, a river of Spain, which runs into the Tagus, near Talavan, in Effremadura.

Tiètcheou, a town of Chines Tartary, in the country of Kokonor: 688 miles S.E. of Hami. N. lat. 33° 60'. E. long. 102° 54'.

Tiéte, or Anhembi, a river of Brazil, which runs into the Parana.

Tifacoum, a word used by some of the chemical writers to express quicksilver.

Tifata Mons, in Ancient Geography, a mountain of Italy, in Campania, near Capua. The table of Peutinger has placed here two temples, one designated by the words "Ad Dianam," the other by those of "Jovis Titifanos." Tifata, a town of Italy, in Latium. Pliny.

Tifatum, a word used by some of the chemical writers to express sulphur.

Tifer, in Geography, a town of the duchy of Stria; 3 miles S. of Cilley.

Tifernum, or Tifernus, in Ancient Geography, a river of Italy, in Samnium.

Tifernum Metaurus, a town of Italy, in Samnium.

Tifernum Tiberinum, or Tifernum of the Tiber, Città di Castello, a town of Italy, in Umbria, to the N.W. towards the banks of the river Tiber. It was municipal.

Tifeselt, in Geography, a town of Foz; 12 miles N.E. of Salle.

Tifagueau, a town of France, in the department of the Vendée; 9 miles E. of Montaigu.

Tifé de Mer, in Natural History, a name given by count Mariâgli to a species of sea-plant, as he supposes it to be, commonly but erroneously reckoned among the sponges, and called by authors a branched sponge. This author has called it by this name from its resemblance to the heads of the Tyspa palustris, or cat's tail, when ripe in the month of September.

The sponges must be of a lax and cavernous texture; but this sub stance is soft and firm, and has no inequalities on its surface, excepting a few short hairs, which give it a velvety look, when first taken out of the water. It is a very elegant and beautiful substance; it grows to two feet in height, and is very elegantly branched; it grows on rocks and stones, and, when first taken out of the sea, is fall of a viscid water, as yellow as the yolk of an egg; but when this water is pressed out, and the substance dries, it loses its yellow, and becomes of a dusky-brown colour; it is very tough and firm while in the water, but when dry it usually
ufually breaks of itself into little pieces, and may be crum-
bled to powder between the fingers. This is a very strong
proof, among others, of its not being of the nature of the
fungus.

When viewed by the microscope, the whole surface is
found to be covered with extremely fine and slender hairs;
and, among these, there is an infinity of little apertures,
through which the sea-water makes its way.

When a branch of it is cut transversely, there are seen a
number of long and fine canals, by means of which the water,
received at these superficial apertures, is conveyed to its
whole substance. Marig. Hist. de la Mer, p. 82.

Substances of this kind are now known to be of animal
and not of vegetable origin. See CORAL.

TIPPENETH, in Geography, a town of Prussia, in the
province of Natangis; 10 miles S. of Brandenburg.

TIFESCH, or TIFAS, anciently Thesfes, a town of
Alegis; 40 miles S. of Bona. N. lat. 36° 20'. E. long.
7° 49'.

TIFLISBERG, a mountain of Switzerland, between
the cantons of Uri and Unterwalden.

TIGA, in Ancient Geography, a town of Africa, in Mau-
ritania Caesariana, near the coast of the Atlantic. Strabo.

TIGA, in Geography, a small island in the East Indian
sea, near the north-west coast of the island of Borneo.
N. lat. 6° 25'. E. long. 112° 14'.

TIGAON, an island in the Indian sea, near the north-
west coast of the island of Borneo. N. lat. 6° 10'. E.
long. 128° 48'.

TIGARA, in Ancient Geography, a town of Africa, in
the interior of Mauritania Caesariana. Ptol.

TIGAREA, in Botany, a barbarous or arbitrary name,
of which its publisher Aublet has given no explanation.—

Schreber admitted the genus, under the name of Rhinum,
in his Gen. 701, but in his Addenda to that work, 833, re-
duced it to Tetacera; see that article. Mr. Pursh, how-
ever, has restored the genus and the name, in his Flora
America Septentrionalis, 333, where he has, not without some
doubt, referred it to a very curious new shrub, found in the
meadows of the Rocky-mountains, and on the Columbia
river, by the name of T. tridentata, t. 15. This has crowded,
 wedge-shaped, hoary, three-toothed leaves, and solitary, ter-
 minal, yellow flowers, the size of hawthorn-blossoms. That
it is very distinct in genus from Aublet's Tigarea we have no
doubt, being very nearly akin to the Rubus japonicus of
Linnaeus, Corchorus japonicus of Thunberg, as has lately
been pointed out by M. De Candolle, in a paper read be-
fore the Linnean Society. However, it seems to us that the genus
of neither of these shrubs can as yet be determined, for want
of perfect fruit.

TIGAUDA, in Ancient Geography, a municipal town of
Africa, in Mauritania Caesariana, upon the route from Rufucurrum to Cala, between Cettlemum Tingitanum and

TIGE, in Architecture, a French term for the shaft or
full of a column, comprehended between the astragal and
the capital.

TIGEGUACU, in Ornithology, the name of a small Bra-
silian bird, of the size of a sparrow, and with a ridged and
triangular bill, in which it resembles the mouche-rolle; its
eyes are of a fine blue, and its legs and feet yellow; it is all
over of a deep black, but that it has a large blood-red spot
on the top of its head; its tail is short and black.

TIGELLIUS, in Biography, a musician, born in Sar-
dinia, grandson of Phaneus, a musician in great favour at
Rome in the time of Julius Caesar. Horace has alluded him
down to posterity as a merciless spendthrift, and an egregious
coccomb.

"Ambibjarum collegia Pharmacopoeæ
Mendici, Mimos, Balatrones, hoc genus omne
Mætum, ac felicitum illi cantoris morte Tigellii
Quippe benignus erat."—Sat. lib. i. 2.

Tigellius was not only much in favour with Julius Caesar,
but afterwards with Cleopatra and Augustus: he was an
able musician, an ingenious buffoon, and subtle courtier.

What Horace has said of his caprice, has often been applied,
and we fear will ever continue to be applied, to musicians of
a similar disposition.

"Omnibus hoc vitium ut cantoribus, inter amicos
Ut nunquam isudcant animum cantare rogati;
Injuxi nunquam defident."—Sat. lib. i. 3.

TIGENHAGEN, in Geography, a town of Prussian
Pomerelia; 12 miles N. of Marienburg.

TIGENWIT, a town of Africa, in Negroland; 45
miles N. of Arguin.

TIGER, a small island in the Spanish Main, near the
coast of Darien. N. lat. 8° 35'. W. long. 77° 30'.

Tiger, Tigres, in the Linnean system of Zoology, is a
species of cat, or Felis Tigres; which see.

The tiger (formed of 713, jagutis, a dart, whence 7137)
has its name from its fupposed swiftness. See the article
Felis Tigris.

Tiger, American. See Felis Onca.

Tiger-Cat. See Felis Canepinis.

Tiger, Hunting, or Leopard. See Felis Leopardus.

Tiger, Man. See MANTICAR.

Tiger-Shell, a name given to the red voluta, with large
white spots.

In the Linnean system, the tiger-shell is a species of the
cypraea. See SHELLS.

TIGGREE, in Geography, a town of Hindooblan,
in the circum of Sumbul; 17 miles S. of Nidjibabad.

TIGH, in our Old Writers, a clove or inclofure men-
tioned in ancient charters, and is still used in Kent in the
same fenfe.

TIGHMAN'S ISLAND, in Geography, a small island
in the Chelfapeak. N. lat. 38° 48'. E. long. 76° 21'.

TIGHT, in Sea Language, expresses the quality by
which a vessel refits the penetration of any fluid, whether
compri{ing its surface, or contained within it. Hence a
ship is said to be tight, when her planks are so compact
and solid, as to prevent the entrance of the water in which it
is immersed; and a cafe is called tight, when the flaves are so
close, that none of the liquid contained in it can effc throug
or between them. In both fenes, tight is opposed to leaky.

Falconer.

TIGILLUM, a word used by fome chemifirs to express
the tile with which they cover the mouth of their crucibles;
and, by others, for the crucible itself.

TIGILSKOI, in Geography, a town of Kamtschatka;
80 miles W. of Ukinfoi. N. lat. 57° 20'. E. long.
150° 44'.

TIGINE. See BENDER.

TIGIS HERBA, in Ancient Geography, a town of
Africa, in the interior of Mauritania Caesariana, near a river, and S.
of Icofium. In the Itin. of Anton, it is marked on the
route from Rufucurrum to Scalda.

TIGLUM, in Botany. See PINE NUTS, &c.

TIGNALLE, in Geography, a town of the ifland of Cor-
fica; 30 miles S.E. of Corte.

TIGNARES,
TIGNARES, a town of Brafil, and chief place in the captainship of Rio Grande.

TIGNES, a town of France, in the department of Mont Blanc; 3 miles S.E. of St. Maurice.

TIGRA, in Ancient Geography, a town of Lower Media, on the route from Viminacium to Nicomedea, between Exantapritida and Apphia. Anton. Itin.

TIGRAH, in Geography, a town of Hindooftan, in Barhar; 40 miles E.S.E. of Hajjopour. N. lat. 25° 28' E. long. 86° 7'.

TIGNANA, in Ancient Geography, a town of Asia, in the interior of Media. Ptol.

TIGNANAMA, a town of Asia, in the Greater Armenia, and one of those which were situated to the E. of the sources of the Tigris. Ptol.

TIGRANES, the Great, in Biography, king of Armenia, after having been delivered by his father as a hostage to the Parthians, was liberated and assumed the crown about the year B.C. 93. Having formed an alliance with Mithridates, king of Pontus, against the Romans, he married Cleopatra, daughter of that prince: and, according to the terms of his alliance, he reduced Cappadocia, and caufed Ariarathes, the son of Mithridates, to occupy the throne instead of Ariobarzanes, who was supported by the Romans. Soon after this event, Tigranes was offered the crown of Syria, and accepted it B.C. 83; and when he had taken posfeffion of the kingdom, governed it for many years by a lieutenant. He then invaded Leffer Armenia, and completely ruined it in the course of one campaign. Having made various other conquests, he founded the city of Tigranocerta, on the spot in Armenia where he had received the crown. He afterwards joined Mithridates, his father-in-law, in a war against the Romans; but when Mithridates, after having been defeated by Lucullus, took refuge in Armenia, he was coldly received by Tigranes, who granted him a cafe for his residence, with a royal allowance. By a series of subsequent adventures, which proved successful, Tigranes was fo elated, that he assumed the title of king of kings, and exalted from all who approached him tokens of the most humiliating reverence. A change however in his situation was rapidly approaching; for Lucullus, the Roman general, having reduced the kingdom of Pontus, availed himself of a preconcerted circumstance for marching in a hostile manner into Armenia, and laid siege to Tigranocerta. Tigranes advanced to its relief; but meeting with Lucullus at the head of a small army, an engagement ensued, the refult of which was the pufilannimous flight of Tigranes, and the dispersion of his numerous army; and though he received considerable succour from Mithridates, and levied fresh troops, he could not prevent the surrender of Tigranocerta to Lucullus; and this surrender was followed by a signal defeat of the united forces of Mithridates and Tigranes; upon which the latter prince withdrew to the remotest part of his dominions. When Pompey succeded Lucullus in the command of the Roman army, Mithridates and Tigranes, availing themselves of an interval of inaction, recovered Armenia and a great part of Pontus; but their success was interrupted by the rebellion of the son of Tigranes, who took upon himself, against his father; but being defeated, he fought refuge in Persia, and perfuaded Phraatas, the sovereign of that country, to declare war against the Armenians. Phraatas, with a numerous army under his command, compelled Tigranes to withdraw to the mountains, and besieged his capital Artaxata. The younger Tigranes being left in command of the Parthian army, was defeated by his father, who raised the fiege of Artaxata. Tigranes afterwards joined the Romans, and conducted Pompey into Armenia against his father. Unable to refit this invasion, he determined to surrender himself to Pompey, and to confide in his generosity. Upon being introduced to the presence of the Roman general, he took off his diadem, and prostrated himself at Pompey's feet. Pompey raised him, and replaced the royal diadem; and in compromising the dispute between the father and fon, restored to the former the kingdom of Armenia, and the greatest part of Mecopotamia, but imposed upon him a fine of 6000 talents for making war upon the Roman people. He was also obliged to refund the crown of Syria, which he had held for eighteen years, and likewise the provinces of Cappadocia and Cilicia. From this time Tigranes was received as a friend and ally of the Roman people; and by maintaining their friendship, he was enabled to retain his dominions in peace to the end of his life, which terminated in the eighty-fifth year of his age. Anc. Un. Hift.

TIGRANOCERTA, Sered, in Ancient Geography, a town of Asia, in Greater Armenia, at some distance to the left of the Tigris, on the river Nechoeirus, and N.W. of its mouth in the Tigris. This town was built by Tigranes, in the time of the Mithridatic war. According to Plutarch, it was large, handsome, populous, powerful, and rich. Tacitus reports that Tigranocerta was situated on an eminence, nearly surrounded by the Nechoeirus, and that it was well fortified and garrisoned.

TIGRÈ, in Geography, a small island in the Pacific ocean, at the entrance into Amiapalla bay. N. lat. 13° 10'. W. long. 88° 44'.

Tigrè, a province of Abyssinia, about 200 miles in length, and 120 in breadth. What in a special manner makes the riches of Tigré, is, that it lies near the market, which is Arabia; and all the merchandise destined to cross the Red sea must pass through this province, so that the governor has the choice of all commodities wherewith to make his market. The strongest male, the most beautiful female, the purest gold, the largest teeth of ivory, all must pass through his hand.

TIGRÍDIA, in Botany, the Flos Tigrídis of old authors, so called from its beautifully spotted corolla, resembling the skin of a tiger, or rather of a leopard or lynx. This fine Mexican plant, being known to systematic botanists from early engravings only, did not find a place in their arrangements; till Mutis sent a drawing of it to Linnaeus, under the name of Pavonia, in honour of one of his ablest pupils, Pavon, as appears by his letters; and not, as some have supposed, because of any resemblance in the spots of the flower to a peacock's tail. Being judged a Ferraria, it was referred to that genus in the Supplementum; but Jussieu, and after him Mr. Gawler, has restored the genus of Mutis, under the above name, there being another Pavonia, which the reader may see in its proper place.—Juff. Gen. 57. Gawler, (now Kew Bellenden,) in Sims and Kon. Ann. Bot. v. 1. 246. Ait. Hort. Kew. v. 4. 137. (Ferraria; Lanarick Illust. t. 569.)—Clavis and order, Monadelphie Triandra. Nat. Ord. Enfete, Linn. Gawler. Irides, Juff.

Gen. Ch. Common Sasbeath, two-edged, of two comphried pointed valves; partial ones smaller, two-ranked, alternate, single-flowered. Perianth none. Cor. superior, regular, of six petals; the three outermost ovate-oblong, acute, concave at the base, slightly contracted towards the middle; three innermost much smaller, oblong-fiddle-shaped, pointed, convex, recurved, haftate at the base. Stam. Filaments three, firmly united into a triangular, abrupt, erect column, longer than the inner petals; anthers sessile at the top of the column,
column, erect, linear-oblong, acute, converging at the points, burbling externally. *Pilf*. German oblong, abrupt, with three rounded angles; style thread-shaped, rather longer than the column of the flaments; stigmas three, slender, acute, deeply divided. *Peric*. Capsule oblong, bluntly triangular, abrupt and spurred at the top, of three cells and three valves, the partitions from the centre of each valve. Seeds numerous, nearly globose, ranged in a double row in each cell, somewhat angular from mutual pressure.

1. T. Pavonia. Mexican Tiger-flower. Redout. Liliac. t. 5. Gawler n. 1. Att. t. 1. (Ferraria pavonia; Linn. Suppl. 407. Willd. Sp. Pl. v. 3. 581. Cavan. Diff. 342. t. 18. F. An. Andr. Repof. t. 178. F. Tigridia; Curt. Mag. t. 532. Ocoloxochilus, feu Flore Tigris; Hernand. Mex. 276. Tigrisid flor; Dodon. Pempt. 693. Tier. Em. 122.)—Native of Mexico and Peru. Said to have been first introduced into the gardens of this country, about the year 1796, by Ellis Hodgson, esq. of Everton, near Liverpool, who liberally communicated it to the nurseriesmen about London, so that now few ornamental flowers are more easily obtainable. If treated as a greenhouse plant, like the Cape bulbs, the *Tigrisida* flowers in spring, ripening abundance of seeds. If planted in the open ground in March or April, the more dry or sandy the soil the better, it will blossom in succession through the autumn, at the end of which the bulbs should be taken up, carefully dried, freed from their very succulent fibres, and preserved from frost till the following spring. Though each flower lasts but one day, as every plant bears several, a plentiful succession may readily be had. The *root* is an ovate bulb, which is eatable when roasted, tasting like a chicenut; from its base are lent down several long, perpendicular, tapering, very juicy, downy fibres. *Spem* two or three feet high, erect, round, leafy, somewhat branched. *Leaves* several, erect, fowder-shaped, many-ribbed, flat-ted, smooth, a foot long. *Flower* nodorous, three or four inches broad, so splendidly variegated with scarlet, crimson, purple and yellow, that no description can do it justice. The ends of the larger petals are scarlet; their middle yellow; their base, like the whole surface of the smaller ones, richly spotted. *Stamens* and *pilif* red. It increases by bulbous offsets, as well as by seeds.

TIGRINI, ORAZIO, in Biography, a canon of Arezzo, who published at Venice, in 1588, a Musical Compendium; "Compendio della Muflica," which he dedicated to Zarlinno, from whom he received a letter of thanks for the laurel-crown with which he had bound his brows; which letter is prefixed to the work, with complimentary verfs innumerable from other friends. This Compendium is not only well digested by the author, but rendered more clear and pleasant in the perusal, by the printer, who has made use of large Roman types, instead of Italian, in which most of the books that were published in Italy, before the present century, were printed. This author is the firft, in our recollection, who has cenfurcd the impropriety and aburdity of composing music for the church upon the fubject of old and vulgar ballad tunes. The cadences which he has given in three, four, five, and fix parts, and which are good examples of ecclefiaftical counterpoint, have been almost all used by Morley, without once mentioning Tigrini's name, either in the text or catalogue of authors whom he has cited. Zarlinno, who had adopted the four new ecclefiaftical tones proposed by Glaerus, was followed by Tigrini, with whom they seem to have flopped: as no more than the eight ancient tones ap-

peared afterwards to have been acknowledged by orthodox ecclefiaftical composers; and Zarlinno himself, in the fmall editions of his works, relinquished the idea of twelve modes: as no new harmony or modulation was furnished by the additional four to the contrapuntift, without violating the ancient rules of canto-forno, which confine all its melody to the different species of octave. It appears from this Compendium, that contrapunto alla mente, or extemporary difcant upon a plain-fong, was still practiced in the churches of Italy.

TIGRIS, in Ancient and Modern Geography, a large river of Asia, which has its source in the mountains of Great Armenia, about 15 miles S. of the sources of the Euphrates, and pursues nearly a regular course S.E., until its junction with that river at Korna, 50 miles above Basforsa. Formerly these rivers disfighmed themselves separately into the Persian gulf; but they now fall into the sea by a common canal, about 70 miles S. of Basforsa. In the time of Pliny their separate beds might be seen. According to the fame author, it was named "Deglito," from its source to mount Taurus, which it traversed; and from the place of its discharge on the other side of the mountain, to the sea or Persian gulf, it was called Tigris. This author fays that it passed through the lake of Aréhufa, without mixing its waters with those of the lake. Strabo and Arrian denominated the mouth of the Tigris "Pafitigris," and Pliny gives this name to that part of the river which separated into two arms, that, after enclofing an ifland, joined again, and fell into the same bed. Mofes (Gen. ii. 14.) calls this river, as it has been fupposed, Hiddekel. The cavern of mount Taurus, through which it is faid to have paffed, was called "Zoroanda;" and as a proof that it was the fame river which entered the cavern and paffed out of it, any fubfance thrown into the river on one fide of the mountain was difcharged by it on the other.

The ancient Perifans called this river "Teer," the arrow, from the rapidity of its current; and it is now called "Degila," and "Shat-Bagad," the river of Bagdad. The united rivers of the Tigris and Euphrates are denominated "Shat-ul-Arab;" which fee.

The Tigris, though a far left noble fire than the En- phrates, is one of the moft celebrated rivers in history; and many famous cities have, at different periods, decorated its banks; among which we may reckon, in ancient times, those of Nineveh, Seleucia, Ctefiphon; and in fubfequent periods, those of Bagdad, Mofil, Diarbekir, &c.

This river is navigable for boats of twenty or thirty tons burthen as far as the mouth of the Odonneh, but no farther; and the commerce of Mofil is confequently carried on by rafts, supported by inflated sheep-kkins. The rafts are floated down the river, and when arrived at Bagdad, the wood of which they are compofed is fold without a lofs, and the kkins conveyed back to Mofil by camel. The Tigris is, on an average, between Bagdad and Korna, about 200 yards wide. The banks are steep, and, for the most part, overgrown with brush-wood, the haunts of lions and other wild beafts. The Tigris rises twice in the year; the first and great rife is in April, and is caufed by the melting of the fnows in the mountains of Armenia; and the other is in November, produced by the periodical rains. A boat, with a fair wind, will sometimes pafs from Bagdad to Basforsa in fix days, but the common paffage is from eight to ten.

The banks of the Tigris, from Tavqua-Kefra to Korna, cannot beef of a fingle village, or even habitation, with the exception of Koot, a miserable place, containing 40 or 50 mud-huts. The city of WAfth, repeatedly mentioned in the Arabian histories, is no longer a place of any confequence; it stands on the banks of the Hye, or great canal.

From Korna to the neighbourhood of Basforsa, Basforsa or 4 M.

Baira,
Table of Contents

Bafrn, there is little or no cultivation; but from thence the country bordering on the banks of the river is covered with plantations of date-trees, which continue, without interruption, almost to the mouth of the Shat-ul-Arab.

Tirandonte, a fountain of Athis, in the mountains S. of Maxome, which formed a stream that ran towards the S.E. and discharged itself into the lake Arethusa.

Tigris, in Geography, a river of China, between Canton and the sea, so called by Europeans.

Tigris, in Zoology. See Felis Tigris.

Tiguanalpa, in Geography, a town of Mexico, in the province of Nicaragua, on a river which runs into Amapala bay; 80 miles N. of Leon. N. lat. 13° 50'. W. long. 87° 36'.

Tigullaca, a town of Peru, in the diocese of La Paz; 10 miles N. of Puno.

Tigurini, in Ancient Geography, a people of Gaul, who established themselves in a canton of the Helvetians, and who joined the Cimbri when they made an attempt to pass into Italy.

Tigurinus Pages, one of the four cantons which composed the Helvetian confederacy; supposed to be Zürich.

Tigutia, a place of Italy, in Liguria, N.E. of Monflur.

Tigny, in Geography, a town of France, in the department of the Loiré; 12 miles S.E. of Orleans.

Tihan, a town of Hungary; 20 miles S.W. of Stuhlweissenburg.

Tihoe, a bay on the S. coast of the island of Bouro. S. lat. 3° 44'. E. long. 126° 27'.

Tihol, in Natural History, a name given by the people of the Philippine islands to a species of crane very frequent among them, and remarkable for its size, being taller than a man when it stands erect, and holds up its neck. They call it also sometimes tipul.

Tib, Et, in Geography, a town of Persia, in the province of Chufistan, on the Ahuaz river; 70 miles N.W. of Tiflis.

Tieguacu-Paroara, in Ornithology, the name of a Brazilian bird, of the fize of a lark; it has a short and thick beak, brown above and whitish below; its head, throat, sides, and the lower part of its neck, are of a fine yellow, variegated with red in the female, and all over of a perfect blood-red in the male; the upper part of the neck, and the whole back, are grey, with a mixture of brown; the wings are brown, tipped with white; the tail is of the same colour; and the sides of the neck, the breast, belly, and thighs, are white. Marggraves's Hift. Brasil.

Thepiranga, the name of a Brazilian bird of the sparrow kind. It is a little larger than the lark; its whole body, neck, and head, are of a very fine red or blood colour, and its wings and tail black.

There is another species also of this bird, which is of the size of a sparrow, and is of a blueish-grey on the back, white on the belly, and of a sea-green on the wings; the legs of this are of a pale grey. Marggraves's Hift. Brasil.

Tijuola, in Geography, a town of Spain, in the province of Granada; 5 miles S.W. of Purchena.

Tijuoca, a cultivated valley of the Brazils, in the vicinity of Rio de Janeiro, situated, as it were, in the bottom of a funnel, being surrounded on all sides by mountains, excepting to the southward, where a small opening admits an arm of the sea. The valley is watered by a clear stream, precipitated down a steep and broad rock of granite, forming a magnificent cascade. The soil requires little labour of cultivation: indigo, manioc, coffee, cacao or chocolate trees, sugar-canes, plantains, and orange and lime-trees growing promiscuously, and some spontaneously, in the space of twenty square yards. Coffee and indigo claim the chief attention. The temperature of the valley is very hot, on account of its confined situation and the reflection of the mountains. Fahrenheit's thermometer in the shade at 92°. Staunton's Emb. to China, vol. 1.

Tiz, or Tiz, a town of Persia, in the province of Mecran, at the mouth of the Kurene; 75 miles S. of Kidge, N. lat. 25° 25'. E. long. 60° 24'.

Tikax, a town of Mexico, in Yucatan; 68 miles S. of Merida.

Tike, the Zendat name for an otter, of which there are many to be found about that island. Phil. Trans. N° 473, fec. 8.

Tike is also used for a small bullock or heifer, for a particular sort of worm, and in Scotland for a dog.

Tikib, in Geography, a town of Denmark, in the island of Zealand; 4 miles S.W. of Helsingor.

Tikithockthock, a settlement on the E. coast of Labrador. N. lat. 56° 15'. W. long. 60° 27'.

Tikoo, a town of Bengal; 30 miles S.W. of Ramgur. N. lat. 23° 29'. W. long. 84° 55'.

Tikotschin, a town of the duchy of Warsaw; 24 miles N. of Bilefsk.

Til, a town of Persia, in the province of Adirbeiztan; 60 miles N.W. of Tauris.

Tila nav, one of the Lipari islands; 6 miles S.S.W. of Stromboli.

Tilamungalum, a town of Hindoostan, in Myore; 5 miles S. of Outfloor.

Tilborg, a town of Brabant, celebrated for its manufacture of cloth; 10 miles S. of Bois-le-Duc.

Tilburkeah, a town of Bengal; 30 miles N.N.E. of Doeca.

Tilbury, a township of Upper Canada, near lake St. Clair.

Tilbury, Welf, a village and parish in the hundred of Barfable, and county of Eflyx, England; is situated 24 miles S. by W. from Chelmsford, and 27 E. by S. from London. It appears to have been an episcopal seat of Cedd, bishop of the East Saxons, who in the 7th century propagated the Christian religion in this country, and built churches in several places, but "especially," as Bede reports, "in the city, which, in the language of the Saxons, is called Ythanecestre; and also in that which is named Tilaburgh (the first of which places is on the banks of the river Pant, the other on the banks of the Thames), where gathering a flock of fervants of Christ, he taught them to observe the discipline of a regular life, as far as those rude people were then capable." Ythanecestre is supposed to have stood at the mouth of the river Pant, or Blackwater, but has been entirely engulfed by the sea. Tilbury is now only a small village, containing, as the return of the year 1811 states, 44 houses and 17 inhabitants. A medicinal spring was discovered here in the year 1727, of great efficacy in cures of haemorrhage, fevers, and some other distempers. (See Tilbury-Water.)

The marshes in this, and the contiguous parishes, are chiefly rented by the grazing butchers of London, who generally flock them with Lincolnshire and Leicestershire wethers, which are sent hither about Michaelmas, and fed till Chriftmas, when they are conveyed to the metropolis for sale.

On the banks of the Thames, in this parish, is Tilbury-Fort, originally built as a kind of block-house by Henry VIII., but enlarged into a regular fortification by Charles II., after the Dutch had failed up the river in the year.
year 1667, and burnt three English men of war at Chatham. Various additions have been since made; and it is now strongly garrisoned, and defended by a great number of guns. Some traces of the camp formed here to oppose the threatened invasion of the Spanish armada, in the time of Elizabeth, are yet visible.—Beauties of England and Wales, vol. v. Essex; by J. Britton and E. W. Brayley.

TILbury-Water, in Medicine, is an acidulous or saline water, issuing from a spring situated near a farm-house at West Tilbury, near Tilbury-Fort, in Essex. This water is of a straw-colour, soft and smooth to the palate, but leaving, after agitation in the mouth, a small degree of roughness on the tongue; it throws up a scum variegated with several colours, which feels greasy; and effervesces with spirit of vitriol; it mixes smooth with milk, but curdles with soap; when boiled, it turns milky, but is fined by a fourth part of mountain-wine, and by acids; it operates chiefly by urine, though it is somewhat purgative, and increases perspiration. This water is esteemed for removing glandular obstructions, and hence is also recommended in fevers and cutaneous diseases; it is good in bloody fluxes, purgings, and the like; in disorders of the stomach arising from acidity, in the gravel, fluor albus, and immoderate flux of the menes. As a diuretic, it is beneficial in dropsical complaints. It gently warms the stomach, strengthens the appetite, and promotes digestion. The usual dose is a quart a-day. This water is supposed to owe its virtue to a native alkaline salt, which may be obtained from it by evaporation, and to its fixed air, which, however, being very volatile, soon exhalas when the water is heated or stands for some time exposed. Elliot’s Account of Mineral Waters, &c. p. 220.

TILCARA, in Geography, a town of South America, in the province of Tucuman; 32 miles N.W. of St. Salvador de Jugui.

TILDZ DAGHI, a mountain of Asiatic Turkey; 10 miles S. of Tocat.

TILE. See Tyle.

Tiles, Draining, in Agriculture, such as are made of particular forms and dimensions, for the purpose of draining and taking away the water that stagnates in or upon land. They are laid to constitute a very neat and convenient, as well as cheap and beneficial material for this use in a great many cases, especially as they are exempt from the common duties on ordinary tiles and bricks. They have the advantage too of being capable of being laid with much facility and dispatch, and of requiring less cutting than in the methods usually had recourse to in the common practice of freeing land from wetnesses. They are made and employed in some districts, as Cheshire, &c. with complete success and much utility.

Tile-Earth, that sort of earthy material of the strong clayey kind which is used in the making of tiles. It is also a term in farming which is sometimes employed to signify a strong, stiff, stubborn sort of land or soil that cannot be brought into cultivation, and be managed without very great labour, trouble, and expense, but which, when once reduced and got into order, is, in some cases, very productive and laiting in its returns. Vaft strength of men and teams is often requisite in working such lands as farms, as they cannot be effectually improved and got into a proper state, except by the application and incorporation of large quantities of different proper rich earthy and other suitable substances.

The farmer should always calculate well before engaging farms confining greatly of this sort of land or soil.

The general opinion among the most attentive and diligent farmers in the county of Essex is, that even the

pallure lands upon the wet, cold, tile-earth bottoms, should be kept under the plough two or three years in twenty, in order to render them in the most suitable and productive state.

Tile, or Tyle, in Allying, a small flat piece of dried earth, used to cover the vessels in which metals are in fusion.

There are made of a mixture of clay and sand, or powder of flints, or broken crucibles, made into a paste, and spread thin with a rolling-pin, on a table or flat stone. From these cakes or plates, pieces are to be cut with a knife, to the shape and size of the mouths of the vessels to be closed. It is best then to pare away the borders of the under surface of the piece thus cut off, that this surface may immediately touch all the way the edge of the mouth of the vessel, leaving a prominent rim, by which means the tile fits close upon the vessel, and is not so easily displaced by accidents, as a touch of the poker, or of the coals put on to mend the fire, as it otherwise would be. Finally, put on the middle of the outer surface a small bit of the same matter, which serves as a kind of handle, by means of which it may be conveniently managed by the tongs, and easily taken off and put on again at pleasure. Cramer, Art. Alfi. p. 66.

TILENUS, DABLE, in Biography, a doctor and professor of theology at Sedan, in France, was born in Silefia, in 1563, and was the first foreigner who wrote against Arminius, though he afterwards changed his opinion and supported the doctrine of that theologian. He also took part in a violent controversy with Du Moulin. A reconciliation was attempted between the disputants, in which the elector palatine, the duke de Bonilac, and king James I. of England, interposed; and a national synod of the French churches was held for this purpose at Tonneins in 1614. The attempt to produce a pacification failed; and TILENUS was deprived of his professorship in 1619 or 1620. He then removed to Paris, and afterwards maintained for five days, at Orleans, a disputation with John Cameron on grace and free-will. In a letter addresed to the people of Scotland, he accused the Presbyterians of introducing too many changes in the form of their religion, and praised the people of England for admiring episcopacy. King James I. cauconf this letter to be printed, and invited the author to England, with an offer of a penion. TILENUS accepted the offer; but returning to France in order to arrange his affairs, an outcry was in the meanwhile raised against him in England, and he therefore determined to remain at Paris, where he died in 1633. He was the author of many works in Latin and French, which it is needless to recite. Gen. Diog.

TILGUN, in Geography, a town of Asiatic Turkey, in Caramanias; 36 miles E.N.E. of Akkahir.

TILHARA, a town of Hindooan, in Rohulcan; 30 miles S.S.E. of Berilly.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, concave, coloured, deciduous segments, about as large as the corolla. Car. Petals five, alternate with the calyx, oblong, obtuse, crenate at the summit. Nectary a scale at the base of each petal, not universal. Stem. Filaments numerous,
Tilia.

anthers, thread-shaped, the length of the corolla; anthers of two nearly orbicular discurvated lobes, bursting outwards.

pijn. German superior, roundish; style thread-shaped, the length of the flaminis; stigma obtuse, with five angles.

peric. Capsule globose, angular, coriaceous or membranous, bursting tardily at the base, of five valves and five cells.

seeds solitary, roundish.

obst. Two or three of the cells are generally abortive and obliterated. The nectary seems confined to the American species.

eff. ch. Calyx in five deep segments, deciduous. Petals five. Capsule superior, roundish, angular, of five cells, and five valves.

An important genus, of useful, as well as ornamental, hardy deciduous trees. The bark serves for cordage, and for those very serviceable mats, manufactured in Russia, so well known to our gardeners, and so useful for packing. The smooth, soft, white, clove-grained wood is esteemed by carvers, and was preferred by the inimitable Gibbons, for those feloons of flowers, fruit, dead game, &c. with which his free and expeditious hand adorned most of the great houses in England. The leaves are sometimes given to cattle in seasons of scarcity in the North. The whole plant abounds with mucilage, and the sap is reported to afford some fugar. Nothing is more deliciously fragrant than the flowers of the whole genus, which were frequent in great numbers, as they yield plenty of honey.

section 1. flowers without the scaly nectaries. European species.

1. T. europaea. Common Smooth Lime-tree. Linn. Sp. Pl. 733. Willd. n. 1. Ait. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 610. Fl. Dan. t. 533. (T. platyphylos; Scop. Carn. v. 1. 375; Venten. n. 2. T. vulgarius platyphylos; Bauh. Hist. v. 1. p. 2. 133. Rail Syn. ed. 2. 316. T. femina; Ger. Em. 1483. Nectaries none. Capsule coriaceous. Leaves heart-shaped, undivided; smooth and somewhat glaucous beneath, with the branching of their veins woolly. Branches and footstalks smooth. Native of woods and the borders of meadows, or the slopes of hills, in various parts of Europe, from Sweden to Greece, flowering early in July. A tall upright tree, with smooth, spreading, round branches, green when tender, afterwards brown. Leaves alternate, on longish stalks, pointed, sharply serrated, almost orbicular, about three inches in diameter, entire at the base, and their fides rather unequal or oblique in that part: their upper surface of a full bright green, quite smooth: under paler, somewhat glaucous, with a yellowish prominent midrib, and several other ribs, either opposite from the central one, or radiating from the base, subdivided, connected by parallel tranverse veins, all smooth as well as the surface of the leaf, except at the base of each side-rib, where is a small, depressed, axillary, fringe-like tuft of hairs. stipules none. Flower-stalks axillary, solitary, shorter than the leaves, smooth, slender, each bearing an irregular umbel or cyme of yellowish flowers, and very remarkable for a large, solitary, oblong, obtuse, entire, veiny bracteas, of a pale greenish hue, and smooth surface, united firmly to the stalk, and falling off with it. The germen is very woolly. Capsule obovate, or angular, especially when it ripens more than one seed, which is not often the case. The flowers are delightfully fragrant, especially at night. This is the kind of Lime most usually planted for avenues, nor can any thing be more desirable for that purpose. It appears to have taken place of our more ancient elms in king William's time, when also it was equally popular in France. The branches naturally feather down to the ground, but will bear clipping without injury. The leaves fall perhaps the first of all our native trees, especially in the squares of London, where the Lime nevert heless bears the smoky atmosphere tolerably well.

Whether the T. ulmifolia, femine hexagona of Merrett, mentioned by Didennius in his edition of Ray's Synophs, 473, be a variety of this, with more perfect fruit, or of any other species, we have no means of determining.

2. T. corallina. Red-twigged Downy Lime-tree. (T. europaea; Ait. Hort. Kew. ed. 1. v. 2. 229; ed. 2. n. 1. 6; Fl. Brit. n. 1. T. grandifolia; Ehrh. Arb. n. 8. T. folis mollitirh hirtifus, viminibus rubris, fructu tetragonoto; Rail Syn. ed. 2. 316. Nectaries none. Capsule coriaceous. Leaves heart-shaped, undivided; downy beneath, with the branching of their veins woolly. Branches and footstalks downy. Native of various parts of Europe. Plentiful in Stokenchurch woods, Oxfordshire, where it was first noticed by Bobart, and where its shining red twigs are very conspicuous. This character, however, is not invariable. We have the same species in Norfolk with brown twigs, and it seems to be often planted indifferently with the former. They have not yet been separated as species, nor did Ehrhart, in publishing the present under the appellation of grandifolia, mean any thing further than to distinguish it, in common with the foregoing, from his parvisepala, hereafter described. We therefore prefer an older and less ambiguous name. Professor Mertens, who has studied these trees in Germany, observes that corallina flowers a fortnight earlier than europaea. As to their specific difference, it appears chiefly to depend on the fine soft hairs, which clothe the backs of the leaves, and especially cover their ribs, fringing their minutest veins in a delicate and regular manner. These hairs are condensed into little axillary tufts, at the origin of each principal vein. In the inflorescence or flowers we perceive no material difference. The capitule has four or five angles. The famous old Lime in the church-yard of Zellitz near Gutenberg, in Bohemia, which is said to have borne hooded leaves, since a parcel of monks were hanged upon it, proves, by an authentic specimen sent us by professor Jacquin, to be this species, not the foregoing.

3. T. parvisepala. Small-leaved Lime-tree. Ehrh. Arb. n. 36. Pl. Off. n. 125. Sm. Engl. Bot. t. 1705. Ait. n. 2. "Schkuhr Handb. v. 2. 72. t. 141." (T. microphylla; Venten. n. 1. Sav. Etr. loc. 1. 152. T. europaea; Fl. Brit. n. 1. T. ulmifolia; Scop. Carn. v. 1. 374. T. fylvefirs; Trag. Hist. 1111. T. folio minore; Bauh. Hist. v. 1. p. 2. 137. Rail Syn. ed. 2. 316. T. bohemica, &c.; Till. Pl. 165. t. 49. f. 3. )—Nectaries none. Capsule roundish, very thin. Leaves heart-shaped, sharply serrated, somewhat lobed; smooth and glaucous beneath, with dense, axillary or scattered, tufts of hair. —Native of Germany, Carniola, Switzerland, Italy, France, and England. Ray says it frequently occurs in Essex and Suffolk, as well as in Lincolnshire and elsewhere. It flowers a month later than even the first species, not being in full perfection before August. The leaves are but about half the size of either of the foregoing, their ferratures sharper, tufts of axillary hair larger, and often accompanied by large hairy blotches. Footstalks slender, and often of a longer proportion, quite smooth. Flowers smaller, smelling like a Honeyflick. Capitule small, roundish, scarcely angular, rarely perfecting more than one seed, its coat thin and tender compared with either of the former species, on which circumstance M. Ventenat chiefly founded its distinct character. We do not find that part so unlike them in firmness, as in thickness; but we have no doubt of the species being perfectly distinct. By planting this intermixed with the others about houses, in avenues, &c. a longer
TILIA.

longer succession of fragrance from their blossoms might be obtained.

4. T. americana. Broad-leaved Lime-tree. Linn. Sp. Pl. 733. Willd. n. 2. Ait. n. 3. (T. glabra; Venten. n. 3. "Mem. de Pinif. v. 4. t. 2." Pursh n. 1. T. canadensis; Michaux Boreal.-Amer. v. 1. 306.)—Neetaries present. Leaves orbicular-heart-shaped, abrupt with a point, sharply serrated; their veins minutely hairy beneath. Petals abrupt, crenate. Capsule ovate, somewhat ribbed. In the woods of Canada and the northern United States, and on the mountains, as far as South Carolina, flowering in May and June. It is known by the name of Lime-tree or Line-tree, Bafe-wood, or Spoon-wood, and is both useful and ornamental. Pursh. Kalin first made the plant known to Linneas, and it was suppos'd by him to be the only American species of Tilia. The stem is laid to be eighty feet high. The branches are brown, smooth. Leaves larger than any of our European species, and of a more orbicular or rather elliptical form, abrupt rather than heart-shaped at their base; of a fine green above, turning red in autumn; much paler beneath; finely veined and smooth on both sides, except that all their veins are minutely hairy (not fringed like T. cordifolia) beneath, and even the smaller ones, as well as the larger, are furnished with little auxiliary hairs. Flowers corymbose; their common stalk about twice the length of the footstalks. Petals, according to Ventenat, abrupt, and toothed towards the end. We have not examined the flowers.

6. T. pubescens. Hoary Lime-tree. Ait. n. 4. Willd. n. 3. Venten. n. 4. "Mem. de Pinif. v. 4. t. 10. t. 3." Pursh n. 3.—Neetaries present. Leaves heart-shaped, pointed, coarsely serrated; abrupt and unequal at the base; downy beneath. Panicles forked, compound. Petals acute.—In clove copses, and on the banks of rivers, from Virginia to Georgia, flowering from May to July. Pursh. Its thinner-leaved variety was long ago brought from Louisiana to the Paris gardens, and Jussieu gave it the name of multiforma, which is very apt, but has never been published till lately. Cateley is reported to have introduced this species into England before the year 1726. If our memory does not deceive us, it is to be met with at Bulletrode, and in other old plantations, and the flowers are more highly fragrant than any others of the genus. Its growth is laid not to be so lofty as that of T. americana. The leaves are smaller, obliquely heart-shaped, with very broad and pointed serratures; their under side extremely soft to the touch, but not white, though paler than the upper, and somewhat hoary. There are scarcely any auxiliary tufts of hair to the veins, except on the older denudated leaves. Flower-stalks twice as long as the footstalks, branched at the top into a forked, spreading, downy panicle of numerous flowers. The petals are rather pointed, as Ventenat describes them; and not emarginate, as in his and Pursh's specific definition. We readily concur with these authors, that the Louisiana tree, called multiforma, is a mere variety, and but a slight one. Our description of the inflorescence and flowers is taken from this variety. It is hardly necessary to mention that all these American Lime-trees bear the same peculiar fort of bractea as those of Europe.

7. T. alba. White Lime-tree. Ait. n. 5. Willd. n. 4. "Wald坐. et Kitaib. Hung. t. 3." Jacq. Hort. Schoenbr. v. 3. 18. t. 283. (T. rotundifolia; Venten. n. 5. "Mem. de l'Inst. v. 4. 12. t. 4."—Neetaries present. Leaves deeply heart-shaped, obscurely lobed, sharply serrated; downy and white beneath.—Native of woods in Hungary. Willdenow. Found by Bruguier and Olivier near Conftantine, Ventenat. It was erroneously reported by our gardeners to come from America, as every new plant, at one period, was supposed to do. More recently, every novelty has been attributed to Botany Bay.—This is a hardy tree in England, but does not flourish so well as any of the preceding. The deep, and more even, heart-shaped figure of the leaves, and their snow-white under surface, readily characterize this species. Its light-yellow, cymose or panicled flowers are said to have the scent of a jonquil.

8. T. heterophylla. Various-leaved Lime-tree. Venten. n. 6. "Mem. de l'Inst. v. 4. 16. t. 5." Pursh n. 4. (T. alba; Sm. Inf. of Georgia, v. 1. 21. t. 11.)—"Leaves ovate, sharply serrated; white and downy beneath; either heart-shaped, or obliquely, or equally, abrupt, at the base. Capsule globose, obscurely ribbed."—On the banks of the Ohio and Missiliphi, flowering in June. A very handsome and desirable ornamental tree. Pursh. Ventenat says it is distinguished from the last by many characters. The young branches, and buds, are smooth, of a purple colour inclining to black. Leaves delicately serrated, pointed, with tufts of reddish axillary hairs to the veins. Flower-stalks almost as long as the leaves, being thrice the length of T. alba. We have seen no specimen of this species, but it has probably been introduced into the gardens by some of our collectors from America. It is extremely likely to be the Warhew of Mr. Abbot, in our Inflets of Georgia, t. 11; which from the above-mentioned error of the gardeners respecting T. alba, we supposed could be no other than that species, now known not to grow in America. The Warhew is said to be very like the European Lime-tree, except being always a low bush or shrub. Mr. Abbot's figure answers so well to Ventenat's and Pursh's definitions, as to leave scarcely a doubt on the subject, except only that the latter speaks of T. heterophylla as an ornamental tree. It may attain a greater size in one part of the country than in another.

We feel much regret in rejecting our late esteemed correspondent M. Ventenat's suppos'd improvements in the nomenclature of the species of Tilia. But besides their appearing to us uniformly for the worse, as usual in all such alterations that ever came in our way, we greatly prefer established names; which though occasionally erroneous or ambiguous, have generally acquired associations that compensate for any defects.

TILIA, in Gardening, contains plants of the ornamental tree kind, among which the species most cultivated are, the European lime-tree (T. europea); the broad-leaved American lime-tree (T. americana); the pubescens Carolina lime-tree (T. pubescens); and the white lime-tree (T. alba).

The first sort, though little used, is a handsome tree, having a smooth taper straight trunk, and the branches forming a beautiful cone. The foliage is also smooth and elegant: it grows to a very large size, and affords good shade: it makes a fine detached object in parks and open lawns, planted singly: the branches are so tough as seldom to be broken by the winds, and the flowers have a delightful fragrance: the wood is soft, but capable of being turned into light
light bowls and dishes, &c. There are several varieties of
it, as the narrow-leaved, the broad-leaved, the elm-leaved,
the red-twiggled, the smooth small-leaved, the smooth
large-leaved, the soft hairy-leaved, the wrinkled-leaved,
and the striped-leaved.

Cultures.—These trees may be increased by seeds, layers,
and cuttings. The seed, when ripe in the autumn, should
be beaten down, keeping the green-twiggled and red-
twiggled kinds separate; and be sown soon after, or
prefered dry and found till spring; sowing it in a bed or
border of common earth; previously digging the ground,
and dividing it into four-feet wide beds; drawing the earth
off the surface evenly, about an inch deep, into the alleys;
then sowing the seeds thinly, touching them lightly down
into the earth with the back of the spade, directly earthing
them over to the above depth.

When they come up in the spring, the beds should be
kept clean from weeds, giving moderate waterings in dry
weather, to forward the plants in growth as much as possible,
in order to be fit for planting out in nursery-rows by the au-
tumn or spring following; though, if they have not root rather
weakly, they should stand another year, then be planted out
in rows two feet wide and a half afunder, by eighteen inches di-
tance in the lines, to remain three or four years more to
acquire a proper size for the purposes intended, trimming
off the large side-branches from the lower part of the stem
occasionally, to encourage their aspiring more expeditiously
at top, which should be suffered to remain entire: these
plants, when raised from seed, generally assume a more hand-
fome and expeditious growth than such as are raised from
layers and cuttings. When they are from about five or six
to eight or ten feet high, they are of proper size for final
planting out; though, when digged as forest-trees for timber, it is advisable to plant them finally while they are
young, as more than from three or four to five or six
feet high.

They are all raised readily by the layer method; and for
this purpose proper flushes must be prepared, and the young
shoots of a year or two old are the proper parts for being
laid down, which should be performed in autumn or winter,
by fit-laying, shortening the tops of each layer within a
little of the ground: they are mostly rooted by the autumn
following, and fit to plant out in nursery-rows, being then
manured as the seedlings.

When cuttings are employed, the strong young shoots of
the year should be chosen in autumn or spring, and planted
in a moist good soil; or any scarce sorts may be planted
several together in pots, and plunged in a hot-bed, as they
more readily strike root in that way.

These two last methods are the proper ones for raising
the varieties with certainty.

These trees are of a quick handsome growth, and succeed
in almost any soil and exposure. They are some of them
employed for their fine appearance, others for the exquisitely
sweet smell of their flowers, and most of them for the use
of their wood. The plants of them are also occasionally made
use of in forming hedges in particular situations, but they
are not by any means well calculated for this purpose.

As timber trees, their wood is found highly valuable on
account of its softness, lightness, and toughness, for the making
of various sorts of household utensils, as bowls, basins,
&c. as well as for different purposes in the business of carving,
gilding, turning, spining, &c.

All these trees afford ornament and variety among other
deciduous trees in the shrubbery, plantations, &c.

TILLIACEÆ, in Botany, a natural order of plants, the
seventy-ninth in Jussieu's system, or the nineteenth of his thir-
teenth clas, of which Tilia, the Lime-tree, is an example.
See GNERIA for the full characters of this thirteenth clas.
Those of the order in question are thus given.

Galax either of many leaves, or in many deep segments.
Petales definite, diminutive, (wanting in Shanesia,) alternate
with the segment leaves of the calyx, and for the most part
agreeing with them in number. Stamens generally indefinite
in number, and distinct. German simple. Style frequently
single, rarely either multiplied, or wanting. Stigma either
simple or divided. Fruit in some instances pulpy; in others
capsular, mostly with several cells, having one or many
seeds in each, the partitions from the centre of each valve.
Corollum of the seed flat, surrounded by a fleshy albumen.
Stem arborescent or shrubby; rarely herbaceous. Leaves
alternate, simple, accompanied by stipules.

Section 1. Staminæ definite in number, more or less com-
bined in their lower part, or at the very base. These are
termed by Jussieu "double Tiliae." They consist of
Waldenia, Hermannia, and Mabernia.

Sec. 2. Staminiæ differ 들어 indefinite. Fruit of many
ells. Genuine Tiliae

Antichorus; Cordycus; Helicia; Triangula; Spar-
mannia; Shanesia; Aipeia of Aublet, which is Aepilia
of Schreber; Muntingia; Flacourtia of L'Heritier; Oenoba
of Forlank, Lamarck Illhfr. t. 471; Sturjus; Grewia; and
Tilia.

Sec. 3. Staminiæ nulli, indefinite. Fruit of one cell.
General allied to Tiliae.

Bisa; Laetia; and Banara of Aublet and Schreber.

The author hints that this order might possibly, with pro-
priety, receive a reinforcement of several polytelas polypo-
dandous genera, at present not well understood, and there
fore annexed to other orders, among which he and in
doubt. He names Sorania of Aublet (see Mappia); Car-
tina of the same (see Doliocarpus); Cleyera of Thum-
berg (see Ternstroemia); Vallea of Linneus; Dicerca
of Porter (see Elrocarpus); Coipaia, Mabernia (see Bonvelli);
Hosmiia (see Mryndenorum); Vantanea (see Lenniscia)
all of Aublet; and Trilæ of Linneus.
The reader will be able to form his own opinion on these
matters, by turning to these articles in their proper places,
much of the genera and their affinities having become better
known since the publication of Jussieu's work.

The characters of his Tiliae are hardly to be distinguis-
hed from those of his next order Ciflæ, the principal difference
confiding in the straight corollum, and more copious albumen,
of the former.

TILLLABARUM, in Ancient Geography, a town of
Africa Propria, upon the route from Tacape to the Greater
Leptis, between Thebelamum and Adaghmagdum. Anton.
Itin.

TILLÆA, in Botany, was dedicated by Micheli (followed
by Linneus) to the honour of his friend and fellow-labourer
Michael Angelo Tili, who published a splendid and rich
catalogue of the garden of Pisa, of which he had the care,
in 1723. He was a member of the Royal Society of
London, as well as of the Botanical Society of Florence,
and corresponded with the chief botanists of his time, in
England, Holland, and elsewhere. He travelled to Con-
Succulenta, Linn. Semperivina, Juss.

Gen. Ch. Cal. Peria inferior, in four deep, flat,
ovate, large segments. Cor. Petals four, ovate, acute, flat,
rather
rather smaller than the calyx. Stem. Filaments four, simple, shorter than the corolla; anthers small, roundish. Petals four; style simple; stigma obtuse. Perci Capsules four, oblong, pointed, reflexed, the length of the calyx, burbling longitudinally along the upper edge into two valves, with one cell. Seeds two, or many more, in each cell, ovate.

Obf. T. muscofa has the parts of fructification usually in three, not four. Gertner discovered its flowers to be sometimes even five-cleft. He justly remarks, that such differences of number are in this natural order of little importance, and that Tillaea differs from Cragfalia in nothing but the want of nectariferous scales below the germs.

Eff. Ch. Calyx in three, four, or five segments. Petals as many. Nectaries none. Capsules three, four, or five, burbling inwards. Seeds several in each capsule.

3. T. Vialissii. Stalked French Tillaea. Willd. n. 3. (Sedum minimum annuum, flore roso tetravapalo; Vaill. Paris. 182. 1. 13. t. 3.)—Stem erect, much branched. Leaves ovate, clasping the stem, shorter than the flower-stalks.—Native of France. Observed by Vaillant, in the forest of Fontaines-Poues, where water has stagnated in winter, flowering in March to August. Root annual, of a few small tufted white fibres. Stem an inch or two high, repeatedly branched, scarcely forked, purplish. Leaves in pairs creasing each other, very thick, pointed, gibbous underneath, dark green, about two lines long. Petals four, rose-coloured, with a dark-coloured mid-rib. Seeds numerous, black, very minute.—The broader thicker leaves, and the much longer flower-stalks, render this very distinct, as Wildenow observes, from T. aquatica.

4. T. peduncularis. Long-stalked Brazil Tillaea.—Stem erect. Leaves lanceolate, acute. Flower-stalks often twice the length of the leaves. Capsules abrupt.—Gathered by Commeron, in marshy spots that had been overflowed, at Monte Video. This grows in tufts, and has very much the habit of T. aquatica, for which possibly it may have been taken. There appears nevertheless much difference between them. The whole herb, in the present instance, is red, and the flowers rose-coloured, growing on long stalks, which, though indeed variable, are never less than half the length of the leaves, and often twice their length. The shape of the leaves agrees with aquatica; but the capsules when expanded are more abrupt, and even irregularly heart-shaped.

Stems procumbent, branched. Leaves obtuse. Flowers mostly three-cleft. Calyx and petals taper-pointed.—Native of sandy barren ground in the more temperate parts of Europe, flowering in summer. Abundant on sandy heaths near Norwich, Bury, Brandon, &c. The variety 3 is brought from Africa, from Lima, and even from New South Wales. We can find no difference in the dried specimens, except their being larger than our's, with somewhat of a glaucous hue, and the flowers partly flaked, more numerous, and all, as far as can be examined, five-cleft and pentandrous, just like Gertner's plate of T. muscofa.

The British specimens of the muscofa are from one to two inches high, strongly tinged with a blood-red, ascending, branched, with a fibrous annual root. Leaves elliptical, thick, obtuse, somewhat channelled above; clasping their stem at the base. Flowers mostly three-cleft, sessile; their petals white, with a taper red point, less than the calyx. Seeds only two in each capsule.

We scruple to retain in this genus four other species admitted by Willdenow. The first is T. capenfa, Linn. Suppl. 129. Willd. n. 4; evidently, as Thunberg calls it, a Cragfalia, by its purple triangular nectaries, though, on account of its four-cleft flowers, made a Tillaea by Linnaeus and Willdenow.

T. perfoliata, Linn. Suppl. 129. Willd. n. 5; T. umbellata, Willd. n. 6; and T. decumbens, Willd. n. 7; all referred to Cragfalia by Thunberg, have none of them fallen under our inspection; but as Willdenow avows having been guided by number, we have no scruple in removing them hence.

So also Cragfalia muscofata, Forst. Magell. 167; gathered by that author, as well as by Commeron, Menzies, Banks, and Solander, at Staten land, is most certainly a Cragfalia, because of its nectaries; though, on account of its four-cleft flowers, it has been taken by some great botanists for a Tillaea.

**TILLAGE**, in Agriculture, the practice of tillimg or cultivating land, especially of the arable kind, or the means of bringing it into a state of preparation for the growth of different sorts of arable crops.

Of all the arts, says Vattel, tillage, or agriculture, is the most useful and necessary. It is the nursing-father of the state. It forms the surest resource and the most solid fund of riches and commerce, for people who enjoy a happy climate. This object, therefore, deserves the utmost attention of government: and it ought carefully to avoid every thing capable of discouraging the husbandman, or of diverting him from the labours of agriculture. Those taxes, those excessive and ill-proportioned impositions, the burden of which falls almost entirely upon the cultivators; and the vexations they suffer from the commissioners who levy them, take from the unhappy peasant the means of cultivating the earth, and depopulate the country. Spain is the most fertile and the worst cultivated country in Europe. The church poffeffes too much land, and the undertakers of the royal magazines, who are authorized to purchase, at a low price, all the corn they find in the possession of a peasant, above what is necessary for the subsistence of himself and
is, finally, to greatly discourage the husbandman, that he sows no more corn than is necessary for the support of his own household. Whence frequently arises the greatest scarcity in a country capable of feeding its neighbours.

Another abuse injurious to agriculture is, the contempt cast upon the husbandman. The inhabitants of cities, even the most servile artists, and the most lazy citizens, consider him that cultivates the earth with a disdainful eye; they humble and discourage him. They dare to despise a profession that feeds the human race; the natural employment of man. A little insignificant mechanic places far beneath him the beloved employment of the first confuls and dictators of Rome. China has wisely prevented this abuse; agriculture is there held in honour, and to preserve this happy manner of thinking, every year, on a solemn day, the emperor himself, followed by his whole court, sets his hand to the plough, and fows a small piece of land. Hence China is the best cultivated country in the world: it nourishes an innumerable multitude of people, that at first appears to the traveller too great for the space they possest. Besides, the cultivation of the soil is an obligation imposed by nature on mankind.

The most proper forts of soils for the purposes of tillage-cultivation, are all those of the more dry and friable kinds, whether the depth of earth or mould, or what is often termed flake in them, be only light or considerable; as under different circumstances these differences fit them for the production of different forts of crops, the methods of cultivation in which are fully explained under their different proper heads.

In this view, all the various denominations of light soils, such, for instance, as gravels, sands, light chalks, and thin loamy lands, are well adapted, in most cafes, to the purposes of tillage, from their being, in general, pretty well suited to the various forts of grain, as well as to the raising of such green and root-crops as are necessary in the support and management of different kinds of live-flock. The more deep, loamy, chalky, and gravelly forts of land, where they can be kept sufficiently dry, and in a proper state, during the winter season, may likewise, in many cafes, be well employed in tillage-cultivation, especially when they do not produce and afford an abundant and useful fort of herbage for the keeping of animals, or other uses. All the lands of the sward-kind, or in the state of grats, which are liable to be infected with the mois-plant, or to become over-run with a moffy covering, may, in common too, be managed under the tillage-sytem with much advantage, and better than in such a state of grats.

In some cafes, lands may be suited to convertible tillage, or alternately that of grain and grats, with vast benefit to the farmer. It has been remarked on this fort of tillage by a late writer, that land may in this way often be turned to better account by ploughing and tilling it eight or ten years, and then laying it down to grats, in order to take up another part or portion, than by the common method, but especially where the land is subject to ant-hills; as the paring and burning destroys all such hills, and such land is sure to bring abundant crops of corn. And that there are very few situations that have dry land and soil fit for the plough, but what would bring more profit under tillage than by lying in the state of old grats; for when such good land as this is well laid down to grats, with plenty of good proper feeds, after a course of tillage, an acre of it will keep as much flock as four acres would which were produced in the natural way, and this is what makes its great value. Such tillage-land as this, it is said, is worth more money than the finest grats-land in the kingdom; as, on the fine marshes so much boasted of, the earliest of the summer-flock comes to market at the very time when all forts of vegetables are in plenty, such as peas, beans, and many others, and when meat consequentially is sure to fall in price; and great numbers of grats-fed beasts, or cattle and sheep, come together. Besides, the very best grats-lands send only two sheep in the two early months of April and May from an acre; but the best tillage-land will send ten from an acre, and have them ready any time in the winter, when meat is the dearest. Thus, it is contended that ten acres of turnips will send one hundred sheep in the dearest time to the market, but that it will take fifty acres of the best land in grats, to send the same number to the market.

It is therefore concluded that, in this way, the tillage-farmer sends three hundred acres of corn to market, and as many fat sheep besides, acre for acre, as the best grazing-land; and that by still other improved methods of management, as that of the culture of flax for the use of the feed in fattening live-flock, and some others of a similar description, the tillage-farmer may derive greater profit than by the turnip practice, from the large quantity of winter-fattened animals, and the vast supply of dung or manure which is thus raised and provided.

Although the necessity of good tillage in the preparation of land for cropping be now pretty well understood by the practical farmer, and has been inculcated occasionally under different heads in the present work, it requires to be well explained in some of its procceses. It has indeed been observed in the Agricultural Survey of the County of Hereford, after noticing that the Romans were convinced of the good effects of this fort of preparation, as Pliny has remarked the advantages of frequent ploughing and turning over the soil in Tuscany; and that, in this country, Evelyn suggested its power of so altering a soil from its former nature, as to render the hardest and harshest as well as most uncivil clay obsequious to the husbandman; that tillage also destroys weeds, and reduces the earth to small particles, rendering it sufficiently loose and porous to admit of the cafy growth and extension of the roots and fibres of the grain to be cultivated in or upon it. And that the spade is well adapted to these purposes, because it moves the ground eight or ten inches deep, turns it upside down, and covers the weeds with a quantity of earth, under which they rot, and contribute towards its fertilization and improvement; and that this mode is founded on the just idea or notion of the Flemings, that a farm should resemble a garden as nearly as possible. But that as the spade method is much too tedious and laborious, as well as too expensive, to be practised on the larger scale of a farm, the plough is therefore subtiltuted, as cheaper and more expeditious, but that, in general, it does not till the earth to deeply, and often moves it in large bodies or maffes, without sufficiently breaking it into pieces. In order to remedy this inconvenience, the celebrated Mr. Tull, is said, recommended a plough of his own invention, which had four coulters instead of one, and thus divided the earth raised by the shares into several narrow strips; but the resistence occasioned by the additional coulters was found to require a greater strength in horses than the profits of the experiment and work would warrant. It was, however, afterwards ascertained by a distinguished foreigner, Mr. de Chateauneuf, that the breadth of the furrow should be proportioned to the fineness of the soil or land; and that thus the resistence may be regulated on all kinds of land or soil. But the operation of repeated crosses-ploughing, and the use of other tools, as now generally practised, aided as they are by full expoure
exposure to frost, rain, &c. to effectually break down the hardest clods, that other measures are, it is thought, rendered less necessary. Since the above was written, however, many useful instruments have been formed, by which tillage-cultivation is not only rendered more effective, but more easy and expeditious, as may be seen by the descriptions which have been given of them under their different proper heads. See Drag, Scarifier, Scurifier, Spike-Roller, &c.

M. Duhamel has since too observed in his "Elements of Agriculture," that some believe it is more advantageous to increase the fertility of land by frequent ploughing and other means than by manure; because, in general, only a certain quantity of manure can be procured; as twenty acres of land will, in common cafes, scarcely produce as much manure as is necessary for five; whereas the particles of the earth may be divided and subdivided almost to infinity. The aids, therefore, which are derived from manure, must, it is supposed, be limited, whilst no bounds can be set on the benefits that may accrue from ploughing or breaking down and reducing the parts of the soil. This appears, the writer thinks, to be over-rating the advantages of breaking the soil down in other ways; but, it is certain, that when the particles of land or soil adhere to closely together as to impede the extension of the roots of plants, income of the food and nourishment they require, the plants themselves cannot grow with proper vigour, or yield a proper produce. This is therefore to be corrected by frequent ploughings, &c. And that, lastly, repeated ploughings and other such means enable the land to receive and retain all the benefits to be derived from the floating vapours and dews of the atmosphere, which falling on hard ground, where it cannot readily penetrate, is quickly exhaled by the next day's sun and wind.

Notwithstanding these remarks, it may, however, be noticed, that no tillage or breaking down of the parts of the soil, though ever so complete and effectual, can wholly supply the place of manure, although it may greatly contribute, in different instances, to affist its fertility.

These are some of the more general and particular ways in which tillage becomes so essential and effectual in promoting the fertility and improvement of land; but there are a few others, the procresses of which may be seen under their proper heads.

In the tillage-cultivation for most sorts of crops of the grain or corn kinds, as well as some others, it becomes effectually necessary that the soil should be reduced to a very considerable degree of fineness, or what is frequently termed tilth by writers on husbandry; as, where this is not the case, they cannot be so well provided with food or nourishment, or be kept so perfectly and so sufficiently clean and free from weedy matters. There are other reasons too that require, at least, the more superficial parts of the soils to be in a fine condition of tilth for the receiving of such crops, which are those of the young tender roots of the new rising plants being thereby rendered more capable of fixing themselves perfectly in the mould which is produced, and of their drawing from it a more regular supply of food, in consequence of the more equal diffusion of moisture and other substances through it, which must necessarily take place. Besides, it is favourable in other ways, as by such tillage the seed-corn is not only more capable of being perfectly but equally covered, in consequence of which the vegetation and growth of the young plants of it are more equal and expeditious.

But besides the rate and condition of the soil or land in regard to tilth, it should be in a suitable situation in respect to dryness; as where there is too great a degree of moisture in it, the tillage can neither be performed in a proper manner, nor the feed-corn be put in without the danger of sustaining injury by becoming rotten before the vegetative processes take place, as not unfrequently happens to pea and other garden crops, when put into the soil during the moist winter months: and where, on the contrary, the land is too dry a rate, the tillage is improper to be effectual, as causing too much exhalation, by which the feed-corn, when put in at such periods, may be much injured by the want of that moisture which is necessary for perfect vegetation. Under the last circumstances too, it may be more liable to be destroyed by worms, grubs, and other insects. On these accounts the arable farmer should, of course, be equally attentive to the tillage preparation of the soil, and the condition in which it may be cropped to the greatest advantage, and with the greatest chance of success.

The writer of the "Elements of Agricultural Chemistry" states, that in all cafes of tillage, the feeds should be put in so as to be fully exposed to the influence of the air. And that one cause of the unproductiveness of cold clayey adhesive soils is, that the feed becomes coated with matter impermeable to air. All immediate tillage, for putting in crops, should consequently be performed as much as possible in suitably dry weather on such sorts of land.

In sandy soils, he says, the earth is always sufficiently penetrable by the atmosphere; but in clayey soils there can fearfully be too great a mechanical division of the parts in the procceds of tillage.

In general, the best and most effectual method of breaking down and bringing land into the rate of proper tillage, is by the use of the plough and different other implements of the harrow kind, such as those which have been noticed above, suited to the intention of the cultivator, and the peculiar nature of the land or soil. The tillage with the plough should consistently be performed according to the nature of the soil, and that of the crop which is to be sown or set, and the operations which are afterwards to be executed upon it. But to whatever depth this may be proper to be done, it is of much consequence to have it performed in an exact and effectual manner; as on this not unfrequently depends the difference between a good and bad crop, as well as that between the animals employed in the labour moving with ease and with difficulty. The repetitions in the tillage of this sort must be constantly regulated by the quality and circumstances of the land and the designs of the farmer, as some sorts and cafes of land require much more tillage than others. This point is most decidedly evinced in the Agricultural Survey of the County of Gloucester. On the Cotswolds, it is the practice, the writer remarks, to sow their crops one ploughing, experience having proved that frequent ploughings or tillage on these light soils, weaken the plaster of the land, and are productive of injury.

On the strong lands or soils of the county of Essex, the most intelligent and successful practical farmers, it is said, are those who are the most careful in the repetition of tillage of the plough kind, to which they constantly attribute great powers and effects. The strong heavy lands have it eight or more times in many cafes, even for barley or oats; and on those which are light, the general system of tillage is mostly four or five times for the different fallow crops. In this last intention, it is not unusual to commence the first tillage ploughing towards November, continuing it nearly or quite to the end of March, after barley sowing; and if at the first period of such tillage the ridges be laid a little round, so as to be water-flows and, after that well water furrowed, the tillage is greatly promoted. The land is mostly first

Vol. XXXV.
TILLAGE.

first broken up into ridges of eight or twelve nine-inch furrows; then crossed, and the ridge given in different ways very often during the former season, carefully turning up and exposing every time a different surface, as much as possible, to the sun and air: before harvest it is got up on four-furrow ridges, when, after that season is over, it has again immediately another tillage ploughing; and if the weather be suitable, it is done twice, leaving it upon the ridge for the ensuing winter; the latter the last tillage furrow is given the better, in this district, for preventing the black graps-weed getting up; after which the whole is well water-furrowed for taking off any water that may be upon it: by these means the land is much earlier got upon in the spring season than could otherwise be done, and in confequence, when the tillage for barley is performed, such stiff tenacious lands break down into the finest tith it is almost possible to conceive.

In executing the work of tillage on ridges for wheat, or any other sort of crop, great attention is here bestowed on turning the furrows well, drawing them straight, making them alike in size, and lapping them with such regularity on to each other, that the harrow tools cannot fail to lay hold of them all with facility; the flutting-up furrow more especially is drawn with perfect straightness, exactly turned, swept out with cleeves, and at the same time the space between the ridges kept in too wide a flane.

But notwithstanding this great and frequent tillage, in some places they do not venture in the seed on the autumnal furrow, but give a spring plough tillage, though perhaps some other tool of the tillage kind might answer better in many cases, and be far more expeditious.

The most proper and suitable depths of tillage for different sorts of soils, have probably not yet been well ascertained; but such as have a good strong staple, require much more deep tillage than those of the light kind. Whether flat-work tillage, as practised in Norfolk, or that of feathered, as employed in Essex, has the advantage, is not properly decided, but probably each may have a superiority on different sorts of land; the great point of importance is that of allowing the covering of the seed well.

The plan of tillage given below has been advised in the Corrected Agricultural Survey of the County of Salop, for the lighter sorts of friable lands, on a farm of four hundred acres: first, the wheat stubble is to be harrowed by drawing the harrows one way, which lays the stubble; and by returning back along the same stroke, they draw the greater part of that which was gathered by the harrows; and a proper person following them with a fork, unloads them, and lays the stubble in heaps, to be dispersed as directed below.

This stubble ground has the tillage of ploughing from the middle of November to the end of the following month; about the beginning of March it has that of cross-ploughing given it, and when dry, well harrowed; and when the weather is suitable, much of the couch-grafs is got out of it and burnt; but when not so, it is, in this way, checked in its growth during the seed-time, and the hufmefs is more easily performed; which is to be done in the month of May and the two succeeding ones, in which the fallow lands have the tillage of three ploughings and sufficient harrowings to prepare them for turnips, for which eight cubic yards of reduced dung, or seventy-two bushels of clover-lime, are laid upon the acre; which are ploughed in at the last tillage-furrow, though sooner, it is thought, would be better, if the dung be reduced enough by that time, or the land be so clean as not to require much harrowing. Turnip-feed, one pound to the acre, is then sown from the 7th of June to the 14th of the following month, the plant being twice hoed; the average produce is from 21 to 21. 15s.

As the same land becomes cleared of its crop of turnips, it has the tillage of ploughing and harrowing, preparatively for a crop of barley: and being again tilled, by being ploughed up in butts or lands five yards in width, from the latter end of March to the latter end of the following month, is sowed with three and a half statute bushels of barley, fourteen pounds of common red clover-feed, and one peck of fine rye-grafs-feed to each acre: the average produce is about forty bushels, of the statute kind, of barley to the acre.

The young clover which is not eaten between December and May, in the part which is mowed, on an average produces about two wagon-loads, or a ton and a half to the acre. In the succeeding month of October, it is ploughed in the tillage of nine-inch furrows and five inches deep, and sowed with two and a half bushels of wheat; the produce about seventeen bushels the acre.

The turnip-crop is generally dispofed of somewhat in this manner: first, by drawing home theoje under the hedges, at the beginning of November, and some of the largest over the rest of the field, taking all up where the hedges and carts are to pass. When the tops and small roots are cut off, they carry them home, and place them in heaps of about twelve cart-loads each, in the form of the cone of a wheat-rick, covering them a foot thick with straw and thatch. These serve as a resource in time of frost and snow, for the beasts that are stall-fed, of which there are generally twenty yearly; and a man and boy, with one horse and cart, supply them; leaving ultimately in the fields as many turnips to be eaten off upon the land by sheep, as to ensure fertility enough for the crops of barley, &c. as the barley, being too rank, commonly spoils the young clover growing with it. Another advantage in this plan of tillage, which is obtained by stall-feeding with turnips, is the making a large quantity of straw into manure at home; which is the best use that can be made of it, as straw-food is not an improver of cattle-rock.

This method of tillage or cultivation for dry lands, is recommended to those who have been in the practice or custom of long tillages, and without the ufe of general turning, to be continued for so long as two courses of tillage, that is, eight years; by which time their land will be clean, and more fit for what is conceived to be a more beneficial mode of husbandry, and which mode is now, it is said, pursued; namely, fifth turnips, managed and manured for as above; second, barley; third, pife; in rows one foot and a half, land-hoed, and weeded; fourth, barley, with ten pounds of common clover, four pounds of white Dutch clover-feed, two pounds of trefoil-feed, and one peck of fine rye-grafs-feed, eight cubic yards of rotten dung, or seventy-two bushels of stone-lime laid upon the young clover in November; fifth year, now or graze the land; the sixth, graze until October; and the seventh, give a plough tillage, and sow with wheat as before; the land muck'd for turnips, and lime or compost of lime, and earth or mud, &c. laid on the young clover in the autumn. This is believed to be a more profitable course of tillage, after land has been got into order, than that which was previously practised, affording a greater change, and thereby obviating the failure both of turnips and clover, and occasioning more grass-land, which for many years has there exceeded the tillage in point of profit.

As an improvement of wheat-lands, or mixed foils upon clay, the mode of tillage directed below is advised to be practised.
The turf or other land being well ploughed or tilled, and laid dry before Christmas, in the following month of April sow the land with four and a half statute bushels of oats, plough and lay it dry in the autumn, and in the month of May and the two following ones, give it three good tillage ploughings and harrowings, with some rollings, &c. so as to reduce it well; being thus drawn up and laid dry, it may continue in that state to the middle of September; though made both fine and clean, it sometimes gets such an adhesive and binding quality, and consequently works lumpy, and therefore has the texture and quality which the farmer, by milikake, is afraid of losing by making his land clean. It is, however, it is said, in the three above months, when the sun is powerful, that land is to be cleared of tillage: a ploughing in August is seldom of much worth.

If manured with lime, lay eighty bushels upon the acre; if with dung, ten cubical yards to each acre, either ploughed under at the July tillage ploughing, or before. From the 20th of September to the 10th of the succeeding month, sow wheat nine statute pecks to the acre, after having hoaked the fame not more than eight hours in mild brine, and dried it with lime, to prevent the blight. The next autumn plough the corn stubble, and at the end of March plant beans or peas in rows one foot asunder, hand-hoe and weed them. Plough in the autumn, and now oats in the spring, and lay down with ten pounds of red clover-feed, four pounds of white Dutch clover-feed, and one peck of rye-grafs-feed to each acre. Manure the land in seeds in the autumn, and let it lie in fward two or three years, as it may be required. At the next breaking up, plant the land with beans, hand-hoe and weed them; the ensiling autumn sow it with wheat, then with beans in rows, hand-hoe and weed that crop; then put in oats and lay down with feeds, as before. In lieu of one of the hoeing crops, if the land be not too wet, potatoes may be planted, which would be found very profitable to the wheat-land farmer; being very useful food for feeding or milking cows in the winter season. The farmer should follow for the first crop in one tillage, and hoe the next, and so proceed alternately; the summer fun to wheat lands being certainly useful, and also the manuring with dung or lime in an alternate manner. Where marle is to be procured at convenient distances, nothing turns to more profit upon open foils, with either clay or dry bottoms, marle laid upon the fward in the autumn, and to lie one year, is commonly the best practice, especially if the marle be not perfectly good. Lime is sure to pay well the next tillage course.

On this mode of tillage it is, however, remarked, that good farmers, on light soils, will entertain the plan here prescribed with some caution, and that their apprehensions of a crop of couch will often outweigh their hopes of a crop of clover. That peafe are precarious; one week's hot weather whilst in blow is often fatal to the crop.

It is added too, on the authority of Mr. Harries, after noticing the insufficiency of some fellow tillage lands, that there are many active farmers who begin the tillage on their fallows in January, and by repeated ploughings, harrowings, and rollings, bring them into very good order for wheat. Others graze the second year's clover until about the middle of the summer, and sometimes mow it at that time: if the soil be dry and the summer favourable, they bring it into very good tillage order by feed-time. It would, however, it is thought, be better tillage husbandry to raise a crop of turnips on such lands, after wheat or barley. If this was done, at least in every course of tillage, a good crop of wheat would be grown upon clover layers, upon one tillage ploughing, at a light expense. It is frequently his custom to break up his clover layers of the first or second year, if they are tolerably clean, upon one ploughing, putting upon the plough a cutting tool or instrument, which is there termed a fur or flay, that cuts or pares off the surface turf, and lays it in the bottom of the fward. Lately, a clover layer was worked with this instrument upon the plough, and after the feed was harrowed in, scarcely any of the surface turfy matter came upon the ploughed surface, the field looking as well, and appearing as clean, as though it had been fown upon fallow tillage.

Some, however, on hollow lands, do not approve of this skimming or paring tillage; as flicing the surface of such soils they consider much worse than turning it over in the ordinary manner, and letting the surface vegetable matters be laid into the furrows in a fort of diagonal position, though some of them should even appear out in the seams. The notion is notwithstanding probably erroneous, as such surface produce is always, in some way or other, to be rorted and got rid of, as in every mode of tillage it is ploughed in or under, and the main point is how to get the most speedily and completely quit of it, and to render it the most useful to the crop which is to be put in. These are certainly the belt and most fully accomplished by taking it wholly off by such a cutting apparatus, and placing it at the bottom of the furrows, which must also leave the hollowness of the land at the same time.

In the breaking-up tillage of old gras-lands, it must be executed in a manner suitable to the nature, state, and quality of the soil, whatever that may be, reducing and breaking the turfy fward well and carefully down, and clearing it effectually from defects and vermin of all forts by proper crops, such as those of the pea, bean, teasel, and other similar kinds, before the introduction of those of the grain fort. In this way, the lands will not only be the belt brought into a proper state of tillage, but the corn-crops the most effectually secured from the danger of worms, grubs, and other noxious vermin.

It has been remarked by the writer of the Corrected Agricultural Survey of the County of Norfolk, that for the last four or five-and-thirty years that he has examined West Norfolk with the eye of a farmer, the change in the tillage system, which has taken place in that vall arable diocrit, has not been great. At the early part of that period, the tillage course was, it is said, first, turnips; second, barley; third, grasses for two, or, in a few cases, three years; fourth, white corn: on the better foils, wheat; on others rye, &c. The only material change that has occurred, has been, it is thought, in the grasses: the variation, which, it is believed, first took place from forty to fifty years ago, was shortening the duration from three years to two; in both cases giving what may be called a fort of half-fallow the last year, by means of a half-ploughing, soon after the middle of the summer. Above thirty years ago, the writer, it is said, contended, both in print and in conversation, against it, but was held cheap for entertaining any doubts of the propriety of the practice. He has lived, however, it is observed, to see this change also in a great measure take place amongst the best farmers, who now give only one ploughing for the winter corn, whether wheat or tares; or in the spring for peas. That it is an improvement cannot be questioned, it is thought. The argument for it, founded on the invention of the drill-roller, and on the introduction of the drill-plough, is good, it is said, but not singular, as the practice of dibbling is like-wise far more adapted to a whole than to a broken furrow; and for broad-cast common sowing, if we are able to cover the feed by harrowing on stiff soils, once ploughed, it is evident the same practice might be better followed on sand. The

4 N 2
other reason for the former system, spear-grass getting a head in a layer, is quite inadmissible; it is thought; as he must entirely agree with Mr. Orman, a large tillage cultivator in that district, that no weeds, the feeds of which are not carried by the wind, will be found in a layer, if they were not for them.

It is contended likewise, that the variations which have taken place in the village crops put in upon layers, are neither great, nor are they peculiar to the above county; the principal one is that of raising peas on the flag, and then the wheat, and others. an admirable system, which, it is said, has long been practised by good farmers in Suffolk, and, it is believed, till earlier in Kent. That Mr. Purdie's mode of substituting tares holds on the same principle. Considering the very great size and value of white pease-straw, well got, as sheep food, which is no where better understood than in Kent, it is thought there is no tillage husbandry better adapted to a sheep-farm, than this of peas or tares preceding the wheat crop.

But it is thought that a very great and important change has taken place in the application of village crops to sheep instead of bullocks and cows. Formerly the farmers consumed much of their straw by cattle; now the best of them have it all trod into marnure. Sheep are the main grazing flock, and no more cattle kept than for treading, not eating straw while feeding on oil-cake and other such food. This has, it is contended, a very important change, which has had a considerable effect, and which has depended not a little on the introduction of South Down sheep. Yet, it is, as it were, the grand object in the whole tillage system, the singular readiness with which the farmers of West Norfolk have adhered to the well-grounded antipathy to the taking of two crops of white corn in succession: this is talked of elsewhere, it is said, but no where so steadfastly adhered to as in this district. It is this maxim, it is said, which has preserved the effect of their meal on thin-soiled lands of the wheat kind in such a manner, that the district continues highly productive, under an almost regularly increasing rent for more than sixty years, or three leaves of twenty-one years each; and by means of which great tracts have been made da fecond, and even a third time with much advantage. This tillage system, it is supposed, has been that to which the title of Norfolk husbandry has been long, and it now peculiarly appropriated; and by no means that of the management of the very rich district of East Norfolk, where the soil is naturally among the finest in the kingdom, and consequently where the merit of the farmer must be of an inferior stamp; barley there, it is said, very generally follows wheat; an incorrect tillage husbandry, detracting no praise, but condemnation. The celebrity of the county in general was not heard of, it is said, until the vast improvements of heaths, walks, sheep-walks, and warrens, by enclosure, and marling took place in consequence of the exertions of Mr. Allen, of Lyng-Heane, lord Townshend, and Mr. Morley, who were in the first thirty years of the preceding century. They were happily, it is said, imitated by many others; an excellent system of tillage management introduced, and such improvements wrought, that effates and lands which were heretofore too insignificant to be known, became objects of public attention in the capital. The fame of Norfolk, it is remarked, gradually expanded, and the husbandry of the county was celebrated before East Norfolk was heard of by beyond the conversation of Norwich and Yarmouth. It is, it was said, that without a continuance of constant tillage management and persevering exertions, West Norfolk would even again become the residence of poverty and rabbits. But let the meadows be improved; irrigation be practiced wherever it is applicable; the remaining wastes cultivated; and this district will, it is maintained, become a garden. Such are the utility and importance of good tillage and other systems in the cultivation and improvement of land.

In conclusion, it may be flated from the Corrected Agricultural Report of the County of Hereford, that the importance of the tillage farmer cannot be disputed; and yet that perhaps no branch of the art of husbandry is clogged with so many obstacles and impediments to its improvement and success. The advantages of the grazing system over that of tillage-cultivation, hold out a great inducement to the farmer to convert his tillage land into pasture, the immediate effect of which must be felt in the reduced quantity and increased price of grain of every description. And unfortunately, this is not the only obstacle or hindrance to the tillage farmer; the tax on horses used in agriculture operates also against the proper tillage culture of the ground. It was probably suppos'd, it is said, by the framers of this duty, that the number of horses would thus be diminished, and that of oxen increased; but it should be recollected that oxen, valuable as they sometimes are as auxiliaries, can never be made the substitute of horses for tillage; their constitution and habits will not admit of it; and the shoe with which they are occasionally furnished, affords but an imperfect protection to the foot on hard lands or stony roads. See Team.

No check, but every encouragement, should certainly be given to tillage, or the means of raising and providing the broad-corn for the increasing population of the country. See Supply and Compopulation.

TILLAGE Farm, that fort of farm which is, for the most part, cultivated under the arable or tillage system, or that by means of the plough. See Farm.

TILLANDSIA, in Botany, was so named by Linnaeus, in memory of an early Swedish botanist, Dr. Elias Till-lands, professor of physic at Abo, who died in 1692, aged 52, after having published in 1683 an octavo alphabetical catalogue, in Latin and Swedish, of the wild, as well as cultivated, plants of the neighbourhood of his residence. This little volume was accompanied, or soon followed, by another, containing a rude, but often expressive, wooden cuts, of 158 plants, mentioned in the foregoing catalogue. It is a defect in these cuts that they are not always original; an influence of which occurred to the writer of the present article, while preparing a critical dissertation on some British species of Hieracium, see Tr. of Linn. Soc. v. 9. p. 232. The Pilofella, t. 14. of Tillands proving a copy of Tabernemontus, rendered his work of no authority in an important point; though such a defect was not previously known, even to his learned countryman the late Mr. Dryander; and the book funk immediately in his effimation, except as a rarity.—A curious reason for the name of Tillandsia, as applied to the genus of which we are about to speak, is given by Linnaeus himself, in his Protectiones in Ordines Naturae Plantarum, published by Giseke, p. 291. "Tillandsia cannot bear water, and therefore I have given this name to the genus, from a professor at Abo, who in his youth having an unprofitable passage from Stockholm to that place, no sooner set his foot on shore, than he vowed never again to venture himself upon the sea. He changed his original name to Tillandsia, which means on, or by, land; and when he had subse- quently occasion to return to Sweden, he preferred a circuitous journey of 200 Swedish miles through Lapland, to avoid going eight miles by sea." This circumstance is also alluded to in the Tour in Lapland, published from the journal of Linnaeus in 1811, v. 1. 43. One of the most inviudious cenfor
TILLANDSIA.

Gen. Ch. Cal. Perianth inferior, of one leaf, oblong, erect, permanent, in three oblong-lanceolate, pointed segments. Cor. of one petal, tubular; tube long, inflated: limb small, erect, in three obtuse segments. Stam. Filaments fix, linear, inserted into the tube of the corolla, and of the same length; anthers acute, incumbent, in the throat of the tube. Pfr. German superior, oblong, tapering at each end; style thread-shaped, the length of the flaments; stigma three-cleft, obtuse. Peris. Capsule elongated, bluntly triangular, pointed, scarcely separated into more than one cell, of three valves. Seeds few, cylindrical, each supported on a long flake of aggregate fibres, forming a feathery wing.

1. T. tenuisulata. Bottle Tillandsia. Linn. Sp. Pl. 409. Willd. n. 1. Ait. n. 1. (Viseum carphylophoides maximum, flore tripetalacto pallido luteo, femine filamento; Sloane Jam. v. i. 188.)—Leaves linear, channelled, recurved; dilated and inflated at the base. Stem closely paned.—Found on the borders of large trees in Jamaica, where it is known by the name of Wild Pine. Sloane observes that the long, tough, smooth fibres of the root, which is perennial, do not infestate themselves into the bark or wood, to draw nourishment from thence, but merely grasp the branch, fixing themselves firmly to the bark for support. Stem solitary, round, smooth, leafy, three or four feet high. Leaves numerous, often a yard long, channelled, entire, tapering to a very tender point, recurved, striated; paler beneath, and clothed with extremely minute chaffy scales like powder; the radical ones greatly enlarged and tumid at the base, where they form a sort of oval hollow vessel, which holds a quantity of water, collected during the wet season, from the rain trickling down the channels of the leaves. In this it is said that small aquatic animals sometimes take refuge, while birds, and even men, are reported to have derived a welcome supply of drink. The water seems destined to support the plant during drought, when it would otherwise obtain nothing by its roots; but this tender stock is enough to preserve life, and indeed a considerable degree of luxuriance. The flowers are of a pale greenish-yellow, with purple anthers, and compose a close branched panicle. The long branching down which accompanies each flower, and is inserted into its base, carries it to a distance, and readily clings to the rough barks of trees, where the feel speedily vegetates. When the stem is wounded, a clear white mucilaginous gum exudes. Sloane.

2. T. serrata. Serrated Tillandsia. Linn. Sp. Pl. 409. Willd. n. 2. Ait. n. 2. (Caraguata elata et fiscata, folis serratis; Plum. Ic. 63. t. 75. f. 1.)—Leaves flat, smooth, with strong spinous serratures; entire towards the base. Spike compound. Bractees with spinous teeth.—Native of Jamaica. Brought to Kew, with the foregoing, by captain Bligh, in 1793. This is a large flower perennial plant, with the aspect of an Albeg, but not fo succulent. The leaves are two or three feet long, and two inches broad, their upper part especially bordered with hooked spines; their under side curiously and minutely dotted between the numerous fine ribs. Stem and compound spike befit with broad, ovate, pointed bractees, with spines are more direct and tooth-like; the under side ribbed and dotted in the manner of the leaves.

3. T. Engallata. Tongue-leaved Tillandsia. Linn. Sp. Pl. 409. Willd. n. 3. Ait. n. 3. Jacq. Amer. 92. t. 62. (Caraguata latifolia elavata; Plum. Ic. 63. t. 74. Viseum carphylophoides maximum, capitulis in fummetate conglomeratiss.; Sloane Jam. v. i. 189. t. 122.)—Leaves flat, somewhat tongue-shaped, smooth, entire, as well as the crowded bractees.—Native of old trees in the vault forest of Martinico, as well as of Jamaica, where it is said to flow water, like the first species. In size it agrees with the second, but the entire leaves, and the clothed leaf head or spike of flowers, abundantly distinguish that before us. Jacquin says the flowers are yellow, inodorous, three inches long.

4. T. tienuifolia. Slender-leaved Tillandsia. Linn. Sp. Pl. 410. Willd. n. 4. Swartz Ind. Occ. v. i. 591. (Renalmia fissa multiplici, angustifolia, flore cuneo; Plum. Ic. 234. t. 238. f. 2. Viseum carphylophoides minus, foliorum inus viridibus spicibus fabrubicundis, flore tripetale purpureo, femine filamento.; Sloane Jam. v. i. 192. t. 122. f. 1.)—Leaves linear-thread-shaped, channelled, erect, taper-pointed. Spikes alternate, imbricated. Flowers two-ranked.—Parasitical, like all the foregoing, on the branches of trees in the West Indies. The stem is a foot high, simple, entirely concealed by the broad leafbase of the leaves which clothe it. The radical leaves are very numerous, above a span long, very tender, resembling those of some long-leaved kinds of Pinus, but more tapering and channelled; moderately dilated, fleshy, downy and rufly, at the base. Those of the stem are much shorter, and almost fetaceous, though their base is still broader. Spike three or four, alternate, sufflo, imperfettly two-ranked, lanceolate, an inch long, proceeding from broad fleshy bractees. Flowers imbricated in two rows, blue. Linnæus quotes by mistake a synonym of Jacquin, belonging to the following.

5. T. flexuosa. Zigzag Tillandsia. Swartz Ind. Occ. 592. Willd. n. 5. Ait. n. 4. (T. tienuifolia; Jacq. Amer. 92. t. 63.)—Leaves linear-lanceolate, channelled, recurved. Spike lax, zigzag. Flowers two-ranked, dilant. —On trees near the sea in Jamaica, as well as near Carthage in South America. Extremely unlike the last. The leaves are very broad and concave in their lower part, consoled about the base of the stem, green, elegantly marked with broad, whitish, minutely scaly, transverse stripes; their points recurved in all directions. Stem twice as tall as the leaves, being two or three feet high, mostly subdivided in the upper part, inviolate with close red sheaths, and terminating in two or three long, lax, zigzag spikes, with triangular falks. Flowers about an inch or more in number. Calyx coloured, near an inch long. Corolla still longer, with reflexed segments, at first blue, then red, as we presume from Dr. Swartz's description and the analogy of T. flava hereafter described. Capsule long, of three cells, the valves black and shining on the inside.

6. T. feaece. Setaceous Tillandsia. Swartz Ind. Occ. 593. Willd. n. 6. —Leaves linear-thread-shaped, recurved, nearly smooth. Spike simple, with two-ranked imbricated bractees.—Found on trees in Jamaica. Stem a foot or more in height, round, nearly upright, clothed with alternate, broad, bristle-pointed bractees. Radical leaves nearly equal in length to the stem, numerous, fleshy at the base, greyish, rigid, somewhat mealy as it were, with very minute scales.
TILLANDSIA.

teces. Spike terminal, solitary, ovato-lanceolate. Flowers alternate. Moth like T. tenella, L. n. 4, but differing in its recurved leaves, and simple solitary spike.

7. T. paniculata. Equated Tillandsia. Linn. Sp. Pl. 418. Willd. n. 7. Lamarck v. 1. n. 6. (Renalmia ramosiflora, flavus variegatus et circinatis; Plum. Lc. 233. f. 135.)—Radical leaves very short, lanceolate. Stem panical, twice compound. Spikes erect. Segments of the corolla linear, spiral.—Native of South America. We know nothing of this species but from Plumier, whose figure represents numerous, crowded, erect, concave radical leaves, and a stem alternately branched from the very bottom, with two-ranked reclining branches, laden with ascending spikes. A copy, in our possession, of his original drawing shews the flowers to be four inches long.—We have no good authority for Browne's synonym, cited by authors, nor does it, if correct, throw any light upon this very obscure species. Lamarck informs us, from Plumier's manuscripts, that the stem is sometimes taller than a man; that the calyx is spotted with green and purple; corolla of a violet blue, dotted with purple, its long narrow segments becoming spiral as they expand. This is the circumstance to which Plumier's definition alludes. His greatly reduced plate is not sufficiently exact to explain it, and Linnaeus inaccurately copied folis for floribus, in which Willdenow, of course, follows him without the least enquiry.

8. T. falcifolia. Falcate Tillandsia. Swartz Ind. Occ. 586. Willd. n. 8.—'Leaves lanceolate-awl-shaped, erect, straight. Spikes lateral, two-ranked, imbricated.'—Found on trees in Jamaica, in thickets near the sea-shore. Stem one or two feet high, leafy, simple. Radical leaves broad, concave, and sheathing, at the base; lanceolate and tapering upward, very slightly recurved; downy externally; those of the stem shorter, somewhat imbricated, ovate, with long awl-shaped points. Spike alternate, lateral and terminal, two-edged, an inch broad, with imbricated ovate bracts, membranous at the margin. Flowers solitary. Capsule an inch long. Swartz. Lamarck's T. clavata, cited by Willdenow with a mark of doubt, belongs to T. mongolchaya, n. 11, as evidently appears from Plumier's synonym, the figure belonging to which these writers overlooked.

10. T. polyfchia. Many-Spiked Tillandsia. Linn. Sp. Pl. 410. Willd. n. 10. (Renalmia epica multipeti, floro albo; Plum. Gen. 37. albo as Linnaeus supposieb. R. alia, epica multipeti, anguifolia; ibid. 37. Viscum carpylophloides anguifolium, floribus carulis: Catebl. Carol. v. 2. 89. t. 89?)—'Stalk bearing imbricated lateral spikes.'—Native of South America. We can make out nothing further of this species, nor how Linnaeus came to a knowledge of it, there being no specimen in his herbarium. Swartz however appears to be acquainted with the plant; for his remarks under n. 13. and 14.

11. T. mongolchaya. Single-Spiked Tillandsia. Linn. Sp. Pl. 410. Willd. n. 11. (T. clavata; Lamarck Dict. v. 1. n. 4. Renalmia clavata, floribus niveis; Plum. Ic. 233. f. 238. f. 1. R. non ranofa squamata, et floribus niveis; Plum. Gen. 37.)—Leaves radical, linear, channelled, recurved; broad and sheathing at the base. Stem simple, clothed with imbricated scales. Spike simple. Bracteas ovate, concave. —Native of the West Indies. Plumier gathered it on old trees in Hisspaniola. The numerous radical leaves spread widely in every direction, being about a foot long, and two inches broad, so much recurved that their points touch the branch on which the plant is fixed. Stem from fifteen to eighteen inches high, erect, round, firm, quite simple, as well as its spike. Bracteas white, streaked or dotted with red. Corolla snow-white; its limb in three deep ovate segments.

12. T. pruinos. Frosted Broad-leaved Tillandsia. Swartz Ind. Occ. 594. Willd. n. 12.—Leaves lanceolate, taper-pointed, recurved, clothed with flaggy scales. Spike simple, with imbricated, pointed, downy bracteas.—Found on the arms and stems of aged trees in Jamaica, as well as in Brasil. Stem a foot or more in height, simple, leafy. Radical leaves a foot long, spreading variously, near an inch broad at the bottom, but soon contracted into a long taper point, flat, densely clothed all over with flaggy, torn, peltate, shinning scales, the marginal ones flat, imbricated, and much dilated; stem-leaves much shorter and narrower. Spike terminal, solitary, simple, an inch long, ovate. Bracteas ovate, bluntish, concave. Corolla blue, longer than the bracteas. Capsule oblong, triangular, smooth.

13. T. canescens. Hoary Tillandsia. Swartz Ind. Occ. 595. Willd. n. 13.—'Radical leaves linear, erect, hoary, as tall as the stems. Spikes about three, terminal.'—Native of Jamaica, on trees near the sea-shore. Perennial, about a foot high, with short, simple, curling, fibrous roots. Stem simple, leafy. Radical leaves imbricated, linear, rigid, whitish or hoary; with very broad, ovate, concave, tumid, membranous, sheathing bases; stem-leaves tapering, acute, with more lax sheaths. Spikes usually three, crowded at the top of the stem, sessile, ovate, acute, flatish. Bracteas two-ranked, imbricated, ovato-lanceolate, smooth. Corolla red, with long segments. Nearly related to T. polyfchia, but that species is taller, with recurved, zigzag, smooth leaves, and numerous, scattered, lanceolate spikes. Swartz.

14. T. anguifolia. Narrow and long-leaved Tillandsia. Swartz Ind. Occ. 596. Willd. n. 14.—'Leaves linear-lanceolate, nearly erect, smooth, taller than the stem. Spikes somewhat cluttered.'—Found on the trunks and branches of trees, in Jamaica and Hispaniola. Perennial. Stem two feet high, nearly upright, simple, leafy. Leaves all imbricated, broad and sheathing at the base, lanceolate, narrow towards the end, straight, striated; the sheaths of the radical ones broadest, and rather inflated. Spikes numerous, scattered, somewhat cluttered, alternate, separated by leafy sheaths, imperfectly imbricated, compressed, lanceolate, many-flowered, an inch and half long. Flowers two-ranked. Bracteas imbricated, equitant, ovate, pointed, keeled, striated, smooth. Capsules elongated, pointed, triangular, smooth, extending beyond the bracteas. This likewise is cautiously to be distinguished from T. polyfchia, by having more upright leaves, longer than the stem, and the spikes separated by leafy sheaths. Swartz. Nothing is mentioned respecting the colour of the flowers.

TILLANDSIA.

roves, by lady Ncalk, about the year 1799. The root is somewhat tuberous, with many tough smooth fibres. Stem about six inches high, surroun ded, and almost concealed, by the dense tuft of very numerous radical leaves, which are sometimes all cur ved to one side, five or six inches long, pale green, frosted, as if it were, with hoary scaly pubescence, thickset towards the base. Spike three inches long, simple, many-flowered, with beautiful large white bracteas, tinged and tipped with rose-colour; the lower ones ending in leafy points. Calyx of the colour of the bracteas, but hardly so long. Corolla with obtuse, emarginate, convolute segments, at first of a rich deep blue, but finally changing to a deep red. Capsule dark brown, an inch long. This is, no doubt, very different from T. monophylla, though Linnaeus's account of that species may be, as unjustly hinted in the Bot. Mag., incomplete. T. flbrida flowers in November. It is said to live and blossom when suspended by a thread in a warm room. Few plants are more elegant or singular.

16. T. recurvata. Recurved-leaved Tillandsia. Linn. Sp. Pl. 410. Willd. n. 15. Ait. n. 6. Pursh n. 1. Swartz Obs. 121. (Vifcum caryophylloides minus, folvis pruinae infar candicantibus, flore tripetalo purpureo, femine frailmento; Sloane Jam. v. l. 190. f. 121. f. 1.)—Leaves radical, awl-shaped, scaly, recurved. Stalks naked, two-flowered. Native of the trunks of old rotten trees, in Jamaica and the Braful, as well as in Florida and Georgia, growing in dense tufts. The flens are very short, clothed with crowded, spreading, recurved, sheathing leaves, two or three inches long, downy with minute hoary scales. Stalks terminal. foliary, four inches high, slender, round, naked and smooth, each bearing at the top two upright flowers, enveloped in a pair of sheathing, furrowed, dotted bracteas. Segments of the corolla blue, obtuse, scarcely extending beyond the calyx. Anthers yellow. Capsule an inch long, slender, brown and shining, enveloped in the pale segments of the permanent calyx, which are as long, and nearly as broad, as the valves. Sloane says it draws its nourishment from rain water, falling into the cavity made by the leaves.

17. T. uineoides. Long-moifs Tillandsia. Linn. Sp. Pl. 411. Willd. n. 16. Pursh n. 2. (Vifcum caryophylloides tenuefimum, e ramulis arborearum usculi in modum dendronum, folvis pruinae infar candicantibus, flore tripetalo, femine frailmento; Sloane Jam. v. l. 191. f. 122. f. 2, 3. Cuceuta ramis arborearum innoacent, &;c; Pluk. Phyt. l. 26. f. 5; also f. 6.)—Stem much branched, thread-shaped, twifted, minutely scaly, as well as the awl-shaped channelled leaves. Native of shady woods from Virginia to Florida, as also of the West Indies and the Braful, flowering in July. The long winged contorted flens creep over the flems and branches of old trees, and even along a rope or hair line, if put in their way, the roots scarcely fixing themselves, or deriving any sustenance, from either. The flens are, according to Mr. Pursh, of a yellowish-green. When the hoary flaggoy cost of the plant is separated by beating or rubbing, the remains of the flens look like a mass of curling black horse-hair, and serve, like that, to stuff mattresses, &e; In this denuded state the flems are represented, along with the perfect plant, by Sloane as well as Pluknet.

M. Poiret, in Lamarck Dict. v. 7. 666—673, has greatly enriched this genus, not only with all the species published by Dr. Swartz, and which we likewise have adopted, but also with ten bevides, adopted from the Flora Peruviana of Ruiz and Pavon. That our work may not be incomplete, we shall briefly mention thee in the order in which M. Poiret has arranged them, trusting to him for the references, which we have not the means of consulting. He introduces them all, except the last, between the angulifolias, our n. 14, and recurvata, n. 16.

19. T. maculata. Spotted-leaved Tillandsia. Poiret n. 10. Fl. Peruv. v. 3. 40. t. 257.—Leaves radical, lanceolate-fivefold-shaped, shining; revolute at the point. Panicle alternately branched. Spikes nearly simple, many-flowered. Native of rocks and trees, in the middle of the great forests of the Andes, flowering from July to September. The leaves are channelled, polished on both sides, covered with red or purplish spots. Every part of the plant is often red. Stems three feet high, simple, jointed, with an oval scale, or bractea, at each joint. Panicle terminal, eighteen inches long, red, composed of alternate, nearly simple, spikes, furnished with numerous, oval-lanceolate, pointed bracteas, reddish as well as the calyx. Corolla violet, small.

20. T. rubra. Red Tillandsia. Poiret n. 11. Fl. Peruv. v. 3. 40. t. 266.—Leaves radical, sword-shaped, somewhat pointed. Panicle simple, spikes undivided. Native of rocks in Peru, flowering in March and April. The leaves are about two feet long, spreading or recurved; of a shining green above; silverly white beneath. Stems foliary, erect, two or three feet high; clothed with sheathing scales below; terminating in a straight reddish panicle, composed of many simple, alternate, oblong, lanceolate, divaricating spikes. Bracteas red, pointed, keeled, an inch in length. Flowers imbricated, seilloe. Calyx yellowish-red. Corolla small, violet, with reflexed segments.

Leaves solitary, in Peru, flowering in Jan. and July. The perennial root throws out many prostrate leafy joints. Leaves spreading, fix to nine inches long, with eight. Spike solitary, a foot high, simple, clothed with long-rolled leaflets. Panicled rosy-coloured, of from five to nine alternate leaflets, with oval, concave, white bracteas. Flowers sessile, with rose-coloured bracteas and calyx. Corolla white, with a white tube. Capsule purplish; deep purple within.

24. T. hypophtla. Seven-flowered Tillandia. Fl. Peruv. v. 3. 21. (T. hypophtha; Poiret. n. 15.)—Leaves radical, sword-shaped, tapering, very acute. Spike solitary, simple, of about seven flowers. Native of rocks and trees, among precipices, in Peru, flowering from June to August. Leaves, falcate, and rather downy. Stem near a foot high, quite simple, fealy. Flowers sessile, in two ranks, with lanceolate violet-coloured bracteas. Petals white, tipped with violet. We presume that M. Poiret has erred in his specific name.

26. T. capillaris. Capillary Tillandia. Poiret n. 17. Fl. Peruv. v. 3. 12. t. 271. f. C. —Leaves linear-awn-shaped. Stem forked. Stalks axillary, mostly single-flowered, capillary, smooth, thrice, as long as the leaves. On rocks, walls, and trees, in Peru, flowering in November and December. This species is said to be related in many respects to the T. recurvata, n. 16, but differs in having forked stems; more numerous and broader leaves, contracted at their base, and not recurved; capillary flowers; and solitary bracteas to each flower. (We would observe that the last character is found in the recurvata.) The plant forms dense, leafy, whitish, tufts, the leaves being clothed with very minute mealy scales. Stems about six inches high, forked several times, furnished with two-ranked, crowded, imbricated, reflexed, linear-awn-shaped leaves, striated at their base, and half clasping the stem. Stalks straight, bearing one or two flowers, with a solitary, ribbed, smooth bractea, and a leaf at their base. Calyx scarious, dark violet. Corolla white, hardly longer than the calyx. Anthers yellow. Capsule linear, twice the length of the calyx, dark violet within.

TILLANJONG, in Geography, one of the Nicobar islands, in the Indian sea. N. lat. 8° 31'. E. long. 94° 9'.

TILLE, A, a river of France, which runs into the Saône, about 3 miles below Autunne.

Tille, a town of France, in the department of the Oise; 3 miles of Beauvais.

TILIEE, a town of Bengal; 28 miles N.W. of Dacca.

TILLEMANS, Peter, in Biography, was born at Antwerp in 1684, and visited England in 1708, where he attracted attention by his excellent copies from the pictures of Bourgognone and Teniers, of whose works he preferred the freedom and spirit. He also painted landscapes with small figures, views of gentlemen's seats, sea-ports, &c., and met with very considerable employment. The duke of Devonshire favoured him, and for him he painted a picture of Chatsworth, which gained him considerable eclat. He died here in 1744.

TILLEMONT, Louis Sébastien le Nain de, a French ecclesiastical writer, was born at Paris in 1637; and in the school of the Port-Royal, into which he was admitted at the age of ten, he discovered promising talents and a pious disposition. From early life he devoted himself to the study of ecclesiastical antiquity, and made collections, principally relating to the first six centuries, with a view of composing a history of the church. Model and diffident, as well as learned, he deferred taking prelates' orders till his 40th year; and having done this, he declined all preferment, and retired first to Port-Royal-des-Champs, and then to Tillemont, near Vincennes, prosecuting his literary labours, and keeping in view his main object: he subject himself at the same time to very rigid penitentiary discipline. His austerity and intense application debilitated his constitution to such a degree, that he died in 1698, at the age of 61 years.

The plan of his great work comprehended two parts, viz. the secular and the ecclesiastical history of the period of which he professed to treat. Accordingly the first part, entitled "Memoires pour servir à l'Histoire Ecclesiastique des six premiers Siecles," was comprised in 16 vols. 4to. of which four volumes were published in his life-time, and twelve more after his death. The other part, entitled "L'Histoire des Empereurs et des autres Princes qui ont regne durant les six premiers Siecles de l'Eglise," consists of 6 vols. 4to. the last being left in MS. and not published till 1758, being published with the emperor Antonius. Dupin, though he disapproves the method of Tillemont, observes, that great instruction may be derived from his history, especially with respect to critical and chronological matters. His style merits no commendation. Gibbon, who often quotes his History of the Emperors, and praises his scrupulous accuracy, finds frequent occasion to confine his bigotry, and remarks, that "he never dismisses a virtuous emperor without pronouncing his damnation." Moreti, Gen. Biog.

TILLENENSEE, in Geography, a lake of Prussia, 8 miles W. of Luck.

TILLER, or Tallar, in Husbandry, a little young tree, left to grow till it be fallable.

Tiller is also a term used by farmers to signify, that the produce of the grain branches out into several flakes; in which sense it denotes the same thing with the Latin word fruitare.

It has been suggested by the writer of the "Elements of Agricultural Chemistry," that in the tillering of corn, that is, the production of new flasks round the original plume, there is every reason to believe that oxygen must be absorbed; for the flake at which the tillering takes place, always contains sugar, and the roots arise from a part which is deprived of light. The drill-husbandry is therefore supposed to favour this process; as loofe earth is thrown by the hoeing round the flake; and they are preserved from light, and yet supplied with oxygen. The writer has counted from forty to one hundred and twenty flakes produced from a grain of wheat, in a moderately good crop of the drilled kind. And we are informed, it is said, by Sir Kenelm Digby, in 1669, that there was
in the possession of the fathers of the Christian doctrine at Paris, a plant of barley, which they, at that time, kept by them as a curiosity, and which consisted of two hundred and forty-nine stalks springing from one root, or grain; and in which they counted above eighteen thousand grains, or fards of barley.

It is noticed, too, that the great increase which takes place in the transplantation of wheat, depends upon the circumstance, that each layer thrown out in tillering may be removed, and treated as a distinct plant.

The following statement is given in the fifty-eighth volume of the Philosophical Transactions, at p. 103: Mr. C. Miller of Cambridge, sowed some wheat on the 2d of June, 1706; and on the 8th of August, a plant was taken and separated into eighteen parts, and replanted; these plants were again taken up, and divided in the months of September and October, and planted out separately to fland the winter, which division produced sixty-seven plants. They were again taken up in March and April, and produced five hundred plants: the number of ears thus formed from one grain of wheat was twenty-one thousand one hundred and nine, which gave three pecks and three-quarters of corn, that weighed 47 lbs. 7 oz.; and that were eliminated at five hundred and twenty-six thousand eight hundred and forty grains.

There is a number of facts and cases of the vast increase of grain crops by tillering, scattered through the writings on agriculture and husbandry, which clearly shew the great utility and importance of it in the raising of such crops.

TILLER of a Ship, a long piece of timber (which should be straight-grained and free from knots) fitted into the head of the rudder as a lever, to turn it from one side to the other, in order to steer the ship. This term, or bieb, is used for the handle of a boat's rudder.

TILLER-ROPE, a kind of tackle, communicating with the ship's fide, and usually composed of untailed rope-yarn for the purpose of traversing more readily through the blocks or pulleys; this tackle serves to guide and assist the operations of the tiller, and in all large vessels is wound about a wheel, which acts upon it with the powers of a crane or windlass.

TILLERING, in Agriculture. See Tiller.

TILLEWALL, in Geography, a town of Prussia, in Oberland; 5 miles N.E. of Eylau.

TILLIERES, a town of France, in the department of the Eure; 6 miles N.E. of Verneuil.

TILLING, a town of Sweden, in the province of Upland; 23 miles S.E. of Upsal.

TILLIUM, or TILLUM, in Ancient Geography, a town on the western coast of the island of Sardinia, between the promontory Gordionum and port Nymphaeus. Ptol.

TILLONGSCHOOL, or KATCHAUL, in Geography, one of the Nicobar islands, of a triangular form, about 36 miles in circumference. N. lat. 7° 58'. E. long. 93° 59'.

TILLOT, Le, a town of France, in the department of the Vosges; 12 miles S.E. of Plombieres.

TILLOTSON, John, in Biography, a celebrated English prelate, defended from an ancient family in Chezfield, was the son of Robert Tillotson, a clothier at Sowerby, in the parish of Halifax, Yorkshire, where he was born in the year 1630. Having been brought up in the principles of his father, who was a Calvinistic puritan, and discovering an inclination to literature, he was entered in his 17th year a pensioner of Clare-Hall, Cambridge. In 1651 he was elected fellow of his college, and took pupils, to whose moral and religious instruction he was duly attentive. At this time, he was in his sentiments Calvinistic, heard such preachers, and used extemporaneous prayer. His views of theology were enlarged soon after he left college in 1656, by the influence of Chillingworth's "Religion of Protestants." But retaining his attachment to the Presbyterian form of church government, he was received into the family of Edmund Prideaux, attorney general to the Protector, as chaplain and tutor to his son. He attended the Savoy conference in July 1661, and preached a sermon (the first which he preached) at their morning exercise in Cripplegate, in the month of September. Under the Act of Uniformity in 1662, to which he submitted, he became curate at Chevening, in Kent. In 1664 he married the daughter of Dr. French, canon of Christchurch, by a sister of Oliver Cromwell; and in 1665 he was appointed lecturer to the parish of St. Laurence Jewry. His reputation as a preacher was very considerably increased at this time by his printed sermon, "On the Wisdom of being religious." His controversy on popery commenced with the publication of his "Rule of Faith," in answer to a book written by a convert to the Roman church. The part he took in a scheme for comprehending dissenters under the establishment, evinced his respect for that description of Christians and Protestants. (See Comprehension.) In 1666 he took his degree of D.D., and in 1669 he was made a king's chaplain, and was presented to a prebend of Canterbury. When King Charles, in 1672, issued a declaration for liberty of conscience, with a view of favouring the Roman Catholics, the bishops took the alarm, and recommended to the clergy to preach against popery. The king was displeased, and Tillotson, at a meeting of the clergy convoked by the bishop of London, furnished the following apology for their conduct: "That since his majesty professed the Protestant religion, it would be an unprecedented thing that he should forbid his clergy to preach in defence of a faith which they believed, and which he declared to be his own." Soon after this he preached a sermon at Whitehall on the hazard of salvation in the church of Rome; and yet, offensive as this sermon must have been, he was advanced, in 1672, to the deanery of Canterbury, which was followed, in 1673, by a presentation to a prebend of St. Paul's. At this time he published Dr. Wilkins's "Principles of Natural Religion," with a recommendatory preface; and the author, who died in his house, committed to him the draft of his papers. A familiar truth was reposed in him by Dr. Barrow. His dread of popery induced him, in 1680, to preach before the king a sermon, afterwards published by the royal command, and entitled "The Protestant Religion vindicated from the Charge of Singularity and Novelty." In this sermon a paragraph was introduced which incurred the charge of intolerance. "I cannot think," says he, "till I be better informed, which I am always ready to be, that any pretence of conscience warrants any man that is not extraordinarily commissioned, as the apostles and first preachers of the gospel were, and cannot justify that commission by miracles, as they did, to afford the established religion of a nation, though it be false, and openly to draw men off from the profession of it, in contempt of the magistrate and the law. All that persens of a different religion can in such a case reasonably pretend to is, to enjoy the private liberty and exercise of their own conscience and religion, for which they
they ought to be very thankful, and to forbear the open making of profelytes to their own religion, (though they be never to fear that they are in the right,) till they have either an extraordinary commission from God to that purpose, or the providence of God make way for it by the permission of the magistrate." The king speedily told the preacher delivered the sermon, but a nobleman at the close of it said to him, "It is a pity your majesty was asleep, for we have had the rarest piece of Hobbbin that ever you heard in your life," to which Charles replied, "Oldshiff, then he shall print it," which was the cause of the order. The paragraph was unworthy of Dr. Tillotson, and gave very general offence, both to the established clergy and Presbyterians. Tillotson was an ardent promoter of the Bill of Exclusion, nor would he concur in the addrefs of the London clergy to the king on his declaration that he could not content to fuch a bill. In 1682 he took occasion to vindicate the character of Dr. Wilkins from the asperions of Anthony Wood, by a preface to a volume of sermons, which he published from the doctor's MSS. He was also the editor, in 1683, of Dr. Barrow's sermons, in 3 vols. fol. It has been regretted as an inconsistency in the character of Tillotson, that when in company with Burnet he attended the lord Ruffel preparatory to his execution, they should urge this martyr to liberty to acknowledge the absolute unlawsfulness of resistence, though they were soon after decided friends to the revolution. By a "Discourse against Transubstantiation," and another "Against Pur- gatory," he commenced a prolonged controversy with the Papists. In 1683 he avowed himself a warm advocate for tendering charitable relief to the French refugees, on the repeal of the edict of Nantes; and in reply to Dr. Beveridge, the prebendary of Canterbury, who objected to reading a brief for this purpose, as contrary to the rubric, he remonstrated, by saying, "Doctor, Doctor, charity is above rubrics." After the settlement of the prince of Orange at St. James's, he was instrumental in persuading the princes Anne, who consulted him, to acquiesce in giving up her claim to the crown during the life of William, in cafe of her father's dying before him. After the revolution, no obstacle remained to the full gratification of his desires of advancement, which, however, he professed to be very limited. In 1689 he was appointed clerk of the closet to the king, and permitted to exchange the deanship of Canterbury for that of St. Paul's. During archbishop San- croft's suppfension for refusing to take the oaths to the new government, Dr. Tillotson was appointed to execute the archiepiscopal jurifduction; and it was then determined that he should have possession of the see. His whole conduct at this time evinced his attachment to the principles of toleration and civil liberty; and he was active in his endeavours for promoting a comprehension, though they ultimately proved unsuccessful. He also failed in introducing a new book of Homilies; and in a sermon preached before the queen, against the absolute eternity of hell torments, he excited the refentment and opposition of the orthodox party. After some reluctance on his part, he was consecrated to the arch- bishopric of Canterbury in May 1691, and also in a little while sworn a member of the privy-council. From this time he became very obnoxious to the high-church zealots, who attacked him in a variety of ways. Among other charges against him, one was his attachment to Socinian principles, which seems to have had no other foundation than his rational defence of Christianity, and his friendship and intercourse with Locke, Limborch, and Le Clerc; and for repelling which, he caufed to be republished, in 1693, four of his sermons "On the Divinity and Incarnation of our Saviour." — "If this be Socinianism, for a man to inquire into the grounds and reafons of the Christian religion, and to endeavour to give a rational account of it," says he in one of his pofthumous sermons, alluding to this charge, and also to the character of Chillingworth, "I know no way but that all considerate inquisitive men, that are above fancy and enthusiasm, must be either Socinians or Atheists." Dr. Jortin, in reference to this unfounded accusation, observes, "Tillotson had made some conceptions concerning the Socinians, which never were, nor ever will be, forgiven him, and had broken an ancient and fundamental rule of theological controversy: 'Allow not an adversary to have either common sense, or common honesty.' " After an examination of bishop Burnet's exposition of the thirty-nine articles, which he lent him in MS., he concludes his eulogy on the bishop's prudence and ability with observing, "The account given of Athanafius's creed seems to be no- wise satisfactory; I wish we were well rid of it." The archbishop's affiduity and zeal in the duties of his exalted station were highly exemplary and laudable; and yet they were not sufficient to silence the clamours of his enemies. At length the period of his usefulness terminated, in consequence of a paralytic stroke, which feized him, November 1694, in the chapel of Whitehall, and which, on the fifth day, proved fatal, in the 56th year of his age. His funeral, at the church of St. Laurence Jewry, was attended by many peers of rank. He left a widow, but no children; and as he took no pains to accumulate property, his debts could not have been paid, if the king had not remitted his fift- fruits; and the copy-right of his sermons was the only pro- vision which he left for his widow, to which a peniion, feeled upon her by the crown, was added.

"The temper and character of Dr. Tillotson," says one of his biographers, "were intitled to every encomium. He was humble, open, and sincere, of kind and tender affection, extremely bountiful in his charities, and forgiving of injurie, in which last virtue he was severely tried. His public principles bore the stamp of his disposition; they were philanthropical, tolerant, and liberal; and if he retained some predilections for the sect in which he had been educated, the chief professional fault with which he has been charged, candour will make due allowance for the effect of early habit. In some points he was, perhaps, too compliant, and was led into some inconsistencies; but the times were difficult, and his intentions seem to have always pure. As a writer, he is principally remembered for his sermons, which have long maintained a place amongst the most popular compositions of that class in the English language. A folio volume, comprising his "Rule of Faith," and sermons, was printed in his lifetime; and after his death two more folio volumes of sermons were published by his chaplain, Dr. Barker. Abroad, as well as at home, his works have been held in high estimation. The character given of them by Le Clerc, in his "Bibliotheca Choisis," is as follows: "The archbishop's merit was beyond any commendation he could give. It consisted in the union of extraordinary clearness of head, great penetration, an exquisite talent of reasoning, a profound knowledge of genuine theology, solid piety, a moft singular perspicacity, and unaffected elegance of style; with every other quality that could be defined in a man of his order; and whereas compositions of this kind are commonly mere rhetorical and popular decla- nation, better to be heard from the pulpit than read in print, his are for the most part exact differentiations, capable of bearing the test of the most rigorous examination." Addison considered the sermons of Tillotson as a standard of purity of the English language. Dryden acknowledges,
that if he had any talent for English prose, it was derived from frequent perusal of Tillofon's writings. Mr. Melmoth, however, in his "Fitzpont's Letters," expresses a very different, and in our judgment a less just or to say the least, a less candid opinion. He speaks of "his words as frequently ill chosen, and almost always ill placed; his periods as tedious and unharmonious; and his metaphors as generally mean, and often ridiculous." Notwithstanding these reflections, Tillofon's sermons, though surpassed by the correctness and elegance of modern compositions in this department, and less perused than formerly, will not cease to be regarded as a valuable part of English literature.

TILLS, in Agriculture, a term signifying tares or vetches in many places, in both the northern and southern parts of the kingdom.

TILLURAH, in Geography, a town of Bengal; 21 miles E.N.E. of Purneiah.—Alfo, a town of Hindoostan, in Bahar; 22 miles S. of Patna. N. lat. 25° 14'. E. long. 85° 22'.

TILLY, a town of Canada, on the St. Laurence; 10 miles S.W. of Quebec.—Alfo, a town of France, in the department of the Meufe; 9 miles S. of Verdun.—Alfo, a town of France, in the department of the Eure; 9 miles S.E. of Grand Andelys.—Alfo, a town of France, in the department of the Sambre and Meufe; 6 miles W. of Gemblours.

TILLY la Campagne, a town of France, in the department of the Calvados; 4 miles S.S.E. of Caen.

TILLY Vrois, a town of France, in the department of the Calvados; 9 miles W. of Caen.

TILLY Land, in Agriculture, that part which is, for the most part, con skład and composed of materials of the till kind.

These kinds of land, in their original flates, are in general of a very barren and unproductive nature; but when they have been fully turned over by the plough or other means, well and effectually wrought and reduced by other proper tools, and their parts completely divided and exposed to the alternate action of different agents, such as the frost and thaw, of drought, dew, and rain, with the many other improving effects of the atmosphere which surround them; and withal limed, separated in their parts, and enriched by calcareous and other suitable manures and substan ces, they become, in various instances, of a far less strong and stubborn nature, and greatly more disposed to the raising of good and plentiful crops upon them. They are commonly much ameliorated and improved at first by growing beans, tares, and rape in succession with wheat and other suitable sorts of grain, having the green crops so managed as to fland as close, thick, and thorn ing, as possible on the land. See Land and Soil.

TILMUS, 71° 30', a term used by some of the medical writers to express the effect of a fort of delirium, in which people pulse the bed-clothes, or pick out threads from the sheets. This is usually esteemed a dangerous symptom.

TILNOR, in Geography, a town of Bengal; 60 miles N.N.W. of Midnapour.

TILO-GRAMMUM, Ouol, or Ongli, in Ancient Geography, a town of India, situated, according to Ptolemy, to the right of the moft western arm of the Ganges, about 23° lat.

TILOTAMA, a nymph celebrated for her beauty in the mythological and amatory poems of the Hindos. She appears to have been one of that numerous class of females, who, under the name of Upars, arose from the churred ocean, as described under our article Kurmanathara: a fable as prolific of poetical notions, and as often referred to, as any in the whole range of invention. The chief of these Upars, or water-nymphs, was Rhenba, of whom some mention is made under her name in this work. They are described in numerous Hindu poems with all the warmth and fancy that may be predicated of "youthful poets when they love;" and in terms too glowing for readers beyond the tropics. Under the name of another of these beautiful damsels, Mirnaka, we have said something of them. See also Uparsa.

The name of the elegant nymph, the subject of this article, occurs in an inscription on a copper-plate found in the Deccan, bearing date A.D. 1359. The inscription is given in the 9th volume of the Asiatic Researches, and records a grant for pious purposes. After much adulation of the mother of the royal donor, it is said that "by the charms of her graceful gait the obscure Tilotama."

TILOUTTAH, in Geography, a town of Hindoostan, in Bahar; 10 miles S.S.E. of Saferam. N. lat. 24° 48'. E. long. 84° 15'.

TILOX, in Ancient Geography, a promontory on the northern coast of the island of Corsica, between the mouth of the river Valerius and Cadiz Littus.

TILPHOSSAEUM, a small country of Greece, in Thessaly.

TILSIT, in Geography, a town of Prussia, in the Lithuanian department, large, rich, and commercial. It obtained the privileges of a city in the year 1552, though the castle is said to have been flanding so early as 1280. The river Menel, which runs along the N. side of the town, opens to it a very advantageous trade with Königsberg, in corn, linseed, butter, and other provisions. Tilsit, properly so called, consists of two long streets, of a proportionate breadth, which are called the German-street and the High-street, contiguous to which are the suburbs called the "Liberty." The number of houses in this city is about 600, and the inhabitants amount to 7000 souls. The ecclesiastical buildings are an evangelical or Lutheran German church, a Lithuanian church, and a Calvinist or reformed church. Without the town is a Lutheran chapel, and about an English mile from it a Roman Catholic chapel. The flat country about Tilsit, which is about 16 miles in length, and as many in breadth, is one of the most fertile spots in the whole kingdom: the inhabitants of it breed great numbers of horned cattle, and furnish not only Prussia, but likewise other provinces, with excellent butter and cheese; and the fisheries in this place are also considerable. The hordes are large and strong, but clumsy. Barley is almost the only grain grown in these parts, which afford little or no wood. The marsh-land is, in spring, exposed to inundations by the overflowing of the rivers, which often do great damage. In 1867, it was taken by the French; soon after which a peace was made between France, Russia, and Prussia, called the "Peace of Tilsit"; 50 miles N.E. of Königsberg. N. lat. 55° 8'. E. long. 23° 8'.

TILT. See Tournament.

TILT, in Rural Economy, a term signifying the arched or other covering of a cart, wagon, or other carriage.

The hoops for supporting the tilts in these cafes, may be fastened upon the fides of the carriage-frames, after being properly prepared and bent in a fort of half-circular manner, in several different ways, but the fastening by means of screws is probably the best, where they are to remain fixed.

TILT-BOAT, a boat covered with a tilt, i.e. a cloth, or tarpawing, sustained by bails or hoops over the stern, for the
the sheltering of passengers. Such are some of those which carry passengers between London and Gravesend.

The Tilt-Hammer is a large and heavy hammer, adapted to be put in rapid motion by the power of a water-wheel or steam-engine.

The tilt-hammer is distinguished from the lift-hammer, or forge-hammer, by the manner in which it is lifted up by the cogs of a wheel which is turned by the mill.

The forge-hammer is mounted on a centre of motion at the extremity of the haft or handle of the hammer opposite to the head of the hammer, and the cogs of the wheel operate beneath the helve near the head, to lift or toss up the hammer against a strong wooden spring called the rabbit, which is firmly fixed over the head of the hammer. This spring reflects the hammer down upon the anvil with greater force and smartness than the hammer would descend by the action of gravity alone. A lift forge-hammer is described under the article Iron. See Plate IV. Iron Manufacture.

The tilt-hammer is poised on pivots or a centre of motion, which is about the middle of the length of the helve, or sometimes at two-thirds from the head. The cogs of the wheel are made to act on the tail of the helve beyond the centre of motion, and they press down the end of the tail, and thus cause a correspondent elevation of the head of the hammer. Sometimes the spring is placed over the head of the hammer, the same as a lift-hammer; but more commonly, the tail of the hammer is made to strike against a fixed floor; and when the head of the hammer is thrown up suddenly, the momentum given to it causes the head to rise up after the tail strikes the floor, and thus bends the helve, which by its elasticity causes the head of the hammer to descend smartly upon the anvil.

The tilt-mills in the neighbourhood of Sheffield are very simple: they are worked by a small water-wheel, upon the axis of which is a wheel with a great number of cogs, fixed in its circumference. These successively depress the tail of the hammer, and raise its head: the hammer falls by its own weight, aided by the spring of the helve, upon the hot metal. The size of the water-wheel, and the number of cogs in the wheel, are adapted to produce from three hundred to four hundred strokes per minute.

This great number requires the water-wheel to move with a velocity which is inconsistent with the best mode of applying the fall of water, because it is well known that water, as well as any other heavy body, can only descend with a certain speed. If, therefore, the floats of the wheel are required to turn with a great rapidity, it is evident the proportion of work the wheel will perform, will be too small in proportion to the quantity of water expended. For this reason, it is found to be a great improvement in tilt-mills to add cog-wheels which will give the hammers a sufficient velocity, while the water-wheel turns at such a rate as is found to produce the greatest power from a given quantity of water.

A capital mill of this kind is delineated in Plate VIII. Iron Manufacture. It was made at the Carron iron-works in Scotland, after designs of the celebrated Mr. Smeaton. It is adapted for forging iron into bars, and has three tilt-hammers of different powers for different kinds of work. These hammers are not made to strike so quick as is usual in the Sheffield mills for the tilting and drawing out steel bars; but by giving a greater number of cogs to the wheels, the requisite rapidity may be obtained without increasing the speed of the water-wheel. A capital mill was built at Sheffield about six years ago, which is on Mr. Smeaton's plan, except in the proportions of the wheels, and its performance is superior to any of the other tilt-mills.

A A, in the plan fig. 1. are the walls of the building; B B the great water-wheel, which is of the kind called a breast-wheel. (See Water-Wheel.) It is 18 feet diameter and 5 feet broad. The total descent of the water which actuates it is 7 feet 2 inches, and it falls upon the float-boards rather below the centre of the wheel, being retained against the floats by what is called the breasting, that is, a sweep or curved wall of masonry, which is accurately adapted to the float-boards of the wheel, and as close to them as is possible, to avoid touching.

The axis C of the water-wheel is carried through the wall A, and on the extreme end of it is a large iron wheel D, of 90 wooden teeth, 9 feet 6 inches diameter. This turns a pinion E of 30 teeth, and 3 feet 2 inches diameter. The pinion is fixed on one end of a cast-iron axis G G, which is made very large, for strength, and hollow within, like a pipe. The gudgeons b and c are fixed into it at each end, and upon these gudgeons it revolves. F F is a cast-iron fly-wheel, fixed on the axis close to the pinion; it is 12 feet diameter, and the rim 6 inches by 5. The weight is very considerable, and gives it a momentum to regulate the motion of the whole mill, and equalize all irregularities which arise from the successive actions of the mill to raise the three hammers, L M, and N.

Each hammer has a separate cog-wheel, K K, and H H, to give it motion, which is effected by the cogs of these wheels acting upon the tails of the hammers and prepping them down. This is explained by the elevation fig. 2. where c is the iron head of the hammer, f its centre of motion, and d the tail or extreme end, upon which the cogs of the wheel act, and which is plated with iron on the upper side, to prevent it from wearing.

P is the anvil-block, which must be placed on a very firm foundation, to resist the incessant shocks to which it is subjected: the centre, f s or axis of the hammer, is supported in a cast-iron frame, g h, called the hirth. When the cogs of the wheel strike the tail of the hammer suddenly down, and raise the head, the lower side of the tail of the hammer strikes upon a support n, which acts to stop the ascent of the head of the hammer c, when it arrives at the desired height; but as the hammer is thrown up with a considerable velocity as well as force, the effort of the head c to continue its motion, after the tail strikes the stop n, acts to bend the helve L of the hammer, and the elasticity of the helve recoils the hammer down upon the anvil with a re-doubled force and velocity to that which it would acquire from the action of gravity alone.

To obtain this action of recoil, the hirth g h must be held down as firmly as possible; and for this purpose, four strong iron bolts are carried down from the four angles of the bottom plate h, and made fast to the solid basis of stone R S, upon which the whole rests: upon these bases are placed four layers of timbers, i i, l m, which are laid one upon another, and the timbers of each layer are laid crossways over the others. Each layer consists of several pieces laid side by side, and they are slightly treenailed together; to form a platform. Each platform is rather less than that upon which it rests, so as to form a pillar of solid timber; on the top of which the hirth-frame g h is placed, and firmly held down by the four bolts, which descend through all the platforms, and have secure fastenings in the solid masonry beneath.

The float n is supported by a similar pillar, but smaller, and composed of three layers: the upper piece n, which is seen crossways in fig. 2 is about three feet long, and the under side is hollowed, so that the piece bears only upon the two ends, leaving a vacancy beneath it, which occasions it
TIL

it to bend or spring every time the tail of the hammer strikes upon it, and this aids the recoiling action very much.

The axis on which the hammer moves is formed by a ring of cast-iron, through which the whole of the hammer is put, and held fast by wedging round it. The ring has a projecting trunnion on each side, ending in an obtrude conical point, which is received in a socket firmly fixed in the hilt-frame g b by screws and wedges, one of which is seen at r. These two sockets are thus capable of adjustment, so as to make the hammer face fall flat upon the anvil. The three wheels K, I, H, are of different sizes and numbers of cogs to produce that velocity in each hammer which is best adapted for the work it is to perform; thus, the wheel K for the great hammer has eight cogs, and therefore produces eight blows of the hammer for each revolution of the fly-wheel; the wheel I for the middle hammer has twelve cogs; and the wheel H for the small hammer sixteen; the latter will therefore make two strokes for every one of the great hammer. In fixing the three wheels upon the great shaft G H, care is taken that they shall produce the blows of the different hammers in a regular succession, and equalize as much as possible the force which the water-wheel must exert. The wheels are fixed upon the shaft by means of a wedging of hard wood, driven in all round; the wood, being capable of yielding a little to the shocks occasioned by the cogs meeting the tails of the hammers, renders the concussions less violent.

The following are the principal dimensions:
The head of the great hammer, P, weighs 34 cwt., and it is intended to make 150 blows per minute; it is lifted 17 inches from the anvil at every blow.
The middle hammer, M, is 2 cwt., and makes 225 blows per minute; it is lifted 14 inches each time.
The small hammer, N, weighs 1 cwt., and makes 300 blows per minute; it is lifted only 12 inches.

To produce these velocities, the great axis G must make 182 turns per minute; and the cog-wheels E and D, being in the proportion of one to three, the water-wheel must make 63 revolutions per minute; the water-wheel being 18 feet diameter, its circumference will be $18 \times 3.1416 = 56.54$, or 56 feet: this multiplied by 6.25 is about 353 feet motion per minute, or divided by 60 = 5.9 feet motion per second for the circumference of the water-wheel.

The tilt-mills employed in the manufacture of steel, do not have the great hammer P, but the largest they use is about the size of that at M, and is adapted for welding faggots of steel to make hearth steel: the other two hammers are about the size of N, and are made to work much quicker, viz. from 350 to 400 blows per minute. This is very safely accomplished by making the wheels E and F as 1 to 4, instead of 1 to 3, as shown in the drawing.

TILTH, in Agriculture, a term used to signify the condition of the earth or soil after the land has been ploughed and broken down by the harrow or other tool of the same kind; or the state and circumstances of the ground in regard to tillage, or heart, as relating to manure. Thus we have a good and bad tilth, as well as land in and out of tilth, in works on agriculture.

TILTIL, in Geography, a town of Chili; 30 miles S.E. of Valparaiso.

TILTING of Steel, the process by which bliftered steel, or steel in the raw state, is rendered ductile and fit for the purposes of various manufactures. Tilting consists in hammering or forging the steel by a large hammer called a tilt. See Tilt-Hammer.

Steel is formed by two processes; one in which it is made at once from pig or crude iron in the finery, nearly in the same manner as making bar-iron: this is called natural steel. In the second process, malleable iron, in bars, is embedded in charcoal or other carbonaceous matter, and exposed to a considerable heat, till the iron is thought to have penetrated sufficiently into the iron to have changed it into steel. This is called converting the iron by cementation with charcoal; and the furnace in which the operation is performed is called a converting furnace.

The object of this process of cementation, is to impregnate the iron with a certain quantity of carbon, to be derived from the charcoal: like many other simple operations, it requires great care and nicety to perform it properly, when put in practice on a large scale. The iron must be exposed to the action of a intense heat in contact with carbon (but defended from the access of oxygen), until the iron imbibes a portion of carbon and becomes steel.

The quantity of carbon which must be combined with iron to produce steel, admits of considerable latitude, and the qualities of the steel vary in the same proportion: with too little carbon, steel will be soft; and not sufficiently hard when it has been suddenly cooled by plunging in water. It has a rough and somewhat fibrous fracture, and in general may be said to possess many of the qualities of malleable iron. On the other hand, in proportion as the quantity of carbon is diminished, an over-cemented steel, containing an excess of carbon, is brittle, easily fusible, excessively hard after being suddenly cooled, and is liable to crack on the sudden change of temperature iron hot to cold.

All these properties are an approach to crude iron.

The received opinion respecting steel and the best cast-iron is, that they have the same constituent parts, but in different proportions; the former containing a smaller proportion of carbon than the latter. All the crude or cast-iron of commerce contains oxygen in greater or less proportion, but the best steel is supposed to be nearly free from this. Mr. David Muirhead, whose great practical and theoretical knowledge entitles his opinion to the greatest respect, supposes that the carbon contained in cast-iron and in steel, exists in very different states; and that steel is a combination of iron with pure carbon, similar to the diamond, but that crude iron, is iron containing the oxyd of carbon, which is charcoal. This opinion is founded upon the result of a very numerous series of experiments, many of which he communicated to the Philosophical Magazine, vol. xiii. He found that a piece of Swedish bar-iron, weighing 885 grains, introduced into a Stourbridge clay crucible, and half its weight, (442 grains) of charcoal well prepared; a clay cover, fitting exactly, being placed on, and the whole exposed to a moderate heat for half an hour; that the result was, a perfect button of super-carbonated crude iron, weighing 928 grains, which therefore had gained 44 per cent. on its original weight; while the charcoal, which remained in the crucible, in an intensely black state, weighed 290 grains, having lost 34.4 per cent. of its original weight.

In a second experiment, made in a similar manner, but with only a quarter of the charcoal, the iron gained $\frac{1}{19}$ of its original weight, and the loss in charcoal was 45 per cent.; the metal was richly carbonated. When one-sixth of charcoal was used, the iron produced, resembled the produce of Nos. 1. and 2. of the crude iron of commerce; its weight was increased $\frac{1}{20}$; and 57 per cent. of the charcoal disappeared in the process.

With one-eighth of charcoal, the iron gained $\frac{1}{22}$ of its original weight.
original weight; and the weight of the charcoal which disappeared was 67.5\% per cent. The metallic button was very highly carbonated, and apparently formed an entire mass of carburet.

One-ninth of charcoal produced a super-carbonated button of crude iron, rather inferior to the preceding in point of carbonization: its surface was smooth, and of a dull lead-colour, entirely free from the usual shining specks of carburet, which very rich crude iron contains upon its surface. It had gained equal to \(\frac{1}{9}\)th in weight by the fusion; and the loss in charcoal was 80 per cent.

When treated in the same manner with \(\frac{1}{9}\)th of its weight of charcoal, the iron gained weight equal to \(\frac{1}{9}\)th parts; and 84.5 per cent. of the charcoal disappeared in the process. The metallic button possessed an uniformly smooth surface, partially covered with carburet.

One-fifteenth part of charcoal, exposed to a heat sufficient to melt it, was all lost; the metal gained \(\frac{1}{15}\)th in weight, which was exactly half the weight of charcoal lost. The surface of the button was not carbonated, as the foregoing experiments: the colour was bluish-black, smooth in the centre, but a little oxidized towards the edges. The fracture was that of close dark-grey crude iron; the crystals much closer and more minute than in the preceding experiments. Its quality was such as manufacturers term No. 2. grey melting pig-iron.

When only \(\frac{1}{15}\)th part of charcoal was employed, none of which remained after the fusion, the iron gained \(\frac{1}{15}\) parts in weight; a small portion of amber-coloured glass was found round the edges of the button. The fracture of the metal was smooth silver-white, occasionally furred with carbonaceous specks in form of small grains: it exactly resembled mottled pig-iron.

With \(\frac{1}{15}\)th part of charcoal, the metal gained \(\frac{1}{15}\) parts in weight, the whole of the charcoal disappearing. The upper surface of the button was smooth, but the under considerably pitted. The concaves were checked with the rude crystallization peculiar to cast-iron. Its fracture was bright silver-white, destitute of grain, and exhibiting a very perfect streaky crystallization glistening radiated: its resemblance was strikingly similar to that of highly-blown crude iron, prepared in the foundry for making malleable iron.

A piece of Swedish iron was placed in \(\frac{1}{15}\)th its weight of charcoal; the fusion of the mixture produced a metallic button weighing \(\frac{17}{15}\) parts more than the iron employed, which increase is not quite a quarter of the loss in charcoal, which wholly disappeared in the experiment. The upper surface of the button was smooth without configuration, but the under surface was uneven, and covered with minute but perfect crystallization: its fracture was blueish silver-white, composed of flat dazzling crystals, proceeding in lines from a centre to the edges of the button. Here it was evident, that from the small proportion of carbon combined with the iron, it was found to assume the earliest stage of granulation approaching to the state of steel. The brilliant concretions observable in the surface of the button were too indistinguishable for steel capable of bearing the hammer.

When the proportion of the charcoal was reduced to \(\frac{1}{15}\)th of the iron, its consequent increase was but \(\frac{1}{15}\)th part. The upper surface of the button was smooth, with a faint impression of a chequered crystallization: the under surface possessed some large pits similarly though more perfectly crystallized: the fracture was one shade of blue beyond the last experiment. A regular granulated surface, composed of flat oblong crystals, was observable, still too indistinguishable and too much on edge for workable steel.

With only \(\frac{1}{15}\)th of the weight of charcoal, the button was deficient \(\frac{1}{15}\)th part of its weight originally used, yet the whole of the charcoal was lost. The surfaces of this button were uniformly smooth; the fracture dense, and displaying a grain peculiar to highly carbonated blistered steel. When put under the hammer with a low red heat, it withstood a few blows, but afterwards parted.

Charcoal \(\frac{1}{12}\): the metallic button weighed \(\frac{1}{31}\) less than the iron employed. Its surface was wavy and crystallized: the under surface was rough, and contained one large pit accurately crystallized: the fracture was regularly granulated, small but distinct, and of a light blueish colour. The crystals, though distinct, were not so prominent as those of easy drawing cast-steel; it however burned with the usual degree of caution necessary in the working of cast-steel. The bar of steel formed from the button was very proper for file-making, and other purposes requiring highly converted steel.

The proportion was reduced to \(\frac{1}{12}\)th part the weight of iron; the produce was \(\frac{1}{22}\) less than the original weight of iron. The surface of the button was smooth, without crystallization: the under surface rough, and presented one large pit in the centre, faintly marked with the usual crystalline appearance. The fracture presented regular light-blue grains, distinct and more prominent than in the last experiment. One half of this button was drawn into a neat square bar, and proved excellent steel. One end of it, being loose and shelled, welded tolerably well, and hardened afterwards with a low heat. From its quality, it seemed adapted for manufacturing penknives, razors, &c. poffessing neither the extremes of hardness nor softness.

Mr. Mitheu continued this series of experiments till the proportion of charcoal became so small as \(\frac{1}{15}\)th part; and he gives the following conclusions, deduced from the results.

In the above experiments it will be seen, that when more than \(\frac{1}{15}\)th part of charcoal is employed, the weight of the produce is increased; but when less than \(\frac{1}{15}\)th part is used, a loss is experienced proportional to the diminution of the carbon. The increase of weight of the iron is by no means equal to the loss in the charcoal, never exceeding the half thereof; but this is accounted for in other experiments made by Mr. Mitheu, where charcoal was found to be transmitted through close crucibles in a high degree of heat.

The French chemists made a direct experiment to prove that the diamond is really carbon in a crystallized state. By inclining a small diamond in a piece of malleable iron, and melting this in a close crucible, it was found to be converted into steel, and the diamond had disappeared.

The manufacture of natural steel is carried on in Germany, and Swedenborgius gives us the following account of the method used in Dalecarlia for making steel from cast-iron.

The
The ore from which the crude iron to be converted into steel is obtained, is of a good kind; it is black, friable, and composed of many small grains: it produces very tough iron. The conversion into steel is made upon a forge-hearth, something smaller than that commonly used for converting cast-iron into malleable iron: the sides and bottom are made of cast-iron; the tuerie is placed with little inclination on one of the side-plates; the breadth of the fire-place is fourteen inches, its length is greater: the lower part of the tuerie is six inches and a half above the bottom: in the interior part of the fire-place, there is an oblong opening for the flowing of the superfluous scoria.

The workmen first put scoria on the bottom, then charcoal and powder of charcoal, and upon these the cast-iron, run or cut into small pieces. They cover the iron with more charcoal, and excite the fire. When the pieces of iron are of a red white, and before they begin to melt, they flop the bellows, and carry the mafs under a large hammer, where they break it into pieces of three or four pounds each: the pieces are again brought to the hearth, and laid within reach of the workman, who plungs some of them into the fire and covers them with coal. The bellows are made to blow slowly till the iron is liquefied, when the fire is increased; and when the fusion has been long enough continued, the scoria is allowed to flow out, and at that time the iron hardens. The workman adds more of the pieces of crude iron, which he treats in the same manner, and so on a third and fourth time, till he obtains a mass of steel of about a hundred pounds, which is generally done in about four hours. This mass is carried to the hammer, where it is forged and cut into four pieces, which are further heated into square bars four or five feet long. When the steel is thus forged, it is thrown into water, that it may be easily broken, for it is yet crude and coarse-grained. The steel is then broken in pieces, and carried to another hearth, similar to the former. The pieces are laid regularly in the fire-place, first two parallel, upon which seven or eight others are placed across; then a third row across the second in such a manner, that there is a space left between those of the same row: the whole is then covered with charcoal, and the fire is excited. In about half or three quarters of an hour the pieces are made hot enough, and are then taken from the fire one by one, to the hammer, to be forged into little bars from half a foot to two feet long, and while hot, are thrown into water to be hardened. Of these pieces, sixteen or twenty are put together, so as to make a bundle, which is heated and welded, and afterwards forged into bars four inches thick, which are then broken into pieces of convenient length for use.

Converting of Steel by Cementation with Charcoal.—The quality of steel is intimately connected with that of the iron from which it is converted, and the iron made in Sweden is esteemed the best for the purposes of cementation. This process is almost wholly in the hands of the English, who pay a higher price for the iron, and by that means secure nearly all the iron of Röllagia, which is the best iron of Sweden.

The best marks of Swedish iron are: that called the hoop L, which is denoted by a circle, with an L in the centre; thus, [Circle L]: the G L; thus, [Circle G]: the double bullets; thus, [Circle Q]: the iron of these three marks bears nearly the same price, which is sometimes as high as 40L. per ton.

There are also the Swedish marks; as P L, [Circle P]: the hoop S, [Circle P]: and the gridiron, [Circle L]: which are worth a few pounds per ton less than the former; viz. from 34L to 38L, when the bell marks are 40L.

The Russian marks are, first, that called the C C N D: the mark is six Russian letters, C H E P B, worth about 37L per ton, when the others are at 40L. and the P S I, which is marked by the Russian letters P S I, is so inferior, as to sell for only 26L. or 27L.

It is to be lamented that, in the present state of our iron manufacture, we are unable to produce malleable iron which is equally fit for converting into steel with the Russian and Swedish iron. The general opinion upon this deficiency is, that it arises from some inferiority in the foreign ores of iron, but more immediately from the circumstance of their using charcoal of wood instead of the coke of pit-coal in smelting or reviving them; and some of our manufacturers do not hesitate to assert, that they can make iron with charcoal equal to the foreign in quality; but that in respect to price, the circumstances of this country will not allow them to cope with those countries, where the destruction of wood is in some measure considered as beneficial, by clearing the land for the operations of husbandry.

The Swedish and Russian iron is imported into this country by iron merchants in immense quantities, together, this trade being in the hands of a few individuals: by them it is retailed in smaller portions to the converters, whose furnaces are chiefly about Sheffield and Newcassel, who, after cementation, dispose of the greater part of it to the manufacturers of steel goods in the plate of blistered bars. Its value is estimated by the Swedish or Russian marks of iron, which still remain upon the bars. The manufacturers sell their bars to the tills, where they are made into common steel and shear or German steel, or they melt it to form cast-steel.

The conversion of iron into steel is performed in a furnace, hence called a converting furnace. The external building is a large and tall cone, similar to a glafs-house, within which, one or two large crucibles, called pots, are placed, and surrounded by flues in a manner befitting to communicate a constant and regular heat to every part of them. In these pots the iron bars are placed, being stratified in pulverized charcoal, and the pots are covered over with sand to exclude the external air.

A more perfect idea of the converting furnace will be had by referring to Plate VII. of Iron Manufacture, which contains a horizontal plan and two vertical sections of one of the furnaces used in the neighbourhood of Sheffield, with two pots for containing the iron. In all the figures, the same letters of reference denote the same parts. C is the external cone, built of brick or flone work; its diameter at the bottom varies in different furnaces, according to the size of the pots it contains: its extreme height from the ground to its vertex should not be less than forty or fifty feet to cause a proper draught. To create a sufficient heat for the procists, the top of the cone usually terminates with a cylinidrical chimney of some feet in height. The conical form of the external building is by no means essential; any form will operate in the same manner, if it is of a proper height; some are in practice built nearly in the shape of the small end of an egg, with a round chimney upon the top. The lower part of the cone is built square or octagonal, as is the plan of fig. 3. The sides are carried up until they meet the cone, giving the furnace the appearance of a cone cut to a square or octagonal prism at its base, and exhibiting the parabola where every side intersects the cone.

The conical building contains within it a smaller furnace, called...
called the vault, built of fire-brick or flue, which will withstand the action of a moist intense heat, without cracking or vitrification. D D in the section is the dome of the vault, and E E its upright sides, the space between which, and the wall of the external building, is filled up with rubbish and sand. The vault, as is shown in the plan, is always four-sided, that it may contain the pots which receive the iron bars to be converted. A B represent the two pots, built of fire-clay, each ten feet long, three feet deep, and two feet nine inches wide; the space between them is twelve inches wide; and directly beneath it is the fire-grate. The pots are supported by a number of detached courses of fire-brick, as shown at ee (fig. 1), which leave spaces between them, called flues, to conduct the flame under the pots: in the same manner, the sides of the pots are supported from the vertical walls of the vault, and from each other, by a few detached flues, (f, fig. 1.) placed so that they may intercept as little as possible of the heat from the contents of the pots. The adjacent sides of the pots are supported from one another by small piers of flue-work, which are also perforated, as shown at d (fig. 2.) to give passage to the flame. The bottoms of the pots are built of a double course of brick-work, about six inches thick; the sides are cut together are built of a single course of flue, about five inches in thickness; and the other parts of the pots are flue courses about three inches, the flue not requiring so much strength, because they have left heat and pressure to refulg.

The vault has ten flues or short chimneys, E E, rising from it; two on each side, to carry off the smoke into the great cone, shown in the plan 3, communicating with each side, and two at each end.

In the front of the furnace, at H, an aperture is made through the external building, and another corresponding in the wall of the vault; these openings form the door, at which a man enters the vault to put in or take out the iron: but when the furnace is lighted, these doors are closed by fire-bricks luted with fire-clay. Each pot has also small openings in its end, through which the ends of two or three of the bars are left projecting in such a manner, that by only removing one loose brick from the external building, the bars can be drawn out without disturbing the process, to examine the progress of the conversion from time to time: these are called the tap-holes; they should be placed in the centre of the pots, that a fair and equal balance may be formed from their result of the rest of its contents.

a b, in the elevation, is the fire-grate, formed of bars laid over the ash-pit I, which must have a free communication with the open air, that it may convey a current of fresh air to supply the combustion. The ash-pit should also have steps down to it, that the attendant to the furnace may get down to examine by the light, whether the fire upon the whole length of the grate is equally intense; and if any part appear dull, he uses a long iron hook to thrust up between the bars and open a passage for the air. The fire-place is open at both ends, and has no doors. The fire-grate is laid nearly on a level with the floor of the warehouse, before the furnace, and the fireman always keeps a heap of coals piled up before the apertures of the grate, to close the opening. This forms a simple and effective door; and when the furnace requires a fresh supply of fuel, a portion of the heap of coals is thrown in by a long hook, and the heat renewed, to stop any air from entering into the furnace, except that which has passed upwards through the ignited fuel, and by that means contributed to the combustion.

The fire-flues that compose all those parts of the furnace which are exposed to the action of the heat, are first hewn nearly to size, and finished by grinding two surfaces together, so that they make very perfect and close joints; when laid together, they are cemented with well-tempered fire-clay, mixed very thin with water. The fire-clay which answers best for this purpose, is that brought from Stourbridge, in Staffordshire, and is the fame of which the celebrated Stourbridge crucibles are composed; but very good fire-clay for the purpose is procured from Birkin-lane, near Chelford. When the furnace has been once burnt, this clay becomes equally hard with the flue, and is less liable to fly or vitrify in an intense heat, than any other known cement.

The process of charging the furnace with iron for conversion is conducted as follows. The bars of iron are first cut to the length of the pot; and for this purpose an anvil is placed at such a distance from the edge of the building, that the distance from the edge of a cold chisel wedged into the eye of the anvil, to the wall, will be just the length of the pots. One workman places the end of a bar against the wall, and lays the other end across the edge of the chisel, whilst another with a pile hammer strikes upon the bar till it is cut half through; then it is turned the other side upwards, and the end cut completely off. By this gauge the bars are all cut to one length, and a man enters through the door in the vault, to dispose of them in the pots: he is provided with a bale of fine pulverized charcoal, a sieve, and a shovel. An iron plate is put into the furnace, and lays over the space between the two pots to form the floor, upon which the man stands while at work. He commences his operations by sifted a layer of charcoal over the bottom of the pot, about half an inch thick, and he is careful in using the sieve to lay the charcoal of an even thickness in every part; but if it should not be carefully done, he levels it with the shovel. The workman on the outside now introduces the bars into the furnace through a hole, made by taking out a brick in the wall, just over the end of one of the pots, and the workman within deposits them upon the stratum of charcoal in the bottom of the pot, arranging them parallel to each other, and leaving an interval of about an inch between each bar. When the bottom of the pot is in this manner covered with iron bars, charcoal is again sifted upon them, and levelled with the shovel, to fill up the intermediate spaces between the bars, and to cover them about an inch thick; another layer of bars is then introduced into the furnace, placed upon the charcoal, and in its turn covered over with a stratum of charcoal; and in this manner the pot is filled to within two inches of the top. A layer of the sand which is found in the bottom of grindstone troughs, is then spread three or four inches thick upon the whole, to cover the pots up close, and prevent the access of the common air and flame. In placing the successive layers of bars in the pot, it is proper that each should be laid over the space between two of the bars in the layer beneath, because each bar will then be surrounded by a greater thickness of charcoal, than it would if they were laid directly over each other. Two or three of the bars should be left somewhat longer than the rest, and their ends should project through the trial-holes in the ends of the pots, and fastened round them in the holes to keep out the air.

The pots being both filled and covered up with the sand and rammed down, the holes for introducing the bars are closed by a brick or fire-clone, and luted with fire-clay. The apertures through the outer wall opposite the ends of the trial-holes are also stopped and luted. The iron plate upon which the man food is now removed, and the doors in the vault closed up by bricks wet with fire-clay; next, the opening in the external building is shut up, and the furnace is charged ready for lighting.

The furnace is kindled by lighted wood placed on the fire-grate, then a few coals are thrown in, and when well lighted, the quantity is increased; the heat thus generated rareifies the air contained in the vault and in the great cone; and
and being thus rendered of less specific gravity than the external air, it rises up in the cone, and a fresh supply rushes in through the bars of the grate, to restore the equilibrium. By going through the fire, this air parts with its oxygen, and excites the combustion, and becoming heated, rises up the chimney, and causes a very strong draught of air to enter the fire.

At first kindling, the fuel is supplied in small quantities, that the heat in the furnace may be gradually increased, and not endanger the cracking of the flues; in a few hours time the quantity of fuel is increased, so as to produce the full heat, which is to be maintained as equally as possible throughout the whole process. The fuel, which is pit-coal, is introduced at both ends of the grate, through small arches in the wall, which are in a line and on a level with the fire-grate, a quantity of coals being always left before the end of the arch to stop it up, and prevent any air getting into the furnace, without passing through the grate. Part of these coals is forced into the furnace, as before mentioned, when it requires a supply of fuel, which is generally at intervals of about half an hour each. The fireman frequently examines the appearance of the under side of the fire-grate, and judges from it the state of the fire; he improves it where necessary, as before described, by thrashing a hook up between the bars to make way for the air.

The flame arising from the ignited fuel upon the grate partly proceeds upwards between the pots, and heats them by that means; it then strikes the roof of the vault, and is reverberated down upon the pots, and escapes through the five flues or chimneys in the vault. The draught also draws the flame from the grate under the pots, and round the outside and ends. The principal object in this stage of the process, is to maintain the same degree of heat in every part of the pot, that every bar may be equally converted in the same space of time. The roof of the vault must be built of very good stone (none being better than from Roches quarry, in Atherover), to withstand the great heat exerted upon it; it is customary to build them very thin, and cover the outside with a small thickness of dry sand to keep them tight, in case of smoke cracking.

In this way the fire is kept up in as equal a manner as possible, until the iron is supposed to have imbied a sufficient portion of carbon from the charcoal to render it fit for its intended purpose: in this circumstance, the manufacturer regulates his judgment by his experience of former processes. About the time that he supposes the conversion to be sufficiently advanced, one of the trial-bars is drawn out from the pot, and by comparing the size of the blisters raised upon its surface with another bar which is known to be sufficiently carbonated, an idea is formed of the state of the furnace, and accordingly the fire is, at the proper time, discontinued, and the furnace is suffered to cool. Some manufacturers proceed to make experiment of the trial-bar by hardening and tempering it, so as to prove to a certainty the degree of its conversion, the blisters being found in some degree fallacious; for their size depends as much upon the degree of heat to which the bar has been exposed, as upon its carbonization, and the rapidity with which the conversion has carried on, rather than its actual state.

The time which the iron is required to be in the process of cementation depends upon a variety of concurrent circumstances. 1. The degree of carbonization required to form a steel of the proper quality; this varies with the use the steel is to be applied to. 2. The heat it is subjected to. 3. The nature of the iron employed in the process. The combinations of these circumstances are so numerous, that nothing but long experience can determine the proper duration of the process.

In general terms it may be observed, that a short period will produce a steel very soft and tenacious, which, when properly treated, will possess ductility as its most striking property, and is therefore very proper for springs, wire-drawing, and other purposes requiring ductility, but without the hardness requisite for edge-tools. The period of cementation for such steel varies in different manufactories, from four to six days and nights.

Steel which requires more hardness, but at the same time sufficient tenacity to resist sudden shocks, such as the edge-tools for working wood are subject to, must be cemented a longer time. This, which is mostly tilted into plain steel, is cemented five, or seven, or eight days, according to the heat and the quality of iron employed. The steel employed for manufacturing tools for cutting metals and hard substances being but small in demand compared with the others, is not cemented a longer time, but is returned into the furnace at the next charge, along with a charge of iron, and cemented again with fresh charcoal: this is termed double converted steel.

But for some fewer purporses, such as the turning and boring of cast-iron, the steel is converted three times; in this state it becomes so hard and brittle as to be totally unfit for any purpose requiring tenacity, or for any cutting edge which is less than an angle of 70 degrees, or it would be continually breaking.

The steel which is requisite for the processes, must be as great as to give the iron nearly a welding heat, but if carried farther, will endanger melting the bars when the process has proceeded some time; an accident which has frequently occurred through the inattention of the fireman. It is observed by manufacturers, that the carbonization proceeds quicker when the heat is greatest, and for this reason the duration of the processes varies in different furnaces, in some measure from their construction, in urging a greater heat, and this depends chiefly upon the height of the chimney, and the draught it occasions.

When the conversion is supposed to be complete, the furnace is suffered to cool, until a man can conveniently enter the furnace, to take out the bars and remaining charcoal, and prepare the furnace for a new charge. The bars which are brought out are (from being covered with blisters upon the surface) termed blistered steel.

On examination of the fracture of a blistered bar, it is found full of internal cracks, which are generally parallel to the flat side of the bar: some of them are larger than others, and extend the parts of the bar sufficiently to raise numerous protuberances or blisters upon its surface. These cracks have every appearance of being opened by the expansive force of some gas generated in the iron during the process, but what the nature of this gas is, still remains to be investigated. It seems to arise from the body of the iron itself, by the crack being within the solid substance of the bar. The fracture of the blistered steel is exceedingly irregular, of a white colour, like frosted glass, and appears like an irregular crystallization; but the facets exhibited are larger in proportion as the cementation has been longer continued, and from this reason they are larger towards the surface of the bar than in its centre.

The furnace above described is of that kind which is esteemed the best for the processes, and is most generally employed in and about the neighbourhood of Sheffield in Yorkshire, where the manufacture of steel is carried on at a larger scale than in any other part of England. The furnaces used at Newcastle, which is another seat of this trade, are very similar.

The charge consists of twelve tons, each pot containing six tons of iron; and it is necessary that all the bars converted...
TILTING OF STEEL.

at one proceeds he of the same size, or the smaller ones would be thoroughly converted before the others had taken up a sufficient dose of carbon. This large quantity of a single article is more than the trade of some manufacturers will dispose of, they therefore employ smaller furnaces, which contain only eight tons, and such are generally constructed but with one pot ten feet in length, three feet broad, and two feet deep: the fire-place is directly beneath the pot, twenty inches wide, and fluxes are carried round it on both sides and ends: the vault and chimney of such a furnace are the same as the double pot. It is found by experience that the small furnaces consume somewhat more fuel in proportion to the quantity of iron they convert, than the large ones, because the heat lost in the beginning and end of the processes, and that transmitted through the walls of the building, is the same in both inferences.

Mr. Daniel Little of America, in 1785, recommended a new substance to be used in the cementation of steel instead of charcoal: it is the marine plant known by the name of rockweed, or rockware, and is found in great plenty on rocky shores in America. It was to be prepared by first mowing it from the rocks by the scythe or sickle, and spreading it out on dry land till the rains have washed off the greater part of the sea-salt; it was then to be dried and pulverized, and may be used as any other cement for making of steel. He says that he discovered this property in an experiment where a small piece of iron was put into a crucible, and filled with the powdered plant as a cement: after it had been exposed to little more than a cherry heat for five or six hours, it was converted into steel.

All cemented steel in its raw state, after it is taken from the converting furnace, is called blistered steel; because the surfaces of the bars are covered with blisters, and on breaking a bar it is found to be full of cavities within, which seem to have been opened by some gas generated in the iron when in the processes of cementation, and to have raised the surface into blisters, which are hollow within. In this state the steel is not fit for any purpose, because of the numerous cavities, and from the great disposition it has to break with the most irregular and rugged fracture imaginable. To render it found and tenacious, it must be well hammered while at a moderate heat, which operation is termed tilting the steel, because it is done under the tilt-hammer, worked by machinery. There are many reasons why the hammering of steel cannot be sufficiently performed by hand: the principal are, that the expense of labour would be too great to answer, and that a man could not strike hard and quick enough, to complete the operation at one heat of the steel: if more than one heat is taken, the steel will not receive so much advantage from the hammering, because when it is heated, its pores are opened; and if suffered to cool without hammering, the grain of the steel will be found considerably coarser; therefore, every time it is heated, the good effects of the previous hammering are in a great measure lost. Tilt-hammers are worked by water-wheels or steam-engines, according to the local situation of the manufactory. (See a description in the article Tilt-Hammer, Plate VIII. Iron Manufacture.)

The same axis is made to actuate three or four tilt-hammers placed side by side, and the hammers are not all of equal lengths, each one being shorter than the next: by this arrangement, when they are all working together, the workman of one tilt does not inconvenience those employed at the other two. The anvils of the hammers are nearly on a level, or at most only a few inches above the surface of the ground; and the workman fits his or her foot, for the purpose, in a direction perpendicular to the heave of the tilt, upon a seat which is suspended from the roof of the building by two iron rods: by this means he can with the greatest ease advance to or from the hammer, by just touching the ground with his foot, and pushing himself backwards or forwards as he suits in the working. The three seats are in parallel directions, but sufficiently distant from each other, in consequence of the different lengths of the hammers, to allow the workmen to perform their business. At a convenient distance from each tilt, is placed the forge for heating the steel. The two forges for the small hammers are placed together under the same dome, while the other forge is by itself near the great hammer. The bellows for the hammers are worked by a small crank on the end of the gudgeon of the shaft; they are placed over-head in the roof of the building, and a copper pipe conveys the air to the tue iron. The forges are like those used by smiths, except that they have a small cover built of fire-brick over the hearth: the cover is square within, about eight inches wide, eight high, and eighteen inches or two feet long. It is open in front, to introduce the bars. The coals are placed on the hearth, as smiths usually do, and the brick cover acts, to reverberate the flame down upon the steel, and give a very regular heat. Each workman at the tilt is attended by two boys, who heat the steel at the forge, and convey it to the workman, that he may lose no time: another boy attends each tilt to take away the finished rods and cut them to length, and then to straighten them.

The operations of the tilt are conducted in the following manner: Suppose a piece of steel has been heated by one of the boys, and brought to the man at the hammer, he places it upon the anvil, at a point nearest to the centre of the hammer, where its surface is reduced to a round edge, about an inch wide; the face of the hammer is made round, to correspond with the anvil, and from its similarity to the edge of a smith's hammer, may be called the pen of the hammer and anvil. The machine is always in rapid motion, and between every stroke that the hammer makes, he moves the bar forwards on the anvil, that it may be struck by the edge of the hammer in a fresh place. If the bar is flat, as blistered steel usually is, it is first hammered in this manner upon its edge, to reduce it to a square, and at the same time draw it out in length. When it has been hammered thus all its length, the surface becomes indented on both sides by the edges of the hammer, the anvil being bounded by waving lines. This first operation is called notching down. The tilt then removes the bar beneath the flat face of the hammer, and the rod is flattened at every stroke, and all the indentation removed; when he gradually recedes from the hammer, drawing the rod along, and flattening it all the way. When the end of the rod comes under the hammer, he turns the other face of the rod upwards, and advancing to the hammer, pushes the rod forwards under it: in this manner he proceeds, flattening it on one side or the other, until he brings it to the proper figure, which he tries by a gauge. The moment it is finished, the boy brings another piece of hot steel, which he places under the hammer, and then the other boy takes away the finished rod from the tilt, who takes the fresh piece: in doing this, they are careful that the hot piece of steel is placed under the hammer before the other is taken away, that the faces of the hammer and anvil may not strike together, when there would be danger of breaking them, as they are both made of cast-iron: the second piece is tilted in the same manner as before, and when finished, is changed for another.

The perfection of tilting steel, depends upon drawing out a rod perfectly straight to the same size in every part of its length. Many workmen, particularly at Sheffield, have acquired such skill and dexterity in the management of the rod while under the tilt, that their work is as straight and even
as though it had been drawn through a steel-plate, in the same manner as wire, and all its angles perfectly square: its surface is of a black polish, and so smooth as though it had been filed. All artists use the square steel rods for making their tools; and the straightness and regularity of the rods are such, that a person who has not been an eye-witness of the operation, would scarcely believe it possible to produce such accurate work from the blows of a hammer. The points to be attended to by a tilter are, that in notching down the bar to draw it out to length and size, he cau- ses the blows to fall exactly at equal distances from each other, unless (which seldom happens) the bar should have any part thicker than the rest; it frousks much, and is a little nearer together in that place, to reduce it all to one size. Afterwards, to flatten the bar, he must be careful to place the bar truly flat upon the anvil, and hold it in the same plane, while he draws the bar under the hammer, and that he moves himself with a perfectly equable motion, that every part of the bar may be alike subjected to the action of the hammer: the surface will then be true, and free from undulations. Another circumstance to be attended to, is, when he turns the bar upon the anvil to hammer the adjacent sides, that he makes them truly square to the former sides. These things must all be done in so little time, that it requires long practice and experience to perform them well. Beginners are always apt, when they place their feet on the ground, to move themselves too quick just at that time, which causes the bar to be thicker at that place.

The different methods of conducting the operation of tilting, give the steel different qualities, which are distinguished into 1. Common steel; 2. Shear or Newcastle steel, also called German steel; and 3. Tilted cast steel.

Common steel is made by tilting bars of blistered steel, and drawing them out into rods of any size. The blistered bars are of various sizes, but in general about an inch and a half broad by half an inch thick. If these are to be drawn into rods half an inch square, they are broken into convenient lengths to handle, and one end of each piece is heated to a good welding heat by the boy who attends the forge, who puts three or four in the fire together, and, according to their size, he learns by experience at what time he must put every one into the fire, that it may acquire the proper degree of heat by the time that the tilter shall have just finished the other bars.

The tilter first begins by notching down the narrow edge of the bar, holding the other end of it in his hand, and notches down such a length of it as experience teaches him will be sufficient to form a rod of the length and size required. The notching on the edge of the bar rather increases its thickness, while it diminishes its breadth, and brings it nearly to the square figure of a rod: he then flattens it, and begins again to notch it down upon the broad side; afterwards he again flattens it; then proceeds to notch it upon the edge, and afterwards to flatten it once or twice on both sides, and the rod is finished.

When a skilful tilter has been some hours at work upon rods of one fize, he judges by sight when the rod is of the proper fize; but on first beginning, he tries it by a gauge, and flattens it repeatedly, if necessary, the boy bringing a piece of hot steel to place under the hammer while he is gauging, and which is drawn out in its turn. When the tilting is completely finished, the steel rod is taken away by another boy, who, with a pair of thcares, cuts off the rod from the blistered bar from which it was drawn out. He places the rod on a flat caft-iron table, and sets it truly straight by a hammer, then stumps the bar with a mark of the quality of the steel, and it is finished.

All these operations are performed in so short a time, that the rod still retains a red heat; but this will excite less surprize when it is considered that the hammer strikes four hundred blows per minute, and falls with great weight, so that it soon completes the work, and it is very probable that the great percussion it exerts upon the steel in some measure prefers the heat. It is well known that blacksmiths are in the constant habit of lighting a match to kindle their fire, by only hammering a small piece of iron quickly, and turning it about under the hammer, and in a short time it acquires sufficient heat to inflame the sulphur of the match. This heat most probably arises from the friction which the hammer cau- ses amongst the particles of the iron, by rubbing them violently against one another; and the smiths observ e, that the iron will not become red-hot if it is always struck upon the same face; but it must be turned round, that a new surface may be continually exposed to the action of the hammer.

Steel is so called, because the thcares for dressing woollen cloth are made of it. It is also called Newcastle steel, because formerly made there; and German steel, because the natural steel in Germany is treated in the same way; it is likewise called faggotted steel. To make steel, the bars of blistered steel are broken into lengths of about eighteen inches; then four or more of these are laid together with one of double the length, and all four are tied together with pieces of small steel: this is called a faggot, and is placed in the forge, to be heated to a good welding heat; it is then taken to the tilt, and notched down on both sides, to weld all the bars together, and close up the internal flaws. The workman holds the faggot by the end of the long bar as a handle; the operation of welding takes but a few seconds, and a small rod is then drawn out from a piece of the end, in the same manner as drawing out common steel.

Cast steel is prepared by melting fragments of blistered steel, and casting them into an ingot. (See STEEL.) The ingot is then drawn out under the tilt into the required fize, and the manner of doing this is the same as for common steel.

It is the custom of the manufacturers of cutlery and steel goods to purchase steel from the converting furnaces in the plate of blistered bars, which they send to the tilt-mills to be drawn out into the fize they require for their use: this is done at regular prices. In tilting steel, a trifling loft is sustained by the metal oxidizing upon the surface, and throwing off black scales. The manufacturers are in the habit of allowing 46 to 8 lbs. per hundred weight for such lofts: this latitude is given, because in drawing the bars out into rods of a small fize, the waile must necessarily be greater; the metal being much longer exposed to oxidation, and the surface throwing off more scales.

TILUTHA, in Ancient Geography, an island of Asia, in the Euphrates, about 33° 55' lat.

TILWARAH, in Geography, a town of Hindoostan, in Gurry Mundella; 5 miles S. of Gurrah.

TIM, a town of Ruffia, in the government of Kurak; 44 miles E. of Kurak. N. lat. 51° 40'. E. long. 35° 34'.

TIMA, TIMAH, TAIMA, TALBA, or TI ALBA, a town of Arabia, in the province of Nedsjed; 180 miles N.N.E. of Medina.

TIMACUM, in Ancient Geography, a town placed by Ptolemy in Upper Media, at a distance from the Danube.

TILÆA, a town of Asia, in the interior of Bithynia. Ptol.

TILMæUS, the Locr'ian, in Biography, was a philosopher of the italic school, and flourished in the time of Plate, who derived from him principally the doctrine of Pythagoras, and whose book, entitled "Tilmæus," was 4 P 2 founded
TIM

The timariots are obliged to serve in war, personally, with as many men and horses for service as their timar, by the estimate made of it, contains 2500 apers, or about $6. stering; and to maintain them constantly mounted and armed after their manner, to be ready to march at all hours when commanded, and that on pain of death; nothing, not even sickness itself, being allowed to excuse them.

Besides this service, they likewise pay an acknowledgment of one-tenth of their revenue. If they have any children of age to bear arms, and fit for the service after their decease, or, in defect of this, if they have any relations that have the least interest, the timar is used to be continued to them on the same conditions, otherwise it is transferred to others.

If the revenue thus held of the grand signior exceed 15,000 apers, or 36l. sterling, they who hold it are not called timariots, but sibaffi, or zaims: these always have the administration of justice in the place, under the fagiac of the province.

The timariots have different appointments, from 4000 or 5000 apers, equal to about 12l. sterling, to 20,000 apers, but unless their timar exceed 8000 apers, they are never obliged to march, except when the grand signior goes to the army in person, on which occasion none are exempted.

The origin of the timariots is referred to the first sultans, who, being masters of the fiefs or lands of the empire, erected them into baronies or commanderies, to reward the services of their bravest soldiers; and especially to raise and keep on foot a number of troops without disbursing any money.

But it was Solyman II. that first established the order and discipline among these barons, or knights of the empire; and by his order it was, that the number of horsemen each should maintain was regulated.

This body has heretofore been not only exceedingly powerful, but great and illustrious throughout all the empire; but avarice, the ordinary fault of the Orientals, has occasioned their declension of late years.

The viceroys and governors of provinces manage their matters so at court, that timars, even out of their jurisdiction, are given to their domestics, or to such as will give them the mohl money for them.

There are two kinds of timariots, the one appointed by the Porte, the other by the viceroy of the country; but the revenues of both are less than those of the zaims, and their equipage and tents less in proportion.

Those who have their patents from the court, have from 5000 or 6000 apers to 15,999 apers per annum; if they have one apser more, they become zaims. Those who receive their patents from the viceroy, have from 3000 to 6000 apers per annum.

This cavalry is better disciplined than that properly called the Iphahis, though the Iphahis be the neatest and briskest. These have only light in plateaus; whereas the zaims and timariots are divided into regiments, and commanded by colonels, under the direction of bakhaws. The bakhaw of Aleppo, when in the army, is colonel-general of this militia.

TIMARIOTISTAN, in Geography, a town of Persia, in the province of Farilkan; 15 miles E. of Pafa.

TIMAVO, a river of Carniola, which runs into the gulf of Trieste, near Duino.

TIMAVUS, in Ancient Geography, a fountain, lake, river, and port of Venetia.

TIMBANG, in Commerce, a measure at Batavia for rice, pepper,

founded on his book "On the Nature of Things." Prorus preferred a small treatise of Timaeus "On the Soul of the World," and it is prefixed to some editions of Plato's Timaeus. In this treatise, chiefly Pythagorean, he differs from Pythagoras in the following particulars: viz. that, instead of one whole, or monad, he supposes two independent causes of nature, God and Mind, the source of intelligent nature, and Necessity or Matter, the original of bodies; and that he explains the cause of the formation of the world, from the external action of God upon matter, after the pattern or ideas existing in his own mind. Upon a comparison of this piece with Plato's Timaeus, it will be found that the Athenian philosopher has obscured the simple doctrine of the Loecian with fancies drawn from his own imagination, or from the Egyptian schools.

In the time of Ptolemy Philadelphus there was a Sicilian, named Timaeus, who was a celebrated historian; but none of his writings are extant. He died at the age of 96, B.C. 262. Brucker by Enfield, vol. 1.

TIMAGENUS, in Ancient Geography, an island in the Arctic gulf. Ptol.

TIMANNA, in Geography, a town of South America, in the province of Popayan; 80 miles E. of Popayan. N. lat. 2° 12'. E. long. 74° 46'.

TIMANTHE, in Biography, a famous Grecian painter, was, as it is said, a native of Cythnos, one of the islands called Cyclades, or of Sicvyn, and flourished about the year B.C. 400. The mind of this artist is supposed to have surpassed his art, in the exercise of which he displayed great skill, so that in his performances, something was to be understood, which he did not express. As an instance of this, we are referred to his picture of Iphigenia about to be sacrificed, in which, having exhausted every variety of the expression of grief in the other spectators, he has thrown a veil over the face of her father, thus intimating that his anguish surpassed all external tokens. In his Sleeping Cyclops, exhibited in a small tablet, he has introduced Satyrs measuring his thumb with a thyrus, in order to give an idea of the magnitude of the principal figure. At Samos he was a competitor with the famous Parrhasius in a piece, of which the subject was the judgment for the arms of Achilles, between Ajax and Ulyseus; on this occasion the prize was awarded to Timanthes. In the temple of Peace at Rome a hero of admirable workmanship by the same artist was preferred. Pliny Nat. Hist.

TIMAR, a tract or portion of land, which the grand signior grants to a person on condition of serving him in war, or horseback.

Some define the timar a portion of land assigned to a saphi, or other person to serve on horseback, to enjoy, during life, for his subfiliation.

Menaski describes it as a stipend or revenue, granted to old soldiers who have deferved well, in lands, and possessions of castles, towns, villages, fields, or in tithes, and other fruits and incomes; sometimes with the privilege, jurisdiction, or signory of the said places.

The timar is a kind of fief granted for life. The whole Ottoman empire is divided into fagacaries, or baronies, under which all fuch as hold timars, who are called timariots, are bound to fatisfy themselves when summoned upon any expedition. Timars may be resigned as benefices among us, only obtaining the content of the begleheroy, or governor of the province. Indeed, for timars of above 2000 apers per annum, cal. a sain, the grand vizier alone grants dispensations.

TIMARIOTS, those who enjoy lands on the footing and tenure of timars. See Timar.
pepper, and other dry goods. It is reckoned at ten facks, or five pikuls: another measure is called kulaack, and weighs 74 cattis: 7 kulacks make one timbaug, liquid measure.

**TIMBER**, in *Geography*, a river of Prussian Lithuania, which runs into the Neman; 4 miles N. E. of Wipe.—Also, a town of Prussian Lithuania, 6 miles W. of Ingham.

**Timber**, or **Timber-Trees**, in *Rural Economy*, that sort of wood produce which is useful and proper for the purposes of building, the construction of tools, implements, carriages, &c.; or such large trees of different sorts as have reached their full or suitable states of growth, and are in situations fit for being cut down for use. The various kinds of trees which are the most useful and important in this intention, have been noticed and considered in speaking of the nature of common and other plantations and planting; but they are chiefly the different sorts of pines, the larch, the birch, the common ash, the mountain-ash, the beech, the fycamore, the elm, the oak, the hopt: and common chestnuts, the alder, and the poplar. However, in general, the oak, the ash, the elm, the larch, and the Scotch pine, are by much the most useful and valuable for all the different uses of this nature.

We shall here mention from Evelyn's Sylva, &c. some of those kinds of timber that are most serviceable, and give a brief view of the uses to which they are applied, referring to their several denominations and other collateral articles for a further detail.

1. **Oak**, the uses of which need no enumeration; to endure all fasons and weathers, there is no wood like it: hence its use in pales, shingles, posts, rails, boards, &c. For water-works, it is second to none; and where it lies exposed both to air and water, there is none equal to it.

2. **Elm**: this, felled between November and February, is all spine or heart, and no sap; and is of singular use in places where it is either always wet, or always dry; its toughnefs likewise makes it of use to wheelwrights, millwrights, &c.: nor must it be omitted, that its not being liable to break and fly in chips, makes it fit for dressers and planks to chop on.

3. **Beech**: its chief use is in turnery, joinery, upholterly, and the like, as being of a clean, white, fine grain, not apt to bend nor split: it has been sometimes, especially of late, used for building-timber, and if it lie cleanly wet, is judged to outlast oak.

4. **Abe**: its use is almost universal; it is good for building, or other occasions where it may lie dry: it serves the carpenter, cooper, turner, ploughwright, wheelwright, gardener; as also it is used at tea for oars, handspikes, &c.

5. **Fir**, commonly known by the name of deal, is of late much used in building, especially within doors, for floors, ceilings, windowfr, and most works of ornament.

6. **Walnut-tree**: this is of universal ufe, excepting for the outsides of buildings; none is better for the joiner's use, it being of a more curious brown colour than beech, and less subject to worms.

7. **Chesnut-tree**: next to oak, is the timber most sought for by joiners and carpenters. It is very lasting.

8. **Service-tree**, used in joinery, as being of a delicate grain, and fit for curiosities: it also yields beams of considerable size, proper for building.

9. **Poplar, abrided and open**, differing very little from one another, are much used of late instead of fir: they look as well, and are tougher and harder.

10. **Alder**, much used for fewer or pipes to convey water: when kept always wet, it grows hard like a stone; but where sometimes wet, and sometimes dry, it rots presently.

The uses of timber are so many, and so great, that the procuring of a sufficient supply of it extremely well deserves the care of every estate; as it must be a great disadvantage to it to be obliged to have recourse to its neighbours, and purchase, at a very considerable and continually renewed expense, what might, by an early economy, be sufficiently supplied at home.

This economy, however, must be applied in time; for our natural indolence, our love to reap the advantages of every thing ourselves, and our little care for posterity, give great room to fear succeeding ages will want wood, both for private and public exigencies. All our arts should be employed on this subject, with two views, the one to preserve and cherish our growing wood, the other to renew the trees which have been, and are continually cut down.

The quantity of acorns which the oak bears, has made many people suppute, that Nature has taken care for a renewal for us; and that of this vast quantity of seed, which annually fall, there will be always an over-sufficient supply of young trees, which will grow up in the place of the old ones: but experience proves, that this is by no means the case. The greater number of the fallen acorns is devoured by many different animals, for whose nourishment Nature has provided that abundance of them: and of those which escape this fate, we are to consider how few can come to good, from the natural accidents they are unavoidably exposed to; they fall on a covered ground, where dead leaves, and decayed parts of branches of trees, usually prevent their touching the earth, into which they are to shoot; or, if they can shoot here, it is merely from the surface, where they are, in their slow growth, liable, while very tender, to all the inclemencies of frosts; and add to this, that it is very difficult for such tender plants as the young feedlings of these to find room for growth or nourishment among the every-way spreading roots of other trees; and the continual shade and want of free air, must render them very weakly and irregular in their growth, even supposing them to get over all the other difficulties.

It is very certain, that timber-trees of oak are frequently met with among the underwood of forests; but we shall always find this to be the case, not in the close places, but in certain spots, where there has been a vacancy or opening; and that usually, where there are not, nor have at any time been, oaks in the neighbourhood of the spot. The acorns that fall from the oaks usually come to nothing from the before-mentioned accidents; and these trees which grow at distances, are owing to the acorns brought thither by birds, and accidentally dropped there. This is an inference familiarly verified, by observing, that there are frequently little bushes near wood, which, though of white-thorn or other trees, are usually surrounded and ornamented with young oaks; the jays and the like granivorous birds are the authors of this crop; for bringing the acorns from the adjoining woods, to eat under these bushes, they drop many by the way, which they do not trouble themselves to look for on the ground, and which having here a freer ground to strike root into, and an open air to grow in, seldom fail of coming to good, unless destroyed when young.

In order to the preservation of our growing timber-trees, it would be a very useful law, that all who cut down any number of oaks, should also leave a number in good condition for after-cutting; and that no timber should be cut down, but at a proper age, in regard to the nature of the soil;
failing; since it is certain, that trees grow to their perfection at very different periods of time, in proportion to the depth of soil they have to grow in; and that as it is, on the one hand, not for the interest of the state to suffer trees to be cut till at their perfection for size and founds, so after they are arrived at their perfection, it is equally certain that they gradually decay.

The quality of the soil the tree stands in may be necessary to be observed to this purpose; but the quantity or depth of it is the great subject of enquirie; and a great number of observations has proved, that the proper season for cutting oaks, in a soil of two feet and a half deep, is at fifty years old; those which stand in a soil of three feet and a half deep, should not be cut down before seventy years; and those which stand in a soil of four feet and a half deep, or more than that, will increase in goodness and in size till they are a hundred years old; and observation has proved, that after these several periods, the trees begin to decay.

This seems the best rule to establish, in regard to the common soils; but those which grow in a lighter or more sandy soil, may have their periods changed from these to forty, to sixty, and to eighty years at the greatest depth; and after these times it is always best to fell the wood meant for public service, whether then wanted or not, since it is much better to keep it in public magazines, than to leave it to be daily decaying.

Heaths, and other uncultivated places, where there is no regular growth of wood, but where fern and useless plants alone seem to flourish, usually afford also some sprawling trees of the oak. These probably have had their origin from acorns dropped by birds; but they seldom grow tall or regular; since, not having been defended from the injuries of cattle, they are usually browsed on, and fluntet while young, and so become crooked and short-trunked, or pollard-trees. These, though not of such value as the more regular oaks, yet deserve care, both with respect to their preservation and felling; since they afford a number of trees naturally bent, and formed for many parts of ship-building.

The little care usually taken of these trees, though on this occasion of great value, seems to threaten a general loss of them; but as trees, thus naturally crooked and bent, are of value, it is a laudable attempt to try at the finding of a regular method of producing such; and this is easily practicable, by following the same methods by which these wild ones become so. They wholly owe their figure to the cattle’s biting off their tops while young, and afterwards biting off again the tops of the shoots from the first wound. In this manner, if a number of young trees, set apart for the experiment, have their tops cut off at two, four, six, eight, ten, and twelve feet from the ground, and four years afterwards the shoots from these flunted tops are again cut in the same manner, the trees will be found afterwards to grow up in all the irregularly crooked figures that can be conceived, and by this means a supply of naturally crooked wood may be raised for all the occasions of ship-building, with infinitely greater ease, and more certainty, than by the method proposed by some, of bending them down with weights tied to their tops while young. See Growth of Crooked Timber.

As to the supply of young wood in the place of what is cut down, there are some circumstances which have not had the attention paid to them which they deserve. The spring frosts, which come on at a time when the shoots, by which nature is to raise the supply for what is cut down, are just preparing to grow, are of prodigious injury, and do not less mischief to thee than to the young shoots of garden plants, though the diligent hopes of the succession of the proprietor, and usually also the distance of the place, and want of repeated observations, occasion its not being perceived. This, however, may in a great measure be guarded against. Frequent experiments and repeated observations prove, that the mischief done by these frosts affect in a much greater degree those shoots which are exposed to the south, than those which face the north; and that it is greatly more possible against such as are wholly exposed to the wind, than against such as are sheltered. These known circumstances may give the hint to a method of saving, at least, a great part of the wood to be felled from this destruction, to its renewal, by the making it a rule to begin cutting down on the north side; and, as the whole felling is a work of some years, the standing wood of every season will defend the young shoots of the newly-cut stumps the following spring, not only from the south exposure, but will shelter them also from the wind.

Many prudent managers have made fine eftates of their coppice-woods, by regularly felling a certain portion every year, and providing for a renewal of the first cutting, against the felling of the last portion, by proportioning the time of growth to the quantity to be cut every year; and there is great interest to be made of a true knowledge of the growth of wood in this manner. Whoever observes the growth of young trees, will find that the second year’s growth is much more considerable than that of the first; the third year is more than that of the second, and so on for many years; the yearly growths of young wood greatly increasing every season up to a certain time or age of the tree, after which the increase in bulk, by growth, becomes gradually less. The great advantage to be made of coppice-wood, would be by knowing this interesting period, and feizing on it, always to cut down the trees jut at that time when they arrived at the end of their quick growth, and so setting nature to work with new shoots, to employ the same on enriching again the owner. Regular observation and experiment alone can ascertain this happy period; but any man who has much coppice-wood upon his estate, may affure himself of it, by cutting a given quantity every year, for ten years successively, and then carefully reviewing the differences of the yearly produce. Memoirs Acad. Sc. Ann. 1739.

On the businefs of raifing and growing good timber, or trees of that fort, Mr. Loudon has thrown out fome interefting, ingenious, and philosophical hints and suggestions, as well as flated fome strong facts in confirmation of them, in his work on forming and improving country refidences. It is confidered as remarkable, that the matter has never particularly engaged the attention of thofe who have been employed in describing the methods of rearing trees. The effects of culture on other vegetables is fo great, it is faid, as always to change their appearance, and not unfrequently to alter, in a confiderable degree, their nature. The common culinmary vegetables, and cultivated graffes, affume fome different an appearance in our fields and gardens from what they do in a ftate of wild nature, that even a perfon accu- tom’d to the nature of plants might eafily be deceived in regard to the species or kind. The fame general laws operate upon the whole kingdom of vegetables; and whence it is thought plain, that the effects of culture upon trees, though different in degree, must be analogous in their nature. It is true, it is faid, that as yet we are pollefsed of no great number of either experiments or observations, to enable us to determine with minute accuracy the precise extent of
of these effects; but still a person practically conversant with the
subject, who shall pay attention to what he may notice to
be taking place in different parts of the country, and
who professes a sufficient knowledge of the vegetable
kingdom and physiology to reason from analogy, may, it is
thought, deduce such general consequences, as will suggest
important practical rules and regulations.

It may be proper, it is said, to remark, that by culture
is not meant merely the operations upon the soil, or on even
the form of the particular tree; but every thing that tends
to remove it from its natural state in order to accelerate vege-
tation. It is considered too, that a tree is in a natural state
whenever it has sprung up fortuitously, and propagates itself
without aid from man: whether it be in crowded forests, woody
wales, or in scattered groups on hills or commons.

Some trees and other vegetables may be said to be natural-
ized to situations which, but for art, they probably never
would have grown upon. Thus, for instance, mountain
plants are sometimes found common in plains, and even
meadows; and alpine trees which disseminate themselves in
level and warmer parts of the country: but then the person
who is conversant with such matters, by comparing the effects
of these different situations on the vegetable, always knows to
select as general nature that which perfects all the arts,
and where the soil and situation be best suited for the repro-
duction of the species or fort, and the prolongation of indi-
vidual life. These rules are, it is said, founded in nature.

For example: no person, judging from them, could mistake
a warm English common as the natural soil and situation of
Scotch firs, though they not frequently disseminate them-

selves there. Is, indeed, well known to every one in the
leaf conversant with the vegetable economy, that in all her-
baceous vegetables, and even shrubs of considerable size,
the effect of removal to an improved soil, climate, and situation,
is to expand the parts of the whole vegetable: that the
effect of removing or cutting off part of the vegetable above
ground is to expand those parts which remain: that the
effect of removing anything of the parts under ground, or of
removing the whole vegetable into a colder climate and less
congenial soil and situation, is to contract or confound the
whole. This, were it necessary, could, it is said, be
illustrated in a thousand instances from the commonest vege-
tables: but for the present purpose, it is only necessary to
notice further, that this takes place more or less in a degree
corresponding with the rapidity of the growth of the vegetable,
and its duration. Thus, all the annual grasse are much far-
ther removed from a state of nature by culture than the per-
ennial ones. So are the annual garden vegetables, as cab-
nages, legumes, and spinach, in opposition to strawberries,
aparagus, and many others. Quick growing trees or shrubs,
as willows, raspberries, and some others, are also much easier
removed from their natural state, than such as oaks, thorns,
hollies, and heaths, which grow much slower. If these
remarks and conclusions be just and well-founded, which, it
is supposed, none will deny, it must follow that the same
general effects take place more or less on all trees; that
when they are removed into a colder climate, or have part of
their roots cut off, it will in some degree contract the fibre
of the wood, and render it a of more fold and hard texture;
and that when they are removed into a warmer climate, have
most of their branches taken off, or are placed in a better
state, it must, by accelerating their growth, it is thought,
tend to expand the fibre of the wood, and of course render
the wood fitter and more liable to suffer by the action of
the common elements, when the tree is cut down and applied
to use. That this does really take place, will, it is said, be
gathered from the detached facts stated below, which have
come to the writer's knowledge, and to which every prac-
tical unprejudiced person, who has visited different parts
of the kingdom, will, it is thought, be able to add many
others from his particular observation, attention, and exa-
mination.

First, that every hedger and forester knows, that furze and
thorns, which have been cultivated in fields or hedges, are
of a much softer or wider grain, and are much easier cut over
with the hedge-bill, than such as spring up from feed in a
wild fenery, and never undergo any sort of pruning or cut-
ing in, nor any kind of culture in any way. They know
too, that in a common to be cleared of furze or thorns, or
in a hedge to be cut over, there are some parts which require
a much lighter stroke of the hedge-bill than others; and
that those parts easiest to cut, are uniformly those where the
plants have grown the quickest:—gardeners experience the
same thing in pruning or cutting over fruit-trees or shrubs.
Thus the difference between the texture of the cultivated
and the wild rasperry is, it is said, striking, though the stem
of one is nearly double the thickness of that of the other.
In all the other of these cases, the stem of both are sup-
posed alike in diameter and cleanliness, or absence of knots;
though the same thing would, it is thought, take place in
a considerable degree, even if the stem of the cultivated or
quick growing one were thicker than that of the other in
the wild state. Supposing that there were no other proofs
this, it is contended, clearly shews that cultivation, or what-
ever tends to increase the growth of a tree, tends likewise to
expand the vegetable fibre. But there are other conver-
uing proofs, it is said, which demonstrate this, and at the same
time shew, what few, it is supposed, will doubt, that when
the vegetable fibre is expanded, or when the annual ringlets
or circles of wood, produced by a tree, are soft and larger
than the general annual increasement of such tree, the timber
must be less hard, and more permeable by air, water, heat,
and other matters, and, of course, inferior for all the pur-
poses of timber.

Secondly, that it is well known that the common oak in
Italy, where it grows faster than in this country, is com-
paratively of short duration. And that the oak which grows
on the mountains of the Highlands of Scotland is much
harder and closer than any produced in England, though
on these mountains it seldom attains one-tenth part of the size
of English trees. Every country carpenter in Scotland
knows, it is said, the extreme difference between the dura-
tion of Highland and English oak for spakes of wheels.
Many hedge-carpenters in both parts of the country know
the relative duration of transplanted or plantation oaks, that
is, the young oaks which are thinned out from thriving
plantations of this sort, and those from natural forests, when
employed as posts for railing. From different observations
which the writer has made in Monmouthshire and Hereford-
shire, the duration of the oak in these counties, it is thought,
more inferior to what it is in Cumberland and Yorkshire:
that is, it is thought no exaggeration, when it is said that the
difference is as eight to ten. Some timber dealers are known by
the writer, who, in purchasing it, pay attention to the dif-
fERENCE of soil and situation even in the same woods. When
they can find oak in exposed situations and on deep clay soil,
and ash on rocky fleeps, they always give them the preference
in their purchases as timber.

Thirdly; that a known fact is stated by the writer which is
said to be of such importance, that it is trusted, if it does
not satisfy every unprejudiced person in respect to the truth
of the general principles which are wished to be here laid
and explained, it will at least arrest the attention of all
those who are interested in the quality as well as mere bulk
of
of timber: and this, it is thought, may lead to more extensive observations, and perhaps more favourable conclusions relative to it.

The plantations of the timber kind which were made at Kinnaird castle in the years 1750—1790, are, it is said, well known in the north of Scotland. They were chiefly of deciduous trees, among which were generally introduced larches for shelter. These larches, in some places, grow with astonishing rapidity. On many slopes, where the surface-soil was good though not deep, and the sub-soil a sandy gravel, they advanced upwards of five feet a year for the first six or eight years after being put in. As they overtopped and crowded the deciduous trees, they were gradually felled; and as much had been said about the durability of larch-wood, the first trees that were cut down were fawn up, and applied to a purpose: which was perhaps, it is thought, one of the best tells of their durable properties. This purpose was the foot-paths of peach-houses and vineyards, where they were exposed to alternate drought and moisture, heat and cold, and where common deal and other kinds of wood had repeatedly failed. The larch deal of these trees was, it is stated, applied in the same way as the others, and in lefs than two years was completely rotten and destroyed!

It may, it is conceived, be alleged by some, that this could only hold true in regard to the dead, or late formed wood: but the heart, or red central wood which was present, though it lasted longer, did not, it is affirmed, endure three years! The vast number of these trees annually taken down, were afterwards, it is said, chiefly made use of as fuel; and though this wood had been affected not to flame, or be consumed without the assistance of other wood, it did not, in this case, flame violently, but it burned by itself without care or attention, and unassembled from other timber-wood, producing numerous fires for labourer's uses. In rendering it fit for this purpose too, the workmen found it extremely brittle, a tree a foot in diameter being often broken with the greatest ease, by means of two or three blows given with the back of the hatchet. The tops and side-branches of them were likewise remarkably light and brittle, as are known to many pence in that part of the country as well as this. See Timber, Crooked Growth of.

These facts are said to deserve a very serious attention, and to lead to very important conclusions, in respect to the cultivation and growth of this tree as timber in this country. They are not solitary ones: for though, as yet, sufficient time has not elapsed for a fair trial of this wood in different soils and situations, yet some have found it much les durable than others; and that an attentive, nice observer, will, it is thought, perceive larch-trees in some rich warm situations in a decaying state, and others growing so rapidly, or so much side-lobbed or pruned, as to fuggest doubts, whether their duration will be much longer than those of the above castle.

And, fourthly, that in Scotland, the difference of durability between common fir-wood which has been of slow growth, and that which has been forced, as it is termed, either by shelter, advantageous soil, situation, or climate, or by lopping off the side-branches, is known to every carpenter in the more northern parts of it, especially in the districts of Perth, Stirling, and Argyll. There, it is said, they distinguish the wood cut as timber in the native forests, from that obtained in plantations, by calling the former highland-fir, and the latter park-fir. The highland-fir is most esteemed, on account of its greater durability, being frequently found undecayed in ancient buildings when other forts are entirely wasted. These circumstances are strongly supported, it is thought, by Mr. Lambert, who, in speaking of the genus Picea, has said, that "this striking difference between the highland and park fir, is probably to be attributed to the mountainous and rocky situations in which the native timber is found, and where, the trees being of slow growth, the wood is consequently of a harder texture." The same writer is of opinion too, it is said, that few species of pines will endure more than forty years in the soils in which they are commonly set out or planted in England. Indeed, there are many proofs of this, it is thought, from Crock, Kew, and other places; though, there are some excellent fir-trees at Langhangles, where the soil is deep and cold, that are much older than that period. The greater durability of the former fort of fir-timber may be daily seen, it is said, in the still more northern districts of Aberdeen, Banff, and some others, during the removal of old farm-houses and cottages; whereas a piece of the highland-fir appears, it is always of a much deeper yellow than the park or low country fir. At Gogar, it is said, some large fir-trees were taken down in 1795: they grew upon a deep cold loam; the wood was fawn up, and was found of excellent quality as timber. About a mile from this, at Lenny Park, a dry bank is covered with fir-trees of greater age than those of the former situation; some of them have been taken down at different periods before and since that time, and have uniformly been found of inferior quality as timber-wood. In 1804, too, a number of fir-trees were taken down from the rocky banks of the Almond, between Craige Hall and Crumfont House; and they were found of excellent quality in their wood. While at Bevelaw, there are extensive plantations of fir-trees, which have been often thinned; but the trees have grown so fast, and been so much cut or pruned in the branches, that they never last long, it is said, as paling. All these cases have either come under the writer's own particular notice, or that of a relation of his, who highly interests in the value of park-fir, and, of course, has paid a more than common attention to the matter. A great number of other instances might, it is said, be here added, but it is unnecessary: and the comparison of the wood of the common crab, the father of the orchard, with that of the cultivated apple, is in support of the same. Any person who will take the trouble to examine the fir-woods at Gordon Castle, and contrast them with others in the county of Perth, and those in England, will, it is thought, unquestionably come to these conclusions: that growth is essentially necessary to the durability of fir-timber; and that wherever the accumulation of wood has been accelerated by culture of the soil, improvement of the climate, or by cutting and pruning, it is injured in quality in proportion to the ratio in which these agents have been employed. It is not said, that no branches should ever be cut from fir-trees, but that it is certain that judgment must direct to cut off, in general only, such as indicate that they are no longer of much use, which is easily discovered by marks of approaching decay.

Much of the above principles, reasoning, and conclusions, is probably, in some measure, equally applicable to other sorts of timber.

In the raising and growth of timber of the fir or Scots pine kind, it is found not well suited to very elevated situations, as the sharpness of keenness of such exposures bring it too quickly into a state of decay and death. The writer of an agricultural survey of one of the more northern districts of Scotland has remarked, that there is a kind of laminated clay, much disposed to dissolve with water, which is not favourable to the growth of this, or any of the pine tribe. It succeeds very well, it is said, however, in most
moist parts of the clay ground of that tract, if care be taken to prevent flagrant water. It does exceedingly well too on land covering the freestone rock; but that the belt timber of this fort is produced on hard dry gravelly soils. But that the Siberian pine, and some others of a similar nature, have been introduced with very little success. The short intervals of mild weather which happen in the beginning of the spring, excite them to vegetate too early, and the next cold blast destroys the young buds. The New England pine thrives in a tolerable soil, until from twelve to twenty years of age, in proportion to the nature of the exposure, after which it generally begins to decay. And that the spruce is likewise unfit to weather the storm on the greatest heights. It succeeds on the hard dry rock where the Scots pine dies, but frequently decays at the end of eighteen or twenty years, on stiff wet clay. Its most favourite soil for timber is that which is dry and gravelly. The silver fir thrives in clay soils, where the spruce fails; nor is it adverse to the hard rock or gravelly soil, which probably affords the belt timber; but it makes little or no progress on any soil that is very poor. It unfortunately too frequently suffers feverishly from the frosty mists of the spring, especially in its youth, or more early states of growth. However, the larix or larch is now found to be the most hardy alpine plant. In moist places, it makes greater progress than almost any other timber-tree, and there is scarcely any soil, that is not drowned with water, on which it will not succeed. It suffers most in too luxurious situations, where its soft shoots, unable to keep erect, bend away from the slightest gale, and its timber produce is probably the worst. It is liable while young, in some situations, to be much injured or wholly destroyed by early spring frosts taking place after mild weather has brought on its vegetation, and is occasionally feized with disease, and dies when placed on miry clay.

It is suggested that the birch is next to the larch in the progress of its growth, and equal to it in ability to stand the blast in alpine situations; and that it is superior to it in the plain. But in whatever situation it is placed, it delights most in a light soil and dry bottom, probably producing in such the belt timber-wood. It, however, thrives in moist soils, with very moderate draining.

The ash also, when it enjoys a sufficient depth of good soil, is capable of braving the storm, and pulling up its head in the most exposed situations; however, in a thin soil, covering a stiff argillaceous bottom, it can make no progress. It notwithstanding thrives well in some marthy soils, where the banks are steep, so that the water gets away without flagrating. On dry rocky steeples, the timber is probably the best. It forms perhaps the most important wood in the country as timber, being useful in all its ages and states, and fit for most purposes.

The mountain-ash is likewise a hardy native, which grows freely in almost all soils and exposures; but its favourite situation seems to be in hanging banks, among woods and coppices, where the timber-wood is perhaps the best. This and the gean-tree, or wild cherry, raise and propagate themselves much when left at liberty, by putting up or out suckers from their roots.

The beech is said to come near to the ash in capability of braving the storm, and has much the advantage of it in thriving in poor or stiff soils; but there are some barren argillaceous bottoms too much even for the beech; and it is most successful, and affords the belt timber, in friable soils. Its shoots, while young, are soon affected by frost, but the tree speedily recovers.

The fycamore and elm require a light soil, and a dry, open under-fruit; and when this is the case, the timber is the best, and the trees thrive in a situation pretty much exposed. They form good timber too on some soils of a heavier nature.

In regard to the oak, it is less patient of the blast than most of the timber-trees of the forest. Being late in putting forth its leaves, it continues to grow till the season is far advanced; and the immature wood of its late shoots, unable to fulfill the piercing effects of the cold wind in exposed situations, withers before the next spring; so that, like Penelope's web, the progress of one season is undone in the following. The most favourable situations for the oak, as timber or otherwise, are therefore hollows or hugging slopes, where the sharp cutting winds are broken by the neighbouring heights. In such situations, if flagrant moisture be avoided, it will thrive in the stiffest soils, and with its strong roots penetrate the deepest bottoms, affording good timber. Though the growth of this tree be slow in infancy, when it is placed in a favourable situation, it will make a progress in the course of fifty years, little inferior to many other kinds, and at length arrive at a great size of timber. See these timber-trees.

It has been found that the horse chestnut-tree thrives well on the lower grounds, and deep soils only. The sweet chestnut, which quickly becomes a timber-tree in districts more northern than this, does not succeed here. Its feasons of growth are too early, or too late, for the climate. In its height, it bears some resemblance to the Siberian pine, &c.; in its fall, to the oak; its early growths being almost as early as the former, and its later being nearly as late as those of the latter, and still more soft and susceptible of the cold. Hence its shoots are alternately put forth and destroyed, and it generally becomes a low, stunted, shrubby tree. But this, it is said, does not seem to have always been the case. The fate of the common walnut, which may be considered almost as much a timber as a fruit-tree, is nearly the same with that of the sweet chestnut. It probably affords the belt timber on dry friable soils of some depth.

The poplar and most of that tribe delight most in water-formed soils, but are commonly averse to marsh, and, when happily situated, make quicker progress than almost any other sorts of trees, producing much light useful timber. See Chesnut, Walnut, and Poplar.

Management of Timber.—The rules and regulations for the management of fir and other timber-trees, which are given below, deserve attention. Mr. Salmon, of Woburn, in Bedfordshire, who is in favour of much lopping or cutting of the side-branches of fir-timber, remarks, in a late volume of the Transactions of the Society of Arts, &c. that considering the purposes that this sort of timber is commonly applied to, it must occur that clearness of knots, straightness, length, and equality of size of the trunk, constitute its perfection, and that, if deficient in all these, it is of no value but for the fire. Next to these considerations, and the prospect of an improved knowledge of raising and cultivating this kind of timber-wood, it may, it is said, be a fair question, if our own country be not capable of producing this timber little or not at all inferior to foreign fir? In this country at present, fir appears, it is thought, not for any length of time to have been considered much otherwise than as ornamental. For this purpose they sever only for a certain time, which, when past, it has been their fate to be cut down long before having attained maturity. But from the great extent of ground now covered with this sort of timber-tree, it is to be hoped, it is said, that another century may obtain to English fir some of the character of the oak of the fame country: towards such an end, if attainable,
every means should, it is said, be used, and towards which nothing appears more likely to succeed, than a well-grounded general or practical mode of management, from the time of the trees being put out, to their greatest imaginable age of improvement. That a knowledge of such may by perseverance be gained, is not, it is said, much to be doubted, as from different specimens there appears great reason to conclude, that early and proper side-lopping the branches, and thinning out the young trees, will form a considerable feature in the plan and system to be adopted and pursued.

The subjoined plans and rules for the general management in these cases, are given as the partial result of practical experience, but of only a few years' observations.

In the raising of this sort of timber, from every authority and observation, there can be no doubt, it is thought, that all firs should be set out or planted thick or near together, as not more than four or five feet apart. That where firs of the same kind are put out together, there are lfs of fops of plants, too, from one foot not overgrowing and destroying the others; consequently, that it appears advisable that all the different sorts should be set out separately by themselves. If any admixture at all be admitted, the Scotch fir and larch may, perhaps, be set together; but this is not certain, and they will unquestionably be better separate on two accounts. First, because they are not so likely to injure each other; and, Second, because the larch may be put into the foil best suited for it, and the Scotch fir the fame. And that in raising any particular fort extensively, it may be right to have a few of the spruce fort, or others, on the out or exposed sides, to prevent mischief from sudden gults or blasts of wind: but if the situation be not liable to such gults, the spruce had better be omitted, being mechanical agents only, and, by excluding the fum and air, act against the operations of nature. However, in these limits, ornamental is not, it is said, considered, but only timber: if the former be wanted, and profit alto, then the spruce, the larch, the silver, and some other forts, may be combined.

It is contended, that from some years' observations on cutting out and side-lopping the branches, and the efficacies thereof, it appears certain that fir-trees, whenever they arrive at a certain age, should be cut or lopped to a certain height; and that for regulating thereof, the simple rule given below is recommended: the cutting-in to commence when the trees are five years old, or when there is discernible five tier of boughs and the shoot; the three lower tier of boughs are then to be taken off. After the first lopping or cutting-in, the trees to be left alone for four or five years, and then, and at every succeeding four or five years, the cuttings-in to be repeated, till the flam of the tree be clear to forty feet high, after which, as to such side-lopping, it may be left to nature.

The rule for the height of thinning and cutting-in, after the firft time, to be half the extreme height of the tree, until they attain twenty years' growth, and after that time, half the height of the tree, and as many feet more as it is inches in diameter at four feet from the ground. This cutting-out and retrenching the branches of such trees is known, from repeated observations, it is said, not to be excessive; and that the rule is calculated to check the too tapering top, and for strengthening the slender bottom, by carrying the cutting and retrenching to a greater proportionate degree, in a ratio compounded of the height and bottom bulk; and by this rule, too, it may be observed, that the trees will be at top clothed with somewhat less than half their branches. The proper time for such cutting-in as, it is said, between September and April, and the tool to be employed in the busines, the saw.

It is noticed, that orderly thinning the trees at certain periods, when for timber, is the next essential to that of cutting in and lopping their side-branches; and that for this purpose, observations have been made on the most orderly and thriving collections of this sort of trees, and the sub-joined simple rule is laid down: keep the distance of the trees from each other equal to one-fifth of their height. In the application of this rule to this purpose, it is evident that each individual tree can never be made to comply, for the original distance (even if set out in the most regular order) will allow only for certain modifications, by taking out every other tree, and so on; but even if the obtaining such equal distance were practicable, experience would show, it is thought, that another way should be preferred, of which the eye must be the judge, by taking out such trees as are leafy thriving, and near all to other good trees, &c. &c. at the same time keeping in view the rule laid down: the directions and rules for which, given below, may easily be proved, by measuring a chain square, or any quantity of the land, and counting the trees therein; then, by trying the height of two or three trees in that quarter, and taking one-fifth of such for the distance, it would be readily seen how many trees for timber should be contained in the piece measured; or the practice may be more simply regulated, it is said, by taking the distance of eight or ten such trees added together, the average of which should be equal to a fifth of the height of the trees. In these rules and directions there is nothing impracticable or complicated, it is thought.

The writer states, too, that he has for years known the expence and produce of this side-trimming alone, and finds that in Bedfordshire the produce of it doubly repays the charge or cost; and that although some experimenters may differ from him, or time may show some reason for somewhat deviating from his rule, it is presumed all will agree that some simple plan is advisable, instead of having timber collections and woods mismanaged, to the great loss of the community and their proprietors. If such a plan of proceeding, as is here proposed, be generally promulgated, if not perfect, it will most likely, it is thought, in time become so, and thereby have its advantage; and in order to promote this, these concluding remarks are given: in the common course of gardening, it is understood that cutting and trimming invigorate the tree; that taking off the side-branches makes the upright ones shoot the stronger; and by cutting out the dead and decayed wood, the tree is kept alive: some of this doctrine will, it is supposed, certainly apply to the tribe of firs; it will certainly, too, sublimate clean timber-wood for knots; and of this treatment, from their particular uses, they of all other trees stand in most need, and will be the most improved by it. And that should it be admitted that the like treatment would on the fir, as well as other trees, produce the like effect, it would lead to a well-grounded expectation that, as well as producing clearest of knots, straightest, and length, the same operation would advance the quality nearer to that of foreign fir; for it may be traced, that where trees are tall and clear of boughs or knots, the whole sublimate of the wood is better and of finer grain, and that it appears likely that such will always be the case: the reason of which may probably, it is thought, be inferred from the sap having farther to rise and descend, and having no boughs to divert or delay it, the circulation must be more free and rapid, most increase be left in the neighbourhood of the boughs at the top of the tree, and lead on the fides at the lower part, conseqently adding to the length of the head, and rendering more fine each annual increas to the body; thereby producing a close-grained, clean, long, and regular caly-
easy-tapering useful piece of timber, instead of a coarsely-grained, short, sudden-tapering trunk, with a quantity of boughs and knots.

The foregoing rules, directions, and observations, are meant, it is said, to apply to fir-timber only, but to a certain extent they may be applied to other timber; though by no means in the same degree or age. But if had recourse to as far as the first fourteen years of their growth, and then such cutting and side-lopping be altogether omitted, and the thinning out very much increased, any collection of such timber-trees would, it is thought, be rendered much more valuable than if left to nature.

The first of the above writers has, however, already stated, that the general effects of side-cutting or lopping the branches of fir, and probably some other timber-trees, are of a corresponding nature with that of culture; that is, to increase the quantity of timber produce. And that the particular manner in which it does this, is by directing the greater part of the sap, which commonly spreads itself in the side-branches, into the main stem. This, of course, necessarily enlarge that stem in a more than ordinary degree, by increasing the annual layers or circles of wood.

Now if the tree happen to be in a warie foil and climate than those which are natural to it, this will, it is supposed, be of some advantage, as the extra increase of timber will still be of a quality not inferior to what would take place in its natural state; or, in other words, it will agree with that state of quality and quantity of timber which the nature of the species, or sort of tree, admits of being produced. But if the tree be in its natural foil, the annual increased produce of timber occasioned by this cutting or lopping the side-branches, must necessarily injure its quality, in a degree corresponding with the increased quantity. And if the tree be in a better climate and foil than that which is natural to it, and at the same time the annual increase of wood be promoted by such cutting means, it is evident, it is said, that such wood must be of a very indifferent quality from that produced in its natural state.

Consequently, although it might, in some degree, it is supposed, be shown from vegetable anatomy, and the analogy of what takes place in herbaceous vegetables, it is preferred to deduce, from the facts stated above, this proposition: that whatever tends to increase the wood in a greater degree than what is natural to the species or kind when in its natural foil, must injure the quality of timber. Cutting or lopping the side-branches tends to increase this in a considerable degree; and, therefore, it must, it is thought, be a pernicious practice, in so far as it is used in these cases.

It has been shown, it is said, in a very striking manner by Mr. Knight, that timber is produced, or rather that the alburnum, or sap-wood, is rendered ligneous, by the motion of the tree during the deficient of the true sap. It is sufficiently known, too, to all who have attended to the physiology of vegetables, and greatly confirmed by some experiments not long ago communicated to the Royal Society by the same writer; that the solid tissue of the wood greatly depends upon the quantity of sap, which must necessarily defend, and likewise on the flowings of its deficient. Now both these requisites are, it is contended, materially increased by side-shoots or branches, which retain a large quantity of sap, and by their junction with the stem occasion a contraction and twisted direction of the vessels, that obstruct the progress of this juice. That this is true in fact, is well known to those accustomed to make wine from maple or birch trees, as in this business it is found that those trees which have the fewest side-branches, bleed more freely than the others, but during a much shorter pace of time. These hints, consequently, afford additional evidence against the practice of cutting or lopping the side-branches of timber-trees, and especially against that of using it for fir-trees, which, as the above writer justly remarks, it is said, have larger vessels than most others, and therefore, when in an improved foil and climate, side-branches for the above purposes are essentially necessary, if solid, resistant, and durable timber be the object in view.

The following conclusions may, of course, be drawn in respect to the management of timber-trees from the above facts and remarks. First, that timber-trees should be set out in foil, situations, and climates, as much as possible analogous to those of their natural state; and that it is chiefly in this state, or where there are some defects in regard to them, that such cutting or lopping and culture can be exercised with advantage. Secondly, that in proportion to the superiority of the foil, &c. in which trees are put, over the natural foil of such trees; in the same proportion lopping and cultivating the soil ought to be avoided, and thinning encouraged. Thirdly, that particular regard should be had to the soil and situation, where either larches or any of the pine tribe are placed out to remain finally for produce as timber: for as the roots of these chiefly run along the surface, and as in them the great current of the sap is principally confined to one channel, that is, the trunk, and the tribe of trees is, of course, peculiarly liable to change when subjected to unnatural agency of these kinds. Fourthly, that the only way in which oak-timber of safe quality can be raised and provided for the navy of this country, is by inclining, preferring from cattle, and properly managing, those royal forests where oak is the natural produce of the foil. The neglect of this advice, there is reason to fear, it is said, may at some future day be regretted. For park-oak, as has been seen, is by no means unfrequently much inferior to that of the forest kind in durability. And that, lastly, as the advice advised tends to render trees characteristic of their peculiar species or kind, it must consequently be the most agreeable to ornament too, or the principles of natural taste.

The necessity of considering, thus fully, this branch of the management of timber-trees is; because the matter feems, it is said, to have been almost entirely overlooked by practical men, who, appears, in general, to think culture and lopping, or cutting-in, of no other utility than to increase the produce in the quantity of timber. Though they are not, however, to be discarded in many other views, yet if solid and durable timber be the object, they ought, it is thought, to be had recourse to with caution, and in a discriminative manner. As a contrary plan of proceeding has been attempted to be enforced by some, as has been seen, it is thought necessary to arouse the attention of the country to the raising and improved management of the important article of timber, especially as the confquences of that plan are supposed to be more dangerous, as they cannot easily discover themselves until it be too late to apply a remedy.

In the management of timber-trees of the deciduous kinds, the lopping, cutting-in, and thinning, should be practised, in some measure, on the same principles as the above, but according to the particular nature, circumstances, and habits of growth of the different sorts; being constantly executed in such a manner, as to prevent any injury or inconvenience arising by the too extensive growth of the lateral shoots or branches, these being too few in number for the proper retention of the sap; and without the trees being left at too great a distance, and too naked and exposed. The trees for timber too are always to be kept clear of all foul wood, and any branches to be removed, taken off in a clean, careful, up-ward
T IM E R.

ward direction, as where the parts are left in any way rugged or uneven, they are liable to catch and detain the wet and moisture, and conduct it to the hearts of the trees, by which they are not only greatly hurt in their growths, but often much spoiled as timber-wood. The thinning of the trees for timber should be performed at different suitable periods, so as to prevent too much crowding, and afford proper room for the full growth and increase of their wood, on the principles laid down above. See Pruning and Thinning.

Sir Humphrey Davy has remarked in a late work, that trees poising the firmeat and the leafy porous heart-wood, are the longest in duration. That, in general, the quantity of charcoal afforded by woods, offers a tolerably accurate indication of their durability: these most abundant in charcoal and earthy matter are most permanent; and those that contain the largest proportion of galeous elements are the most destructible. That, amongst our own trees, the chestnut and the oak are pre-eminent as to durability; and the chestnut affords rather more carbonaceous matter than the oak. That, in old Gothic buildings, these woods have been sometimes mistaken one for the other; but they may be easily known by this circumstance, that the pores in the albumen of the oak are much larger and more thickly set, and are easily distinguished: whilst the pores in the chestnut require glaftics to be seen distinctly. That, in consequence of the flow decay of the heart-wood of the oak and the chestnut, these trees, under favourable circumstances, attain an age, it is said, which cannot be much short of a thousand years. The beech, the ash, and the fycamore, most likely, never live half so long.

It is noticed too, that the oak and chestnut decay much sooner in a moist situation than in a dry sandy soil; and that their timber is less firm. The sap-veins, in such cafes, are more expanded, though less nourishing matter is carried into them; and the general texture of the formations of wood necerallarly less firm. Such wood, it is said, splits more easily, and is more liable to be affected by variations in the state of the atmosphere.

The same trees, in general, are likewise much longer lived in the northern than in the southern climates. The reason of which seems to be, it is thought, that all fermentation and decomposition are checked by cold; and that at very low temperatures, both animal and vegetable matters altogether reft pufetration: and in the northern winter, not only vegetable life, but likewise vegetable decay muft be at a stand.

The antiputrefcent quality of cold climates is, it is said, fully illustrated in the instances of the rhinoceros and mammoth lately found in Siberia entire, beneath the frozen soil, in which they most probably have exilled from the time of the deluge.

Trees that grow in situations much exposed to winds, have harder and firmer wood than such as are considerably sheltered. The dense sap is determined, by the agitation of the smaller branches, to the trunk and large branches; where the new albumen formed is consequently thicke and firm: such trees abound in the crooked limbs fitted for forming knee-timber, which is necessary for joining the decks and the fides of ships. The gales in elevated situations gradually act so as to give the tree the form best calculated to refit their effects. And the mountain oak rifes robust and sturdily; fixed firmly in the soil, and able to oppose the full force of the tempest.

Different plates of timber are chosen for different uses, but the above writer remarks, that ship-builders prefer for their purposes that kind of oak-timber afforded by trees that have had their bark stripped off in the spring, and which have been cut in the autumn or winter following. The reason of the superiority of this timber is, it is thought, that the concrete sap is expanded in the spring in the sprouting of the leaf; and the circulation being destroyed, it is not formed anew: and the wood, having its pores free from faceharine matter, is less liable to undergo fermentation from the action of moisiture and air.

It must, however, be considered as very extraordinary, that in a country where the navy is a matter of such vital importance, and in districts where the oak, or other forts of timber-wood useful for the same purpose, may be said to be almost staple articles, no complete or satisfactory trials should have yet been made of the means of increasing the duration of such timber, which are mostly fo readily practicable, and so very material in their consequences.

Felling of Timber.—The proper periods or times of cutting down, or making falls of timber, as they are often called, must evidently, in some measure, depend upon and be regulated by the nature and the differences in the circumstances of the growths of the same or different kinds of trees. But as in them, as well as other living matters, there seem to be three stages of growth; as that of their early rising, their middle mature state, and that of their decline or decay; they may serve as more satisfactory guides in the business. In the first, the growth is mostly soft and rapid; in the second, it becomes firm, strong, and perfect; and in the last, it begins to become weak and unfoold. Mr. Loudon has considered the beginning of the middlemost of these stages as the most profitable period or season for felling of timber; as after that time, though the tree may appear found and healthy, its annual increase is so little, that the cutting it down and replacing it may be more beneficial than letting it remain. The number of years that a tree may stand before it arrives at such a flate, mutt, it is said, vary in different soils, situations, and exposures; but the period itself may readily and without difficulty be ascertained,—by the annual shows, the flate of the bark, and by taking the circumference of the tree at the same place for two or three successive seians, and comparing the difference. In the view of profit from timber produce, it is of material consequence, it is said, to cut down such collections of trees at maturity, or in their vigour and perfection, which, from supposo, for the oak, where the foil is natural, is from about the age of fifty to sixty or seventy years' growth. Many trees will stand a half, others a whole century after they are full grown, appear quite healthy, and, at the same time, make little or no increase of timber. There are particular cafes too, depending on the nature and state of the markets, in which it may even be more profitable to cut timber before it is arrived at a full growth than afterwards.

It may be difficult, it is thought, to say when timber, which is principally planted for ornament, should be cut down. A tree, when young and fresh, is beautiful; when middle-aged, it is more or less picturesque; when in old age, strikingly so, with a degree of grandeur; and its greatest height of picturesque and sublimity, is when decaying under the pressure of age. Hence it is conceived, that if ornament, or expression, which is a more appropriate term, were the sole object in view, trees need almost never be cut down. But most perfons have a feeling of what is beautiful; and though all may be fruck with grandeur or sublimity, few have so much enthusiasm as to sacrifice the profit of valuable timber, for the pleasure of enjoying either of those characters.

The time and manner of cutting underwood and underground will be seen under these heads.

There are perfons in this country, who, unquestionably from
TIMBER.

from neglect and mismanagement of their timber, are now, it is said, losing annually very handsome incomes. The lots of price which generally follows the refusal of a good or high offer, the certain lots of interest, the decay of timber, and the injuries arising from the incumbrance of full-grown trees, are irretrievable losses, which those who have the care and management of timber should studiously endeavour to avoid. But while the disadvantages of suffering timber to stand until it be overgrown are thus held out, it is far from proper or advisable to propose or favour the premature felling of it.

The season of the year for this work usually commences about the end of April; because the sap then rises, which makes the bark run freely, as it is technically termed; that is, it drains off the trees freely; so that where a quantity of timber for ordinary uses is to be felled, that statute I. c. 22. formerly required it to be done between the 1st of April and the last of June, for the advantage of taming; but this act was repealed by 48 Geo. III.

However, the opinions and practices of authors are very different as to the best season for felling timber: Vitruvius recommends an autumnal fall; others advise December and January: Cato was of opinion, that trees should have borne their fruit before felling; at least, that their fruit should be first ripe; which coincides with the sentiments of Vitruvius.

In effect, though timber unbarked be most obnoxious to worms, yet we find the wild oak, and many other kinds, if felled too late, when the sap begins to be full, to be very subject to worms; whereas about mid-winter, it neither calls rifts, nor twines. If trees were felled at a more early season than April, it is said that the timber would be better seasoned.

It is, indeed, the common opinion, that timber which is felled in winter, is stronger, and more lasting, as being more firm and clove, than that which is felled in summer. But M. Leuwenheuck apprehends that there is no difference, except in the bark, and outermost ring of the wood, which in the summer are fester, and more easily pierced by the worm: wood confining of hollow pipes, which, both in summer and winter, are full of moisture, and do not shrink in winter; and therefore the wood cannot be closer at one time than another, for if otherwise, it would be full of cracks and clefts. The unexpected and sudden rotting of some timber, he conceives to proceed from some inward decay in the tree before it was felled: having observed all trees to begin to decay at first in the midspring or heart of the tree. Phil. Trans. No. 215. or Abr. vol. i. p. 592.

The ancients had a great regard to the age of the moon in the felling of their timber. If their rules availed, they are these: fell timber in the wane, or four days after new moon; some say, let it be the half quarter. Pliny orders it to be in the very article of the change, which happens on the last day of the winter solstice, the timber, says he, will be immortal: Columella says, from the twentieth to the twenty-eighth day: Cato, four days after the full: Vegetius, from the fifteenth to the twenty-fifth, for ship-timber; but never in the increase, trees then most abounding with moisture, the only source of putrefaction.

Some even have a regard to the temper and time of the day; the wind to be low, neither east nor west, neither in froat, wet, nor dewy weather, and finally, never in the forenoon.

Laudy, some regard is had to the species: fir is best felled when it begins to spring, both as it then quits its cost belf, and as the wood, according to Theophrastus, is by that means rendered wonderfully durable in water. Elan, says Mr. Workidge, is to be felled between November and Ja-

mmary, in which case it will be all heart, at least the sap will be very inconsiderable: this, he adds, is also the only good season for felling ash. Some authors add farther, that in felling timber, care should be taken, first, only to cut it into the heart, and so to let it stand till dry; by which means the moisiture is evaporated in drops, which would otherwise occasion putrefaction.

M. de Buffon observes, as a circumstance which greatly increases the strength and solidity of timber, that the trees intended to be felled for service, should first be striped round of their bark, and suffer to stand till dry upon the spot before the cutting. The fappy part, or blea of the oak, becomes by this management as hard and firm as the heart, and the real strength and density of the wood has been proved by many experiments to be greatly increased by it: nor is this practice detrimental to the proprietor, because the remaining stumps of these trees send up their young shoots as vigorously, as if they had been cut down in their natural condition. Mem. de l'Acad. Sc. Par. 1739.

When any tree is to be cut down for timber, the first thing to be taken care of is a skilful disbranching such limbs as may injure it in its fall. In felling the tree, it should always be cut as close to the ground as possible, unless it is intended to be grubbed up and this will be of advantage both to the timber and the wood; for timber is never so much valued, if it be known to grow out of old stumps.

There are several different modes made use of in felling or taking down timber, and they must necessarily be somewhat various, according to the nature, extent, and kind, of which the collection may be, as well as in the methods of performing the work: thus, in groves of the deciduous timber kind, the trees are mostly felled felled by gradually taking or thinning them out as they arrive at maturity; which, where they are to be continued, should be cut over by the surface of the ground, and the stumps be each separally well felled in, that by defending them from cattle, new trees may be produced; but when not deftined to be continued, they may at once be rooted out. Groves of the fir or pine fort, or any single fir-tree of any kind, should at once be taken out by the roots. In woods, any timber-trees that may be cut down, should have their places as nearly as possible supplied by fappings, or any other proper forts of young timber-trees. However, previous to the work of felling, the trees should be marked by a proper person; in performing which, in a fall of timber, regard is to be had to the relative state of standing in the trees. In clove timber-woods, the whole or nearly the whole may be marked and taken down; as if some which appear flourishing be left standing, they will not only be liable and in danger of being hurt in taking the others down; but, in consequence of their situation in regard to exposure being changed, will no longer continue to flourish. As their atmosphere is not only thus altered, and rendered too cool, perhaps, for their acquired habit, by the removal of the adjoining trees; but they thereby get room to throw out fiddle-shoots from their stumps; in consequence of which their tops die, and their growth is irrecoverably stinted. While, on the contrary, in open woods of the same kind, thin hedge-rows, and other open spaces, such timber-trees only as are ripe for the axe, or are suitable for the intended purpose, should be marked; the youthful growing trees being left to be benefited most probably by an increase of air and head room, in an atmosphere and exposure to which they are habituated and accustomed. On estates that are timbered, it is directed that they should be frequently gone over by proper persons, who, let the price and demand for timber be what they may, should mark every tree which
TIMBER.

waters the appearance of decay. Where the demand is brisk and the price high, he should go two steps further, and mark not only such as are full grown, but such also as are near perfection; for the interest of the money, the discernment of the approaching young timbers, and the comparative advantages of a good market, are not to be bartered for any increas of timber which can reasonably be expected from trees in the last stage of their growth.

In the work of felling timber, three distinct methods are practised and had recourse to in different cases: as, first, that of cutting the trees above ground: severing them from their roots, by means of the axe or the saw; leaving what are termed floods, to occupy the spots where they stood. Second, that of cutting them, within the ground, with the axe and mattock; but leaving the principal part of the roots in the soil. And third, that of grubbing them up by the roots, by the use of the spade and mattock; thus throwing them down with the butts and large roots adhering to the stumps. The preference to be given to one or other of the two first modes of taking down timber-trees, is, it is said, chiefly on the nature of the future application of the land upon which they grow. If it be intended to remain in the state of woodland, the first method, or the second, if too much of the main roots be not cut away, is the best and most eligible. But if the land is to be cleared for the purposes of agriculture, where sufficient hands can be had for dispatching the busines, the second is, by far, the best. The last is improper in most cases.

The writer of the rural economy of the midland district, sees, that there the methods of focking, axe-grubbing, and axe-falling are practised. That the first is a kind of partial grubbing, in which the roots are cut through a foot or more from the stem; and, again, a foot or more from the inner cutting; taking up a short length of the thickest part of the roots, and digging a trench round the tree, wide enough to come at the downward roots. That the second, or axe-grubbing, is somewhat similar to the mode of grub-felling described below, except that the end of the butt is left larger in these places than in that case. And that the third, or axe-falling, is the common method of Yorkshire, and other places, of cutting off above ground, with the axe; a method which is seldom practised, except in some few cases where another crop of timber, or of coppice-wood, is designed to be taken. Stocking is the prevailing mode;—the charge for taking down varying with the size of the tree: for a tree of two feet in diameter, it is about a shilling; and about four pence more for cutting off the butt; the focking and butting being, for the most part, left together. Other modes, too, are practised in other districts in performing the busines; as that of fawing the trees off in an horizontal manner close by the surface of the ground, by means of a long faw with one or both handles fixed on the upper side, the trees being firt dipped in by the axe on the faling side.

The method of felling timber practised in the county of Norfolk, is said, by the same writer, to be uniform, and perhaps peculiar to the county. It is very aptly called grub-felling; the operation partaking both of grubbing and of felling with the axe, in the common way above ground; a method which is walleful of timber. The woodman of this district, therefore, fells below the surface of the ground, by cutting off the horizontal roots close to the stem, which, instead of shortening, he, in effect, lengthens, by adding to it a conical point, cut out of the crown of the root; so that by this way of proceeding, a greater length of timber is obtained, than by first grubbing and afterwards cutting off the butt with a faw. Grub-felling is, it is thought, without doubt, the most eligible way of taking down hedge-row timber; and this, it is supposed, accounts for its being the established practice in the above county.

The disposal of timber, which often takes place before it is cut down, is to be regulated by the occasion of it, as arising from the sale of the timber, or other causes and circum- stances. It is, however, for the proper and beneficial sale and cut it down before its most profitable state of growth is reached; though this principle may sometimes be set aside by particular circumstances, as the nature of a market; the value of the land it encumbers by its growth, being greater than its annual increase; the interest of the money it is worth, with that of the growth from the floods, being greater than the increase of the standing timber, &c.

It is conseqently rarely advantageous to suffer timber to remain upon its roots, after it has attained its full growth;—as, in this cafe, the whole of the interest is lost, it is said, to the owner; while the use of one of the most valuable articles of the produce of the country is lost to it and the whole community.

In speaking of oak-timber, the late bishop of Landaff has given some useful and interesting remarks in regard to the disposal of it, in the introduction to the Agricultural Report of the State of the County of Wellington. Where profit is considered, it is said every tree should be cut down and sold, when the annual increase in value of the tree by its growth, is less than the annual interest of the money it would fall for. This being admitted, it is only necessary to inquire into the annual increase in the value of oaks of different ages. After different statements, thirty-six shillings each are fixed upon as the price of trees that should be cut down and sold; as, if they be cut down before they arrive at that value, or if they be allowed to remain until they will fall for a much higher price, the proprietor of the soil or land on which they grow will be a looser. It is noticed too, as being the general opinion, that it is more profitable to fell and fell oak-wood at fifty or fifty years' growth, than to let it stand for newy timber to eighty or a hundred, owing to the low price that is now paid for oak-trees of large dimensions, either by the Navy Board or the East India Company. On this account, it is advised making a much greater increase of price than ordinary on timber of this sort of large common, as in place of four or five pounds the load, if eight or nine were given for trees containing one hundred cubic feet and upwards, every perfon in the kingdom, it is thought, would have a reasonable motive for letting his timber stand until it became of a size fit for the use of the navy; whereas, according to the present established price, it is every one's interest to cut down and fell their trees before they arrive at a proper size to be useful as navy timber. This suggests, too, the necessity of attending to the royal forests in a more particular manner; and may be an additional inducement to the trying the cultivation and growth of the larch in them, and training it for ship-timber. See TIMBER, Crooked Growth of.

There are several different modes of disposing of timber, according to the nature of it, the situation, and the customs of the districts to which it belongs; but the principal of them are, first, that of selling the trees standing; either by auction, by receiving written proposals, or by bargain and sale: second, cutting the trees down, and selling them in the rough; by any of the above modes; third, converting the fallen trees; that is, cutting them up into wares to which they are best adapted, or which are most salable in the particular situation. On a large timbered estate, the first mode
is, in common, the most advicable to be had recourse to; in which case, an accurate valuation of the marked trees is to be made, before they are offered for sale: and, in the case of oak timber-wood, it is mostly proper, and always satisfactory, to have separate valuations of the timber and the bark.

In felling timber in the county of Norfolk, the prevailing practice is, according to the writer of the rural economy of that district, to fell it standing, at so much a ton when fallen; measuring the timber down to fix inches timber girt; the topwood and the bark (of oak) becoming the property of the purchaser; who is usually at the expense of taking it down. And it is customary there, too, for the purchaser to dispose of the bark (of oak), and sometimes the topwood, by the same admeasurement.

In the midland districts, after disposing of and cutting out the timber, the arms or boughs of the trees are cut up into posts, rails, and cord-wood for charcoal; the sprays being mostly made up into faggots.

The relative value of different sorts of timber may be said to depend almost wholly upon local circumstances, as those of contiguity and facility of being taken to the places where they are the most largely made use of, or where only employed. Some sorts are, however, everywhere valuable on account of either their general application, or their scarcity, such as the oak, the ash, the elm, the beech, and the still more valuable larch, and others of the firrt description: and of the latter, the common chestnat, the yew, the box, and the holly. The light products of different kinds, afforded by some timber-trees, are also of great use and value in mfull places.

Hunter, in his "Evelyn's Sylva," has justly remarked, that every person who can measure timber, thinks himself qualified to value standing trees; but that such men are often deceived in their estimates. That it is the perfect knowledge of the application of the different shaped trees that enables a man to be correct in such valuations. That a foot of wood may be of little importance to one trade, but of great value to another. This is the grand secret, it is thought, which enriches the purchasers of standing timber.

On the whole, the great and constant demand for timber, on account of the increasing scarcity of it, should induce the proprietors of lands which are proper and suitable for it, to attend as much as is possible to the raising and providing of this great object of rural economy, and national as well as individual wealth.

_Timber, Hardening of._ See Hardening of Timber, and Seafoning of Timber.

_Timber, Seafoning of._ A term used to express the preparing of timber after it is felled, for cutting and working up for use.

As soon as felled, it should be laid up in some dry airy place, but out of the reach of too much wind or sun, which, when in excess, will subject it to crack and fly. It is not to be fet upright, but laid along, one tree upon another, only with some short blocks between, to give it the better airing, and prevent its becoming mouldy, which will rot the surface, and produce mushrooms on it. Some persons daub the trees all over with cow-dung, which occasions their drying equally, and prevents their cracking, as they are otherwise very apt to do.

Some recommend the burying of timber in the earth, as the best of all ways of seafoning it; and others have found it a fine preservative to bury their timber under the wheat in their granaries; but this cannot be made a general practice.

In Norway, they seafon their deal planks, by laying them in salt-water for three or four days, when new fawed, and then drying them in the sun; this is found a great advantage to them; but neither this, nor any thing else, can prevent their shrinking. And it has been recommended to lay boards, planks, &c. in some pool or running stream for a few days, to extract the sap from them, and afterwards to dry them in the sun or air; by this means, it is said, they will be preserved from chopping, casing, or clearing; but against shrinking there is no remedy. Mr. Evelyn particularly recommends this method for fir. See Hardening of Timber.

The seafoning of timber by fire is the best way of all, for piles and other pieces that are to stand under the earth, or water. The Venetians first found out this method, and the way by which they do it is this: they put the piece to be seafoned into a strong and violent flame; in this they continually turn it round by means of an engine, and take it out when it is every way covered with a black coaly crust; by this means the internal part of the wood is so hardened, that neither earth nor water can damage it for a long time afterwards. This method is practised in many places for seafoning the polls for paling of parks, &c. and has this to recommend it, that in the very oldst ruins we have ever been acquainted with, there have been discovered many times pieces of charcoal, all of which have been found uninjured, though buried in the earth for ever fo many ages. This method of seafoning timber is practised in many parts of England, and has been much recommended, both as to economy and effect.

For this purpose, all that is necessary is to light a fire upon the ground, which shall be surrounded with a wall built with loose bricks or stones, and then, when the pieces of timber are laid across the walls, to turn them round carefully so as to present every part to the action of the fire in succession, and when the whole surface, to the depth of three quarters of an inch or an inch, is converted to charcoal, they will be sufficiently prepared. While burning, they should have a temporary covering of boughs or other fuel to prevent them from the action of the atmosphere, which would be apt to convert part of the wood into ashes. See Parke's Essays, vol. ii. See also Charring of Polls.

An ingenious friend of the editor objects to this practice. The opinion that paint is a preservative of wood is almost universal. Nevertheless, we shall now it to be not only erroneous, but that in most cases the use of paint accelerates the destruction of every species of wood to which it is applied.

The decay of wood is occasioned by internal, not external moisture, and this only when it becomes flagrant. As long as there is a free circulation, no decay takes place. Stop the circulation, and if there be any moisture whatever in the wood, flagnation commences, putrefection ensues, and the destruction will proceed with an activity in proportion to the quantity and close confinement of the internal moisture. When wood is thoroughly painted on every side, it is evident that the moisture within it is completely sealed up, and which necessarily becoming flagrant, the decomposition and decay of the timber immediately commence. Hence it is clear, that painting of wood, as above stated, in every case, except only when it is entirely free from moisture, or as it is called thoroughly seafoned, must be as effectual a method as any that can be devised for accelerating its decay.

Wood that is painted only on one side, will, ceteris paribus, last as long again as that which is painted on both sides. And that which is not painted at all will be most durable. Experiment will prove this to be the fact, whether the wood is exposed to the weather or not.
It is seldom that we meet with either a scaffold-pole or a scaffold-board (such as are used by builders) that is rotten, although they are of fir, and are alternately wet and dry, and defend from father to son for several generations. The reason is, they are never painted.

Examine any old building, and it will be found that no part of the wood or timber is in a found state, excepting that which has escaped the painter's brush. The wainscot, doors, windows, &c. will be found to be rotten, when the floors and timbers, although alternately wet and dry from peripherical washing, are perfectly sound, because they have never been painted.

It is a common practice in London to cover the bafe- ment floors with painted oil-cloth; and it is allowing to see how soon, in these cafes, the floors are rotten, and which is called the dry rot, but which is never once suspected to be the slippage of circulation by the use of the oil-cloth. Were carpets substituted for the painted cloths, no such effect would take place.

The dry rot in buildings, and particularly in the nay, is comparatively a modern disease, and has very much increased since the pernicious practice of painting has become so general. The ancient city of Chester, where so much timber was introduced into the outides of the buildings, and which is now black with age, but never painted, is a striking illustration of this theory. The fame may be remarked of the villages at a distance from the metropolis, where the outide wood-work of the buildings, such as doors, windows, window-shutters, weather-boarding, &c. which have never been painted, are nevertheless found, and yet some of them so ancient as to defy all enquiry as to their age. How different this from the gentlemen's houses near London or other great towns, where the gates, posts, rails, and palfisades are kept constantly well painted, but are seldom found to last longer than ten or a dozen years at all.

Paint indeed conceals from the eye the destruction which it occasions; and our readers will doubtles by this time begin to suspect their former opinions of it to be erroneous. We shall therefore only mention two other instances, which came under our own observation, to shew that wood never ought to be painted, except for the purpose of ornament.

A few years ago, some old houses were pulled down near the Monument in London. Several of the principal timbers were so forchored and burnt on the outide, that an enquiry took place as to the cause of it; and it was clearly ascertained, that the timbers in question must have been preserved from the ruins of the great fire of London in 1666, so that this wood must now be much more than 150 years old; yet the writer of this article lately saw that same fir-timber sawed out into deals, and again used as new stuff, being to all appearance as found as ever. The only perceptible difference was in the colour, which was darker than deals generally are.

The other instance referred to is the late old Jewry chapel in London. When that building was taken down, the pewsh, which were of oak, and the seats, which were deal (but never had been painted) were found to be in no perfect a state of foundness, that they were removed to the new building in Jewin-street, and where there is no doubt they will remain as long as the building itself, although these paid deal seats are known to be considerably more than one hundred years old.

The most effectual method of preserving timber from decay is to char it; but when the purpose to which it is to be applied will not admit of that operation, the next best method is to wash it over with charcoal and water, similar to white-washing. Either of these methods will certainly preserve it from the dry rot, charcoal being the greatest antiputrefcent known, and no moisture within the influence of its action will become putrid or decomposed, and we have already shewn that this must take place before wood will perish. It may be further observed, that vegetation cannot take place where charcoal or charring is used, and the dry rot is always accompanied with that species of vegetation called fungi, and this fungus never occurs till decomposition or decay has begun.

When boarded floors are to be laid upon or very near the ground, it should be fiowed over with dry ashes, and the joints and underside of the boards either charred or painted over with charcoal-wash, as before directed. The same should be done with the side of the wainscot next the walls.

As painting is indelispensable from the fashion of the times, to doors, window-shutters, wainscot, &c. it would be well to have them painted once over in the carpenter's shop when the stuff is perfectly dry, and finished afterward in the building for which they are prepared.

If the best feafoned stuff be put up unpainted in a new building, the quantity of moisture it will imbibe from the brick-work, plaffter, &c. before it can be painted, will defeat all former care of well feaoning.

As to fiawes, mahogany is unquestionably the cheapest article they can be made of; for deal, when painted only a few times, will have cost more than the difference of price of that very superior wood, both as to look and durability. Air that is stagnant is equally pernicious as stagnant moisture. When it is in that state, it soon becomes decomposed, and the hydrogen gas fixing upon wood, ropes, paper, and other vegetable substances, quickly brings on their destruction. Ventilation, and the use of charcoal, are the best preventives.

The above hints will be sufficient to guide the intelligent workman in all other cafes.

Though it does not properly belong to this article, it may not be amiss to mention, that these observations are quite inapplicable to the preservation of iron. Iron decays from the effect of external moisture, and the action of the atmosphere upon its surface, which produces oxidation, and which is the sole cause of its decay. This is only to be prevented by painting.

TIMBER, Preferving of. When boards, &c. are dried, seafoned, and fixed in their places, care is to be taken to defend and preferv them; to which the smearing of them with linseed-oil, tar, or the like oleaginous matter, contributes very much.

The ancients advise the smoke-drying of all instruments made of wood, by hanging them up in the chimneys where wood-fires are used. The whole benefit arising from this seems to be, that the oil of the burst wood enters, as it ascends in the smoke, into the pores of that which is proposed to be preferved.

The Dutch prefer their gates, portcullices, drawbridges, flaver, &c. by coating them over with a mixture of pitch and tar, on which they strew small pieces of cockle and other shells, beaten almost to powder, and mixed with sea-fand, which encrusts and arms them wonderfully against all assaults of wind and weather.

Timber felled before the sap is perfectly at rest, is very subject to the worms; to prevent or cure which, Mr. Evelyn gives us the following secret, as most approved: Put common sulphur into a cucurbit, with as much aquafortis
three
strength, the fte was as glafs, as marble, few to It careful in any faid, naval with larger is and, is more and, is would, is more

TIMBER.

as will cover it three fingers deep; diftil it to a drynes, and let it have two or three rectifications.

Lay the sulphur remaining at bottom on a marble, or in a glafs, and, with the oil it diffolves into, anoint the timber.

This, he adds, not only infallibly prevents or cures the worminefs, but preserves all kinds of woods, and even many other things, as ropes, nets, and masts, from putrefaftion, either in air, water, or snow.

For fuch as would go a shorter way to work, two or three anointings with linfed-oil may do very well.

As to the chaps, or elefts, green timber is liable to after working, and which is a very great defect in many fine buildings, they are clofed by anointing, fuppilng, and foaking it with the fat of beef-broth, twice or thrice repeated.—Some carpenters ufe greafe and faw-duft mingled for the fame purpofe. But the former method is excellent. Mortimer’s Husbandry, vol. ii. p. 104.

TIMBER, Strength of: See STRENGTH OF MATERIALS, and BEAM.

TIMBER, Crooked, Growth of; the means of raisiog and providing bent or twifted timber of different forts for the purpofe of ship-building and many other ufls. It has been noticed by Mr. London, that the form of the larch timber-tree is unufual for fome of the purpofes of naval architecture; and that to render it more proper and fuitable for fuch ufls, cutting or pruning it has been advised by some; and, what is still lefs practicable, shading it, by others: but that when its mode of growth is well confidered, it will be found that neither of thefe methods would prove eficual. The Former could not fucceed, it is fuppofed, because in the larch and fir-tribe one fem conftantly takes the lead; and that in this fem alone is contained the timber. The latter, or shade, might, it is thought, produce a crooked enough fem; but that in regard to strength, or timber produce, it would evidently be fo deficient, as to be totally unfit for naval architecture. In confequence of which, he has recommended the plan of bending the young trees as preferable to every other practice; and as this mode may, at fome future period, perhaps be deemed of public importance, he has given a few remarks concerning the method that should be adopted and employed in the buftinefs.

It is faid that, in the firft place, fuppoing a timber plantaftion or wood to be planted in regular rows, fifteen feet apart, and the fame distance in the row; and grown from fifteen to twenty years; in bending or rendering the trees crooked, begin with the firft row, and let every other tree be bent down in different degrees, and tied to the intermediate ones which remain erect, or be faftened to the ground. After the trees have had the growth of seven or eight years longer in that situation or position, they may be bent backwards, fo as to have somewhat the form of the letter S, the tops or leading shoots rising directly upwards again from the upper bents, and the bent trees be either tied to themfelves between the bent parts, to keep them in their proper bent position, or to the trees on the fides, or to any of the trees which surround them, as may be found to be most convenient and necessary. When the ropes have held the trees in these situations or positions for a few more years, they will have received, and retained, in fome meafe, the above crooked appearance; which is a form that will afford knee and other pieces, which are of great ufe in ship-building, and which always, it is faid, bear a higher price than any other form of even oak-timber. Some trees need, however, it is thought, only be bent gently on one fide, and others a little more fo. This variation in the inclination of the trees, with thofe which fhould be left erect, would, it is fuppofed, ferve to produce and afford proper shelter for the whole timber plantations to which they might belong, according to the ules or purpofes for which they are intended, or to the form which is moft in demand. This plan is certainly thought worthy of a trial; and there is no great reafon to doubt its succiff; for the practice of bending trees is not new; as it was advised by Evelyn, and practiced by the Romans in Virgil’s time.

It is probable, too, that fome other forts of timber-trees may be grown in this way with advantage.

It is fuggcfted, that in planting the larch for this, or any other purpofe, a careful attention fhould be had to the choice of a proper foil, as when the tree is in one which is not too rich, it reaches a large fize, and soon arrives at maturity; and that it is obvious, that if the above method were adopted, the timber would be fit for building the largest ships fifty years after it was planted, and for building smaller vessels much sooner. And that there is abundant evidence, that it would grow to a sufficient fize for this ufe in all the mountaneous parts of the ifland; moreover, that the experiments which have been made by Mr. Knight, on the fap and wood of trees, as well as common observation, prove, that the circumstance of bending, especially in an open exposure, would produce a much thicker trunk and a larger quantity of timber, in a given time, than a ftrait tree. These circumftances, in conneftion with the valuable qualities of this tree as ship-timber, and the growing fecacy of that article in this country, lead the writer to fuggcft the propriety of devoting fome extent of the national forests to the cultivation and rafting of the larch as timber, either bent in different ways, or even allowed to take its natural form; as the firft cofl of planting and fencing in, even for five hundred acres, would not exceed 1000l., and the yearly expences afterwards would be but a mere trifle. The culture of the oak, and perhaps fome other timber-trees, fhould not, however, be neglected in the smallest degree: but when it is considered that this tree takes two or three hundred years to come to perfection, and the larch not above half a cenfury, reflecting at the fame time on the approaching fecacy of oak-timber fit for the navy, these hints and remarks may not, it is thought, be unworthy of the attention of the legislature, or from other quarters. See TIMBER and TREE.

The excellent properties of larch-timber, for the ufe of the navy, have been noticed by many, as those of refifting different dangerous effefts. Anderson, in his Catalogue of Trees, afferts, it is faid, that it does not fly in splinters by the impulfe of a ball in an engagement; that no force of heat makes it flame; but that when thrown into a strong fire it consumes imperceptibly. How many accidents then, it is asked, might be prevented by a greater ufe of this timber, if applied in ships? Many lives are loft by the splinters of oak in naval warfare: all these would be faved to the flate by having the planks of war-ships made of it. Decks of the fame materials would refift fire, either accidental or defigned; for although burning materials in time will force their way through a plank of larch, yet it never would spread to the adjoining plank. To be in a ship on fire at sea, is certainly, it is faid, the moft dreadful situation in which any perfon can be placed: every exertion, therefore, to prevent fuch calamity, is the duty of all well-wifers of their country. Beside thefe advantages arising from the ufe of the larch as timber, there is another of no small importance to a warlike and commercial nation, the saving of expence in ship-building; as by experience it is found that it lasts longer than oak under water, and worms will not touch it. Sailors are faid indeed to put larch chips among their clothes; which are found by experience to prevent vermin,
vermin, mould, &c. Consequendy, in place of renewing ships of war every twenty or thirty years, their existence may, it is thought, be lengthened to thirfe that time.

Many other interesting circumstances and facts in support of these statements may also be met with in Newton's Vitruvius, which we have not room to admit in this place.

**Timber. Age of the Growth of.** The limit to the growth and increase of wood in trees of this sort. It has been remarked by a late writer, that from the old alburnum of such trees being gradually converted into heart-wood, and being continually pressed upon by the expansive force of the new fibres, it becomes harder, denser, and at length loses altogether its vasaclar structure; and in a certain time obeying the common laws of dead matter, decays, decomposes, and is converted into aceriform and carbonic elements; into those principles from which it was originally formed. The decay of the heart-wood would consequently seem to constitute the great limit to the age and size of timber or trees of that kind. This is more liable to take place in some cafes than in others. The age of growth in timber-trees is, however, mostly ascertained by the rings or layers of which they are formed.

In regard to the age of the growth of the oak, the writer of the rural economy of the midland counties has remarked, that there has been lately a fall of timber in the woods there, including some large timber-trees. That he counted the rings of one which was found at the butt: the number, as nearly as he could ascertain it, was two hundred. But those of the last forty or fifty years' growth were thin, he could not count them with certainty; though with sufficient accuracy upon which to ground the calculations given below. The girt of this tree, in the girding place, was nine feet, the diameter of which was something more than thirty-four inches. And the estimated growth, in this part, was thirty inches diameter during the first hundred and fifty years, and four inches (two inches thick) in the half fifty years. The length of the stem was twenty-two feet. The contents of the whole were one hundred and ten feet of timber. Those of the first hundred and fifty years' growth, eighty-five feet; leaving twenty-five feet for the growth of the last fifty years. It is therefore observed, that although the increase of diameter had been comparatively small during the last fifty years, the increase of timber had been nearly as great as in the first stages.

But supposing, it is said, that this tree had been taken down at one hundred and fifty years old, it would, at 22 a foot, have produced 81 10s.; the interest of which would have amounted, in the course of fifty years, to more than 20l.; besides the use of the land during that time: whereas the tree, at that rate, is now worth only 1l. These calculations and inferences are not, however, it is said, intended to excite a spirit of fellling timber prematurely, or at too early an age, a spirit which is already too prevalent; but to endeavour to decide on the most proper age of growth for its being cut down; it being an incontrovertible fact, that, in point of utility, public and private, the fault of suffering timber to stand too great an age, is infinitely greater than that of cutting it down before it has attained its full growth or age. In the latter case, it is said, there is no waste; the interest of money, and the succeeding shoots, or the use of the land, stand against the loss of growth of timber. But, in the former, the principal, interest, aftershoot, and the use of the land, are all thrown away: so that the community, as well as the proprietors, are losers by the management. In the one case, cutting part before it be fit, may save other trees which are more fully grown; but, in the other, the whole is lost. Leaving, it is said, the preservation and management of ship-timber to those to whom it properly belongs, it does not follow that, because it is wrong to suffer timber to stand to waste, it is right to take it down before it be of a proper age, or sufficiently grown, for the purpose of ship-building. It is not overgrown, but over-growing timber which is fit for that use. Timber is seldom cut down prematurely, or at too early an age, but by the necellitous; or by those who have only a temporary posseffion in their respective estates. And what argument, it is asked, can prevail with this class of proprietors? Another class, and it is trusted by much the largest, is composed of those who, considering their timber merely as a profitable part of their several estates, take it down whenever it becomes full-grown, and a fair opportunity offers. And a third class of this sort of proprietors consists of those who, though false pride, false fear, or false economy, suffer their timber to stand until it be over-grown: and if the writer have any other motive for making known the above minutes on the ages of timber-trees, than that of recording facts, it is the desire of placing in its proper light, the improvident management of this class of timber proprietors; and, at the same time, to endeavour to form just ideas of a subject, which has not, hitherto, been brought before the public; but which is pre-eminently entitled to public notice and discussion.

It is additionally stated, that this matter having been rendered, in a considerable degree, familiar to the writer by many years' observation and practice, he may here set down what appears to him the proper ages of growth for cutting down the four following species or sorts of timber.

1. Poplar, from thirty to fifty years old.
2. Elm, from fifty to a hundred.
3. Ash, from fifty to a hundred.
4. Oak, from one to two hundred.

But it is said that it very much depends on situation, and on the soil and subsoil in which timber-trees are rooted. On dry abborant soils, the oak and the elm, at least, are observed to go off much sooner than in cooler more retentive situations. And in a wood, on a dry loam, with a rocky subsoil, the oak was found going fast to decay at two hundred years old; while in another, in a cooler situation, it was found, but unprofitable, at that age: and in a third, perhaps a full cooler spot, it was found, profitable, and wearing every appearance of being in a fit state of growth for being taken down at the age of a hundred and fifty years. These three woods were those of Merevale, Bagot-park, and Staffold, in the midland districts of this country. A full knowledge of the age of growth in timber-trees is a matter of great utility and advantage to the proprietors of wooded lands.

**Timber. Marking of.** The putting of such marks upon timber-trees, or large falls of timber, as may be necessary to distinguish them in felling, and which are of a proper age and growth for being taken down. It is usually performed by means of an instrument of the compaffes kind, by which a circle, with a number, or some other particular fort of mark, is formed on the tree. It is of great use and advantage in felling and disposing of timber, to have this business executed in a careful and judicious manner. See Timber.

**Timber, Measuring of.** See Mensuration and Sliding-Rule.

For finding the area of a board or plank, the rule is simple and easy; which is that of multiplying the length by the mean breadth. If the board is tapering, the breadths at the ends should be added together, and half the sum will be the mean breadth. The method by the sliding-rule is too obvious to need being mentioned.
TIMBER.

Timber-Carriage, that fort of wheel-carriage which is contrived and constructed for the purpose of conveying heavy and other timber. Carriages for this use are formed in a strong firm manner, but in different methods, according to circumstances, and the nature of the timber to be drawn. They are sometimes made with four wheels, but much more frequently only with two. They have occasionally shafts too, but are more often constructed with a pole merely. These carriages, the writer of the rural economy of Norfolk remarks, are in that district, as in most other places, of two kinds; the four-wheeled fort of carriage, provincially “a dray,” and the pair of wheels, provincially “a gill.” The last is made in the ufe. The construction of the griff of this county is, it is said, similar to that of the timber-wheels of most other counties; namely, a pair of tall wheels, with a crooked axle-tree, surmounted by a block; to which axle is fixed a pair of shafts, or sometimes a single pole only. But it is noticed, that the method of using them there, is different from that which has been observed in other places; where the only ufe they are put to is to raise the butt-end of a large timber to be drawn a short distance; the top-end being suffered to drag behind upon the ground, to the great injury of the turf, or the road upon which it is drawn.

In the above county, however, a large flock of timber, or perhaps three or four smaller ones, are, it is observed, entirely flung to the axle; so that, in drawing, no part of them whatever touches the ground; the top-end or part being generally drawn foremost, and the end towards the horses always the heaviest.

It is stated, that the method of taking up a piece of timber is this: the horses being taken of, the wheels are run, by hand, aside the timber to be flung, until the axle is judged to be a few inches behind the balance-point: or, which is better, a chain is flung put round the timber, and the wheels run up to it. It is difficult to ascertain the exact place of fixing the chain by the eye; but nevertheless, a perfon accustomed to fling timber in this manner, will, it is said, come very near the truth. The chain hooked, and the axle brought into its proper situation, the shafts, or pole, are thrown back in the usual manner; the chain carried over the block, brought round the pole, its ends made fast, and the shafts or pole brought down again by the horses; by which means the timber is lifted from the ground, and unfurled to the axle. If the required point of balance be not hit upon at the first trial, the shafts are suffered to rise again, the chain is unhooked, and shifted to its proper situation; the shafts being then again pulled down, are bound by an iron trace, or small chain, close down to the timber; while another small chain or trace is fastened round the foremost end to hook the horses to; the team drawing by the timber, and not by the pole or shafts.

It is supposed, that the utility of having a super-balance of weight forward is two-fold: if the piece were flung in exact equilibrium, it would, upon the road, be in perpetual vibration; thereby rendering the pull unsteady, and extremely inconvenient to the horses: whereas, by throwing the balance forward, the traces are commonly kept down constantly in their proper place, and the pull becomes uniform: if, however, too much weight were to be thrown forward, the draught of the horses would not raise the point of the timber from the ground; the friction would, of course, increase the draught, and the road be at the same time hurt. It therefore follows, it is said, that the proper weight to be thrown forward is such as is enough to prevent a vibration, but not so much as to prevent the point from being raised from the road by the draught of the horses upon level ground. And that the other advantage, by a super-balance forward, is gained in going down a hill; in which case, the draught not being wanted, the point, of course, falls to the ground, and serves as a pall to regulate the motion of the carriage: if the super-balance alone be not sufficient to check the too great rapidity of the motion, the driver adds, it is said, his own weight. Likewise, if, in ascending a hill, the balance be lost; he, in like manner, seats himself upon the fore-part of the load, thereby keeping it down to its proper level.

It is added, that this method of conveying timber may, if possible, be in ufe in other districts; but the writer has not seen it practised any where except in the above country; and that it is known to be an excellent, but not a common mode of practice.

It is of great utility and convenience for timber proprietors and dealers to be always provided with good carriages of this fort.

Timber Hedge-Row, such trees of this kind as are raised and grown in the lines and rows of the hedges. It has been long a disputed point among the writers on agriculture, and which is not yet fully decided, whether it is admissible or not to have trees of this fort in the directions of the hedges: some strongly contending for its utility, on the grounds of the shelter, shade, and timber afforded by the practice; while others as strongly oppose it, on the score of the injury which it does to the crops and the hedges under the trees, as well as the obstruction which it affords in working the land, when in the tillage state. However, in many situations and cafes, there can be no doubt of the advantage of having timber-trees of the hedge-row kind, when under proper and suitable management.

It has been well observed by an able writer on the manners and practices of the country, that although a few trees growing in a hedge, when considered singly, may have little effect, and be of no great value or consequence; yet that a number of hedge-rows, all properly interplied with timber-trees, will completely change the appearance of a hilly country or district, improve its climate, and yield a considerable quantity of timber to the owners of the lands. The consideration of the matter must, of course, it is thought, be of great importance to the landed interest of some parts of the island, especially those in the more northern or mountainous districts of the kingdom. What is necessary to be said on this subject here, may consequently be introduced under the heads of the nature of the lands where timber of the hedge-row kind may be raised and grown without injury to the farmer; and the species or fort of trees which is most proper to be raised in such cases. In regard to the interest of the farmer, the lands which are the most evidently and suitably adapted for the growth of hedge-row timber-trees are all those which are naked and much exposed, and which are kept for the most part under pature; and in so far as the beauty of a country or district, the improvement of its climate, and the health of its inhabitants, are concerned, the hedge-rows of the rilling-grounds alone should be occupied by trees, except a few in the valleys, by the sides of public roads or rivers, to form fore-grounds to the rest of the country or district; and a few near houses or villages to group with them, and afford a richness to their appearance. In low rich valleys between mountains, which are kept in perpetual aration, the hedge-rows should not be taken up by timber-trees of this fort. But a country or district wholly level, as many of the counties and districts in the southern parts of the kingdom are, may sometimes have the hedge-rows partially let with trees, without doing any great injury to the farmer.
TINMER.

Tfarmer; while, if properly managed, it may vary the country, and improve its climate. In such levels, the hedges should, however, be kept very low, and the trees be trained crotch with single items, and few lateral arms or boughs near the surface; or, as is done in some places, the width of an ordinary ridge may be left on each side of the hedge, to be kept in perpetual pasture, which prevents the corn from being too much injured by the trees, and is a great ornament to a farm. This last mode is, however, not without its disadvantages, as it is liable to disseminate and fill the adjoining tillage-lands with the seeds of noxious and hurtful weeds. However, in cafes where the whole farm is to be kept in perpetual pasture, the trees may often be allowed to extend their branches, and the hedges may be kept high or low, at pleasure. Moist or clayey soils should never, when under perpetual aration, be fet with hedge-row trees; and indeed, before they are put into such rows anywhere, or in any cafe, a full consideration and estimate should, it is said, be made of their effect on the annual rent of the land, on their intrinsic value, on the climate, and on the appearance of the country.

The writer of the Yorkshire rural economy considers this an interesting subject to the proprietors of inclosed estates. The old inclosed parts of that neighbourhood, when seen at some distance, have, it is said, the appearance of woodlands; the inclosures being mostly narrow, and full of hedge-row timber. The age, on a par, is about 50 years. In half a century more, the value of the timber of some parts of it, if suffered to stand, will probably be equal to the value of the land; a circumstance, it is supposed, of no small import to the owner. But the detriment to the occupier requires to be considered. In this county, it seems, it is said, to be a general idea, founded perhaps on experience, that lofty hedge-rows are beneficial to grafs-land; increasing its productiveness by their warmth, and giving shelter and shade to pasturing-flock. The roots even of the ash are considered as offensive to land in the state of grafs; in which state the grounds, thus loaded with hedges and timber-trees, are almost universally kept. Indeed it would be impossible, in their present state, to occupy them as arable land. They are entire inclosures, every foot of the areas of which must necessarily be occupied by alien roots; nevertheless they give an ample supply of hay and pasturage; one to two tons of hay an acre; and, in many of them, three acres will afford sufficient pasturage for two cows of the largest size. The rent from thirty to forty shillings an acre. Strong evidence this, it is said, that the roots of the ash are not very hurtful to grafs-land.

It is evident, however, it is thought, that the oak, when suffered to thrall its low spreading head into the inclosure, is injurious to the herbage beneath it; that the leaves of the ash are very detrimental to after-grafts; and that the hedges are annually receiving irreparable damage; no general plan of training up the trees with tall items having, it is believed, in any instance, been adopted, so as to prevent, in any complete manner, such effects.

On these accounts it is concluded, that the advantages accruing from the planting of timber-trees in the hedge-rows of inclosed common fields, of a foil and lying in a situation adapted to grafs, are far superior to any disadvantages arising therefrom, even where they have been suffered to grow in a state of almost total neglect. And that land which has lain open, and which has been kept in a state of aration during a succession of ages, is equally productive of grafs and trees. That it is generally good management to let it lie in grafs for some length of time, after inclosure. Besides, that in the above neighbourhood, it is evident to common observation, that trees flourish with unusual vigour in newly-inclosed lands of arable fields; and that their injury to grafs-land is inconsiderable, when compared with the value of the timber which they produce. The low spreading heads of the oak, and the leaves of the ash, appear to be the chief incompatibilities of these two sorts of trees to grafs-land.

But as an alternation of corn and grafs is, it is thought, generally eligible on lands which our ancestors have made choice of for common fields; and as the roots of the ash are not only obstructions to the plough, but the general nature of the plants is, in a singular degree, inimical to corn; it is consequently necessary to eradicate the ash from the hedge-rows, before the land be again broken up for arable; or to preclude this tedious operation, in the first instance, by planting oak in its stead. It is conceived that the head of the oak may be raised to such a height, as not to be injurious to grafs, nor to the hedge, while yet in a youthful state, even though it were suffered to run up to its natural height.

The roots of the fir tribe of trees afford equal obstructions to the plough; they are, of course, equally objectionable in the hedge-rows of arable fields.

It is suggested, in conclusion, that whenever the inclosures are broken up for corn, the hedges should, in common good management, be headed down, and kept in a dwarfish state; in which state, tall stembled oaks would be a valuable source of timber, without being, in almost any degree, injurious either to the hedges, or to the corn growing under them. But the training of young oaks, and the general management of hedge-row timber, cannot, with any degree of prudence, be left to a mere occupier. When intended as nurseries of timber, they should, it is conceived, be under the immediate direction and management of a person proper for the purpose. See Pollard and Fence.

The writer of the Gloucester report on Agriculture, however, remarks, that the practice of planting timber-trees at all in hedges is liable to objections; for if the tree be left to take its natural growth, which is the best mode of raising it for good timber, the lower fence is ruined by its shade and drippings; or if they are cut up and threated into naked poles, or pollarded for the sake of the top or fire-wood, the timber is injured, and the beauty of the tree destroyed. A better plan is it, it is thought, to affign certain spots on estates for the purpose of raising timber-trees only. This would eventually be no waste of land, because the grafs or corn growing near the hedges, which are filled with timber or fruit-trees, is worth little or nothing. In the small inclosures at the angles of a field, for instance, the trees might take their natural growth; and this would be more rapid, in consequence of their being planted in clumps, and protected. If, however, the old mode of planting in hedge-rows shou'd be continued, the ash may be the best for the purpose. The timber, in some respects, is superior to elm, and, in various cafes, useful where that cannot be applied. In durability it almost rivals the oak, and its growth is improved by being kept to a single item, the only mode of treatment in which trees should be admitted into hedge-rows at all, but which few other trees will bear. The oak and beech particularly, when footed as to become heart-wood, appear to be greatly hurt by the losses of their side branches; the immediate effect of which is a retardation of growth; and it is said, that the oak will not thrive for ten years after this operation; and of the elm, that it is injured, though apparently suffering less. It is, however, to be noticed, that the finest and soundest trees are those which have been most left to their natural growth.
In what relates to the most proper sorts of trees for putting in hedge-rows, in different cases, it may be further noticed, that when the soil is good and deep, according to the first of the above writers, the oak and Scotch elm may be the most suitable; in strong land, the ash; in poor soils, the beech, sycamore, and birch; in cafes of moil soils, as meadows and such like places, the Lombardy poplar, which, besides its timber produce, forms, when in rows, a clofe, erect, narrow hedge, fifty or sixty feet high, in a few years. Such hedges are, however, of no very great value, whether the trees be cut low, or allowed to rise to their full height. The oak and the above sort of elm proper better, it is said, in hedge-rows than in any other situations; their roots have a free range in the adjoining inclosures, while their tops shoot out vigorously on every side, thus often producing excellent ship-timber. More remarks of this nature may be met with in Kent's hints, and Marshall's work on planting. The beech, it is thought, is peculiarly suited for thin soils and exposed situations. When put out about ten or twelve feet asunder, it affords excellent shelter, and, at the same time, a very confiderable quantity of timber. The ash and the sycamore will rise and grow erect on the most exposed upland situations, or near the sea. When put out in good soils, they should generally be trained to one stem; in which state, their timber produce is the most valuable and useful. The reifinous tribe and the evergreen sorts of trees are, for the most part, improper for being set out in hedge-rows. In the different cyder districts or counties in the southern parts of the kingdom, fruit-trees are not unfrequently introduced into the hedge-rows; the practice of which might probably be advantageously had recourse to in many other districts and counties in the same part of the country, as well as in several more to the north. In many different situations they would be a valuable acquisition, without doing any injury, or taking up the more useful part of the land.

In a great number of districts and places where hedge-row timber exists, the situation is often improper, and the management wretchedly bad and negligent; in consequence of which, it has frequently become an injury to the farmer, without yielding any advantage to the proprietor. Two more glaring instances of this cannot, it is thought, be given than in the tall naked elms, and pollarded oaks, which prevail in many places in the southern parts of the illand: the former, by improper lopping and cutting, are worth nothing; and the latter, by being cut over at the height of eight or ten feet, form ugly bully-headed trees, which do great injury and mischief to the farmer, and yield nothing to the owner. In defence of such practices, it has been said, that fuel alone is the intended produce; but certainly it would be much the best method, in such cafes, it is thought, to allot a space or portion by itself for the purpose of raising fuel, and devote the hedge-rows to the more important uses of producing timber. The fuel part of the land might be rented by the farmer, and the hedge-rows belong exclusively to the proprietor. Keeping each sort of woody collection strictly characteristic of its kind is, it is thought, as beneficial in the raising of trees, as the division of labour is in political economy. There is a great number of situations and places in the more northern parts of the illand, as well perhaps as in some others, where hedge-row timber might be cultivated to the advantage of both the landlord and tenant, and the great ornament of the country. Suppose, it is said, an estate of two thousand acres, divided into fields of ten acres each, and the hedge-rows planted with trees at fifteen feet apart; this would be above the rate of eight trees upon the acre, or sixteen thousand trees in the hedges only. At the end of thirty years, if well managed, they would be worth from twenty to forty shillings each; but say only thirty shillings each, this would be sixteen thousand pounds; a very considerable sum, it is said, for a proprietor of only two thousand acres to receive every thirty years, above the annual rent of his estate.

These hints and observations place the utility and importance of hedge-row planting, where it can be done with propriety, in a striking point of view.

**Timber-Inpector**, a term applied to a person who is appointed to inspect and examine the fates of timber-woods, plantations, and forests in any district or place. It has been suggested by the writer of the corrected account of the fates of agriculture in the county of Devon, that, as it is evident that the timber in that county is waiting in a very alarming manner, and the fame is the case in many other timber-wooded districts, it is necessary that an ordinance should be made, that in future no timber-tree should be cut down, or legally exposed for sale, without having the mark of the timber inspector of the district affixed to it, and a certificate accompanying it. This fort of officer should, it is thought, be appointed and paid by government, and to whom annual returns should be made of all matters and circumstances appertaining to his duty, which should also extend to the inspection and examination of all young timber-plantations, &c., where it should be required that he should not only see that a certain number of young trees is planted for every timber-tree that is cut down, but that the same young trees and plantations are well fenced in and protected. That on his observing such timber woodland fences insufficient for their safety, and their owners perfectly unmindful of the report he has made, he should be empowered to order and direct the necessary repairs to be done, and to be enabled to recover the amount of such expense, by levying an immediate distress upon the moveables on the premises of the parties.

It would unquestionably be of great utility and advantage in increasing the quantity, and improving the quality of timber, to have such inspectors in all timber-wooded districts of every description.

**Timber-Plantation**, that fort which is made simply for the purpose of raising and producing timber. Several points and circumstances are necessary to be attended to in the performance of this business, in order to render such plantations the most expeditiously and abundantly productive, such as the proper choice of soil, situation, and exposure, as well as proper fencing in, thinning, training, and pruning, all of which are noticed and explained under their appropriate heads. See Plantation, Planing, Pruning, Thinning, Timber, &c.

**Timber-Repairs**, such as are done by some sort of timber, to be cut down on estates, &c. Rough timber is mostly allowed for repairs to be done by tenants, and it is commonly the custom of this country to permit the topwood of the trees to be taken by them for their trouble and expences in various ways with such timber. In some cases, however, the contrary mode takes place, such topwood being charged to them at a moderate rate or price. And, in all cases, it is thought by the writer of the work on "Landed Property," that the tenant should be charged for the bark of oak-timber, which is now become scarce and of great value, he being allowed for peeling and for carriage to market, or other places.

It is advised that the neat value of the bark and the topwood, where it is charged in these cases of repairs, should be made a fair estimate of when the timber is marked, and charged to tenants in a sum certain. By this means they become,
come, it is thought, interested in the pedling and harvesting or lecouring of the bark: no waile is consequently incurred through their neglect, or any unfair dealings rised; nor is there any disputable account to be settled, on the rent-days between them and the receivers.

In the view too of enabling the acting managers, in such cafes, to *j(e)le*3, in the belt and readiest manner, proper trees for the several different sorts of repairs that may, from time to time, be required, — let, it is said, the woodmen, or those who have the immediate charge of the timber of estates, be directed to note down, in going their rounds, such trees as may be faulty, and are likely to go soon to decay, or which are thinnest in their growth, or too much crowded, and, in general, such as are proper to be taken down for the different uses of estates: whether for erecting or repairing buildings, or for gates or other purposes: in order that they may be able to lead or direct, without loss of time, the acting managers and the carpenters or builders of estates, with the intimates, in their hands, of the quantity and quality of the timber which is requisite to the trees most proper for any given purpose: thus preserving the *crop* of sole timber from unnecessary spoilation, by a lefs discriminate choice or method of proceeding.

*Timber, Stick of,* a term frequently applied to any large boled or flemmed tree of the timber kind: a fine, large, perfect timber-tree. See *Timber and Tree.*

*Timber-Trees,* the wood of timber, before it is felled, particularly that of oak, &c. See *Trees.*

For the raising, planting, transplanting, pruning, &c. of timber-trees, see *Seminary, Nursery, Pruning, and Transplanting.*

*Timber-Wood,* a term signifying that sort of wood which is employed or designed for the raising and growth of timber, in contradistinction to that of the under-wood or coppice kinds, or such as has little or no bruff-wood or under-growth in it. There are but few cafes in which it is not advantageous for timber-woods to be kept pretty clear and free from most sorts of under-growths, especially where they approach near the trees. See *Wood.*

*Timber-Wood or Tree, Register of,* the account which is necessary to be kept of the timber-wood or trees of that kind, which are growing upon the different parts of a timbered estate. The writer of a late work on "Landed Property," has advised that it should consist of all that is met with on the several divisions of an estate; setting forth the number of such trees in each of the different woods, groves, hedge-rows, and all other places, with the several species or kinds, the number which is affixed to each, and the admeasurement of each of them. Separate accounts, containing those trees of each particular division, being entered and kept; for the satisfaction and occasional use of the land-manager and the woodland. Such lists or registers are always of great utility and benefit to the proprietors of timber-wooded estates, as ascertaining their nature, rate, and situation in many different respects.

*Timber-Lads,* in our *Old Writers,* a service by which tenants were to carry timber from the woods to the lord's house.

*Timber, Bearing of,* See *Bearing.*

*Timber-Work, Catalogue of,* See *Casing.*

*Timber of Timber of Furs,* as ermines, martens, fables, and the like, denotes forty lkins; of other lkins, five score. *Ruff.*

"*Hic civitas (i.e. Cæstria) nunc reddébat de firma 45 libras et tres timbris pellium marternum.*" L.L. Edw. Conf.

*Timbers of Ermin, in Heraldry,* denote the ranks or rows of ermin in noblemen's coats.

*Timber, in Falconry.* To timber, is to nettle, or make a net, as birds of prey do.

*Timber, Prick, in Botany.* See *Spindle-Tree.*

*Timbers, in Ship-Building,* the ribs of a ship, or the incurved pieces of wood branching outward from the keel in a vertical direction, so as to give strength, figure, and solidity to the whole fabric.

One timber in a ship is composed of several pieces united into one frame, which accordingly is called by the artificers a frame of timbers. The timbers whose planes are perpendicular to the keel, are called *square-timbers;* and those which are placed obliquely on the keel, as at the extremities of a ship, are called *cont-timbers.* The foremoll of those pieces on the ship's bow are called the *knuckle-timbers;* and the hindermost on the quarter, the *fashion-pieces.* See *Ship-Building.*

*Timber and Room, or Room and Space,* is the distance between the moulding edges of two adjoining timbers, which must always contain the breadth of two timbers; and sometimes two or three inches between them.

*TIMBO,* in Geography, a town of Africa, on the Grain Coast. N. lat. 5° 28'. W. long. 6° 29'.

*TIMBRE,* or *Timmer,* in *Heraldry,* denotes the crest of an armory, or whatever is placed atop of the escutcheon, to distinguish the degree of nobility, either ecleiastic or secular.

Such as the papal tiara, cardinal's hat, the crofs, mitre, coronet, mortier, and particularly the caffes or helmets, which the ancients called more especially timbers, from their resembling a kind of bell without a clapper, which the French call timbre, or because they resounded like those timbers when struck. This is the opinion of Loifeau, who derives the word from the Latin, *tintimabulum.*

*TIMBREL,* *Tabret,* or *Tambour de Bafque,* in *Musica,* is an instrument of very high antiquity; having been in use among the Hebrews, Greeks, and Romans. To the rim were hung bells or pieces of metal.

*TIME* is a portion or part of infinite duration. It is generally measured by motion, and chiefly by the motions of the heavenly bodies.

There is nothing perhaps of which the mind is less capable of forming a distinct idea than time, unconnected with the motions of sensible objects; and yet, on account of this connection, every one thinks it a subject with which he is familiarly acquainted, until an explanation is required.

The opinions of ancient philosophers on the subject are generally vague and contradictory. Pythagoras and Heraclitus maintained that time was a subsistance, but the Stoics considered it as unsubstantiated. Aristotle and the Peripatetics define time to be "a multitude of parts of motion, which pass and succeed each other in a continual flux, and have relations to each other, inasmuch as some are anterior and others posterior." Archytas defined it to be "a continued and indivisibly flux of *nows* or inflants."

The Epicureans considered "time as merely an object of the imagination, or an attribute given to things by the mind while contemplating them either as enduring or ceasing; as pooffing a longer or shorter existence, as enjoying such existence, as having enjoyed it, or as being about to enjoy it."

Lucretius, the great poet and philosopher of this sect, defines time as follows:

"*Tempus item per se non est, sed rebus ab ipsis Consequitur fenus, transactum quid fit in aëro; Tum, quae res insit, quid porro deinde fequatur: Nec per se quemquum tempus tentire futendum est Sememum ab rerum motu, placideque quiete.*"

Lib. i. 460.

Thus
TIME.

Thus translated by Creech:

"Time of itself is nothing, but from thought Receives its rise, by labouring fancy wrought. From things considered, whilst we think on some As present, some as past, or yet to come. No thought can think on time, that's still confess. But thinks on things in motion or at rest."

The above opinion of Lucretius, though supported by many of the ancients, and even by some of the moderns, does not appear to have been falsified philosophers in general. Cicero says (I de Invent.) "difficile est tempus definire." Thus also St. Austin (2 Confess. 24) observes, "si nemo cx me quærat quid fit tempus, feio; fe quærenti explicare velim, nescio."

Locke seems to have considered time more profoundly than perhaps any other philosopher. The following are among his opinions on the subject. Human Underst. vol. i. ch. 14.

"The answer of a great man to one who asked him what time was, 'si non rogas intelligo,' (which amounts to this; the more I set my self to think of it, the less I understand it,) might perhaps persuade one that time, which reveals all things, is not itself to be discovered. Duration, time, and eternity, are, not without reason, thought to have something very abstruse in their nature."

"To understand time and eternity aright, we ought with attention to consider what idea it is we have of duration, and how we came by it. 'Tis evident to one who will but observe what pastes in his own mind, that there is a train of ideas which constantly succeed one another in his understanding as long as he is awake. Reflection on these appearances of several ideas, one after another in our minds, is that which furnishes us with the idea of succession; and the distance between the appearance of any two ideas in our minds, is that which we call duration (which see). Having thus got the idea of duration, the next thing natural for the mind to do, is to get some measure of this common duration, whereby it might judge of its different lengths, and consider the distinct order wherein several things exist; without which, a great part of our knowledge would be confounded, and a great part of history rendered very useless. This consideration of duration, as set out by certain periods, and marked by certain measures or epochs, is that, I think, which most properly we call time."

Nearly according to the above our modern Encyclopedia defines time; viz. "a succession of phenomena in the universe, or a mode of duration marked by certain periods and measures, and principally by the motions or apparent revolutions of the sun." Others define time to be "the duration of a thing, the existence of which is not without beginning or end, which distinguishes time from eternity."

Time is distinguished into absolute and relative. Absolute time is considered in itself, without any relation to bodies or their motions flowing uniformly. Relative time is the sensible measure of any portion of duration by means of motion. As the equal and uniform flux of time does not affect our senses; and as there is nothing in this flux that can make us know immediately time itself; we must, of necessity, have recourse to some motion, by which we can determine the quantity of time, by comparing parts of time with those of space that the moving body traverses. Therefore, as we judge that times are equal, when they flow whilst a body which is in an uniform motion traverses equal spaces; so likewise we judge that times are equal, when they flow whilst the sun, moon, and the other celestial luminaries, complete their ordinary revolutions, which to our senses appear uniform. See Motion.

But as the flowing of time cannot be accelerated nor retarded; as all bodies move sometimes quicker and sometimes slower; and as there is perhaps no perfectly uniform motion in nature, except the earth's rotation on its axis, some authors are of opinion that absolute time cannot be concluded to be something really distinct from motion; for supposing for a moment the earth and the other planets have been without motion ever since the creation, does it thence follow that the course of time would have been stopped or interrupted? Would not the duration of this state of rest have been equal to the time which has elapsed since the creation?

As absolute time is a quantity which flows in a uniform manner, and which is very simple in its nature, mathematicians represent it to the imagination by the most simple sensible magnitudes, particularly by right lines and by circles, with which absolute time appears to have a great analogy in respect of succession, the simplicity of parts, &c.

In fact, it is not absolutely necessary to measure time by motion; for the constant and periodic return of a thing which happens or manifests itself by intervals equally distant from each other, as, for instance, the budding of a plant, &c. may do the same thing. It is laid there are people in America who reckon years by the arrival and departure of birds. Time is usually represented by the uniform motion of a point that describes a right line. The point is the succedent state, present successively at different places, and producing by its succession a continual succession, to which we attach the idea of time. The uniform motion of an object also measures time; for when this motion takes place, the moving body traverses, for example, one foot in the same time in which it has traversed a fift foot; therefore, the duration of things that co-exist with the moving body whilst it traverses one foot being taken as one, the duration of those that will co-exist with its motion whilst it will be traversing two feet will be two, and so on; so that by this means time becomes commensurable, since we can assign the reason of one duration to another duration that we had taken for unity. Thus, in clocks, the hand moves uniformly in a circle: the twelfth part of the circumference of this circle is unity, and time is measured by this unity, by saying two hours, three hours, &c. So likewise one year is taken for one, because the revolutions of the sun in the equinoxes are equal, or nearly so, to our years and we make use of it to measure other durations in relation with this unity. We know the attempts made by astronomers to find a uniform motion, to enable them to measure time exactly; and this is what has been done by means of pendulums. See Pendulum.

There is no measure of time exactly correct. Every one has his own measure of time in the quickness or slowness with which his ideas succeed each other; and from these different degrees of quickness in different persons, or in the same person at different times, arise these modes of speaking; I have found the time very long, or very short; for time appears long to us, when the ideas succeed each other slowly in our mind, and vice versa. The measures of time are arbitrary, and may vary among different people: the only one that is universal is the present instant; and yet some deny the existence of present time, as being constantly on the wing; or, according to Horace, (Carmen XI.)

"Dum loquimur fugerit invida atas."

Time is indeed an inexhaustible subject for figurative and poetical allusions, and even for paradoxes. Thus, it is said to
TIME.

to owe its own immaterial being to the creation of material order: to have all its portions measured by the periodical motions of matter, and yet to be distinct from, and independent of, these motions for its existence, though it could not exist until they existed: also that it operates upon every thing, yet touches nothing. Many other contradictory properties might be mentioned, but such tend to darken rather than to elucidate the subject. Some philosophers have gone even so far as to deny the existence of time; for if there be no present, there cannot be any future, and the past certainly has no existence.

We now come to consider the application of mathematics to time, as connected with astronomical computations, where the subject is accurately calculated, and rendered subservient to the important purposes of measuring space, by which the longitude is determined both in the heavens and on earth.

Astronomical time is distinguished into solar or apparent time, mean time, and sidereal time.

Apparent time, also called true solar and astronomical time, is regulated by the apparent motions of the sun. Mean or mean solar time, also called equated time, is a mean or average of apparent time: and sidereal time is shown by the diurnal revolutions of the fixed stars.

An apparent day is the interval between two successive transits of the sun's centre over the same meridian, which interval is subject to continual variations, owing to the eccentricity of the earth's orbit, and the obliquity of the ecliptic to the equator. Thence variations are computed in a table, for which see EQUATION Of Time.

A mean day is the interval that would be observed between two successive transits of the sun's centre over the same meridian, if the earth's orbit were circular, and the sun always in the equinoctial. Thus the intervals or transits would be all equal, such as are shown by a clock that goes exactly 24 hours in a day, and 365 $\frac{1}{4}$ $^b$ 48$m$ 48$^s$ in a year. A clock thus set is said to be adjusted to mean time.

A sidereal day is the interval between two successive transits of a star over the same meridian; which interval is uniform, because all the fixed stars make their revolutions in equal times, owing to the uniformity of the earth's diurnal rotation on its axis.

The sidereal day is shorter than the mean solar day by $3m$ 56$^{1/2}$ sidereal time. This difference arises from the sun's apparent annual motion from west to east, which leaves the star as it were behind. Thus, if the sun and a star be observed on any day to pass the meridian at the same instant, the next day, when the star returns to the meridian, the sun will have advanced about a degree earlier (his daily portion of the ecliptic): and, as the earth's diurnal rotation on its axis is from west to east, the star will come to the meridian before the sun, inasmuch that at the end of the year it will have gained a day on the sun, that is, it will have passed the meridian 366 times, while the sun will have passed it but 365 times. Now as the sun appears to perform his revolution of 360° in a year, say, as 360 $^b$ 48$m$ 48$^s$; 360$^b$ = 90$^b$ 59$^m$ 8$^s$, which is the space the sun would describe in a day, if all the days were of an equal length; and this space reduced to time, = 3$^b$ 56$^{1/2}$ 55 = the excess of a mean day above a sidereal day, in sidereal time, or 3$^b$ 55$^{1/2}$ in mean solar time.

It therefore appears that the earth describes about its axis an arc of 360° 59$^m$ 8$^s$ in a mean solar day, and an arc of 360° in a sidereal day; therefore, as 360 $^b$ 59$^m$ 8$^s$ : 360$^b$ :: $24^b$ : $23^b$ 56$^b$ 4$^b$.09 = the length of a sidereal day in mean solar time, or the interval between two successive transits of a star over the same meridian.

Hence the following general rule for converting sidereal to mean time, and the contrary:

As $24^b$ : $23^b$ 56$^b$ 4$^b$.09 :: any portion of sidereal time to its equivalent in mean time. And as $23^b$ 56$^b$ 4$^b$.09 : $24^b$ :: any portion of mean time to its equivalent in sidereal time.

Thus Tables I. and II. in our article Chronometer are computed.

From what has been said, it is evident that apparent and mean time are the same, with respect to the length of the hour, minute, and second of each, as well as of the year; but the hour, minute, and second of sidereal time are respectively less in the above proportion. It is only the solar and mean days that differ, and this variation is marked by the times of commencement. Thus the apparent day always begins when the sun's centre is on the meridian; but the mean day commences sometimes sooner and sometimes later, as computed in the tables of the equation of time. See EQUATION Of Time.

The reduction of time, that is, to turn apparent, mean, and sidereal time into each other, may be performed by the following theorems, taken from Kelly's Spheres, p. 208, ed. 4.

Let A = apparent time.
M = mean time.
S = sidereal time.
E = the equation of time at apparent noon.
$\epsilon$ = the daily difference of the equation of time.
R = the sun's right ascension at apparent noon.
r = the daily increase of the sun's right ascension.
N = the sun's mean right ascension at mean noon.
i.e. = the sidereal time at mean noon.
m = the reduction of sidereal time at the rate of $3^{1/2}$ 55$^{1/2}$ for 24 hours sidereal time.
s = the reduction of mean to sidereal time, at the rate of $3^{1/2}$ 56$^{1/2}$ for 24 hours mean time.

And let ± signify that addition or subtraction which is to be used according as the quantity under consideration is increasing or decreasing.

Also let $\Lambda' = M + E$, as applied in case 2.

Formulae for the Reduction of Time.

The
The foregoing six cases comprehend all the varieties that occur in the reduction of time; and for their numerical illustration, see our article CHRONOMETER.

For the application of time to the measurement of space and motion, see Longitude and Lunar Observations.

Time, Civil, is almanac time accommodated to civil uses, and formed and distinguished into years, months, days, and hours, with their subdivisions: the reckoning of the hours as civil to twelve twice over, is meant to mark the natural day.

Time, in Heathen Mythology, was perfomnified and deified. Saturn was usually the symbol of it. Time was represented with wings, to mark the rapidity with which it passes, and with a scythe, to signify its ravages. It was divided into several parts; the century, the generation or space of thirty years, the lunarium, the year, the seasons, the months, the days, and the hours; and each of these parts had its particular figure in men or women, according as their names were matrilineal or patrilineal; their images were used in religious ceremonies.

Time, in Music, is an affection of sound, by which we denominate it long or short, with regard to its continuance in the same degree of tune.

Time and tune are the great properties of sound, on whose difference or proportions music depends: each has its several charms: where the time or duration of the notes is equal, the differences of tune alone are capable of entertaining us with endless pleasure.

And of the power of time alone, i.e. of the pleasures arising from the various measures of long and short, swift and slow, we have an instance in the drum, which has no difference of notes, as to tune.

Time, in music, is considered either with respect to the absolute duration of the notes, i.e. the duration considered in every note by itself, and measured by some external notion foreign to the music; in respect to which the composition is said to be quick or slow: or it is considered with respect to the relative quantity or proportion of the notes compared with one another. See Note.

The signs or characters by which the time of notes is represented, are shewn under the article CHARACTERS, in Music, where the names, proportions, &c. are also explained.

A semi-breve, for instance, is marked to be equal to two minimis, a minim to two crotchetts, a crotchet to two quaveris, and so on, still in a duplicate ratio, i.e. in the ratio of 2:1. Now where the notes respect each other thus, i.e. where they are in this ratio, the music is said to be in duplo, i.e. double or common time.

When the several notes are triple of each other, or in the ratio 3:1, that is, when the semi-breve is equal to three minimis, the minim to three crotchetts, &c. the music is said to be in triple time.

To render this part as simple as possible, the proportions already stated among the notes are fixed and invariable: and to express the proportion of 3:1, a point (.) is added to the right side of any note, which is deemed equivalent to half of it; and by this means a pointed semi-breve, O, becomes equal to three minimis, and so of the rest.

From hence arise several other ratios constituting new kinds of triple time; as 2:3 and 3:4, &c. but these, Mr. Malcolm observes, are of no real service, and are not perceived without a painful attention. For the proportions of the times of notes, to afford us pleasure, must be such as are not difficultly perceived; on which account the only ratios fit for music, beside that of equality, are the double and triple.

Vol. XXXV.

Time, Common or Duplo, is of two species: the first, when every bar or measure is equal to a semi-breve, or its value in any combination of notes of a less quantity. The second, where every bar is equal to a minim, or its value in less notes. The movements of this kind of measure are various, but there are three common distinctions; the first slow, signified at the beginning by the mark C; the second quick, signified by \( \frac{1}{4} \); the third very quick, signified by \( \frac{1}{4} \).

But what that slow, quick, and quick is, is very uncertain, and only to be learned by practice. The nearest measure we know of, is to make a quaver the length of the pulse of a good watch; then a crotchett will be equal to two pulses, a minim to four, and the whole measure or semi-breve to eight. This may be reputed the measure of quick time; as for the slow, it is as long again, and the quick is only half as long.

Some propose to measure it by imagining the bar as actually divided into four crotchets, in the first kind, and to make the whole as long as one may distinctly pronounce these four words, one, two, three, four, all of equal length; so that the first crotchett may be applied to one, the second to two, &c. and for other notes proportionally; and this is made the brisk movement of common time.

The whole measure then of common time is equal to a semi-breve, or a minim; but these are variously subdivided into notes of less quantities.

Now to keep the time equal, we must use of a motion of the hand or foot, thus: knowing the true time of a crotchett, we shall suppose the measure or bar actually subdivided into four crotchets for the first species of common time; then half the measure will be two crotchets; therefore the hand or foot being up, if we put it down with the very beginning of the first note or crotchett, and then raise it with the third, and then down to begin the next measure; this is called beating of time.

By practice, they get a habit of making this motion very equal, and consequently of dividing the measure or bar into equal parts, up and down; as also of taking all the notes in the just proportion, so as to begin and end them precisely with the beating. In the measure of two crotchets, they beat down the first, and the second up. Some call each half of the measure in common time, a time; and so they call this the mode or measure of two times, or the duplo measure.

Again, some mark the measure of two crotchets with a 2 or 4, signifying it to be equal to two notes, of which four make a semi-breve; and some mark it 4 for quavers. Malcolm's Music, p. 385, &c.

Time, for Triple. See TRIPLE-TIME.

Time-Table. See CHARACTERS, FRANCO, and PLATE 1.*

Time, in Fencing. There are three kinds of time; that of the sword, that of the foot, and that of the whole body. All the times that are perceived out of their measure, are only to be considered as peals, or feats, to deceive and amuse the enemy. See FENCING.

Time, in the Manege, is sometimes taken for the motion of a horfe, that observes measure and junctures in performing a manege; and sometimes it signifies the interval between two of his motions. In the manege of a step and a leap, the horse makes by turns a corvet between two capricoes; and in that case the corvet is one time that prepares the horse for the capricoes.

4 S
TIM

The times observed in making a flop are nothing but so many falcades.

Tima also signifies the effect of one of the aids; thus, we say, a good horseman disposes his horse for the effects of the heel, by beginning with one time of the legs, and never runs precipitately upon his times.

Time of flowering Flowers, in Gardening, among florists, the period or season of exhibiting those of the finer kinds, either on the summer stages for this purpose, or in other places. For some sorts of flowers, as those of the auricula and other similar kinds, it is usually from about the latter part of April until about the beginning of May, in situations near the metropolis, in which length of period or season there are commonly about four such shows at different suitable intervals of time.

In other sorts of fine flowers, the shows are mostly somewhat later, and do not last any great length of time, as for tulips, carnations, and some other similar kinds; and there are still a few others which last differently in regard to time, or a great part of the summer season. See Summer-Stages.

Time-Keeper, in a general sense, denote instruments adapted for measuring time. See Chronometer.

TIMELIFORME, in Geography, a bay of the North Sea, on the coast of Norway; 32 miles W. of Romfidal.

TIMEN-GUY, in Rigging, a rope fastened at one end to the fore-shrouds, and nailed at the other end to the anchor-stock, on the bow, to prevent the fore-sheet from entangling.

TIMENS, in Geography, a town of Norway, in the province of Christianfand; 15 miles S. of Stavanger.

TIMERA, a town in Sweden, in the province of Melpadla; 5 miles S. of Sundsvall.

TIMERY, a town of Hindoostan, in the Carnatic; 6 miles S. of Arcot.

TIMERYCOTTA, a town and fortress of Hindoostan, in Golconda; 53 miles S.E. of Hyderabad. N. lat. 15° 20'. E. long. 79° 26'.

TIMERYDURGAM, a town of Hindoostan, in Baramaul; 21 miles N.N.W. of Darcmpoury.

TIMESQUIT, or TIMESQUIT, a town of Africa, in the country of Darah; 80 miles W. of Tafilet.

TIMETHUS, in Antique Geography, a river of Sicily, the mount of which is placed by Ptolemy between Tyndarium and Agathyrum.

TIMICI, Abat-el-Wed, a place in Africa, S.E. of Arimara, on the banks of one of the rivers which formed the Caritum; and in which are ruins.

TIMIRU, in Geography, a town of the island of Cuba; 20 miles W.S.W. of Villa del Príncipe.

TIMMER. See TIMBER and TIMIRE.

TIMMIA, in Botany, received that name from the celebrated Hedwig, in compliment to his correspondent Mr. Joachim Christian Timm, an apothecary and principal magistrate at Malchin, who published Flora Megapolitana Præ-dromus, in 1788. This makes an octavo volume, containing the names, characters, places of growth, &c. of the native plants of Mecklenburg-Schwerin, disposed according to the Linnaean system, with the abolition of the 20th, 21st, 22d, and 23d classes, and a separation of all the grasses and grafs-like plants together, into a clafs by themselves. The number of species is 1200, of which 50 belong to the Cryptogamia, the other classes being far from rich. Neither does the work contain any critical observations to compensate for the inconvenience of the above changes.—Hedw. Crypt. v. 1. 83. Sp. Mufc. 176. Schreb. Gen. 761. Timm. Megapol. 234.—Clafs and order, Cryptogamia Mufci. Nat. Ord. Mufci.

Eff. Ch. Capule ovate. Outer fringe of fifteen pointed teeth; inner membraneous, with jointed teeth combined at the top. Male flowers on the same plant, axillary, flaked, bud-shaped.

The known species are two only. T. megapolitana, Hedw. Crypt. v. 1. 83, t. 31, found near Malchin, growing in boggy ground among Carices, as well as in North America; and T. andrica, Hedw. Sp. Mufc. 176. t. 42. f. 1—7, native of Scheneberg, a celebrated Austrian mountain. Both have the habit of Bryum, or Mnium; see those articles. We cannot consider Timmia as an admirable genus, being distinguished from Bryum merely by the connexion of the points of the inner fringe, like Pohlia of Hedwig, which the reader will find in its proper place. Under the head of Fringe of Mufci we have suggested the objections to founding genera on the differences of figure in the inner fringe, which are uncertain, variable, very difficult to observe, and lead to unnatural distinctions. Characters derived from the situation of the male flowers are subject to still greater difficulties and objections.

TIMISKAMAIN LAKE, in Geography, a lake of North America, in Canada. This lake gives name to a tribe of Indians near it. N. lat. 47° 30'. W. long. 86° 46'.

TIMMS, a town of North Carolina; 15 miles S.S.E. of Fayetteville.

TIMOAN, an island in the East Indian Sea, inhabited by Malays; ships may obtain wood and water; the anchorage is good almost all round the island; but the inhabitants are fairly and inoffensive. N. lat. 2° 58'. E. long. 104° 25'.

TIMOCHARIS, in Biography, an astronomer of Alexandria, who flourished in the third century B.C. He observed B.C. 294, on the 5th of March, four hours before midnight, a conjunction of the moon with the Spica Virginis, the star being then, according to him, 8° W. from the equinoctial point.

TIMOK, in Geography, a river of Servia, which rises in mount Hamus, and runs into the Danube, 6 miles N. of Viddin.

TIMOLEON, in Biography, a distinguished example of patriotism and attachment to liberty, was of noble parentage, and a native of Corinth. His discriminating character was exhibited at an early age in the refuge of his brother Timophanes at a moment of danger, when he was thrown from his horse in an engagement with the Argives, and surrounded by the enemy. Timoleon flew to his aid, covered him with his shield, and after receiving many wounds, liberated his brother. This same brother, being placed by the Corinthians for the safety of their city at the head of a standing body of mercenaries, assumed the sovereignty of the state; but Timoleon, dreading the subversion of the liberty of his country by the ambition of his own brother, renounced against his proceedings; and, finding his own attempts for restraining him ineffectual, engaged two friends to concur with him in his efforts; but their united endeavours proving of no avail, Timoleon is said to have flown by him weeping, with his face covered, while his associates dispatched the tyrant. Such is the account of Plutarch; but Diodorus says, that Timoleon killed his brother with his own hand. This act,
act, however, followed by the reproaches of his friends, and by the imprecations of his mother, was the occasion of poignant diftre to Timoleon; so that he withdrew from all public affairs, and for some years wandered about in the most disconsolate state, in the most gloomy recesses of his grounds, without ever approaching the city. After a retirement of twenty years, the Syracusans applied to Corinth for succour in a season of calamity, occasioned by domesimal tyrants, and by the hostile preparations of the Carthaginians. The Corinthians passed a vote for granting the affiance that was required, and Timoleon, in preference to many others who were proposed, was appointed their general. Timoleon failed for Sicily in the year B.C. 344, with a fleet of about ten sail, and arriving, by a stratagem, in the port of Tauro-
menium, disembarked his army, consisting of no more than one thousand men. Success and victory attended his arms; and having become master of Syracuse, he destroyed its citadel as a nest of tyrants, and caused to be erected in its place a hall of judicature; thus intimating, that the state was now to be governed by laws, and not by arms. He also colonized the city, which had been depopulated, by an importation of Greeks, and by inviting all the fugitives to return. Timoleon at the same time extended his attention to the other cities of Sicily, reducing those inhabitants who had usurped authority to the rank of private citizens, or fending them as exiles to Corinth. He prepared likewise to refit the Car-
thaginians, who were sending a powerful army against the island; and with a small force, but by extraordinary displays of valour and military skill, totally defeated them. He afterwards directed his attention to the internal state of Si-
cily, and by the meafures which he adopted, settled its in-
habitants in the unmoled poffeffion of the advantages which they enjoyed in a fertile soil and propitious climate. The Sicilians acknowledged their obligations with gratitude and refeft, and confidered Timoleon as the common father of the nation. Having fixed his abode in Syracuse, he went to Corinth for his wife and family, and lived as a private ci-
tizen, refpected and esteemed for his virtues. Two dema-
gogues, however, contrived to disturb his tranquillity, and 
brought charges againft him, which he thought unworthy of refutation, and in reference to which he merely said, “he could not sufficiently express his gratitude to the gods for allowing him to fee the time when the Syracusans enjoyed 
the liberty of speaking what they thought proper.” Whilft 
Greece was involved in the calamities of a civil war, and in 
conflicts which terminated in the loss of public liberty, Ti-
moleon was unmolested and tranquil, in a country which he had contributed to render happy. Fortunately in all his tran-
actions after he left Corinth, he averted his succesfes to the goddes Fortune, and dedicated to her the house in which he resided. It has been observed, that in the fystem of the ancient, a regard to these nominal and fictitious deities did not exclude their belief of a superintending providence; and a particular infiance occurs in the history of Timoleon which would lead him to imagine that his life and its inci-
dents were under a providential care and direction. Soon 
after his arrival in Sicily, two strangers were hired to affafi-
nate him; and whilst he was facrificing in the temple of Adra
cum, where he then lived, these murderers mixed in the thron, and were preparing to execute their commiffion. At this instant a man gave one of them a blow on the head with his sword, which laid him at his feet, and then flid to the top of a rock. The other, supposing their defign had been discovered, laid hold of the altar, and intreated Timo-
leon to spare his life, on condition of his revealing the whole
plot. The first fugitive being brought down from the rock, affected that he had committed no crime, becaufe the
man whom he had strick had murdered his father in the city 
of Leontium. Such an escape would naturally impress a 
mind less thoughtful than that of Timoleon.

At a late period Timoleon lost his fight, and this affliction he bore with perfect resignation; and it was alleviated to 
him by the affiduous attentions of the Syracusans. In his 
old age he was revered by the Syracusans as a father in the 
midft of his family: and at length terminated his life by a 
flight diseafe, in the year B.C. 335. His funeral obsequies 
were attended by a great number of people; and when the 
body was placed on the pile, a herald made the following 
proclamation: “The people of Syracuse inter Timoleon the 
Corinthian, the son of Timodamus, at the expence of two 
hundred minae; they honour him, moreover, through all 
time, with annual games, to be celebrated with music, horseracing, and wrestling; as the man who destroyed tyrants, 
subdued barbarians, repeopled great cities which lay defo-
late, and restored to the Sicilians their laws and privileges.” A monument was afterwards erected to his memory in the mar-
ket-place, which being surrounded with porticoes and other public buildings, was made a place of exercise for the 
youth, and named the “Timeonicum.” Plut. Vit. Timol. 

TIMON the Philofian, a disciple of Pyrrho, flourifhed in the time of Ptolemy Philadephus, and lived to the age of 
nineti ninety years. At an early age he visited Megara, for 
the advantage of Stilpo’s instructions in dialectics, and after-
wards removed to Elea, where he became a hearer of Pyrrho. 
He first profefled philosophy at Chalcodon, and afterwards 
at Athens, where he remained till his death. He took no 
little pains to invite disciples to his school, that it has been 
fait of him, that as the Scythians shot flying, Timon gained 
pupils by running from them. This indifference to his pro-
feffion was probably owing to his love of eafe and indulgence; 
for he was fond of rural retirfment, and so much addicted 
to wine, that he held a successful content with several 
celebrated champions in drinking. This disposition pro-
bably led him to embrace the indolent doctrine of fepticifm. 
He feems to have treated the opinions and difputes of the 
philofophers with contempt, for he wrote with farceiftic in-
numer against the whole body. His poem, entitled “Sili,” 
often quoted by the ancients, was a keen satire, abounding 
with bitter invectives againft men and doctrines. The 
remaining fragments of this poem have been indifcreetly 
collected by Henry Stephens, in his “Poetis Philofophici.” 
The public succession of profeflers in the Pyrrhic school 
terminated with Timon. Brucker by Enfield.

TIMON, Samuell, a writer of history, was born at Tiri
nau, in Hungary, and died at Caftoria, in 1736, at the age of 
sixty-one years. In 1693 he entered among the Jesuifs, 
and being of feeble constitution, declined the labours of the 
society, and devoted himfelf to literarv occupation, parti-
cularly to the history of his own country, in reference to which he published several works. Nouv. Dict. Hist.

TIMONELLE, Timoner, Fr., in Sea Language, the 
helmman, or perfon who manages the helm to direct the 
ship’s course.

TIMONITIS, in Ancient Geography, a country of Afia, 
in Paphlagonia, in the vicinijty of Bithynia. Strabo and 
Ptolemy.

TIMONVILLE, in Geography, a town of France, in 
the department of the Mofelle; 9 miles W. of Morhang.

TIMOOGOODA, a town of Hindooftan, in the cir-
cuit of Ciacaco; 90 miles S.W. of Cicaco.

TIMOFFEEVA, a town of Russia, in the government of 
Irkutsk, on the Ilm; 32 miles N.W. of Vorcholenk.

TIMOR, an island in the East India sea, about 120 
miles
TIM

The Portuguese were the first Europeans who formed any kind of settlement on this island, who fled to it as a place of refuge from their enemies, the Dutch. But they were purged by those implacable enemies, and in the year 1613 driven from Copen, or Coupang, a town situated at the west end of the island, where the Dutch have ever since poissified and garri\oned a fort which the Portuguese had erected. The chief of the natives, or king of the island, is by the Dutch called k\yfer (emperor). Some Portuguese reside in the north part of the island. The principal productions are faders or fandal wood and wax, which the Dutch receive in exchange for coarse linens or piece-goods; but on the whole, the profit arising from the commerce is little more than sufficient to defray the expenses, and the settlement in all probability is continued merely to keep out other nations. S. lat. 7° 16' to 10° 24'. E. long. 124° to 126° 21'.

TIMOROSO, in the Italian Mufier, intimates that the song is to be played or sung in such a manner as to express an awe or dread, either to shew respect, or to reprefent fear.

TIMOROUS, in the Mange. See STARTING, SKIT\ISH, &c.

TIMOTEO DA URBINO, in Biography, whose real name was T. della Vite, was born at Urbino in 1470. He received his education as an artist under F. Francia, at Bologna, but at the age of twenty-fix returned to his native city, whence he soon after went to Rome to fee his countryman, Raphael, and the great works in the Vatican which had recently acquired for him so much renown. Raphael employed him in painting the Sibyls in the church of La Pace, and was delighted with his ability in the performance; so much so, that he allowed him to retain the Cartoon. After this he returned to Urbino, and there executed several great works for the cathedral and other public buildings. He improved his style, as it was natural he should, under the tuition of his great master: and his latter productions exhibit much grace and vigour in their execution. His most celebrated works are, the Conception, in the church of the Osservanti, at Urbino; and Christ appearing to Mary Magdalen, in S. Angelo, at Cagli. He died in 1524, aged fifty-four.

TIMOTHEUS, one of the most celebrated poet-muficians of antiquity, was born at Miletus, an Ionian city of Caria, 246 B.C. He was contemporary with Philip of Macedon, and not only excelled in lyric and dithyrambic poetry, but in his performance upon the cithara. According to Paufanias, he perfected that instrument by the addition of four new flings to the seven which it had before; though Suidas says it had nine before, and that Timotheus only added two, the tenth and eleventh, to that number.

It seems necessary here to state the several claims made in favour of different persons who have been said to have extended the limits of the Greek musical scale.

Many ancient and respectable writers tell us, that before the time of Terpander, the Cretan lyre had only four flings; and, if we may believe Suidas, it remained in this state 856 years, from the time of Amphion, till Terpander added to it three new flings, which extended the musical scale to a heptachord, or seventh, and supplied the player with two conjunct tetrachords.

It was about 150 years after this period, that Pythagoras is said to have added an eighth fing to the lyre, in order to complete the octave, which consisted of two disjunct tetrachords.

These dates of the several additions to the scale, at such diftant periods, though perhaps not exact, may, however, if near the truth, shew the slow progress of human knowledge, and the continued ignorance of barbarous times. But if we wonder at the music of Greece remaining so many ages in this circumscribed state, it may be asked, why that of China and Peria is not better now, though the inhabitants of those countries have long been civilized, and accustomed to luxuries and refinements.

Bothus gives a different history of the scale, and tells us that the syturn did not long remain in such narrow limits as a tetrachord. Chorebas, the son of Athis, or Atys, king of Lydia, added a fifth fing, Hyagnis a sixth, Terpander a seventh, and, at length, Lycabon of Samos, an eighth. But all these accounts are irreconcilable with Homer's Hymn to Mercury, where the chelys, or tetrachord, the invention of which he ascribes to that god, is said to have had seven flings. There are many claimants among the musicians of ancient Greece, to the flings that were afterwards added to these, by which the scale, in the time of Aritoxenus, was extended to two octaves. Athenæus, more than one, speaks of the nine-flinged instrument; and Ion of Chios, a tragic and lyric poet and philosopher, who first recited his pieces in the 82d Olympiad, 452 B.C. mentions, in some verses quoted by Euclid, the ten-flinged lyre; a proof that the third conjunct tetrachord was added to the scale in his time, which was about fifty years after Pythagoras is supposed to have constructed the octachord.

The different claimants among the Greeks to the fame musical discoveries, only prove that music was cultivated in different countries; and that the inhabitants of each country invented and improved their own instruments, some of which happening to resemble those of other parts of Greece, rendered it difficult for historians to avoid attributing the same invention to different persons. Thus the single flute was given to Minerva, and to Maryyas; the lyxyn, or sifula, to Pan, and to Cybele; and the lyre, or cithara, to Mercury, Apollo, Amphion, Lutus, and Orpheus. Indeed, the mere addition of a fing or two to an instrument without a neck, was so obvious and easy, that it is scarcely possible not to conceive many people to have done it at the same time.

With respect to the number of flings on the lyre of Timotheus, the account of Paufanias and Suidas is confirmed in the famous decree against him, for which see SENATUS-CONSULTUM.

It appears from Suidas, that the poetical and musical compositions of Timotheus were very numerous, and of various kinds. He attributes to him nineteen noms, or canticles, in hexameters; thirty-fix prosms, or preludes; eighteen dithyrambs; twenty-one hymns; the poem in praise of Diana; one panegyric; three tragedies, the Persians, Phinidas, and Laertes; to which must be added a fourth, mentioned by several ancient authors, called "Niobe," without forgetting the poem on "The Birth of Bacchus," Stephen of Byzantium makes him author of eighteen books of nomes, or airs, for the cithara, to eight thousand verses, and of a thousand Plegyias, or preludes, for the names of the flute.

A musician so long eminent as Timotheus, must have excited great desire in young students to become his pupils; but, according to Bartholomus, he used to exact a double price from all such as had previously received instructions from any other master; saying, that he would rather instruct those who knew nothing, for half price, than have the trouble of untaching...
The produce per acre is

Weight when dry of produce of fame space

Weight lost by produce of fame space in drying

Weight of nutritive matter afforded by fame

Weight of nutritive matter, lost by leaving the crop ripe, exceeding one half of its value

At the time the feed is ripe:

 Produce per acre

Weight when dry of produce of fame space

Weight lost by produce of fame space in drying

Nutritive matter afforded by produce of fame space

Latter-math, produce per acre

Affords of nutritive matter

Sixty-four drachms of the straws, afford seven drachms of nutritive matter. The nutritive powers of the straws simply, therefore, it is said, exceed those of the leaves, in proportion of 28 to 8; and the grasfs at the time of flowering, to that at the time the feed is ripe, as 10 to 23; and the latter-math to the grasfs of the flowering crop, as 8 to 10.

From the whole of these particulars, the comparative merits
ments of this grass will, it is supposed, appear to be very great; to which may be added the abundance of fine foliage which it affords early in the spring; in which respect it is inferior, it is said, to the fertile meadow-grasses and narrow-leaved meadow-grass. The value of the straws at the time the feed is ripe, exceeds that of the grass at the time of flowering, as 28 to 10; a circumstance which increases its value, it is thought, above many others: for, by this property, its valuable early foliage may be cropped, to an advanced period of the season, without injury to the crop of hay, which, in other grasses that send forth their flowering straws early as the seafon, would cause a loss of nearly one-half of the value of the crop, as is clearly shown in many instances; and this property of the straw itself, makes the plant peculiarly valuable for the purpose of hay.

In the smaller variety of this grass, the produce per acre on the farm of good land, at the time of ripening the feed; the weight when dry; the loss of weight in drying; and the nutritive matter afforded, are all very considerably less than in the above fort. In the latter-kind produced on the same farm, the quantity is the same as in that, but the nutritive matter afforded by it something less, as may be seen in the work referred to above.

In the bulbous-stalked species, the produce of the acre in the same kind of land, at the time of flowering; the weight when dry; that lost by the produce of the same space in drying; and the quantity of nutritive matter afforded by it, are all rated in the same work to be greatly less than in the first kind. And that this grass is inferior in many respects to that of the first kind. That it is sparingly found in meadows. And that from the number of bulbs which grow out of the straws, a greater proportion of nutritive matter might have been expected. This seems to prove, it is said, that these bulbs, in this fort of grass, do not form so valuable a part of the plant as the joint, which are so conspicuous in the first kind, the nutritive powers of which exceed those of this bulbous-stalked kind, as 8 to 28.

The qualities and useful properties of timothy grass are thus well pointed out and determined. See Pileum and Grass.

TIMOU, or Tumen, in Geography, a town of Thibet; 225 miles E.S.E. of Laffa.

TIMOUR, or TAMERLANE, in Biography, a famous Oriental conqueror, was born at the village of Sebazar, in the territory of Caffi, 40 miles S. of Samarcand, in the year 1356. At the time of his birth, the Khans of Caffgar, with an army of Getz or Kalmucks, invaded Transoxiana. In 1557, Timour, having lately lost his father, collected a number of followers with a view of delivering his country; but being defeated by them, he retreated to the desert, and his army was there further diminished by an action with the Getz. He then wandered with his wife and seven companions, and being arrested, was kept two months in prison. Upon his liberation he swam over the rapid stream of Oxus or Jihon, and for some months led the life of a vagrant. In process of time, and on return to his native country, he was at the head of a considerable force, which enabled him to expel the Getz from Transoxiana. After a civil war between him and his brother-in-law, the Emir Houftein, who was defeated and put to death, Timour, at a general diet held in 1370, was seated on the throne of Zagatai, at the city of Balk, and invested with the high title of Sahb Karan, or emperor of the Age; upon which he repaired to Samarcand, which became the seat of his empire. In consequence of this elevation, his ambition was directed to greater objects; and having reunited to Zagatai its former dependencies, Karizme and Kandahar, he fixed his views on the kingdoms of Iran or Peria, which were then occupied by various usurpers. Having reduced to subjection Ibrahim, the prince of Shirwan, and secured the conquest of Erars or Peria proper, by the defeat and death of Shah Manfour, its prince, and the extirpation of his male progeny, he advanced from Shiraz to the Persian gulf, and exacted from the rich city of Ormuz an annual tribute. He then proceeded as a conqueror through the whole course of the Tigris and Euphrates from their sources to their mouths, entered Edessa, and reduced the Christians in the mountains of Georgia. Retaliating upon the Geze the invasion of his country, he passed the Shihon, and subdued the kingdom of Caffgar. In his several expeditions he penetrated as far as 480 leagues to the N.E. of Samarcand, and his emirs crossed the Irritift into Siberia, another scene of his adventures and conquests near Kipzak or Western Tartary. Having entertained at his court Tottamish, a fugitive prince of that country, he sent him back with an army which established him in the Mogul empire of the North. Tottamish, however, after a reign of ten years, unmindful of his obligations to his benefactor, entered Peria with a mighty army, pillaged the Shihon, burnt the palaces of Timour, and reduced him to the necessity of contending for his capital and empire. His triumph was of no long duration; for Tottamish was defeated, Kipzak was invaded, and Tottamish was again encountered and routed. This pursuit led Timour to the tributary provinces of Ruffia, and a duke of the reigning family was made captive on the ruins of Yeletz, his capital. Timour then marched southwards, and having pillaged, reduced to ashes the commercial city of Azoph, and also those of Serai and Atfrachan. Under the influence of that ambition which was his ruling principle, he determined, in 1398, on the invasion of Hindoostan, and taking advantage of the rebellion against the weak Sultan Mahmood, he led an army of 62 squadrons, each of 1000 horse, and found great difficulty in traversing one of the snowy ridges between the Jihon and the Indus. Having crost the Indus at Attock, he entered the Panjab, and formed a junction with one of his grandsons, who had reduced Moultan. He then advanced towards Delhi, and having overthrown the army of Mahmood with its elephants, took possession of the capital, which he defolated by pillage and massacre. In this part of his march he manifested his religious zeal, by destroying infidels and idolators without mercy, and having passed the Ganges about 100 miles N.E. of Delhi, he slaughtered a great number of the Guebres, or fire-worshippers. Whilft he was thus engaged, he received intelligence of the disturbances that had occurred on the confines of Georgia and Anatolia, of the revolt of the Christians, and of the ambitious projects of the Turkish sultan Bajazet. Having issued orders to his commanders, he hastened back to Samarcand; and after a short interval of repose, he proclaimed a seven years' expedition to the western parts of Asia. In the year 1400 he began with the Georgian Christians, and soon reduced them to the alternative of tribute or the Koran, and to prisoners he allowed no other choice but death or abjuring their religion. Returning from this warfare, he gave audience to the embassadors of Bajazet, and after some time spent in mutual complaints and menaces, Timour laid siege to Siwas or Sebastie, on the borders of Anatolia, which he took and destroyed, burying alive with savage cruelty the Armenian garrison of 4000 men. He then invaded Serbia, and advanced towards Aleppo, from which he issued a numerous and well-appointed force to engage his army, the front of which was covered by a line of Indian elephants, carrying turrets filled with archers and
and Greek fire. This formidable host threw the Syrians into disorder, and they fled with precipitation into the city, whether the enemy accompanied them. Timour soon became master of this opulent capital. While the streets were trembling with blood and refounding with cries, the conqueror held a theological conference with the doctors of the law; protesting, towards the close of his harangue, that he was not a man of blood, that he was not the aggressor in any of his wars, and that his enemies brought upon themselves the calamities they suffered: at the same time his soldiers were piling up a certain tale of heads of the enemy, in conformity to his orders, which, according to his custom, were afterwards piled up in columns and pyramids. From Aleppo, Timour proceeded to Balbeek, which he took, and then advanced towards Damascus. The sultan of Egypt had made great preparations for the defence of the city, and also for the affailement of the invader; but the plot of using poisoned daggers was discovered. The sultan pretended submission, and thus intended to put Timour off his guard; in the accomplishment of this artifice, the camp of Timour was suddenly attacked by the Syrian army, and thrown into disorder; but as soon as order was restored, the Syrians were repulsed, and driven to the gates of Damascus with great slaughter. The sultan in the mean while had returned to Egypt, and the city was left to make the best possible terms with the conqueror. During a truce, the soldiers broke into the city, massacred a great part of the inhabitants, and made captives of the reft, carried off a great quantity of rich plunder, and the city was reduced to ashes. Bagdad was the next place of importance to which Timour directed his views. Here Timour attended in person, and ordered a blockadé; after 40 days' defence on the part of the inhabitants, a form was commanded; and the death of some of the affailants was avenged by a massacre which produced a pyramid of 90,000 heads. The city was completely razed, with the exception of mosques, hospitals, and colleges. Timour's next object was the Ottoman empire. Having confounded the court-astronomers, and obtained a favourable answer, he put himself at the head of an almost innumerable force, and moved from the Araxes through Armenia and Anatolia, determining to carry the war to the heart of his rival's dominions. By his rapid advances, he invaded Angora before Bajazet was apprized of his movement. Upon receiving this intelligence, the Ottoman hastened to its relief with a very large army. An engagement ensued, and the contest, which was very sanguinary, was at length decided by the defeat and capture of the Turkish emperor. This battle was fought in July 1402. Bourfa, Nice, and Smyrna were successively captured with the fame circumstances of cruelty that marked the progress of Timour's arms.

Timour's conquests were extended from the Irititch and Volga to the Parthian gulf, and from the Ganges to the Archipelago; and beyond these limits his name was a found of terror. Several princes purchased his favour by tributes, or by extraordinary tokens of respect. His want of shipping prevented his entrance into Europe. From his various expeditions, Timour did not return to Samarcand until the summer of 1404. In that capital, he displayed his magnificence and power in dispensing rewards and punishments, attending to the complaints of his people, erecting palaces and temples, and giving audience to ambassadors from Egypt, Arabia, India, Tartary, Russia, and Spain. Although he had professed satisfaction with the extent of his empire, yet he indulged a project of ambition of very great magnitude, which was that of the conquest of China. His preparations for this grand expedition were proportioned to its magnitude: 200,000 veteran soldiers were mustered, and they were furnished with means for conveying necessaries over the deserts which separate Samarcand from Pekin. The aged emperor mounted his horse in the winter fadon, crossed the Sihon on the ice, and advanced to the distance of 500 miles from his capital; but at the camp of Otrar he was seized with a fever, which fatigued, and the imprudent use of iced water, soon rendered mortal. He was not unappricized of his danger; and having summoned round him his empresses and principal emirs, he declared his grandson Mehmet Jehan Ghir his universal heir and successer, and exacted an oath of obedience to him. He thus expired April 14, 1405, in the 70th year of his age, and the 35th from his elevation to the throne of Zagatai. He left 53 descendants, and his posterity are to this day invested with the title of the Mogul emperors, although the power and dominions have passed into other hands.

His person and character are described by one of his biographers in the following terms: 'Timour was tall and corpulent, with a wide forehead and large head, a pleasing countenance, and fair complexion. He had broad shoulders and strong limbs, but was maimed in one hand and lame of the right side. His eyes were full of fire; his voice was loud and commanding; his constitution hardy and vigorous; his understandings found; and his mind firm and itself. In conversation he was grave and modest, and he prided himself in an attachment to truth. He delighted in reading history, and in disputing topics of science with the learned. His religion was fierce and fanatical, and he actually had, or affected to have, the superstitious reverence for omens, prophecies, saints, and astrologers, which is general in the East. He conducted his government alone, without favourites or minions, and its spirit was absolute and uncontrolled. It was his boast to have introduced security and order throughout his wide dominions, and he challenged the praise of a benefactor to mankind; but no conquests have been attended with greater destruction of human lives, and greater devastation of flourishing cities and districts, than his were; and his ambition prompted him to extend his authority beyond the possible limits of a single government. He was not, however, a mere barbarian conqueror; but, if his institutions can be relied on as genuine, had enlarged ideas of the administration of a great empire.' The "Institutions of Timour" have been made known in Europe by two translations from a Persian version: one in English by major Davy and professor White, Oxford, 1783; and the other in French, by M. Langles, Paris, 1787. Mod. Univer. Hist. Gibbon's Rom. Emp. Gen. Biog.

TIMOURKENG, or Fortres of Iron, in Geography, a town of Thibet; 60 miles W.N.W. of Latac. TIMPALU, a town on the W. coast of the island of Cebes. N. lat. 1° 10'. E. long. 119° 40'. TIMPANO, Ital., a kettle-drum. See Tympanum and Tymbales.

TIMPE, or Tymphe, in Coinage, an old silver coin of Poland. The tyrpe, or tympe, was reckoned at eighteen groschen, and the florins were valued at thirty groschen.

TIMURCOUGH, in Geography, a town of Thibet; 54 miles W.N.W. of Latach. N. lat. 35° 12'. E. long. 77° 12'. TIMUS, in Ancient Geography, a town of Asia Minor, destroyed by an earthquake.

TIMYKA, a town of Asia, in Iriaia.

TIN, Stannum, Jupiter, a whitish metal, fiftier, leafy elastic, and leafy sonorous, than any other metal, excepting lead. In the Chaldee language, 3131, tin signifies sile, mud, or dirt; and
and when the Phœnicians came into Cornwall, and saw this metal in its ancient bumpy state, they called it "the mud;" and hence, some have said, the name tin, in Corn-British flon, is derived. Some of the ancients called it plumppum album, white lead, probably to distinguish it from common lead; not knowing that it was radically another metal.

This metal, denominated κασσίτηρ by the Greeks, and flanum by the Latin, seems to have been known from the most remote ages. It is mentioned by Moses; see Numbr. xxxi. chap. 22. It was transported to the East from Spain and Britain by the Phœnicians, with which nations they are said to have carried on a lucrative commerce. Homer mentions it; and by Aristotle, the epithet Κασσίτηρ, or Καστίς, is applied to it, indicating plainly the country from which it was procured. See Tin-Trade of Britain.

Tin-Stone, in Mineralogy, is the most common ore of tin, and is nearly a pure oxyd of that metal. The colour is brown, which passes from a blackish-brown to black, and from a red-brown to yellowish and greenish-white. It occurs crystallized and amorphous, and in grains and rolled pieces, varying from the magnitude of a grain of sand to that of an egg, or larger. The primitive form of the crystal is a flat octahedron: the angles are 112° 12′ and 65° 50′. The figure of the crystals is seldom perfect; sometimes a rectangular prism is interposed between the pyramids that form the octahedron. The edges and summits of the crystals are frequently bevilled or truncated, from which a great variety of secondary forms is derived. The crystals are also frequently united, forming compound crystals or macles: indeed, so numerous are the secondary crystals of tin, that more than one hundred and eighty forms of single crystals have been observed, besides the compound crystals, of which there is a considerable variety. The surface of the crystals is commonly smooth and splendid, but is sometimes streaked. The structure is laminar, but the laminae are rarely vifible. The fracture is uneven and imperfectly conchoidal, with a more or less shining and roughish lustre. When the laminar structure is displayed, the lustre is highly splendent. The crystals are semi-transparent or opaque, the darker colours being opaque, the lighter sometimes nearly transparent; and the intermediate shades are only translucent, or translucid at the edges. The streak is a greyish-white. Tin-stone is hard, scarcely yielding to the knife, and giving sparks with flint. It is brittle and heavy. The specific gravity varies from 6.759 to 6.970.

Before the blowpipe it decrepitates, and becomes paler; when finely pounded and mixed with borax, it is reducible on charcoal to the metallic state.

Tin-stone contains the following constituent parts, according to Klaproth:

Some analyses of tin-stone give from two to three per cent. of alumina. The tin-stone of Cornwall, dressed in the common manner, is reckoned rich if it yield 65 per cent. of tin. Tin-stone may be distinguished from wolfram by its superior hardness, as it gives sparks with flint, but wolfram yields easily to the knife. The powder of tin-stone is a greyish-white, that of wolfram a reddish-brown. It is distinguished from blende by its superior hardness, and its not emitting a sulphurous odour when pounded. By its greater specific gravity and lustre, it may be distinguished from garnet; and from felspar, by its colour, lustre, form, and higher specific gravity. This ore occurs in veins and beds, and differmated in granite rocks. The veins intersect rocks of granite, gneiss, mica-slate, and slate: tin-stone occurs also in alluvial soil in the districts that contain tin-veins. See Stream-Tin.

Wood-tin is a species of tin-stone, or oxyd of tin, found with fire-stone in rolled pieces, which are wedge-shaped or reniform, and sometimes globular. The structure is diversely fibrous, with concentric laminae; and from the supposed resemblance to the transverse section of fine-grained wood, it received its name. The colour is commonly hairbrown or wood-brown, passing into yellowish-grey. The lustre is glimmering or silky. It is opaque, hard, and brittle: the specific gravity is 6.450. It is infusible before the blowpipe, but is changed to a brownish-red colour. When strongly heated in a charcoal crucible, it yields about 75 per cent. of metallic tin. The constituent parts are, according to Vauquelin,

In Cornwall, this ore is almost always found with fire-stone, and never in veins: it is said, however, to have been recently met with in cellular quartz, but in very minute pieces. It is one of the most common ores of tin in Mexico, and occurs in veins that traverse a porphyritic trap, and also in alluvial depositions. In some wood-tin, there is a small, black, smooth globe, from which, as from a centre, the Fibres diverge: this has received the name of bird's-eye tin. Wood-tin, in its structure and mode of formation, probably bears a near analogy to the kidney-shaped hematite iron-ore.

Bell-metal, Tin Pyrites, or Sulphuret of Tin, is an extremely rare ore of this metal, being found only in Cornwall, at Huel rock, in a vein accompanied with sulphuret of zinc and iron. Its colour is fleazy-grey, passing into yellowish-white: it has a metallic lustre, and granular uneven fracture: it yields easily to the knife, and is brittle. The specific gravity is 4.350. It fuses into a black flag before the blowpipe, exhalting at the time a sulphurous odour. It communicates a yellow or green colour to borax. The constituent parts differ in different specimens; according to Klaproth, they are as under:

Klaproth observes, that the darker varieties of this ore are considerably poorer in tin than the lighter, but the proportion of iron increasest.

Analysis of the Ores of Tin.—The analyses in the dry way were made by Klaproth in charcoal crucibles in the following manner, in which the results were always found to be constant. The ore was broken, and well cleaned from the matrix. One hundred grains were introduced into the cavity of a charcoal crucible, closing its orifice with a flopper of charcoal. The charcoal crucible was then fitted close into one of baked clay, and placed upon the forge-hearth before the nozzle of the bellows. The contents in the charcoal crucible were reduced to the metallic state by exposing it to a strong blast for half an hour. The button of metallic tin produced was a little blackish on the sides, and
and its surface coated with a greenish crust. From one hundred grains of Bohemian tin-flour, seventy-two grains and a half of tin were produced. Wood-tin and stream-tin were treated in a similar manner. Brown tin-flour, exposed to a porcelain fire in a clay crucible, formed a clear dense glass, greenish-grey in the middle, but of a bright yellow on the sides and top. The interior of the vessel was glazed, of a milk-white, and overlaid with many small groups of needle-shaped crystals of a light-brown colour. The inner surface of the lid was lined with similar crystals.

Analytical of Tin-Stone in the humid way.—To Klesproth we are indebted for the discovery of a simple and effectual mode of analysing tin-flour in the humid way. Boil 100 grains of this ore, finely pounded, with a solution of 600 grains of caustic potash. Evaporate to dryness, and then ignite the mass moderately for half an hour. Add boiling water, which dissolves the principal part of the mass, and the residue must again be ignited with six times its weight of caustic potas, and dissolved in water, as before. Add this to the last solution, and saturate the whole with muriatic acid, which will throw down an oxyd of tin. Let this be re-dissolved by an additional quantity of muriatic acid, and precipitated again by carbonate of soda; when liquified, and dried in a gentle heat, it acquires the form of bright-yellowish transparent lumps. This precipitate must be finely powdered, and once more dissolved in muriatic acid, diffused by a gentle heat. The insoluble part consists of silex. Dilute the solution, which is colourless, with from two to three parts of water, and introduce a thick of zinc, round which the tin will collect in a metallic flake in the form of delicate dendritic lamine. Scrape off the tin, wash, dry, and fuse it under a cover of tallow in a capsule placed on charcoal. A button of fine metallic tin will remain at the bottom, the weight of which, deducted from that of the ore, indicates the proportion of oxygen.

Analytical of Bell-metal Ore, or Tin Pyrites.—To two drachms of finely powdered ore, add one ounce of muriatic acid, and half an ounce of nitric acid: this will dissolve the greater portion of the metallic part without heat, but a gentle heat must be applied to dissolve the whole. The sulphur will float on the surface of the solution, and separate by filtration. To the solution add carbonate of potash, which produces a greenish precipitate; let this be dissolved in diluted muriatic acid, and introduce a cylinder of pure tin, the weight of which is to be previously ascertained. By this means the copper will be separated in a metallic flake. The cylinder of tin must now be carefully weighed, and the quantity which it has lost must be noted, and a cylinder of zinc must be introduced into the foregoing solution: this will separate all the tin, which must be melted with tallow and weighed. Deduct the quantity of tin which was lost by the cylinder, and the remainder will be the quantity of tin from the ore, held in the solution.

The sulphur separated by the first filtration must be ignited, and the unconfumed residue, dissolved in nitro-muriatic acid, must be added to the solution, in order to obtain the whole of the contents. The undissolved part will be the sileceous matrix.

The copper may be briskly digested in nitric acid, which will leave behind a minute portion of oxyd of tin, and afterwards the precise quantity of pure copper contained in the ore.

The method of getting, preparing, &c. the tin in the Cornish mines, much the best and most confiderable in the world, is given us in the Philoephalical Transactions, Abr. vol. ii. p. 569, &c. and more distinctly and fully in Pryce's Mineralogy. Vol. XXXV.

The working of the tin-mines is very hard and difficult, not only by reason of the great depth which the veins descend to, even as low as sixty fathoms; but also because the rocks, through which passages are frequently cut, are extremely hard. Nor is the soft shakking earth found in the tin-mines much less inconvenient to the workmen, both by reason of the fetid, malignant vapours it exhales, and of the current of water often met with in them: these disadvantages often render it impracticable for the workmen to hold it above four hours together.

The existence of native tin has been always doubted, and till of late absolutely denied by all mineralogists, both ancient and modern: however, Mr. Borlase, in his Natural History of Cornwall, p. 185, suggested, that its existence was far from being improbable; but he afterwards discovered three specimens of this metal, native or pure, of which he presented an account to the Royal Society. Mr. Mendes da Costa made several experiments on one of these specimens, with a view of proving that it was really tin; from which he infers, that it is perfectly ductile and malleable; and being bent between the teeth, gives the same cracking noise as tin always does: in an open fire it melts easily, calcines on the surface, and smokes; but forced in a stronger fire with borax, it detonates with small phosphorescent sparkes, which is a property of pure tin; and it is only corroded to a white ashes in spirit of nitre, and oil of tartar, of deliquium being added to the solution, none of it was precipitated: whence he concludes, that it was pure tin. Phileol. Trans. vol. ivi. art. 7. 39. Native tin is also said to have been found in Saxony and Malacea.

The ores of tin may be generally classed into shoad, stream, and bald or mine tin. The shoad is disjunct, and scattered to some distance from its parent lode, and is pebbly or smoothly angular, of various sizes, from half an ounce to some pounds weight. See Shoad.

Stream-tin ore is the same as shoad, but smaller sized, &c. See Stream-Tin and Streaming.

Bal or mine tin-ore often rises very rich; and influences frequently occur, in which it has been discovered in the richest and purest state imaginable. This kind of rich ore consists of the blackest grains or cralysts, and is usually found at a moderate depth, or within the day-side of forty fathoms.

When the tin-ore is raised, or dug and drawn out of the mine, and laid by the shaft, it is first spalled, as the process is termed, which consists in braking it into smaller fragments, and separating it from the worthless parts. When the best parts are sorted, they are divided into heaps by a hand-barrow, containing a sack and a half, or eighteen gallons. Each of these shares, called doles, being turned over, equally levelled and mixed, is then divided with a shovel into two equal parts; and after being bruised by large fedges to the size of a hazel-nut, is equally levelled and divided into four parts: the bruising and divisions are repeated at pleasure, till the quantity designed for sampling is well mixed, and made as fine as common sand. To make a rough guess, or coarse essay, the sampler takes a handful of it, and washes it on a shovel, till the impure parts are carried off by the water, and the more solid and heavy particles, that are left behind, are bruised with a fledge on the shovel, till the whole assumes the appearance of mud. This is again washed, and by a peculiar motion the metallic particles are collected together on the fore-part of the shovel. By repeating these brisings, washings, and motions, it becomes clean black tin, fit for the smelting-furnace. This is called a shon, (probably from the French avant, foremost,) as it is thrown upon the point of the shovel by the dexterity of
of the sample titer. After the tin is thus cleaned, it is
dried; and if there be as much black tin as will cover a
shilling, or equal to the weight of a shilling, it is called a
scilling wav, which is not rich; but if the van will cover or
equal the weight of a crown-piece, it is good tin-fluff, and
called a crown van. The shilling van, the tinners say, will
produce one hundred avoidance weight of block or white
tin; and the crown van will yield five hundred weight of
block tin, for every hundred sacks in measure of the respec-
tive doles from which the sample or van was taken, and to
in proportion, to the richest tin-fluff, called fowel, which
is reckoned at the rate of ten thousand of white tin-metal
for every hundred sacks. But a better judgment may be
formed from the measure of a wine half-pint, than from a
handful, which is indeed accounted a half pint. When the
tin, thus measured, is reduced clean, and to a proper fize,
by using a large hovel, and taking off the fixed tin on an-
other hovel, the van is dried in a hovel upon the fire, and
then weighed by pennyweights and grains; and for every
pennyweight and half the faven, the weights, will produce
be one hundred weight of black tin for every hundred sacks
of tin-fluff; and for three pennyweights, two hundred weight,
&c. in the fame proportion; and if be tin worth ten for
twenty, or one for two, then the tin-fluff is valued at five
hundred weight of block or white tin for every hundred
sacks: if it be worth twelve for twenty, the fluff is valued
at five hundred weight of white tin a hundred; or if it be
worth only eight for twenty, it is only valued at four
hundred weight of white tin a hundred, &c. This black tin is
rather of a liver colour, though called black in contra-
diffinition from white tin, or the metal produced from this
black ore; it is very heavy, and may in general be com-
cuted to hold one-half clean metal, and fome of it will pro-
duce thirteen, or even fourteen parts in twenty; whence
the mode of expressing so much white tin for twenty of
black tin, i.e. eight for twenty, ten for twenty, twelve for
twenty, &c. Thus, if the van of one hundred sacks
of tin-fluff weighs six pennyweights, being four hundred
weight of black tin at twelve for twenty, the white tin or
metal must be two hundred weight one quarter sixteen
pounds.

In this method of sampling, the tinners form a near
conjecture of the quantity of white tin which thofe doles of
tin-fluff will produce at the melting-house, when it is
dressed, and brought into black tin. But if the black tin is
combined with any bad mixture, as of mock-lead, copper,
or munde, after the van is brufed fine and wathed, they
lay the hovelf over the fire, and burn the black tin, flirring
it continually, till it has done foaking: they then wafh
it again on the hovel, and thus the heterogeneous matter,
becoming light by being burnt, is carried off by the water:
for when black tin is calcined or burnt, it still retains its
specific gravity; but copper, lead, and other crude mine-
als, become much lighter by torrefaction, and are easily
separated from the tin by water. In the dressing and ma-
agement of tin by flamping, &c. there are obtained two
forts of black tin, viz. the crop and rough, or the crop
and leavings of tin. The firft is the prime tin; immedi-
ately separable from the bafer parts by its superior weight
and riches. The latter is that which is carried off, and
mixed with the lighter earthy parts, by being under fize,
and, therefore, more eafily carried off by the water.
The tin-fluff, after this previous preparation and adjuf-
tment, is carried to the flamping-mill, in order to be dried
or pounded.

This operation of pounding in the flamping-mill is effen-
tial to the complete preparation of the ore from the matrix,
through which it is diffaminated. If full of fame, it is
thrown into a pit, called a buddle, to wash away the earthy
matter, and render the flamping more free, without choking
the grates. The ore is flowed into a kind of floping
channel of timber, called the pafs, whence it flides by its own
weight, and the affifiance of a small stream of water, into
the box where the lifters work: the lifters are raised by a
water-wheel, and are armed at the bottom with large
mallets of iron, weighing nearly two hundred weight each;
these pound or flamp the ore sufficiently to enable it to
pafs through the holes of an iron grate fixed at one end
of the box. To affift its pulvcrization, a rill of water keeps
it continually wet, and it is carried by a small gutter into
the fire-pit, where it makes its first deposition; the lighter
particles running forward with the water into the middle
pit, then into a third, where what is called the flame settles.

(See Drefling of Ores, and Buddle.) From these pits
the ore is carried to the kewe, which is a large vat containing
water; in which it is farther purified by an operation
termed packing, and which confifts in beating the upper
part of the contents with mallets for fonie minutes, by
which the lighter particles are kept fupended, while the
the tin-ore, from its great fpetic gravity, subsides. The wafer
is flimmed and laid by, to be again buddled, under the
name of the flimpings. The tin is lifted through a copper-
bottom fieve into another kewe of water, by which the
gravelly wafte still remaining is separated from the clean tin;
and the tin that runs through the fieve, if it requires no
farther buddling, may be cleaned by repeatedly toffing
and packing it as before. If it be neccafary to buddle it again
after it is lifted, let it be buddled and distributed in three
parts, viz. the crop or pureft, the creaft or next i in purity,
and the hind-crest or tail, which is the moft impure. The
crop is to be cleaned by toffing, &c. and the creaft muff
be buddled again, and out of this muff be referved as much
as may be cleaned by toffing and packing. The remainder
must be cleaned by an operation called dillingeigh, from
dilliegh, to let go, or fend away. A dillingeigh is a large
fine hair-fieve, which the dredger holds in a kewe one-third
full of water, into which the tin is thrown by a fhovelful
at a time, and which is fhook so as to put the tin into
motion: one fide of this dillingeigh is dipped in water,
and raised again in fuch a manner, that the wafte may run over,
which is laid afide to mix with the flimpings, to make the
samples of low value, called the rough (or raw) tin. This
ufually undergoes another operation, in which, by a rill of
water passing over the buddle in which it is placed, it is
farther cleaned, and then dillingeighed, fo as to be fit to mix
with the crop-tin.

Upon the fame mechanicall principle of feparation, the
timer is capable of efimating the value of a fample of ore.
For this purpose, the ponded tin-ore, or tin-fluff, as it is
called, is placed on a fhovelf and washed under a ftream,
till the impure earthy parts are carried off by the water from
its fides, when, by a particular and dexterous motion, not
eafily defcrib'd, all the metallic particles are collected to-
gether on the fore-part of the fhovelf: this operation is
called vanning, which we have already defcribed.

When the tin-ore is contaminated with the different pyri-
tous ores of copper, arfene, and iron, it is firit roafed in
a burning-houfe, and then washed in water, by which means
the tin, which is heavy, is eafily feparated.

By this procfs, as at prent conducted in Cornwall, a
considerable quantity of copper is left; for being converted
into fulphate of copper, which is folution in water, it is left
by washing: whereas, if the roafed ore were fuffered to
remain in a close pit for a few days, and the water drawn
off
off into another pit, the copper might be separated by iron in a metallic flake.

The leavings of tin, consisting of the flame and tails, i.e., of tin-mud and tin-gravel, are dressed by a particular kind of apparatus, for the construction and use of which, we must refer to Pryce’s Min. Corn. p. 226, &c.

Each flamping-mill, which has constant work and water, will employ one man and five boys; and one hundred sacks are carried, flamped, and dressed, in the space of a few days, at the average rate of about four-pence per sack, or one guinea and a half per hundred.

When the tin-ore is brushed, it is divided into as many shares as there are lords and proprietors.

The next operation pertaining to tin-ore, or black tin, is that of smelting it. The Phoenicians, who traded to Cornwall for tin in the earlier ages, probably conducted this process by digging a hole in the ground, and emitting the ore on a charcoal fire, which perhaps was excited by a bellows. But having no idea of confining the fire, and directing its force on the substance to be smelted, they made no use of furnaces, either simple or reverberatory. Charcoal was long used in the operation of melting, till at length necessity suggested the introduction of pit-coal; and in the second year of queen Anne, a patent was granted for melting black tin with fossil coal in iron furnaces. The invention of reverberatory-furnaces built with brick, stone, sand, lime, and clay, soon followed this discovery: the form of which, being simple, has admitted of little improvement to the present time. The charge for one of the tin smelting-furnaces is from five to fix hundred weight of black tin, well mixed with a tenth or twelfth or eighth weight of culm, which is a species of coal from South Wales, that is very free from sulphur. The furnace is charged through a hole in its side with a shovel, and the tin levell’d over the bottom with an iron rake or paddle. The apertures are then closed, and the fire raised to a very great strength, in which state it is left for four or five hours, when the door is taken off, and the whole charge well stirred together. The flake of the metal is examined, and more culm thrown in if necessary; the furnace is again closed, and the fire kept up till the end of about fix hours from its receiving the charge; when it is again examined, and if proper, it is then tapped, and the metal let out into a fixed bason made of clay, and large enough to hold somewhat more than the metal of the charge. The scoria in the bottom of the furnace is raked out at the mouth into a small pit made for this purpose, where it generally forms itself into a cake. When cold, it is carried to the flamping-mill, in order to separate the globules of melted tin disseminated through the scoria or flag. This, being broke by hammers to the size of goose eggs, is put into the first flamping-mill, and passed through small iron bars; by which means the pillon (for so all tin recovered out of the flags is called) of the larger size is taken out and prevented from choice by too much flamping. The refuse of this first flamping is put into other flamping-mills of a second, third, or even fourth size. Of the pillon, separated from the scoria, all the rough or grainy parts are considered as metals, and refined accordingly, by being smelted without any flux, and the produce of this smelting refined, with the tin first tapped.

The tin in the bason, or float (as it is called), as soon as it comes down to a moderate heat, is lided out into the moulds, in slabs or pigs of about three-fourths of a hundred weight.

The method of smelting in Saxony and Bohemia, does not differ greatly from that practiced in Cornwall. When the ore has been roasting it is walked upon tables, to separate the oxyd of iron and the oxyd of copper, which are lighter than tin-ore. At Alt-Saint-John, the oxyd of tin is mixed with the black oxyd of iron; this is separated by a powerful magnet, which is drawn over the table. That the powdered oxyd of tin may not be blown away by the blast of the furnace, it is previously moistened with water; but as the flame always carries away a part of the ore, a chamber is constructed about the middle of the chimney, made of wood lined with clay, where the powdered ore that has been driven up by the flame is deposited.

The next process is that of refining. The furnace having, by the side of the small float now described, a larger one capable of holding twenty, or more blocks, is for this purpose suffered to cool to a certain degree, and then charged full with the slabs just mentioned, the tap-hole being kept open, so that as the tin melts in this moderate fire, it makes its exit through it to the float; where, while running out, it is frequently stirred and tossed by a ladleful at a time held arm-high, letting it fall in a stream into the masts of metal, when the scum which arises is taken off. While the metal already put into the furnace is melting, more is added, so as to be just enough to fill the float with good tin: and this, after being tossed and skimmed as before, and suffered to cool to a proper temper, is carried in iron ladles to moulds holding generally somewhat above three hundred weight (then denominated block-tin), where they are marked as the smelters chafe with their house mark, which may be a pelican, plume of feathers, flag, or horse, by laying brads or iron flamps, in the face of the blocks while the tin is in a fluid state, and yet cool enough to sustain the flamping iron. The blocks are then ready to be weighed, numbered, and sent to the nearest coinage town to be coined. The privileged towns for coinage of tin, were anciently Liskeard, Lostwithiel, Truro, and Helston: but soon after the Restoration, Penzance was added to the number; in which last place there is every quarter more tin coined than in the towns of Liskeard, Lostwithiel, and Helston, for a whole year. When the tin is brought to be coined, the assayer’s deputy assays it by cutting off with a chisel and hammer a piece of one of the lower corners of the block, about a pound weight, partly by cutting and partly by breaking, in order to prove the roughness of the metal. If it is a pure good tin, the face of the block is flamped with the duech feal, which flamps is a permit for the owner to sell, and at the same time an assurance that the tin so marked has been examined and found merchantable. The flamping of this impression by a hammer is coin’g the tin, and the man who does it is called the hammer-man. The duech feal is argent, a lion rampant gules, crowned or, with a border garnished with bezants.

The dropp’d part remaining in the furnace is by an increasing fire wholly melted, which is then tapped into the small float, where the tin subding, and the drops rising to the top, the latter is taken off, and the tin laded into small slabs, as at first, to be again refined. The tin that remains in and about the scoria and dro’s of the last tappings, &c. is recovered by repeated smelttings, till at last, being almost entirely drained of that metal, they become what the workmen generally call hard head, and esteemed of no further value.

M. Grosch, in the Memoirs of the Academy of Sciences of Paris, has delivered a method he had invented of separating tin from lead or silver. Having tried an experiment on the scoria of metal, which contained with the tin a large quantity of silver, it seemed to him that one great step toward the separation of the silver, was the haftening of the calcination of the tin, and with this view he tried a mixture

4 T 2
of charcoal, saltpetre, and earth, which he put together
into the coppel with the fcorze. It is easy to see that a de-
tonation would happen from this, and this must greatly add
to the force of the fire, in acting upon the fcorze, while the
ferruginous matter well known to be contained in the char-
coal mixed itself with the tin, and must greatly accelerate
its calcination, divide its parts, and give the fire a new action
over it. The confequence of this perfectly answered expec-
tation, and recovered a large quantity of filver from the 
scorze, in which the tin had before held it firmly imbedded;
repeated experiments proved the truth of this obervation,
and it was found to be easy by this means at any time to se-
parate filver from tin, or to purify filver without loss, by
means of lead in which tin has accidentally been imbedded.
The fcorze in which tin is mixed with filver, are com-
pared of tin half calcined, and run into an opaque vitrified
fublimate, which forms a sort of net-work, in which the
filver is confined in extremely small particles. If this is
thrown into aqua fortis, the water is dissolved; but then it
requires a very strong fire to make the tin loft its metallic
form; finally, if the whole is finely powdered, and then
put into this menstruum, the filver only is taken up or
dissolved, the tin remaining untouched at the bottom of the
veffel.
The fame gentleman found also a method of separating
fiver from tin, by means of corrosive fublimate of mer-
cury. To conceive the manner in which this separation is
effected, a piece of tin need only be call into a folution of
fublimate; in which cafe the acid of the felf-falt is feen
to leave the mercury in order to fix upon the tin.
And, according to the fame principle, if fublimate cor-
rofive be added to a mixture of tin and filver, the fame
efect is produced, the acid affixes itself to the tin, and
makes with it a butyrum joviale or butter of tin, the mer-
cury becomes diffipated in the mean time by the action of
the fire, and the filver remains pure and alone; but in this
experiment, if too much corrosive fublimate be added, there
is danger of lofing fome of the filver; fince the abundant
acid will prey upon and carry off a part of that metal,
making a fort of luna cornex which diffipates itself in the
air, or if the operation be performed in a clofe veffel, a
butyrum luminare.
Gold may also be purified from tin in this manner, and in
this there is no rilk of losf, fince the acid which takes up
the tin has not the leaf power over that metal: in all these
proceffes, however, the operator must avoid the fames iffin-
ging from the crucible, far they are very dangerous.
These methods of separating of tin from filver are very
certain and infallable, but they are too expeffive to be em-
ployed in common, and in larger works.
The separating of tin from lead to be employed in the
refining of filver is a matter of great importance; and this
may be done in the following manner: melt the lead, and
when in folution throw into it a quantity of filings of iron,
then inceafe the fire to a considerable degree, and the sur-
f ace of the metal will be covered with a fort of feum, which
is no other than the iron and tin. At this time there should
be a little alkali falt thrown in, and by this means the fcorze
readily separate themselves, and the pure lead remains in
form of a regulus at the bottom. The fame method may be
used to separate tin from filver in the larger way, but it
will be neceffary for this purpofe to add fome lead; fince
otherwise the folution will be very flow and difficult, and the
tin will calcine without separating from the filver. This is
a very easy and very cheap method, and will obviate moft of
the miffakes which happen to the refiners, of which they
would have much ftreas frequent reafon to complain, if they
nicely examined the lead they were to employ. But if gold
or filver be mixed with tin, the shortef method in small
quantities is to calcine the whole very briefly, and in order
to complete the vitrification and seperation of the tin, to
call in a little glafs of lead, which will immediately join itfelf
with it and carry it off from the mafs.
It may feem singular that iron being one of the hardeft
of the metals to melt, and tin being of all the eaffieft, they
fhoild fo readily and eafily unite in these experiments; but
this feems to be the reulf of one of thoie natural and unex-
pected alliances which accident frequently discovers to us in
bodies. There is one conjecture, however, that may be
worthy a place in this refearch, which is, that all tin-ore
contains a quantity of arffenic; and it is well known that iron
very readily mixes with arffenic, and is employed to separa-
tethe arffenic from other ores, and a regulus may be formed
of arffenic and iron. It is eafy to fuppofe that tin is, in its me-
talline form, not wholly divifted of the arffenic it contained
when in the ore; and if this be allowed, it is no wonder that
the two metals are eafily brought together by the medita-
Mr. Cramer gives the practical rules of separating filver
from tin, thus: Divide one centner of tin into two equal parts;
put each of these into a feparate telt, and add to each fixteen
centners of granulated lead, and one of copper; put the
whole under the muffle, and make a very strong fire; the
tin will be calcined immediately, and will fwim upon the lead.
Then inceafe the fire a little, till the affhes of the tin that
fwm upon the surface do no longer fparkle: when you fee
this, add with a ladle two centners of glafs of lead to each
test, in fuch a manner that it may be spread wide over the
whole surface of the refected calx; the calx will then change
its form of powder into that of glafs; then inceafe the fire
to its highest degree, fir up the whole with an iron rod made
warm; and when the fcufpiration is perfected, pour out the
flafs into a mould; the fcorze being feparated, put both
the regulufes into two coppels well heated; and into a third
put fixteen centners of lead, and one of the fame copper
used in the procefs: examine all these beads after the cop-
pelling is over; if the two firft weigh exactly alike, it is a pro-
of the procefs has been well performed; and by subtracting
the weight of the bead, feparated from the third pan, from
the joint weight of the other two, the remainder is the
weight of the pure filver contained in the quantity of tin
which was examined. Cramer's Art of Allaying, p. 228.
Tin is found in Europe, Asia, and America, but has not
hitherto been discovered in the continent of Africa. This
metal is much lefs generally difteminated than gold, filver,
iron, copper, or lead; but where it occurs, it is moft of-
freuently in large quantities. In Asia it is found on the coaft
of Sumatra, and in Siam and Pegu. It is principally im-
ported into our Indian pofteffions from Queda, Jemfelen,
Tavai in Lower Siam, and the inlands of Banca. The tin-
mine of Banca are faid to be of great extent; and Mr. El-
more informs us, that no lefs than from forty to fixty thou-
sand pefuls of tin are furnifhed by these mines annually.
Tin is faid also to be found at a place five days' journey
from Nankin in China. The Indian tin was known to the ancients.
Diodorus Siculus mentions it among the productions of
India. Tin-flone is found in Mexico in the rate of stream-
tin, and is procured from alluvial depofitions by washing.
It is alfo faid to occur in Chili.
Tin-ore occurs in Saxony and Bohemia in beds, and
difteminated in granite rocks; it is found also in veins in rocks
of granite, gneifs, and mica-flate. Alluvial depofitions of
tin are alfo met with in these districts. The mines fometimes
confift of a mafs of ore formed by the junetion of a multitude
of
of small veins which pass through the rocks in different directions. These veins also contain topazes. Brounart Traité Elémentaire.

Tin is found near Monterey, in the province of Galicia in Spain, in veins which traverse granite and mica-flate. This ore has recently been discovered in small quantities in grains and crystallites, in a rock of granite at Puy les Vignes, in the vicinity of St. Leonhard, in the department of Haute-Vienne in France. It occurs in veins with wolfram, arséniac pyrites, and marten arseniate of copper.

The most considerable repository of tin-ore in Europe is that of Cornwall. The greatest part of the tin consumed in Europe is procured from thence; and Camden even supposes this abundance of tin in Cornwall and Devonshire, to have given the original denomination Britain to the whole kingdom. In the Syriac language, carataneane, or bartaneane, signifies land of tin; from which Bochart derives the name Britain. It occurs in Cornwall, both in veins and alluvial depositions, in various parts of the county. Alluvial depositions of this ore are also met with on Dart-moor, in Devonshire. The veins which contain tin interject both granite and slate rocks; the latter are provincially called killet. These veins vary in width, and sometimes contain large masses of the ore. One block was raised from the mine called Polberrow, in St. Agnes, which weighed more than twelve hundred pounds, and produced more than half that weight of pure metal. Tin-flone generally occupies the upper part of veins, and is succeeded by copper-ore; but there are instances of tin occurring at the depth of two hundred fathoms. Different modifications of the forms of the crystallites are peculiar to certain veins. Crytallites of tin-flone are also disseminated in some of the granite rocks in the vicinity of veins: the crystallites appear to occupy the place of mica. Where the tin-flone is disseminated in flate, it is generally in small firings or minute veins. See Mine and Veins.

The workmen distinguish several kinds of tin; as mortin, which is the best sort, a fool of which weighs eighty pounds; and mine-din, which is the next, the fool of it weighing about fifty-two or fifty pounds. The tin got from the loft, gravelly earth, they call pyram-din, to distinguish it from that obtained from the mines, which is better by almost half. See Stream-Tin Ore.

Grain-tin denotes the ore of tin that is sometimes dug very rich in the form of grains or pebbles, or else in larger pieces, composed of many such distinct grains, united in one mass, always of a black or dark brown colour, pointed like diamonds. Grain-tin is also used to signify the purest and finest block or white tin, mixed with charcoal in the blast or blowing-house furnace, which never had any brood or foreign mixture in the mine: whereas the mine-tin is usually corrupted with some portion of mundic, or other mineral, and is always mixed with a bituminous fire, which communicates a harsh fulphurous quality to the metal. Grain-tin is peculiarly produced from stream-work, and is worth several shillings per hundred more than mine-tin. See Streaming.

See on this article Macquer's Chem. Dict. art. Tine; and Pryce's Mineralogia Cornubiensis, fol. 1778.

There is a curiosity in the Cornish mines, which is this: that in digging at the depth of forty or fifty fathoms, they frequently meet with large timbers, full entire.

Childrey, in his Natural History, goes back as far as the deluge to place them there; but, without having recourse to so great antiquity, they who believe that the mines, when exhausted of their ore, or mineral matter, renew and fill again in course of time, will soon solve the difficulty, by supposing that, in the first working of these mines, these timbers had been let down to serve as props and pillars.

But there are other people who will think this renewal of the mines itself a difficulty as great as the former. However, what the former author says, viz. that in some places in the mines they likewise find pick-axes, &c. with wooden shafts, as also brass nails, and that even a medal of Domitian has been found in one, seems to countenance the opinion.

For the use of tin in the composition of pewter, see Pewter.

Tin: Trade of Britain. That tin was procured from Britain in a very early age, appears probable from the concurrent testimony of the most ancient historians. The Phenicians are said by Strabo to have passed the pillars of Hercules, now the straits of Gibraltar, about twelve hundred years before Christ. At what precise period they discovered the Cafiterides, or Tin islands, is unknown, nor is their exact situation determined; but it is generally believed that the Saillies islands, and the western part of Britain, were the places from whence these early navigators procured the tin which they exported to other countries. The Phenicians were extremely anxious to conceal from the rest of the world the true situation of the Caffiterides. Herodotus, who wrote about four hundred and fifty years before Christ, could not learn where these islands were situated; but he supposed that tin, like amber, was brought from the remotest parts of Europe. Strabo relates, that the captain of a Phenician vessel returning from Britain seeing himself pursued by a Roman galley, chose rather to run his vessel among the rocks, that the Romans might experience the like fate, than be the means of discovering so valuable a commerce to the enemies of his country. The captain having escaped from the wreck, claimed from his country compensation for the loss of his vessel and the cargo: and it is said he was paid from the public treasury the amount of his claims. By these precautions, the Phenicians are said to have enjoyed a profitable trade to these islands for about three hundred years. The secret was at length discovered, and the Greeks, Gauls, and Romans, came in successively for a share of this trade. The Phenician Greeks established a colony at Marseille five hundred and forty years before Christ: and after the destruction of Carthage, carried on this commerce; they endeavoured to conceal from the Romans their knowledge of the British islands; for on being questioned by Scipio respecting the situation and extent of those islands from whence the tin was brought, they declared that they were entirely unknown to them. The Phenicians, in their voyage to Britain, are said to have failed from Cadiz to the harbour of the Artabici, near Cape Finisterre, from whence, after four days’ sail, they arrived in Britain. Strabo relates, that Publius Licius Croassus having made fruitless attempts to discover whence the tin was brought, at length succeeded, and arrived in Britain. It is uncertain when this Croassus lived, and even who he was, there being two of this name; the father, who was proconsul of Spain, and the son, who had a command under Cesar in Gaul.

Diodorus Siculus, who wrote during the time of Augustus, appears, from the quotation which we shall subjoin, that in that period, Tin was an article of considerable exchange. He says, Dr. Borlase. Polybius the historian is said to have described it; and that work is commended, Tin: Trade of Britain. That tin was procured from Britain in a very early age, appears probable from the concurrent testimony of the most ancient historians. The Phenicians are said by Strabo to have passed the pillars of Hercules, now the straits of Gibraltar, about twelve hundred years before Christ. At what precise period they discovered the Cafiterides, or Tin islands, is unknown, nor is their exact situation determined; but it is generally believed that the Saillies islands, and the western part of Britain, were the places from whence these early navigators procured the tin which they exported to other countries. Diodorus Siculus, who wrote during the time of Augustus, appears, from the quotation which we shall subjoin, that in that period, Tin was an article of considerable exchange. He says, Dr. Borlase. Polybius the historian is said to have described it; and that work is commended.
TIN.

The short description of the tin-trade given by Diodorus Siculus deserves particular attention. "These men (the tinners) manufacture the tin by working the ground which produces it with much skill. For though the land is rocky, it has soft veins running through it, in which the tinners find the treasure, which they extract, melt, and purify. Then shaping it by moulds into a cubical figure, they carry it off to a certain island lying near the British shore, which they call Leitis; for at the recess of the sea between the island and the main land, the passage being dry, the tinners embrace the opportunity, and carry the tin over in carts to the Leitis, or Port; for it must be observed, that the islands which lie between the continent and Britain have this peculiarity, that when the tide is full they are real islands, but when the sea recedes they are so many peninsulas. From this island the merchants bring the tin of the natives, and export it into Gaul; and finally through Gaul, by a journey of about thirty days, to the mouth of the Rhone;" lib. 4. Ptolemaus, as quoted by Strabo, says the port to which tin was brought in the south of France was Marseilles.

To what uses the nations of antiquity applied all the tin which they obtained with so much labour from Britain, is not precisely known. The Phoenicians celebrated for their skill in the art of dyeing; and the Tyrian purple, which was either a bright crimson or a scarlet, was held in the highest estimation; hence it has been conjectured, with much probability, that the Phoenicians were acquainted with the use of the solution of tin in the preparation of that colour. In the modern art of dyeing scarlet or crimson, the solution of tin in the nitro-muriatic acid is essentially necessary to communicate those colours to woollen cloths or stuffs, a practice which is probably derived from the ancient manufacturers of the East.

The mirrors of the civilized nations of antiquity were made of a composition of copper and tin. The most ancient account that we have of these mirrors is that in Exodus, chap. xxxviii. 8. "And he made the laver of brass (a mixture of copper and tin), and the foot of brass of the mirrors of the women." The Jewish women probably received these mirrors from the Egyptians when they left the country; for it was the custom of the Egyptians to carry a mirror in their left hand, when they went to their temples. Cyril de Aodo.

Pliny says that the best specula were anciently made at Brundulum of copper and tin. The metallic mixture of tin and copper, for rendering the latter metal white, is mentioned by Arifotole. (De Mirab.) This composition is still in use for the specula of reflecting telescopes. (See Speculum.) The ancients also made use of an alloy of tin with copper and lead for pot-metal. In the time of Pliny, pot-metal, ollaria temperatura, was made of two pounds of lead, and an equal quantity of tin, mixed with one hundred pounds of copper. From the same writer we learn, that the bronze of which the Romans made their statuettes, and the plates on which they engraved their inscriptions, was composed of one hundred pounds of copper, mixed with twelve pounds and a half of an alloy made of equal parts of lead and tin. He informs us also that tin, plumbum album, was employed in coating or lining copper vessels, to render them more wholesome; and it appears that the Romans not only used pure tin, but the same mixture of tin and lead which some of our workmen use at this time in lining vessels. A mixture of equal parts of tin and lead they called argentarium; a mixture of two parts of lead and one of tin they called tertiarium; and with two parts of tin and one of lead, they tinned whatever vessels they thought fit. (Watton's Chemical Essays, vol. iv.) In the manufacture of arms, the ancients used an alloy of tin with copper, their brases being a composition of these metals; but by what method they were enabled to communicate to it the necessary degree of hardness is unknown.

What was the relative value of tin, compared with that of gold and silver, as estimated by the Phoenicians, the Greeks, or the Romans, is uncertain. The process of extracting tin from its ores was probably very imperfect, and remained so in this country to the time of Elizabeth, when Carew informs us that Sir Francis Godolphin introduced great improvements in the tin-works.

The reverberatory-furnace appears, from Dr. Borlase, to have been introduced into Cornwall about the beginning of the last century; and about the same time the introduction of pit-coal became general, the wood of the country having been nearly exhausted. Sir Bevil Granville had previously made many experiments for melting tin with pit-coal, but without success, when the ore was smelted at the blowing-houses by large bellows worked by a water-wheel.

Whether the Phoenicians or the Greeks interfered themselves in the management of the tin-mines, or whether they were simply merchants purchasing and exporting the tin, is uncertain. It appears, however, by the passage quoted from Diodorus Siculus, that the veins of tin-ore were worked as mines; though it has been, and is still generally believed, that true tin was only ore worked by the ancients. From the testimony of Strabo, Pliny, and others, the Romans not only traded to Britain for tin, but improved the art of mining in Cornwall. The Romans being the conquerors, and the Britons under them having probably little or no property, they were the working miners, but under what regulations is uncertain. The Saxons did not obtain possession of Cornwall till the reign of Athelstan, and neither they nor the Danes appear to have directed their attention to the mines. After the Norman conquest, the working of mines is said to have yielded great profit. In the time of King John, however, the right of working tin being as yet, says Borlase, wholly in the king, as Earl of Cornwall, the property of the miners was precarious and unsettled, and all the tin that was raised was engrossed and managed by the Jews. The tin-farm of Cornwall at this time amounted to no more than one hundred marks, according to which valuation, the Bishop of Exeter received them, and still receives from the Duke of Cornwall, the annual sum of 6l. 13s. 4d., for low was the tin profits then in Cornwall; whereas in Devonshire, the tin was then farmed at 100l. yearly. King John, sensible of the languishing state of the mines, granted the county of Cornwall some privileges, and is said to have also granted a charter to the tinners.

In the time of Henry III. the tin-mines of Spain, which had been worked by the Moors, were stopped, and Cornwall had all the trade of Europe for tin. In the eighteenth year of Edward I., the Jews being banished from the kingdom, the mines were again neglected for want of proper encouragement to labour, and security to enjoy and dispose of the products. In consequence of a petition from some Cornish gentlemen to Edmund, Earl of Cornwall, a charter was obtained with more explicit grants of privileges of keeping courts of judicature, and managing and deciding minster causes. About this time, says Borlase, it appears that the rights of bounding or dividing tin grounds into separate portions, for encouraging the search for tin, were more regularly adjudged, and various laws introduced for the protection of the miner.
In the thirty-third year of Edward I. the above charter seems to have been confirmed, and the tinners of Cornwall were made a distinct body from those of Devonshire, before which time the tinners of both counties were accustomed to meet on Hingston-Hill every seventh or eighth year, to concert the common interest of both parties. Two coinages of tin yearly were also granted by this charter, and the tinners had the liberty of selling their own tin, unless the king insinuated on buying it himself. Other laws and regulations for the encouragement and protection of the miners, were passed in the reigns of Edward III., Henry VII., and Elizabeth. The mines having been much neglected during the reign of Mary, Elizabeth invited German miners into the country, and great encouragement was given to mining operations in Cornwall, and various parts of England. The quantity of tin procured annually in the succeeding reigns of James I. and Charles, amounted to fifteen hundred tons. During, and for some time after the civil wars, the tin-trade declined, but revived again in the reign of George I., and has since been increasing. For an account of the annual products of the tin-mines of Cornwall and Devonshire, see the article Mines.

All the transactions connected with the tin-mines are under the control of the flanmary laws; courts are held every six months, and they decide by juries of six persons, with a progressive appeal to the lord warden and lords of the duke of Cornwall's council. By whatever method or accident a vein is discovered, permission of the proprietor must be obtained before any operations can be commenced, except in the case of such tin-mines as are anciently embounded according to the provision of the flanmary laws. (See Stannary Courts.) The owner of the foil is technically called the lord, whose share (which is called his dyke) is generally one-sixth or one-eighth of the ore. The duke of Cornwall receives a duty of four shillings per hundred weight of tin, which is taken when the tin is assayed and licensed; this process is called the coinage, from the French word coin, a corner. A corner is chopped off each block at the office, and if it be found sufficiently pure, the blocks are flemmed with the arms of the duke. The annual revenue of the tin is about 10,000l.; the average annual amount being about 3200 tons, and the value about 120l. per ton. The mode of assay is obviously rude and imperfect; and we have heard that foreigners have recently complained that the British tin was not so pure as that obtained from the Earl. But whatever be the purity of British tin, there can be no doubt that it is greatly adulterated on the continent. It is said that every tin-founder in Holland has English flumps, and be the quality of the tin what it may, the inscription makes it pass for English. The metal with which British tin is adulterated on the continent is lead, which being five times cheaper, and when mixed in small quantities not easily detected, the temptation for such fraud is great. It is not true, as alleged by some foreign writers of respectability, that British tin is purposely alloyed with certain portions of copper and lead before it is exported from Cornwall. The ore of tin, in the tin-mines of Cornwall, are so intimately associated with portions of copper-ore, lead-ore, arfennical pyrites, and other metals, of which a small mixture will remain in the block-tin, and can only be separated by subsequent refining, that any considerable portion of alloy may be detected by the increase of specific gravity. Grain-tin, which is the purest tin of commerce, is smelted from the finest ore by a charcoal fire; the common block-tin is smelted with pit-coal or culm, as before stated. Grain-tin is used for various purposes in the arts, where tin of the purest quality is required.

Long as the tin-mines of Cornwall have been worked, they still continue to supply in abundance this useful metal; but from the greater extent of the present works, and from the circumstance of tin always occupying the upper part of the vein, we may infer that the tin-mines of that county will be exhausted at no very distant period. At present, the principal part of the tin is obtained from the western extremity of the county; but when the tin-mines in that district are worked out, we may consider the tin-trade of Cornwall as nearly extinct. The granitic range of Dartmoor, in Devonshire, has been less explored than Cornwall; but there is reason to believe that the metallic repositories of tin and copper which it contains will furnish an ample field for the industry of future adventurers, and a failure in the supply from Cornwall would greatly enhance the price of this metal, and give increased spirit to mining speculations.

Tin, in Chemistry and the Arts. The colour of tin is white, like that of silver; it has a fusible tale, and when rubbed, emits a peculiar smell: its hardness is greater than that of lead, and less than that of zinc: its specific gravity is stated by Briffon to be 7.291, and it is said to become a little greater by hammering; it is very malleable, and may be beaten into very thin leaves. Tin-foil, as it is termed, is usually about 1/2500th of an inch in thickness; but this is by no means the utmost degree of thinness which it will bear. Its ductility and tenacity are rather low: a tin wire, 1/8th of an inch in diameter, is blunted by Mufflesbroek (as quoted by Dr. Thomson) to be capable of supporting a weight of 31 lbs. only, without breaking. Tin may be easily bent, and when bent, produces a peculiar cracking noise: it fuses at about 442° of Fahrenheit's scale, but will bear a most intense heat before it is volatilized. On being exposed to the atmosphere, its surface becomes slightly tarnished, but it undergoes no other change. When kept under cold water it undergoes no change; but red-hot tin, exposed to the vapour of water, decomposes it, an oxyd of tin is formed, and hydrogen gas is evolved. Exposed to the action of the air in a melted state, it quickly becomes covered with a greyish powder, or oxyd; and if the heat is very violent, it is flated to take fire, and to burn with a pale white light.

Tin unites with oxygen in two proportions, as has been lately proved by Gay Lussac, in opposition to Berzelius, who concluded from his experiments that there were three oxyds of tin. (See Annal. de Chimie et Phys. vol. i. p. 40.)

The first oxyd, or protoxyd, of tin, consists of about

\[
\text{Tin} \quad \text{Oxygen} \quad \text{100}.
\]

The second, or peroxyd, of about

\[
\text{Tin} \quad \text{Oxygen} \quad \text{27.2}
\]

This gives the weight of the atom 7.332. Dr. Thomson is inclined to consider it as 7.375; but it perhaps will be found hereafter either 7.25 or 7.5. The first of these oxyds may be formed by dissolving tin in muriatic acid, either by means of heat, or by adding occasionally a little nitric acid; when dissolved, it add to it a solution of potash; a white precipitate falls, which is partly taken up again; but the remainder, on standing, assumes a dark grey colour, and even a metallic lustre; and on being heated to whitening, is pure protoxyd of tin. The peroxyd may be formed by boiling
boiling the protoxyd in dilute nitric acid, drying by evaporation, and heating to reduce.

Tin forms likewise two combinations with chlorine. When tin is burnt in chlorine, a very volatile clear liquor is formed, a non-conductor of electricity, and which, when mixed with a little water, becomes a solid crystalline substance, a true muriate of tin, containing the peroxvd of tin. This compound has been called the *smoking liquor of Libavius*, from its discoverer, who formed it by distilling together amalgam of tin and corrosive sublimate. According to the experiments of Dr. John Davy, it consists of two atoms or proportions of chlorine united to one of tin; or of about

*Prochloride of tin,* first described by Dr. J. Davy, is a grey, semi-transparent, crystalline solid, and may be formed by heating together amalgam of tin and calomel. According to the same chemist, it consists of one atom or proportion of chlorine united to one of tin; or of about

Tin combines readily with sulphur and phosphorus, but not with hydrogen, azote, carbon, or boron.

There are two sulphures of tin; the first may be formed by fusing tin and sulphur together: it is of a blueish colour, and lamellated structure; and from the experiments of Dr. J. Davy, consists of one proportion of tin united to one of sulphur. The other sulphuret of tin is made by heating together the peroxvd of tin and sulphur. It is of a beautiful gold colour, and appears in fine flakes. It was formerly called *aurum mufiueum,* and various complicated processes given for forming it. Pelletier and Proust investigated its nature, and concluded it to be a compound of oxyd of tin and sulphur; but Dr. Davy has shown that this is not the case, and that it consists merely of one proportion of metallic tin united to one proportion of sulphur.

The phosphuret of tin may be formed by heating the two substances together. Only one phosphuret is known; it has a metallic appearance, and is so soft, that it may be cut with a knife. When gently heated in the air, the phosphorus takes fire. According to the experiments of Sir H. Davy, it contains about 17 per cent. of phosphorus, and consists therefore of one atom or proportion of phosphorus united to one of tin.

Tin combines with most of the metals, and some of its alloys are much employed.

Its alloys with the metals of the fixed alkalies speedily tarnish in the air, and effervesce in water.

It readily unites with gold by fusion, and was formerly supposed to have the property of rendering this metal brittle; but this has been more recently denied. An alloy of 11 gold and 1 of tin, was found by Mr. Hatchett to have a pale whitish colour, brittle when thick, but when cut thin, capable of being bent easily. Its fracture was fine-grained, and of an earthly appearance. Mr. Alchorne found, that gold alloyed with no more than 4% of tin, retains its ductility sufficiently to be rolled and flamed in the usual manner. But Mr. Tillet showed, that when heated to redness, the tin melts, and the alloy falls to pieces.

Its alloys with platina, according to Dr. Lewis, are brittle and dark-colored, when the two metals are in equal proportions. The alloys of tin and silver are very hard and brittle. The alloys, or rather amalgams, of tin and mercury differ in hardness, according to the proportions in which the two metals are mixed: three parts of mercury and one of tin form an amalgam which crystallizes in cubes, or, according to Sage, in the form of brilliant square plates, thin towards the edges. Tin readily combines with copper, and forms alloys exceedingly useful for a variety of purposes, as will be briefly noticed when we speak of the uses of this metal. Tin does not readily combine with iron, but their union may be effected by fusing them together in close vessels; it combines with zinc by fusion, and the alloy is harder than zinc, and stronger than tin: with lead it readily unites in all proportions, and the lead by the addition becomes considerably harder.

The oxyds of tin are capable of combining with the alkalies, and of forming with them peculiar compounds.

*Salts of Tin.*—Tin is oxydated and dissolved by many of the acids, and forms salts, differing in their nature according to the degree of oxydizement of the metal.

*Nitrates of Tin.*—Concentrated nitric acid (specific gravity 1.48) poured on tin, exerts but little action upon it; but if a little water be added, a violent action is exerted, and peroxvd of tin is formed, which separates in the form of a white powder, this oxyd being apparently incapable of combining with nitric acid: in this case, both the acid and the water are decomposed, and nitrate of ammonia is formed; but if the acid be diluted, and care be taken to moderate its action upon the metal, the water only is chiefly decomposed, and the protoxyd of tin is formed, which combining with the nitric acid, forms a solution of a yellow colour, which is a real nitrate of tin. Still, however, a little nitrate of ammonia is formed, and the nitrate of tin itself is not permanent, the metal continuing to pass to the flate of peroxvd, and gradually separating. The same change is produced by heating the solution, a precipitate being deposited, which, however, is partly subnitate of tin.

*Muriates of Tin.*—We have already spoken of the chlorides, or compounds of tin with chlorine. Now if water be added to these chlorides, they are converted into muriates of tin. The muriate of tin, in which the metal is in the flate of protoxyd, may be formed, however, by dissolving tin in about four times its weight of muriatic acid: hydrogen escapes, and the solution has a brownish-yellow colour, and yields, on evaporation, small needle-shaped crystals, soluble in water, and somewhat deliquecent. Water poured upon it in small quantity decomposes it, and converts it into a submuriate, which is precipitated, and a super-muriate, which remains in solution. A similar effect is produced by the alkalies, when not added in excess. This muriate of tin, formed of the protoxyd, has a great tendency to combine with oxygen, and to pass into the flate of muriates with the peroxvd, and this property enables it to exert many curious effects upon other metallic salts. Thus, for example, the red oxyd of mercury, the black oxyd of manganese, the white oxyd of antimony, the oxys of zinc and silver, are deprived of their oxygen by this salt, and reduced to the metallic flate. The muriate of tin with the peroxvd of the metal may be formed as before mentioned. It is capable of crystallizing, and possesses properties quite different from those of the muriate above described. It is much used by dyers, who generally form it by dissolving tin in nitro-muriatic acid.

*Sulphate of Tin.*—Sulphuric acid, when cold, has little action on tin, but assifled by a moderate heat, it attracts oxygen from it; sulphurous acid gas is evolved, and a sulphate of tin is formed, which yields, when evaporated, small needle-formed crystals. It is probable there are two sulphates
TIN.

It was formerly recommended for its antihelminthic virtues; but it is possible, says Dr. Lewis, that these may proceed not so much from the pure metal, as from a certain substan-
tance of a different or arsenical nature, of which the purest
fors of tin are found to participate.

The principal preparations of tin are as follow:

Tin, Butter of, is a name given by some chemists to a
combination of tin with the concentrated marine acid of cor-
rive sublimate. It is procured by reducing these sub-
stances into small parts, and mixing them together: this
mixture will, by degrees, be moistened by the hu-
midity of the air. The decomposition of the corruive
sublimate by the tin is more speedily effected by distillation.

Tin, Calx of, is the metal reduced into powder, either
by means of fire, or by being diffused in an acid menstruum,
and precipitated with an alkali.

Tin, Ceruif of. See Spanifh White.

Tin, Diaphoretic of. See Antihelminthic Pomeri.

Tin, Flowers of, are a kind of white coferetic, or paint
for the complexion, drawn from tin with fal ammoniac, by
means of sublimation.

Tin, Gold-coloured preparation of, is made by adding fix
ounces of mercury to twelve of melted tin, pulverizing the
cold mafs, mixing with it seven ounces of flowers of sulphur
and fix of fal ammoniac, and subliming in a mafrafs.

This preparation is called aurum mosiicum, and as a medi-
cine is little regarded, though formerly much esteemed
against hysterical and hypochondriacal complaints, malignant
fevers, and venereal disorders. Upon experiment, it appears
to be little more than calx of tin.

Tin, Salt of, Sal Jovis, is prepared from twelve ounces
of calx of tin, and four of aqua regia, diluted with twenty-four
of water; after digestion for two days, the veffel is to be
shaken, the more ponderous part of the calx suffered to set-
tle, the turbid liquor poured off, and evaporated almoft to
dryness, and the mafs further exacated on brown paper;
to the remaining calx half the quantity of fresh menstruum
is to be added, and the procesg repeated. Dr. Lewis's ex-
perience has not enabled him to pronounce on the virtues of
this falt, which is in talle very sharp and corruive: he thinks
it needful to calcine the metal, as tin uncalcin'd diffolves
much more eafily and plentifully, and the solution is in both
cafes the fame. According to Hoffmann, the solution of tin
is a strong purgative. Lewis's Mat. Med.

Tin: is also a word used by some of the chemical writers
to express fulphur.

Tin-Coping, in Rural Economy, a fort of covering of this
kind of metallic subfance in the flace form, which is not un-
commonly employed on the upper parts of the frames,
flats, or fladdles of corn-flacks, for the purpose of pre-
venting defruutive vermin from entering or getting into
them. It is a cheap, ready, convenient, and useful mate-
rial in this intention, in many cafes, which the arable farmer
should not be inattentive to in his flack-yard.

Tin-Floors, a contrivance used by our husbandmen who
propagate hops, to dry them after the gathering. See Oost.

It is thus done: Let a square brick room be built, with
a door on one side, and a long fire-place of a foot wide in the
middle, reaching almost across it; let holes be made at the
sides of this fire-place, to let out the heat into the room;
and at the height of five feet above this, let a door be made
of laths of an inch thick, laid lattice-wise. Let this be
covered with great plates of double tin, taking care that the
joinings of the tin be well foldered, and lie upon the laths,
now over the interlacies, which may be about four inches
wide. Let a row of boards be fitted round the edge of

Vol. XXXV.
TIN

this floor, to keep the hops from falling off; then lay on a covering of hops of a foot thick, and make a small fire of charcoal in the mouth of the fire-place, and the hops will dry very quickly and very regularly. They may be continually stirred about while drying, and, when dry, a part of the bearded edge of the kiln may be taken down, and the dried parcel thrust out, and a fresh parcel laid on in its place. A very small quantity of fuel is sufficient in this way, and any fuel will do, for the smoke never comes at the hops. There is a very great improvement fill upon this method of drying hops, used by some people: this is the making of a wooden cover, of the size of the tin-floor; this is covered with plates of tin nailed on, and is suspended over the kiln in such a manner, that it may be let down at pleasure, when the lower parts of the hops are dry. This is to be let down within ten inches of their surface, and there it acts as a reverberatory, and drives back the heat on the upper ones, so that they are dried as soon as the lower ones. Thus all the trouble of turning is saved, and the hops are much better dried than in any other way. Mortimer's Husbandry, p. 186. See VENTILATOR.

Tin-Feil. See FOIL, FOLLATING, and LOOKING-Glass.

Tin-Hatch, in Mining, a term used by the people of Cornwall, to express the opening into a tin-mine. They also call it tin-shaft.

They make several openings in the sides of the hills where they expect veins of ore to be. All these, except that which opens on the head of the mine, are called effay-hatches; but that which does fo, is made their entrance afterwards, and changes its name to that of the tin-hatch. See HATCHES and SHAFT.

Tin-Hoop for Cheefs, in Rural Economy, a light thin hoop constructed of this fort of sheet metallic fulbance, that is sometimes employed in cheese-making, for holding and keeping the curd together while it is breaking and being crumbled down into the filling-vat, in order to prevent the trouble of raising and holding up the corners of the cloth which is made use of in the bulling. It is usually about nine inches in breadth, and formed so as exactly to fit the top part of the cheese-vat on which it rests when used. These hoops are sometimes made of other materials, as wood, &c. and are useful in saving time and trouble.

Tin-Oré, called tin-fluff by the miners in Cornwall. See TIN-STONE.

M. Gellert directs, that ores of tin should be assayed in the following manner: Mix a quintal of tin-ore, washed, pulverized, and twice roasted, with half a quintal of calcined borax, and half a quintal of pulverized pitch; these are to be put into a crucible, moistened with charcoal-dust and water, and the crucible placed in an air-furnace: after the pitch is burnt, give a violent fire during a quarter of an hour, and then withdraw the crucible. If the ore be not very well washed from the earthy matter, as it ought to be, a larger quantity of borax is requisite, with some powdered glafs, by which the too quick fusion of the borax is retarded, and the precipitation of the earthy matter is prevented. If the ore contains iron, to the above mixture may be added some alkaline salt. See MOOR-STONE.

The method of assaying tin-ore, says Mr. Pryce, is very easy; for in its form and size of black tin (which is the ore dried by flamping, several washings, and calcination, if mineralized with vitriolic, arsenical, or sulphureous pyrites) great part of the work is done, and little more remains than fusion, which is accomplished by a red heat in the following process: Take four or five ounces of black tin as emptied from the facks, mix it well with about one-fifth part of its weight of powdered culm; put the mixture in a black-lead crucible, on the wind furnace, and, in about twenty minutes, the metal will be found precipitated to the bottom of the crucible, the culm and scoria floating on the tin. On the surface of this matter there will be globules of tin; and therefore the mixture should be stirred with an iron rod, to make them fall into the tin at the bottom. Close the furnace, and let the whole remain in fusion from three to five minutes. Keep in readiness an iron or brass mortar, and an ingot-mould about six inches long; pour the tin into the ingot, and empty the culm and scoria into the mortar, separating what remains in and about the crucible with a sharp iron. As soon as cold, put them into another mortar, and pulverize them gently, fo as to separate the scoria from the largest of the globules of tin. Select the larger globules, and pulverize the remainder a second time; then put this stuff, twice powdered, on a shovell, and paffing it often through water, in the same manner as the lighter parts are washed from ores in vaning, and the smaller globules will remain on the shovell; and thefe, with the larger (both together being generally called pillon-tin), being added to, and weighed with the ingot, dew the produce in metal of the four or five ounces assayed. See Macquer's Chem. Dict.; and Pryce's Min. Corn. p. 269.

Tin-Plates, an article of manufacture very common among us, and vulgarly called tin. It is iron plated over with tin. The French call it fer blanc, white iron, as we sometimes do in England. It was once known under a distinct name, lattin, under which article the proceeds of manufacturing it is described.

The procws used for this purpose near Caermarthen, in South Wales, which is described by Mr. Donovan, in his "Descriptive Excursions through South Wales in 1805," is as follows:

The iron-ore employed in this manufactury is the common kind of the country, intermixed with a large portion of the fine haematite from Ulverstone, in Lancashire, which gives a very fine metal. This too is melted with charcoal instead of coke, to produce a metal of the greatest purity and extensibility, and chofens of texture, which qualities are particularly required in this manufactury. The reduced ore is melted in the usual manner, and cast into pigs, which are then wrought by the hammer into long flat bars, that are afterwards cut into pieces of about ten inches in length. These are then wrought into plates by being heated red-hot, and passed through a flattening-mill, which consists of two large cylinders of steel, cafe-hardened and secured in a frame of iron. These are placed contiguous to each other, but with a certain interval of space, and revolve in a contrary direction, fo that when one end of the bar is thult in the space between the cylinders, the whole is drawn through and proportionally extended and flattened in the paffage. The distance between the cylinders, which of course determines the thickness of the plate, is maintained and regulated by screws which can be altered at pleasure. When the bar is thus made into a plate of twice the thickness of the ordinary plates, it is heated red-hot, cut in two by a pair of shears, and one piece folded exactly over the other, and both repassd repeatedly through the cylinders till the folded plate has extended to the same length and breadth as the plate was before cutting. It is then clipped round the edges, and the two plates torn afunder (which requires some little force) after which they are each finished by passing through a finer rolling-prea, fo as to take away every creafe or inequality in the plate, and those that are too rough to pass through this finer prea are thrown aside.

The plates are then steeped in a very weak acid liquor, and when taken out are scourcd thoroughly with bra, fo as
to be quite bright and polished to enable the tin to adhere. The tin is melted in deep rectangular crucibles, and kept fluid by a moderate charcoal fire beneath. To prevent its calcination, a quantity of grease prepared from linseed-oil and fish is constantly kept floating on the surface of the tin, and renewed as it evaporates off, which gives an excellingly nafcent fench. The plate is then taken up by one corner by a pair of pincers, and dipped vertically into the tin, and when withdrawn is found beautifully white and re- splendent with the coating of this metal that adheres to it. This dipping is repeated three times for what is called single tin-plate, and fix times for the double plate. The plates are then only cleansed and sanded, and are fit for use.

We shall here add, with regard to the history of this manufacture, that in the year 1681, tin-plates were made in England by one Andrew Yarranton, who was sent to Bohemia to learn the manner of making them. But the manufacture was discontinued by his employers, and afterwards so much disregarded, as to be reckoned among the projects called bubbles of the year 1720; however, it was revived, and brought to such perfection about the year 1740, that very little of it was imported from foreign parts; our own plates being of a finer gloo, or coat, than that made beyond sea, the latter being hampered, and ours being drawn under a rolling-mill. And. Hilt. Com. vol. ii. p. 175, 361.

The two principal wholesale houses for this manufacture in London, are those of Jones and Taylor in Tottenham-court Road, and Howard and Co., in Old-street Road.

TINA, a name given by the old medical writers to a bath made of a strong decoction of many carminative ingredients to be used in the colic.

TINA, in Geography. See KNIN.

TINAGOB, a town on the W. coast of the island of Samar. N. lat. 12° 5'. E. long. 124° 50'.

TINALMO, a town on the S. coast of the island of Lucon. N. lat. 15° 38'. E. long. 122° 42'.

TINAMASAKI, a town of Japan, on the S. coast of the island of Niphon. N. lat. 34° 12'. E. long. 136° 57'.

TINAPA, a town of Mexico, in the province of New Biscay; 120 miles N.W. of Duranga.

TINARA, a town of Nubia, on the Nile; 200 miles S.S.W. of Syene.

TINCA, the Tinch, in Ichthyology. See CYPRINUS TINCA, and TENCH.

TINCA MARINA, the fast-trench, a name given by some authors to the common turdus, called in English the eelrasp, and physis.

TINCAL, is a name given to borax in the crude state in which it is brought from India, and before it is refined. It consists of small crytals of a yellowish colour, and it has a greasy or unctuous touch. See BORAX.

According to M. Cadet, it contains a larger quantity of the peculiar vitreous earth of borax than the refined salt commonly sold does. See BORAX.

TINCAUSARIS, in Ancient Geography, a place of Africa, in Cyrenaica, on the route from Carthage to Alexandria, between Boreum and Attica. Anton. Itin.

TINCHEBRAY, in Geography, a town of France, in the department of the Orne; 10 miles N. of Domfront.

TINCO, a town of Spain, in the province of Afturias; 20 miles N.W. of Oviedo.

TINCONTUM, or TINCNCOUM, in Ancient Geography, a town of Lyonnese Gaul, between Avarican and Decidua. Anton. Itin.

TINCTOR, John, in Biography, born at Nivelle, in Brabant, and flourished about the year 1474. He was a great musician, long in the service of Ferdinand of Aragon, king of Naples and Sicily, who reigned from 1458 to 1516, and styles himself his arch-deacon, chaplain, and cantor. Besides several musical tracts by this early writer on counterpoint, he was author of the first musical dictionary. All written music in counterpoint during the fifteenth century was composed for voices, at least we have never seen any other; and being intended for the church, was set to Latin words: so that the first terms used in the art, were likewise in that language; and these were so numerous in Tinctor's time, that he collected them, under the title of "Terminorum Muficii Difinitorium," and printed them at Naples. This was doubtless not only the first musical dictionary that was ever compiled, but the first book that was printed on the subject of music in general. The work is so rare, that we have never been able to find it, except in his majesty's inelimanible library. In this "Difinitorium," we first met with the precise definition of the four principal parts in vocal counterpoint: <em>canus</em>, <em>altus</em>, <em>tenor</em>, and <em>basse</em>; which fee under their several heads.

Tinctor, in one of his tracts, gives to the English the invention of counterpoint. See DUNSTABLE.

Walther seems never to have heard of Tinctor's "Difinitorium;" yet he gives the title of his three tracts: "De Arte Contra puncti," "De Tonis," and "De Origine Musicæ," from Gfner's Bibl. Univ.

TINCTORUM RUBIA. See MADDER.

TINCTURE, TINCURA, in Pharmacy and Chemistry, a separation of the finer and more volatile parts of a mixed body, made by means of a proper menstruum dissolving the same.

Tincture is more particularly used for an extract of part of the substance of a body, especially its flavour and colour, which are thereby communicated to the menstruum.

Tinctures, in the Materia Medica, are spirituous solutions of such of the proximate principles of vegetables and animals, as are soluble in pure alcohol or in proof-spirit; and they are said to have been invented about the end of the thirteenth century, by a professor of medicine at Montpelier, called Arnold de Villa Nova. From vegetable matter submitted to its action, alcohol takes up fugar, resin, extractive, tannin, cinchonin, camphor, volatile oils, several acids, and the narcotic principle; proof-spirit also takes up the whole of these partially, and is beside the proper menstruum for gum-resins; so that alcohol, either in a concentrated or diluted form, is capable of separating the greater part of the active principles of vegetables from the ligneous inert fibres. The tinctures obtained from animal substances are very few in number, and the principles taken up by the spirit are analogous to those enumerated above, belonging to the vegetable kingdom.

Pure alcohol is required in very few infusions only for the formation of tinctures, proof-spirit being adequate for almost every purpose. The dilution of the spirit, however, must be varied according to the known principles of the infusions to be submitted to its action: when resin predominates, it must necessarily be more concentrated; when gum-resin or extractive is the most abundant constituent, proof-spirit then must be employed. In consequence of the great affinity of water for alcohol, the addition of it to alcoholic tinctures separates the resin, camphor, and volatile oils they contain; but water is generally miscible with tinctures made with proof-spirit, without producing any decomposition. Tinctures are not liable to fuller spontaneous decomposition, as is the case with infusions and decoctions; and, independently of the lofs which takes place from the evaporation of the spirit and the volatile oils, if the bottles containing tinctures be closely corked, they may be
be kept for an indefinite length of time, and their virtues remain unimpaired.

Tinctures are prepared by macerating the ingredients in the spirit in a temperature not exceeding 80°, at which degree, by allowing the menstruum to remain on the ingredients for a sufficient length of time, all the principles that can prove useful in the tincture are extracted, and the solvent saturated. The ingredients must be dried and reduced to a coarse powder, and the maceration made in close vessels, and assisted by frequent agitation. When completely made, tinctures should not be allowed to remain upon the ingredients, but be filtered through bulblous paper, and kept in this state in well-corked bottles.

The chief use of this class of preparations is to cause infusions and decoctions to which they are added, to fit lighter upon the stomach, or to unite with them some active principle, which the water is incapable of extracting; Thomson's London Dispensatory.

A great variety of tinctures may be given to common water, and many remarkable things occur in their changes on the addition of common menstrua. Take a large spoonful of the syrup of pomegranate-flowers, mix it with five spoonfuls of water; the mixture will be of a very lively and brilliant red: for a violet colour, take the same quantity of syrup of violets and the same of water. When these tinctures are thus prepared, have at hand a phial, in which is a small portion of oil of tartar, which will only look like water remaining after the washing of the phial. Pour the red or the violet tincture into this phial, and it immediately becomes a fine graft-green. Dissolve in a quantity of a walnut of crude salt ammoniac in a glass of water, pour all out except three or four drops at the bottom, and pour into this glass the fine red liquor, and it immediately becomes black as ink. In order to change the purple liquor red, only have a small quantity of spirit of vitriol in the bottom of a phial, and pour into this the violet water; it immediately on this becomes of a florid red.

Steep Brandi wood in common water, or in white wine, twenty hours; the liquor will then look of the colour of red wine: pour this into a glass washed with vinegar, and it becomes of a fine yellow, like fack. If this experiment be made with white wine, the wood and the vinegar make so little alteration in it, that it may be drank afterwards, and the whole process seems a way of turning red port into fack. Into this liquor, when yellow, put a few drops of a tincture of benjamin made in spirit of wine, and it immediately loses its yellow colour and becomes white. Beat some galls to fine powder, and rub the powder on a towel; then put into a bacon of water, in which any person is going to wash their hands and face, a small piece of common green vitriol, or copperas: after the person has washed, let them have this towel to wipe on, and the hands and face will be as black as if washed with the common writing-ink; the copperas in the water and the galls on the towel making real ink where they mix. This does no lauirng injury to the skin, but will come off again upon washing with soap. Phil. Trans. N° 238, p. 88.

We shall here enumerate and describe the principal tinctures that occur in the materia medica.

**Tincture of Acetate of Iron** is prepared, according to the Dub. Phar. by adding together two ounces of acetate of kali and one ounce of sulphate of iron in a rongeware mortar, till they unite in a soft mass, and when dried by a moderate heat, triturating it with two pints of rectified spirit of wine; and then digesting it for seven days in a phial, closely corked, and frequently agitated, and then pouring the clear tincture from the face.

**Tincture of Acetate of Iron with Alcohol**, is prepared by rubbing together sulphate of iron and acetate of alkali, of each an ounce, and proceeding as in the former article, triturating with two pints of alcohol; and digesting for twenty-four hours. These tinctures have a peculiar odour, a reddish-brown colour, and a warm acid taste; and poffefs the fame medical properties as the other preparations of iron. The dose of either may be from 1/1 x to 3/4j., given in water or any other suitable vehicle.

**Tincture of Acetate of Zinc of the Dub. Ph.,** is obtained by rubbing sulphate of zinc and acetate of kali, of each an ounce, and adding one pint of rectified spirit of wine, and then macerating for a week with occasional agitation, and filtering through paper. This tincture is astringent, but requires to be diluted with water, before it is used either as a collyrium or an injection. It may be beneficially employed as an internal remedy in dysepsia and other debilities of the stomach.

**Tincture of Aloes of the Lond. Ph.,** is prepared by macerating of extract of spikèd aloes powdered, half an ounce; of extract of liquorice, an ounce and a half; of water, a pint; and of rectified spirit, four fluid-ounces, in a fand-bath until the extract is dissolved, and then draining.

The tincture of aloes of the Dub. Ph. is obtained by digesting for seven days, half an ounce of focotarine aloes powdered, an ounce and a half of extract of liquorice dissolved in eight ounces of boiling water, and eight fluid-ounces of proof-spirit, and then draining.

The tincture of focotarine aloes of the Edinb. Ph. is formed by digesting for seven days, with a gentle heat, in a close vessel, often shaken, half an ounce of focotarine aloes in powder, an ounce and a half of extract of liquorice, four ounces of alcohol, and a pound of water; and pouring off the clear tincture. Its dose is from 1/1 x to 3/4j.

**Tincture, ethereal, of aloes of the Edinb. Ph.,** is prepared by digesting an ounce and a half of myrrh with a pound of sulphuric ether with alcohol, for four days, in a cloked bottle, and then adding one ounce of English saffron cut, and one and a half of focotarine aloes in powder; digesting again for four days, and pouring off the tincture. This is a warm stomachic purgative, and is given with advantage in dysepsia affections, jaundice, gout, chlorosis, and other cases in which aloetics are proper; in doses of 1/1 x or 3/4j as a stomachic, and in larger doses as a brisk purge.

**Tincture, compound, of aloes of the Lond. and Dub. Ph.,** is prepared by macerating for fourteen days (seven days Dub.), of extract of spikèd aloes powdered, and saffron, of each three ounces, in two pints of tincture of myrrh; and draining.

**Tincture of aloes and myrrh of the Edinb. Ph.,** is prepared by mixing a pound and a half of alcohol with half a pound of water, and then adding two ounces of myrrh in powder; digesting for four days; and, lastly, adding of focotarine aloes in powder an ounce and a half, and an ounce of English saffron cut; digesting again for three days, and pouring off the clear tincture. This tincture may be administered in the same cases and doses as the former; and it is occasionally used as a local stimulant to foul ulcers.

The tincture of aloes, formerly called tinctura srica, and hiera pica, was ordered to be made by digisting five ounces of the powder, called hiera pica, or a powder formed of eight parts of aloes and two of canella alba, in five pints of mountain wine; or an ounce of aloes, with one drachm of the leffer cardamom seeds, and the same quantity of ginger, in two pouds of the same wine. Lewis.

Dr. Buchanan directs this tincture to be made by infusing an ounce of focotarine aloes in powder, and two drachms of Virginia flake-root, and as much ginger, in a pint of mountain
TINCTURE.

mountain wine and half a pint of brandy, for a week, frequently shaking the bottle, and strainning off the tincture. This, he says, is a safe and useful purge for persons of a languid and phlegmatic habit; but it is thought to have better effect when taken in small doses as a laxative. The dose, as a purge, is from one to two ounces.

Tincture of Ambergris. See Ambergris.

Tincture of Angustura Bark. See Angustura.

Tincture of Antimony used to be thus made: Take half of tartar, a pound; antimony, half a pound; rectified spirit of wine, a quart; reduce the antimony to powder, and mix it with the half by fusion over a strong fire. When it is cold powder it, and pour on the spirit of wine; digest them together in a sand-heat, and then filter off the clear tincture for use. The half of tartar yields a tincture as well as antimony. It is a diaphoretic and attendant. See Antimony.

This tincture, on an empty stomach, is said to have sometimes proved emetic.

Tincture Anisophyllosis. See Tinctura Saturnina.

Tincture Aromatic, may be prepared by infusing two ounces of Jamaica pepper in two pints of brandy, without heat, for a few days, and then straining off the tincture. This will answer all the intentions of the more costly preparations of this kind.

Tincture of Assafetida. See Assafetida.

Tinctura Auranti, Tincture of Orange-peel, is obtained in the Lond. and Dub. Ph., by macerating three ounces of fresh orange-peel in two pints of proof-spirit for fourteen days (three days Dub.), and filtering. This is an useful adjunct to infusions and decoctions in dyspepsia, communicating to them an agreeable flavour, and not decomposable by water.

Tincture of Bark. See Anoustrera and Tincture of Cinchona.

Tincture of Benzoin, Compound, of the Lond. and Dub. Ph., is prepared by macerating for fourteen days (seven days Dub.), three ounces of benzoin, two ounces of flower balfam strained, one ounce of balfam of Tolu, and half an ounce of spiced aloes, in two pints of rectified spirit, and filtering.

The compound tincture of benzoin of the Edinb. Ph., or Traumatic balfam, is obtained by digging for seven days, three ounces of benzoin in powder, two ounces of balfam of Peru, half an ounce of hepatic aloe in powder, in two pints of alcohol, and filtering through paper. This tincture is a stimulating expectorant, and sometimes prescribed in chronic catarrh and old athmatical cæs; but chiefly used as an external application to wounds and languid ulcers. Its dose is from 1/3 ij to 1/5 j, or more. See Benzoin.

Tincture of Calumba of the Lond. Ph., is had by macerating for fourteen days of calumba (or Columbia) root sliced, two ounces and a half, in two pints of proof-spirit, and filtering.

The Edinb. tincture of calumba is obtained by digging for seven days, two ounces of calumba root in powder, in two pounds of proof-spirit, and filtering through paper. This is an useful addition to inflamatic infusions and decoctions. See Columbia.

Tincture of Camphor, Compound, is ordered by the Lond. Ph. to be prepared by macerating for fourteen days, of camphor two scruples, of hard opium powdered and acid of benzoin, of each one drachm, in two pints of proof-spirit, and filtering.

The camphorated tincture of opium, or "paregoric elixir," is obtained by digging for ten days, of hard purified opium in powder, and benzoic acid, of each a drachm, of camphor two scruples, of essential oil of aniseed a drachm, in two pints of proof-spirit, and filtering. This is an useful anodyne in chronic asthma, hooping-cough, and catarrh after the inflammatory symptoms have abated, and contributes to allay the frequent cough. The dose is from 1/3 j to 1/5 j occasionally, using after it the inhaler, and 1/5 j in cases where quiet, rather than sleep, is required. See Camphor.

Tincture of Capsicum of the Lond. Ph., is obtained by macerating for fourteen days, an ounce of capsicum berries in two pints of proof-spirit, and filtering. The dose is from 1/3 j to 1/5 j occasionally, using after it the inhaler, and 1/5 j in cases where quiet, rather than sleep, is required. See Capsicum.

Tincture of Cardamom of the Lond. and Dub. Ph., is prepared by macerating for fourteen days (seven days Dub.) three ounces of cardamom seeds husked and bruised, in two pints of proof-spirit, and filtering.

The tincture of cardamom, or "tinctura amomi repentina," of the Edinb. Ph. is had by digging for seven days, four ounces of lesser cardamom seeds bruised, in two pounds and a half of proof-spirit, and filtering through paper.

The compound tincture of cardamom of the Lond. and Dub. Ph. is prepared by macerating for fourteen days, cardamom seeds (husked Dub.) castor oil, and ethereal oil, of each, in powder, two drachms, cinnamon bark bruised half an ounce, molasses four ounces, in two pints of proof-spirit, and filtering. These are agreeable additions to inflamatic infusions.

Tincture of Cassia. See Cascara.

Tincture of Caffeina. See Caffeina.

Tincture of Caffier of the Lond. and Dub. Ph., is formed by macerating for seven days, of caffer powder two ounces, in two pints of rectified spirit (proof-spirit Dub.) and filtering. The Edinb. Ph. directs an ounce and a half of Russian caffer powder to be macerated for seven days in one pound of alcohol, and then filtered. The dose is from 1/3 j to 1/5 j. See Caffer.

The compound tincture of caffer of the Edinb. Ph. is obtained by digging for seven days, one ounce of Russian caffer powder, half an ounce of alfafaetida, in a pound of ammoniated alcohol, and filtering through paper. This is advantageously given in hysteria, cramp of the stomach, and flatulent colic, to the extent of 1/5 j for a dose.

Tincture of Catechu of the Lond. and Dub. Ph., is prepared by macerating for fourteen (seven Dub.) days, three ounces of extract of catechu, and two ounces of cinnamon bark bruised, in two pints of proof-spirit, and filtering.

The tincture of catechu, formerly Japanese tincture of Edinb. Ph., is prepared by digging for seven days, three ounces of extract of catechu in powder, two ounces of cinnamon bark bruised, in two pounds and a half of proof-spirit, and filtering through paper. This tincture is a folution of tannin, extractive matter, and the oil of cinnamon. The dose, in cases where astringents are required, is from 1/5 j to 1/5 j, taken in water or wine, or cretaceous mixture.

Tincture of Cinchona of the Lond. Ph., is obtained by macerating for fourteen days, seven ounces of lance-leaved cinchona bark in powder, in two pints of proof-spirit, and filtering.

The tincture of cinchona of the Edinb. and Dub. Ph. is had by digging for seven days, four ounces of cinchona bark in powder, in two pounds and a half (two pints Dub.) of proof-spirit, and filtering through paper. The dose is from 1/3 j to 1/5 j.

For the compound tincture of cinchona, see Snake-root.

This is the name as the celebrated tincture of Huxham, who
TINCTURE.

who gave it in intermittents and low nervous fevers, in diluted wine or other proper vehicle, with 10 or 15 drops of
elixir of vitriol (aromatic sulphuric acid, Edinb.) in doses of
from f$\frac{1}{2}$j to f$\frac{3}{4}$ij, or more in intermittents. See CINCHONA.

TINCTURE of Cinnamon of the Lond. and Dub. Ph., is
obtained by macerating for fourteen days (seven days Dub.)
three ounces of cinnamon bark bruised (three ounces and a
half Dub.) in two pints of proof-spirit, and filtering. The
dose, as a fit adjunct to the chalk mixture and astringent
infusions, is from f$\frac{1}{2}$j to f$\frac{3}{4}$ij.

The compound tincture of cinnamon of the Lond. and Dub.
Ph., is prepared by macerating for seven days (seven days Dub.)
six drachms of cinnamon bark bruised, three drachms of
cardamom seeds bruised, long-pepper powdered and
ginger, of each two drachms, in two pints of proof-
spirit, and filtering. The

The compound tincture of cinnamon of Edinb. is formed by
digelling for seven days, cinnamon bark bruised, lefter

cardamom seeds bruised, of each one ounce, long-pepper in
powder two drachms, in two pounds and a half of proof-
spirit, and filtering through paper. This is benefically
used in flatulencies, atomic gout, languors, and debility, in
doses of f$\frac{3}{4}$ij or f$\frac{1}{2}$j properly diluted.

TINCTURA Crocei, or Tincture of Saffron of the Edinb. and
Dub. Ph., is prepared by digelling for seven days, one
ounce of English saffron cut in shreds in fifteen ounces (a
pint Dub.) of proof-spirit, and filtering through paper. See
CROCUS and SAFFRON.

TINCTURE of Fox-glove (Digitalis) of the Lond. Ph., is
obtained by macerating of fox-glove leaves dried (rejecting
the large ones) and reduced to a coarse powder, two
ounces, in a pint of proof-spirit, and filtering. The Dub.
Ph. directs two ounces of fox-glove leaves (the larger ones
rejected) dried and coarsely powdered, in a pint of proof-
spirit, and then to filter.

The tincture of fox-glove of Edinb. Ph. is had by digelling
for seven days, one ounce of fox-glove leaves dried, in eight
ounces of proof-spirit, and filtering through paper. The
dose of this tincture should be m$\frac{3}{2}$ at first, and gradually
increased.

TINCTURE of Galbanum of the Dub. Ph., is formed by
digelling for seven days, two ounces of galbanum cut into
small pieces, in two pints of proof-spirit, and then filtering.
Used as tincture of aalstexta, but less nauseous and less
powerful.

TINCTURE of Gall (Dub.) is prepared by macerating for
seven days, four ounces of gall in powder, in two pints of
proof-spirit, and then filtering. The dose, as an astringent,
is from f$\frac{1}{2}$j to f$\frac{3}{4}$ij.

TINCTURE of Gentian, Compound, (Lond. and Dub.) is
obtained by macerating for fourteen days (seven days Dub.)
two ounces of gentian root cut, one ounce of orange-peel
dried, half an ounce of cardamom seeds bruised, in two
pints of proof-spirit, and filtering. The

The compound tincture of gentian, commonly called "flo-
manic tincture," of Edinb. Ph., is prepared by digelling
for seven days, two ounces of gentian root sliced and
bruised, one ounce of orange-peel dried and bruised, half
an ounce of canella alba bruised, half a drachm of cochi-
nical in powder, in two pints and a half of proof-spirit,
and filtering through paper. This is an elegant Ronmanic
bitter and cordial, but in dyspepsia the infusion is preferable.
See GENTIAN.

TINCTURE of Gold. See AURUM POTABILE, and Chemical
HISTORY of GOLD.

TINCTURE of Guaiac of the Lond. and Dub. Ph., is pre-
pared by macerating for fourteen days (seven days Dub.)
half a pound of guaiac powdered (four ounces Dub.), in
two pints of proof-spirit, and filtering.

The tincture of guaiac of the Edinb. Ph., is formed by di-
gelling for seven days, one pound of guaiac powdered, in
two pounds and a half of alcohol, and filtering through paper.
Administered in the form of a draught, it must be
triturated with yolk of egg or mucilage, that it may com-
bine with water. The dose is from f$\frac{3}{4}$j to f$\frac{3}{4}$ij, in any con-
venient vehicle.

The ammoniated tincture of guaiacum of the Lond. and
Dub. Ph., is obtained by macerating for fourteen days (seven
days Edinb. and Dub.), four ounces of guaiac in powder,
in two pints of compound spirit of ammonia, and filtering.
The dose is from f$\frac{3}{4}$j to f$\frac{3}{4}$ij, triturated with any mucous or
vivid matter. See GUAIACUM.

TINCTURE of Black Hellebore of the Lond. Ph., is
obtained by macerating for fourteen days, four ounces of
the root of black hellebore sliced, in two pints of proof-spirit,
and filtering.

The tincture of black hellebore of the Edinb. and Dub. Ph.,
is prepared by digelling for seven days, four ounces of black
hellebore root bruised (powdered Dub.), half a drachm (two
brookles Dub.) of cochinical in powder, in two pounds and
a half (two pints Dub.) of proof-spirit, and filtering through paper. This tincture was regarded by Dr. Mead
as a powerful emmenagogue, and is still ordered in uterine
obstructions, and in some cutaneous affections. The dose
is from m$\frac{3}{4}$ij to f$\frac{3}{4}$ij, in any appropriate vehicle. See
HELLEBORE.

TINCTURE of White Hellebore. See TINCTURA VERATRI
Albi.

TINCTURE of Henbane of the Lond. Ph., is formed by
macerating for fourteen days, four ounces of the dried leaves
of henbane in two pints of proof-spirit, and filtering. The
Dub. Ph. directs to digell for seven days, two ounces and
a quarter of dried leaves of black henbane, in coarse powder,
in a pint of proof-spirit, and then straining.

The tincture of black henbane of the Edinb. Ph. is had by
digelling for seven days, one ounce of the dried leaves of
black henbane in eight ounces of proof-spirit, and filtering
through paper. In a dose of f$\frac{3}{4}$ij, it seldom fails of pro-
curing sleep and quiet, and does not affect the head or pro-
cude cooffiveness. In cafes of diarrhoea, a few drops of tinc-
ture of opium should be added to counteract its tendency
to pass off by the bowels.

TINCTURE of Hops of the Lond. Ph., is formed by ma-
cerating for fourteen days, five ounces of hops in two pints of
proof-spirit, and straining. This has been recommended
as a substitute for tincture of opium in gout and rheumatism.
The dose is from f$\frac{3}{4}$ij to f$\frac{3}{4}$ij, or more. See HOPS.

TINCTURE of Jalap of the Lond. Ph., is made by macer-
ating for fourteen days, two ounces of jalap root powdered,
in two pints of proof-spirit, and filtering. The Dub. Ph.
orders five ounces of jalap root in coarse powder, to be
digell for seven days in two pints of proof-spirit, and
then filtered.

The tincture of jalap of the Edinb. Ph. is formed by digell-
ing for seven days, three ounces of jalap root in powder, in
fifteen ounces of proof-spirit, and straining. See JALAP.

TINCTURE, Japanese. See TINCTURE of Catechu.

TINCTURE of Kino is obtained by macerating for four-
ten days, three ounces of kino in powder, in two pints of
proof-spirit, and filtering through paper. In the Edinb.
and Dub. Ph. two ounces of kino (three ounces Dub.) are
digell for two days in a pint and a half of proof-spirit,
and filtered through paper. The dose is from f$\frac{3}{4}$j to f$\frac{3}{4}$ij.

TINCTURE of Lacca. See LAC.
TINCTURE Lytta, or Tincture of Blistering Fly. See Lytta.

TINCTURA Martis cum Spiritu Salis, a medicine thus prepared: Take filings of iron, half a pound; Glæber's spirit of fixen, fift, three pounds; digest all together without heat, as long as the spirit will work upon the filings; then, after the faces have subided, pour off the clear liquor, evaporating it to one pound, and adding of rectified spirit of wine three pints.

Some combine the acid and inflammable spirits first, and digest three ounces of iron-filings in a quart of the dulcified compound. A few drops of this tincture are a sufficient dose. This tincture is good in all the cases in which the sal marris is fo.

TINCTURE of Martial Flowers. See Iron.

TINCTURE of Metals, called Lily of Paracelsus, may be prepared by melting together in a crucible two parts of metallic regulus of antimony, one part of fine tin, and one part of pure copper. The alloy thus compounded is to be powdered, when cold, and mixed with three of its weight of purified nitre. The mixture is to be thrown, at different times, into a red-hot crucible, where it detonates, and is exposed to a violent fire, till the metals be perfectly reduced to cakes. The matter is to be taken from the crucible, while red-hot, and immediately thrown into a heated iron mortar, where it is quickly powdered. The powder, while hot, is to be put into a matras, and upon it some rectified spirit of wine is to be poured to a height equal to the breadth of four fingers. The digestion is continued during some days, or till the spirit of wine has acquired a very deep yellowish-red colour. The spirit is to be decanted and kept in a bottle.

This tincture, although no part of the metals, reduced by calcination almost to the state of pure earths, can be dissolved by the spirit of urine, has a spirituous, faponaceous, acid, and alkaline character, and has been successfully used, when the fibres and vesicles require to be excited and animated, as in apoplexies, palpies, and dropsies. It is also capable of accelerating the motion of the blood, and of increasing certain secretions and excretions, particularly sweat and urine. The dose is from six or twelve drops to forty, or even more, and must be administered in some proper cordial. Macqueir's Dict. Chem.

TINCTURE of Marullae of Iron. See Iron.

TINCTURE of Myal of the Dub. Ph., is obtained by digesting for seven days, two drachmas of musk in powder, in a pint of rectified spirit, and then straining.

TINCTURE of Musk is directed, in the Edinb. Ph. of 1783, to be made by dissolving two drachmas of musk, in a pound of rectified spirit.

TINCTURE of Myrb of the Lond. Ph., is prepared by macerating for fourteen days, three ounces of myrrh bruised, in twenty-two fluid-ounces of rectified spirit, and a pint and a half of water, and filtering. The Edinb. Ph. directs three ounces of myrrh in powder to be digested for seven days, in twenty ounces of alcohol and ten ounces of water, and filtered through paper. The Dub. Ph. orders three ounces of myrrh bruised to be digested for seven days, in a pint and a half of proof-spirit and half a pint of rectified spirit, and then strained.

This tincture is tincce and deobdulent; it is used now generally in gargles, combined with infusions of roses and acids; or applied to foul ulcers and exfoliating bones, or diluted with water, as a wash for the mouth when the gums are spongy. The dose is from f3s to f3.

TINCTURE of Opium of the Lond. Ph., is formed by macerating for fourteen days, two ounces and a half of hard opium powdered, in two pints of proof-spirit, and straining.

The tincture of opium of Edinb. Ph. or Thebaic tincture, or liquid laudanum, is obtained by macerating for seven days, two ounces of opium in two pounds of proof-spirit, and filtering through paper.

TINCTURE of opium, or Thebaic tincture of Dub. Ph. is prepared by digesting for seven days, ten drachmas of purified hard opium in coarse powder, in a pint of proof-spirit, then straining. The usual dose is from 1/12 to 1/2x. In colica pictonum, f3j, given before purges, facilitates their action, and renders the relief more speedy; and in tetanus, f3ys have been advantageously given in divided doses, in twenty-six hours. The tincture externally applied allays local pain, and afflicts in relaxing the fpasm in lock-jaw and similar affections.

The ammoniated tincture of opium of the Edinb. Ph. is formed by digesting for seven days, in a clove phial, three drachmas of benzoic acid, and the same quantity of English saffron, cut in threads, two drachmas of opium, half a drachm of volatile oil of aniseed, in sixteen ounces of ammoniated alcohol, and filtering through paper. This tincture is used in hooping-coughs and phthisic althaea. Each f3j contains gr. j. of opium. See Opium.

TINCTURE of Quaffia of the Dub. Ph., is obtained by digesting for seven days, an ounce of chips of quaffia wood in two pints of proof-spirit.

TINCTURE of Rhubarb. See Rhubarb.

TINCTURE of Saffron. See Tinctura Croci.

TINCTURE of Sena. See Sena.

TINCTURE of Salt of Tartar, is made by pouring some rectified spirits of wine, to a height equal to the breadth of three or four fingers, into a heated matras, that contains some hot falt of tartar, which has been previously fused in a crucible and powdered. The matras is to be closed, and the digestion continued for several days with a gentle heat, or till the spirit of wine has acquired a fine reddish-yellow colour.

This is essentially the same as tincture of metals, their medicinal qualities being the same.

TINCTURA Saturnina, the lead tincture, a name given in the late London Diffenatary to the tincture before called tinctura antiphlogistica, because it was used to check the immoderate sweats in hectic complaints.

This is made of fugar of lead and green vitriol, of each two ounces, and of rectified spirit a quart. The fals are separately to be reduced to powder, and then put into the spirit, then the whole is to stand some days without heat to extract the tincture, and afterwards filtered through paper.

Many persons have found great perplexity in making this tincture, it having at first began to shew a good colour, but afterwards loll: this accident is owing to the heat usually employed in making the tincture.

This tincture is a powerful lytic, and is often used with good success in hectic fevers, spitting of blood, heat of the kidneys, simple gonorrhæas, flux albus, and tabes dorsalis.

It was first recommended by Etmuller; who, from its effect, gave it the name of tinctura antiphlogistica, which our College of Physicians changed to that of tinctura fatarina. The Edinb. Ph. directed it to be made of three ounces of the sugar and two of the vitriol, to a quart of spirit, and in the heat of the foreign ones. Mr. Boyle recommends it, and our most eminent physicians formerly used it, notwithstanding that some authors consider it as a dangerous medicine, on account of its principal ingredient, the fuscum fatarum, which some call a low poison. Whether it be fo
or not when given in substance, it is certain that there is a
great difference between a corrosive fals so given, and a
tincture made of the same, in spirit of wine, and given in
small doses, as Dr. Mead observes; who adds, that in slow
hectic fevers attended with a balsam; profuse sweats, and
a colliquation of the humours, he reckons two or three
drachms, given at different times, in cooling liquors, every
twenty-four hours, to be a convenient dose. But the usual
dose was from fifteen to thirty drops in Brutfon water, or
some temperate or cool julep.

Concerning the danger of saturnine preparations, when
applied to the purposes of internal medicine, see for George
Baker’s farther Observations on the Poifon of Lead, in
Med. Tranf. vol. ii. p. 446, &c. See also Colica Da-
monitorium, Lead, Saccharum Saturni, and Vinegar of
Lead.

Tincture of Snake-root. See Snake-root.
Tincture of Soot. See Soot.
Tincture of Squills. See Squills.
Tincture of Spanish Flicks, or Tinctura Cantharides. See
Tincture Lythie.

Tinctura Syphica, a form of medicine made with very
little trouble and apparatus, and serving to supply the
place of that elaborate preparation the tincture of Helveti-
tus: it is preferred in the late Lond. Ph., and is to be
made by mixing a drachm of calcined green vitriol with a
quarter of French brandy tinctured by the cafe: this is to
be shook together, that the brandy may turn black, and then
strained off for use.

Tincture of Sulphur. See Sulphur.
Tincture Thebaica. See Tincture of Opium.
Tincture of the Balfam of Toha of the Edinb. Ph., is
made by digesting an ounce and a half of the balfam in
a pound of alcohol in a gentle heat, till the balfam is disso-
volved, and filtering through paper.

This tincture poiffesses all the virtues of the balfam; and
in coughs, and other complaints of the breath, a tea-spoonful
or two of it may be taken in a bit of loaf-sugar.

But it is chiefly used for making the syrup. An ounce
of the tincture, properly mixed with two pounds of simple
syrup, will make what is commonly called the balsamic syrup.

See Syrup.

Tincture of Valerian of the Lond. and Dub. Ph., is
prepared by macerating for fourteen days (seven days Dub.)
four ounces of valerian root in powder, in two pints of
proof-spirit.

The ammoniated tincture of valerian of the Lond. Ph.
is obtained by macerating for fourteen days, four ounces of
valerian root in two pints of aromatic spirit of ammonia,
and filtering. The Dub. Ph. directs two ounces of valerian
root in powder to be digested for seven days in a pint of
spirit of ammonia. It is beneficially employed in hyfeteria
and other nervous affections, in doses of 1/2 to 3/4, given
in milk, or some other bland fluid.

Tinctura Veratri Albi, Tincture of White Hellebore, of
the Edinb. Ph., is made by digesting for seven days, eight
ounces of white hellebore-root bruised, in a pound and a half
of proof-spirit, and filtering through paper. This tincture is
employed to excite vomiting in maniacal and apoplectic cafes,
and as an alternate in cutaneous eruptions. It is given in
doses of 1/2 to 1/2., but its effects are sometimes very vi-
lent. Thomson’s Dispenfatory.

Tinctura Zingiberis, or Tincture of Ginger, of the Lond.
and Dub. Ph., is formed by macerating for fourteen days
(seven days Dub.) two ounces of ginger-root sliced, in
two pints of proof-spirit, and filtering. This is useful as a
stimulant and carminative, in atomic gout when it attacks
the flomach, in flatulent colic, and as a corrector of griping
purgatives.

Tincture is also applied by the Herald to the colours
used in escutcheons, or coats of arms; under which, with
them, are likewise included the two metals, or and argent,
because often represented by yellow and white. See

COLOUR.

Tincture comprehends colours and fur.

The writers on heraldry have had great disputation, which
of these colours or tinctures are the most honourable. All
agree in giving the pre-eminence to the metals gold and sil-
ver, that is, to the yellow and white colours: as to the
others, some esteem them more noble as they approach more
to light, that is, to white. Upton, on this account,
ranges them thus: azure or blue, gules or red, purpure or
purple, vert or green, fable or black: others wholly dif-
ferent from this, and prefer those colours most which can be seen
at the greatest distance; with these, fable or black is the
most honourable or first colour; and they allege the imperial
black eagle, placed in a white field, as an instance of this.
Leigh prefers the red to the blue, as the red has some alliance
to gold, and the blue to silver; the fable is generally pre-
ferr to green and purple, by those who give the red and blue the first places: it is in this efteme on account of its
strong appearance; and green is preferred to purple,
because the latter is but of very late use in heraldry, and is
called a new colour.

All the precedance given to tinctures must however be
considered with this special proviso, that there is no particular
reason for bearing them otherwise in the arms of kings,
doms and families. In all coats of arms there should be
two colours or tinctures; and it is the general rule that the
field should be of a nobler colour than the figures placed upon
it: thus in the arms of Scotland the field is yellow,
and the lion placed upon it red; and if the field consists of
two different colours parted by fefs or by pale, then the no-
blest colour must always be in the belt place, as on the
upper part, or on the right hand of the field; but all these
rules are to be understood with this limitation, that there are
no other special reasons in the family for the contrary. Nef-
bitt’s Heraldry, p. 19.

The two metals, or and argent, and the four colours,
black, red, blue, and green, (see COLOUR,) are the several
tinctures, says Edmondfon, of which the fields and all
charges of arms ought in strictness to be made; excepting,
however, such charges as are to be borne in their own pro-
or natural colour; which bearings, not having in blaz-
on any particular technical or fixed terms, are all com-
prehended under the word proper. As to the tinctures purpur,
tawny, and fanguine, these, being mixtures, are now seldom,
if ever, used, either for fields or charges, though they are
ranked among those, which, as some whimsical heralds say,
have mythical significations, and represent the moral, politi-
cal, and military virtues of those who originally bore their
arms so coloured or tinctured. Some heralds, says the
above-named writer, have blazoned the armorial colours in dif-
terent terms, according to the rank and dignity of the perfon
whose arms they are describing. Accordingly, the arms of
gentlemen, squires, knights, and baronets, are to be blaz-
oned by tinctures; those of nobles by precious stones; and
those of sovereign princes, kings, and emperors, by planets:
but this mode of blazoning would, he thinks, introduce into
the science of heraldry great absurdity and confusion, and
render blazons in some cases very ridiculous.

TINCULEN, or Tinzulen, in Geography, a town of
Africa, in the country of Darah; 120 miles S.W. of Ta-
filet.

TINDAL,
TINDAL, Matthew, LL.D. in Biography, a reputed deist, was the son of a clergyman, and born at Beer-Ferres, in Devonshire, about the year 1652. From Lincoln college, Oxford, into which he was admitted in 1672, he was removed to Exeter college; and having graduated B.A., he was elected fellow of All-Souls college, and became LL.D. in 1685. About this time, the reign of James II., he was beset by some of the popish emissaries, who were then active and indiscriminate in making profesties, and converted to popery; but, upon farther examination, he returned to the church of England in 1687. To the revolution he was ardently attached; and having been admitted an advocate, he often sat as judge in the court of delegates, and had a pension from the crown of 200l. per annum. Tindal was both a political and theological writer, and under the latter description he published "A Letter to the Clergy of both Universities," on the subject of the Trinity and the Arian creed, with a view to some alterations in the Liturgy, which were subjects of discussion. But the treatise that attracted principal notice appeared in 1706, and was entitled "The Rights of the Christian Church asserted against the Romish and all other Priefts who claim an independent Power over it;" with a Preface, concerning the Government of the Church of England, as by Law established." This publication roused the animadversions of the high-church clergy, and the venders of it were legally indicted. The favourable notice taken of this work by Le Clerc, in his "Bibliothèque Choixée," gave great offence to the lower house of convocation; and this learned body circulated a declaration, implicating the foreign critic, and others of similar sentiments, which Le Clerc himself, and many other persons, thought to be unjust and illiberal. Tindal also published a defence of his work, the second edition of which, in two parts, was ordered by a vote of the house of commons, to be burnt in the same fire with Sacheverel's sermons, in the year 1716. Some time after, the lower house of convocation, Atterbury being prosecutor, on a representation of the state of religion in the kingdom, animadverted on the dangerous consequences of the doctrine of necessity. To which Tindal replied, by asserting the truth and usefulness of that doctrine. Of the subjects and tendency of his political writings, it is now needless to give any account. It will be sufficient to observe that he was an advocate for the Hanoverian succession, and for the Whig ministry of that period. Hitherto Tindal had made no direct attack against religion; but in 1730 he no longer disguising his sentiments, which were announced to the public in a treatise entitled "Christianity as old as the Creation, or the Gospel a Reproduction of the Religion of Nature." He disclaims, indeed, in words, opposition to the divine authority of the Christian religion, and denominates himself and his friends "Christian Deists;" but in reality it was his evident and avowed purpose to shew, that there neither has been, nor can be, any external revelation distinct from what he terms "the internal revelation of the law of nature in the hearts of all mankind." Tindal was attacked by Dr. Waterland, who treated him with a degree of contempt which called forth the animadversions of Dr. Middleton. The author, though declining in health, wrote in his own defence, but conceptions of the gall-bladder, with which he had been long afflicted, terminated his life in the year 1733. His remains were interred in Clerkenwell church, agreeable to his own desire, near those of Dr. Burnet, bishop of Salisbury. A second volume of his "Christianity as old as the Creation" was left in MS.; but the publication of it was prevented by Dr. Gibson, bishop of London. His first work had given occasion to so many unanswerable defences of Christianity, that the learned bishop was unnecessarily alarmed, when he prevented further diffusion of this interesting subject.

TINDAL, Nicholas, the nephew of the former, was educated at Exeter college, Oxford, and had different preferments in the church. He died in 1774, at a very advanced age, at Greenwich Hospital, of which he was chaplain. Among his literary undertakings, the most considerable was a translation of Rapin's History of England, with a continuation. Biog. Brit.

TINDALE. See Tyndale.

TINDEL, in Geography, a town of Africa, in the country of Zenhaga, on the sea-coast; 18 miles S.S.E. of Cape Mirik.

TINDERCOTTA, a town of Hindoostan, in the Carnatic; 15 miles E. of Tiiagar.

TINDERO, a town of Sweden, in the province of Mendapedia; 12 miles N.E. of Sundsvall.

TINE, in Agriculture, a term applied to a tooth or spike, which is set or placed in any kind of tool or implement, but especially those of the harrow, drag, and other similar kinds.

Tines for this use should, for the most part, be a little curved or racked forward towards the points, as laying hold of the ground better, and in a more perfect manner. Sometimes tines are necessary to be felled a little in the points and front edges, in order to prevent the wear of them, and render them more effectual in tearing, cutting up, and dividing the land.

TINE, or Tyne, in Geography, a river of England, which rises in two streams, one called the North Tyne, which rises on the borders of Scotland, in the north-west part of the county of Northumberland; the other, which is called the South Tyne, rises about seven miles S. from Aldithome, in Cumberland: both these streams unite near Hexham, from whence the united stream proceeds to Newcastle, and from thence to the German sea, at Tynemouth.

TINEA, a river of France, which rises in the Alps, and runs into the Var, about 12 miles N. of Nice.

Tine, in Medicine. See Porrigo.

Tine, in Natural History. See Moth, &c.

TINH, in Geography, a town of Egypt, situated between the south extremity of lake Menzaleh and the Mediterranean, near the ancient Pelusium, and on a canal formerly called the Pelusian or Bubastie mouth of the Nile; through which Alexander passed with his fleet from Gaza; this canal is now chocked up with mud; 80 miles N.N.E. of Cairo. N. lat. 30° 48'. E. long. 38° 45'.—Allen, a town of Africa, in Tripoli, on a river which runs into the gulf of Sidra. N. lat. 30° 5'. E. long. 15° 12'.

TINÉHALY, a poll-town of the county of Wicklow, Ireland; 41 miles S. by W. from Dublin.

TINEMAN, in our Old Writers, a petty officer in the forlorn, who had the nocturnal care of vert and veinison, and other employments in the forest.

TINÉMAR, in Geography, a town of Ceylon; 10 miles S.W. of Trinamaly.

TINEMOUTH. See Tyne-mouth.

TINET, Tinettum, in our Old Writers, is used for brushwood and thorns to make and repair hedges. In Herefordshire, to tine a gap in a hedge, is to fill it up with thorns, that cattle may not pass through it.

TINETO, in Geography, a small island near the coast of Genoa, at the entrance of the gulf of Spezze. See Tino.

TINEVELLY, or Palamocotta, a city of Hindostan, and capital of a province of the same name, in the Carnatic;
TIN

TINAG, a town of Peru, in the province of Lima; 15 miles S.E. of Cuzco.

TINGIS, Tingier, a town of Africa, situated upon a plain between the promontory, the coasts, and the mouth of the river Valon, according to Ptolemy, which was called Carthage. Mela says that it was a very ancient city, founded by the giant Antaeus. It gave name to Mauritania Tingitana, of which it was the capital. Pliny says that it took the name of Julia Traducta, when the emperor Claudius lent it a colony. Pharamus, in Strabo, calls it Tingena, and says that a son of Tinga by Hercules, called Sophax, founded it, and gave it the name after that of his mother.

TIN-GLASS, a name frequently given to the semi-metal bifmuth.

TING-NGAN, in Geography, a town of China, of the third rank, in Kiang-tcheou, in the island of Hainan.

TINGO, or Tenna, a town of Italy, which runs into the Adriatic, 3 miles N. of Fermo.

TINGORAN, a small town in the Chinese sea, near the coast of Malaca. N. lat. 4° 18'. E. long. 103° 33'.

TINGORALLY, a town of Hindoostan, Malacca; 40 miles W.S.W. of Calcutta. N. lat. 22° 4'. E. long. 87° 52'.

TINGRACALLY, a town of Bengal; 16 miles E. of Mahmoudpur.

TINGRECOTTA, a town of Hindoostan, and Baramaul; 16 miles S.E. of Darampore.

TINGRI, a town of Tibet. Here the Nepalese were defeated by the troops of China in 1792; 22 miles S.W. of Zungang.

TING-TCHEOU, a city of China, of the first rank, in Fo-kien; 870 miles S. of Peking. N. lat. 25° 48'. E. long. 116° 4'.

TINGUIRICA, a river of Chili, which runs into the Rheel; 40 miles from its mouth.

TINGUZGALPA, a town of Mexico, in the province of Nicaragua; 80 miles N.W. of Leon.

TINGWALLA, an island of Shetland; 4 miles W.N.W. of Lerwick.

TINTAGELL, a town of the island of Shetland; 4 miles W.N.W. of Lerwick.

TINIAN, a cluster of small islands in the Chinefe sea, near the coast of Malaca. N. lat. 2° 25'. E. long. 102° 31'.

TINIGA, a town of Peru, in the province of Lima; 15 miles S.E. of Cuzco.

TINIGS, Tingier, a town of Africa, situated upon a plain between the promontory, the coasts, and the mouth of the river Valon, according to Ptolemy, which was called Carthage. Mela says that it was a very ancient city, founded by the giant Antaeus. It gave name to Mauritania Tingitana, of which it was the capital. Pliny says that it took the name of Julia Traducta, when the emperor Claudius lent it a colony. Pharamus, in Strabo, calls it Tingena, and says that a son of Tinga by Hercules, called Sophax, founded it, and gave it the name after that of his mother.

TIN-Glass, a name frequently given to the semi-metal bifmuth.

TIN-NGAN, in Geography, a town of China, of the third rank, in Quang-tong, on the river of Limou; 17 miles S. of Kiong-tcheou, in the island of Hainan.

TINGO, or Tenna, a town of Italy, which runs into the Adriatic, 3 miles N. of Fermo.

TINGORAN, a small town in the Chinese sea, near the coast of Malaca. N. lat. 4° 18'. E. long. 103° 33'.

TINGORALLY, a town of Hindoostan, Malacca; 40 miles W.S.W. of Calcutta. N. lat. 22° 4'. E. long. 87° 52'.

TINGRACALLY, a town of Bengal; 16 miles E. of Mahmoudpur.

TINGRECOTTA, a town of Hindoostan, and Baramaul; 16 miles S.E. of Darampore.

TINGRI, a town of Tibet. Here the Nepalese were defeated by the troops of China in 1792; 22 miles S.W. of Zungang.

TING-TCHEOU, a city of China, of the first rank, in Fo-kien; 870 miles S. of Peking. N. lat. 25° 48'. E. long. 116° 4'.

TINGUIRICA, a river of Chili, which runs into the Rheel; 40 miles from its mouth.

TINGUZGALPA, a town of Mexico, in the province of Nicaragua; 80 miles N.W. of Leon.

TINGWALLA, an island of Shetland; 4 miles W.N.W. of Lerwick.

TINIAN, a cluster of small islands in the Chinefe sea, near the coast of Malaca. N. lat. 2° 25'. E. long. 102° 31'.

TINIGA, a town of Peru, in the province of Lima; 15 miles S.E. of Cuzco.

TINIGS, Tingier, a town of Africa, situated upon a plain between the promontory, the coasts, and the mouth of the river Valon, according to Ptolemy, which was called Carthage. Mela says that it was a very ancient city, founded by the giant Antaeus. It gave name to Mauritania Tingitana, of which it was the capital. Pliny says that it took the name of Julia Traducta, when the emperor Claudius lent it a colony. Pharamus, in Strabo, calls it Tingena, and says that a son of Tinga by Hercules, called Sophax, founded it, and gave it the name after that of his mother.

TIN-Glass, a name frequently given to the semi-metal bifmuth.

TIN-NGAN, in Geography, a town of China, of the third rank, in Quang-tong, on the river of Limou; 17 miles S. of Kiong-tcheou, in the island of Hainan.

TINGO, or Tenna, a town of Italy, which runs into the Adriatic, 3 miles N. of Fermo.

TINGORAN, a small town in the Chinese sea, near the coast of Malaca. N. lat. 4° 18'. E. long. 103° 33'.

TINGORALLY, a town of Hindoostan, Malacca; 40 miles W.S.W. of Calcutta. N. lat. 22° 4'. E. long. 87° 52'.

TINGRACALLY, a town of Bengal; 16 miles E. of Mahmoudpur.

TINGRECOTTA, a town of Hindoostan, and Baramaul; 16 miles S.E. of Darampore.
TINIAN, in Geography, one of the Ladrone islands, in the North Pacific ocean, about 42 miles in circumference, first discovered by the crew of a Manila ship, which was cast away here in the year 1538. The author of Anfon's Voyage gives a pleasing description of this island, as found by the crew of the Centurion, in the year 1742. Commodore Byron, who visited it in the year 1765, and anchored on the south-west end of the island, in the same place where the Centurion lay, instead of delightful lawns, found the trees and underwood so thick, that in endeavouring to force a passage through, they were entangled and cut as if with whip-cord. After they had cleared the weed, which they imagined was the same at which lord Anfon filled his casks, commodore Byron found the water brackish, and full of worms. He says, "the road also where the ships lay was a dangerous situation at this season (Auguftr 1st), for the bottom is a hard sand, and large coral rocks; and the anchor having no hold in the sand, is in perpetual danger of being cut to pieces by the coral; to prevent which as much as possible, I rounded the cables, and buoyed them up with empty water-casks. Another precaution also was taught me by experience, for at first I moored, but finding the cables much damaged, I resolved to be single for the future, that by veering away, or leaving in, as we should have more or less wind, we might always keep them from being slack, and consequently from rubbing, and this expedient succeeded to my will. At the full and change of the moon, a prodigious swell tumbles in here, so that I never saw ships at anchor roll so much as ours did while we lay here; and it once drove in from the westward with such violence, and broke so high upon the reef, that I was obliged to put to sea for a week; for if our cable had parted in the night, and the wind had been upon the shore, which sometimes happens for two or three days together, the ship must inevitably have been loft upon the rocks. I soon found that the island produced limes, four oranges, cocoa-nuts, bread-fruit, guavas, and papaus in abundance; but we found no watermelons, feertry-grafs, or forest. Notwithstanding the fatigue and difficulties that we had endured, and the various climates we had passed through, neither of the ships had yet lost a single man since their failing from England, but while we lay here two died of fevers, a disease with which many were seized, though we all recovered very fast from the fever. I am indeed of opinion that this is one of the most unhealthy spots in the world, at least during the season in which we were here. The rains were violent, and almost incessant; and the heat so great as to endanger suffocation: besides the inconvenience which we suffered from the weather, we were incessantly tormented by the flies in the day, and by the mufquitos in the night. The island also swarms with centipedes and scorpions, and a large black ant, fearfully inferior to either in the malignity of its bite. Besides these, here were venomous insects without numbers, altogether unknown to us, by which many of us suffered so severely, that we were afraid to lie down in our beds: nor were those on board in a much better situation than those on shore, for great numbers of these creatures being carried into the ship with the wood, they took possession of every birth, and left the poor seamen no place of rest either below or upon the deck. Our principal resource for fresh meat was the wild hog, with which the island abounds. These creatures are very fierce, and some of them are so large, that a carcase frequently weighs 200 pounds. Mr. Gore, one of our mates, at last discovered a pleasant spot on the north-west part of the island, where cattle were in great plenty, and whence they might be brought to the tents by sea. We were now upon the whole pretty well supplied with provisions, especially as we baked fresh bread every day for the sick; and the fatigue of our people being less, there were fewer ill with the fever; but several of them were so disordered by eating a very fine-looking fish which we caught here, that their recovery was for a long time doubtful. The author of lord Anfon's voyage says, that the people on board the Centurion thought it prudent to abstain from fish, as the few which they caught at their first arrival surfeited those who eat of them. Besides the fruit that has been mentioned already, this island produces cotton and indigo in abundance, and would certainly be of great value if it were situated in the West Indies. The surgen of the Tamar enclosed a large spot of ground here, and made a very pretty garden, but he did not stay long enough to derive any advantage from it. Captain Wallis touched upon this island in 1767; and obtained beef, pork, poultry, papaw apples, bread-fruit, limes, oranges, and every refreshment mentioned in the account of lord Anfon's voyage. The sick began to recover as soon as they went on shore; but flesh meat would not keep sweet for scarcely one day. N. lat. 14° 55'. W. long. 214° 7'.'

TINICUM, a township of Pennsylvania, in the county of Bucks, containing 1017 inhabitants; 20 miles N. of Philadelphia.—Alfo, a township of Pennsylvania, in the county of Delaware, containing 249 inhabitants.

TINNETZ, a town of Austrian Poland; 4 miles W. of Cracow.

TINIMA, a town of the island of Cuba; 22 miles W.N.W. of Bayamo.

TINING, in Agriculture. See TINE. See also TILLAGE.

TININGBURG, in Geography, a town of Hungary; 16 miles N. of Presburg.

TINISSI, a town of Bohemia, in the circle of Konigigratz; 10 miles S.E. of Konigigratz.

TINIT, a town of Africa, in Zanzibar, on the coast; 25 miles S.S.E. of Cape Mirik.

TINJULEEN, a town of Africa, in the country of Darah; 105 miles S.E. of Morocco. N. lat. 29° 30'. W. long. 2° 30'.

TINKER'S ISLAND, one of the Elizabeth's Islands, near the coast of America.

TINKLING or Tingling of the Ear. See TINGITUS.

TINMOUTH, in Geography, a post-town of the state of Vermont, in the county of Rutland, containing 1001 inhabitants; 8 miles S. of Rutland.—Alfo, a town of Nova Scotia, on the east coast, formerly called Pittow.

TINNA, or TINA, in Ancient Geography, a river of the isle of Albion, between the gulfs Tana and Boderia, according to Tolemy, supposed to be the river Eden, in Fife. —Alfo, a small river of Italy, in Picenum.

TINNE, in Geography, a town of Africa, in Msina, on the north side of the Niger; 130 miles W.S.W. of Tombooto.

TINNING, the covering or lining any thing with melted tin, or with tin reduced to a very thin leaf.

Looking-glass is foliated or tinned with thin leaves of beaten tin, applied and fastened to them by means of quicksilver. See Looking-Glass.

Kitchen utensils are tinned with melted tin; and locks, bits, spurs, &c. with leaf-tin, by the help of fire.

For the method of tinning iron-plates, see LATTIN and Tin-Plates.

Copper and brass are covered over with tin by the help of Sal ammoniac, the acid of which cleans the surface of the metals.
metals to be tinned, and the oily matter contained in it furnishes the phlogifon (according to the old system) that is necessary in this operation. The copper, or brass, being made hot enough to melt tin laid upon it, is interleaved over with fial ammoniac, and the melted tin rubbed about the plate. The fial ammoniac takes up the dross of the tin, and leaves the tin to flow freely upon the metal. As the surface of copper is continually altered by the mere action of the air, the workmen, before the tinning of any vessel, scrape its surface with a fied instrument till it be clean and bright; then they place the vessel upon kindled coals, and heat it to a certain degree: as soon as it is hot, in some processes of tinning, they rub it with pitch, and apply the melted tin, which they spread upon the surface of the copper by means of bars. For this purpose pure tin is seldom used; but, in general, two parts of tin are alloyed with one part of lead.

The pitch used in this latter mode of tinning is quite necessary, because the degree of heat given to the copper is sufficient to calcine its surface in some degree; and this alteration, however slight, would prevent the perfect adhesion of the tin, unless by means of the pitch the phlogifon was restored to it at the very instant of the application of the tin. The pitch also prevents the flight calcination which would happen on the surface of the tin, or revives the small particles of calx which are formed during the operation. In either way, or in the method of tinning iron plates, the success of the operation depends on the facility with which tin unites with these metals, which incorporates with them, diffuses in some measure their surface, and forms a kind of alloy, at least when the tinning is well performed; and moreover, on the cleanliness of the surfaces, both of the melted tin, and of the copper or iron to which it is applied; for the metals cannot perfectly unite unless they are in a metallic state, and free even from their own earth or calx.

It has been alleged that copper vessels, so pernicious in themselves, are not perfectly preferred from rust or verdigris by tinning; and, besides, tin itself is combined with arsenic, and lead is also used in tinning. M. Malouin has, therefore, proposed in his Memoirs on Zinc (Mem. de l'Acad. Sc. 1742.) to substitute that metal in place of lead and tin, for the tinning of iron and copper vessels; the greater hardness of the zinc, it is thought, would render it less liable to be worn, and the dangerous effects of lead and tin would be avoided. Macquer's Dict. Chem. Engl. edit.

The plumbers, on some occasions, tin or whiten their sheets of lead; in order to which they have a tinning furnace, filled with live coal, at the two sides of which two men are placed, who hold up the sheets over the fire to heat: and the tin-leaves being laid over them, as fast as the sheets grow hot, and the tin melts, they spread it, and make it take by rubbing it with towel and rain.

TINNITUS AURINUM. A very common disease in the fenes of hearing, is when certain sounds, like those of a drum, a bell, the falling of water, &c. are heard, when no such noises actually exist, or can be heard by other persons. This affection is called tinnitus aurium, of which various kinds have been oberved. For the most part, it is a very light transient disorder; but sometimes it is most obstinate, long continued, and troublesome. It sometimes arises from the flighted case, such as any thing partially flapping up the meatus auditorius, or Euftachius tube itself, so that the free passage of air into the cavity of the tympanum is interrupted. A kind of tinnitus is heard by the most healthy when they yawn.

A much more frequent and troublesome species of tinnitus accompanies many diseases both of the feble and nervous kind. This is said to be occasioned partly by the increased impetus of the blood towards the head, with an increase of sensibility in the nervous system itself, so that the very beatings of the arteries are heard; and partly by the augmented irritability and spasmatic motions of the little muscles within the organ of hearing. In fevers, the throbbing of the carotid arteries at the sides of the fella turcica has produced excusive annoyance in particular individuals, especially when they were in the recumbent posture; and the celebrated Haller informs us, that when he was afflicted with fever, he suffered much from the beating sensation caused in his ears, as he suppos'd, from the pulsation of the carotids in the neighbourhood of those organs.

According to writers, tinnitus aurium sometimes arises from a vehement affection of the mind; sometimes from a disorder in the stomatch; sometimes from rheumatism extending its effects to the ears and head; or from a catarrh, producing a temporary obstruction in the Euftachian tube. In the foregoing examples, the cure of the affection of the ear depends upon the removal of the other disorders, of which it is merely an effect.

In certain cases, tinnitus aurium occurs as a separate independent disorder, and may be the caufe of long-continued, distressing suffering. The existence of unreal sounds in the organ of hearing generally prevents the patient from hearing distinctly other fonorous impressions, and, of course, more or less deafness is a common attendant of the complaint.

The writer of this article lately had a patient, who is attacked five or six times every year with tinnitus aurium, which ceases for several days the most annoying sensations in the ears, and a considerable degree of deafness. The disorder is always accompanied with severe pain in the branches of the nerve coming out of the infra-orbital foramen, head-ache, indigestion, and many symptoms of the nervous and bilious kind.

In this case, relief is obtained by fomenting the affected ear with a decoction of poppies, and washing out the meatus auditorius with a fyring and warm water. However, these means are always affiliated with a few doses of calomel and rhubarb, without which, in all probability, the local applications would not entirely answer.

We have also had other cases, in which a strong solution of opium in water, camphorated oil, blisters, &c. were the remedies employed.

The tinnitus aurium, produced by fevers, sometimes does not subside at their termination, but lasts, either in a continued or periodical form, during life. Two such infancies are now within our own recollection; and every man of experience must have witnessed the fame thing.

TINNUNCULUS, in Ornithology, the name of one of the long-winged hawks, called by Linneus Falco tinnunculus; which is it.

It is about the size of a common pigeon. Its bill is short, crooked, and very sharp, and covered with yellow skin at the top; near this the bill is white, elsewhere it is blue; its tongue is biff; its mouth very wide, and its palate blue; its head is large and flattened, and is of an ash-colour, with longitudinal streaks of black; its back and wings are brown, variegated with black spots; its rump is grey, with some transverse black spots; and its breast and belly of a pale rust-colour, with a few longitudinal streaks of black; its tail is long and pointed, its tip of a pale ferruginous hue, with a broad transverse streak of black over it; and the rest of the tail is a mixed grey and brown, with black spots and streaks; its legs and feet are of a fine yellow.

The tinnunculus, or keelrel, breeds in the hollows of trees, in the holes of high rocks, towers, and ruined buildings:
buildings: it lays four eggs, which are white, variegated with a number of red spots; its food is field-mice, small birds, and insects.

This is the hawk which we so frequently observe in the air fixed in one place, and as it were fanning with its wings, at which time it is watching for its prey. It flings up the indiglided fur and feathers in form of a round ball. Ray and Pennant.

TINO, in Geography, a small island near the coast of Genoa, at the entrance of the gulf of Spezzia; 8 miles S. of Spezza. N. lat. 44° 3'. E. long. 9° 40'. See Tineto.

Tino. See Texos.

The form of this island is oval, about 60 miles in circumference. It is mountainous, but its rich plains are decked by the opulence of industry. Its fruits are excellent and its wine good; but the most abundant of its productions is silk, which is manufactured by the females, who are highly commended for the beauty of their perfons and the elegance of their dress. The inhabitants are active and industrious, most of whom are of the Greek church, though it is the seat of a Roman Catholic bishop. It is reckoned one of the most agreeable islands of Greece, but has no good harbour. The small town of San Nicolo is built on the ruins of the ancient Tinos. Its capital bears the name of the island. N. lat. 37° 30'. E. long. 25° 8'.

Tinphadum, or Tiphadum, in Ancient Geography, a place of Africa, in Numidia, upon the route from Theveti to Sittens, between Thevetie and Vegefolis. Ant. Itin.

TINSEDA, in Geography, a town of Africa, in the country of Darah. N. lat. 27° 30'. W. long. 5° 46'.

TINTA, a town of Peru, in the bishopric of Cufco, and jurisdiction of Canas y Canches, sometimes also called Tinta; 60 miles S. of Cufco.

TINTENIAC, a town of France, in the department of the Ille and Vilaine; 9 miles S.E. of Dinan.

Tintinabulum, among the Ancients. See Bell. Tinto, in Geography, a river of Spain, in the province of Seville, which owes its name to its waters being tinged of a yellow colour. It is also of a petrifying quality; and it is said that it destroys all verdure, and that no fish can live in it. Its nature, however, is changed by the confluence of other rivulets; for when it passes by Niebla, it is not different from other rivers: and it falls into the Atlantic, six leagues lower down, at the town of Huelva, where it is two leagues broad, and admits the passage of large vessels as high as San Juan del Puerto, three leagues above Huelva.

TINTON, a town of the state of New Jersey, near the sea; 12 miles E. of Freehold, in the county of Monmouth.

TINTOQUE, a town of Mexico, in the province of Xalisco; 45 miles S.S.W. of Compotella.

Tintoretto, II., in Biography, the cognomen of a celebrated Venetian painter, whose real name was Giscopo Robuuti. He was born at Venice in 1512, the son of a dyer; from whence he acquired the name of II Tintoretto. His natural disposition towards the art of drawing manifested itself very early, and his father had the wisdom to indulge it; and feeling it likely to lead to something decisive, caused him to be instructed in painting, and finally placed him as a pupil with Titian, then in the prime enjoyment of his reputation and power. It is a painful thing to relate, and a severe lesson to the pride of the most able, that where so much ability, so much honour and wealth abode, the mean and degrading passion of jealousy should have found encouragement. Titian, the great, the honoured Titian, that man who possessed a mind capable of grasping almost all the art of painting required, who was richly and highly honoured, courted, and employed, is said (and the truth of the story rests upon too found authority) to have been with the corroding pangs of jealousy the early essays of his pupil Tintoretto, and to have permitted it to operate so strongly upon him, that he excluded the dreaded object from his house, about ten days after his admission.

But the aspiring talents of the young painter were not to be damped by so mean a measure, though even in the powerful hands of Titian. To him disaffection from the eye of a master was emancipation. He dared to think for himself, and boldly aimed at election in art, and an union unthought of till then; and as Lanzi says, generously aspired at the honour of being the founder of a school and style of his own, by combining the form of the great Florentine, M. Angelo, with the colour of his former master. To maintain a due excitement to the performance of so bold an undertaking, he wrote upon the wall of his study, "I l'ingegno di Michel Angelo e il colorito di Tiziano;" and with all the ardour of an intrepid mind, endeavoured to perfect the task he had assigned himself, by copying whatever pictures of Titian he could procure during the day, and drawing by night from calcts taken from the works of M. Angelo, together with many others he procured from ancient respectable statuary. It is doubtless to his studies by night and the lamp, that he acquired that perfect mastery of chiaro- scuro, those decided masses of light and shade, which distinguishes his works, both in his groups and single figures. Add to these labours, that he modelled in wood and clay, and cloathed his figures rudely, arranging them in different lights, and sometimes hanging them from the ceiling, to acquire, by drawing from them in that position, the knowledge of the figlio in fis, then much in use for the adornment of ceilings, and in the houses of the grandees. By these deep studies, and a perfect knowledge of anatomy, he was enabled to exert the exuberant and glowing fancy with which nature had blessed him, in the freest and boldest manner; and had he always applied his powers with equal intenseness with a careful discrimination of what was due to his own honour, there can be no doubt but that he would have left a name unrivalled in art. This for some time he attended to, and some of his best works lack only character and expression to place them in the highest rank. The large picture which lately adorned the walls of the Louvre, but is now returned to its original sitation, the Scuola di S. Marco at Venice, is a work of this class, which he painted when only 36 years old; and another is the Crucifixion, in the Scuola di S. Rocco. The former is known by the name of II Servo, and represents the miracle of St. Mark defending, and breaking the bonds of a slave condemned to death by Turks. Grand but not correct in its style of design, astonishing the mind by the intrepid boldness of its colour and execution, it displays more complete mastery of the materials of art than is to be found in the works of any other painter. If there be any fault in this astonishing performance, it is that the subject is lost in the splendour of the execution, the spirit in the matter in which it is embodied. The fame cannot be said of the Crucifixion above mentioned, in which the glowing deep and ominous tone preserved through the whole, produces the most perfect unity, gives strength of expression to the picture, and overwhems the spectator with terror. All seems to be hushed in silence round the central figure of the Saviour suspended on the crosses, with his faithful mother, and a group of male and female mourners at his feet; and though many are the improprieties of costume and of action, yet all vanish in the power which comprefses them to a single point, and we do not detect them till we recover from the first impression. Unhappily for his fame, he was not always so careful in his labours;
labours; and the impetuosity of his mind, or perhaps the feelings of his employers, who were numerous, did not allow him sufficient time to do justice to himself; and he permitted many pictures to leave his studio, possessing only the freedom of colour and execution which peculiarly belonged to his pencil.

Tintoretto was so certain of his execution, that he is said by Sandrart to have frequently wrought without a previous sketch, or any preparatory outline, finishing as he went on, and adapting his labours to the price he was to receive; not sufficiently considering that his works would outlive their author, and deprive him of a large portion of the fame so justly due to his power, when efficiently exercised. It was, therefore, truly observed by An. Caracci, that in some of his works, Tintoretto was not inferior to Titian, while in others he fell below himself.

One remarkable influence of his intrepidity and impetuosity of genius, and promptness of execution, is related by Vasari, viz.: The confraternity of S. Rocco at Venice had determined to decorate their church with a picture of the apotheosis of their patron saint, and defirous of having the choice of good designs, commissioned some of the most eminent artists to make compositions for their erection. Paolo Veronese, A. Schiavone, Salviati, Zuccherio, and Tintoretto, were the competitors. On the day appointed for their decision, the good fathers were astounded to find a finished picture by Tintoretto placed in the appointed situation; and when they remonstrated upon fo extraordinary a proceeding, as they had only required a design from him, he told them that was his way of making designs, and that if they hesitated to pay him for his trouble, they were welcome to the picture, which was allowed to keep possession of its honours. His compeers rendered due justice to fo extraordinary an exertion, and denominated him Il furioso Tintoretto.

To do justice to the power of Tintoretto, he must be contemplated on the grand theatre of his pictorial existence, viz. at Venice, where alone his grander works are to be found; and there the public buildings are filled with them, in the higher and lower degrees of excellence. In style, the grandeur which he borrowed of Michael Angelo was rather muscular enlargement of line, and that not always correct, than feclct or characteristic; and it is not often that he rises above common nature; mostly so in his female characters, though they are often too slender for truth of action, and too affected for grace. His touch is delightfully free, with a full impaso of colour, and his chiaroscuro of the richest and most brilliant kind. He lived to the great age of 82, and died at Venice in 1594.

Tintoretto left a daughter named Marietta Robusti, who was born at Venice in 1560, and whom he instructed in the art of painting, principally in portraiture, in which she acquired considerable practice and reputation; painting many of the principal personages in her native city. She had the honour to be invited to the courts of the emperors Maximilian and of Philip king of Spain; but her father would not be prevailed upon to part with her. She died soon after him, in 1590. He left also a son, Domenico Robusti, who practiced the art with considerable success, though not with the fire of invention or execution which characterized his father’s productions. He was born at Venice also, in 1562. His principal works are in the Sala di Coniglio and the Scuola di San Marco at Venice. Portraiture was, however, his principal occupation, and most suited to his genius; and he had the honour of being eminently patronized. He died in 1637.

TINURTIUM, Tournus, in Ancient Geography, a town of Gaul, on the route from Lugdunum to Gergovia. Anton. Itin.

TINUS, in Botany, a name in Pliny, book 15, chap. 39, for what he says is sometimes termed a sort of wild laurel, and is distinguished by the blue colour of its berries. This description is universally agreed to apply to our Laurus-tinus, Vitanum Tinus of Linnaeus; a plant likewise indicated by Ovid’s

*Etot bicolor myrtus, et bacis coroala tinus.*

Linnaeus has transferred this name to a West Indian shrub, supposed by him to constitute a new genus, having some resemblance to the above shrub.—Linn. Gen. 200. Schreb. 276. Jull. 264. and 451.—Cliffs and order, Eneacandra Menegynia.

The characters of this however were discovered by Swartz to be founded in error, the plant being a genuine species of CLEITHRA; see that article, n. 5.

The origin of the word Tinus has been fought by Vaillant in the Greek *tinos*, small, or dwarf, as meaning a smaller or more humble kind of laurel; but this is scarcely correct, nor does the derivation by any means satisfy us.

TINZ, in Geography, a town of Silezia, in the principality of Brie; 22 miles W. of Brie.

TINZULIN. See TINULEN.

TIO, a town of South America, in the province of Cordova; 70 miles E. of Cordova.

TIOGA, a county of New York, erected from Montgomery county in 1751, and from the E. part of this county. The county of Brome was erected in 1806. Tioga is bounded N. by a small angle of Steuben county, and by Seneca and Cayuga counties; E. by Brome county, S. by the state of Pennsylvania, and W. by Steuben county. Its form is nearly that of a square, 26 by 34 miles; its area 571,506 acres: between 42° 54' and 42° 25' lat., and 2° 14' and 3° W. long. from New York. Its towns are Condor, Caroline, Catharinas, Cayuta, Chemung, Denby, Elmira, Owego, and Spencer its capital. Its eastern part is traversed by the Susquehanna; and the Tioga, the principal W. branch of that river, waters the S.W. part. The surface is considerably broken and hilly. It is rapidly increasing in population, and contains a large proportion of good farming land. Rafts, arks, and small boats descend the waters of this county, and find the principal market at Baltimore, in Maryland. Tioga sends one member to the house of assembly.

Tioga, a large township in the S.W. corner of Brome county, 13 miles W. of Chenango Point; bounded N. by Berkshire, E. by Union, S. by the state of Pennsylvania, and W. by Tioga county; about 15 miles long from N. to S., and 7 broad, having the Susquehanna running W. across its centre. The soil is various, and the surface uneven. It yields various kinds of trees, grain, and pasture. Fruit in general succeeds well, and apples are no where better. This town has been settled since about 1790. —Alto, a river of New York, which runs into the Susquehanna at Tioga Point, N. lat. 41° 56', W. long. 76° 33'.

TIOLO, a town of Italy, in the Valtelline; 10 miles S.W. of Bormio.

TION, a river of France, which runs from the lake of Annecy to the Siers.

TIOOKIEA, one of King George's islands, in the South Pacific ocean, discovered by commodore Byron. It is a low island, with a large lake in the centre. Captain Cook went to examine a creek, which he supposed communicated with the lake. They found the creek fifty fathoms wide at the entrance, and thirty deep; farther in thirty wide and twelve deep; the bottom everywhere rocky, and the sides bounded with coral rocks: dogs seemed to be in great plenty, but no fruit
fruit was seen but cocoa-nuts. The inhabitants of this island, and perhaps of all the low ones, are of a much darker colour than those of the higher islands, and seem to be of a more savage disposition. This may be owing to their situation, nature not having bestowed her favours on these low islands with that profusion she had done to some of the others. The inhabitants are chiefly beholden to the sea for their subsistence; consequently are much exposed to the sun and weather, and by that means become more dark in colour, and more hardy and robust, for there is no doubt of their being of the same nation. Captain Cook's people observed that they were stout well-made men, and had marked on their bodies the figure of a fish, a very good emblem of their profession. S. lat. 14° 27'. W. long. 144° 56'.

TIPASA, in Ancient Geography, a town of Italy, in the country of the Sabines, on the route from Reate to Liffa, between Latia and Liffa.

TIORNEBIERG, a small island in the Baltic, near the south coast of Lolland. N. lat. 54° 42'. E. long. 11° 18'.

TIPRESA, a town of Hindostan, in Oude; 10 miles S.E. of Goorapour.

TIPARENUS INSULA, now Specia, in Ancient Geography, the isle of Tiparenus, situated in the Argolic gulf, separated by a small canal from the continent, which established a communication between the gulf of Hermione and the Argolic.

TIPASA, TIPA, a town of Africa, in Mauritania Cesariana, according to Ptolemy and the Itin. Anton. having the title of colony, and situated on the route from Carthage to Tingis, between Cerasarea Colonia and Casa Calunti. It still prefers its ancient port, and has some remains of ancient walls.

TIRE, or TYPE, in Rural Economy, a trap or device of the wooden box, or excavated earth kind, for catching or taking rabbits, &c. These traps or nets are set or formed in a particular track at the time the rabbits have departed from the warrens, or parts of them, in search of food, all the other holes or ways of return being flapped up. Dogs are then employed in forcing the rabbits to return, when they are taken in the traps or nets. The traps are formed of different numbers and sizes, according to the nature and extent of the warren.

TIPER, or TIPA, in Geography, a country of Asia, annexed to Bengal, bounded on the N. by Silhet, on the E. by Ava, on the S. by Chittagong, and on the W. by Daec, about 100 miles long, and 50 broad: the inhabitants are said to be most subject to goitres or wens in the throat, a disease generally attributed to the water drank. Comilla is the chief town. A town of the same name is laid down in some maps, as situated on the river. N. lat. 24° 20'. E. long. 118°.

TIPHA, in Ancient Geography, a small town of Greece, in Bucotia, situated on the gulf of Corinth, in which was a temple of Hercules, whose feast was annually celebrated. Paulanias.

TIPICA PRINCEPS, one of the Hebrew accents, sometimes serving for a comma, and marked under a letter (').

TIPHA, in Entomology, a genus of the Hymenopterous order of insects, in the Gmelinian frymer of Linnaeus; the characters of which are, that the mouth has a membranous roundish jaw, a mandible arched, and acute, a short tridentated lip, and no tongue; the feelers are four, filiform, unequal, stretched out in the middle of the lip; and the antennae unifiliform and arched. This genus includes the following species.

- Vespaformis. Black, with a ferruginous abdomen, black at the base, and cyanous wings. The sphex vespaformis of Fabricius. Found in Malabar.
- Grassicornis. Black, the abdomen with three bands, the legs ferruginous, and the wings cyanous. Found in Spain.
- NIGRA. Black, without spots. An European insect.
- MEMORATA. Black, with the four hinder thigs angulated and red. Found in England.
- Histrionica. Black, thorax maculated, abdomen with five yellow bands, the two foremost interrupted. Found in China.
- Quinquecincta. Black, thorax spotted, abdomen with five yellow bands, the second interrupted. Found in England.
- Ciliata. Black, the segments of the abdomen yellow, with ciliated margin. Found in Spain.
- Hesperaethus. Black, the abdomen with five yellow spots on each side, the toes and legs red. Found in South America.
- Ephippium. Black, the thorax with a red dorval spot. Found in South America.
- Radula. Hairs black, thorax reddish before, the second and third segments of the abdomen yellow. Found in New Holland.
- Dorsata. Black, the second and third segments of the abdomen yellow. A Comandell insect.
- Rupicormis. Ferruginous spotted with black, yellow abdomen, and four black bands. Found in Tranquebar.
- Tricincta. Black, the abdomen with three yellow bands, the anus and legs ferruginous. Found in South America.
- Collaris. Black, the thorax on the fore-part cinerous villous, behind reticu, with cinerous wings. Found in Malabar.
- Pedestrus. Apterous, black variegated with yellow, thorax compressed. Found in New Holland.
- Tiphle, in Ichthology, a name by which some authors express the acus, or tobacco-pipe fish.
- TIPICA, in Geography, a town of Peru; 30 miles E. of Lipis.
- TIPING, a town of Corea; 25 miles S.E. of King-kia-tao.
- TIPOCA, or TAPICA, a town given by some authors to a fort of cream or flour made from the yucca or manihot-root, by maceration of it in water, after expressing the juice.
- TIPOR, in Geography, a town on the west coast of Celebes. S. lat. 2° 5'. E. long. 119° 22'.
- Tippacanos Creek, a river of North America, which
which runs into the Wabash, N. lat. 40° 18'. W. long. 86° 56'.

TIPPALE, a river of England, in Northumberland, which runs into the Tyne, near Haltwhistle.

TIPPERARY, a county in the province of Munster, Ireland, extending in a very irregular form between the King's and Queen's counties on the north, the latter county and that of Kilkenny on the east, the counties of Waterford and Cork on the south, and those of Limerick, Clare, and Galway on the west. From the two latter counties, the river Shannon forms a natural boundary; as the river Suir does from Waterford for about 14 miles on the south. The length from north to south is 52 Irish (or 734 English) miles, and its breadth 31 Irish (or 393 English) miles. It contains 554,690 acres, or 867 square Irish miles, equal to 823,988 acres, or 1,420 square English miles, including bogs, mountain, and waste. There are twelve baronies, two of which, Upper and Lower Ormond, gave the title of duke, as they now do that of earl, to the family of Boteler, or Butler, so distinguished in Irish history. The population of Ireland not having yet been satisfactorily ascertained, little can be said on the subject. Dr. Beaufort stated the number of houses in 1792, at 30,705; and from the means of information he had, and his usual accuracy, there can be little doubt of his correctness: but from the great increase of tillage since that time, the number of houses must have increased, though Tipperary has had more caucuses to retard this increase than any other county in Ireland: 30,703 haunds, at an average of 4½ souls per house, would be about 169,000; but if, according to Mr. Buffle's opinion, as given in the Tracts of the Irish Academy, we take 6½ as the average, it would exceed 190,000, a very small population for such an extent of ground. The number of parishes is 187, which, when Dr. Beaufort wrote, were comprised in 63 benefices, and had only 46 churches. A number of churches have however been since built, as well as several glebe-houses, and some benefices have been divided; to which the exertions of the present archbishop of Cashel (Brodrick) have greatly contributed. Unions of parishes which were formed, when from the state of the country the income of a parish was very small, and the number of inhabitants very few, are now as unnecessary as they are injurious. The archbishopric of Cashel, and bishopric of Emily, which are united, contain 116 parishes, Waterford 32, and Killaloe 41. Tipperary returns four members to the imperial parliament, two knights of the shire, and two for the boroughs of Clonmel and Cashel. This reduction was less than in most other counties, as Tipperary had only three boroughs before the Union, of which Feather was disfranchised. Though the towns represented are considerable ones, especially Clonmel, yet the boroughs are both what are called close ones, the proprietors in fact exercising an undisputed right of chusing the member. The lands of Tipperary have been always ranked amongst the most productive in Ireland, and one tract in particular, including the neighbourhoods of Tipperary and Cashel, has been called the Golden vale, on account of its extraordinary fertility. It has however been always a great grazing country; and as this system drives the peafantry into barren mountains, or forces them to crowd into towns and villages, that they may procure a precarious and wretched subsistence, they too commonly become turbulent, violent, and discontented. Whether this be the cause or not, such is certainly the character of the peafantry of this county, who have been engaged in every disturbance, and who are now groaning under an infurrection act, attended with enormous expense, which the usual parliamentary opponents of government could not object to, and which, though there is an apparent calm, it would be yet unsafe to repeal. The increase of tillage would operate favourably, but the exemption of grazing land from every kind of tithe, operates as an encouragement to it, which the present state of the market for grain is not likely to counteract. Whilst, however, Tipperary contains a considerable portion of very fertile land, it has also extensive tracts of bog and mountain. Of the former, the most extensive is a tract lying in the north-east of the county, between the towns of Roscrea, Templemore, Limerford, Littleton, and New Birmingham, and forming a part of the Great Bog of Allen. This was surveyed by Mr. Ather, of Castle-comer, under the directions of the commissioners for enquiring into the nature, extent, &c. of the bogs of Ireland; and from his report it would appear, that about 36,000 acres, mostly in this county, might be safely reclaimed, and at a moderate expense, on account of the favourable situation for draining, and the abundance of limestone gravel, of which the district is principally composed, and which is the best material for reclaiming them. To the south of this range of bog, and situated between the small town of Killenaule and the county of Kilkenny, is the coal district. It resembles what has been called the Leinster coal district in the very able geological and mining report lately given of that district by Richard Griffith, efq., mining engineer to the Dublin Society. It seems indeed to be only a continuation of that district, and is separated from it by a secondary limestone country. The species of coal is the carbonaceous or stone-coal, better known by the name of Kilkenny coal. To the south of this, and in the south-eastern angle of the county, is Sliebh-na-man mountain. On the borders of the county of Waterford, over the town of Cloghen, are the Knockmeal-down mountains, which occupy a considerable space in both counties. Nearly parallel to these, and north of them, are the lofty Galtees, extending from the borders of Cork and Limerick to the town of Caher. Between these and the town of Tipperary is the lower range, called Sliebh-na-muck; but the greatest extent of mountain crosses the county from south-west to north-east, running from the county of Limerick to the Queen's county, and completely separating the two Ormonde from the rest of the county. The high hills adjoining Limerick are called the Keppe mountains, from the highest of them, which is a remarkable object to the traveller and the adjoining country. The hills near the small town of Silvermines, have been marked in some maps as the Silvermines mountains; others have been called the Devil's Bit; and adjoining the Queen's county, they take the name of the Sliebh-bloom mountains. In this district, lead and copper mines have been wrought with various success; and some parts of it afford fine mill-races. The river Suir rises in the north of the county, near Roscrea, and flows from north to south, when it takes an easterly direction, and becomes the boundary between it and Waterford. This and its tributary streams afford an abundant supply of water, and turn a very great number of boulting-mills. The western division of the county has the Shannon for its boundary, and is well watered by the streams which flow to it from the range of mountains above mentioned. Clonmel, on the Suir, and at the southern extremity of the county, is the thre-town, and though very inconveniently situated for the affizes, has an excellent gaol, court-house, &c. It is a place of considerable trade, and one of the principal inland towns of Ireland. Cashel, Roscrea, Nenagh, Tipperary, Carrick, and some others mentioned in their proper places, are of respectable size, but none of them distinguished for trade or manufactures, unless we except the manufactory of ratteens.
Tipperary was, previous to the arrival of the English, a part of the kingdom of Munster; sometimes separated as an independent soverignty under the kings or princes of Cashel. The name Ormond is a corruption of Oir Momond, i.e. East Munster, and was so called in opposition to Desmond, South Munster, and Thomond, North Munster. After the English settlement, the O'Brien's were confined to Thomond, the Fitzgeralds established themselves in Desmond, and the Butlers became the possessors of Ormond and Kilkenny, acknowledging indeed the sovereignty of England, but maintaining such authority as rendered it only nominal. The counties of Kilkenny and Tipperary were palatinate; and it was not till the attainer of the duke of Ormond, in 1716, that this distinct jurisdiction was abolished. As the inhabitants of Tipperary were actively engaged against the Protestants in 1641 and the succeeding years, great fortifications took place on Cromwell's successes, and many of the present landholders are descendants from his officers. Tipperary abounds with ruins. The number of old castles is very great, some of them boldly situated, and forming very striking objects to the traveller: such as the castle of Ardbranant, built by king John, and that of Cabier, on an island in the Suir. The chief ecclesiastical ruins are those of Holycrofs, Monaincha, and Cashel, which all deserve to be visited by the curious. No authentic account has been published of the county of Tipperary, and there appear to be very scanty materials for its history.

Tipperary, a market and port-town in the county of the same name, 87 miles S.W. from Dublin, and about 20 miles N.W. from Clonmel, on the road to Limerick. Its name is said to be in Irish Tiobrad-arain, signifying the well of the territory called Arain. The town is not large, and appears to be in a ruined condition, though it was formerly of sufficient importance to give its name to the county. The adjoining country is very rich, and there are some fine feats, especially Thomlawn, the splendid feat of the earl of Llandaff, defended from the Mr. Matthew whom Swift visited; and Damers-Court, a feat of the earl of Dorchester. In the neighbourhood are the ruins of Emly, the church of which was once the metropolitan church of Munster, and which still gives name to a bishoppical see of Cashel.

Tipul. See Tipula.

TIPREE, a dry meature at Bombay; where the candy contains 8 parshes, the parsh 16 adowles, 64 feers, or 128 tippees. Rice is sold by the batty measure, in which the morah = 4 candies, or 25 parshes, the parsh 20 adowles, 150 feers, or 300 tippees. A candy is = 25 Winchefter bufheles nearly.

Tipsa, in Geography, a town of Algiers, in the province of Constantia, on the borders of Tunis, near the banks of the Melagge, anciently called Tipaza; at present a frontier city and garrison of the Algerines. This place, which enjoys a fine situation, with some mountains at a small distance, Rill preserves the principal gate, several fragments of old walls, and other marks of the rank and figure it formerly obtained among the cities of Numidia; 85 miles S.E. of Constantia. N. lat. 35° 27'. E. long. 8°.

TIPSTAVES, officers appointed by the marshal of the king's bench, to attend the judges with a rod or staff tipped with silver, and take charge of such prisoners as are either committed, or turned over at the judge's chambers.

The denomination is also sometimes given to those more frequently called bodons; who are the wardens of the fleet's officers, attending the king's court with a painted staff, for the taking into custody such prisoners as are committed by the court; and to attend such prisoners as go at large by licence.

Tipul, in Natural History, a name given by the people of the Philippine islands, to a species of crane common there, and so tall, that when it flands erect, it can look over a man's head. See Dongo.

Tipula, in Entomology, a genus of the Diptera order of insects, the characters of which are, that the mouth has a short proboscis, membranaceous, canaliculated on the back, receiving a bristle; the haustellum short, without a vagina; the feelers two, incurved, equal, filiform, longer than the head; the antennæ are mossily filiform.

The smaller species of this genus so much resemble gnats, that the generality of authors, not excepting even Goedart and Swammerdam, have confound the two genera, and described these among the gnats.

The long form of the body, the position of the wings, and the length and position of the legs, are the circumstances that make the resemblance between the gnats and tipula; but the structure and organs of the head are alone a very sufficient distinction.

As the tipula differ from the gnats in the figure of the mouth, and in being without a trunk, they differ as much from the other flies of that character, by resembling the gnat in the shape of their body. They differ also in the conformation of the mouth, and its several parts and organs. The opening of the mouth is a slit extending itself from the fore part of the head toward the hinder part, and its lips cannot be called upper and lower; but they are lateral ones. When the body of the creature is pressed, this mouth opens, and shews what seem to be a second pair of lips within. These are more firmly closed than the others, and resemble only certain duplications of the floor. The exterior lips are cartilaginous, and are furnished with short hairs; the interior are perfectly smooth, and of a fleshy texture. The head of the tipula is of a long and slender figure; the lips are articulated at the extremity of this head, and on each side there stands, on the upper part, a fort of beard, which, when minutely examined, is found to be articulated in the manner of the antennæ of insects. These two beards, in their usual position, are placed close together, and bent forwards over the head; their office seems to be the covering of the aperture of the mouth. These seem constantly to be found in all species of the tipula, and placed exactly in the same manner.

The largest species of tipulae are usually found in our meadows, and those are in no danger of being confounded with the gnat kind, their size alone being a sufficient obvious distinction. These are often found of nearly an inch in length from head to tail; but their bodies are very slender, and are composed of only nine rings. The male tipula is easily distinguished, at sight, from the female; it is much shorter in the body, and is thicker at the tail than any where else; this tail usually turns upwards, whereas that of the female is placed in the same line with the body, and is slender, and composed of several fealy parts, proceeding from the last ring of the body. These creatures are found in our meadows through the whole summer; but the end of September and beginning of October is the time when they are most of all plentiful.

The legs of these creatures are greatly disproportioned to the body, according to the common rules of nature, especially the hinder pair, which are in the larger species usually three times the length of the body.

This large species is a creature of no great beauty; its body is of a brownish colour, and its corcel is so elevated, that the creature seems hump-backed; the head is small, and
the neck very short; the reticulated eyes are so large, that they cover almost the whole surface of the head; these are of a greenish colour, with a cast of purple, when viewed in some lights. Reaumur supposes that two very lucid specks, on the anterior part of the breast, are eyes, though placed in so very singular a manner; the wings of this creature are long, but very narrow, and seem fearfully well proportioned to the size of the animal; they are transparent, but have a flight call of brown; and their ribs, when viewed by the microscope, appear beft with scales, or feathers, in the manner of those of the great kind. Some species of the tipula have them also fringed with these scales at the edges; there are no ailerous, or petty wings, at the origin of these, but in the place of them are two very fine balancers or mallets; these have long pedicles, and roundish or oval heads; the frigmenta of the corselet are four; one pair is placed immediately underneath these balancers, and the other immediately below the first pair of legs; the first pair is very long, the others small, and those on the rings of the body, if there be any, are too small for our flight, even with good glasses. Each ring of the body is compoied of two half cylinders, which are joined into one, by means of a membrance, which gives them room to digest or close up at the creature’s pleasure. The large tipula all carry two anten- nas, or horns, upon their heads; but these are of no remark- able structure, they are only compoied of a great number of joints, each covered with a fine downy hairiness; and at the joining of each to the next, there is a tuft of longer and more stiff hairs. This is the description of the common large tipula which we find in the meadows, and in almost all its parts is applicable to the generality of the larger species of these insects.

The smaller kinds are very numerous, and of great variety. These are frequent in all places, and at all seasons of the year; the spring shews us immense clouds of them, and even the coldest winter’s day shews a great number of them in the sun-shine about noon. These creatures fly much better than the larger tipula; they seem indeed to be almost continually upon the wing, and their manner of flight is very singular; they are continually mounting and descending again, and that without quitting the direction of the line in which they go forward; this they will often do for many hours together. In tracing these flies from their origin, they are all found to be produced from worms which have no legs, and have a regular faly head. Thofe from which the larger tipula are pro- duced live under ground; they are molt fond of marshy places, but any ground will do that is not often disturbed. They usually are found about an inch under the surface, and are fo plentiful in some places as greatly to injure the herbage.

These creatures do not find it necessary to their living, that plants should be upon the surface of the earth in which they live. There is frequently found in the hollows of the trunks of old trees, a fort of earth which seldom produces any vegetables; yet the female flies of this species well know that their young will find a proper habitation there; and there are usually found great numbers of them in all these places. The hollow elm and willow, fo common in our hedges, and by ditch sides, afford innumerable proofs of this; but it must be observed, that they are only found in such earth of this kind as is continually somewhat moist.

M. Reaumur mentions a very singular species of large tipula, which was produced with him from one of the worms found in the earth of an old elm; this was of the larger kind, and had some beautiful spots on the wings. It had also a very elegant tufted antenna; whereas, in the common large tipula, these are plain and simply granulated ones, as well in the males as females. Reaumur’s Hist. Inf. vol. ix. p. 7, &c.

The numerous species are distributed, by Gmelin, into several classes, as follow:

*With patent Wings.*

**PECTINICORNIS.** With pectinated antennæ; the wings with a black spot; the thorax yellowish. Found in moist places in Europe.

**RIVOSA.** With hyaline wings; rivules brown, with a snowy spot. Frequent in Europe.

**Sinuata.** With white wings, fringed margin and spots brown; cinereous body, and ferruginous feet. Found in the north of Europe.

**Quadrimaculata.** With wings brown-veiny, margin and four spots brown; abdomen above yellowish. There is a variety denominated *calmarinella.* Found in the meadows of Europe.

**Crocata.** With wings having a brown spot; abdomen black, yellow bands. Frequent in the north of Europe.

**Oleracea.** With hyaline wings; the margin of the rib brown. Found in Europe at the roots of pot-herbs, grain, &c. &c.

**Hortorum.** With hyaline wings; scattered obfolute spots. Found among the pot-herb plants of Europe.

**Tricolor.** With white wings; the exterior margin and bilid apex brown. Found in North America.

**Triangularis.** With wings dimidiate-brown, and white triangular spot. Found in Scotland.

**Variegata.** Black; base and sides of the abdomen red, spotted with yellow. Found in the gardens of Europe.

**Contaminata.** Black, with white wings; two bands, and a point black. Found in moist places of Europe.

**Lunata.** With ash-coloured wings, and white marginal lunule. Found in the meadows of Europe.

**Turcica.** With veiny wings; white marginal lunule; cinereous body, and abdomen with a black dorsal line.

**Pratensis.** With variegated thorax; brown abdomen; sides spotted with yellow; front tawny. Found in the meadows of Europe, destroying the roots of grasses.

**Dorsalis.** Yellowish; brown back; hyaline wings; marginal spot black. Found in Germany and Italy.

**Plumea.** Brown-cinereous, with white wings; rib and nerves black. An Italian insect.

**Terestris.** With hyaline wings; brown marginal point; back of the abdomen cinereous. Found in Europe. See *Crane-Fly.*

**Corymbica.** With hyaline wings, marginal point brown; abdomen yellow; three lines brown. Found in Europe at the roots of plants.

**Nigra.** With brown wings, and black body. Found among the plants of Europe.

**Albimana.** Black, with teltaceous thighs, and hinder tarsi white.

**Costalis.** Sordidly yellow; with antennae twice longer than the body; hyaline wings, and brownish coila. Found in Van Diemen’s Land.

**Clavipes.** Brown; with tarsi annulated with white in the middle; ovate, inerinfated. Found in North America.

**Atrata.** With glaucescent wings; marginal point and body black; first segment of the abdomen and feet red. An European insect.

**Bimaculata.** With hyaline wings; two brown spots; the middle of the abdomen spotted ferruginous; plumose ante- nnae; as the former.
**TIPULA.**

**ANNULATA.** With wings variegated with brown; thighs with white rings; as the former.

**OCELLARIS.** With whitish wings, very numerous, blackish, ocellar spots. North of Europe.

**CINEREA.** With whitish wings, three brown spots, cinereous unpotted body. A Norwegian insect.

**FASCIATA.** With whitish wings, four brown flexuose bands; abdomen and feet yellowish. Found in the marshes of Sweden.

**MELANOCYPHALA.** Telfaceous; head and dorsal line of the thorax black; wings hyaline; three brown streaks. A Cayenne insect.

**SEXPECTATA.** With white wings; three marginal brown points; thorax compressed, yellow; dorsal line black. Found in Italy.

**FLAVIPES.** Brown, with obscure wings spotted cinereous, and three brown costal spots; feet yellowish; joints brown.

**TRIPOUNDATA.** With hyaline wings; three marginal brown points; yellow body. Found in Italy.

**FLAVEOENSIS.** With unpotted yellow body; brown back. Found in the fields of Europe.

**ENSIFORMIS.** With lanceolate ferrulate antennae; wings, veins, and spot black. Found in Sweden.

**REGULATIONIS.** With hyaline gloppy wings; cinereous brown body. Found frequently in Europe.

**PILOPI.** Cinereous; with frilled brownish wings; fore-moll legs hairy.

**MOLIO.** Black; with white wings; marginal point brown; pallid feet.

**REPLICATA.** With hyaline wings; margin flinder, recurved; body brown; simple antenne. Found in the waters of the north of Europe.

**MONOPTERA.** Black; with feet and pedes pallid. North of Europe.

**ARUNDINETI.** Whitish; villiform antenne; black eyes. Found among the reeds of Europe.

**BARRACORNIS.** Black; with plumose antenne; simple at the apex. Found occasionally in Europe.

**GIGANTEA.** With wings brown, hyaline, waved longitudinally in the middle. Found in the gardens of Austria and France.

**VESOSA.** With hyaline wings; veins brown, and brown margin. In Upper Austria.

**PLICATA.** Cinereous; with hyaline wings; brown veins; external margin and middle line interwoven in small folds. In Upper Austria.

**PUNCTATA.** With hyaline wings, pointed with black; external margin spotted with black. As the former.

**PHAGONITIDIS.** Yellow; with black head, hyaline wings, and three black points. Found among the reeds in Austria.

**LINEATA.** Yellow; pointed with three lines on the thorax, and four on the abdomen. Austria and Carniola.

**OCREATA.** Black; with hyaline wings, spotted and pointed with black; the band before the hinder tarsi white. Upper Austria.

**BIFASCIATA.** Yellow; with hyaline wings, subfuscicicat with brown. Upper Austria.

**DEPRESSA.** With cinereous thorax; abdomen yellow, depressed; wings yellowish-brown; four marginal spots brown. An European insect.

**DISCOLOR.** Cinereous; abdomen on both sides yellowish; wings with brown and white spot. As the former.

**PELOCINATA.** Black; with antennae semi-pectinated; glaucous wings; marginal point and apex large; thighs and legs red; apices black. As before.

**VERSICOLOR.** Yellow; thorax yellow, spotted with black; abdomen and back, beneath and sides, cinereous; wings, veins, and spot brown. As before.

**MACULATA.** Black; bill, legs, and apex of abdomen yellowish; wings with scattered brown spots. As before.

**LUTEA.** Pale yellow; with yellowish wings. As before.

**FUSCA.** Black; with two yellowish bands on the abdomen; white wings, spotted with black; yellowish legs, joints, and foiles; with the toes brown. As before.

**QUADRIFASCIATA.** Cinereous-yellowish; with grey wings; four yellowish bands, and margin of coila pointed; with yellow legs; black joints. As before.

**OCTOPUNCTATA.** With white wings; eight black points; black abdomen; thorax and legs pale. Found at Paris.

**PARISIENSIS.** Green; with hyaline wings; brown band; the two bands of the abdomen and anus black. As before.

**SECOALIS.** Cinereous; with ciliated wings; eyes, antennae annulated with white; the apex of the abdomen and feet black. Found in fields of rye. Gmelin queries whether the two last species belong to this tribe of insects.

* With incumbent Wings: "Culiciform."

**PLUMOSA.** With greenish thorax; white wings; brown point; and plumose antennae. In the marshes of Europe.

**LITTORALIS.** Greenish; with unpotted wings; and fore-legs very long. In the maritime parts of Europe.

**CINCA.** Livid; with wings and three marginal spots black; the abdomen black, annulated with white. Found in Sweden.

**MOTITRACTRIX.** With fore-legs very large and motatory; with white ring. Frequent in Europe, yellow-green.

**PILOCORNIS.** Blackish; fore-legs as before; thorax lined; white wings unpotted.

**FASCIULATA.** Black; fore-legs as before; sides of the abdomen spotted with ferruginous. Found in Germany.

**TENVENS.** Ferruginous; with white unpotted wings; fore-legs very long and pale. In marshes of Denmark.

**VIBRATORIA.** Fore-legs very large, motatory; white at the apex. Found in marshes of Europe.

**VARIA.** Brown; fore-legs elongated; abdomen yellowish; wings variegated with white and black.

**TREMULA.** Fore-legs very long, motatory; black, with white wings. In the marshes of Sweden.

**FLEXILIS.** Fore-legs motatory, all pallid; wings with duskyish band. In the watery places of Europe.

**MOLISSIS.** With white legs, nine black rings; wings varied with white and cinereous. In the gardens of Europe.

**ZONATA.** Pallid; with wings, two bands, and three points brown; thighs with brown angle. Found in Orford.

**VIRENS.** Green; with unpotted wings; brown foils. A Swedish insect.

**VIRIDULA.** Green; with antennae verticillate, hairy; pallid legs. North of Europe.

**GENICULATA.** Beneath yellowish; lines of the thorax and back of the abdomen black, with white immaculate wings.

**PALLIDES.** Smooth-brown; with hyaline unpotted wings, and pallid legs.

**MACROCEPHALA.** Greenish; with eyes and back of the thorax black. In the marshes and moil shores of Europe.

**PUSILLA.** Green; with three black spots on the hinder
part of the thorax; antennae of the male plumose. In the
ixes of Europe.

MARG. Black, smooth; with blackish wings; fore
thighs furrowed inwards. In the dunghills and potter
ole of Europe: probably a variety of hortulana?

THOMAS. Black, smooth; with black wings; sides of
the abdomen marked with a saffron line. At Upfal.

CHRYSANTHEM. Black, smooth; the abdomen red at
the base; the antenna incrassated, pilose. On the crysan-
themus coronarius of Spain.

FERRUGIATA. Black, smooth; brown wings; abdomen
brown-ferruginous. South of Europe.

JOHNANNIS. Black, smooth; white wings; black point;
short antenna; black legs. In shady parts of Europe.

POMONE. Black, smooth; hyaline wings; black point;
ferruginous thighs. In the plains of England and
Norway.

RUFOCULLIS. Black, smooth; red thorax. At the
Cape of Good Hope.

BREVICORNIS. Black, smooth; with wings blackish at
the margin; abdomen brown; fore-arms spinose. In the
shady gardens of Europe.

PUTERIS. Brown; the base of the wings cinereous. In
the tending soil at the commencement of spring.

FERRIS. Black, obovate, hairy; with blackish wings.
An European insect in clofe places.

INSULARIS. Black, hairy; with ferruginous legs, hinder
elongated.

FORCIPATA. With cylindrical black abdomen; wings
brown-thaline; anus appendicularte. An English insect.

VERNANS. Cinereous; thorax black-lienated; white
wings spotted with brown. In meadows of Denmark.

FLORILEGA. Black, fikken. On the apple-flowers of
Europe, which it destroys.

HORTELANA. With hyaline wings; exterior margin
black. In the flowers of alparragus and apple.

PHALENOIDES. With wings deflexed, cinereous, ovate-
laneculated, ciliated. In the walls of dunghills and mixens
of Europe.

HIRTA. Hairy; with wings deflexed, ovate-ciliated,
telfellated with white and black. In Lapland.

PERSICARIA. Black; with wings incumbent, subic-
ulated; under the leaves of the peach-tree.

NOTATA. Black; with white wings; with a white spot
in front of the sides of the abdomen. In Europe.

JUNIPERINUS. Cinereous; with white wings; margin
villosa; found in the juniper.

CUOCIFORMIS. Cinereous, with pallic legs; wings
marked with two blackish spots. At Upfal.

INCARNATA. Incarnate; with moderate antennse. At
Upfal.

PALUSTRIS. Pallid; black head; reddish abdomen. In
marshes of Europe.

LONGICORNIS. With antennae longer than the incarnate
body. In most places of Europe.

RUPICERES. Black; with red legs; wings black in the
middle; yellowish at the base. North of Europe.

STICTICA. Black; segments of the abdomen white at
the apex; wings with a brown point. In Germany.

PALLIDA. Pallid, pilose; legs punctated with black.
In Germany.

HAFNIENSIS. Brown; lateral line of the thorax and
legs white, unpotted.

FLABELLICORNIS. Pallid; abdomen annulated with
black; wings spotted. Germany.

BIPUNCTATA. Brown; wings cinereous; marginal
point white. Found in Europe.
learning as astonished his readers; but the public in general was still more astonished at his finishing the whole work in eleven years, consisting of thirteen large volumes in 4to.; a work which, by its immense erudition, profound critical disquisitions, and judgment in every kind of literature, acquired him the praise of the whole republic of letters.

Besides this great work, he published during the same period the life of St. Olympia; a letter on the comparative excellence of Italian and Spanish literature; the life of Fulvio Testo; the two first volumes of the Biblioteca Modenese; and all the articles which he furnished to the twenty-three first volumes of the Giornale di Modena, a kind of review and history of new books and discoveries in arts and sciences within the year.

He was knighted by the duke of Modena, though a regular ecclesiastic, and ennobled by his fellow-citizens at Bergamo. To enable him to proceed in his great work with more convenience, his patron augmented his appointment, and gave him an assistant in the library.

His correspondence with the learned throughout Europe must have occupied much of his time; as at his decease, among his papers were found materials for twenty-eight volumes of original letters addressed to him as author of the Literary History of Italy, and editor of the Giornale di Modena. In his numerous works, as well as in those of greater volume and importance, he discovers himself to have been gifted with a quick penetration, and possessed of great facility in writing, as well as a clear conception of the works of others, which to have acquired, must have been studied with constant application.

This admirable writer died at the age of sixty-two, of a bloody flux, in 1794.

From this celebrated work, we expected to acquire new and authentic information concerning the rise and progress of music previous to the seventeenth century, in a country which has taught every other part of Europe all the refinements of the art, a country which we fought in vain, by travelling, conversation, and the perusal of all the books written by the natives which we could procure on the subject, to trace the origin of Italian melody. Dull and pedantic elementary books we procured in abundance; but scarcely any that we could read with pleasure, previous to the establishment of the opera at the beginning of the seventeenth century. Quadri's heavy volumes are filled without taste, feeble, or feeble-minded concerning the authenticity of facts. Padre Martini, unfortunately for modern musical history, did not live to finish his plan; having advanced no farther than the ancient music of the Greeks.

Tiraboschi is copious on all other parts of literature, arts, and sciences. It is only on music, and musical writers, our peculiar research, that we have ever found him unfavourable: we never consulted him on any other subject unprofitably. The little he tells us of Pythagoras, Arithoxenus, the Etruscans, and Guido, we had often previously read in innumerable books in various languages.

He speaks of the Lyric poetry of the Greeks and Romans; but that of the Italians has not furnished an article. We did hope to be informed what kind of melodies were set to the songs of Dante, Petrarch, and Boccaccio. We could not reasonably expect specimens of this melody in notation, any more than prints of pictures and buildings that are mentioned in his work; but when a capital work of Raphael, Michael Angelo, or Palladio is mentioned, we are generally told where it is to be seen, or at least where it has been seen. Had Tiraboschi told his readers where the original melodies to the songs of the old Italian poets were to be found, it would have been a great satisfaction to those who consult books for useful and solid information, or seek in them for any thing but mere amusement.

Of the latter century he says nothing, as his plan went no farther than the end of the seventeenth century. And, indeed, of that period, his information is very scanty; neither Carulli nor Stradella, the two best composers which Italy had then produced; nor among contemporary theorists, or writers on harmonics, is any notice taken of Lemme Rossi, or Daniel Bartoli, authors of two books, which in a general history of literature ought to have been mentioned. See Bartoli, and Rossi.

TIRACHEA, in Ancient Geography, a town of Judea, in the Decapolis, on the coast of the sea of Galilee.

TIRADE, in French Music, formerly implied what the Greeks meant by ἀγωγή, ἀγωγα, ἀδιάτικος, the filling up a wide interval by the intermediate diatonic notes. (See GREEK MUSIC.) But, at present, tirade seems nearly equivalent to velocitas in Italian; a division, a flight.

TIRAGHT, in Geography, an island in the Atlantic, near the W. coast of Ireland; 8 miles S.W. of Dunmore-Head.

TIRAMANGALUM, a town of Hindoostan, in Madura; 10 miles S.W. of Madura.

TIRAMANY-MUTTOO, a river of Hindoostan, which runs into the Caunvery; 8 miles N. of Carroor.

TIRAN. See TYRAN.

TIRANADUM, or TIRINADUM, in Ancient Geography, a town of Africa, in Mauritania Caesarea, on the route from Carthage to Caesarea, between Rapidum and Caput-Ciillanum. Anton. Itin.

TIRANDURG, in Geography, a town of Hindoostan, in Myfors; 12 miles S.S.E. of Orifoor.

TIRANO, a town of Italy, in the department of the Lano, late belonging to the Grifons, the capital of the Upper Terzero, and residence of a governor called Podela, on the Adda, which divides it into two parts, connected by a stone bridge of a single arch: formerly surrounded with walls by Ludovico Sforza, as a defence against the Grifons, who destroyed the fortifications when they gained possession of the Valtelina. The chief trade is in wine and silk, which is not confiderable. The wine is sent into the country of the Grifons, to Bormio, and into the territories of Venice; the silk, which is drawn from this district of the Valtelina, is not of the best quality, nor very abundant; part is forwarded to Venice, and the remainder, through Chiavenna, to Germany. About half a mile from the town, on the other side of the Adda, is the church of the Madonna, or Virgin, much visited by Catholic pilgrims; the modern buildings annexed to what remains of the old edifice is in an elegant style of architecture, and the era of it is 1533, the ancient part having been erected in 1266. In the area before the church is held the fair of Tirano, remarkable for the number of cattle brought hither for sale; they are fed upon the highest Alps, where they continue until the snow begins to fall, and are chiefly sent from hence into Italy. The fair is in October, and lasts three days, during which time the authority of the podela is suspended, and the governor of the Valtelina has absolute jurisdiction over the town and the district; 44 miles E.N.E. of Morbegno.

TIRANY, a town of Hindoostan, in the Carnatic; 3 miles N. of Ootatore.

TIRATA, in old Italian Music, implied a regular accent or defect of notes of the same kind; but, at present, the term has a more extensive acceptation than its original import, drawn out: as when a subject is well treated, producive
The TIR

ductive of beautiful paffages, made the molt of by a com-
poler; it is thain said to be ben tirato.
TIRBIA, in Geography, a town of Spain, in Catalo-}
nia; 16 miles N.W. of Urgel.
TIRE, or, as the leamen pronounce it, tier of guns.
See Tire.
TIREBOLI, in Geography, a river of Turkish Arme-
nia, which runs into the Black sea at Tireboli.—Also, a
town of Turkish Armenia, on the Black sea, at the mouth
of a river of the same name; 20 miles N.E. of Kerfour.
TIREH, a town of Abijat Turkey, in Natolia, sitiuated
on the Meimder; the inhabitants are chiefly Turks: 32
miles N.E. of Smyrna. N. lat. 38° 8'. E. long. 27° 46'.
TIRES of Wheels, in Rural Economy, the straps, flaps,
bands, or hoops of iron which are put round them for the
purpose of guarding and protecting them against the ef-
ects of the roads, as well as securing and keeping them tight in
their different parts. The most advantageous and benefic-}
ental form of tire for wheels of different kinds and breadths in
different points of view, have probably not yet been well af-
certained. It is obvious, however, that it should be such as
may have the least possible tendency to penetrate and de-
stroy the surfaces on which the wheels act and move. It
would appear, that almost all of those who have written on
this subject, have gone upon a wrong or false principle;
early all having directed that the exterior fence, when
more bands than one are used, as in the case of broad-wheeled waggons, should be unequal; in such a man-
er as that the centre band may receive the whole of the
preasure, when the road is even and composed of hard ma-
terials; the other bands being only in readiness to fulfill
their portions of the burden, when, either from unevennesses
or the want of firmness in it, they may be brought into
contact with it.
It is well known, however, to every one, that it is the
nature of a wedge to work its way, when forcibly applied
to a cleft or opening; and that the extent of its penetration
will depend on the sharpness or acuteness of its wedge-
form, and the power by which it is impelled. Admitting
this to be the fact, it is plain that every wheel, the tire of
which acts in the smallest degree as a wedge, must enter a
loose foil, surface, or road, more or less, in proportion as its
edge or projection is more or less acute and protruding,
or the contrary.
A rolling cylinder is not easily capable of penetrating
below the surface, for this reason, that it presents no one
protruding point; but where a rolling body swells out in a
projecting manner in the middle, it will unquestionably act
or work deeper in that part where it is the most promi-
ent, than in any other, as it is a sort of obtuse wedge.
And such must be the case in every wheel of which the
tire is not cylindrical; as when its protruding part gets in,
the whole body soon finds its way.
A broad flat tire is not, however, without its inconve-
nience; as, whether the road be good or bad, it presents
the same surface, and, of course, is as much refisted in its
front, while on a hard surface, as while on one into which it
sinks. Consequently, the cylindrical tire can never draw
light and free, though it will not by any means penetrate
deeply into any tolerably sound surface.
Flat tires are probably, however, the belt of any for
narrow wheels.
In consequence of the above, it has been proposed by
some, that every wheel should be furnished with a concave
or hollow tire which is cylindrical; but, that, after leaving
two rims, of proportionate breadth, at the edges, the whole
intermediate space should be scooped out, or otherwise hol-
lowed. By this means, on hard roads, the wheel would
ride on the two rims only; while on soft roads, the whole
would bear up the burden. All such wheels, the tires of
which have even the smallest tendency to a wedge-like
form, invariably, it is said, throw the foil or earth from
them; squeezing it out at the sides, and burying them-
selves, not only in the furrows they make, but under the
very mud which they force from out of them; while, on the
contrary, the concave tire, it is supposed, keeps in the
soft soil, until, indeed, it be in an absolutely floppy flat,
and forces it, by compulsion, to bear up the weight or
burthen. It is observed, that let two wheels be tried on a
meadow which is not very firm in its surface, the cylin-
drical tired wheel will, affixed, act better than that with a
receding or convex edged fort of tire; but that the con-
cave tired wheel could not, it is believed, fail to disply
its superiority in several of the most defirable points and
respects.
Let it be supposed that the tire of a waggon-wheel is
nine inches in breadth, and cylindrical: at the two edges
leave a band of one inch in breadth, or more; then groove
out the intermediate space, to an inch and a half in depth
in the centre, rounding it in gradually. Such a tired wheel
would, it is said, on a hard road, present only two inches of
bearing; while the refusal would gradually increase in propor-
tion as the incumbent weight, and the loofness of the surface over which it may be proceeding,
should bring the whole to bear in an equal manner.
The soft foil could not escape so easily, at least, it is conceived,
from under a concave tire, as those of the opposite kind,
consequently it could not add to the exterior impediments of
wheels.
It must nevertheless be admitted, it is said, that the con-
cave tire is liable to some disadvantage; for instance, it will
at times clog, and, possibly, not only choke its own groove,
but even accumulate considerably more; which will adhere
to the clay and other matters with which the groove may be
filled. In this way, it would, in fact, it is thought, be-
come, in a certain measure, cylindrical. But that if it did
no more than fill its groove on heavy soils, it would not
prove so highly objectionable; for, on such, the whole
breadth of the tire ought to press the foil or surface.
The remedy suggested for the above inconvenience, in
such cases, is that of a suitable fixed speror, which has no
difficulty in it, at least, for carriages on one pair of wheels,
or for the hind wheels of waggons. Such a speror, and the
mode of fixing it in such cases, may be seen described in
speaking of sperors for different kinds of implements,
tools, &c.
These hints and suggestions may be useful in leading to
farther improvements on the tires of wheels, which is a
matter of great importance in different points of view, and
which, as has been seen, has yet been thought but little
upon in a proper manner. See Wheel.
TIREMEG LAKE, in Geography, a lake of North
America. N. lat. 61° 52'. W. long. 107°.
TIRGUBIS, or TIGUMI, in Ancient Geography, a town
of Afla, in Mefopotamia, on the banks of the river Chas-
boras, according to the Theodosian table and Ptolemy;
fituated N.W. of Refana.
TIRGUL, in Geography, a town of European Turkey,
in Moldavia; 62 miles W. of Jaffy.
TIRGULFORMOSA, a town of European Turkey,
in Moldavia; 20 miles W. of Jaffy.
TIRING,
TIRING, in Falconry, is the giving a hawk the leg or pinion of a fowl to pluck at. Dic. Ruft.

TIRIPANGADA, in Ancient Geography, a town of India, on the north side of the Ganges. Ptol.

TIRIPIN, in Geography, a sea-port of South America, in the province of Cumana.

TIRISTA, in Ancient Geography, a town of Lower Myfia, near the Danube, between Trirnanium and Duruf- torum. Ptol.

TIRISTRIA, or Tetria, a promontory of Lower Myfia, on the Euxine sea, between Dionylopolis and Odus-thus. Ptol.

TIRKA, in Geography, a town of Africa, in the kingdom of Ghana, on the north side of the Niger; 120 miles E. of Ghana. N. lat. 3° 26'. E. long. 14° 30'.

TIRLEMTON, a town of France, in the department of the Dyle, called by the people of the country Toren; on the Geete. It was anciently one of the principal cities of Brabant, and made a fourth quarter in the assembly of the States; but that precedence was afterwards removed to Bois-le-Duc. It certainly has been a very flourishing and populous city, and many vestiges of its grandeur are yet visible; but it has suffered much by war, and other calamities; 9 miles S.E. of Louvaine.

TIRMAKUL, a fort of Hindooflan, near Gooty, taken by the British in 1801.

TIRMANIZ, a mountain extending from Bukovina to Transylvania.

TIRNA, a river of Hungary, which runs into the Danube, a few miles below Presburg.

TIRNAU, a town of Hungary, containing nine churches, and as many convents. This town was built in the thirteenth century; 20 miles E.N.E. of Presburg. N. lat. 48° 31'. E. long. 19° 44'.

TIRIAN, See TARBON.

TIROCOOR, a town of Hindooflan, in Golconda; 8 miles S. of Calloor.

TIRRETO, a town of Naples, in Calabria Ultra; 15 miles E.S.E. of Reggio.

TIRROUP-MEW, a town of the Birman empire; the meaning of the word is the Chinefe land, and the appellation was derived from a victory obtained over the Chinefe some centuries ago, when they invaded Birmah; 35 miles N.E. of Pegu.

TIRSA, in Ancient Geography, a town of Macedonia, in Mygodia.

TIRSCHNIED, in Geography, a town of Bavaria; 28 miles N.N.E. of Amberg.

TIRSCHNITZ, a town of Bohemia, in the circle of Kauzim; 4 miles N.W. of Kottetsz.

TIRISO, in Ethnology, a name given by Gaza and some other authors to the placeana of Willughby and others, the parge or marjum. Phyll, Bellonius, and many others call it turjof.

TIRSRUM, in Geography, a town of Sweden, in Earl Gotland; 25 miles S. of Linkoping.

TIRUA, a small island in the Pacific ocean, near the coast of Chili. N. lat. 35° 30'.

TIRUAN, a town of Hindooflan, in Bundeucund; 20 miles N.E. of Callinger.

TIRUMBORE, a town of Hindooflan, in Madura; 7 miles N.E. of Madura.

TIRUN, or TEBRONE, a name given to tribes who live chiefly on the N.E. coast of Borneo, and are reckoned a savage and piratical race, addicted to eating the flesh of their enemies. Their language is peculiar. It is probable, however, that they are only a tribe of Idan, who are imagined to be only a race of Harafors or Alfeors, as they are termed by the Dutch, who seem to be the most original race of all the eastern islands, excepting perhaps the Papuas. The Idan are sometimes termed Marit; they are certainly the original inhabitants of Borneo, and resemble the Harafors usually in stature, agility, colour, and manners. The Harafors are indigenous in almost all the eastern isles, and are sometimes found on the same island with the Papuas or oriental negroes. They are often lighter in colour than the Mahometan races, and generally excel them in strength and activity. They are universally rude and uncalled, and where they have not been reduced to the state of slaves of the soil, their manners have a general resemblance. In their manners, the most singular feature is the necessity imposed on every perfon, of some time in his life embracing his hands in human blood; and, in general, among all their tribes, as well as the Idan, no person is permitted to marry, till he can show the skull of a man whom he has slain. They eat the flesh of their enemies, like the Battas, and drink out of their skulls; and the ornaments of their houses are human skulls and teeth, which are consequently of great request among them, as formerly in Sumatra, the ancient inhabitants of which are said to have originally had no other money than the skulls of their enemies. The Harafors are found in all the Moluccas, in Celebes, the Philippines, and Maguindano, where they are termed Subano or Manubu; and the ferocious race mentioned by Marfin, who live inland from Samanka in Sumatra, and are accounted to avenge their own faults by offering the heads of strangers to the chiefs of their villages, are probably of the same description. Ab. Ref. vol. x.

TIRULELORE, a town of Hindooflan, in the Carnatic; 20 miles E. of Tanjore.

TIRY, or TIRED, one of the islands of the Hebrides, situated in the district of Mull, and shire of Argyile, Scotland, is about 11 miles in length, and 24 miles in breadth. Its coast is mottly rocky, and intersected with many beautiful sandy bays, some of them a mile broad. About one-half of the surface is arable, intersected with small rocks and rising grounds, none of which are above 250 feet above the sea-level; but the surface in general is so even, that the waves are often seen from the shore rising apparently several feet above the level of the other. In the centre of the island is a large plain, which contains about 12,000 Scotch acres, and is elevated about six feet only above high-water mark; consequently, in stormy weather the sea often meets across this plain, and is productive of bad confquences. The inhabitants have endeavoured to avert this evil by building a defence of stone and earth on the one side, while the sea, on the other, has raised a considerable barrier of bowlder stones; yet neither has been sufficient to re-fill the waves of the Atlantic. Here are several lakes, covering in all about 600 acres; in one of these is a small island, on which are the remains of an ancient castle, on the site of which a neat house has been erected for the residence of the factor of the duke of Argyile, who is proprietor of the whole island. The fisheries employ a number of hands, as well as the manufacture of kelp, of which about 245 tons are annually made. The hill of Cean-Mharra, the western point of the island, is remarkable for a great number of large natural caves, frequented by innumerable flocks of sea-fowls. Here are the remains of many Danish forts, and also of several old chapels, at some of which burying-grounds and crosses are still visible. In the time of St. Columba, this appears to have been part of the patrimony of
of that church. Here is a parochial school, and also one established by the Society for Promoting Christian Knowledge, both of which are well attended. The population of the parish (which comprehends the islands of Coll, Gurna, and Tirey) was, in the year 1811, estimated at 3186. There is a regular ferry from Tirey to Coll, three miles distant, which is often dangerous, owing to a heavy swell from the Atlantic, and a rapid current over rocks and shifting sands. The two islands appear to have been formerly united: the isle of Gurna, which lies in the sound, being apparently part of the intermediate land which has escaped submergence. — Beauties of Scotland, vol. v. Carliile's Topographical Dictionary of Scotland, vol. ii.

TIRYNS, in Ancient Geography, a town of the Argolid, N. of Midea, situated in an enclosure of the mountains; called anciently Halicis, or the town of fishermens, from its having been the abode of the Heroniean fishermen. In the time of Pausanias it was in ruins.

TISŒUS, or TISÉUM, a very lofty mountain of Thebaly.

TISALPHATA, a town of Mesopotamia, situated W. of Tigris, on one of the small rivers which discharged themselves into the Mygdonius.

TISBURY, in Geography, a small fishing town on the N. coast of Martha's Vineyard, belonging to the state of Massachusetts.

TISCHNOWITZ, a town of Moravia, in the circle of Brunn; 13 miles N.W. of Brunn.

TISDALE, TUSCHRA, or Thybrus, in Ancient Geography, a town of Africa, six leagues S.W. of Sarfura and five leagues S.W. of Achola. It has many ancient relics of altars, inscriptions, columns, and fragments of marble statues; and also the remains of an amphitheatre.

TISEBARICA, a country of Ethiopia, according to Arrian, which commenced near the port of Berenice, and extended along the Red sea, as far as the country of the Mofchophas.

TISHEET, in Geography, a town of Africa, with a salt-mine; 150 miles N. of Benown. N. lat. 17° 20'. W. long. 26° 10'.

TISHOLTZ, a town of Hungary; 10 miles E.N.E. of Libethen.

TISDIUM, in Ancient Geography, a town of Africa, the command of which, according to Sallust, was given by Metellus to Jugurtha.

TISPHONE, in Mythology, one of the three Furies. She is represented by the poets with vipers, sometimes as loyle serpents, intermixed with her hair, and sometimes as serpents growing from her head instead of hair. As she is one of the chief of all the infernal executioners, her robe is described either as dropping with fresh blood, or sniff with human gore: this robe is fastened round her with a serpent instead of a girdle; and she has sometimes vipers twisted round her arms instead of bracelets. They sometimes give her a torch in her hand wet with blood; sometimes a torch in one hand and a serpent in the other; and sometimes serpents in both.

TISTR, or TISI, in Chronology, the first Hebrew month of the civil year, and the seventh of the ecclesiastical or sacred year.

The Hebrews call it raft-habanna, that is, the beginning of the year. It answered to part of our September and October. On the first day of this month was kept the feast of trumpets, because the beginning of the year was then proclaimed by sound of trumpets. On this day they refrained from all sorts of fervile busineses, and offered in sacrifice a calf, a ram, and seven lambs. Levit. xxiii. 24. Numb. xxix. 1.

The tenth day of this month was the great day of expiation, and on the fiftenth the feast of Tabernacles began, which lasted till the twenty-second day inclusively. See SCENOPHEIA.

TISSA, in Ancient Geography, a small town of Sicily, at the northern foot of Etna, near the river Onobola. Ptol.

TISANAH, in Geography, a town of Hindoo, in the cercar of Sumbul; 16 miles S.W. of Sumbul.

TISIA, a town of Bengal; 35 miles S.E. of Patamow.

TISUE, CELLULAR, in Anatomy, the cellular substance. It is an expression borrowed from the tisue cellulare of the French, who also call it tisue muqueux. See CELLULAR Substance.

TISTE, in Geography, a port-town of Germany, in the county of Verden; 26 miles N.E. of Rotenburg.

TISURUS, TOZER, in Ancient Geography, a town of Africa Propria, S. of Adrametum, and 4 leagues S.W. of Tichafa. It has some Roman remains.

TIT, in Geography, a town of Morocco, near the Atlantic ocean; 8 miles S.W. of Mazagan.

TIT, in Rural Economy, a term provincially applied to a small flift horse, or fort of poney, and sometimes to other horses, as a handsome or ugly tit, &c.

TITALBARY, in Geography, a town of Bengal; 20 miles N.N.W. of Goragot.

TITALEE, a town of Bengal; 6 miles E. of Moorshedabad.

TITALLYA, a town of Bengal; 50 miles N. of Dinagepour.

TITAN. See LEVANT.

TITANA, in Ancient Geography, a town of Sicynia, E. of the river Sitia, and W. of the river Aephus; situated on a mountain, and regarded as a fortified town. Here was a temple of Eucalphius, and a statue of this god; and also a statue of Hygeia. In the temple of Eucalphius were nourished sacred serpents.—Allo, a small country of Sicynia,—Allo, a river of Asia, which had its source in mount Zagrus, and flowed into the river Sillas.

TITANIA, win, in Antiquity, a festival in memory of the Titans.

TITANIDÆ, or ARTEMIDÆ, the seven daughters of Chronus, son of Uranus, by Aftarte.

TITANIS, in Ancient Geography, the seven daughters of the western coast of Corfica, between the mouth of the river Ticarius and the town of Differa. Ptol.

TITANUM, in Mineralogy, a metal originally discovered by Mr. Gregor of Cornwall, in the grains of a black mineral found in the bed of a rivulet in the valley of Menai, in that county. It occurs also in different states of oxidation or intermixture in various parts of the world; and, according to the recent observations of M. Cordier, is a constituent part of most volcanic rocks. The oxyd of titaniu is reduced by exposure to an intense heat, being previously moistened with oil and surrounded by powdered charcoal.
TITANIUM.

Botany Bay.

Iserine is so called from having been originally found near the source of the river Iser, in Silesia: it is disseminated in a black, brownish black, with iron-fand. It occurs also with similar fand in the bed of the river Don, in Aberdeenshire. It is fusible in iron fand, but not in oxand. It is found in small grains and rolled pieces, with a rough and glimmering surface. The internal luftre is semi-metallic. Its fracture is conchoidal, which distinguishes it from menachanite, to which it bears a near resemblance. The specific gravity is 4.5. Before the blowpipe it melts into a blackish-brown coloured glass, which is slightly attracted by the magnet. The mineral acids have no sensible effect on it, but the acid of fugar extracts a portion of the titanium. According to Dr. Thompson, its constituent parts are

Nigrine; Titane oxyd ferrifere de Haüy, is so called on account of its colour, which inclines to a velvet-black. It occurs, like the preceding species, in angular grains and in rolled pieces. The external luftre is glimmering, that of the fracture shining; the fracture is imperfectly foliated. It is opaque, and harder than menachanite. Nigrine is brittle, and gives a yellowish streak. The specific gravity varies from 3.700 to 4.740. It is not attracted by the magnet, and is infusible by the blowpipe, but with the addition of borax melts to a transparent hyacinth red globule. The acid of fugar extracts the titanium from this ore. It is found in alluvial ground in Transylvania, Bavaria, and the island of Ceylon: it occurs also in the granite of the Uralian mountains.

The constituent parts of nigrine are given as under:

Transylvania. Klaproth.

Octahedrite; Schorl bleu, Romé de Lisle; Titane anatafe, Haüy. This ore of titanium is so called from its constant occurrence in crystallized forms, which are varieties of the octahedron.
and brittle. The crystals are small; the surface is transfusively iridescent, and has a semi-metallic lustre; the internal lustre is also brilliant. The structure is foliated. This mineral is more or less semi-transparent; it scratches glass, and is brittle. The specific gravity, according to Haüy, is 3.8571. The colour of oolchydron is indigo-blue, paling through many shades to brown. It is infusible by the blowpipe, but with borax it forms a reddish-brown coloured glas. At the extremity of the flame, the brown colour changes to blue, and becomes opaque; by the continued action of the blowpipe, the brown colour reappears, and may be again changed by variation of temperature. This mineral is rare; it occurs in veins with felspar, azinite, rock-crystal, and chlorite, in the primitive rocks of Dauphiny, and in drusy cavities in limestone, at Hadeland, in Norway.

_Sphen e and Rutile._—These ores of titanium have been already described. (See _Sphen e_ and _Rutile_.) In addition to those articles we may state, that common sphenite has been discovered in small crystals in the heath of the mountains in Galloway, and on the south side of Loch-Nefs; in the granite of Bennevis and Aberdene; and also in other parts of Scotland. Rutile has also been discovered in the granite of Caingorm, and near to Beddgelert, in Carnarvonshire.

_TITANOS_, a word used by some authors to express lime; by others of the calc of burnt gypsum or plaster of Paris, and by others a lustrum of quicklime.

_TITANS_, _TITANIS_, _TITANS_, in the _Ancient Mythology_, the fons of Uranus or Cetus, and Veïa, or Titza, or Terra, i.e. of Heaven and Earth, according to Hefiod and Appollodorus; or, which comes to the same thing, of Ethere and Tellus, according to Hyginus. They are said to have derived their name from their mother, and hence the most ancient fabulous histories have made them pafs for sons of the Earth. Appollodorus reckons five Titans: Oceanus, Cetus, Hyperion, Crius, Iapetus, and Saturn or Cronus; Hyginus also reckons five, viz. Briareus, Gyges, Sterope, Atlas, Hyperion, and Cottus; but he seems to include the hundred-handed giants in the number, which Appollodorus, and the generality of mythologists, distinguish from the Titans.

The tradition is, that Cetus, by the same wife Veïa, had Briareus, Gyges, and Cottus, the hundred-handed giants, and had chained them up in Tartarus: Veïa, the earth, their mother, repenting this treatment, rai'd the Titans against their father, her husband; all, excepting Oceanus, made war upon him and dethroned him, setting up Saturn in his place.

Saturn, it seems, proved no more favourable to them than his father; but continued the giants in their prizon. Upon this, Jupiter revolted against Saturn; serving him as he had done Cetus; and rescued the three giants; who afterwards proved of great service to him in the war which the Titans waged against him.

This war lasted ten years: but at length the Titans were vanquished; Jupiter remained in peaceable possession of heaven; and the Titans were buried under huge mountains thrown on their heads.

Hyginus gives another origin of the Titans: he derives them from Titan, Saturn's eldest brother, by Cetus and Veïa; who, though presumptive heir of heaven, yet finding his father and mother more inclined for Saturn than for him, surrendered to him right of succession, on condition he should not bring up any male child, that the empire of heaven might revert to his own line the Titans.

But Jupiter, Neptune, and Pluto, having been afterwards ficed by the artifice of Ops, Titan, and his sons the Titans, made war on Saturn, who had dispossessed his father Uranus of the throne, and acquired an extensive empire, vanquished and imprisoned him; thus he continued in the power of his enemies, till Jupiter, who had been conveyed by his mother Rhea for safety to the Isle of Crete, being grown up, left Crete, made war on the Titans, and delivered his father.

Having re-established him on the throne, he returned to the place of his retreat. Saturn afterwards regained for some time in tranquillity; but upon consulting an oracle, he received information that he would be exposed to danger from the young progeny of his sons. Accordingly he recurred to all possible means for getting aid of Jupiter. Having fought him in Crete, he was betrayed and constrained to make a hasty retreat into the Peloponnesus. Thither Jupiter pursued him, and obliged him to take sanctuary in Italy, under the protection of Janus.

The Titans, thus, dispersed through several countries of Greece, being jealous of the power of this new conqueror, as they had been of his father's, levied troops against Saturn, and gave him battle; but being defeated, they retired into the interior parts of Spain, whither Saturn followed them. Jupiter fought them out in their retreat, and beat them for the last time near Tartessus, and with this battle terminated the war, which had lasted ten years. Saturn made his escape into Sicily, and there, as it is said, died from grief. With this last victory, and the defeat of Saturn, commenced the reign of Jupiter. During the war of the Titans, Atlas feiz'd on those provinces of Africa which were remote from the centre of the empire. Pluto was sent governor of the western parts of the empire of the Titans, of the Gauls, and Spain, which government, after the death of Pluto, was given to Mercury, who is said to have become the great divinity of the Celts; and Jupiter referred to himself the whole East, that is, Greece, the Isles, and that part of Asia whence his ancestors came. For the explication of the fable that represents the Titans as thrall'd down to Tartarus by Saturn, see _Tartarus_.

The most judicious among our mythologists, such as Gerard Voëlius, Marfham, Bochart, and father Thomassin, are of opinion that the partition of the world among the fons of Noah, Shem, Ham, and Japhet, was the original of the tradition of the fame partition among Jupiter, Neptune, and Pluto; and hence they have been led to form comparisons between the three fabulous princes, and the three fons of the patriarch. Accordingly the learned Pezron contends that the division which was made of this vast empire, came in after-times to be taken for the partition of the world: that Asia remaining in the hands of Jupiter, the most potent of the three brothers, made him look upon as the god of Olympus, a celebrated mountain where he had his residence, and which was afterwards taken for heaven itself: that the fons and islands which fell to Neptune, occasioned their giving him the title of god of the sea; and that Spain, the extremity of the then known world, thought to be a very low country in respect of Asia, and famous for its excellent mines of gold and silver, falling to Pluto, occasioned him to be taken for the god of the inferior regions. However this be, the empire of the Titans, according to the ancients, was very extensive. These princes were poiffessed of Phrygia, Thrace, a part of Greece, the island of Crete, and several other provinces, to the inund receifes of Spain. To these Sancho-family tends to join Syria; and Diodorus adds a part of Africa and the kingdoms of Mauritania.

T. Pezron, in his _Antiquity of the Cельt_, makes that people to be the fame with the Titans; and their princes to be the same with the giants in Scripture. According to him, the
The Titans were the descendants of Gomer, the son of Japhet. He adds, that the word Titan is perfect Celtic, and derives it from τίταν, earth, and δεν or δεν, man; and hence it was the Greeks also called them very properly γηγενες, earth-born.

Banier observes, that although most of the ancients have confounded the giants (see Rebel Giants) with the Titans, they ought to be distinguished. The latter, he says, were of an illusrious family, and extended their empire over one part of the world; the others were so many banditti diffpered over Thessaly, who occasioned great trouble to the Titans. Hefiod distinguishes them from one another, and states that the giants were not born till long after the overthrow of the Titans, and after the wars which they carried on against the others. The occasion of confounding them seems to have been, that both the giants and the Titans made war upon the gods; with this difference, that the Titans, though of the same race, had often separate interests; some taking part with Saturn, and others with Jupiter; whereas the giants were a gang of robbers, who had a design equally upon all the Titans. Both giants and Titans were represented as sons of Heaven and Earth, and hence they have been confounded, for want of considering, what Apollodorus says, that Earth brought forth the giants only because she was incensed against Jupiter for keeping the Titans shut up in Tartarus. Thus the Titans were born long before the giants.

The Titans, according to the learned Mr. Bryant, were those Cuthites, or sons of Chus, called giants, who were employed in building the tower of Babel, and who were afterwards difabled. See Dispersion of Mankind.

He supposes that they were denominiated from their religion and place of worship, Titans, which is represented as the mother of these people, being compounded of Τιταν, and signifying literally a bright or earth-like sun; of the Greeks, and therefore expressing the figure as well as the materials of the ancient altar, which consisted of a conical hill of earth, in the shape of a woman's breast. These altars were also called Tit-an and Tit-anis, from the great fountain of light, flyled An and Anis. Hence many places were called Titana, and Titana, where the worship of the sun prevailed; for Anes and Hono signified the fountain of light or fire. Titan was sometimes expressed Titana, and by the Ionians Tithena; and Tithena was said to be the nurse of the Titans. But Titana their mother, and Tithena their nurse, were all of the same nature, viz. altars razed of soil. He adds, in his account of the disperion of the Titans, and of the floods which preceded (Theogon. ver. 676, &c.), that the Deity at last interposed, and put the Titans to flight, and condemned them to reside in Tartarus at the extremities of the earth; but Mr. Bryant observes, that he has confounded the history by supposing the giants and Titans to have been different perons. The sons of Chus, he says, were the aggressors in those acts of rebellion described by the poets as the war of the giants, who were also represented under the character of the Titanians. The fictions of the poets with regard to the banishment of the Titans after their war against heaven, took their rise from this true history. A large body of Titanians, after the dispersion, settled in Mauritania, upon the Atlantic ocean, which is the region flyled Tartarus, and represented as the realms of night; because it was situated in respect to Greece towards the regions of the setting sun. The term ζενε, by which it was expressed, signified both the west and darkness; as did also Ereb, ζενε, whence Erbus, which was also another name for Tartarus, to which the poets condemned the Titans and giants. The first war of the Titans, according to this ingenious writer, confisted in acts of apostacy and rebellion against heaven; and this refers to that part of the history of the fons of Chus, which represents them as building a mighty city in the region, which they had usurped, and erecting a lofty tower, to prevent their being scattered abroad: but there was another war in which they were engaged with men, which happened in confequence of the dispersion. This was no other than the war mentioned by Moses, which was carried on by four kings of the family of Shem, against the fons of Ham and Chus, to avenge themselves of these enemies by whom they had been greatly aggrieved. See Bryant's Analysis of Ancient Mythology, vol. iii. p. 48, &c. p. 71, &c.

The word Titan is also used by the poets for the sun, in which case it is likewise Celtic, though from another root, being formed from ις, house or habitation, and ην, fire.

Hefychius observes, that Titan is likewise used for lodoimite. He adds, that it is also one of the names of Assyrian, in which case it must be written Tisian, in Greek, to contain the numerical letters of 666. which in the Apocalypse, xiii. 18, is the number of the beast. TITANUS, in Ancient Geography, a town of Asia Minor, on the coast of the Aeolide, on the banks of a river of the same name.

TITARESSUS, a town of Asia, in Lesser Armenia, in the country named Malitane. Ptol.

TITARESUS, or Titaresus, a river of Thrasyly, mentioned by Homer, which had its source in mount Titarus.

TITAY, in Geography, a town of Bengal; 55 miles N. of Dinagopour.

TITCHFIELD, a small market-town in the hundred of the same name, in the Portford division of the county of Hants, England; is situated near the Titchfield river, 3 miles W. from Fareham, and 58 miles S.W. from London. It is inhabited by many respectable families. The church, which is the only object of particular notice, is a spacious edifice, of the workmanship of different ages: the N. nave is said to have been built by William of Wykeham; but the S. nave is more ancient. In the S. chancel is an interesting monument to the memory of Sir Thomas Wriothesley, 1st earl of Southampton, Jane his lady, and Henry their son, the second earl; all of whom are represented by effigies on the tomb. Four annual fairs are held in Titchfield; and a weekly market on Saturdays. The population of the parish, under the act of 1811, was returned as 3227, the number of houses at 535.

At a short distance from the town, on the N., are the ruins of Titchfield House, the ancient seat of the Wriothesleys. It was erected, by the 1st earl of Southampton, on the site, and with the materials of an abbey, founded for Premonstratensian canons, by bishop Peter de Rupibus, in the year 1231. The annual revenues of this establishment, at the period of the dissolution, amounted, according to Dugdale, to 246l. 16s. 1d.; but according to Speed, to 280l. 19s. 4d. Its possessions were then granted by Henry VIII. to his favourite secretary, Wriothesley, who built here, Leland reports, "a righte fourteen houses, and having a good gate, and a conduit caflelid in the middle of the court of it, in the very fame place where the late monaftic foode." This building is now in a very dilapidated state: the entrance gateway is the principal part left standing; fourteen rooms having been recently pulled down for the sake of the materials. The estate is the property of John Delmé, esq. of Cam's Hall. In Titchfield House, Charles I. was concealed after his escape from Hampton Court in 1647, and previous to his resigning himself to colonel Hammond, who...

TITCHVINE, a town of Ruffia, in the government of Nvgorod, on the river Stias, 84 miles N.N.E. of Novgorod. N. lat. 59° 52'. E. long. 33° 14'.

TITE. See Tithe.

TITEA, in Mythology, the wife of Uranus or Cebus, by whom he is said to have had eighteen children, each of which had his own name, though they were generally designated by the appellation of Titan; which see. This princess, after her death, received divine honours, and she was called after her name.

TITERNUD, in Geography, a town of Norway, in the province of Agerhus; 38 miles N. of Christiana.

TITIENIDIA, zeum, in Antiquity, a Spartan festival, so called from zealot, nurset, who at this time carried the male infants committed to their charge to the temple of Diana Corynthia. For the ceremonies observed on this occasion, see Potter, Archæol. Græc. lib. ii. cap. 20. tom. i. p. 432, seq.

TITHE, Tythes, Tenth, Decima, or Diximes, the tenth part of the increase, yearly arising and renewing from the profits of lands, the rock upon lands, and the personal industry of the inhabitants; allotted to the clergy for their maintenance.

Tithes essentially differ from offerings, oblations, and endowments, which are the customary payments for communicants at Easter, for marriages, christenings, churching of women, burials, and such like. See Oblations.

Tithes, with regard to their several kinds or natures, are personal, predial, and mixt.

Tithes, Personal, are those due or accruing from the profits of labour, art, trade, navigation, and industry of men; and of these, only the tenth part of the clear gains and profits is due; after charges deducted.

Tithes, Predial, are those which arise merely and immediately from the ground; as grain of all sorts, hay, wood, fruits, herbs; for a piece of land or ground, being called in Latin præedium (whether it be arable, meadow, or pasture), the fruit or produce of it is called predial.

Tithes, Mixt, are those which arise not immediately from the ground, but from things immediately nourished by the ground; as from beasts, and other animals fed with the fruits of the earth; as colts, calves, lambs, chickens, milk, cheese, eggs.

Tithes, with regard to their value, are divided into great and small.

Tithes, Great, are those of corn, hay, and wood.

Tithes, Small, are the predial tithes of other kinds, together with those that are called mixt and personal. It is said, that this division may be altered by custom, which will make wood a small tithe in the endowment of the vicar; by quantity, which will confer a small tithe into great, if the parish is generally cultivated with it; and by change of place, which makes the same things, e.g. hops in gardens, small tithes, in fields great tithes. But it has been admitted, that the quantity of land within any parish, that is cultivated for a particular produce, cannot change the nature of the tithe; and, according to this opinion, the law is now settled, that the tithes are to be denominated great or small, according to the nature and quality of them, and not according to the quantity.

It has been laid by lord Coke and many others, that before the council of Lateran in the year 1185, a man might have given his tithes to what church or monastery he pleased; but this is denied by Dr. Prideaux. It is now certain, that

tithes of common right do belong to that church, within the precincts of whose parish they arise; and this regulation, corresponding with the ancient Law of the land, was enjoined by a decretal epistle of Innocent III. to the archbishop of Canterbury, in the year 1200. (2 Infr. 641. 2 Blackf. Com. 27.) But though one person may prefer to have tithes within the parish of another; this is what is called a "portion of tithes." (Gibson, 663.) Tithes extra-parochial, or within the compass of no certain parish, belong to the crown, and may be granted to whom the king will. 1 Roll's Abr. 657. 2 Infr. 647.

It is a general rule, that of common right tithes are to be paid for every thing that yields an annual increace; but this rule admits of exceptions, e.g. the tithe is due from farron, though gathered but once in three years; and on wood that is felled or lopped, called clyva cedaw, though it is not renewed every year: and on the other hand, tithes shall be paid for the produce of seeds, as of clover, found on the same ground, thoug renewed oftener than once a year. No tithes shall be paid of common right for any thing that is of the substance of the earth, or which is not of annual increace, as lime, coal, tin, lead, and such like; nor for creatures that are fere nature, or of a wild nature, as deer, hawks, fish, &c. whose increace is so as to profit the owner is not annual, but casual; unless tithes in either of these cases are payable by custom. Degge, p. 2. c. 8. 1 Infr. 651. 664.

Lands, and their occupiers, may be exempted or discharged from the payment of tithes, either in part or totally, by a real composition, or by custom and prescription.

A real composition is when an agreement is made between the owner of the lands, and the parson or vicar, with the consent of the ordinary or patron, that such lands shall for the future be discharged from payment of tithes, by reason of some land, or other real recompence given to the parson, in lieu and satisfaction thereof. But these compositions are now restrained by the disabling statute 13 Eliz. cap. 10. See Composition.

A parson may bind himself by deed to accept of a composition for tithes during life, or incumbency of a particular living. It is also very common to agree by parol for an annual composition for tithes, which binds the parties to it till sufficient notice given of dissent from the agreement, but what is sufficient notice to determine such an agreement, has never been decided in terms. See Leases by Statute.

A discharge by custom or prescription is, where time out of mind such persons, or such lands, have been either partially or totally discharged from the payment of tithes. The difference between custom and prescription is this: Custom is that which gives right to a province, county, hundred, city, or town, and is common to all within the respective limits; in pleading of which it is alleged, that in such a county or the like, there is, and time out of memory hath been, such a custom used and approved therein. Prescription is that which gives a right to some particular house, farm, or other thing; in pleading of which it is alleged, that all they whole estate is had in such land, have time out of mind paid so much yearly, or the like, in full satisfaction of all tithes arising on those lands. (Gibson, 674.) And there is this difference between a prescriptive and customary modius, that the former is annexed to the lands which it covers, whereas the latter exists in action of law, independent of the lands by force of the custom of the district. In a prescriptive modius, therefore, the lands must be definite, and not liable to shift. And therefore a bill to establish a modius for every ancient farm, but not setting out the abutments of each, was dismissed,
TITHES.

diminished, although it was stated that the whole parish consisted of ancient farms. (See Custom and Prescription.)

This custom, or preference, is either de modo decimandi, (see Modus Decimandi,) or de non decimando. No modus can be established at this day, but by act of parliament. A modus founded upon good considerations may be in various ways discharged, and tithes become due in kind: as,

1. Where land is converted to other uses: so, when the preference is for hay and grases, specially, in so many acres of land; if the land is converted into a hop-garden or tilage, the preference is gone.

2. By the alteration or destruction of the thing for which the money was paid: as where two fulling-mills were under the same roof, and turned into a corn-mill; where also there was one pair of rolls in a mill, and another pair was added; and where the water-course was altered by the owner, and the mill was pulled down and re-edified upon it; in all these cases, it was adjudged that the modus was gone. But where a man was feated of eight acres of meadow and one of pasture, for the tithes whereof he had paid time out of mind 51. 4d. and afterwards the owner built a corn-mill upon the same; it was adjudged that he should pay no tithes for the corn-mill, because the land was discharged by the modus. 2 Inf. 490.

3. By non-payment of the consideration, or payment of tithes in kind, for so long a time as to destroy the possibility of making proof that such custom or prescription was: but an interruption for some short time only, will not discharge it; especially if made by the lessee, to the prejudice of the lessor. Watf. c. 47.

The rule is, that the modus is to be fixed for in the ecclesiastical court, as well as the very tithe; and if it be allowed between the parties, they shall proceed there; but if the custom be denied, it must be tried at the common law; and if it be found for the custom, then a consultation must go; otherwise the prohibition standeth. The like is affirmed, in case a jury upon an issue joined in a prohibition upon a modus decimandi, find a different modus; since a modus is found, they shall not have consultation. 2 Inf. 490.

The principal reason why the courts of common law prohibit the spiritual court from trying of moduces, is, that whereas every modus is less than the real value, the rule of the canon law is, that less than the real value shall not be taken, and that a custom to the contrary is void; and that the ecclesiastical and temporal laws differ in the times of limitation, forty years or under making a good custom by the ecclesiastical laws, whereas by the temporal laws it must be beyond the time of memory. Gibf. 691.

But the spiritual courts have commonly allowed and do allow pleas of modus decimandi; and the averment in the prohibition is not that they do take cognizance, but that the plea hath been offered and refused; which supposeth, that if the plea be admitted, the prohibition ought not to go. And accordingly it hath been affirmed by Doderidge and others, that the spiritual court may as well try the modus, as the right of tithes, and that a prohibition is not to be granted, till the spiritual court either refuse to admit the plea, or proceed to try it by methods different from the rules of the temporal law, as to the time of limitation, or number of witnesses, or the like. And where lord Coke contended for the contrary doctrine, it was declared by Kelyng and Twidacen, that in case one libel for a modus decimandi, if the spiritual court allow the plea, they may try it. Gibf. 691.

But, notwithstanding it, feemeth now to be clearly settled, that if a modus decimandi be fixed for in the ecclesiastical court, a prohibition lies to stop the trial of it, if the modus be denied; and the reason is not upon the account that the spiritual court wants jurisdiction, but in regard of the notion the temporal law hath of custom, different from the spiritual: and seeing that every modus is due by custom, it is the common law only that can determine, what time and usage with us shall be sufficient to create such custom, that is, time beyond all memory to the contrary. Whereas by the spiritual law, sometimes ten years, sometimes twenty, they will adjudge sufficient to create a custom. And prohibitions in such cases are granted, not because the spiritual court hath not jurisdiction of the matter, but in respect of the trial which is to be by the temporal law only; and if upon the trial it be found for the modus, the proceedings shall go on in the spiritual court; if against the modus, the prohibition shall stand. Watf. c. 56.

If in the trial of a modus, the defendant permits the spiritual court to proceed to sentence, he is then too late to come for a prohibition; because it is only for defect of trial, and not for defect of jurisdiction: but a man is never too late for a prohibition, where it is for defect of jurisdiction. Bumb. 17. 10 East's Rep. 349.

A bill in equity, in the nature of a bill of peace, will also lie to establish a modus, where a suit has been instituted for tithes in kind; but a bill to establish a modus or customary payment in lieu of tithes, cannot be supported, where there has been no attempt to enforce the payment of tithes in kind. Gwill. 1596.

The following moduses have been established as good, by decisions in the courts of law: One penny for ancient gardens and orchards. (Bumb. 79.) Seventeen-pence for every cow having a calf, for the tithe of the milk and calf; eleven-pence for the tithe of the milk of a milk cow, milked without a calf; for every heifer, the first year she has a calf, thirteen-pence for the milk and calf—these payable at Michaelmas. Eight-pence for every hoghead of cyder, made of apples grown in the parish; for hoard apples, one penny; for firewood sold on the farm, one heath penny; for fruit, herbs, roots, and other garden stuff, a garden penny; for a calf, one penny;—these payable at Easter. (Bumb. 57.) Eight-pence for a cow, four-pence for an heifer; three shillings and four-pence, payable at Easter, for every score of sheep born out of the parish, and so proportionably for a lease number than twenty, or for a lesse time than a year, for their wool and lambs. (Bumb. 171.) Two-pence an hoghead for cyder. (Roll. Abr. 649.) The non-resident occupiers of land in B. and W. to pay on Good Friday, or as soon after as demanded, four-pence an acre for the tithe of hay, and the herbage of pasture lands not ploughed or sown but, if residenst, to pay tithes in kind. (2 P. Wms. 565.) Four-pence an acre for high land, and three-pence an acre for low land. (Ibid.) Twelve-pence for an acre of low meadow, and eight-pence for an acre of high meadow, for the tithe of hay. (1 Bro. P. C. 214.) One penny for hay for an ancient meadow, with the demesne lands thereunto belonging, containing 60 acres, &c. One pound six shillings and eight-pence for an ancient tenement, containing 625 acres, for hay, small tithes, and Eater offerings. (Bumb. 161.) Nine cart-loads of logwood, delivered to the rector by the lord of the manor, for himself and tenants, in lieu of all tithes. (Bumb. 279.) So of six pounds per annum. (Cro. Eliz. 559.) A halfpenny for each calf, in lieu of calves, payable on Wednesday before Easter. A smock penny for firewood. An halfpenny, payable on Shear-day, for the wool of each sheep dying between Candlemas and Shear-day. Four-pence a month, payable on Shear-day, for the tithe wool of every hundred sheep born in the parish, which were brought in after the 2d day of February. Three
Three eggs for every cock and hen, duck and drake, payable on Wednesday before Easter, in lieu of tithes of eggs, and chickens and ducks hatched in the parishes. (Bunb. 307.)

Thirty eggs for all tithes of eggs. (1 Roll's Abr. 648. 651. 2 Salk. 676.) The tenth chees made from the 18th of May until the fall of August, in discharge of the tithes of milk. (Cro. Eliz. 669.) An halfpenny for the wool of sheep sold after shearing, and before Michaelmas. (Moore. 911.)

One penny per head for sheep brought into the parishes after Candlemas, and clipt in the parishes, in lieu of tithes of wool; three pence per head for sheep in the parishes before Candlemas, and carried out before shearing time, though the wool tithe is not then actually due. (1 Ant. 341.) It is a good modus for an innkeeper, that in consideration that he and all, &c. have paid tithes hay and grain growing upon the land belonging to the said inn, and have paid tithes for all their own cattle feeding upon the land, that they have been time, &c. discharged of the tithes of the horses of their guests agisted in the said land, when they travel by the said inn; for some have said that this was but a personal tithes, and others have said that no tithes should be paid for such agistment by the common law, without any modus. 9 Vin. Ab. 13.

The things that are titheable are, for the most part, as follows: corn is a predial great tithe, and titheable according to the custom of the place, commonly by the tenth shock, cock, or sheaf. Beams and pease, expended in the house, are subject to no tithes; but if they are gathered to be sold, or to feed hogs, they are titheable, and are in their nature great tithes. Hay is a predial great tithe, and is to be tithe in swearth or cocks, according to the custom of the place. Clover, rape, and wood, are small tithes; heath, furze, and broom are also titheable: but no tithe shall be paid of fern. (2 Ant. 651.) The tithe agistment is a small tithe, and due of common right. Wood is a predial tithe, but whether great or small, hath been questioned between the parsons and the vicars; but it has been resolved, that if a vicar be endowed with the small tithes, and has always had tithewood, in such case it shall be accounted a small tithe, otherwise it is to be accounted among the great tithes. Timber fit for building of houses and ships, and comprehending oak, elm, and ash, are exempted from tithes, by 2 Edw. III. c. 3: but timber-trees, cut and corded for fuel, have been adjudged to pay tithes, as well as under-wood; however, no tithe shall be paid for the roots of trees, for wood cut for husbandry or fuel, for hurdles of sheep, for hop-poles, and for making of bricks, and also fruit-trees. When the wood is titheable, it is fet out while standing by the tenth acre, pole, or perch; or, when cut down, by the tenth faggot or billet.

Of under-woods sold standing, the tithe shall be paid, not by the seller, but by the buyer. The tithe of flax and hemp is a small tithe, and by statute this is charged at 5̅ per acre. (11 & 12 Will. c. 16.) The tithe of madder is also a small tithe, and charged at 5̅ per acre, by 31 Geo. II. c. 12. The tithe of hops is predial, and reckoned among small tithes; it is not to be paid till after they are picked, and before they are dried, every tenth measure. Out of gardens is paid tithe of all garden herbs and plants, which are small tithes, and may be demanded in kind: potatoes and turnips are also small tithes, as are likewise tobacco and saffron. However, in lieu of the tithes of gardens, a certain consideration in money is paid, either by custom, or by agreement with the parson. Fruits of trees, as apples, pears, plums, cherries, and the like, are predial tithes, to be paid in kind when they are gathered, unless there is some modus, or rate-tithe, paid in lieu of them. The tenth calf is due to the parson of common right; and if there are seven, he shall have one; if under seven, a halfpenny, or what custom shall direct, for each calf. But in most places, at this day, the custom hath obtained, that if there are five, the parson shall have the value of half a calf, lamb, or other fuch like; if there are six, he shall have one entire; and shall receive or pay out respectively a proportionable sum for each number under five, or above six. Colts and pigs are titheable in the same manner as calves; and the time of payment of their tithes is when they are so old that they may be weaned. Wool and lamb are generally reckoned mixt small tithes. Milk is a mixt tithe; where tithe-milk is paid in kind, no tithe-cheese is due; and where tithe-cheese is paid in kind, no tithe-milk is due. The tithe of milk is to be paid, not by the tenth part of every meal, but by every tenth meal entire. Deer and conies, being fere nature, are not titheable of common right, but by special custom. Of fowls, which are domestic, as geese, hens, and ducks, tithes are to be paid, either by paying the tenth egg, or the tenth of their young, according to custom. It hath been adjudged, that the paying of thirty eggs in Lent, is a good modus for all tithes of eggs. Bees are free of tithes, but the wax and honey are chargeable at the rate of the tenth measure of honey, and the tenth weight of wax. By the books of common law it appears, that some tithe or other is due for a mill. Fish in ponds and private fisheries, and in common rivers, are titheable only by custom. Firth taken in the sea are chargeable by custom as a personal tithe. Personal tithes are regulated by Stat. 2 & 3 Edw. VI. c. 13; but personal tithes are now scarcely anywhere paid in England, unlefs for mills or fish caught in the sea, and then payable where the party hears divine service, and receives the sacrament.

The manner or form of setting out or payment of tithes, is for the most part governed by the custom of the place. The parson, vicar, impropritor, or farmer, cannot come himself, and set forth his tithes, without the licence and consent of the owner; for if of his own head he shall tithe the corn or hay of any land-holder within his parish, and carry it away, he is a trespasser, and an action will lie against him for it. But every person is bound of common right, to cut down, and set out the tithes of his own lands. And that it may be done faithfully and without fraud, the laws of the church entitle the parson to have notice given him; but by the declaration of the common law, such notice is not necessary. Yet nevertheless, the common law declareth a custom of titling without view to be an absurd custom; and by the statute of 2 & 3 Edw. VI. c. 13, it is enacted, that at all times whensoever, and as often as any predial tithes shall be due at the tithing of the same, he shall be lawful to every party to whom any of the said tithes ought to be paid, or his deputy or servant, to view and see the said tithes to be justly and truly set forth and severed from the nine parts.

The care of the tithes, as to waste or spoiling, after sequestration, rests upon the parson, and not upon the owner of the land. For it is deemed that the parson is at his peril to take notice of the tithes being set out; and if it hath been declared, that although the parson must ought de jure to reap the corn, yet he is not bound to guard the tithes of the parson. Gibb. 689.

But after the tithes are set forth, he may of common right come himself, or his servants, and spread abroad, dry and stack this corn, hay, or the like, in any convenient place or places upon the ground where the same grew, till it be sufficiently weathered and fit to be carried into the barn. But he must not take a longer time for the doing thereof, than what is convenient and necessary; and what shall be deemed a convenient and necessary time, the law doth not nor can define: for the quantity of the corn or hay, and the weather,
TITHES.

Tithes are recoverable in the spiritual court by the canon law, and by divers statutes, as the statute of *circumspice agatis*, 13 Edw. III. I. 4.; the statute of *articuli eleri*, 9 Edw. II. I. 1. c. 1. 18 Edw. III. III. 3. c. 7. 1 Rich II. c. 13. 14. 27 Hen. VIII. cap. 20. 32 Hen. VIII. c. 7. 2 & 3 Edw. VI. c. 13. 7 & 8 Will. III. c. 6. 34. 1 Geo. II. c. 6. 27 Geo. II. c. 20.

Tithes in London are subject to particular regulations. By a decree made in 1545, according to the statute 37 Hen. VIII. c. 12, it is ordered, that the citizens and inhabitants of London and its liberties, shall yearly pay their tithes to the parsons, vicars, and curates, after the rate of 16s. 4d. for every 10s. annual rent, and 21. 9d. for every 20s. rent, and to above the rent of 20s. by the year, ascending from 10s. to 10s., according to the said rate. The wife, children, servants, or others of their family, taking the tithes of the church at Easler, shall pay 2d. for their four offering days yearly, &c. Notwithstanding the settlement of this decree, divers prescriptions for the payment of lesser rates than the parsons might require by it (as to pay 10s. for the tithes of a house, although its rent was 40l. a year, or more) have been gained and allowed. But by 22 & 23 Ch. II. c. 15, after the fire of London, annual certain tithes, or sums of money in lieu of tithes, for fifty-one churches, were appointed to be raised by afeffions, in the manner prescribed by the said act. For the receipts of the ministers of the fifty new churches, provision is made by the several acts of parliament relating to them, to be raised from the duties on coals. There are also particular statutes for particular churches, in London and in other places.

Original and History of Tithes.—The custom of giving or paying tithes is very ancient; in Gen. xiv. 20, Abraham gives Melchisedec the tenth of all the spoils he had taken from the four kings he had defeated: in Gen. xxviii. 22. Jacob makes a vow at Bethel, to give the tenth of all the riches he shall gather in that fojourn, to God. But these tithes were free and voluntary, and, besides, differed in divers other respects from what was afterwards called tithes: what Melchisedec received, was only the tenth of the spoils, not of Abraham's possessions; and this once, not annually; and besides, not as maintenance, which Melchisedec wanted not, but as homage; add, that this was only from one priest to another; for Abraham had not only a priest in his loins, but was a priest himself. And as to Jacob, who was also a priest, what he did was the effect of a vow, voluntarily taken, to offer the tenth of all he should possess; not to any other priest, but to God himself upon an altar.

Tithes were first legally enjoined by Moses, Lev. xxvii. 30. Numb. xviii. 21. Deut. xiv. 22. That legislator obliged the Israelites to the payment of several kinds of tithes: as,

1. The first tithes were a tithe of all the fruits given to the Levites: this was not taken till after the oblation called *terumah*, which was a tenth part allotted to the priests, had been made.

2. The second tithes was a tenth part of the nine remaining, after payment of the first tithes. This tithes was set apart in each family, and the master of the family was obliged to carry it to Jerusalem, and to use it there; or, in case he could not, he was to redeem it, or convert it into money: in which case he was to add a fifth to it, and carry the money to Jerusalem.

3. The tithes of the tithe, was the tenth part of all the tithes that had been given to the Levites by the people: for the Levites, after they had got all their tithes of the people, divided the whole into ten parts; and in their turn gave a tithe to the priests.

4. The tithes of the third year was another kind of tithes, not much different from the second tithes, excepting that it was less troublesome; because they did not carry it to Jerusalem either in kind, or in money, but kept it by them, to be spent by the Levites, the strangers, the fatherless, and the widows of the place, Deut. xiv. 28, 29. This was also called the tithe of the poor, and the third tithes; and these third years when it was paid, were called the tithe years. Several learned Jews and Christians, however, conceived that this was not a distinct tithe, but the same as the second; so that, as Mr. Mede apprehends, what was wont in other years to be spent in feasting, was every third year spent upon the poor. All these tithes are calculated to amount to above one-sixth of the revenue of each person.

These matters are all farther explained in the Talmud, in which are two books on tithes: also in the book of benedictions, עָשָׂרְנֵי, in the commentaries of Bartonora, Maimonides, R. Schelomoh Jarrihi, in Scaliger, Amama, Selden, Fricchmann, Quenfant, Varenius, Hottinger, Sigounius, Cunzeus, Godwyn, Leidecker, &c.

Under the new law, tithes are not established by Jesus Christ, or Christian diffusion, as they were under the old law by the ministry of Moses, the Christian priests, and the ministers of the altar of the new covenant, lived at first wholly upon the alms and oblations of the devout. In after-times, the laity gave a certain proportion of their revenues.
TITHES.

revenues to the clergy, but voluntarily, and not out of any
constraint or obligation: the first instances we have of this,
are in the fourth and fifth centuries.

This gift was called tithe, not that it was really a tenth
part of their income, or near to such; but only in imitation
of the tithes of the old law.

In the following ages, the prelates in their councils, in
concert with the princes, made an express law to the pur-
pose; and obliged the laity to give a full tenth part of their
revenues, their fruits, &c. to the ecclesiastics.

This the church enjoyed without disturbance for two or
three centuries; but in the eighth century the laity got hold
of part of these tithes, either by their own authority, or
by grants and donations of the princes; and appropriated
them to their own use.

Some time afterwards they restored them, or applied them
to the founding of monasteries or chapters, and the church
conten ded, at least tacitly, to this restitution. In 1179, the
third council of Lateran, held under Alexander III., com-
manded the laymen to restore all the tithes they yet held to
the church.

In 1215, the fourth council of Lateran, held under
Innocent III., moderated the matter a little; and, without
saying any thing of the tithes which the laity already prof-
fessed, forbade them to appropriate or take any more for
the future.

We may observe, that, upon the first introduction of
tithes, though every man was obliged to pay tithes in general,
yet he might give them to what priests he pleased, which
were called arbitrary confecrations of tithes: or he might pay
them into the hands of the bishop, who distributed among
his diocesan clergy the revenues of the church, which were
then in common. But when dioceses were divided into
parishes, the tithes of each parish were allotted to its own
particular minister; first by common consent, or the ap-
pointments of lords of the manors, and afterwards by the
written law of the land. However, arbitrary confecrations
of tithes took place again afterwards, and became in general
use with us till the time of king John. This was probably
owing to the intrigues of the regular clergy, or monks of
the Benedictine and other rules, and will account for the
number and riches of the monasteries and religious houses
which were founded in those days, and which were fre-
quently endowed with tithes. But in process of years,
the income of the laborious parish-priests being scandalously
reduced by these arbitrary confecrations of tithes, it was
remedied by pope Innocent III. about the year 1200, in
a decretal epistle, sent to the archbishop of Canterbury,
and dated from the palace of Lateran, which enjoined the pay-
ment of tithes to the parsons of the respective parishes,
where every man inhabited, agreeably to what was after-
wards directed by the same pope in other countries. This
epistle, being reasonable and just, and correspondent to the
ancient law, was allowed of, and became lex terra. This
put an effectual stop to all the arbitrary confecrations of
tithes; except some footsteps which still continue in those
portions of tithes, which the parson of one parish hath,
though rarely, a right to claim in another: for it is now
universally held that tithes are due, of common right, to
the parson of the parish, unless there be a special exemption.
This parson of the parish may be either the actual incum-
bent, or else the appropriator of the benefice: appropri-
ations being a method of endowing monasteries, which
seems to have been devised by the regular clergy, by way
of substitution to arbitrary confecrations of tithes.

Fa. Paolo, in his "Treatise of Beneficiary Matters," is
opinion, that the custom of paying tithes, under the new
law, began in France; and affirms, that there are no in-
fances of it before the eighth and ninth centuries: but he
must be mistaken; for in the second council of Matifeona,
held in 585, it is said expressly, that the Christians had a
long time kept inviolate that law of God, by which tithes of
all their fruits was enjoined to be given to the holy places,
&c.

In effect, Orig en (Hom. x. on Numb.) thinks, that the
old laws of Moses, touching the first-fruits and tithes, both
of cattle and of the fruits of the earth, are not abrogated
by the gospel; but ought to be observed on their ancient
footing.

The 5th canon of the council of Matifeona orders tithes
to be paid to the ministers of the church according to
the law of God, and the immemorial custom of the Christians,
for the use of the poor, and the redemption of captives,
and that upon penalty of excommunication: which is the
first penalty we find imposed on such as would not pay
tithe. On which grounds it is that many among the modern
clergy hold their tithes to be juste divino.

Others, on the contrary, plead, that the recompense to
be given church ministers, is differently ordained by God,
according to the differences he has put between his two
great dispensations, the law and the gospel: under the law
he gave them tithes; under the gospel, having left all
things in his church to charity, and Christian freedom,
he has given them only what shall be given them freely,
and in charity. That the law of tithes is in force under the
gospel, all the Protestant divines, except some among the
English, deny; for though hire to the labourer be of moral
and perpetual right, yet that special kind of hire, the tenth,
can be of no right or necessity, but to the special labour
for which God ordained it; that special labour was the Levi-
tical and ceremonial service of the tabernacle, (Numb. xviii.
21. 31.), which was abolished: the right, therefore, of the
special hire must be abolished too.

That tithes were ceremonial, is evident from their not
being given to the Levites till they had been first offered
as an heave-offering to the Lord, ver. 24. 28.

He, then, who by the law brings tithes into the gospel,
brings in likewise a sacrifice, and an altar; without which,
tithes, by the law, were unsanctioned and polluted, ver. 32.
And, therefore, they were never thought of in the first
Christian times, till ceremonial altars and oblations had
been brought back.

The Jews themselves, ever since their temple was de-
stroyed, though they have rabbis, and teachers of the
law, yet pay no tithes, as having no proper Levites to whom
nor any altar upon which to hallow them; which argues
that the Jews themselves never looked on tithes as moral,
but merely ceremonial. Add, that tithes were not allowed
to the priests and Levites merely for their labour in the
tabernacle; but in consideration of this likewise, that they
were not allowed to have any other part or inheritance in
the land (ver. 20. 24.), and, by that means, for a tenth,
lost a twelfth.

Besides, it has been urged, that the priests and Levites
were properly the officers and ministers of state under God
as king of Israel: and the Israelites paying through their
hands one-tenth to him, was agreeable to the custom of
almost all nations to pay one-tenth to their king. Tithes,
therefore, are to be considered as an appendage to the
theocracy, and it has been said, that it will be extremely
difficult to prove, that Christian ministers have a divine
right to demand them, from this circumstance of a con-
stitution peculiar to the Jewish nation. As to the original
of tithes, judge Blackstone observes, that he will not put
the
TITHES.

the title of the clergy to them upon any divine right; though such a right certainly commenced, and, as he apprehends, as certainly ceased, with the Jewish theocracy; yet an honourable and competent maintenance for the ministers of the gospel is, undoubtedly, \textit{jure divino}; whatever the particular mode of that maintenance may be. Accordingly, all municipal laws have provided a liberal and decent maintenance for their national priests or clergy: ours, in particular, have established this of tithes, probably in imitation of the Jewish law; and, perhaps, considering the degenerate state of the world in general, it may be more beneficial to the English clergy to found their title on the law of the land, than upon any divine right whatsoever, unacknowledged and unsupported by temporal functions. But, however beneficial this appointment may be to the clergy, it has been complained of as impolitic in a variety of respects, and peculiarly burdensome to the state.

Mr. Smith observes (Nature and Causes of the Wealth of Nations, vol. iii.), that tithes, as well as other similar taxes on the produce of the land, are in reality taxes upon the rent, and, under the appearance of equality, are very unequal taxes; a certain portion of the produce being in different situations, equivalent to a very different portion of the rent. In some very rich lands the produce is so great, that the one-half of it is fully sufficient to replace to the farmer his capital employed in cultivation, together with the ordinary profits of farming-stock in the neighbourhood. The other half, or, what comes to the same thing, the value of the other half, he could afford to pay as rent to the landlord, if there was no tithe. But if a tenth of the produce is taken from him in the way of tithe, he must require an abatement of the fifth part of his rent, otherwise he cannot get back his capital with the ordinary profit. In this case the rent of the landlord, instead of amounting to a half, or five-tenths of the whole produce, will amount only to four-tenths of it. In poorer lands, on the contrary, the produce is sometimes so small, and the expense of cultivation so great, that it requires four-fifths of the whole produce to replace to the farmer his capital with the ordinary profit. In this case, though there was no tithe, the rent of the landlord could amount to no more than one-fifth or two-tenths of the whole produce. But if the farmer pays one-tenth of the produce in the way of tithe, he must require an equal abatement of the rent of the landlord, which will thus be reduced to one-tenth only of the whole produce. Upon the rent of rich lands, the tithe may sometimes be a tax of no more than one-fifth part, or four thirlings in the pound; whereas, upon that of poorer lands, it may sometimes be a tax of one-half, or of ten thirlings in the pound.

It is a great discouragement to the improvement of land, that a tenth part of the clear produce, without any deduction for the advanced expense of raising that produce, should be alienated from the cultivator of the land to any other person whatever. The improvements of the landlord and the cultivation of the farmer are both checked by this unequal tax upon the rent. The one cannot venture to make the most important, which are generally the most expensive improvements; nor the other to raise the most valuable, which are generally too the most expensive crops; when the church, which lays out no part of the expense, is to share so very largely in the profit. When, instead of the certain portion of the produce of land, or of the price of a certain portion, a certain sum of money is to be paid in full compensation for all tax or tithe; the tax becomes, in this case, exactly of the same nature with the land-tax of England. It neither rises nor falls with the rent of the land. It neither encourages nor discourages improvement. The tithe in the greater part of those parishes which pay what is called a modus in lieu of all other tithes, is a tax of this kind. Some have proposed, as a better method for raising a revenue for the clergy, to lay an equivalent tax upon all estates, cultivated or not cultivated. It is well known, and has often been lamented, even by the clergy themselves, that this method of raising a revenue for their subsistence, is a continual source of dispute between the clergy and their parishioners, and contributes to obstruct the usefulness of their ministry. In Holland, and some other Protestant countries, the civil magistrates have adopted what some have thought a better plan, by allowing their ministers a fixed stipend, paid out of the public funds.

In effect, for the first three hundred years after Chri$t, no mention is made in all ecclesiastical history of any such thing as tithes; though, in that time, altars and oblations had been recalled, and the church had miserably judaized in many other things. The churchmen confessedly lived all that time on free-will offerings: nor could the defect of paying tithes be owing to this, that there were wanting civil magistrates to enjoin it; since Christians, having lands, might have given out of them what they pleased; and the first Christian emperors, who did all things by advice of the bishops, supplied what was wanting to the clergy, not out of tithes, which were never proposed, but out of their own imperial revenues.

The first authority produced, setting aside all the Papistical Constitutions, which few of the patrons of the tithes will insist on, is a provincial synod at Cullen in 356, where tithes are voted to be God's rent: but before that time, divers other abuses and complaints had got ground, as altars, candles at noon, &c. And thus one complaint begat another; as it is certain that tithes suppo[e] altars.

It is not easy to ascertain the time when tithes were first introduced into this country. About the year 794, Offa, king of the Mercians, made a law, by which he gave to the church the tithes of all his kingdom, in order, as it is said, to atone for the death of Ethelbert, king of the East Angles, whom, in the preceding year, he had caused to be so benad murder: But that they were paid in England before this time, by way of offering, according to the ancient usage and decrees of the church, appears from the canons of Egbert, archbishop of York, about the year 750, and from an epistle of Boniface, archbishop of Mentz, written about the same time to Cuthbert, archbishop of Canterbury, and from the 17th canon of the general council held for the whole kingdom at Chalchth, in the year 787. But the law of Offa first gave the church a civil right to them in this land by way of property and inheritance, and enabled the clergy to recover them as their legal due, by the coercion of the civil power. However, this establishment of Offa reached no farther than to the kingdom of Mercia, over which he reigned; until Ethelwulf, about sixty years after, enlarged it for the whole realm of England. See Revenue.

Judge Blackstone says, that possibly tithes in this country were contemporary with the planting of Christianity among the Saxons, by Angulinc, the monk, about the end of the sixth century. But the first mention of them, which he has met with in any written English law, is in a constitutional decree, made in a synod held (as he says) A. D. 786, in which the payment of tithes in general is strongly enjoined. This canon or decree, which did not at first bind the laity, was effectually confirmed by two kingdoms of the heptarchy, in their
TITLES.

By the council of Lateran, held under Alexander III., in 1179, the alienation or inference of tithes is prohibited for the future: where all infeditions made since that time are generally held, by the canonists, illegal.

Some attribute the original of these impropricated tithes to Charles Martel; and hold him damned for first giving the revenues of benefices to secular nobles. But Baronius will have this to be a fable, and refers their origin to the wars in the Holy Land; which is also the opinion of Paquier.

The tribute, it seems, which the Romans imposed on all the provinces of their empire, was a tenth part of all the fruits: hence several authors observe, that the Franks, having conquered the Gauls, and finding the imposition established, they kept it on foot, and gave these titles in fee to their followers: and this, say they, was the origin of imfeffed or impropricated or appropriated tithes. But the truth is, they are not so ancient; nor do we find any mention of them before the reign of Hugh Capet; even the very council of Clermont, held in 1097, as hot as it was in the interest of the church, does not say one word of them; which yet would undoubtedly have made loud complaints of such an usurpation, had it been then known.

TITLES. "Portion of," denotes tithes which the parson of one parish hath a right to claim in the parish of another. These portions, which might probably, at least in part, have been owing to the lord of a manor's estate, extending into districts which are now apportioned into distinct parishes, are in law so distinct from the rectory, that if one who has them purchases the rectory, the portion is not extinct, but remains grantable. The cognizance of these belongs, like that of other tithes, to the ecclesiastical court.

TITLES, as "{O}ffusions to Agriculture," the impediments and hindrances which they throw in the way of the progress and improvement of the land and its cultivation and amendment. It has been said to be the infraction of natural as well as revealed religion, that a portion of our property is due for the maintenance and support of the worship of God, and that "those who serve at the altar, should live by the altar;" but that whether a special proportion of one-tenth of our yearly income from land is due to the clergy by divine and unalterable right, is a point which has been warmly agitated, and much controverted. Under the Jewish government, it is well known that tithes were distinguished to be paid by divine appointment. And it has been stated by Bishop Butler, that under the Mosaic dispensation, God himself allotted to the priests and Levites, tithes and other possessions, and that in these possessions they had a divine right; a property quite superior to all human laws, ecclesiastical as well as civil. But that every donation to the Christian church is that of a human donation, and no more; and therefore cannot give a divine right, but such a right only as must be subject, in common with all other property, to the regulation of human laws. How far the claim to tithes on the principle of divine right remains still established in Catholic countries, is not well known; but this fort of claim to tithes has long since ceased in this country. And it is remarked by a late writer, that the conduct of Henry VIII. of England, and of Charles I. of Scotland, furnishes indubitable proofs of their holding a different opinion; as those kings, on the abolition of popery, in place of transferring the tithes from the Roman Catholic clergy to their successors in office, assumed the right of granting the greatest part of them to the nobility and great laymen of the time; and in the latter kingdom in particular, with the burden only of reasonable stipends to the Protestant clergy. And further, that the grants of tithes...
TITHES.

That the farmer, when he takes a bargain of the farm kind, which is subject to tithes, will undoubtedly estimate the proportion he is to pay to the incumbent, not according to what may have been demanded twenty or thirty years ago, but what it is actually worth at the present moment; and that if, by the lenity or forbearance of the rector or vicar of his parish, he may pay less, he ought to consider it as a sacrifice of which he is often well assured, and as laying him under an obligation which he should endeavour to return by every means in his power. Were this the case, that harmony which the good of religion, and the interest of the parties require, would, it is thought, be preserved inviolate; and that none but the extortionate incumbent would be the object of deferred enmity and reproach. The writer too has seen many good effects resulting from the proprietors of tithable land becoming personally responsible to the clergyman, and letting their estates, especially when there are no leases, tithe-free. The advantage is mutual; and it prevents misunderstandings as well as an opposition of interests, which frequently arise, when the tenant and the incumbent are left to themselves.

That, upon the whole, the rights of the clergy are exacted with extreme moderation, small as many of their livings are, in most parts of this portion of the country. That no very great part of their tithes is taken in kind, in many places; yet that notwithstanding, complaints exist of the hardship of tithes from the farmer, and of the unpleasant situation in which the incumbent is sometimes placed, by trying to raise his humble benefits to two-thirds, or even one-half of its real worth. Hence, it is conceived, there must be something radically wrong in a system, which excites prejudices in the most liberal and enlightened minds, and which equally militates against the interests of religion and those of agriculture.

Having thus briefly stated the nature of the origin of tithes, and the difficulties which attend them, as they respect the clergyman and farmer, it may be proper and necessary to inquire to what uses they were applied, after a legal right to demand them had been obtained, and how far the clergy of the present day follow out in practice the principle on which they were originally made payable. It has been remarked by the writer of the work on Modern Agriculture, that in regard to the question, whether the tithes in this part of this country be now appropriated to the Uses for which they were at first paid, whether voluntarily or by compulsion? it will be necessary to go back to the first introduction of the tithing system into the country. Bede states, it is said, that about the year 597, Gregory the Great, then pope, sent a monk of the name of Autilin into England, to propagate the gospel, and to introduce a system of church-government among the people. Autilin having succeeded to the umlout of his wishes, and having received a grant of land from the then king of Kent, besides donations from private individuals, for the support of himself and the priests whom he had brought along with him, found it necessary to apply to the pope for directions in regard to the manner in which these royal and private donations should be applied. Gregory solved the monk's question, by replying, that it was the custom of the church to divide such voluntary gifts as Christians were pleased to bestow in four parts: to give one to the bishop, another to the inferior clergy, a third to the poor, and to set aside the fourth for erecting and upholding churches or places of worship. And in confirmation of this, it may be noticed, that Blackstone has remarked, that at the first establishment of parochial clergy, the tithes of the parish were distributed in a fourfold division: one for the use of the bishop, another
Tithes.

for maintaining the fabric of the church, a third for the poor, and the fourth to provide for the incumbent; but that when the fees of the bishops became otherwise amply endowed, the bishops were prohibited from demanding their usual share of the tithes, and the division was in three parts only. In considering the state of tithes in the fourteenth century, he likewise takes notice of an act of Richard II. enjoining the bishops to allocate a proper sum out of the tithes of each diocese, for the fullness of poor parishes; remarking, in addition, that it seems the people were frequently sufferers by withholding of those alms, for which, among other purposes, the payment of tithes was originally imposed.

The first of the above two writers observes farther, that at what period the superior clergy of England first possessed themselves of the tithes, in defiance of the original designation, and of many statutes made to enforce an application of them to the uses for which they were first made payable, it is unnecessary to inquire. It will not be denied, however, it is thought, by the keenest flicker for the prerogatives of the church, that in place of one-third of them being applied for the use of the officiating clergy, one-third for the support of the poor, and the remaining third for the repairs of the churches, which, when the bishops had acquired land in mortmain, or free alms, sufficient to support their dignity, was the designation originally intended; the tithes payable in England are now very differently, although not, it is said, so legally, appropriated. Those people, says the writer, who are most disposed to cry out "the church is in danger," when the real or supposed rights of the clergy are invaded by the flighty attempts to alienate the tithes, ought to reflect that the third of all the tithes in England, whether in possession of the church or of the laity, ought to be allowed for the support of the poor; that another third ought to be expended in the repairs of the churches, the expense of which is now defrayed, in almost every instance, by an allowance on the parishes; and that the last third ought to fall to the officiating clergy, many of whom are the most miserable of the sons of men.

But it is not by any means, is it said, intended to censure the present members of the church of England for alienations of rights that took place centuries ago; far less to intone that that respectable body have not an unquestionable right to the value of such a proportion of the produce of the soil, as will enable them to fill the stations in which they are placed with dignity and honour. The object which is here aimed at, is the giving a succinct account of the particulars and circumstances in which the payment of tithes in kind operates against the introduction of improvements in agriculture, and the advancement of religion; and by throwing the reader back to the era in which the alteration in the tithing system was effected in Scotland, to endeavour to point out a way in which the future payment of tithes in England may be arranged, so as to meet the purposes, and most effectually promote the interests of agriculture, without in the smallest degree infringing on the rights of the individuals concerned in paying or receiving them. There are many different ways in which the payment of tithes in kind operates unfavourably to the general advancement and prosperity of the husbandry of this country. According to the writer of the Essays on rural affairs, it is universally considered as a grievance; there being, it is said, fearlessly an agricultural survey of a county, in which it is not stated as an evil that ought to be removed. And this the author thinks no wonder, as the drawing of tithes in kind, when it is examined with attention, will be found to operate directly, in the strictest sense of the word, as a tax on industry; and to be, at the same time, more vexatious in the mode of collecting than perhaps any tax that has ever been adopted, or had recourse to, on any occasion.

It is conceived to be a measure that has an injurious and unfavourable effect on four different descriptions of society, as the farmer, the landlord, the clergyman or proprietor of the tithes, and the public.

As to the first, or the farmer, he is more or less affected, according to the differences of the nature, circumstances, and situation of the land which he may hold. The intelligent writer on Modern Agriculture, noticed above, considers it unfortunate, though certainly the case, that the payment of tithes in kind operates more against the spirited improver than against the slovenly and indolent; and that tithes, as the law now stands, cannot be considered so much the tenth of the natural produce of the soil, as a tenth of the capital employed by the farmer in its cultivation and improvement. For instance, if a farmer pays his ploughman ten pounds a year of wages, his labourer ten-pence a day for his labour, or the landlord a hundred pounds of rent, he must consider himself as advancing one-tenth part of those sums for the purpose of promoting the interest of the tith-ower, who not only receives annually a sum equivalent to the tenth part of this capital, but that tenth improved to the highest degree which the unremittent exertion of the tenant is able to effect. Mr. Locke, it is continued, in his Treatise on Civil Government, remarks, that it is labour which puts the greatest part of the value upon land, without which it would scarcely be worth any thing. That is to say, that we owe the greatest part of all its useful products; for all that the produce of an acre of wheat is more than the produce of an acre of as good land which lies waste, is the effect of labour. Hence, it is thought, the farmer furnishes a fund to purchase the necessary labour, whereby an acre of land is rendered more productive as to afford fix, or eight, or ten shillings yearly of clear revenue to the tithe-owner, which, but for the application of that labour, would have remained unproductive for ever, in so far at least as he was concerned. So much is this the case, it is said, that if a farmer expends one hundred pounds on the purchase of manure, the improvement and cultivation of his farm, and the payment of the rent; and if the value of the crop, when sold, amounts to one hundred and ten pounds, he is actually a loser to the extent of five pounds, or what may be the interest of one hundred pounds for a year. He indeed gets his capital of one hundred pounds returned, but the tithe-owner draws the ten pounds, or rather more, or, which is the same thing, the value; so that the farmer has employed his capital to enable the tithe-owner to draw a dividend of 10 per cent., on that capital, whereas had he lent it in mortgage, or placed it in the funds, he would have benefited himself and his family to the extent of the interest or the dividend which he, in either of these cases, would have himself received. So much, it is said, for the arbitrancy of attempting to improve lands under such circumstances. The able writer of the above named Essays likewise, after stating different ways in which tithes operate against the village or tenant-farmer, truly remarks, that in this country, besides commons and wastes, much very fine land is allowed to remain in grass in a very unproductive state, which, with a little or moderate degree of industry and outlay of money upon it, might be made to yield abundant crops of corn; and the reason assigned for this disgraceful state of management and want of production, which is so called, because, was it altered, even the grafs-land might be safely made twice as productive
TITHES.

ive as it is by a judicious use of the plough, is, that the title of corn-land is so very heavy, as deters the farmer from having recourse to the plough; whereas in Scotland, where the corn-tithe is never drawn in kind, immense tracts of country, which thirty years ago were covered with heath, and totally unproductive even of grass itself, are now converted into fertile fields that yield abundant crops of corn and grasses; and which, if the tithe-laws had there existed, must, in all probability, have continued unproductive until the end of time. This is a contrast that is very striking to every one, it is said, who travels through these parts of that country; and that it brings forward a practical fact, which, ought, it is thought, to outweigh a million of speculative arguments.

The intelligent author of the Present State of Husbandry in Great Britain states, that another grievance to which farmers are subjected, in the payment of tithes in kind, arises from the harsh and oppressive manner in which the payments are sometimes exacted. The nature and extent of this grievance may, it is said, be learned by a perusal of the extract which is given below, from the same writer's Agricultural Report of the County of Northampton; where it is stated, that it has happened, (though, to the credit of the tithe-owners be it said, the infinences are very few or rare,) where, when the tithes have been let for the purpose of oppression, the tithing-man has been known to exert that authority with which he was invested; that he has not only taken the tenth fluck of corn, and the tenth cole of hay, but also the tenth lamb, pig, hen, egg, &c. nay, has even gone into the garden, and taken not only the tenth part of the fruit, but likewise the tenth of the produce of the kitchen-garden. Under such circumstances as these, it may be asked, who is the farmer that would not feel himself aggrieved? From this it must appear, it is thought, obvious, that whether the farmer's interest or happiness be considered, it must be equally his desire that some arrangement should be effected, whereby the payment of tithes in kind should for ever be abolished; for, as the writer of the Agricultural Report of the County of Buckingham very justly, it is said, observes, it may be laid down as a proposition, that whatever profit arises to the cultivator of the soil, by the force of superior ingenuity and industry, should be held sacred by the church and government. If it be otherwise, it discourages the improvement of the soil; and thereby the church prevents the future increase of her tithes, and the government the future increase of its taxes. It has been ably contended by the writer of the Essays on rural subjects, already noticed, that though the tithe-laws are hurtful to the farmer, they are perhaps still more to the proprietor or land-holder. Whatever checks, it is said, the industry of the farmer, must, in a direct manner, diminish the income of the landlord; and as the energy of a farmer, when once excited, is well known to augment in proportion to the advances he has made, whatever checks that energy in the bud, occasions in time a diminution of income to the proprietor, much greater than can be easily conceived. And that, as it is supposed the proportion of rent which can be afforded for arable land, increases with the productivity of that land in a much higher degree than in the ratio of the quantum of the crop; whatever tends to render land permanently more productive than before, if no deduction be made from it, tends, at the same time, to augment the income of the proprietor in a still higher degree than that of its produce. But as it is obvious that the tithe operates as a dead bar to the commencement of improvements in agriculture upon any soil of no great degree of fertility, so as to prevent the beginning of that motion, from the acceleration of which alone the proprietor can hope to derive considerable increase of rent; in all cases his rent is diminished in a much higher ratio than one-tenth, as it might seem to do by those who take only a flight view of the matter. It is added, that should the proprietor of poor lands, seeing the impossibility of the tenant's improving them, attempt to render these more permanently fertile by the outlay of flock upon them, that he never expected to draw back: but would content himself with a reasonable return of interest on the capital in the name of rent, he would not find the cafe much altered. He lets out, it may be supposed, with this principle, that if he can secure a permanent rent, equal to 5 per cent. on the money expended upon them, he will be very well satisfied with it. Let us say, then, that twelve bushels of grain were the next expense of culture, &c. which, on an average of all sorts of corn, was valued at 4s. the bushel; and that he had expended 2s. the acre, the interest of which, at 5 per cent., is 2s. or in other words, five bushels. But that before he can draw this rent free of tithe, the average produce must be, at least, eighteen bushels, out of which must be taken one bushel and nine-tenths, so that instead of five, his rent will be reduced to 3 per cent. nearly; while the titho-owner will be entitled to draw nearly 2 per cent. for ever, on the capital which the improver had thus expended. It is almost needless to add, it is said, that under such circumstances it is vain to look for a general spirit of agriculture, either among proprietors or tenants, to both of which descriptions of persons the operation of the tithe-laws are, it is contended, highly oppressive.

And another instance is stated of very material importance, in which tithe becomes singularly pernicious and prejudicial to proprietors of land. The importance of keeping and preferring the whole produce of the ground upon the farm where it was raised, for the purpose of making manure, seems, it is said, to be very generally understood; as a clause to that effect is universally found inserted in the leases in every county of England, wherever leases are granted at all. What punishment, it is asked, would the proprietors of these lands deem adequate to the crime of selling off the whole produce of the farm every tenth year? Yet great as this crime would be, it would not be adequate, in point of damage to them, to the right of drawing tithe in kind from their arable lands; because the farmer who sold the produce would, at least, become possessed of money to replace, in some degree, by means of extraneous manures, the loss he had incurred by the abstraction of the home-dung. Those who are entitled to draw the tithe in kind are, in fact, by this means, vested with a power of enriching themselves, or their own private property, if they be so inclined, at the expense of every other proprietor around them. In this point of view, therefore, tithes are singularly pernicious to proprietors of land. This is unquestionably an objection to the drawing of tithes in kind that can probably never be well got over by any of those who are so favourable to the present tithe system. It strikes at the very vitals of all our improvements in husbandry and rural buisnesses.

Besides, the writer of the work on modern husbandry considers that inasmuch as the spirit of improvement is depressed and checked, the land-holder must be injured; and that as there are no regulations or laws existing in this country which have such a tendency to impede the introduction of new or improved modes of husbandry as those of exacting the payment of tithes in kind, there are, of course, none that operate so decidedly against the landed interest of the kingdom. If, it is said, the farmer be restrained from including, draining, purchasing manure, in short, from cultivating...
TITHES.

Among the farmers in every age and country, the proprietors and farmers, in consequence of the success of the improvements which in that event would be undertaken, would be enabled to purchase more of the manufactures of the country, pay a greater share of the taxes for the support of the state, and after all, live in a greater state of ease and comfort, than under the existing circumstances they are able to do. In short, it is considered that the abolition of these laws is the only measure that can be adopted with any probability of success, at least the first one that ought to be attended to, with a view of again bringing the corn-trade to turn once more in favour of this country. When all these various circumstances are conjoint; and when it is further considered that, except in Spain and Portugal, there is scarcely a civilized nation in the world where this system of church-slavery is allowed to exist; and that even in Russia tithes are abolished; it may be reasonably hoped that the period is not far distant when England will be relieved by legal and constitutional means, and in consequence of arrangements made on liberal principles, from this almost Egyptian boudage.

It further likewise appears, from the accounts given by different writers on the subject of tithes, that they were paid in the latter end and ages of the Romish church with great reluctance; and even in this country during the reign of Henry VIII. Therefore it is said, that if, when improvements in agriculture were in their infancy, and at a period too when men's minds were held in flavish servitude by the clergy, the payment of tithes in kind could hardly be enforced, can it be supposed wonderful, that in those enlightened days it should be considered as a grievance? At a period when the principles of religion and of real genuine liberty are better ascertained, and more generally known, than in any former age, it is not surprizing that laws compelling the payment of tithes in kind, laws which originated in edicts issued by bigotted kings under the influence of designing priests, should now be found inimical to the best interests of the country, and to the happiness of so many thousands. That this is the case, every inhabitant of this island has ample opportunities of satisfying himself by a perusal of the agricultural reports of the different counties of England and Wales, which have been lately-published. And that as these reports, after having been circulated among the proprietors of land and farmers for their correction and amendment, still contain, in their republication, the same or similar complaints in respect to the hardships which the farmers are subjected to, and the injury which agriculture sustains, by the continuance of the payment of tithes in kind, such complaints may justly be deemed the voice of the people proclaimed in a constitutional way; and as such, merit the most serious and speedy attention of the Legislature and of the clergy.

A few of the injurious effects of the practice of paying tithes in kind have been noticed above, and many more of the hardships proceeding from it are recorded in the different agricultural county surveys and other works which have been only slightly touched upon in what has been already said upon the subject. And the necessity of something effectual being done, in order to the removal of so inconvenient and oppressive a regulation, has been strongly thrown in the writings of the various advocates of the improvements of British husbandry and farming, as well as by many other able and intelligent writers on matters connected with them, but which, for want of room, cannot be considered here.

As, therefore, some reform in the mode of paying tithes in this country must be admitted to be indispensably necessary,
TITHES.

fary, it is to be wished that the legislature, especially at the present time, would devote that attention and consideration to the subject which its importance and necessity demand, and the clergy come forward with such reasonable propositions for the adjustment of the business as may be suitable, as by such means the matter might, and no doubt would, be soon easily settled to the satisfaction of all the parties concerned.

In the view of affording a proper knowledge of the most suitable means of effecting so important an alteration, the author of the "Prefent State of Husbandry" in this island, gives the following clear account of the beneficial arrangement which took place in respect to tithes in Scotland, and of the circumstances which led to it. It is stated, on the authority of Erkine's "Institutes of the Law of Scotland," that the payment of tithes in kind was continued for many ages in that kingdom; and that, owing to the precariousness of the climate, it was attended with more grievous hardships than could have taken place in the southern part of the island. Every Scotch proprietor or farmer, who presumed, after reaping their corns, to carry off any part of them from the field, until the person having right to the tithe had drawn his share, were, from the first establishment of this right, subject to severe penalties. The tithe-owner, on the contrary, either from indulgence, or desire to oppress, or with a view of compelling the proprietor or farmer to purchase his tithes annually at a high price, frequently delayed drawing his share until a great part of the crop or produce was rotten. Notwithstanding several statutes were enacted with a view of checking the oppressive disposition which so often evinced itself in the conduct of the clergy in this respect, yet these grievances continued to exist, or were, at least, until the year 1633: when a decree-arbitrary, passed by Charles I. in 1629, for arranging and determining a mode, to be afterwards adopted, for the payment of tithes, was ratified by parliament.

That during the struggle for the establishment of this or that form of church-government, great alterations had taken place, both in regard to those having right to the tithes, and to the manner in which they were exacted. On the Reformation, the benefices of the church fell to the crown, and were, at different periods, gifted for services, or other considerations; such as for supporting universities, hospitals, &c.; and the persons obtaining them were denominates lords of erection, and sometimes called by other names. They likewise got, or assumed, the right of nominating officiating clergy on all vacancies. These alienations were, by act of parliament, 1587, put a stop to; and such tithes as had not been previously dispossessed, remained with the crown unalienably. The tithes, which were then annexed to the crown, may be valued and leased by the proprietor of the lands, but cannot be purchased. The officers of the crown are in use to grant leaves of this description of tithes for nineteen years, and which are renewed as matters of course on paying a reasonable sum on such renewal. The sum demanded is regulated by the yearly value of the tithes; so that a capital equal to between five and six years' amount of the tithes, laid out at the commencement of the lease, and improved by compound interest, is sufficient to produce such a sum at the expiry as will obtain renewals to perpetuity.

Some of the clergy remained, it is said, in possession of their benefices after the Reformation; and the vacancies that happened in such benefices were filled up by those who assumed the right of presentation. An act of parliament was soon afterwards passed, whereby the patrons were deprived of the right of patronage: but in compensation for this supposed hardship, it was enacted, that the right of all tithes, to be paid by the clergy, should be vested in those who had exercised the right of patronage. Patrons having acquired tithes in this way, are compelled by law to sell them at nine years' purchase of the yearly value of the tithes.

The system of tithes and titling having, however, got into great confusion, in consequence of the various alterations that took place in the government of the church of Scotland, those interested found it necessary to submit their several rights and claims to the determination and final award of Charles I., who, on the 2d of September, 1629, pronounced two decrees-arbitrary, or judgments, which laid the foundation of that arrangement respecting tithes, and the payment of the established clergy in Scotland, which has been productive of so many good consequences.

The most important article in these two decrees-arbitrary, is that which directs the valuation and sale of tithes; after which, the land-holder is entitled to the whole crop upon payment to the proprietor of the tithes of a yearly rent, or to purchase them at an easy rate, subject to a reasonable provision to the clergy. The officers of the crown, by this law, are, it is said, that 'the rule of all tithes, where they are valued jointly with the stock, shall be a fifth part of the constant yearly rent that is paid for the lands.' Another material circumstance in the valuation of tithes in Scotland is, that the rents of mills, those arising from recent improvements, and some others of lesser importance, are deducted from the gross amount.

By these decrees, which were ratified in parliament in 1633, the proprietors of land not having right to the tithes, were not only found entitled to sue the titular in an action at law to ascertain their value, but, unless vested in the crown, to obtain a purchase of them on established terms, as mentioned above. Thus, ever since 1633, every land-holder in Scotland has had it in his power to acquire right to his own tithes, either by purchase, or lease, so that they should be no longer payable in kind. Nevertheless, those who neglect to sue for a valuation may still be subjected to all the inconveniences of the former law; as under such circumstances, those having right to the tithes may draw them in the manner commonly practised in England. The remedy is, however, so easy, that it must be a fool indeed who would subject himself or his tenants to such a flavius fervitude, while he has it in his power, by a simple application to the supreme court of the country, to abolish it for ever.

Some instances are, however, recollected, where proprietors in the north of Scotland, having a right to the tithes, and being unwilling to forego all the power of harassing their tenants, which attached itself to the ancient feudal baron, still continued to draw the tithes for some time. But they at last became ashamed of such conduct; and there is not now, it is said, one instance where tithes are paid in kind, or where the tenants have any concern, either directly or indirectly, with or in the payment of tithes on the north side of the Tweed. How then, it may be asked, are the Scotch clergy provided for? The answer is, it is paid, easy; the stipends provided by law for the maintenance of the Scotch clergy are still payable out of the tithes. The judges of the court of session, who act as commissioners for the arrangement of tithes, have a right to modify reasonable stipends to the parochial clergy. And accordingly, in all such cases, where the clergyman can shew that the parson is a place of more than ordinary reformatory use, that the cure is burdensome, or that the necessaries of life give a high price in that part of the country, or that the scanty
TITHES.

fealty allowance of stipend in that parish bears too small a proportion to the weight of the charge, provided there are free and unappropriated tithes in the parish, the commissioners, on the application of the clergyman, grant an additional stipend, either in money, but more generally, where practicable, in grain, as being least fluctuating in value than money. But that owing to the free tithe in the parish having been previously assigned to the clergyman, some instances do occur, where the commissioners have it not in their power to augment his stipend, although it be too small for the decent maintenance of a numerous family. In all such cases it would, it is thought, be highly proper to apply part of the bishop's tithes, such as are now payable to the crown, to the purpose of rendering the situation of these clergymen, who are so unfortunately situated, more decent and respectable.

In order to the introduction of a suitable arrangement in regard to tithes in this part of the country, it is remarked, that the question has been for some time past very popular, and much agitated; and that many difficulties have been started, apparently for the purpose of rendering it more perplexed and complicated than it is in reality. Holding it as a sacred and inviolable principle, that tithes, as now payable in England, were formerly appropriated for particular purposes, and that although in many instances alienations were made at different periods; yet that as these are expressly or virtually confirmed by those laws which protect national and individual property; therefore tithes, as now payable in the southern part of the island, are payable in conformity to the laws of the country. This being granted, no man who has a regard for justice, who venerates the constitution, or who would not wish to see the rights of property invaded, but must be satisfied, that if the present mode of paying tithes is abolished, the clergy and the lay-proprietors of tithes are, in law, justice, and equity, entitled to an equivalent. What that equivalent ought to be, and in what manner ascertain'd, becomes the question. It is observed, that it is not by appeals to quarter-seessions, nor by special acts of parliament for this or that particular diocese or parish, that this great national question can be determined with propriety; it is only by a submision of all rights and claims of both parties to the determination of some one respectable individual, that the matter can be amicably or equitably decided. And it is thought, that the most proper individual to be made choice of is the sovereign, or person holding the government of the country.

The clergy, it is said, need not be afraid to appeal to such an arbiter, as in the course of a great length of time there has been no instance of any degree of infringement of or upon their rights. The land-holders and lay tithe-owners may keep their minds at ease, as though the most sacred regard for religion has been evinc'd, yet it has been divested of superstitition or bigotry. If, it is continued, Charles I. during the anarchy of church-government that prevailed in his time, found no difficulty in passing a decree in a similar case, which, having received the sanction of parliament as a matter of course, laid the foundation for a just and equitable arrangement of the tithes, the business may unquestionably be accomplished with much less difficulty at the present period. The probable consequences of such a submision would, it is thought, be, that the arbiter would no doubt appoint commissioners to examine and ascertain the yearly value of all the landed property in England, the produce of which is subject to the payment of tithes. Were the yearly value of the lands ascertained by a corn-rent in place of one in money, and which, it is supposed, might be easily done by taking the average price of corn for the seven or ten years or more last past, with the exception, however, of 1795, and some other fewer and dearer years, the clergy could claim no loss, nor would after valuations in consequence of the depreciation in the value of money, be rendered necessary.

This being done, a fifth, a sixth, or any other given proportion of the free rent, after the payment of parliamentary taxes affectting land, would be declared due to the tithe-owner in lieu of the payment of tithes in kind. This clause of the decree would probably, it is thought, be, to compel every lay-owner of tithes to sell his right to the land-holder, at a fair and equitable, but regulated price; and another would most likely be, declaring the clergy entitled for ever to a fifth or sixth, or some other determinate proportion of the present real free rent of all titheable lands, to which they may have right, and subjecting the proprietors to the regular payment thereof. Thus at once would, it is said, a load which has for many ages press'd down the spirit of the English farmers, be removed, and that while all ranks and degrees must applaud the equity and the propriety of the arrangement, a spirit for agricultural improvements would evince itself superior, it is thought, to any of which the records of this country make mention.

It is supposed that this mode is the less exceptionable, as it is almost similar to that adopted when acts of parliament are passed for enclosing particular parishes. At the first meeting of the commissioners named in such acts, they direct, that all having interest may deliver in their claims, and the rights or grounds on which they claim, against a certain day. Thrice being afterwards examined by the commissioners, who are neither more nor less than arbitrers appointed by the legislature, their decision constitutes the law in regard to the right by which the individual proprietors hold the lands, which by the arbiter's award is assigned to them. In place, therefore, of multiplying acts of parliament respecting the adjustment of tithes ad infinitum, one only, and that a very short one, seems necessary, authorizing the governing person to arbitrate between the owners of the tithes and the land-holders; and whose award, like that of the commissioners appointed under acts of parliament for enclosores, should be final, and have the effect of law. Having thus laid down the general principle, it will not be expected that any attempt will be made to combat the little difficulties that may be started against the practicability of carrying the measures founded thereon into effect. These the wisdom of the arbitrator will be fully sufficient to obviate and direct. One thing is certain, it is supposed, namely, that a decree-arbitral or judgment, pronounced by such high authority, and founded on these principles, would give universal satisfaction to every party concerned.

On a matter which is so very interesting and important to the English land-holder and farmer, it will be necessary and useful to bring to the inquirer's notice and attention a few of the different other modes and plans which have been suggested at different times by different writers for effecting the business and adjustment of the matter of tithes.

The intelligent writer of the Essays on rural affairs has supposed, that the tithes of or in England and Wales should be converted, so as to make a payment in money be universally received in lieu of the payments in kind that are at present exigible; but under such modifications as to prevent the possibility of those who are entitled to draw the tithes from suffering by the depreciation in the value of money, which we have seen for a long time past has been going on in a regular progression; and which may be expected to continue; or may, perhaps, as at this time in a neighbouring country, be sunk almost to nothing by some political shock that
TITHE.

that cannot at present be foreseen. With these views, might not, it is asked, a law be obtained, authorizing the valuation of tithes, in every case where either of the parties interested in it should so incline? This might be done, it is said, by a
famous raised against all the parties concerned, either before the sheriff of the county where the property lay, or before any other judge that should be thought more proper for executing the office; who, after hearing the parties, should proceed to make a legal inquest to obtain a clear proof that what had been the amount of the tithes, actually paid and drawn, for five, ten, fifteen, or twenty years past, as should be judged the most proper, out of the several lands in question; specifying distinctly the quantity of each denomination of grain, or other titheable produce. But as it may easily be foreseen, that it would be a matter of great difficulty, in many cases, to get at these facts with precision, might it not be put in the power of the judge, if the parties could not agree as to that particular, to appoint two or more persons of good character in the neighbourhood, to gather up the tithes in kind themselves, fairly and honestly, for five years next to come, without favour to any person; the amount to be delivered to the persons having a right to receive them, after the quantities had been respectively ascertained, so as to admit of the collectors making up an account of the whole, upon oath, to be delivered to the judge; who, from that account so made up, should caue an average to be struck of the quantities of each particular article; which average quantities, after deducting a just proportion for the expense of collecting, and taxes affecting the tithe, should be declared by him to be the legal tithe exigeable from the land in question in all time to come? But as there is room to suspect that the money prices of corn, wool, &c. of different denominations, may rise to be much higher in some future period than it was at that time; instead of then ascertaining the amount of these articles, let it be declared, that the quantities of grain and other articles resulting from the averages respectively, are payable out of the respective lands, leaving the average prices of such grain, wool, &c. to be settled and ascertained each year, as is specified below; declaring that the money which shall arise from the average prices thus ascertained, should be in lieu of the whole tithe that could be exacted each year; the time of payment too to be specified. And, in order to prevent all disputes as to the average prices of these articles in time to come, let the sheriff of each county be authorized and required to make an inquest at a certain period each year of what has been the actual ready money selling price of corn of the preceding year's crop, from the time the crops were reaped till this time, and of wool, as well as of all other titheable articles for the former year, by examining witnesses before a jury to be appointed for that purpose, which prices, after being thus ascertained, should be published and declared to be those by which the quantity of tithe-corn of each particular description, and other titheable articles, contained in any degree of valuation, should be payable for the crop of the preceding year. Thus, it is said, would the tithe-owner be entitled to receive payment of his tithes, without any extraordinary expense or trouble, or unjust deduction or dispute whatever; the farmer would be allowed to carry on his operations uncumbered by those galling restraints which the tithe-laws at present perpetually threw in his way: the proprietor would be at liberty to apply such part of his capital as he might incline, towards promoting agricultural improvements, with a reasonable prospect of being benefited by his exertion: and the public would become possessed of a quantity of surplus produce of land, which it can have no prospect of ever otherwise enjoy, which would be the means of diffusing a perpetual plenty through every corner of the land.

Mr. Pitt, in his account of the agriculture of a midland district, suggests, that the mode or scheme to be adopted as the outline of an exchange of tithes, should be for land, in the manner directed below, as land will always bear a value proportionate to that of its produce, and that even the price or value of labour is measured by the same standard. This is, that an act of parliament should appoint, in every diocese, an equal number of the most respectable clergy and country gentlemen commissioners and trustees, with a power of nominating surveyors, to value all the tithes belonging either to the clergy or laity within the diocese; and that this act should be let give an option to the land-owners of purchasing their respective tithes, at the valuation fixed on them by such commissioners and surveyors; the money arising from such redemption being invested in the funds, or other more proper securities, until a suitable opportunity should offer of laying it out in the purchase of land; and that, where the land-owners should refuse to purchase such tithes, the commissioners should have the power of mortgaging them, or of taking up money on their security, to be invested in the same way with that arising from the tithes actually sold; or after a given time, the trustees might be empowered to let part an allotment of the land of those owners who refuse to purchase, and which, if conveniently situate for the former tithe-owner, might be so applied, otherwise sold; and the money arising from such sale invested as before, until it could be laid out in the purchase of land. The execution of this plan or mode as this would, it is supposed, be attended with infinitely less trouble and expense than now incurred by the annual valuation of tithes; as, should such a regulation be once effected, the business would be settled for ever: while under the present system, the surveyor or valuer's business is never done, but continued from year to year; and, if it should remain, will be from generation to generation. An equivalent in land must certainly, it is thought, be a more solid property than tithes. Land too may be improved in any degree by good management and industry: tithes fluctuate or link in value at the will of the cultivator. Some such commutation as this may, it is thought, be readily and easily effected, and that all parties would be pleased with the alteration.

The concluding remarks and suggestions on this greatly interesting matter, are the result of the investigations and inquiries of two clergy-men, who have been lately engaged in drawing up accounts of the state of the agriculture of two large counties of the kingdom, those of Hereford and Berks. The former states, that of the various modes proposed to effect the desirable object of a general commutation of tithes, that of a corn-rent seems to have met less objection than most others which have been yet proposed; still, however, nothing has been seriously attempted, and the matter remains open to further discussion. It has not, perhaps, if it is said, occurred to every one, that tithes, in their present form, have a direct and powerful tendency towards increasing the prices of wheat and of every other grain, by creating obstacles to its culture, and thus diminishing the quantity which would otherwise be grown. But that the fact, that an acre of land under the culture of wheat is liable to a deduction on account of tithes, is nearly ten-fold proportion to the amount of that acre of land grazed by cattle or sheep, is surely sufficient evidence that tithes must operate unfavourably to the culture of grain, and consequently to its abundance and cheapness. How desirable then is it, it is said, such a commutation as would render this payment equally heavy on every acre of land, according to its value, whether
TITHES.

It be applied to the culture of grain, or to the production of animal food. Under this impression it is here proposed, that in lieu of title, a tax be imposed, on the principle of an equal land-tax, upon every estate, according to its value, for the support of the clergy. The wisdom of parliament would, it is supposed, easily determine how many thillings in every pound of rent would be equal to the revenues to which the clergy have a claim, and that the measure would be greatly facilitated by the investigations occasioned by the income or property act lately in force. The tenant might be made liable in the first instance to the payment of the duty proposed as a substution for the tithe, but in case of his defalcation, the landlord might be made ultimately responsible.

In this mode of arrangement, the clergy, it is supposed, would receive what is their due, a full equivalent for tithes in its present state; the securitv would still attach to the soil itself, and their revenues would still increase with the increase of the value of land and its produce. Encouragement would thus be afforded to increase the culture of grain; the industrious farmer would not have to contribute more than is just proportion; the tithe-owners too would obtain the fair value of their property; the clergy of the church of England would acquire that degree of respect and esteem to which few will deny that they are, in the aggregate, entitled; and, above all, they would be enabled to fulfil the valuable purpose of their institution: while at present, the clergyman who demands but the fair value of his property, becomes hated, and often insulted; and, to use the strong language of some, his “integrity becomes suspected; his every action is seen through a falle medium; and the pastor is lost in the collector of tithes.”

If it should be objected, that under this or any other mode of commutation, the farmer would not eventually be benefited, because the landlord would then receive what is now paid to the tithe-owner; and that the farmer has no just ground of complaint, as he engaged his farm subject to the deduction or payment of tithes: let it be understood that the interest of the community at large, not of any one branch of it, is here contended for.

The writer maintains, that the great object of a commutation of tithes, beyond a religious view of it, is the relief of the corn-field, and not the farmer. Perhaps, it is said, if the subject be well considered, the farmer would gain less in a commutation than any one class of society. Tithes, in their present form, may check his improvements, may contract his system of farming and his capital, may harass his mind, and lead to personal animosities and expensive litigations; but probably his mere payments in lieu of tithe would, on the whole, be as heavy under any commutation, as thence to which he is now liable. The public, it is said, must give that price for grain, at which it will answer the farmer to raise it; and that supposing it possible that the farmers throughout the island were to engage in a combination, to convert so much of their present tillage into pasture, as would leave only half the usual number of acres under corn, the inevitable consequence would be, that grain would fall at an enormous price, and the farmer would receive that increased price, at a time when his expenses were diminished in the proportion of his tillage. Thus the consumer, which is the public, and not the farmer, would suffer; and if a tax, such as tithes, added to the increased price of timber, iron-work, and labour, should induce the farmer gradually but materially to contract his tillage, there could be no hope that grain would be sold during any considerable period at a moderate price; nor could there be an adequate supply for the wants of the country, without the aid of large importations, which are always precarious, and sometimes impossible: and as animal food invariably rises in value with the increased value of grain, the farmer might thus be enriched at the expense of every other branch of the community. The plan or mode here proposed for a commutation would, it is presumed, counteract or prevent these furious evils; encouragement would be given to an extended culture of grain; and a new motive to industry and exertion would be found in the consideration, that the most industrious farmer must contribute an equal sum with the most active and successful cultivator.

The latter of these clergymen thinks, that in regard to tithes in secular hands, though the church may suffer in the amount of its income, it derives a considerable degree of security for what it still possesses, from this very circumstance; and consequently only touches on the subject so far as to propose that they should be commuted for land, according to their value. To this no reasonable objection is seen, or any insuperable difficulty, if a legislative plan were once chalked out for its accomplishment. But as for tithes in the hands of the clergy, whether great or small, it is supposed they might be beneficially commuted, by first taking their fair valuation by two competent sworn commissioners, one of whom should be named by the incumbent, and thus fixing a sum to be paid according to the combined prices of corn, meat, as mutton and beef, and milk, to be taken on the average of the seven preceding years, and to vary with the times every subsequent seven years. And in order to prevent any thing personal between the incumbent and his parishioners, except in the duties of his vocation, the overseers and churchwardens to be made the responsible agents in collecting and paying the sum to be raised, with certain provisions and securities against misapplication and loss.

A corn-rent alone is, it is said, found to be an inadequate mode of commutation; but that taking the three great articles of life in every family, bread, meat, and milk, the clergymen would be secure from injury, and the farmer, paying only in proportion to the value of his produce, would have no reason to complain. It is to be observed, however, that it is wished for the laws to act uniformly for the benefit and security of the parochial minister, without subjugating him to the necessity of coming forward in a personal and partial light. By these means, what he might lose in the influence of fear, would, it is thought, be amply compensated for on the principle of love; without which he can seldom be happy himself, or discharge the duties of his sacred office with effect and satisfaction.

Where lands have been exonerated from tithes by an act of parliament, and an allotment made in land in lieu of them, even where an adequate value has been given, which in no instance that has fallen under the writer's notice is, it is said, really the case, it is throwing too much land into mortmain, it is subjugating the incumbent to all the cares and incumbrances of landed property, and driving him to the necessity of becoming a farmer, for which he is often ill qualified, or of letting lands, according to the existing laws, on such conditions, that improvement must be checked, and industry languish.

In order, however, to obviate some of the evils resulting from a practice that has already, it is said, become too general, it is proposed, that after having reserved a sufficient glebe, which in every instance should be done, with a due regard to the value of the living, the incumbent should be allowed to lease the remainder, at the full value, with the consent of the patron and the bishop, on a running lease, determinable every three or seven years, at the option of either of the two principal contracting parties. A new incumbent
cumbent would thus, it is suppos'd, without waiting too long, have an opportunity of improving his property, if he thought it capable of being so; and the tenant, having a fair prospect of occupying the land under any change, would feel himself equally fate in making improvements, as if he rented of a layman. All dilapidations and repairs on the farm, however, should fall on the tenant; who ought not to be bound in proper covenants, but be obliged to give due security for their performance, as well as the payment of the rent.

Or, to land belonging to the clergy, the corn, meat, and mule rents might, it is said, be applied as well as to tithes with leaves for twenty-one years certain, which would probably be the most eligible mode, as it would give uniformity to the plan of clerical provision, and would always afford an income according to the times.

Upon the whole consideration of the subject, there cannot be any doubt but that great advantage and improvement would arise to agriculture, from some measure of this nature being laid recours to and carried into execution; and though the farmer might not perhaps, on the whole, experience any great diminution in the quantity of money which he would have to pay, he would be wholly freed from the anxiety, trouble, and vexation, which constantly attend the taking of tithes in kind, and at the same time, which is much more important and material, be left at full liberty to exert his utmost endeavours to promote all kinds of improvements, which the nature of his farm may with propriety admit. And in this way, and by such means, the art of agriculture would be carried forward to such a state of improvement and perfection as cannot be easily conceived. Besides, such a measure might have a considerable effect in promoting the inclosure and cultivation of much land still in the disgraceful situation of waste, all which are desirable objects on various accounts in the present state of the country.

Tithe-Rate. See Rate-Tithe.

Tithes, Subtraction of. See Subtraction.

Tithing, Decenna, or Decury, a number or company of ten men, with their families, knit together in a kind of society, and all bound to the king, for the peaceable behaviour of each other.

Anciently no man was suffered to abide in England above forty days, unleas he were enrolled in some tithing. One of the principal inhabitants of the tithing is annually appointed to preside over the rest, being called the tithing-man, the head-borough, and in some countries the bortheider, or borough's elder, being suppos'd the directest man in the borough, town, or tithing. The distribution of England into tithings and hundreds is owing to king Alfred. See DECIERS, FRANK-PLEDGE, and FRIBURGH.

Tithonia, in Botany, so named by professor Desfontaines, in allusion to the glowing light-orange tint of its flowers, which the French call couleur aurore. The fabled favourite of Aurora, Tithonus, is therefore here meant to be commemorated. The allusion would have been still more happy, had the flower been one of the everlasting kind.—Desfont. Ann. du Mus. v. 149. Wildll. Sp. Pl. v. 3. 2246. Jull. 189. Lamarrck Illrtr. t. 708. Poiret in Linn. Dict. v. 7. 690.—Clays and order, Syngenesia Polygama-fruticans. Nat. Ord. Compositae oppositifolias. Linn. Corymbosus, Jull.

Gen. Ch. Common Calyx cylindrical, of a double row of ovate-oblong, acute, flat, nearly equal, erect scales. Cor. compound, radiated. Florets of the disk numerous, all perfect, level-topped, tubular; limb five-toothed; tube inflated near the base. Those of the radius female but abortive, about twelve; limb elliptic-lanceolate, acute, entire, horizontal, flat. Stam. in the disk only, Filaments five, capillary, shorter than the tube; anthers united into a cylinder of the same length. Pijl. in the disk, Germin oblong, slender; style thread-shaped, the length of the petal corolla; stigma two, recurved, obtuse; in the radius, germin very small; style scarcely any. Peric. none, except the unchanged calyx. Seeds in the florets of the disk only, solitary, ovate, smooth; their crown of five short, acute, erect, membranous scales. Recept. convex, chaffy, its scales concave, acute, rather taller than the seeds.

Eff. Ch. Receptacle chaffy, convex. Seed-crown of five chaffy scales. Calyx cylindrical; its scales equal, converging, in two rows. Florets of the disk inflated at the base; those of the radius elliptic-lanceolate.

1. T. tagetiflora. Marigold Tithonia. Desfont. as above, t. 4. Wildll. n. 1.—Native of Vera Cruz. Root annual. Stem erect, alternately branched, leafy, a foot high. Leaves alternate, on long stalks, downy, crenate, reticulated with veins, triple-ribbed; the lower ones deeply three-lobed; upper undivided, ovate, or somewhat heart-shaped, acute. Flowers on long solitary stalks, at the end of each branch, orange-coloured, about the size of a French marigold.

Tithorea, in Ancient Geography, a town of Greece, in the Phocide, on mount Parnassus, 80 stadia from Delphi. This place was famous for its sacred grove dedicated to Minerva, a temple with the statue of this goddess, and the tomb of Antiopé and Phocus. The temple of Eschelapius Argachetes was situated 70 stadia from Tithorea. The inclosure which contained the chapel of Isis was 40 stadia farther distant than the temple of Eschelapius.

Tithrasus, a town of Africa, in Libya, bordered by a river of the same name.

Tithronium, a town of Greece, in the Phocide, in which was a grove sacred to Apollo, with some altar and a temple, but without a sttate. This town was situated 15 stadia from Amphilca and 20 from Drymea, near the river Cephalus. Pausanias.

Tithymaloide, in Botany, so called from its affinity to Tithymalus, the Euphorbia of modern botanists, differs from that indeed merely in having the calyx gibbous on one side at the base.—Tourn. Infl. 654.—Two or three West Indian species of Euphorbia come under this description.

Tithymalus, titum-xo; of Dioscorides, suppos'd to be derived from tidum, the breath, in allusion to the milkiness of the plant.—Tourn. t. 18. See Euphorbia.

Titi, Santi di, in Biography, was born at Citta S. Sepolcro, in the Florentine state, in 1538. He first acquired a knowledge of painting under the tuition of A. Bronzino, and afterwards of Bandinelli, but owes the greater part of his fame to his studies at Rome, where he long resided, and from whence, as Lanzi observes, he carried back to his native country a graceful and scientific style of art, not supported by much ideal beauty, but chiefly characterized by the truth and freshness of nature; and in expression he had few superiors in any school, none in his own. He adorned his pictures with pieces of architecture, which science he in a measure professed, and by its means gave great relief to his figures, and increased the dignity and beauty of his compositions. His principal works are, the Supper at Emmaus, painted for the church of St. Croce, at Florence; the Resurrection of Lazarus, in the Duomo di Volterra; and the Descent of the Holy Spirit, painted for a convent at Citta di Castello. He died at Florence in 1603, aged 65, leaving a son, Tiburio Titii, born at Florence in 1579, who followed the same art with his father, but not with equal success. In
TITIAN.

generally he painted small portraits very skilfully, and made drawings in black-lead; of which there is a large collection in the Florentine gallery, made originally for the cardinal Leopold de Medici. He died in 1657.

TITIAN, the name by which we are acquainted with that great master, who is universally regarded as the head of the Venetian school of painting, Tiziano Vecelli da Cadore. This justly distinguished artist was born of noble parents at the castle of Cadore, in Friuli, in 1489, according to Vafari and Sandrart, though Roldan, and others after him, place the date of his birth three years earlier, in 1477: but as Giorgione was considerably older than he, and was born in 1478, we have preferred the authority of the former, as most likely to be correct. The education he received, first from Sebastiano Zucatti of Trevisi, and afterwards from Giovanni Bellini at Venice, rendered him a diligent and subtle observer of nature. His early works exhibit the greatest correctness of imitation, but in a laboured and minute style, with a finish so highly wrought, that when, at a maturer age, he painted a picture for Ferrara of the tribute-money, in competition with Albert Durer, he excelled in nicety of pencilling that master of minutenefs; with this difference, that his finish did not, like the German's, obtrude itself, and impede the general effect, but obtained grandeur by distance. This picture, to which he made no comparison, as he soon after changed his style, now adorns the gallery of Drefden, and remains a proof of the genius this great artist entertained of the falsity of that taste, which seeks for gratification in mere finish, and which he defetered for the adoption of a style conveying general character instead of identity. It was from the better taste of his fellow pupil, Giorgione, that Titian imbibed a more exalted view of art, and was induced to quit the meaner and more confined style with which he commenced his practice; and some portraits which he painted about this time are scarcely to be distinguished from those of Giorgione himself. But he seems to have found it not exactly to his mind, and soon discovered a variety of style more congenial to his own feelings; less softened, and perhaps less grand, but more agreeable; a style which delights the spectator less by novelty of effect, than by the exactness of truth. His first work in this style, which is entirely his own, and may be denominated Tizianesque, is the archangel Raphael leading Tobiah, painted in his thirtieth year for the facade of S. Marcia; and soon after he painted the Prentation of the Virgin, at the Carita; one of the richest and most numerous of his compositions remaining.

When only eighteen years of age, he had painted a portrait of the head of the Barbarigo family, which excited universal admiration; and he was soon afterwards employed, in concert, or rather in rivalry, with Giorgione, to paint one of the fronts of the Fondaco de Tedeschi, when unhappily the jealousy already subsisting between these great artists was strengthened by the superior encomiums bestowed upon Titian. On the death of Giorgione in 1511, Titian succeeded him in several important commissions, and continuing to increase in renown, was invited to the court of Alfonso, duke of Ferrara, for whom he painted the celebrated picture of Bacchus and Ariadne, now in England. Here he became acquainted with the poet Ariosto, whose portrait he painted, and in return was celebrated by him in his Orlando Furioso.

About 1533, Titian produced the work which, above all others, elevates him in the scale of merit among painters; viz. the celebrated picture of the Death of St. Peter the Martyr, for the church of S. Giovanni and S. Paolo at Venice, which has been considered his chef-d'œuvre in history. This extraordinary picture was one of the first objects of French veneration at Venice. It was painted originally on wood, but was transferred to canvas in France, in consequence of its having been much blighted from the wood by the effect of sea-water in its voyage to Marfellas; and it is now returned to its original station in a more agreeable, if not more perfect condition, than when it was first removed. The excellence of this picture procured him, according to Vafari, a commission from the Senate to paint the battle of Cadore between the Venetians and the Imperialists, or the rout of Giaradadda, in which the action proceeded during a tremendous storm of rain. This grand work was destroyed by fire, but the composition is preferred to us by the print engraved by Fontana. Besides these, he painted several other public works, which, together with the friendly assistance of Pietro Aretino, whose pen delighted to dwell upon the powers of this great artist's pencil, spread his fame in every direction, and he was honoured with a super-abundance of employment. In 1536, when Charles V. came to Bologna to be crowned by pope Clement VII. Titian was sent for by the cardinal Hippolito de Medici to paint the portrait of the monarch, which he did on horseback and in armour; which so pleased Charles, that he gave the painter 1000 crowns of gold, and declared he would never be painted by any body else. When Titian returned to Venice, he found Pordenone much employed and supported by several of the principal personages; but his great superiority soon became too manifest to be resisted, and he was more than ever employed, both publicly and in private.

In 1541 the emperor returned to Bologna, to hold a conference with the pope, and was again painted by Titian, as also the cardinal Hippolito de Medici to paint the portrait of the monarch, which he did on horseback and in armour; which so pleased Charles, that he gave the painter 1000 crowns of gold, and declared he would never be painted by any body else. When Titian returned to Venice, he found Pordenone much employed and supported by several of the principal personages; but his great superiority soon became too manifest to be resisted, and he was more than ever employed, both publicly and in private.

In 1541 the emperor returned to Bologna, to hold a conference with the pope, and was again painted by Titian, as also the cardinal Hippolito de Medici to paint the portrait of the monarch, which he did on horseback and in armour; which so pleased Charles, that he gave the painter 1000 crowns of gold, and declared he would never be painted by any body else. When Titian returned to Venice, he found Pordenone much employed and supported by several of the principal personages; but his great superiority soon became too manifest to be resisted, and he was more than ever employed, both publicly and in private.

Tetian had soon after the honour of painting pope Paul III., when he visited Ferrara in 1543, and was invited by that pontiff to Rome; but he excused himself at that time on account of an engagement with the duke of Urbino, whose portrait he painted with so much fire and truth, that Aretino honoured it with a sonnet, comparing it with that of Alexander by Apelles. He painted also several other pictures for the same duke of Urbino (Francesco Maria), and when he had completed his engagement there, accepted another invitation to Rome, sent by the pope, through the medium of cardinal Beppo.

He arrived there in 1546, according to Vafari, who was already known to Titian, having seen him at Venice, and was on this occasion honoured by the cardinal's appointing him Cicerone to this great painter; to conduct him through the city, and to shew him its beauties. Nothing could be more flattering than his reception by the pope, who immediately upon his arrival assigned him apartments in the Palazzo Belvidere, and employed him in painting his portrait at whole length, and that of the cardinal and the duke Ottavia, which gave universal satisfaction; but an Ecce Homo, which he painted as a present to the pope, was not esteemed by the Roman artists, whose minds were accustomed to the works of Raphael and M. Angelo. The latter is said to have remarked to Vafari, after seeing Titian at work on his Daniel, that it was a great pity the Venetian painters applied themselves so little to design, and had not a better mode of study,
study, being so perfectly skilful in colour and imitation. Adding, "if this man were as much aided by art in design as he is by nature, and most particularly so in giving just resemblance of natural objects, he would be perfect; as he has a noble spirit, and a beautiful and lively manner."

He did not remain long in Rome, but on his return to Venice visited Florence, where he beheld with delight the great works of art with which it was adorned, and visited the grand duke Cosimo, who declined his offer to paint his portrait, perhaps, as Vafari observes, that he might not give umbrage to the ingenious artists of his own city and dominions.

Immediately upon his arrival at Florence, he received an invitation from his patron, Charles V., to visit Spain, and accordingly went to Madrid, where he arrived in 1550. He remained there three years, during which time he painted a great number of portraits and historical pictures. For the portrait which he painted of the emperor, he received 1000 crowns of gold, and was created a knight of the order of St. Jago, and a count palatine of the empire, with a stipend from the treasury of Naples of 200 crowns annually; and to this, Philip II. added afterwards 200 more, besides paying him magnificently for each of his productions.

When Charles had devoted his life to the authorities of a convent, he commissioned him to paint a large picture of the Trinity, accompanied by the Holy Virgin, and surrounded by saints and angels, in which the emperor, and the empress his wife, were represented elevated to the heavens, and in the act of adoration. There is a sketch of it in England, and a print has been engraved from the picture, by which it appears to have been a very grand work.

Though Titian had returned to his native place before Philip II. came into possession of the throne, and was as much engaged as he could be, yet that monarch, when he had built the Escorial, and conceived the idea of enriching it with the most splendid materials, referred to his father’s favourite painter to assist him in perfecting it; and though it does not appear that Titian returned to Spain, yet he must have employed his pencil very skilfully in its service from the very great number of his pictures which are to be found there, many of them among his very finest productions. Several of these have been withdrawn by the scruples of bigotry from public view; and among them his picture of a sleeping Venus, which was presented by Philip IV. to our Charles I., when prince of Wales, on his visit to Spain, and which after his death was purchased by the Spanish ambassador, then resident here.

Titian was invited by Henry VIII. to England, but his numerous engagements on the continent prevented him from coming. He painted, however, two pictures for Henry, which now adorn Cleveland House (the marquis of Staf ford’s). Their subjects are the Bath of Diana, with the unfortunate intrusion of Acteon, and the Discovery of the crime of Calista, and both are exquisite performances, and in tolerably good preservation. They continued in the royal collection till it was dispersed on the death of Charles I., and found their way into the gallery of the duke of Orleans; and on the purchase of the Italian part of that collection being effected by the duke of Bridgewater, the earl of Carlisle, and lord Gower, these pictures fell to the lot of the former of these noblemen.

This great painter is one of the happy few, for whom nature and circumstances have combined in fortunate conjunction. "For him," as Vafari justly observes, "health and fortune laboured, and he received of heaven only happiness and blessings." By him the highest among men, the most learned, and the most beautiful, were proud to have their portraits transmitted to posterity. He was handom in person and graceful in manners, and lived in a style worthy of one so honoured and beloved. These blessings he was permitted to enjoy through a very uncommon portion of human existence, which was at length interrupted by the plague in his 96th year. He appears to have been able to pursue his delightful art to a very advanced period, for Vafari found him painting in 1566, when he visited him at Venice, and speaks of it with pleasure; and though it may well be imagined that the latter productions of his pencil exhibit the strong hand of time, yet they are free and masterly in every thing in which a perfect knowledge of the principles of the art are concerned, and speak only in the execution.

Had Giorgione lived but to one-half of the lengthened years of his great rival, Titian might not perhaps have found, as from his numerous excellent productions he now does. That noble work, the death of St. Peter Martyre, alone fully entitles him to this distinction and honour; perhaps no other production of the pencil is so perfect in the combination of every requisite quality of a fine painting; composition, design, action, expression, chiaro-fcuro, and colour. The choice of the scene, and the accompaniments, are every way adapted to afford in creating alarm and dismay; the tone of evening or twilight spread over the whole, and contrasted to the brilliant ray of heavenly light from above, aids the impression; and the execution is in every part correspondent to the grandeur of form selected. This picture he painted, as we have said, in the prime of his life, when he was about forty-three; and he continued long after to work in the same style, which is of his own creation, and totally different from both his former laboured one, and his latter loose and vague manner. In this picture, every part is wrought to an exact character of representation, though without minuteness, or in any degree trespassing upon the heroic nature of the tragic subject; and there is no introduction of heterogeneous matter, as is too frequently to be found in his lyric productions. Here he appears to have caught a glimpse of the grandeur of Michael Angelo’s style, and to have employed it more effectually than in any other of his works, except perhaps in the figures on the ceiling of the Salute at Venice, and the martyrdom of St. Laurence in the Jefuits’. In general, his selection of form is but little improved upon his model; his male figures being too flabby for character or action, and his females too full for elegance.

The mind of Titian appears to have been of a sedate and rather serious character. There is, as it John Reynolds has observed, "a senatorial dignity about him," which distinguishes him from his compeers of the Venetian school. All his compositions are arranged with gravity; even the gay and sometimes licentious subjects which he now and then amused himself with, are conducted with such a scale of chiaro-fcuro and colour, as gives an air of mortality to their effect, which imposes upon the spectator a tone of sobriety, and induces him to discard those loose thoughts which the gay luxuriance of the style of Rubens, treating the same compositions, would inevitably excite.

Colouring appears to have been the grand foundation of the success of Titian. He knew better than any other painter the just power of each colour of his palette; and by this knowledge, produced a species of chiaro-fcuro independent of light and shade, and perfectly distinct from that of Correggio and Leonardo da Vinci, and more immediately imitative of the general effects of nature. Master of the
means of imitating the most subtle combinations of colour in visible objects, and fully comprehending the degrees of purity or of tone with which colours might be employed individually or collectively, to affix in projecting or withdrawing the various parts of a picture, he never fails to gratify the eye with a full and true relief, correspondent with the nature of the subject. In this quality he was as much ideal, as the Greeks and Florentines were in form; for though the harmony and richness which he produced are to be found occasionally in nature, it is neither her every day attire, nor is it to be comprehended by superficial observers. There is a science of exceeding import to painting in the arrangements of colours, by which a skilful artist will create attraction or disgust, as it pleases him. Change the position of the colours of that most beautiful of nature's works, the rainbow; let the blue and the green occupy the centre, and the red and yellow the edges of it; and judge how far it will decrease in its power of attraction. Of this science, Titian was the first great poiffeur; and as he poiffessed the knowledge of the value of colours, so also did he that of the nature of shade; that colour (to the painter at least, though it be the absence of it to the philosopher) which destroys all colours, and renders all alike obscure; and which is the most difficult of attainment in all that relates to the art of colouring. The tone of shade that Titian employed, whatever be the substance which produced it, was used by no other so successfully, except Tin- toretto. It seems, in its union with the local colours of objects, to have produced the half tints without further labour; or at least to have laid such a foundation, as to have made that of the subsequent painting very trifling; and doubtless this mode of proceeding rendered him able to produce such an infinity of works as appear to have issued from his pencil. His errors flowed naturally, from the cafe with which he produced the beauties of his style; and as the mind was filled with gratification by the delightful harmony and richness of colour his works presented, so it fought the lesf for the qualities of expression, and appropriate drefs and action in the figures; and would not condemn too rudely the frequent admixture of heterogeneous matter.

To the accusations of exhibiting defects like these, the works of Titian are far less justly subject than those of his imitators and succeffcors in the Venetian school of painting; none of whom poiffessed the taste and judgment of this great master, though many were eminently likable in their respective departments.

TITIANO, GIROLAMO DANTE, called IL. According to Ridolfi, he was brought up in the school of Titian, and was employed by that master to assist him in several of his works. By frequently painting in conjunction with him, and sometimes copying his works, some of his pictures, retouched by Titian, have passed for originals by that master. He sometimes painted from his own designs, and his picture in the church of St. Giovanni at Venice, representing S. S. Cojno and Damiano, is worthy of the school in which he was educated. Bryan's Diet.

TITICACCA, or CHUCUITO, in Geography, a lake of South America, in the vicereignty of Buenos Ayres, diocefe of La Paz, and jurifdiction of Chucuito, the figure of which is oval, inclining nearly from N.W. to S.E., its circumference being about 80 leagues, and depth near the shore from four to fix fathoms, and towards the middle forty or fifty, without any shoals. Ten or twelve large rivers, beside a great number of smaller streams, discharge themselves into it. The water, though neither bitter nor brackish, is somewhat turbid, and its taste is so naifeous that it cannot be drank. It abounds with fish of two very different kinds; one large and palatable, called by the Indians Suchis, and the other small, infipid and bony, long since called by the Spaniards Boyas. It has also a great number of geese, and other wild fowl, and the shores are covered with flags and rushes, the materials of which the bridges are made. The western borders of this lake are called Chucuito, and those on the E. are denominated Omacayo. It contains several islands, from one to another of which the Indians pass on their balbas, a kind of rafts, supported by inflated skins. One of these islands is very large, and was anciently one mountain, since levelled by order of the Incas: this gave to the lake its own name of Titicaca, which, in the Indian language, signifies a mountain of lead. In this island the first Inca, Mancho-Capac, the illustrious founder of the empire of Peru, invented his political fable, that the fun, his father, had placed him, together with his fifier and confort Mama Oello Huaco, there, enjoining them to draw the neighbouring people from the ignorance, rudeness, and barbarity in which they lived, and humanize them by customs, laws, and religious rites dictated by himself; and in return for the benefits resulting from this artful stratagem, the island has, by all the Indians, been confidered as fared; and the Incas, determining to erect on it a temple to the fun, caused it to be levelled, that the situation might be more delightful and commodious.

This was one of the most splendid temples in the whole empire. Besides the plates of gold and silver with which its walls were magnificently adorned, it contained an immense collection of riches, all the inhabitants of provinces which depended on the empire, being under an indippensible obligation of visiting it once a year, and offering some gift. Accordingly, they always brought in proportion to their zeal or ability, gold, filver, or jewels. This immense mails of riches, the Indians, on seeing the rapacious violence of the Spaniards, are thought to have thrown into the lake; as it is certainly known they did with regard to a great part of those at Cufco, among which was the famous golden chain made by order of the Inca Huayna-Capac, to celebrate the festival of giving name to his eldest fon. But these valuable effects were thrown into another lake, six leagues S. of Cufco, in the valley of Orcos: and though numbers of Spaniards, animated with the flattering hopes of such immense treafures, made frequent attempts to recover them, the great depth of the water, and the bottom being covered with slime and mud, rendered all their endeavours abortive. For notwithstanding the circuit is not above half a league, yet the depth of water is in most places not less than twenty-three or twenty-four fathom.

Towards the S. part of the lake Titicaca, the banks approach each other, so as to form a kind of bay, which terminates in a river called El Defagurodo, or the drain, and afterwards forms the lake of Parisa, which has no visible outlet; but the many whirl-pools sufficiently indicate that the water suffers by a subterraneous passage. Over the river Defagurodo is built remaining the bridge of ruthels, invented by Capac Yupanqui, the fifth Inca, for transporting his army to the other side, in order to conquer the provinces of Collafuyo. S. lat. 16° 10'. W. long. 69° 56'.

TITILLARES VEN.E, a name given by some authors to the illiac veins.

TITILLATION, TITILLATIO, the act of tickling; i.e. exciting a fort of pleasurable idea, by a gentle application of some light body, upon a nervous part; and which usually tends to produce laughter.

TITILLICUM, a word used by some anatomical writers for the arm-pit.

TITIN ARA, in Geography, a mountain of Russia, in the
TITIOPOLIS, in Ancient Geography, a town of Asia, in Hauria, or the second Cilicia, one of the twenty-three towns, which, according to the Notitia of Hierocles, were under the metropolis of Seleucia; named Titopolis by William of Tyre.

TITUS FLAVUM, in Ancient Geography, a river of Illyria, which discharged itself into the sea at Scardona, and formed an arm of the bay between Liburnia and Dalmatia. Pliny. It is named Titus by Ptolemy.

TITZICHE, in Geography, a populous town of the principal city of Guriel, with a good harbour, on the Black sea. This place is also called Pelhino; 10 miles S. of Puti.

TITLARK, in Ornithology. See ALAUDA PRATENSA.

TITLE, in Civil and Canon Law, denotes a chapter or division of a book.

A title is subdivided into paragraphs, &c.—Each of the fifty books of the Digest consists of a number of titles; some of more, others of less.

TITLE is also an appellation of dignity, distinction, or pre-eminence, given to persons possessed of the same.

The titles of order or dignity, Loyseau observes, should always come immediately after the name, and before the titles of office.

The king of Spain has a whole page of titles, to express the several kingdoms and signories of which he is master. The king of England takes the title of king of Great Britain and Ireland: the king of France, the title of king of France and Navarre: the king of Sweden intitles himself king of the Swedes and Goths: the king of Denmark, king of Denmark and Norway: the king of Sardinia, among his titles, takes that of king of Cyprus andJeruffalem: the duke of Lorraine, the title of king of Jeruffalem, Sicily, &c.

The cardinals take titles from the names of some churches in Rome; as of St. Cecilia, St. Sabina, &c. and they are called cardinals of the title of St. Cecilia, &c.

The emperor can confer the title of prince, or count of the empire; but the right of suffrage in assemblies of the empire depends on the consent of the electors.

The Romans gave the titles of Africenus, Asiaticus, Macedonieus, Numideus, Creticus, Parthicus, Dacieus, &c. in memory of the victories obtained over the people of those countries. The king of Spain, after the like manner, gives honourable titles to his cities, in recompense for their services, or their fidelity.

TITLE expresses also a certain quality ascribed by way of respect to certain princes, &c.

The pope has the title of helieth; a cardinal prince of the blood, that of royal highness, or most royal highness, according to his nearness to the throne; other cardinal princes, most eminent highness; an archbishop, grace and most reverend; a bishop, right reverend; abbots, priests, religious, &c. reverend.

As to secular powers, to the emperor is given the title of imperial majesty; to king, majesty; to the king of France, most Christian majesty; to the king of Spain, catholick majesty; to the king of England, that of defender of the faith; to the Turks, grand signor and highness; to the prince of Wales, royal highness; to the dauphin of France, serene highness; to the grand duke, most serene highness; to the other princes of Italy and Germany, highness; to the doge of Venice, signory; to the grand-marshal of Malta, eminence; to nuncios, and to ambassadors of crowned heads, excellency.

The emperor of China, among his titles, takes that of tief, son of heaven. The Orientals, it is observed, are exceedingly fond of titles: the simple governor of Schiras, for instance, after a pompous enumeration of qualities, lordships, &c. adds the titles of flower of courtesy, nutmeg of conclusion, and rose of delight.

TITLE, in Law, denotes a right which a person has to the possession of any thing.

A title to lands is thus defined by Sir Edward Coke: titulus est justa causa possidenti id quod no grum ostit. It is the means by which the owner of lands hath the just possession of his property. There are several stages or degrees requisite to form a complete title to lands and tenements. The lowest and most imperfect degree of title consists in the mere naked possession, or actual occupation of the estate, without any apparent right, or any shadow or pretence of right, to hold and continue such possession. See Disseisin.

The next step to a good and perfect title is the right of possession, which may reside in one man, while the actual possession is either in himself or another. The third circumstance attending a title is the mere right of property, the jus proprietatis, without either possession or even the right of possession. It is possible that one man may have the possession, another the right of possession, and a third the right of property. But in the union of these three qualifications consists a complete title to lands, tenements, and hereditaments. For it is an ancient maxim of the law, that if no title is completely good, unless the right of possession be joined with the right of property; which right is then designated a double right, jus duplicatum, or droit doux. And when to this double right the actual possession is also united, when there is, according to the expression of Pleta, juris et fejus continens, then, and then only, is the title completely legal.

The statute 32 Hen. VIII. c. 9, hath provided, that no one shall sell or purchase any preferred right or title to land, unless the vendor hath received the profits thereof for one whole year before such grant; or hath been in actual possession of the land, or the revenue or remainder; or on pain that both the purchaser and vendor shall each forfeit the value of such land to the king and the protector.

A title to things personal may be acquired or lost by occupancy, by prerogative, by forfeiture, by custom, by use, by marriage, by judgment, by gift, by contract, by bankruptcy, by testamentary, and by administration. Blackf. Com. B. ii. See Possession and Property.

TITLE is also an authentic instrument, by which a man can prove and make appear his right.

There must be at least colourable title to come into possession of a benefice, otherwise the person is deemed an intruder. For prescription with title, see Prescription.

TITLE, in the Canon Law, is that by virtue of which a beneficiary holds a benefice: such is the collation of an ordinary, or a provision in the court of Rome, founded on a renunciation, permutation, or other legal cause. The title of
of a benefice, or beneficiary, is either a true or a colourable
one. A true or solid title is that which gives a right to
the benefice: such is that received from a collator who has
a right to confer the benefice on a person capable of it, the
usual solemnities being observed. See Collation, &c.
Colourable title is a seeming one; i.e., such an one as ap-
ppears valid, and is not. Such would be that founded on the
collation of a bishop, in case the benefice in question were
not in his collation.

By the canons, a colourable title, though false, produces
two very considerable effects. 1. That, after peaceable pos-
session for three years, the incumbent may defend himself
by the rule de triennali possessione, against such as would dis-
pute the benefice with him. 2. That in case he be profe-
cuted within three years, and obliged to surrender the ben-
efice, he shall not be obliged to restore the produce of it,
during the time he possessed it.

Title is also used, in several ancient synods and councils,
for the church to which a priest was ordained, and where he
was constantly to reside.

"Nullus in presbyterum, nullus in diaconum, nisi ad cer-
tum titulum ordinetur." Concil. Londin. ann. 1125.

There are many reasons why a church might be called
titulus, title: the most probable Cowel takes to be this, that
in ancient days the name of the saint to whom the church
was dedicated was engraved on the porch, as a token that
the saint had a title to that church; whence the church itself
became afterwards to be called titulus.

Titles, or Titular Churches, M. Fleury observes, were
formerly the denomination of a particular kind of churches
at Rome.

In the sixth and seventh centuries, there were four forts
of churches in that metropolis; viz. patriarchal, titular,
diaconal, and erarial. The titulus, titular, were, as it were,
parishes, each assigned to a cardinal-priest, with a certain
district or quarter depending on them, and a font for the
administration of baptism in case of necessity.

Title, Clerical or Sacerdotal, denotes a yearly revenue or
income of the value of fifty crowns, which the candidates
for priesthood were annually obliged to have of their own,
that they might be assured of a subsistence.

By the ancient discipline there were no clerks made, but
in proportion as they were wanted for the service of the
church, which is still observed with regard to bishops; none
being consecrated, but to fill some vacant see.

But for priests, and other clerks, they began to make
vague ordinances in the East as early as in the fifth century:
this occasioned the council of Chalcedon to declare all vague
and absolute ordinances null.

Accordingly the discipline was pretty well observed till
the end of the eleventh century; but then it began to
relax, and the number of priests was exceedingly in-
creased; either because the people became defrons of the
privileges of the clericate, or because the bishops fought to
extend their jurisdiction.

One of the greatest inconveniences of these vague ordina-
tions was poverty, which frequently reduced the priests to
fordid occupations, and even to a shameful begging. To
remedy this, the council of Lateran laid it on the bishops
to provide for the subsistence of such as they should ordain
without title, till such time as they had got a place in the
church that would afford them a settled maintenance.

There was also another expedient found out to elude the
canon of the council of Chalcedon; and it was appointed,
that a priest might be ordained on the title of his patri-
mony; that is, it was not necessary he had any certain place
in the church, provided he had a patrony sufficient for a
creditable subsistence.

The council of Trent retrieved the ancient discipline in
this respect, forbidding all ordination, where the candidate
was not in peaceable possession of a benefice sufficient to
subsist him; and allowing nobody to be ordained on patri-
mony or pension, unless where the bishop declares it to be
expedient for the good of the church: so that the benefice
is the rule, and the patrony the exception. See Ordi-
nation.

But this rule is not regarded, even in some Catholic coun-
tries, particularly France, where the patronal title is the
most frequent; and the title is even fixed to a very moderate
sum.

As to religious, the profession they make in a monastery
serves them for a title, in regard no convent is obliged to
maintain them; and as to mendicants, they are maintained
upon the title of poverty.

The title of the house and society of the Sorbonne are also
ordained without any patronal title, and on the sole title of
poverty; it being supposed a doctor of the Sorbonne
can never want a benefice.

Title for Orders. See DEACON, ORDINATION, and
PRIEST.

TITLIS, in Geography, a mountain of Switzerland, in
the canton of Uri, the most elevated in those parts, and
farcely inferior to the Schreckhorn and Jungfrau; it was
for a long time considered as inaccessible. The summit
of this mountain is called Nollen, and commands a very
picturesque scene of mountains and valleys; 11 miles S.S.W.
of Altorf.

TITMEG, a lake of North America. N. lat. 62° 15',
W. long. 99'.

TITMOUSE, in Ornithology. See PARUS.

TITOTO, in Geography, a town of Naples, in the pro-
vince of Basilicata; 6 miles S.W. of Potenza.

TITONEUS, in Ancient Geography, a mountain situated
on the confines of Thrace and Macedonia.

TITGOVO, in Geography, a town of Russia, in the go-
mernment of Kaluga; 40 miles E.S.E. of Kaluga.

TITSCHEN, New, or Novo Gieli, a town of Mo-
avia, in the circle of Prerau, well built and defended by
walls; 24 miles E.N.E. of Prerau. N. lat. 49° 32'; E.
long. 18° 10'.

TITSCHEN, Al, a town of Moravia; 2 miles S.W.
of New Titchen.

TITSCHEIN, a town of Moravia, in the circle of Ol-
mutz; 16 miles S. of Olmutz; in the circle of Prerau; 8 miles S.W. of Freyberg.

TITTERIE, a southern province of Algiers, which
extends from the river Mafafran, on the W., to the river
Booherak, on the E.; northerly it is bounded by the Me-
diterranean, and southward by Sahara; about 60 miles long
and 40 broad.

TITTERIE Gyras, a lake of Algiers, situated near
mountains; 60 miles S. of Algiers.

TITTERIE Dufb, or Hadjar Titterie, a ridge of precipices
in Algiers; on the summit is a large plain, with only one
narrow road leading up to it, where a tribe of Arabs keep
their granaries; 50 miles S. of Algiers.

TITTING, or DIETTING, a town of Bavaria, in the
bishops' of Aichstatt; 5 miles N. of Aichstatt.

TITTIUS, in Botany, a name given by Rumphius,
Amboyna. v. 3. t. 19, and t. 20, to two very different kinds
of trees, the latter of which is supposed by Jussieu to be a
CORNUTIA. See that article.

TITTAMING, or DITTING, in Geography, a
town...
TITU, in Ancient Geography, a town of India, on this side of the Ganges, which belonged to the Carman. Ptol. TITULAR, or Titulary, denotes a person invested with a title, in virtue of which he holds an office or benefice, whether he performs the functions of it or not. In this sense the term is used in opposition to survivor, and to a person only acting by procuration, or commission. An officer is always reputed titular till he hath resigned his office, and the resignation hath been admitted.

TITULAR, or Titulary, denotes a person invested with a title, in virtue of which he holds an office or benefice, whether he performs the functions of it or not. In this sense the term is used in opposition to survivor, and to a person only acting by procuration, or commission. An officer is always reputed titular till he hath resigned his office, and the resignation hath been admitted.

Titulars of Tithes, a term sometimes applied to persons who had the possession of tithes under the crown in Scotland. They had also other names or titles applied to them in some cases. See Tithes.

TITLULUS, in History, a town of Judaea, in the reign of the Emperor Hadrian. It is difficult to ascertain the exact period of its existence, but it is known to have been a Roman city.

Titus, in Scripture Biography, a disciple and companion of the apostle Paul, who attended him in many peregrinations to Jerusalem, Ephesus, and Crete, and who was deputed by him on several important services. For an account of the epistle addressed to him by St. Paul, see Ephesians.

Titus, in Biography, a Roman emperor, was the eldest son of Vespasian, and born A.D. 40. In the course of his education at the court of Nero, he made a great proficiency in the study of eloquence and poetry. In his military service he first ranked as tribune in Germany, and afterwards in Britain; and by his valor and skill, as well as by the graces of his person and manners, obtained great applause. On his return to Rome, he acquired reputation in the forum as a successful pleader. His first wife was the daughter of a Roman knight, and after her death he married a lady of illustrious descent, whom he divorced after she had borne him one daughter. Having distinguished himself as quaestor, he served as lieutenant under his father in the war of Judea, during which he gained renown, not only by his military enterprises, but by the mildness and generosity of his temper; and though he did not abstain from the indulgences of youthful propensities, he did not neglect serious occupations. When Vespasian, after the death of Otho, was deliberating about assigning the purple, he acted as mediator in the confederacy between him and Mariana, the governor of Syria; and when Vespasian marched to Italy, Titus was entrusted with the prosecution of the war in Judæa. When his father took possession of the imperial authority, he declared Titus his colleague in the confulate, A.D. 70. In that year Jerusalem was taken after a calamitous siege, and the destruction of the temple, which Titus wished to have preserved. After the reduction of Jerusalem, he went to Alexandria, and took part in the superstitions of the consecration of the ox Apis; and after having given audience to the ambassadors of the king of Persia, he hastened to Rome with a view of counteracting some unfavourable rumours, and was honoured with a magnificent triumph. Vespasian admitted him to a participation of the empire, and they continued to co-operate in the exercise of the imperial power, and lived together in amicable intercourse. Suetonius, however, intimates that Titus's conduct was in a variety of respects very far from being irreproachable, either in private life or in his public character. During the war in Judæa, he had indulged a violent passion for Berenice, daughter of Agrippa I. king of the Jews, and widow of Herod, king of Chalcis; and as he followed him to Rome, he gave offence to the people by his attachment to a foreign queen of doubtful reputation; and, as Suetonius says, suspicions were entertained that Titus would eventually prove a second Nero.

Upon the death of Vespasian, A.D. 79, Titus immediately succeeded him; and by his conduct towards his rival Domitian, and to those who adhered to his interest, he gained the affection of the people, and established a character, which has caused him to be recorded under the glorious title of "The Delight of the Human Race." Although his reign was short, it was distinguished by a series of benevolent actions: not always, perhaps, equally liberal in the principle from which they originated. This course of beneficence was commenced by a confirmation of all the grants and donations made by his predecessors. And he thus established a precedent, which governed the conduct of his successors. Upon assuming the office of chief pontiff, he avowed it to be a solemn engagement not to shed the blood of a citizen, and to this resolution he adhered in a conspiracy against himself. In the case of one of the two patricians implicated in this crime, he calmed the anxiety of his mother by deputing a special messenger to assure her that for an's life was in no danger. Besides, he abrogated the law of high-treason with respect to all convicts for words or writings against the person or dignity of the emperor.

It was one of his maxims, "that no one ought to depart discontented from the person of his prince;" and on this he founded his practice of giving hopes to petitioners when he thought it necessary to refuse their requests. If we connect this maxim with his well-known exclamation at the close of a day on which he had conferred no benefit, "My friends I have lost a day," we cannot forbear supposing that the benefits to which he referred were rather acts of private bounty to courtiers or importunate suitors, than the performance of public duties. Many influences occur of his love of popularity, and of the excels in which he indulged it. The public calamities that happened during his reign gave occasion for the exercise and display of his compassion and bounty; such were the great eruption of Mount Vesuvius, which destroyed Herculaneum, Pompeii, and other towns; and the conflagration of Rome, which was followed by a fatidemic disorder. His general conduct entitled him to the affection of his subjects; nor does he seem to have deserved reproach for any act of injustice or oppression. Whist he was on a journey to the country of the Sabines, he was seized with a fever, which terminated fatally, on the 15th of September, A.D. 81, in the 41st year of his age, and after a reign of two years and less than three months. Preparing his dissolution, he lamented his early and premature doom; and yet, though his death was deplored at Rome as a general calamity, it was perhaps, considering the flexibility of his disposition, and his inclination to profuse
TIV

TITWALL, in Geography, a town of Hindoostan, in Baglan; 28 miles E. of Balleen.

TITYRUS MYSN, in Ancient Geography, a mountain in the western part of the isle of Crete, in the country named Cydonia, according to Strabo. On this mountain was a temple named Dictynnaeum Templum. In some copies of Strabo, this mountain and temple are placed in the town of Cydonia.

TITZ, in Geography, a town of France, in the department of the Roer; 4 miles N.E. of Juliers.

TITZLA, a town of Asiatic Turkey, in Caramania, on a salt lake; 60 miles S.W. of Kirkeh.

TIVA, a town of the Arabian Irak; 130 miles W. of Balfour.

TIVER, in Rural Economy, the provincial name of a substance of the colouring ochre kind, used for marking sheep in some places.

TIVERING, a term applied to the act or operation of marking sheep and lambs in different ways, with the material of the tiver kind, in some districts and places, for particular uses and purposes. Thus, it is a practice with some correct sheep-farmers to have their sheep tivered so as to ascertain different points in their management with great exactness. The bows or breasts of the rams are tivered every two or three days in the topping or riding season, and the ewes which are put to them, the first week, marked with one stroke of tiver, thofe of the second week, with two strokes, and so on. The tivering of sheep is also useful on many other occasions for marking and distinguishing the objects and views of the sheep-farmer. The practice of it is very common in the Romney-march system of sheep-grazing. See SHEEP.

TIVERTON, in Geography, anciently called Twyford-town, a borough and market-town in the hundred of the said name, and county of Devon, England; is situated on the banks of a hill between the rivers Exe and Loman, 14 miles N. by E. from Exeter, and 163 miles W. by S. from London. In the time of Alfred it was only a village, but had twelve tithings belonging to it, and was governed by a portreeve. Henry I. granted the manor and lordship to Richard Rivers, afterwards earl of Devon, by whom a castle was erected here about the year 1106, which continued to be the baronial residence for a considerable number of years. The attractions of the castle occasioned a great increase in the buildings and population of Tiverton; and by the favour of the lords, it was invested with the privilege of a market as early as the year 1200. About fifty years afterwards, the stream of water, now called the Town-Leat, was conducted from the distance of five miles to supply the inhabitants; and a piece of waste land, called Elmore Common, was given for the benefit of the poorer claffes, either for paffurage or for cultivation. These advantages continued to attract new settlers; but the most rapid augmentation of the town took place on the final establishment of the woollen manufacture about the year 1500. Towards the close of Elizabeth's reign, Tiverton was the principal place in the county for the manufacture of woollen goods; particularly kerseys, which still continue to be the chief article made here. About this period, the prosperity of the town received a temporary check: in 1591 it was visited by the plague, to which 550 persons fell victims; numbers fled for safety; and the inhabitants were so thinned, that the growing of grafs in the streets is particularly recorded. Scarcely had the town recovered, when it was nearly destroyed by fire, April 3, 1598, when more than four hundred houses were consumed, and thirty-three persons perished in the flames: the value of the property destroyed was estimated at 150,000l. In about a dozen years from that time, Tiverton was again esteemed a town of great importance, and called the chief market-town of the West. Many rich clothiers and merchants lived in it, and 8000 people were constantly employed in its woollen manufactories. The buildings were increasing in number and respectability, and Tiverton would have probably become one of the greatest manufacturing towns in the kingdom, but for a second conflagration, which destroyed nearly all the property of the inhabitants, and wholly blighted their flourishing expectation. In this fire, which happened August 5, 1612, six hundred houses were destroyed, with goods and merchandise to the amount of 200,000l.; and the inhabitants of every description were reduced to the greatest diffreces. The poor manufacturers were distributed in different towns, by which means the advantages of the clothing trade that had hitherto been exclusively enjoyed by Tiverton, were extended to other parts of the county. In the year 1615, Tiverton received its first charter of incorporation from king James; and its government was vested in a mayor, twelve capital burgesses, and twelve assiduous burgesses. The right of returning two members to parliament was also granted to the same persons. This charter continued in force till 1723, when it was forfecuted by neglect, and a new one, exactly similar, was granted by George I. In 1731, a third destructive fire occurred, which again nearly laid waste the town. During the 17th century, the trade and population progressively increased; but in the following century, rapidly declined: a favourable alteration has recently taken place, and the general trade of the town is now on a respectable basis. By the parliamentary return of the year 1811, the number of houses is stated to be 1503, the inhabitants 6732. A weekly market is held on Tuesdays, and two fairs annually. The spot of ground on which Tiverton is built, partakes of a triangular form, from the course of the rivers by which it is bounded. Its greatest length is nearly one mile; its breadth exactly three quarters. The four principal streets form a quadrangle, including an area of gardens, in the centre of which is a bowling-green. Most of the houses are of red brick, or of stone, and are generally covered with blue slate. Those on the outskirts of the town, and at the ends of the streets, which escaped the fire of 1731, are of earth or cob, covered with thatch. The principal buildings are the castle, the church, and the free grammar-school. The castle, from the present remains, appears to have been nearly of a quadrangular form, including an area of about an acre, and surrounded by strong walls, from twenty to twenty-five feet in height. At the angles were embattled towers, about thirty-five feet high. This fortress was secured from attack on the W. side by a steep declivity of about sixty feet, on the edge of which a lofty wall was built. Two wide and deep moats, filled with water from the Town-Leat, defended the whole of the N. and S. walls, to each side of the causeway leading to the gate on the E. This castle has been frequently exposed to sieges: during the reign of Stephen, and in the contest between the houses of York and Lancaster, it was several times subjected to the assaults of the contending parties; and in the civil war of Charles I. being garrisoned for the king, it was besieged and taken by the parliamentary forces. From this period the castle has been falling to decay; and several of the ancient buildings have been converted into the offices of a farm. Great part of the S. and W. walls, with parts of the towers at the angles, are till standing. The moat at the S. side is converted into a good kitchen garden;
garden; that on the N. side is filled up, and made part of a court-yard. The church is situated on an eminence, at a short distance from the castle; and though the work of different ages, is more regular than might have been expected. The S. side is ornamented with much curious sculpture. The tower is a plain stone structure, ornamented with battlements and pinnacles: the height is 116 feet. The interior of the church is spacious, and its chancel is separated from the body of the church by a screen, ornamented with elegant tracery. The church being too small for the reception of the inhabitants of the town, a chapel of ease was erected about the year 1733; and here are also several meeting-houses for dissenters of various denominations. A free grammar-school was erected about the year 1604, pursuant to the will of Peter Blundell, a native, and eminent clothier of this town; who, from a very low origin, by a long life of successful industry acquired an ample fortune; and bequeathed 40,000/ to various charitable purposes. In this school he provided for the instruction of 150 boys; with maintenance for three scholars in each of the universities of Oxford and Cambridge, to be chosen out of his school. Here are also a charity-school, a free English school, several alm-houses, and other endowments for the benefit of the poor inhabitants. The other public buildings are: the town-houfe, a spacious edifice, appropriated to the meetings of the corporation, grand juries, and other public bodies; the market-houfe, a large quadrangular fabric, for the standing and sale of corn; and the hospital or poor-houfe, an extensive structure, erected in 1704, and containing various workshops for the employment of those whom indigence or misfortune may oblige to have recourse to it. The parish of Tiverton is upwards of nine miles in length, and about eight miles in breadth.

At a short distance to the south of Tiverton is Collipriest Houfe, formerly the seat of the Blundell family, but now the property of Thomas Winslow, Esq. who recently rebuilt and enlarged the mansion. It stands on the site of an eminence near the river Exe, having a sloping lawn in front, and a hanging wood behind.—Historical Memoirs of the Town and Parish of Tiverton, &c.; by Martin Dunsford, Exeter, 4to. 1790. Beauties of England and Wales, vol. iv. Devonshire; by J. Britton and E. W. Brayley, 1803.

TIVERTON, a town of Rhode island, in the county of Newport, containing 2837 inhabitants, situated on the Taunton river; 15 miles S.E. of Providence.

TIVHOLM, a small island of Denmark, in the Cattegat; 4 miles N.E. of Fladgard.

TIVIÇA, a town of Spain, in Catalonia; 15 miles N.E. of Tortosa.

TIVIOT, a river of Scotland, which rises about 12 miles S.W. from Hawick, and runs into the Tweed, at Kelso. The valley which it waters is called Tiveidale.

TIUKI-KARAGAN, a cape on the E. side of the Caspian sea; 156 miles S.E. of Astrachan. N. lat. 44° 20'. E. long. 50° 14'.

TIULIT, a town of Africa, in the kingdom of Fez; 12 miles S.W. of Fez.

Tiuumen, a town of Russia, in the government of Tobolofe, at the union of the Pechora and the Tura. This town is not built parallel to the river Tura, but at right angles with it; and the little river Pechora runs through the town, and falls into the Tura at the extremity of it. Over the river is a bridge of eighty-three fathoms in length; and a little below it stands a fort, built with stone, in which is a church of the same materials. Without this fortification, and towards the lower bank of the Tura, are fix wooden churches, a convent of nuns, with a church, and 500 dwelling-houses. At the lower end of the town is an oftreg. Beyond the Tumenka lies the Yamkaia floboda, or suburb, consisting of 250 houses, inhabited by people of all ranks and professions; and at the extremity of this suburb stands a monastery: it has likewise three churches, built of stone. Another suburb lies opposite to Tiumen, on the N. side of the Tura, which is inhabited by Russians, Mahometan Tartars, and Bucorians; 112 miles W.S.W. of Tobolofe. N. lat. 57°. E. long. 66° 14'.

TIVOLI, formerly called Tibur, a town of the Pope's dominion, in the Campagna of Rome, situated on a rocky mountain, planted with olive-trees, which are faid to yield the best oil in Italy; the site of a bishop held immediately under the pope. The town itself is mean, and contains a great number of forges. The cathedral is built on the ruins of a temple of Hercules. In the market-place are two images of Oriental granite, representing Isis, the Egyptian deity. The principal beauty of this place arises from the river Tevere, which falling headlong about fifty feet down the rock, forms a noble cascade, and several lefser ones, called Le Cacaddelle. The latter are extremely picturesque; and is also a deep ravine in the hill, called La Grotta di Nettuno, into which the great cascade falls. To enrich the view, here are some remains of ancient buildings, as the villa of Maxenias, and particularly the little round temple of the Sibyl, as it is commonly called, but rather of Vest[a; one of the most elegant remains of the Grecian architetture. The natural gift will here take pleasure in observing the continual formation of new Tiburtine stone from the deposit of water descending from the calcareous Apennines; 15 miles E.N.E. of Rome. N. lat. 41° 58'. E. long. 12° 46'.

TIURANEN, a small island on the E. side of the gulf of Bothnia. N. lat. 65° 39'. E. long. 24° 46'.

TIUTERS, an island of Russia, in the gulf of Finland; 80 miles E.N.E. of Revel. N. lat. 59° 40'. E. long. 27° 14'.

TIVY, a river of South Wales, which rises about 5 miles N. from Tregaron, and runs into the sea about 5 miles below Cardigan.

TIXIER, John, (Lat. Ravifbus Textor), in Biography, a person of literary character in France, was lord of Ravily in the Nivernois, and educated in the college of Navarre at Paris, where he taught the belles-lettres, and whence he issued many of his publications for the use of his students. In 1500 he was appointed rector of the university of Paris, and he died, as some say in the hospita], in 1522. His works are, "A Collection of Latin Letters," "Dialogues," "Poems," "Epigrams," "Orations," &c. in Latin, written in good style; "Officina, seu potius Nature Historia," &c., several times reprinted; "De Memorabilia et claris Mulleribus, aliquot diversorum Scriptorum Opera," to which he has annexed the life of Joan of France, written by himself. Morevi.

TIZ, in Geography. See Tiz.

TIZRI, in Chronology. See Tisri.

TIZZANO, in Geography, a town of the duchy of Parma; 13 miles S. of Parma.

TIZZANO, in Geography, a town of the duchy of Parma; 13 miles S. of Parma.

TIZZANO, in Geography, a town of the duchy of Parma; 13 miles S. of Parma.

TLACOLOZOLTOL, in Zoology. See Ocelot.

TLAM, or SLAM, in the Alum-Works, a word used by the workmen to express a fort of mud or sourna of which does great hurt to the alum, rendering it foul and coarser. The slam is a muddy substance settling to the bottom of the
the vessels; but in the boiling of the liquor it gives a reddish colour, and disorders the whole works when in any great quantity. They always pHs their liquor over four parcels of the alum-rock, and the leaf, if not carefully calcined, generally gives it this disadvantageous mixture. Phil. Trans. N° 142.

TLANHQUACHUL, in Ornithology, the name of a Brazilian bird, very much approaching to the nature of the European plate, or spoonbill. It is a very voracious bird, and feeds on live fish, but will not take or meddle with dead ones, and is all over of a beautiful red. It has a black ring round the upper part of its neck, and is common about the shores of the sea and rivers.

TLAQUACUM, in Zoology, the name given by the Spaniards, and some others, to a very remarkable animal in America, commonly known among us by the name of the porcup or opoum.

TLAQUATZIN, a name by which the natives in some parts of America call the opoum.

TLAQUATZIN Spinofum., the name by which Hernandez has called the cana, a fort of Brazilian porcupine.

Tlacasa, in Geography, a province of North America, in the government of Mexico; bounded on the N. by Guatema, on the E. by the gulf of Mexico and the province of Guazac; on the S. by the Pacific ocean, and on the W. by the province of Mexico Proper; about 320 miles in length, and from 40 to 120 in breadth. The climate, soil, and produce, are much the same with those of Mexico Proper. On the W. side there is a chain of mountains for the space of eighteen leagues, very well cultivated; and on the N. is also a great ridge of mountains, covered with perpetual snow, the neighbourhood of which expoxes it to horrid tempeuts, hurricanes, and frequent inundations, whereby houses, even on the top of eminences, are sometimes endangered. Yet this is allowed to be the most populous country of all America: and this is partly ascribed to its having been originally an ally to Cortez, in the conquest of Mexico, who obtained a grant of it from the emperor Charles V., also king of Spain, by which it is still exempt from any service or duty whatsoever to that crown, only paying the king of Spain a handful of maize for each head, as an acknowledgment; which inconsiderable parcels were paid, upwards of fifty years ago, to make up 1,300 buffelis; for it produces so much of the Indian corn, that hence it had the name of Tlacsala, that is, the Land of Bread. By this means the towns and villages swarm with Indians. This province was anciently a monarchy, till civil wars arising among the inhabitants, they formed themselves into an aristocracy of many princes, in order to get rid of them. They divided their towns into different districts; each of them nominated one of their chiefs to reside in the court of Tlacsala, where they formed a senate, whose resolutions were a law to the whole. Under this form of government they maintained themselves long while against the kings of Mexico, and continued in it till the reception of the Spaniards under Cortez.

Tlacasa, a town of North America, and anciently the capital of a province to which it gives name, situated on a river, which runs into the Pacific ocean. When the Spaniards first arrived here, it is said to have contained 30,000 inhabitants: and Acosta affirms, that it had a market-place large enough to hold 30,000 buyers and sellers; that in the fumbles were sold less than 1500 sheep, 4000 oxen, and 2000 hogs. But matters were so much altered, that Gemelli, who was here in 1638, says it was then become an ordinary village, with a parish-church, in which hangs up a picture of the ship which brought Cortez to La Vera Cruz. The inhabitants formerly offered up human sacrifices, and when the Spaniards first arrived here, we are told by Diaz del Cañillo, that they found wooden cages, in which prisoners were confined to be fattet for victims; 20 miles N. of Puebla de los Angeles. N. lat. 19° 45'. W. long. 98° 30'.

TLAYOTIC, in Natural History. See Colic-Stone. TLEMSAM, or Telemesen, in Geography. See TREMEECE.

TLETSCH, a town of Russia, in the government of Tobol, on the Irtisch; 72 miles E.S.E. of Tobolik. TLEUQUEHOLTOTOT, in Ornithology, the Mexican name of a bird of the wood-pecker kind, described by Nieremberg under the name of the avis salutiferus; the feathers of a red crest it carries on its head being supposed a remedy for head-aches.

TLOS, in Ancient Geography, a town of Asia Minor, in Lydia, at the pafs of a mountain, on the side of Cybara, according to Strabo. It is placed by Ptolemy in the number of the interior towns of Lydia, in the vicinity of mount Cragas.—Alfo, a town of Asia, in Pifidia. TLMACZOW, in Geography, a town of Moravia, in the circle of Hradich; 15 miles N. of Hradich. TMAIE', a town of Egypt; 12 miles S.E. of anfora.

TMAURUS, in Ancient Geography, a mountain of Epirus, in Thespotia, at the foot of which was a temple. Strabo. It was also called Tamarus and Tornarua.

TMATARACAN, or Tamarican, literally denoting the "swarm of beetles," called in Theodorus's Itinerary "Tamatarse," a name anciently given to the city of Taman, over the suburbs of which extend all the ruins of the ancient city of Phanogoria. The distance across the Bosphorus from Tmataracan to Kertchy, e. e. from Phanogoria to Pantaeopurus, is found to correspond with the actual distance from Taman to Kertchy. Among other antiquities of Taman, one of the most remarkable is the Nau- machia, or amphitheatre for naval battles, not less than 1000 paces in diameter, with its whole area paved. The subterraneous conduits for conveying water still remain, but are applied to other uses. The materials of the ruined buildings do not exist in the isle of Taman, but must have been brought from the Crimea, from Greece, or in later ages, by the Genoese from Italy. The distance from Taman to Yenikele, on the opposite shore, is about 12 miles. Clarke's Travels, vol. ii.

TMESCHEDE, or Muschede, a town of Germany, in the county of Arenberg, on the left side of the Roer; 3 miles N.W. of Arenberg.

TMEIESPETERIS, in Botany, an uncoth, however learned, name, composed of τμητης, a notch, or incision, and περης, a fern, because the capules are seated in the notches of the frond.—Bernhardi in Schrad. Journ. for 1800, 131. t. 2. f. 5. Wild. Sp. Pl. v. 5. 56. Swartz Fil. 187. Labill. Nov. Holl. v. 2. 105. t. 252. This fern is referred by Mr. Brown to Psilotum. (See that article.) We ought there to have noticed Mr. Brown's remark, that the plant of Forlifer differs from Labillardiere's, in not having abrupt leaves, and that it was found in New Zealand, not in the isle of Tana. Willdenow has judiciously observed the difference between Bernhardi's figure, and that of Labillardiere. Mr. Brown says both these species are pastoral, on the stems of arborescent ferns.

TMESES, τμητης, formed from τμητης, in cut, a figure, by which a compound word is separated into two parts, and one or more words interposed between them.

Thus,
Thus, when Terence says, "que meo cunque ano animalium est facere," there is a tmesis; the word sequacque being divided by the interposition of meo.

Lucilius abounds in tmesis; as "fac pe fauitam tacu praterque meum," or "difficio potis eft fegungi, fegque gregarii," and "difcicis difque gregatiis."

TMULOS Moni in Ancient Geography, a mountain of Asfa Minor, in Lydia. Strabo says that the town of Sardis is commanded by the TMolus, a rich mountain, on the summit of which the Persians had erected a turf, from which might be seen all the adjacent fields, which were watered by the Caytulus. According to Homer it obtained, from its extraordinary elevation, the name of Ventalo, or windy. From Pliny we learn that the Paélolus, Chryforrhoas, and the fountain Tame, have their sources in this mountain, and that it produces excellent wine, highly commended by Pliny and Vitruvius. The summit is represented as always covered with snow. It was sometimes denominated Timolis, as by Ovid,

"Dea femeris Nymphae? . . . Timoli."

According to the mythologists, it was in this mountain that Apollo punished Midas, king of Phrygia, by giving him ass's ears.

TMOLUS, a town of Asfa Minor, in Lydia, on mount TMolus. According to Tacitus, TMolus was one of the two towns overthrown by an earthquake, in the fifth year of the reign of Tiberius, A.D. 117, and it was rebuilt by this prince.

TMORUS, the name of one of the summits of the Ceraunian mountains, in Epirus.

TMULGA, in Geography, a town of Algiers; 10 miles E. of Sinaab.

TYNNUS, in Ancient Geography, a town of Asfa Minor, in Caria.

TOA, in Geography, a river of the island of Porto Rico, which runs into the harbour of Porto Rico.

TOAD, Rubeta, Rana Bufo of Linnæus, in Zoology, a creature sufficiently known. See Rana.

The toad has been generally considered as a poisonous animal, but Mr. Pennant apprehends without sufficient reason. They have been taken up in the naked hand without the least injury, and quacks have even eaten them, and drank their juices without damage. Besides, they are common food to many animals, as buzzards, owls, Norfolk plovers, ducks, and snakes; of late, indeed, live toads have been applied to cancers, with a view of curing them: facts have been alleged in proof of their efficacy for this purpose. The mode of applying them has been to put the animal into a linen bag, and to hold its head, pressing out of the bag, to the part, which has been laid hold of and sucked greediness till it dropped off dead. The creature has swelled and appeared to be in great pain; often sweats much and turns pale; and sometimes digresses, recovers, and becomes lively again. For other particulars, we must refer to Mr. Pennant's appendix ubi infra. The time when toads propagate is early in the spring; at which season the females are seen crawling about oppressed by the males, who continue on them for some hours, and adhere so fast as to tear the skin from the part to which they stick. They impregnate the spawn as it is drawn out in long strings, like a necklace. And the female is afflicted by the male, in discharging the spawn, who with his hinder feet pulls out the eggs, while his fore-feet embraces her breast. The eggs are included each in a membraneous coat that is very firm, in which is contained the embryo, and these eggs, fastened to one another by a short but strong cord, form a kind of chaplet, the heads of which are distant from each other about half their length. The male, by drawing this cord with his paw, performs the functions of a midwife, and acquires himself in it, it is said, with a dexterity which could not be expected from so lumpish an animal. Pennant's Brit. Zool. vol. iii. p. 14. p. 385, &c.

The toad of Surinam, or rana pipis of Linnæus, has long been an object of attention to the curious, on account of its enormous bulk and ugly form. Dr. Fermin, in his "Traité des Maladies les plus fréquentes à Surinam," &c. published at Maastricht in 1764, has given some remarks on its mode of generation. Having put three males and a female into an open vessel of water, he observed that one of them had several spots on its back, which were eggs, each containing an embryo. At the end of three weeks, the animal seemed much agitated, and one of the cells on its back bursting open, a young one crept out of it. In five days no less than thirty-five of these cells opened in the same manner and produced as many animals. On the back of one of these which was dissected, there were no less than one hundred and twenty of these cells, each of which considered as a real matrix, in which its eggs are lodged and fecundated; and, indeed, in one of them he discovered an embryo completely formed, enveloped in a kind of placenta, accompanied by two thin transparent membranes, seemingly analogous to the chorion and amnion in other animals. For other species of toad, see RANA.

TOAD-Fish, Rana pipicaris, in Ichthyology. See Lophius Pipicaris, and Sea-Devil.

TOAD-Plas, in Botany. Antirrhinum.

TOAD-Stone, in Mineralogy, a variety of trap-rock. (See Trap.) The toad-stone of Derbyshire is generally a dark-brown basaltic amygdaloid, composed of an intimate intermixture of basalt and green earth, and containing oblong cavities, principally filled with calcareous spar. It sometimes assumes the form and texture of a compact basalt, and is also found in a decomposing soft slate, approaching to clay. In composition and appearance it bears a strong resemblance to some volcanic rocks; and there are certain peculiarities in the geological position of this rock, which have excited considerable attention. Mr. Whitehurst, in his Theory of the Earth, has given a particular account of the Derbyshire toadstone; and has stated the number of beds, and the thickness of each, with that of the mountain lime-stone, with which it alternates, as under:

<table>
<thead>
<tr>
<th>Type of Stone</th>
<th>Thickness</th>
</tr>
</thead>
<tbody>
<tr>
<td>First lime-stone</td>
<td>50 yards</td>
</tr>
<tr>
<td>First toad-stone</td>
<td>16</td>
</tr>
<tr>
<td>Second lime-stone</td>
<td>50</td>
</tr>
<tr>
<td>Second toad-stone</td>
<td>40</td>
</tr>
<tr>
<td>Third lime-stone</td>
<td>60</td>
</tr>
<tr>
<td>Third toad-stone</td>
<td>22</td>
</tr>
<tr>
<td>Fourth lime-stone</td>
<td>not cut through</td>
</tr>
</tbody>
</table>

It appears, however, that the thickness and extent of the toad-stone beds are by no means so regular as those of the other strata, in the same district.

In some situations, one or more of the beds will become very thin, or be entirely wanting; in other situations, a single bed will be found of vast thickness: and masses of this sublance, which cannot be referred to any of the three beds, will be found interposed in the lime-stone strata. In some instances, particularly near Ashover, nodules of lime-stone may be seen imbedded in toad-stone. Farcy's Derbyshire Report, vol. i. p. 276.

The most remarkable phenomenon which the beds of toad-stone present in Derbyshire, is the complete separation of the metallic veins which they generally occasion. The mountain line-
lime-stone of that district is intersected by numerous perpendicular metallic veins, which rise from the lowest lime-stone to the uppermost; but on striking through the vein in the first lime-stone, down to the first toad-stone, the vein will entirely disappear, but on perforating through the toad-stone, it will be found again in the second lime-stone; and the same appearances will be presented on piercing through the second and third beds of lime-stone, and the second and third beds of toad-stone. See Plate IV. Geography, fig. 1, where 1, 2, 3, 4, represent the four beds of lime-stone; b, b, b, the three beds of toad-stone; and v, v, v, v, the metallic vein passing through the different lime-stone beds, but completely cut off or separated by the intervening beds of toad-stone. To account for this interruption of the vein at v, v, Mr. Whitehurst supposes that the toad-stone, in a state of igneous fusion, has burst through the lower strata, and has forced itself between the strata of lime-stone by a lateral motion. Were this the case, we must admit that the toad-stone had risen through fissures or dikes, similar to what exist in many of the northern parts of Britain, and are called whin-dikes. The whin-stone, or basalt, bearing a close resemblance to toad-stone, and the strata in the peak of Derbyston being much fractured, we should feel little difficulty in admitting the probability of Mr. Whitehurst's theory, did it apply to the different phenomena which these beds of toad-stone present. According to this theory, the beds of toad-stone must have been interposed subsequently to the formation of the metallic veins. There are, however, instances, in which very large veins extend from the lime-stone to some depth in the toad-stone, and terminate in small fringes of ore; in other instances, though the ore is not continued through the toad-stone, a small vein filled with spar may be traced from No. 1, the first lime-stone, through b, to No. 2, the second lime-stone. Such instances prove, in the most decisive manner, that the formation of the veins was posterior to that of the toad-stone. Hence we are led to seek for some other cause which may explain the absence of metallic ores in the beds of toad-stone. This subject will be considered when we treat of metallic veins. See TRAP, and VEINS, Mineral and Metallic.

From the experiments of Dr. Withering on this stone with different acids, alkalies, and by fusion, it appears that one hundred parts of it consist of 63½ parts of siliceous earth, 16 of calciform iron, 7½ of carcaseous earth, and 14 of earth of alum. The aggregate of these ingredients is found to weigh 15 parts more than the original mass, which is ascribed to the sublimate capable of uniting with fixable ore, not having been fully agitated with it, as they would be after their precipitation by the earth of alum. (Phil. Tranf. vol. lxxii. part ii. p. 353.) This sublinate differs little from that of haflets: it is fofter, contains a smaller proportion of iron, and a larger of flux.

TOAGAMALLY, in Geography, a town of Hindostan, in the Carnatic; 17 miles W.S.W. of Trichinopoly.

TOAHOUTA, one of the smaller Society islands, near Otaha.

TOAILREH, a town of Egypt, on the coast of the Red sea, where the water is salt; 5 miles N. of Koloum.

TOALDO, Joseph, in Biography, a distinguished philosopher, was born in 1719 at a small village near Marostica, in the valley of Vicenza, at the foot of the Alps, and sent, in the year 1733, to the seminary of Padua, where he studied Latin, rhetoric, philosophy, theology, and particularly mathematics. In this seminary he afterwards became a teacher of grammar, rhetoric, philosophy, and mathematics. His first literary work was a new edition of the writings of Galileo, to which he added several fragments never before published, with a preface and notes. For his services to the above-mentioned seminary he was recommended with the benefice of Montegada, which he enjoyed for 14 years, and which he exchanged for another more convenient, after his appointment by the senate of Venice, in 1762, to the professorship of astronomy and meteorology in the university of Padua. Here he constructed an observatory, begun in 1767 and completed in 1774. In 1769 he published at Padua a short view of plane and spherical trigonometry, entitled "Tavole Trigonometriche, &c," which was reprinted and used in many of the Italian seminaries. He next published a treatise on the influence of the heavenly bodies on the weather and atmosphere, containing the result of a long series of meteorological observations. This work, printed at Padua in 1770, 4to., was translated into different languages, and so well received, that he was admitted into various learned societies. About the same time he prefented to the public essays in favour of electrical conductors, which caused them to be erected in the Venetian territories; also a chronological view of uncommon changes in the weather, with tables of the state of the barometer, and the flux and reflux of the sea. His meteorological journal was begun in 1773, and continued till his death. His celebrity was augmented in 1774 by an answer to a prize question, proposed by the academical society of Montpellier, on meteorology applied to agriculture; and after this time he laboured incessantly in diffusing meteorological science. In 1777 he translated Lalande's Astronomical Tables, and his "Abridged de l'Astronomie," and some time after, his "Astronomie des Danes," erecting also in his observatory a marble bust of that eminent astronomer. From this time he almost restricted his attention to astronomy and meteorology, endeavouring to confirm his hypothesis of the influence of the moon on the different changes of the weather. He also published an historical view of the services rendered by the Venetian schools to astronomy, geography, and navigation. In 1783 he obtained, in conjunction with his nephew Chinnello, who was his assistant in the observatory, the prize offered for the best treatise on the construction of a comparative hygrometer; and in 1784 he published a small work on the longitude, which was well received. He proceeded regularly with his journal till the year 1787, when a small work in two sheets was printed at Venice; and in the following year his Tables of Vitality appeared at Venice and Padua. Of his travels in 1780 and in 1788, in the course of which he examined the place where Hannibal crossed the Alps, the result was inferred in his dissertation on the subject, printed in the fourth volume of the Transactions of the Academy of Padua. But our limits will not allow us to give even the titles of the numerous essays and papers which he published on various subjects, relating principally to meteorology. The journals of the period in which he lived contain many curious pieces contributed by this indefatigable inquirer into the operations and phenomena of nature. Besides his publications, he left in MS. several papers, and particularly observations on the travels of Marco Polo, and on the real epoch of the Chinese wall. The termination of Toaldo's life was accelerated by the chagrin which he felt, in consequence of a fruitless attempt to serve a young man who had been deprived of his office. This irritation affected his health, fo much that in November, 1797, he was attacked by a nervous affection, which in a few days proved fatal, in the 79th year of his age.

"Toaldo," says his biographer, "was of small stature; but, in general, had an engaging appearance that inspired confidence
TOBacco, Nicotiana, in Botany. See Nicoti
TIANA.

TOBacco, Culture and Preparation of. See Nicotiana.

TOBacco, History of. Tobacco was not known in Eu-
rope till after the discovery of America by the Spaniards,
and first imported about the year 1560, as some fry by Sir
Francis Drake.

The Americans of the continent call it petun, thone
of the islands yeh. The Spaniards, who gave it the name
tobaco, took it from Tabaco, a province of Yucatan, where
they first found it, and first learned its use; or, as Ione say,
it derived its name from the island of Tabago, or Tobaco.

The French, at its first introduction among them, gave
it various names; as Nicotiana, or the ambassadore's herb,
John Nicot, then ambassador of Francis Ill, in Por-
tugal; who brought some of it with him from Lisbon,
and presented it to a grand prior of the house of Lorrazin,
and to queen Catherine de Medicis; whence it was also called
queen's herb, and grand prior's herb. They also gave it
other names, which are now all reduced to the original
name of tobacco, or tobacco, from Tabaco, given it by Hern-
dez de Toledo, who first sent it into Spain and Por-
tugal.

It appears from Lobel, that this plant was cultivated in
Britain before the year 1570; and the introduction of the
practice of smoking it in England has been commonly
attributed to Sir Walter Raleigh, about the year 1584. The
cultivation of it is now common in various parts of the
globe; and though prohibited by the laws of this country,
the manufacture of it forms no inconsiderable branch of
commerce.

Tobacco might be cultivated with advantage through
the greater part of Europe; but almost in every part of Europe
it has become a principal subject of taxation; and it has
been supposed, that it would be more difficult to collect a
tax from every farm where this plant might happen to be
cultivated, than to levy one upon its importation at the
custom-house. The cultivation of tobacco has been, upon
this account, most ably, (says Mr. Smith, Wealth
of Nations,) prohibited through the greater part of Europe,
which necessarily gives a sort of monopoly to the countries
where it is allowed; and as Virginia and Maryland produce
the greatest quantity of it, they share largely, though not
without some competitors, in the advantage of this mono-
poly: the cultivation of it, however, is said to be less pro-
fitable than that of sugar. At the time when the author
published his work above cited, about ninety-five thousand
hogsheads of tobacco were annually purchased in Virginia
and Maryland, with a part of the surplus produce of British
industry; but the demand of Great Britain does not require,
perhaps, more than fourteen thousand. If the remaining
eighty-two thousand, therefore, could not be sent abroad
and exchanged for something more in demand at home, the
importation of them must cease immediately, and with it
the productive labour of all these inhabitants of Great Bri-
tain, who are at present employed in preparing the goods
with which these eighty-two thousand hogsheads are an-
ually purchased. Those goods, which are part of the pro-
duce of the land and labour of Great Britain, having no
market at home, and being deprived of that which they had
abroad, must cease to be produced. The most round-about
foreign trade of consumption, therefore, may, upon some
occasions, be as necessary for supporting the productive la-
bour of the country, and the value of its annual produce, as
the most direct. In order to facilitate the great exportation
which was necessary, for getting rid of that which remained
after the home consumption, the whole duties were drawn
back, provided the exportation took place within three
years.

The principal kinds of tobacco imported into England
are, as we have already observed, the Maryland, called
Oroonoko, and the Virginia-tobacco. The former is not
so agreeable to the British taste as the sweet-leafed tobacco
of the latter country; but the northern nations of Europe
are said to like it better.

Besides the tobacco of the West Indies, there are con-
siderable quantities cultivated in the Levant, the coasts
of Greece, and the Archipelago, the island of Malta, and
Italy. The marks of good twist tobacco are a fine shining
cut, an agreeable smell, and that it has been well kept.

In the island of Ceylon, there are two kinds of tobacco
cultivated for profit. They call both kinds dunkol,
which signifies a leaf, the use of which is to be smoked. The
one kind they call fingle dunkol or fingle dunkel, for they make
no difference between the letter s and H in their pronuncia-
tion; the other they call dunkol kappada; kappada signifies
gelding, and is a word of Portuguese origin. This kappada
烟acco is much stronger and more intoxicating than the
other; but both kinds are the produce of the same plant;
only the fingle tobacco has very little care taken of it, being,
after the fowling, in a manner left to itself; while the other
has great pains bestowed upon it during the whole time of
its growth, and till it is fit for use.

Some of the Ceylonese chew this strong tobacco with
their betel; and some, who smoke it alone, use no pipe,
but, taking a long leaf of it, they roll it up into a long
form, and cover it with the leaf of the witttan-ken; they
then light one end of it, and smoke by the other, till the
whole is consumed. Phil. Trans. N° 278, p. 1143.

Although in Russia tobacco is not considered as one of
the general necessaries of the lower classes of the people,
the practice of smoking having been held as a sin to the
end of the 17th century; nevertheless the consumption of it is
by no means small, and of course the importation always
much overbalances the exports. In 1793, the former at St.
Peterburg
Tobacco.

Peterburg alone amounted to upwards of 47,000 rubles; and the latter, from all parts of the empire, barely to 20,000: however, the consumption must have increased, as the education in 1768 is stated by Guldenfzdt at 21,000, and the whole of the importation at 108,000 rubles. The culture has been profitably carried on, since the year 1765, in various districts of the empire. Most of it is obtained in the Malo-Russian governments, where the cultivation was first encouraged; but it has been much cultivated in other regions, e.g. about the Volga and the Samara, and particularly by the Cossacks on the Orénburg and Siberian lines. The greatest part of the Russian tobacco is derived from American, and some Turkish and Persian seeds. In the generality of the southern governments, these plantations admit of being greatly multiplied. The different sorts of tobacco and snuffs prepared from it, which are now in use, are to be attributed to the difference in the climate and soil in which it grows, and the peculiar mode of managing and manufacturing the plant, rather than to any essential difference in its qualities.

Tobacco, in the Materia Medica, &c. This is a well-known drug of a narcotic quality, which it discovers in all persons, even in small quantity, when first applied to them; and when used in large quantities, its effects have sometimes been more violent, so as to have proved a mortal poison. Besides its narcotic qualities, it possesses also a strongly dilating power, perhaps, as Dr. Cullen observes, with respect to the whole system, but especially with respect to the stomach and intestines; so as readily, even in no great doses, to prove emetic and purgative.

The leaves of tobacco have a strong disagreeable smell, and a very acrid burning taste; distilled in a retort, without addition, they yield an acrid, empyreumatic, poisonous oil. They give out their acrid, matter both to water and spirit, but most perfectly to the latter: the aqueous infusions are of a yellow or brown colour, the spirituous of a deep green. The several sorts of tobacco imported from abroad are stronger in taste than that of our own growth, and the extracts made from them much more fiery, but in less quantity.

Tobacco has been employed, in ordinary use, by snuffing, smoking, and chewing; and these practices have been common for more than 200 years to all Europe, and they have more or less prevailed in other parts of the globe. Like other narcotics, the use of it may be introduced by degrees; and its peculiar effects may hardly at all be manifested; but beyond certain limits, violent effects have been sometimes produced on those who have been accustomed to the use of it. The power of habit is often unequal, even among those who have been addicted to this practice. Dr. Cullen mentions a lady, who had been for more than twenty years accustomed to take snuff at all times of the day; but she found at length that indulging much in the use of snuff before dinner took away her appetite; and in process of time, that a single pinch, taken any time before dinner, pulled her appetite for that meal. But when she abstained from the use of it, her appetite returned; and after dinner, for the rest of the day, she took snuff freely without inconvenience. When snuff, that is, tobacco in powder, is first applied to the nose, it proves a stimulus, and excites freezing; but by repetition, that effect entirely ceases.

Snuff, when first employed, if it be not taken in small quantity, and if it be not thrown out immediately by sneezing, occasions some giddiness and confusion of head: but these effects do not occur when persons are habituated to the use of it. But such persons, if it be taken beyond the usual quantity, experience the same consequences; and the effect is manifest, not only on the seneforium, but on other parts of the system, particularly the stomach, occasioning a loss of appetite, and other symptoms of a weakened tone in that organ. Dr. Cullen says, that he has observed several instances of persons who take snuff to excess, suffering from it by a loss of memory, by a fatuity, and by other symptoms of the weakened or feble state of the nervous system, induced before the usual period. He has also found symptoms of dyspepsia, and pains of the stomach, occurring every day, in consequence of excess in the practice of taking snuff. These symptoms have subsided, when the use of snuff has been discontinued. A special effect of snuffing, he says, is its exciting a considerable discharge of mucus from the nose; and there have been several instances of head-aches, tooth-aches, and opthalmia thus relieved: and when this discharge of mucus is considerable, the ceasing or suppression of it, by abstaining from snuff, is apt to occasion those disorders which it had formerly relieved. Another effect of taking snuff is this, that as a part of the snuff is often carried back into the fauces, so a part of this is carried down into the stomach, and then more certainly produces the above-mentioned dyspeptic symptoms.

Smoking, when first practised, shews very strongly the narcotic, vomiting, and even purging powers of tobacco, and it is very often useful as an anodyne; but by repetition these effects disappear, or only shew themselves when the quantity smoked is beyond what habit had before admitted of; and even in persons much accustomed to it, it may be carried so far as to prove a mortal poison. From much snufing, all the same effects may arise which we said might arise from the excess in snuffing.

With respect to the evacuation of mucus which is produced by snuffing, there are analogous effects produced by smoking, which commonly stimulate the mucous follicles of the mouth and fauces, and particularly the excretories of the salivary glands. By the evacuation from both sources, with the concurrence of the narcotic power, the tooth-ache is often greatly relieved by it; but we have not found the smoking relieve head-aches and opthalmia so much as snuffing often does. Sometimes smoking dries the mouth and fauces, and occasions a demand for drink; but, as commonly the stimulus it applies to the mucous follicles and salivary glands draws forth their liquids, it occasions on the other hand a frequent spitting.

So far as this is of the proper saliva, it occasions a want of that liquid so necessary in the business of digestion; and both by this want, and by the narcotic power at the same time applied, the tone of the stomach is often weakened, and every kind of dyspeptic symptoms is produced. Though in smoking a great part of the smoke is again blown out of the mouth, fill a part of it must necessarily pass into the lungs, and its narcotic power applied there often relieves spasmodic asthma; and by its stimulant power it there also sometimes promotes expec tionation, and proves useful in the catarhal or pithous difficulty of breathing.

Smoking has been frequently mentioned as a means of guarding men against contagion. In the case of the plague, the testimony of Dierensbroc is very strong; but Riviens and others give us many facts which contradict this; and Chenu gives a remarkable instance of its inability. We cannot indeed suppose that tobacco contains an antidote of any contagion, or that in general it has any antiseptic power; and therefore we cannot allow that it has any special use in this case: but it is very probable that this and other narcotics, by diminishing sensibility, may render men less liable to contagion; and by rendering the mind less active and anxious, it may also render men less liable to fear, which has
has so often the power of exciting the activity of the contagion. The antilomac powers of tobacco are therefore on the same footing with those of wine, brandy, and opium.

The third mode of using tobacco is that of chewing it, when it excites its narcotic qualities as strongly as in any other way of applying it; though the nauseous taste of it commonly prevents its being carried far in the first practice. When the practice, however, is continued, as it is very difficult to avoid some part of it dissolved in the saliva from going down into the stomach, so this, with the nauseous excitement of the taste, makes vomiting more readily occasioned by this than the other modes of applying it. They are the strong, and even disagreeable impressions repeated, that give the most durable and tenacious habit; and therefore the chewing of tobacco is apt to become one of the habits, and it is therefore in this way that it is ready to be carried to the greatest excesses, and to shew all the effects of the frequent and large use of narcotics. As it commonly produces a considerable evacuation from the mouth and face, so it is the most powerful in relieving the rheumatic affection of tooth-ache. This practice is also the occasion of the greatest waste of saliva; and the effects of this in weakening digestion, and perhaps from thence especially, its noted effect of producing emaciation, may appear.

The effects already recited of the different modes of employing tobacco depend especially upon its narcotic power, and certain circumstances accidentally attending its application to the nose and mouth; but as we have observed before, that beside its narcotic, it possesses also a stimulant power, particularly with respect to the alimentary canal: by this it is frequently employed as a medicine for exciting either vomiting or purging, which it does as it happens to be more immediately applied to the stomach or to the intestines.

An infusion of half a dram to a dram of the dried leaves, or of these as they are commonly prepared for chewing, for an hour or two, in four ounces of boiling water, affords an emetic which has been employed by some practitioners, but more commonly by the vulgar only. As it has no peculiar qualities as an emetic, and its operation is commonly attended with severe sickness, it has not been, nor is it likely ever to come into common practice with physicians.

By long boiling in water, its deleterious power is said to be abated, and at length destroyed; an extract made by long coction, is recommended by Stahl and other German physicians, as the most effectual and safe aperient, detergent, expectorant, diuretic, &c.; but the medicine must necessarily be precocious in strength, and has never come into use among us. Lewis Mat. Med.

It is more commonly employed as a purgative in gypsies; and, as generally very effectual, it is employed in all cases of more obdurate constiffines; and its powers have been celebrated by many authors. Dr. Cullen has known it to be in frequent use with some practitioners: and he adds, it is indeed a very effectual medicine, but attended with this inconvenience, that when the dose happens to be in any excess, it occasions severe sickness at the stomach, and it has been known to frequently occasion vomiting.

A strong decoction of tobacco, with proper carminatives and cathartics, given gypsy-wife, sometimes proves of good effect in what is usually called the stone colic, and also in the iliac passion.

It is well known, that in cases of obdurate constiffines, in ileus and incarcerated hernia, the fume of burning tobacco has been thrown into the anus with great advantage. The fume operates here by the fame qualities that are in the infusions of it above-mentioned; but as the fume reaches much farther into the intestines than infusions can commonly do, it is thereby applied to a larger surface, and may there-fore be a more powerful medicine than the infusions. In several instances, however, says Dr. Cullen, I have been disappointed of its effects, and have been obliged to have recourse to other means.

Bates and Fuller give some receipts, in which tobacco is an ingredient, with mighty encomiums, in allmatic cafes.

Hoffman observes, that horses have been often relieved by this remedy, but in human subjects it has been rarely tried; and says he has known some of the common people, who laboured under excruciating pains of the intestines, freed in an instant from all pain by swallowing the smoke. Both the decoction and the fume have not infrequently been injected in cafes of incarcerated hernia, and often with success. The fume thus applied is recommended as one of the principal means for the relaxation of perfolns apparently dead from drowning or other sudden causes; but some fupplement the narcotic power of tobacco as unfavourable in these cafes.

The infusion of tobacco, when it is carried into the blood-vessels, has sometimes shewn its stimulant powers exerted in the kidneys; and very lately we have had it recommended to us as a powerful diuretic of great service in dropsy. Upon the faith of these recommendations we have now employed this remedy in various cafes of dropsy, but with very little success. From the small doses that are proper to begin with, we have hardly observed any diuretic effects; and though from larger doses they have in some measure appeared, we have seldom found them considerable: and when, to obtain these in a greater degree, we have gone on increasing the doses, we have been constantly restrained by the severe sickness at the stomach, and even vomiting, which they occasioned: so that we have not yet learned the administration of this remedy, so as to render it a certain or convenient remedy in any cases of dropsy.

Tobacco is sometimes employed externally in ungents and lotions, for cleansing foul ulcers, destroying cutaneous infects, and other like purposes: it appears to be destruc-tive to almost all kinds of infects, to those produced on vegetables as well as on animals. Lewis.

A strong decoction of the stalks, with sharp-pointed dock, and salm, is said to be of good service, used externally, in cutaneous disfempers, especially the itch: some boil them for that purpose in urine. The same decoction is said to be efficacious in curing the mange in dogs.

Tobacco beat into a mash with vinegar or brandy, and laid on the stomach, has sometimes good effects in removing hard tumours of the hypochondria. We have the history of two cures made by such applications in the Med. Eff. Edinb. vol. ii. p. 41.

The juice of this plant is said to be good against ulcers and mortifications. Boyle's Works, Abr. vol. i. p. 56.

Some caution, however, Dr. Lewis observes, is requisite even in the external usofs of tobacco, particularly in solutions of continuity; there are instances of its being thus transmitted into the blood, so as to produce violent effects.

A drop or two of the chemical oil of tobacco being put on the tongue of a cat, produces violent convulsions, and death itself in the space of a minute; yet the same oil used in lint, and applied to the teeth, has been found of service in the tooth-ache; though it must be to those that have been used to the taking of tobacco, otherwise great sickness, retching, vomiting, &c. happen; and even in no cafe is the internal use of it warranted by ordinary practice. See experiments on the effects of oil of tobacco on pigeons, by M. Fontana, in which he found vomiting to be a constant effect of this poison, as he calls it, and the lots of motion
TOBACCO.

in the part to which it is applied an occasional or accidental effect, in Phil. Trans. vol. lxx. part i. append. p. 38, or Fontana fur les Poissons, &c. Florenc, quarto.

In cases of oblique ulcers, the infusion has been employed as a lotion with advantage; but the many infirmities of its being absorbed, and thus proving a violent poison, diffused from the practice; especially as there are other medicines of greater efficacy, that may be used more safely. Bergius recommends it to be employed as a fomentation in the paraphysis.

Sim. Paulii, physician to the king of Denmark, in an express treatise on tobacco, observes, that the merchants frequently lay it in hog-houses, to the end that, becoming impregnated with the volatile falt of the excrements, it may be rendered the brisker, more fetid, and stronger.

Amurath IV. emperor of the Turks, the grand duke of Moscovy, and the emperor of Persia, have prohibited the use of tobacco in their states. Our king James I. wrote a treatise expressly against it, entitled "A Counterblaff to Tobacco." By a bull of pope Urban VIII. such are excommunicated as take tobacco in churches.

TOBACCO. Laws and Regulations concerning.—Tobacco is not to be planted in England, on forfeiture of 40l. for every rod of ground thus planted; but this shall not extend to hinder the planting of tobacco in physic gardens, in quantities not exceeding half a pole of ground, and also on forfeiture of 10l. for every rod. (15 Car. II. c. 7. 12 Car. II. c. 34.) And justices of peace have power to issue warrants to confisables, to search after and examine whether any tobacco be fown or planted, and to destroy the fame, which they are to do under penalties, &c. 22 & 23 Car. II. c. 26. 5 Geo. I. c. 11.

The act of 29 Geo. III. c. 68, regulating the importation, exportation, and manufacture of tobacco and snuff, and also that of 30 Geo. III. c. 40, made to explain and amend the former, are fo extended, and comprehend so great a variety of particular regulations, as not to admit of minute recital in this place. The former repeals a considerable number of preceding statutes. By 49 Geo. III. c. 68. and c. 69. all duties under the respective departments of Customs and Excise are repealed, and other duties are granted in lieu of them. Tobacco and snuff are also subject to annual duties by the act for continuing the duties on pensions, offices, &c.; and certain drawbacks are allowed upon the exportation of them; which duties are to be under the management of the commissioners of the customs and excise. 43 Geo. III. c. 68. and c. 69.

No tobacco shall be imported but from America, on pain of forfeiture, with the vessel and its contents; except from Spain, Portugal, and Ireland, from which it may be imported under certain regulations. (29 Geo. III. c. 68.) But tobacco of the territories of Ruffia or Turkey may be imported from thence in British-built ships, and warehoused, and may be exported or entered for home consumption, on payment of the like duties as tobacco of the United States of America; and on its being manufactured in Great Britain and exported shall be entitled to the drawbacks. (43 Geo. III. c. 68.) By 45 Geo. III. c. 57. tobacco, the production of the West Indies or the continent of America, belonging to any foreign European state, may be imported into certain ports specified in the act, and exported to any port of the united kingdom, subject to the regulations of the act; and such tobacco shall pay the same duties as that which is the growth of the British West Indies, or of the United States of America. By 49 Geo. III. c. 25. unmanufactured tobacco may be imported from any place in British vessels navigated according to law, or in foreign ships navigated in any manner whatever belonging to any state in amity with Great Britain; and such tobacco shall be liable to the same regulations as tobacco from the British plantations.

But no tobacco or snuff shall be imported in any vessel of less burthen than 120 tons; nor any tobacco-stalks, tobacco-stalk flour, or snuff-work, in any vessel whatever; nor any tobacco or snuff in casks less than 450lbs. on the like penalty; except loose tobacco for the crew, not exceeding 5lbs. for each perchon; nor shall the vessel be forfeited, if proof be made from the smallness of the quantity that such tobacco or snuff was on board without the knowledge of the owner or master. 29 Geo. III. c. 68.

And no tobacco or snuff shall be exported except at London, Bristol, Liverpool, Lancaster, Cowes, Falmouth, Whitehaven, and Hull (and by 31 Geo. III. c. 47. Newcastle-upon-Tyne); on the like forfeiture. Every manufacturer of tobacco or snuff shall take out a licence from the officers of excise, for which he shall pay, if the quantity of tobacco and snuff-work, weighed by him for manufacture within the year, ending the roth of October previous to his taking out such licence, did not exceed — — — — 20,000 lbs. £ s. d. 2 0 0

If above 20,000 and not exceeding 30,000 3 0 0

30,000 — — 40,000 4 0 0

40,000 — — 50,000 5 0 0

50,000 — — 60,000 6 0 0

60,000 — — 70,000 7 0 0

70,000 — — 80,000 8 0 0

80,000 — — 90,000 9 0 0

90,000 — — 100,000 10 0 0

100,000 — — 120,000 12 0 0

120,000 — — 150,000 15 0 0

150,000 — — — — 20 0 0

Every person who shall first become a manufacturer of tobacco or snuff, shall pay for every such licence 2l., and within ten days after the roth of October next after taking out such licence, such further additional sum, as with the said 2l. shall amount to the duty herein before directed to be paid, according to the quantity of tobacco and snuff-work weighed for manufacture within the preceding year. — — 2 0 0 and a furchage.

And every dealer in tobacco and snuff shall take out a licence in like manner, for which he shall pay, within the liberties of the chief office in London, 5l., elsewhere 2l. 6d. 43 Geo. III. c. 69. Sched. (A.)

But perfons licensed as manufacturers, who shall not fell tobacco in a less quantity than four pounds, nor snuff in two pounds, need not be licensed as dealers. 29 Geo. III. c. 68.

Every person who shall manufacture or deal in tobacco or snuff without taking out such licence; or shall not renew the same ten days at leaft before the end of the year, shall forfeit, if a manufacturer, 200l., and if a dealer, 50l.

But no perfon shall be liable to the said penalty of 50l. for selling unmanufactured tobacco or snuff, whilst remaining in the king's warehouse.

But perfons in partnership need not take out more than one licence for one house.

Every person who shall manufacture tobacco, tobacco-stalks, or returns of tobacco, or flatten any tobacco-stalks, or
or cut the same into Spanish, shall be deemed a manufacturer of tobacco. And every person who shall grind or manufacture any tobacco-flake flour, snuff-work or snuff, shall be deemed a manufacturer of snuff. And every person who shall sell any tobacco, tobacco-flakes, or returns of tobacco, or flakes flattened or cut into Spanish, shall be deemed a dealer in tobacco. And every person who shall sell any tobacco-flake flour, snuff-work or snuff, shall be deemed a dealer in snuff, within the meaning of this act.

Every manufacturer and dealer shall make entry in writing of his house or place intended to be made use of for manufacturing, keeping, or selling tobacco or snuff, three days before he shall begin, on pain of forfeiting 200l., and also the tobacco and snuff there found, together with the casks and package, which may be seized by the officers of the customs or excise.

Every manufacturer, within the limits of the head office, must be an occupier of a tenement of 10l. a-year, and pay to the parish rates; elsewhere, he must pay to the church and poor.

Every such manufacturer shall, three days before he begins, make entry in writing at the excise-office of all mills, presses, engines, rollers, flouses, mullers, or spinning-wheels, intended to be used by him about the manufacturing of tobacco or snuff; on pain of forfeiting 50l. for every such utensil not entered.

Every such manufacturer and dealer shall cause to be put up in large legible characters over his door, or on some conspicuous part of such house or place, the words Manufacturer of, and Dealer in Tobacco and Snuff, or Tobacco or Snuff, or Manufacturer of, or Dealer in Tobacco and Snuff, or Tobacco or Snuff (as the case may be); on the penalty of 50l.

If any person, who has not made such entry as aforesaid, shall put up the said words, he shall forfeit 100l.

And by 30 Geo. III. c. 40, no person shall set up or begin any manufactory of tobacco or snuff within five miles of the sea-coast, except in the ports and places aforesaid, where tobacco may be imported, or places within three miles thereof; or in cities, or the suburbs thereof, and market-towns; and no entry thereof shall be of any avail. But the same shall not extend to places duly entered before the 5th of July, 1789.

But tobacco and snuff may be manufactured by any unlicensed Spanish cutter or snuff-miller at any entered mill, on account of any licensed manufacturer, provided the same be legally permitted from such manufacturer, and for the sole purpose of manufacturing or grinding. 29 Geo. III. c. 68.

Every manufacturer shall give notice in writing to the officers (if in London fix, in cities and market-towns twelve, and elsewhere twenty-four hours), before he shall begin to strip, spin, or press any tobacco for cutting; or make any tobacco into carrots, or flatten any flakes for Spanish; and shall express therein the weight of each article, and the time he intends to begin; and the officer shall attend accordingly, and he shall begin within one hour of the time so mentioned, and shall proceed without delay; and shall afterwards deliver a declaration in writing to such officer, of the quantity intended to be used for each fort of tobacco; on the penalty of 20l. and such notice being void.

30 Geo. III. c. 40.

Provided, that if such tobacco shall afterwards appear to be unfit for the purpose specified in such declaration, it may be applied to any other purpose, on giving 48 hours' notice to the officer of the fort: it is intended for.

Such manufacturer, as soon as the manufacturing is finished, shall deliver to the officer a declaration of the weight of the different sorts of tobacco so manufactured, and the number of the rolls or carrots made, and the weight thereof, and of the tobacco-flakes and returns arising from the operation; and shall keep each fort separate for twenty-four hours, or until an account be taken; on the penalty of 50l.

If any manufacturer shall make, or have in his possession, any roll or carrot tobacco for exportation, which shall have any tobacco-flakes therein, the same shall be forfeited, and may be seized, and he shall also forfeit 50l.

Every person who shall cut any walnut-tree, or other leaves, herbs, or plants, in imitation of tobacco (not being tobacco-leaves or plants); or shall colour the same so as to resemble tobacco; or shall mix any such leaves, herbs, or plants with tobacco; or shall fell, or expel to false, or have in his possession any such leaves, herbs, or plants so cut, coloured, or mixed, shall forfeit the same with the casks and package, which may be seized; and also 200l.

Provided, that nothing herein shall extend to prohibit any such manufacturer from dyeing tobacco, or for having such dye in his possession for that purpose. 30 Geo. III. c. 40.

Every manufacturer of snuff shall provide proper moveable casks for preparing, laying down, or putting into bins snuff-work and tobacco-flakes for flour; and shall place them so as that the officer may conveniently examine and weigh the same at all times; and shall mark every such cask with a progressive number, the same being, and the care and weight thereof; and shall not lay down any snuff-work in any cask not so marked; nor put the same in any bin; on the penalty of 50l. 29 Geo. III. c. 68.

Such manufacturer of snuff shall, before he begins to liquor, or cut any tobacco or flakks, &c. or to lay down any snuff-work, give like notice as aforesaid to the officer, and shall in such notice declare the weights thereof respectively, and the number of each particular cask or bin in which the same is intended to be laid down; and such officer shall attend accordingly; and such person shall begin within one hour of the time so mentioned, and shall without delay proceed therein, until the whole is weighed; and shall then deliver an account in writing of the quantity intended for each fort of snuff or flour; and when put into casks, he shall give a like notice, and in the presence of the officer shall affix to each cask a ticket specifying the number of such casks, and the weight of the snuff-work, &c. therein, and the time when laid down, and what sort of snuff it is intended for; which ticket shall be signed both by such manufacturer or his servant and the officer; and when the same is intended to be taken out to be ground, like notice shall be given, and the same shall be weighed out in the presence of such officer. And no such manufacturer shall mix snuff-work or tobacco-flakes for flour of one making with another; on pain of forfeiting for every offence aforesaid 50l.

Provided always, that if such snuff-work shall afterwards appear to be unfit for the purposes specified in such declaration, or be intended to be manufactured contrary thereto, notice thereof in writing shall be given to the officer within forty-eight hours after the delivery of such declaration, and if such declaration shall be given, specifying the sort it is intended for, and such manufacturer shall proceed therein in manner as aforesaid. 30 Geo. III. c. 40.

Scotch snuff and tobacco-flake flour may be manufactured into brown Scotch snuff, and tobacco-flake flour into rappee snuff, subject to the regulations aforesaid. And on taking
Tobacco.

Stock, certain credits shall be allowed, as set forth in the act; and if on taking such stock any excess be found, the same shall be forfeited, and may be seized. 30 Geo. III. c. 40.

And to snuff-work in operation, tobacco, tobacco-flafls, or flour, or returns of tobacco, may be added, on giving to the officer, previous to such increase being made a like notice, and conforming to the regulations specified in the act.

The whole of any parcel of snuff-work in cure, may be mixed with the whole of any other parcel in cure, although laid down at different times, if the same be mixed in the presence of an officer, to whom notice is to be given as aforesaid.

If any manufacturer has occasion to supply his customers with manufactured tobacco or snuff from any parcel in operation, before the whole be finished, he may, in the presence of an officer, take for the purpose aforesaid any manufactured tobacco or snuff not less than 200 lbs. But if taken without conforming to the regulations specified in the act, he shall forfeit 5s.

And every manufacturer shall diligently manufacture such snuff-work, and flasks for flour, when taken out of such casks, according to the notice given; and when the same is finished, he shall deliver to the officer a declaration in writing of the weight of each for produced, and shall keep the same separate for twenty-four hours, or until the officer shall have taken an account thereof; on the penalty of 50/. 29 Geo. III. c. 68.

Every manufacturer may have a store-room for keeping dried Scotch snuff, but the same shall have but one door or opening, which shall be locked, sealed, and secured by the officer; wherein may be deposited Scotch snuff returned directly from the mill for six months, without being taken as part of his stock. And when the same is intended to be taken out of such room, notice shall be given to the officer, who shall attend and open such room, and such snuff shall be taken out in his presence; and shall be kept separate one making from another; on the penalty of 50/. And if any manufacturer shall open such store-room, except in the presence of an officer, he shall forfeit 200/. Every person, who shall cut any walnut, hop, fycamore, or other leaves, or any other herbs, plants, or materials (not being tobacco-leaves or plants); or shall colour or cure any such, to make the same ressemble tobacco; or shall sell the same, mixed or unmixed, for tobacco;—shall forfeit 5s. a pound, half to the king (charges of the prosecution first deducted), and half with full costs to him who shall sue. 1 Geo. I. st. 2. c. 46.

Every person who shall make, mix, or colour any snuff with ocher, umber, or other colouring, except water tinged with Venetian red only; or shall mix with any fugitive or yellow ebony, touchwood, or other wood, or any dirt, sand, or small tobacco sifted from tobacco,—shall forfeit the same, and 5l. for every pound weight, half to the king, and half to him that shall sue. 1 Geo. I. st. 2. c. 46.

5 Geo. I. c. 11.

And all such leaves and other materials, and all engines, utensils, and tools for working the same, may be searched for and seized, by warrant of three commissioners of the treasury or of the customs. 1 Geo. I. st. 2. c. 46.

If any person shall mix any fugitive, or other wood, or any leaves, herbs, or plants (other than tobacco), or any earth, clay, or tobacco-fand, with any snuff-work or snuff; or shall colour the same with any fort of colouring (water tinged with colour only excepted); he shall forfeit 200/. And if any manufacturer or dealer in snuff shall fall, or expose to sale, or have in his entered premises, any fugitive, yellow ebony, touchwood, logwood, red or Guinea wood, Brazilletto or Jamaica wood, Nicaragua wood, or Saunders wood; or any walnut-tree, hop, or fycamore-leaves; or shall have in his possession any of the aforesaid articles; or any other wood, leaves, herbs, plants, earth, clay, or tobacco-fand, mixed with any snuff-work or snuff; or such snuff-work or snuff-coloured (except as aforesaid); he shall forfeit 50l., and the same shall be forfeited, and may be seized. 29 Geo. III. c. 68.

Any manufacturer of British rappee, Scotch or brown Scotch snuff completely finished, and of which an account has been taken by the officer, may liquor the same, before mixing with snuff of a different making, so as it exceed not the legal credit. And if such manufacturer shall intend to liquor snuff, for which the legal credit has not been received, he shall give notice thereof to the officer. But no snuff shall be liquored in less parcels than 200lbs., nor in more than four different parcels of one making. 30 Geo. III. c. 40.

Snuff, for which such allowance shall have been made, shall be kept separate from all other snuff, and shall be shown to the officer on demand; on the penalty of 20l.

Every manufacturer and dealer, who shall mix Spanish with short cut tobacco, or any tobacco-flafls flour with snuff, or snuff of different sorts the one with the other, shall every day enter in a book or paper, the quantity sold, sent out, or confumd of two pounds or upwards, and the gross weight thereof, and the time when mixed; on pain of forfeiting 50l. 29 Geo. III. c. 68.

When any officer shall discover that the manufacturing of tobacco or snuff is carried on in any unentered place, and that any perfon knowingly alkalts, or is in any ways concerned in carrying on the same, every such perfon shall forfeit 50l. over and above all penalties and forfeitures that the proprietor thereof shall be liable to; and such officer or his assignat, may stop and arrest such perfon, and convey him before a justice, who, on his confession, or the oath of one witness, may convict such perfon of discovered, who shall immediately pay the said penalty to such officer or perfon who brought him; and if not so paid, such justice shall commit him to the house of correction to hard labour for five months from the day of conviction, or until the said penalty be paid. And for a second offence, he shall forfeit 60l., which, if not paid in manner aforesaid, he shall be committed in like manner for one year, or until such penalty be paid.

The offices of excise (between five in the morning and eleven in the evening without a conftable, and between eleven in the evening and five in the morning with a conftable) may enter into any house or place belonging to or made use of by any manufacturer or dealer, and take an account of the stock found therein; and shall give credit (as particularly fet forth in the act). And if at any time any exceeds in stock shall be found, of which no notice has been given to the officer, unless received by permit, the same shall be deemed and taken to be brought in without permit.

Every manufacturer and dealer shall keep sufficient scales and weights for the use of the officers, on the penalty of 100l. And if any such perfon shall, in weighing, use any art or device to prevent such officer from taking a true weight of such tobacco, &c. he shall forfeit 200l. together with such scales and weights, which may be seizes.

And every such manufacturer and dealer shall with a sufficient number of his servants affit such officer in taking such account of stock, on pain of forfeiting 50l.
TOBACCO.

But no officer shall weigh any tobacco, tobacco-stalks, or snuff-work, whilst actually in the operation of manufacture; except snuff-work intended to be sent out or received by permit.

And unmanufactured tobacco, tobacco in the state of operation, and manufactured tobacco, shall be kept separate from each other; on the penalty of 50l.

The officers shall be permitted to take samples of tobacco or snuff, &c. in the possession of any manufacturer or dealer, paying for the same (if demanded) the value or usual price; on the penalty of 100l. upon refusal.

Every manufacturer and dealer shall, in a book or paper, to be furnished by the officers, keep an account of all tobacco, &c. and snuffs which he shall have sold, sent out, or consumed the preceding day, in quantities of 4lbs. or upwards, of tobacco, &c. and 2lbs. or upwards of snuffs; and also another book or paper in like manner, if under 4lbs. of tobacco, &c. of 2lbs. of snuffs. But no such person shall have more than one such book or paper of each sort at the same time, which is to be returned to the officer, if in London, or any city or market-town every six weeks, elsewhere every six months, or when the same is filled up or demanded; and shall be verified on oath. And such books and papers shall lie open for the inspection of the officer, and shall be made up at his request; on the penalty of 100l. for every offence.

If any officer shall discover any increase in stock not legally accounted for, the same shall be deemed and taken to be made by a commodity, for which no duty has been paid, and privately brought in without permit; and such increase shall be forfeited, and may be seized; and the person, in whose stock such increase shall be found, shall also forfeit 2ol.

But Scotch snuff, in the custody of a manufacturer or dealer, not having gained more than 5lbs. in the 10lbs. by the moisture of the air, shall be deemed a fair commodity, and such person shall have credit for the same in his stock, and may remove the same by permit. And such snuff shall be kept separate from all other snuff, and shewn to the officer upon demand; on the penalty of 2ol.

If any manufacturer shall remove any tobacco or snuff out of his entered house or place, before the same has been weighed, and taken an account of by the officer, or shall hide or conceal the same from the view of such officer; he shall forfeit 50l.

And no tobacco (except returns) of 4lbs. and upwards, nor snuff of 2lbs. and upwards, nor any tobacco-stalks, Spanish returns of tobacco, tobacco-stalks for flour, snuff-work, or tobacco-stalk flour, exceeding 200lbs. shall be removed by land or water without a permit, on pain of forfeiting the same, with the casks and package, and also the horses, cattle, boats, barges, and carriages used in conveying the same, which may be seized.

Such officer on request shall grant permits, wherein shall be limited the time for such removal; and if the goods permitted shall not be delivered within the time so limited, the same shall be deemed and taken to be removed without permit.

But no permit shall be granted or be valid for the removal of any snuff-work from one part of the kingdom to another except from the entered premises of a manufacturer of snuff, where the same was laid down to the mill for the purpose of grinding; on forfeiture thereof, together with the horses, cattle, boats, barges, and carriages, which may be seized. 30 Geo. III. c. 40.

And no such permit shall be granted or be valid, unless the request note from such manufacturer or dealer contain the particulars specified in the act, and such permit to correspond with the request note; and if for removing unmanufactured tobacco (other than samples), except the same be in the original package, and be removed according to the regulations specified in the act: and all tobacco, &c. removed contrary thereto shall be forfeited, together with the casks and package, and the horses, cattle, boats, barges, and carriages used in the removal thereof, which may be seized. 29 Geo. III. c. 68.

Provided always, that permits may be granted for the removal of any unmanufactured tobacco, in any quantity not less than 200lbs. in any package whatsoever, from the entered premises of any manufacturer to any mill to be manufactured, and back to such entered premises. 30 Geo. III. c. 40.

And every manufacturer of tobacco or snuff may manufacture their tobacco, tobacco-stalks, snuff-work, and returns of tobacco, at any entered mill, and may remove the same by permit to and from such mill.

Provided, that nothing herein shall extend to prevent any manufacturer from flowing or finishing tobacco, or drying snuff-work at any mill, provided the officer be allowed to weigh and take an account thereof. 29 Geo. III. c. 68.

Where any permit shall be granted for the removal of any tobacco or snuff, &c. and the same shall not be removed agreeable thereto, such permit shall be returned before the expiration of the time limited for such removal; on forfeiture of treble the value of such goods. And where such permit shall not be so returned as aforesaid, and on taking stock a decrease does not appear to answer the contents of such permit, a like quantity shall be forfeited, and may be seized.

No manufacturer, unless licensed as a dealer, shall have a permit for, or shall sell or send out, any manufactured tobacco, Spanish, or returns of tobacco, in a less quantity than 4lbs., nor snuff than 2lbs.; on the penalty of 2ol.

No tobacco, &c. or snuff, &c. shall be brought into any house or place of a manufacturer or dealer without a permit, and also notice thereof shall be given to the officer; on pain of forfeiting the same, together with the casks and package, which may be seized, and such manufacturer or dealer shall also forfeit treble the value thereof.

No tobacco or snuff, &c. shall be removed from any place without the limits of the bills of mortality or excise office in London, to any place within those limits; nor from any place without the limits of the ports herein before enumerated to any place within, or within two miles of those limits; on forfeiture thereof, with the casks and package, and also the vessels, horses, cattle, and carriages employed in removing the same, which may be seized. But the same shall not extend to the legal removal of the several articles specified in the act.

By 30 Geo. III. c. 40. tobacco-stalks stripped from the leaf may be removed, by permit, from any entered premises out of the limits of the bills of mortality, to any place within those limits, subject to the regulations in the aforesaid act, and this act specified.

Any manufacturer or dealer, who hath received into his stock, by permit, any tobacco or snuff, may return the same within forty-eight hours to the person from whom he received it under certain regulations. But if found returned, or re-collected or sold, or shall not be the same identical tobacco or snuff which had been received, without any alteration; the same shall be forfeited, with the casks and package, which may be seized, and the person who shall return the same shall also forfeit 50l. 29 Geo. III. c. 68.
Tobacco

If any tobacco of 4 lbs. or upwards, or snuff of 2 lbs. or upwards, or any tobacco-flasks, &c., shall be found removing, unless between seven in the morning and five in the evening from 25th Sept. to 25th March, and between five in the morning and seven in the evening from 25th March to 25th Sept. (except by a common carrier or vessel which usually goes out of these hours,) the same shall be forfeited, with the cases and package, and the horses, carriages, and vessels made use of in conveying the same, which may be seized, whether the same be accompanied with a permit or not.

If any person whatsoever without a permit, or hawkers with one, shall offer any tobacco, &c., to sale, he shall forfeit the same, together with the package, and also 2s.

And the person to whom it shall be so offered to sale, may seize the same, and carry it to the next warehouse belonging to the customs or excise, and shall bring the person so offering it to sale before a justice, who shall commit him to prison, that he may be prosecuted for such penalty; and the person so assisting the same shall be entitled to the same rewards as the officers of the customs or excise; and in case such person shall defile it, the commissioners may cause three pence for every pound of tobacco, &c., so forfeited to be paid to him, till the same be disposed of, upon a certificate under the hand and seal of such justice, of such offender being committed to prison; and after sale, the money so advanced shall be replaced out of the produce of such sale.

If any person shall counterfeit or forge any permit, he shall forfeit 501.

If any person shall assault, refuse, oppose, molest, obstruct, or hinder any officer in the due execution of this or any other act; or shall rescue any goods which have been seized; or any vessel, horses, cattle, or carriages, which have been forfeited, and for which no particular penalty is provided; he shall forfeit 201.

If any person shall give or offer any bribe, recompense, or reward to any officer to prevent him doing his duty, whether the same be accepted or not, he shall forfeit 501.

No tobacco, snuff, &c. shall be landed, without first making entry thereof with the officers of the customs, on forfeiture thereof, with the cases and package.

If any officer of excise shall have cause to suspeét that any tobacco, &c., or snuff, which shall have been imported contrary to this act, or forfeited by this or any other act, is deposited, lodged, hid, or concealed, if within London or Westminster, or the limits of the chief office, upon oath made before two commissioners, elsewhere upon oath made before one justice setting forth the ground of his suspicion, such commissioners or justice may, by warrant, authorize such officer by day or night, but if in the night, in the presence of a constable, to enter into such suspected place, and to seize and carry away all such tobacco, &c., or snuff which shall be there found, together with the cases and package containing the same. And if any person shall obstruct or hinder any such officer so authorized, or person assisting him in the execution of such warrant, he shall forfeit 100l.

Tobacco and snuff, taken as prize, are subjected to the regulations of this act, by 43 Geo. III. c. 134.

No manufacturer or dealer in tobacco or snuff, or person anywise interested or concerned therein, shall act as a magistrate in the execution of any act relating to tobacco or snuff; and all acts done by such person shall be utterly null and void.

If any tobacco-flasks or items, stripped from the leaf, that are imported, shall be forfeited and burned, and the officer seizing the same shall be allowed one penny for each pound; and every person, who shall be assisting or otherwise concerned in unshipping the same, or to whose hands they shall knowingly come after unshipping, shall forfeit treble value, together with the vessels, bags, casks, or other things, wherein the same are contained, and the horses, cattle, carts, and other carriages, made use of in removing the same; half to the king, and half to such officer of the customs, who shall seize, inform, or sue for the same.

12 Geo. c. 28. 5 Geo. III. c. 43. 8 Geo. c. 18.

All seizures of vessels or boats of 15 tons or under, and of horses or other cattle and carriages, by virtue of any act relating to the customs, may be prosecuted, heard, and determined, before two justices residing near where the seizure was made. 8 Geo. III. c. 18. 5 Geo. III. c. 43. 29 Geo. III. c. 68.

And all penalties and forfeitures in the excise may be pursued for, levied, and mitigated as by the laws of excise, or in the courts of Westminster, half to the king, and half to him who shall sue (unless otherwise particularly directed.) 29 Geo. III. c. 68. 30 Geo. III. c. 40. 43 Geo. III. c. 69.

Tobacco-flasks or items, stripped from the leaf, that are imported, shall be forfeited and burned, and the officer seizing the same shall be allowed one shilling for each pound; and every person, who shall be assisting or otherwise concerned in unshipping the same, or to whose hands they shall knowingly come after unshipping, shall forfeit treble value, together with the vessels, bags, casks, or other things, wherein the same are contained, and the horses, cattle, carts, and other carriages, made use of in removing the same; half to the king, and half to such officer of the customs, who shall seize, inform, or sue for the same.

12 Geo. c. 28. 5 Geo. III. c. 43.

By 24 Geo. II. c. 41. and 26 Geo. II. c. 13. no tobacco or flasks exceeding 24 lbs. weight, nor any snuff exceeding 10 lbs. shall be conveyed by land, without proper certificates, under penalty of forfeiture, together with horses and carriages, and commitment of the carrier to the county-gaol for one month by one justice. The seizure of horses and carriages may be determined by two justices near the place where the seizure was made.

Tobacco, English, Nicotiana minor, or Nicotiana rustica of Linnaeus, is a species of tobacco, which was originally a native of America, but now propagates itself plentifully in England and other parts of Europe. The flowers are of an herbaceous yellow colour, appearing in July, and are succeeded by roundish capsules filled with small seeds, which ripen in autumn. The leaves are said by some to be of the same quality with those of henbane; but by others, to be similar to the preceding, but weaker. They have been sometimes substitutted in our markets, instead of the true tobacco; but are easily distinguished by their smallness and oval shape, and by being furnished with pedicles.

Lewis.

Tobacco, Kaanus. See Kanaster.

Tobacco-Water, among Sheep-Farmers, a liquor prepared by infusing or boiling tobacco in water. A very useful mode of preparing it is, by boiling one pound of tobacco in two gallons of strong salt brine, adding, after the liquid has become cool, about three ounces of the oil of turpentine. It is sometimes, too, the practice to dissolve fifteen or twenty grains, or more, of sublimate or muriated quicksilver in the turpentine, before it is added to the liquor or mixture. A small proportion of corrosive sublimate, dissolved in spirits of wine, is also a safe and next mode of incorporating it with the tobacco-water or liquid.

Tobacco-water, or liquor, is likewise occasionally mixed with other substances; as two pints of it have sometimes three ounces of sulphur mixed in them, being put on a fire until they boil together. The liquor is used in a cold state.
The South Down sheep-farmers have a decoction of tobacco, wildvine-root, and sulphur, which is boiled in brine for a quarter of an hour, and then strained off for use.

Tobacco-water, or liquor, is kept ready prepared for the use of farmers in many places where sheep are largely kept, but it is probably the best way for them to provide their own.

This water, or liquor, is a powerfully efficacious remedy in various cases of the scab kind in sheep, and probably in other animals. It is usually applied by shedding or dividing the wool by the fingers and thumbs, and pouring a little of the liquid in along it. It may be used every night, as there may be occasion. Such diseases are readily removed by it in mott cases, and especially in long-wooled sheep, in which they often take place.

In gardening, the simple water, or liquor, which is prepared by infusing or boiling tobacco in soft water, without any admixture, or having any such fulminations as above dissolved in it, is often found beneficial in destroying and removing insects of different kinds on fruit-trees and fruit-shrubs, by having it repeatedly sprinkled over them by means of a watering-pot, or dew-lyring, or in any other way. Many forts of these trees and shrubs in hot-houses, and other places, are treated in this manner with great effect and advantage in clearing them of such vermin.

Tobacco Key, in Geography, a small island in the bay of Honduras, near the coast of Yucatan. N. lat. 16° 45'; W. long. 88° 35'.

TOBACHTLI, in Ornithology, a name which Nieremberg says is often given to the American bird more commonly called beauth.

TOBAGO, in Geography, one of the Caribbee islands, in the West Indies, about 30 miles in length from south-east to north-west, and about nine in breadth. This island was first discovered by Columbus, in the year 1498; but though projects were formed for settling it, particularly by William, earl of Pembroke, who obtained a grant of it in the year 1628, and also of Barbuda and St. Bernard, they proved ineffectual. About the year 1632, some Zealander, having fitted out a small squadron for trading to those islands, made such a favourable report of this in particular, upon their return home, that the company of merchants to which they belonged undertook to settle it, and gave it the name of New Walcheren, from one of the islands in Zeiland. The new colony, in a short time, increased to about 200, who, finding themselves pestered by the visits of the Caribbee Indians, began to erect a fort for their preservation. The Indians had reconnoited to the Spaniards, who readily granted them assistance. They sent a force upon the island which demolished the rising fort, and exterminated the new colony. It was probably from some Dutch merchants who travelled to Courland, that James, duke of that country, conceived the design of settling Tobago. Being a prince of an active disposition, and finding there was room for such a settlement, he sent over a colony of his own subjects, who settled upon what has since been called Great Courland Bay, and erected a small regular fort, with a town, in the neighbourhood, and the duke's title was further confirmed by a grant from Charles II. king of England, but disputed by the Dutch. Upon the extinction of the Kettler family, dukes of Courland, in the person of Ferdinand, son of duke James, the title of the island of Tobago reverted to the crown of England in 1737. By the treaty of Aix-la-Chapelle in 1748, St. Vincent, Dominica, St. Lucia, and Tobago, were declared neutral, and those who remained of the ancient proprietors were left in unmolested possession. By the 9th article of the peace of Paris, signed on the 10th of February, 1763, the three islands of Dominica, St. Vincent, and Tobago, were assigned to Great Britain, and St. Lucia to France; the Charrabes not being mentioned in the whole transactons, as if no such people existed. The climate of Tobago is far more temperate than could be expected in an island that is but 16 degrees 16 minutes north from the equator; for the heat is allayed by the sea-breezes. Tobago has another favourable circumstance to recommend it, by its lying out of the track of those hurricanes that prove so fatal to the other West India islands. The surface of the island is unequal and agreeably diversified; but no part of it is rugged or impaasible, though its north-west extremity is mountainous. Its soil is of different kinds, but in general the mould is rich and black, and proper for producing, in the greatest plenty, whatever is raised in other parts of the West Indies. The abundance of springs upon the island contributes to its healthfulness, and its bays and creeks are so disposed as to be very commodious for all kinds of shipping. Its situation, however, requires fortifications to render the island secure against the visits of favaxes and enemies. Besides its producing the different kinds of wood that are to be found in the other West India islands, the Dutch affirm, that both the true nutmeg-tree and the cinnamon-tree, with that which produces the real gum copal, grows upon the island, but this assertion wants confirmation. Mr. Blome, who, in 1687, wrote "The present State of our American Islands," says that the soil of Tobago produces Indian corn, Guine corn, peas, beans, French beans, figs, pineapples, pomegranates, oranges, lemons, limes, plantains, bananas, grapes, guavas, tamarinds, prickly pears, papaws, and a variety of other fruits, which are not to be found in Europe. The cocoa-tree grows here to such perfection, that the Indians call it God's tree, as producing both meat, drink, and clothing. Mulk-melons, water-melons, gourds, cucumbers, and pommions, are raised to perfection; neither is there any want of potatoes, yams, carrots, turnips, parnips, onions, and manioc. Wild hogs abounded so much in Tobago, that the people killed at least twenty thousand of them every year without their being feebly diminished. Here are likewise found peecars, remblowing fwee, armillaces, guavos, Indian rabbits, and badgers. Horses, cows, afes, fiepe, deer, goats, and rabbits, were probably introduced by the Dutch, and have multiplied exceedingly. The sea is florid with excellent fish, particularly turtle of every kind, and mullets of a most delicious taste, with other kinds unknown in England. In short, the commodities which the country doth, or may produce, are cocoa-nut, fugar, tobacco, indigo, ginger, farfaparilla, sempervivum, bees'-wax, venellos, natural balm, balm, folk-grafs, green tar, soap-earth, with many curious shells, flones, marcellites, and minerals. In 1791, the island was surrendered to the French on favourable terms. In 1793, it was again taken by the French, and finally retaken by the British. N. lat. 11° 30'; W. long. 62° 30'.

TOBAK, Little, a small island near the coast of Tobago, about two miles long, and one broad.

TOBAK, a town of European Turkey, in Beffarabia, on lake Jalaj. In 1789, the Russians were defeated by the Turks, near this town; 34 miles N.N.W. of Ismail.

TOBAN, a town of the island of Cuba; 16 miles N.E. of Trinidada.
TOBAR, a town of Spain, in Old Castile; 18 miles from Burgos.

TOBATA, in Ancient Geography, a town of Aisa, in the interior of Paphlagonia.

TOBATI, in Geography, a town of Paraguay; 50 miles N.E. of Asumption.

TOBED IUGARLETDEGH, a river of New Brunswick, which runs into the St. John, N. lat. 46° 50'. W. long. 67° 30'.

TOBIANUS, in Ichthyology, a name given by Schonefeldt to others of the ammodytes, or sand-eel.

TOBIRA, or TOBERA, in Botany, a Japanese shrub, figured and described by Kämpfer; see Pittosporum, p. 2. See also EUNOMUS, where its ill-agreement with the latter genus is noticed.

TOBIS, in Ichthyology, a name given by the Swedes to the ammodytes, or sand-eel.

TOBITSCHAU, or Towaczow, in Geography, a town of Moravia, in the circle of Olmutz; 10 miles S. of Olmutz. N. lat. 40° 23'. E. long. 17° 14'.

Tobiis, in Ancient Geography, a river of the isle of Albion, the mouth of which is placed by Ptolemy on the western coast, between the promontory Ofaptorum and that of Ratolathybius.

TOBLER BACH, in Geography, a river of Wurttemberg, which runs into the Glatt, 2 miles N.W. of Sultz.

TOBLPAD, a town of the duchy of Stidia; 8 miles S.W. of Gratz.

TOBOL, a river of Russia, which rises in N. lat. 52° 30', and long. 81°, in the country of the Kirghiz, in the chain of mountains that parts it from the government of Upha. It pours itself into the Irtysh or Irtich at Tobolliks, after running a course of about 500 versts, in which it receives the following rivers: viz. the Ul, the Iet, the Tura, and the Tadv, all which fall into it on the left. Of these, the Tura is the largest; it rises near Verkhoturia, in the Ural mountains, and glides into the Tobol, in lat. 57° 30', after having taken up the rivers Salda, Tagil, Pyshma, Nitza, &c. into which last-mentioned, the Neiva, the Aeth, and the Iribat flow. By this accession of waters, the Tura becomes a considerable river, not much inferior to the Tobol itself. The Iet is likewise a river of some consequence, rising out of a lake two versts from Ekatarinburg; and after having taken up several rivers, as the Siferit, the Sinava, the Tetha, and the Mises, falls into the Tobol, in N. lat. 57°. The Tobol has only low shores; and in the spring season frequently shad its waters far around.

TOBOLOVO, an otfrog of Ruffia, in the government of Tobolliks, on the Enisei. N. lat. 69° 40'. E. long. 86° 42'.

TOBOLSK, a city of Ruffia, and capital of a government, at the confluence of the Irtich and Tobol. It is the see of an archbishop, and was herefore the capital of all Siberia. This city is divided into the Upper and Lower Towns. The Upper Town stands very high, on the east side of the Irtich; and the Lower Town lies on a plain, between the hill on which the former is built, and the river. Both towns taken together are of a very large circumference; but the houses being mostly built with wood, it was nearly consumed by fire about the year 1780, and afterwards rebuilt chiefly of stone. It contains about 15,000 inhabitants. In the Upper Town, which is properly called the city, stands the fort, which was built with stone, by governor Gagarin. In the fort are the governor's court, as it is called, the governor's house, the archbishop's palace, the exchange, and two of the principal churches, which are all stone buildings. The Upper Town, which stands on the east side of the fort, and is inclosed within an earthen rampart, affords nothing remarkable, but a market for provisions and all kinds of small ware, three wooden churches, and a convent. The Lower Town contains a market-place for all kinds of provisions, on which several shops are built. The Upper Town is out of the reach of inundations from the river, by its high situation, which, however, is attended with this inconvenience, that the inhabitants are under a necessity of going down the hill for water. Besides, large mafes of earth fall from the side of a hill, on which the town stands, towards the river, and in a billy year, which obliges the inhabitants to pull down and rebuild the houses that stand near the declivity. The Lower Town, indeed, has water at hand, but is exposed to inundations when the river overflows its banks; but such floods do not happen every year. The town is very populous, and almost the fourth part of its inhabitants is composed of Tartars, who are partly seduced from those that were settled there before the conquest of Siberia, and partly from the Bucharians. These Tartars, in general, behave very quietly, and carry on some manufactures, but practice no mechanic trades. They are very sober, and averse from intemperance, and all kinds of riotous living. The rest of the inhabitants are Russian, whose ancestors were banished bither for their crimes, such as are exiles themselves. As everything is sold here to excessive cheap, that a common man may live very well at Tobolliks at ten rubles a year; indolence and sloth prevail to such a degree, that it is a hard matter to get the least utensil, &c. made, though the town abounds with artificers, who want neither tools nor materials to carry on their respective trades. The commerce is in a flourishing condition in this city; and the traffic which the Bucharian and Kalmuck merchants carry on in Indian goods, with which they supply all Siberia, and part of Russia, is very considerable. All the Chinese caravans are obliged to pass through this town; and all the furs furnished by Siberia are brought into a warehouse in this city, and from hence are forwarded to the Siberian chancery at Moscow. Several of the Swedish officers, who were taken prisoners at the battle of Pultawa, and sent to Tobolliks, set up schools here, in the year 1713, for teaching the children of Swedes, Russians, Cossacks, Tartars, &c. the German, Latin, and French languages, with geography, geometry, and drawing. Many of them also took in boarders. These schools acquired great reputation; so that children were sent hither for education, from a considerable distance, and the exemplary behaviour of these military pedagogues was attended with uncommon success. However, when the peace of Nyftadt was concluded, the Swedish officers returned into their own country, and then these beneficial seminaries of learning dropped of course. Some time after a German school was founded here, under the auspices of the emperors; 1000 miles E. of Moscow, N. lat. 57°. E. long. 68° 14'.

TOBOLSKIAN TARTARS, derive their appellation from the river Tobol, on which they dwell; and they are the descendants of the inhabitants of Iker or Sibir, their ancient capital, which being reduced to a heap of ruins after Yormak's conquest, they abandoned; and instead of it the Ruffians afterwards built Tobolliks. These are diftinguished from the Tartar inhabitants of Tobolliks, who are a barbarian colony. Their number amounts to upwards of 4000 males.

TOBOLSKOI, a government of Russia, extending from N. lat. 55° to 78°. E. long. 59° to 108°, including a considerable part of Siberia. Tobolliks is the capital.

TOBORON,
Tobor, a town of Thibet; 53 miles N. of Tourfan Hotun.

Toboso, El., a town of Spain, in New Castile; 37 miles S. of Hunte.

Tobrana, a town of the island of Cuba; 148 miles S.W. of Havannah.

Tobrus, in Ancient Geography, a town of Africa Propria, in the number of those situated between the river Bagadus and the town of Thilbruck. Potomency.

Tobulla, in Geography, a town of Africa, on the E. coast of Tunis; 8 miles N.W. of Meden.

Toby, a town of Sweden, in Esth Bothnia, near the Gulf; 20 miles N. of Christiandand.

Ton's Creek, a river of Pennsylvania, which runs into the Alleghany, N. lat. 41° 8'. W. long. 79° 40'.

Tocona, a central town of New Granada, E. of Bogota, the capital.

Tocaigh, a bay on the W. coast of the island of Owyhee: the depth of water was 25 fathoms; the bottom a stiff clay, and good holding ground, incommoded by a patch of rocky bottom, which was found to shoal suddenly, and the depth to decrease to 7, 4, and 3 fathoms, about the fourth of a mile to the south-west of the anchoring-place; and consequently to be a very great inconvenience to the roadstead, which at best, in the opinion of captain Vancouver, is but a very indifferent one, being entirely exposed to the north-west winds, and the western oceanic swell, which beats with great violence in the reefs that encompass the shores. These reefs stretch out a mile or upwards, leaving between them and the land a narrow channel, that affords comfortable and commodious landing for small boats and canoes; but the land is at too great a distance from the place of anchorage to allow of prosecuting any debarkation from the ship. N. lat. 20° 3'. E. long. 204° 4'.

Tocaima, a central town of New Granada, in the immediate proximity of Bogota, the capital, and W. of it; founded in 1544, at some distance from the river Poti, called Bogota, not far from its confluence with the river Magdalena. Its situation is bad, exposed to great heats, and numerous venomous creatures, and even deftitude of water. But the district is very fertile in cacao, tobacco, sugar, maize, yuccas, plantains, potatoes, &c. and the fish are abundant in the rivers of Bogota and Fugafagura, though there be many alligators. The inhabitants, about 700, are mostly poor. Here are mines of excellent copper, though not worked.

Tocantins River, a river of South America, formed by the union of a number of small rivers in Brazil, which rise about the 18th or 19th degrees of south latitude, and between the 50th and 51st degrees of west longitude. Its course is due north to the 2d degree of south latitude, when it joins the Guanapu, about 126 miles from the sea, and takes the name of Para, from a city so called.

ToCat, or Tokar, a city of Asiaic Turkey, in the pachalic of Sivas, anciently a city of Pontus, called Berisa. It is situated on the river Tofansu, in the corner of a valley, and almost surrounded with mountains, which afford quaries of marble, and well supplied with water from innumerable springs. On the top of a lofty rocky mountain, on the W. side of the town, are the remains of an old castle. The streets are well paved, but frequently built on uneven ground. The houses are tiled, and mostly built with wood. It is the residence of a caldi, a waiwode, and an aga, commanding a thousand janizaries, and some lapiis. The inhabitants are computed to be 60,000, consisting of 20,000 Turkish families, 4000 Armenians, and about 400 families of Greeks. The Armenians have seven churches, the Greeks only one. The Armenians make an excellent wine, resembling claret in flavour, but stronger. Fruits are abundant in this town, and the grape-vines are excellent. It is the seaport of a metropolitan, dependent on the archbishop of Nefiar, or Guonesare, an ancient city, almost ruined, about two days' journey from Tocat. Here are some manufactories of silk and yellow Turkey leather; but the chief trade is in copper vessels, kettles, candlesticks, &c., which are sent to Constantinople, Egypt, &c. Tucat may be considered as the centre of trade of Asia Minor. The copper is obtained from the mines of Gumicatana, at the distance of three days' journey from Trebifond, and from those of Caltan Boal, yet richer, and situated ten days' journey from Tocat, on the W., towards Angora. The caravans from Diarbek arrive in eighteen days, from Sinob in six, from Burfa in twenty, from Smyrna in twenty-seven, and proportionately less on horseback, or on mules; 40 miles N.W. of Sivas. N. lat. 39° 35'. E. long. 36° 30'.

Toayo. See Toceu.

Tocata, Ital. from tocarr, to touch: to prelude, to touch an instrument, to play a short movement extempore, previous to the performance of a regular piece.

Tocatina, a short prelude, or trial of an instrument.

Toccavienisis Bolus, Boile of Tobay, in the Materia Medica, a fine medicinal earth, dug about Tobay in Transylvania, and esteemed a powerful astringent. Kent-man calls it the bolus Panonica vera; and Crato, bolus Hungarica.

This last author esteemed it superior even to the bole armeniaci of Galen, and had a great opinion of it in malignant fevers. It is a fine and pure earth, and very heavy, moderately compact in its texture, but not very hard; and in colour of a considerably deep and strong yellow. It is naturally of a smooth surface, and does not stain the fingers in handling. It ferments violently with acid menstrua, and does not become red in burning. Hill. See Bol.

Tochen, in Geography, a town of Germany, in the principality of Anhalt Zerbit; 5 miles W. of Zerbit.

Tochu, a town of Africa, in the kingdom of Quoja.

Tocay, in Zoology, the name of a species of Indian lizard, differing in the other kinds, by being spotted all over.

Tocksdorf, in Geography, a town of Prussia, in the province of Bartenland; 6 miles N.W. of Raistenburg.

Tocmia, in Ancient Geography, a town of Arcadia, in the southern part to the N.W. of Megalopolis, and E. of the Alpheus. It stood upon an eminence; but it was in ruins in the time of Paulanias.

Tocmol, in Natural History, a name given by force to the common turtle.

Tocolosida, in Ancient Geography, a town of Africa, in Mauritania Tingitana. Potomency. The Itinerary marks it 48 miles from Tingis, and three miles from Volubils.

Tocorary, or Tukorari, in Geography, a town of Africa, in the country of Ante; 10 miles E. of Infusa.

Tocort. See Teggurt.

Tocosanna, in Ancient Geography, a river of India, on the other side of the Ganges. Potomency places its mouth in the Ganges.

Tocoyena, in Botany, an unexplained name.—Aubl. Guian. 131. t. 50. Jull. 201. Lamatre Illustr. t. 163. 5 E See
TODC

See *Gardinia*, of which this is probably a species. The author calls his only species *T. longiflora*, and his description contains the following particulars.

The stem is three feet high, erect, simple, leafy, scarcely thrubby. Leaves opposite, erect, plant, fifteen inches long, lanceolate, entire, smooth, tapering at each end, on smooth footstalks, about an inch and half in length, attached to a pair of triangular, acute, combined, infrafoliaceous *petals*. Flowers about fourteen in a terminal head, in opposite sepal like pairs, each flower accompanied by two small scale *bracteae*. **Calyx** superior, bell-shaped, in five small segments, measuring with the *gernen* not more than four lines. **Corolla** with a yellowish cylindrical tube, as thick as a goose-quill, and nine or ten inches long, dilated at the throat, and terminating in a white bell-shaped limb, with five ovate, equal, spreading segments. **Anthers** nearly sepal like, between the segments of the corolla, oblong, incumbent. **Gernen** oval, inferior. **Style** capillary, the length of the tube, twisted and hairy for an inch below the top. **Stigma** of two large, compressed, oval lips, included within the throat of the corolla. **Beryl** oval, an inch long, crowned with the calyx, of two cells, with numerous roundish seeds, imbedded in viscous pulpy. The flowers have a very sweet smell. A bulb met with several plants of this species in the wood of Aroura in Guiana, flowering in Aug.-All the leaves were perforated or gnawed by insects. His dried specimen of the flower is as black as ink. If *mannia* of Thunberg and Salibury be distinct from *Gardinia*, the present plant should seem to belong to the former.

**TOCRUM**, in Geography, a town of Bengal; 8 miles S. of Koonda.

**TOCRUR**, a town of Africa, and capital of a kingdom, in Nigria, on the north side of the Niger, W. of Calhna; 270 miles E.N.E. of Tombuctoo. N. lat. 16° 32' E. long. 6° 5'.

**TOCSON HOTUX**, a town of Tiibet; 20 miles W.S.W. of Toufan. N. lat. 43° 26'. E. long. 80° 14'.

**TOCUYO**, a city of South America, in the government of Venezuela, situated in a valley formed by two mountains. Its division and construction are very regular: the streets are on a line, and sufficiently wide. It has a well-built parish church, on which depends a chapel of ease. The Franciscans have one monastery, and the Dominicans another. It is governed by a common-council. The climate is rather cold than hot; and though the sky is often overcast, the air is wholesome. The inhabitants are graziers, agriculturists, artificers, and traders. The wheat of its vicinity is reckoned the best in the province, and furnishes sufficient for the consumption of many towns of the interior. They export from 8000 to 10,000 quintals of flour. From the wool of their sheep they fabricate coverlids, and other cloths, which they carry as far as Maracaibo and Carthagena. They have also tanneries and taweries, and, like the inhabitants of Carora, work up as many as they can of the raw materials, and sell the best. Another article of commerce, very lucrative to the citizens of Tocuo, is salt, which they bring from the salt-ponds of Coro. In this city are reckoned 10,000 persons, who are reproached with the crime of suicide. Tocuyo is 90 leagues distant S.W. of Caracas, and 20 leagues N. of Truxillo. N. lat. 9° 35'. Long. W. of Paris 72° 40'.—Alfo, a river of Venezuela, which discharges itself into the sea, 25 leagues E. of the Gaigues, which runs 16 leagues W. of Coro. The source of Tocuyo is about 15 leagues S. of Carora, upwards of 60 leagues from the sea. It is navigable as far as Banagua, a village situated on its banks, at the distance of 40 leagues from its mouth. Its vicinity furnishes abundance of timber of the largest size, and fit for every kind of building. Depons, vol. i. and ii.

**TOD** of wool is mentioned in the statute 12 Car. II. c. 32. as a weight containing twenty-eight pounds, or two flane. See Weight.

Some will have the word derived from the French, *toile*, a wrapper, within which, by usage, two flanes of wool are folded.

A laft of wool contains 12 facks, a fack 2 weights, 13 todes, 26 flane, 52 cloves, or 354 pounds.

**Tod-Head**, in Geography, a cape on the east coast of Scotland, in the county of Kincardine; 15 miles S. of Stonehaven. N. lat. 56° 51'. W. long. 20° 11'.

**TODDALLA**, in Botany, Juff. 371. Poiert in Lam. Dict. v. 7. 693, a barbarous name made out of the Kaka-todall of Rieceed, Hort mal. v. 5. 81. t. 41. (See Scopolia.)—Toda, with some addition, is the appellation of other Indian plants, as *Todda-pana* of *Cyica cinerinus*, and *Todda-vaddi* of *Oxalis senfiflua*. We humbly hope that the worthy M. Poiret, who is so highly displeased at our wishing to retain a Scopolia, will approve of our having so much laboured to establish a Pomedd. See that article.

**TODDA-PANA**, the name by which many authors call the *palmia farinifera*, or lago-tree.

**TODDINGTON**, or Tuddington, in Geography, an ancient market-town in the hundred of Manhead, and county of Bedford, England; is situated five miles N. by W. from Dunstable, and 39 miles N.W. by N. from London. A market was originally held here on Thursdays, by a grant from king Henry III. in 1218; but this was changed to Saturday, by a charter of Edward II. in 1316, which was confirmed by Richard II. in 1385. In 1881, the market was so considerable, that sixteen butchers rented stalls in the market-place. It gradually declined, and of late years has been wholly discontinued. The market-house was pulled down in 1799, and the materials sold. It is probable, that it had been before discontinued, and afterwards revived, as Leland does not include Toddington in the list of the market-towns in Bedfordshire. A fair was granted by the charters of 1218 and 1316; five are now held in the year. The population return of the year 1811, states the parish to contain 259 houses, and 1143 inhabitants. The manor of Toddington was given by William the Conqueror to Ernulfus de Hedifin, ancestor of the earls of Perch. On the death of the last earl, in 1618, it devolved to the earl of Pembroke, and from him to Paulinus Peyvre, steward of the household to Henry III. From the Peyvre family, the manor defended to Sir Thomas Cheaney, K. G., whose son, Henry, was knighted by queen Elizabeth in 1658, the being then on a visit to him at Toddington. In 1572, the created him lord Cheaney. Lord Cheaney built a noble manor at Toddington, of which nothing now remains but the kitchen, which is remarkably spacious. Toddington church is a handsome structure; the frieze, on the outside, is decorated with grotesque figures of animals. The south transept contains some ancient monuments of the Peyvres, and also those of the Cheaneys. The north transept was the burial-place of the Wentworths, and contains two monuments to lady Maria, and lady Henrietta Wentworth, on each of which 2000l. were expended. Both transepts are in a shameful state of dilapidation. In the year 1443, an hospital was founded at Toddington, by Sir John Broughton, for three poor men, and a master or chaplain, who was to pray for the souls of the Peyvre family. There are now no traces of the hospital: the stones were used in building the market-house. Lyfons's *Magna Britannia*, vol. i. Bedfordshire, 1806.
TODDIPOODY, a town of Hindooftan, in the circuit of Rajamundry; 18 miles E.S.E. of Rajamundry.

TODDI, or TOD, is a juice drawn from various kinds of palms, by cutting off the branch intended by nature to produce fruit, and receiving from the wounded branch the sap which was designed for the nourishment of the future crop. But as toddy, although sweetish when first drawn, is in a state of fermentation in the course of 24 hours, acquiring an intoxicating quality, and thus becomes four and harish, it could not have been the palm-wine of the ancients; which must have kept for some time, as it was carried on the rivers during voyages of many days, and even appears to have been stored up. Todd is used with molasses, rice, and other ingredients, in the distillation of Arrack; which fee. The toddy of the date-tree is said to be of an inferior quality to that from some other kinds of palms. The palm-wine was made in Babylonia, where palms abounded, of the fruit of the palm-tree. This was sweet to the taste, but apt to give the head-ache. The palm, as Herodotus informs us (Clio, c. 193.) produced to the inhabitants of Babylonia, bread, wine, and honey. The wine must have been very plentiful, for he says that the boats which defended the Tigris from Armenia, some of which were very large, were loaded with palm-wine as the principal article of their commerce. We derive similar information from Xenophon, who speaks of the floats that passed the Ephrates at Carmanada, and the Tigris at Cene. We learn, from the travels of M. Burckhardt in Nubia (Nubia) in 1813, that the practice of making wine as an article of commerce is discontinued in Mesopotamia and Babylonia, where the date-trees abounded, and where the profusion of fruit rendered wine so plentiful, because in modern times the want of a proper distribution of water for irrigation, has left only a small proportion of date-trees; and hence it is probable, that none of the fruit can be spared from the necessary demand for food. Kempter is silent on the subject of palm-wine; and this circumstance satisfactorily proves the discontinuance of the practice of making it in those countries. M. Burckhardt tells us, that in all the larger villages of Nubia, the use of palm-wine is very common; and at Derr, the reputed capital of the country, a great quantity of spirit is consumed. The wine, he says, does not taste amifs; but it is too rich and too thick to be drank with pleasure. When the date-fruit has acquired its full maturity, it is thrown into large earthen boilers, and left to boil without interruption for two or three days. It is then strained, and the clear juice put into earthen jars, well closed and buried in the ground, where it ferments. It lies ten or twelve days under ground; at the expiration of which time it is fit to drink. It keeps for twelve months, and then turns sour. The aqua-vite made from dates is of a very good quality, and keeps well for years. People of the upper classes at Derr are every evening intoxicated either with date-wine or spirits, of which great quantities are consumed. They are fond openly. From Stout, southward, through Upper Egypt, date-spirits are made and publicly sold; the pacha receiving a tax upon it from the inn-keepers: they also make a kind of jelly or honey from the dates, which serves for a sweet-meat.

TODDY-Tree. See MAMMEE-Tree.

TODEA, in Botany, a supposed genus of ferns, dedicated by Wildenow to the memory of the Rev. Henry Julius Tode, a clergyman of Mecklenburg, who died in 1797, aged 64. He is distinguished among cryptogamic botanists, as the author of an accurate and practical work, in quarto, with numerous plates, entitled Fungi Mecklenburgensis Slechii, published at Lunenberg, in 1790, to which the reader will find frequent references in our several articles relating to the order of Fungi. This genus, however, is sunk in OsMunda; see that article, n. 3.

TODENDORP, in Geography, a town of the duchy of Holstein; 6 miles N.E. of Hamburg.

TODI, Maria Francisca, in Biography, born in Portugal in 1748, arrived in England in 1777, with Jermoli, as first woman in the comic opera. She must have improved extremely after she left this country, where she remained only one season, and was little noticed; her voice being feeble, and seldom perfectly in tune. But the afterwards became the most captivating singer for taste and expression in cantabile airs, in France and Germany (according to report), that ever appeared in Europe. She was taught by Perez.

TODI, in Geography, a town of the Popedom, in the duchy of Spoleto, near the Tiber, the see of a bishop, immediately under the pope. It contains several churches and convents; 18 miles W. of Spoleto. N. lat. 42° 47'. E. long. 13° 18'.

TODIALOOR, a town of Hindooftan, in the country of Coimbetore; 5 miles N. of Coimbetore.

TODIVESTI, a town of Moldavia; 6 miles N.E. of Soccava.

TODOROVA, a town of Croatia; 18 miles W.N.W. of Novi.

TODOS SANTOS. See All-Saints.

TODS, a town of the slate of Virginia; 9 miles E.N.E. of Hanover.

TODTENVOGEL, in Ornithology, a name by which Gefner and some other authors have called that species of guanche, known in England by the name of the stone-chatter, flour-finch, or moor-sitting.

TODTIBERG, in Geography, a mountain of Switzerland, and reckoned one of the highest in the country, in the road from Difentis to the Griffins.

TODUCÆ, in Ancient Geography, a people of Africa, in Mauritania Cefariensis, towards the source of the river Amphiagia.

TODUS, TODY, in Ornithology, a genus of the order Picc, the characters of which are, that the bill is awl-shaped, somewhat deflated, obtuse, straight, and at its base beft with bristles; the nostrils are ovate and small; the feet are formed for walking; and the outer toe is connected at the base to the middle one.

Species.

VIRIDIS. Green, with a red breast: the green tody. Found in the warmer parts of America, and the neighbouring islands.

CINEREUS. Ash-coloured, with the under part yellow: the Tis-tie of Buffon; the grey and yellow fly-catcher of Edwards. Found in open places of Surinam and Guiana.

Fuscus. Ferruginous, under part olive-coloured, spotted with white; the tail ferruginous, and wings crossed with blackish bar. Found in South America, less than the green.

CARULEUS. Blue, with white throat; temples, throat, and abdomen orange. Found in America, of the size of the green.

VARIES. Varied with blue, black and green; the bill, head, throat, neck, feet, nails, and tail black; the margin of the tail, and the coverts of the wings green. Found in India.

LEUCOCEPHALUS. Black, the head subcrinated; throat and upper part of the neck white: white-headed tody of Latham. Found in America.
TOE

BRACHYURUS. Black, the vertex, neck, back, and short tail black: the short-tailed toady of Latham. Found in America.

PLATYRHYNCHUS. Above lead-coloured hoary, beneath milky; the crown, wing-feathers, and tail black: plumbeous toady of Latham. Found in Surinam.

OSCELOTUS. Above brown and black, underneath very fardil white, with pale throat: the bulky toady of Pentant and Latham. Found in Rhode island.

REGUS. Black and brown; the breast white, fibrated transfusely with blackish; the throat and eye-brows white; the abdomen, rump, and tail red; the crest ferruginous at the apex, tipped with black: king toady of Latham. Found in Cayenne.

PARADISEUS. Crested head black; body white; tail wedge-formed; the intermediate tail-feathers very long; pied bird of paradise of Edwards, and paradise fly-catcher of Latham. It has the following varieties; viz. the tody with wings and tail pale-red; the toody underneath white, the breast from cerulean to cinnamon; and the Brazilian crested tody. Found in Africa and the island of Madagascar.

FERRIGNUS. Ferrugineous-black, underneath ferruginous; wing-feathers marked with a brown bar; cheeks spotted with black and white: the ferruginous-bellied toady of Latham. Found in Cayenne.

NOVES, or GILLARIS. Brown, underneath white; throat white, and breast spotted with brown, above yellow: white-chinned toady of Latham.

PLATYRHYNCHUS, or ROSTRATUS. Brown-yellowish, beneath yellow, throat whitish; vertex lead-coloured, with a white spot upon it; wings and tail brown; bill very broad: the broad-billed toady of Latham.

MACROHYNCHUS, or NASUTUS. Black, bill very broad; skin, sides of the cheeks, abdomen, vent and rump red: the great-billed toady of Latham.

RUBUDULA. Cinnamon, with orange throat and breast, and white abdomen: the red-breasted toady of Latham. Native of New Holland.

XANTHOGASTER, or FLAVIGASTER. Brown-cinnamon, fix inches long; beneath interosseus, with pale bill: the yellowbellied toady of Latham. Native of New Holland.

CRISTATUS. Crest crimson; body brown, spotted with white. Found in Guinea.

TOEBAN, in Geography, a town on the N. coast of the island of Java.

TOELCHUS de APIS, a district of South America, in the country of Patagonia.

TOELCHUS de la Galabola, a district of South America, in the country of Patagonia.

TOE-LING HOTN, a town of Chineese Tartary; 375 miles E.N.E. of Peking. N. lat. 42° 22'. E. long. 123° 20'.

TOE-ENTE, in Commerce, a corn measure in Denmark, equal to 8 schefeils or skiepers, or 32 fotheits or forlings, and 12 toeends = a laf: 100 toeends of Copenhagen, answer to about 49½ English quarters. A laf of Spanish fats, or of colots, contains 18 toeends, and the toende 8 skiepers or 176 pots, which contain 5½ Danish cubic feet; but Norway laf is fold by weight, and the toende muff weigh 250 lbs. Danish weight, or 275 lbs. avoirdupois. A laf of French fats, or of lime, contains 12 toeends, corn measure; a laf of oil, butter, and other fat substances, is 12 toeends, beer measure; and a toende of beer must hold 4½ Danish cubic feet, or 116 pots. By a toe or toende of hard corn is meant as much land as can be tilled with 1 toeend of rye, 1 of barley, and 2 of oats. What is called a toeend of fastland or arable land is the fourth part of the above, and contains 56½ Danish square rothes, or 220 English square perches. Thus the toende of hard corn is = 5½ English acres. A Danish square foot contains about 153 English square inches; or 16 Danish square feet = 17 English square feet nearly.

TOENNI, in Ancient Geography, a people of Germany, in the vicinity of a lake, which was common to them, the Rhzitians, and Vindelicians. Ptol.

TOENIOLOKER, in Geography, a small island in the East Inland sea. S. lat. 5° 30'. E. long. 132° 32'.

TOES, by anatomists called digitis pedis, are the extreme divisions of the feet, answering to the fingers of the hand, and resembling them in figure, and make the third part of the foot. See Extremities.

TOES, Adhesions of the. It is a frequent thing to meet with new-born infants with their fingers or toes cohering or growing together, either by a strict adhesion of the flesh, or else by some loose productions of the skin, as in the feet of ducks and geese; and a disorder of the same kind is also sometimes found in adults, from accidents; as when the fingers or toes have been neglected, after an excoriation of them by burns or wounds. In both these cases the surgeon's assistance is necessary, partly to remove the deformity, and partly to restore the proper use of the fingers.

These adhesions, according to the nature of the disorder, are to be separated by cutting out the intermediate skin, or else barely by dividing them from each other with a pair of scissors. When this is done, to prevent their coheisons again, each finger must be invected separately with a spiral bandage about an inch broad, dipped in lime-water and spirit of wine.

Sometimes the fingers, instead of adhering to each other, grow to the palm of the hand, from wounds or burns, so that they cannot be by any means extended, or drawn back to open the hand. The method of relieving this disorder is first very carefully to separate the fingers from the adhesions of the palm, without injuring their tendons, then drees them with a vulnerary balm, and seareed hilt, and extend them on a ferula or thick palfie-board; and let them remain in this extended posture, separately to be dressed till they are perfectly healed; but at every dressing they must be gently moved, to prevent a rigidity or stiffness of the joints. Heiliter.

TOE, in the Manege, is the lay of the hoof upon the forepart of the foot comprehended between the quarters.

We commonly say the toe before, and the heel behind, in French pince devant et talon derriere; implying, that in horse, the toe of the fore-feet is stronger than the toe of the hind-feet: and, on the other hand, that the heels behind are stronger than those before; and accordingly, in shoeing we drive highest in the toes of the fore-feet, and in the heels of the hind-feet.

A horse that does not rest his hind-feet all equally upon the shoe, but raises his heels, and goes upon the toes of his hind-feet, is called in French rampin.

TOE-HEAD, in Geography, a cape of the county of Cork, Ireland, not far from the Stags of Castlehaven. N. lat. 51° 27'. W. long. 9° 0'.—Also, a cape of Scotland, on the S.W. coast of the island of Lewis, in that part called Harris; 42 miles S.W. of Stornaway. N. lat. 57° 50'. W. long. 7° 5'.

TOE-SHELL, in Conchology. See Pollicipes.

TOE-STICK, in Agriculture, the flack or bar which confines that part of small carts in its place, that contains the load, but which, on being flapped out, lets that or a part of it be discharged. It has been observed in the Corrected Agricultural Report of the County of Norfolk, that Mr. Overman,
TOF

Overman, of Burnham, in that district, has made an improvement in his cart of this kind: instead of the toelick drawing out to let the back or framed part of the cart fold up, and deliver the load or part of it, this contrivance turns in the centre on a pivot, and the hooks which confine it at the ends, are each in a position the reverse of the other, by means of which it is expeditiously effected.

TOESA, in Commerce, a long measure in Spain; the toela or braza is 2 varas, or 6 feet, that is, 66½ English inches; a pavo or pace, is 5 feet; an estadal, 12 feet, or 4 varas; and a cuerda, 8½ varas.

TOESCHI, ALESSANDRO, in Biography, the head of a celebrated musical family from Romaniia, settled at Munich, who in 1750 was appointed concert-maître to the elector of Bavaria’s ecclesiastical band.

TOESCHI, CHARLES JOSPEH, after being director of the chamber-music of the court of Bavaria, in 1756 was appointed first violin in the famous band of the elector palatine at Mannheim. He was five years concert-maître, and engaged in other honourable professional employments about the court of Mannheim till 1786. In 1766 he published at Paris six symphonies; violin quartets; and flute concertos. About the same time, six violin duets, and other works at Amsterdam. His style is full of fire, new effects, and in flow movements, grace and elegance. He was a disciple of the great Stamitz, and died at Mannheim in 1788, in the 60th year of his age, leaving behind him an excellent private character.

TOESCHI, JOHN, concert-maître at Mannheim, and an admirable performer on the violin. He was one of the principal ornaments of the famous court-band in 1756.

TOESCHI, SUSANNAH, a finger of great merit in the service of the court at Munich, brought up under Holtzbauer, the maestro di capella to the elector palatine.

TOESOBUS, in Ancient Geography, a river of the isle of Alphon, which had its mouth, according to Ptolemy, on the western coast, between the gulf Serica and the promontory Ganganorum: probably the river Conway.

TOE-YAH-YAH, in Geography, a bay of Owyhee, one of the Sandwich islands, extending along the whole coast from the westernmost point, to the northern extremity of the island, and bounded to the N. by two very conspicuous hills.

Towards the bottom of the bay there is foul, corally ground, extending upward of a mile from the shore, without which the foundings are regular, with good anchorage, in twenty fathoms. Cook’s Third Voyage, vol. iii.

Gen. Ch. Col. Perianth inferior, of one leaf, membranous, three-eleft, small, persistent. Cor. Petals six, oblong, concave, equal, spreading, permanent, many times longer than the calyx. Stam. Filaments six, opposite to the petals, awl-shaped, simple, smooth, about the length of the corolla; anthers incumbent, roundish-heart-shaped. Fil. Germens three, superior, converging, pointed, terminating in as many short, dilated, vertical styles; stigmas capitate. Peric. Capsules three, connected at the base, gibbous, keeled, membranous, of one cell and two valves, burting chiefly at the inner edge. Seeds numerous, elliptic-oblong, angular, inserted into the inner margin of each valve.

The small membranous permanent calyx, more or less distantly separated from the other parts of the flower by an elongation of the base of the latter, is the very peculiar character of *Tofieldia*. By this it is distinguished from *Helonia*, *Narthecium* and *Anthericum*, with all which it has been confounded; see those articles. *Helonia* moreover has a simple germin and capsule, with very few seeds. *Narthecium* and *Anthericum* have each a simple style; the former hairy filaments, and tunicated seeds; the latter angular seeds.

Five of the six species, now known to compose the genus before us, have been confounded together as one. We shall give their characters, and most essential synonyms.

The whole history of the millakes which have embodied the synonyms and characters, both generic and specific, of *Tofieldia*, have lately been detailed, more at length than suits our purpose here, in a paper communicated to the Linnean Society by the writer of the present article.

The species are all perennial and herbaceous, with simple stems, spikel, or generally cluttered, flowers, sword-shaped, equitant, mostly radical, leaves, the habit of the whole very nearly according with *Narthecium*. The seeds, in some instances, betray an affinity to that genus, in a little membranous appendage at each extremity, as may be seen in our *T. alpina*.

1. *T. palustris*. Scottish Alpodel, or Marth Tofieldia. Huds. n. 1. Pl. Brit. n. 1. Ait. n. 1. Eng. Bot. t. 536. (T. puilla; Purh. n. 1. Anthericum calyculatum; Linn. Sp. Pl. 447). Pl. Lapp. ed. 2. 166 t. 15. f. 3. Pl. Dan. t. 56. Lightf. Scot. 181. t. 8. f. 2. Helonias borealis; Wildl. Sp. Pl. v. 2. 274.)—Head of flowers ovate. Stem smooth, thread-shaped, leafles. Petals obovate, obtuse Germens roundish.—Native of bogs, and the margins of rivulets, on the mountains of Lapland, Scotland, Denmark, and North America, flowering about July. A little smooth plant, of a deep green, with a slender solitary stem, from four to six inches high, naked, except an occasional small leaf at the base. The radical leaves are two inches long, ereft, forming several tufts. Flowers small, pale green, in a solitary ovate-oblong denfe head, scarcely more than half an inch in length, often much less. There are hardly any defirenable bractes, the calyx being cloae to the main stalk, and divided down to the base, into three small, acute, membranous segments. The ret of the flower is elevated on a short stalk within the calyx, which, as the fruit advances, becomes very conspicuous. The calyptra are obovate, each about the size of a mustard-seed, crowded together into a globular form, minutely pointed, and crowned by the filaments.

Michaux and Purh, mistaking what we shall next describe, for the true Linnean *Anthericum calyculatum*, wholly confidered this as a new species. A little examination, of the *Flora Lapponica* in particular, would have prevented this error, though all writers upon European plants have hither-to confounded the two species in question.

TOFIELDIA.

v. 2. 165. Point in Lamarck Dict. v. 4. 431, the synonym confused. Phalangium alpinum palustre, iridis folio; 
Tourn. Infl. 368. Segu. Veron. v. 2. 61. t. 14, copied in 
Lamarck's t. 266. Pseudo-aphelodium fecundus; Chuf. Hift. v. 1. 198. Aphelodium Lascaltrix verus; Ger. Em. 95.)
—Clutjer cylindrical. Bracteas nearly equal in length to the flower-flasks. Stem smooth, bearing two leaves. Petals obovate. Germans oblong.—Very common in moist, gravelly, 
habitats, on the Alps of Austria, Switzerland, Italy, Savoy, and Dauphiny, flowering in August. We know not of its having ever been observed in Britain, notwithstanding the name in Gerarde's herbal, which is misapplied to the figure of this plant, and properly belongs to Narthecium offffragmum, exhibited in the preceding 
page of the same book. Linnaeus knew the present species 
by its synonyms only, cited, with marks of well-founded 
doubt, in his Fl. Lapp. He was led by Dillenius to esteem 
it a mere variety of the foregoing, an opinion generally 
adopted ever since, but certainly for want of due enquiry. 
The alpina is not only twice the size of palaefris, with 
a thicker more woody root, but the flen always bears two 
distant leaves. The flowers form a clufier, not a head or 
spike, from one to two inches long, often interrupted, with 
a concave bractea at the base of cach flusk, about its own 
length. Calyx close to the rest of the flower, rather slightly 
three-cleft. Petals more yellowish. Capiffules oblong, 
combined almost all the way up, thrice as large as in palaefris. 
As the fruit advances, the partial flisks become still more 
evident than in the flower.

3. T. flenopetala. Narrow-petalled Tofieldia. Sm. MSS.
—Clufier, cylindrical. Bracteas overtopping the calyx. 
Stem smooth, bearing two leaves. Petals lanceolate, acute. 
Native of North America, where it was gathered by 
Kalm, whose specimens were referred by Linnaeus to his 
Aanthéricium alpina. They more agree with our T. alpina, 
in size and habit, having two or three leaves on the flusk. 
The clufier is dense and obtuse, an inch and a half long. 
Bracteas very different from that species, being 
lanceolate, and always as long as the partial flusk and calyx 
taken together; sometimes much longer. Calyx broad and 
shallow, unequally notched. Petals greenish-white, lanceo- 
late, narrow and acute, not obovate. Anthers pointed. 
Germens tapering into stiles twice the length of the fore- 
goin. No doubt can exist of this being a most distinct 
species. We find no indications of it in the works of 
Micha us or Pursé, nor is its precise place of growth known.

4. T. cermus. Drooping-flowered Tofieldia. Sm. MSS. 
(Aanthéricium n. 39; Linn. Sib. v. 1. 73. t. 18. f. 2.)
—Clufier cylindrical. Flowers drooping. Bracteas very 
short. Flower-flisks smooth, the length of the corolla. 
Stem leaves.—Found by Gmelin in mountainous woods in 
Siberia, flowering late in July. This is a species so 
evidently distinct from all the foregoing, that we cannot ac- 
count for their having been confounded; except by sup- 
pofing that Linnaeus, not having specimens of cach in fruit 
as well as in flower, too hastily considered the various 
appearances before him, as caused by different stages of 
growth. The drooping flowers, and quite pendulous fruit, 
of the present plant are remarkable at first sight; and the 
former are expressed in Gmelin's figure. These characters 
are too decided, in both our specimens, to be attributed to 
any accident in drying. The whole plant indeed is larger 
than any of the former three, with more creeping roots. 
Stem a foot high, or more, quite leafless, except at the very 
bottom, glaucous in the upper part. Leaves near three 
iches long, narrow, with a small oblique point, such as 
may be seen in some of the leaves of most of the species, 
except flenopetala, whose foliage is peculiar for its long 
strait, taper points. Clufier erect, smooth, two inches 
long while in flower, near four when in seed, rather lax, 
many-flowered, fiercely interrupted. Flower-flisks spreading, 
slender, scattered, about an eighth of an inch long, 
and still longer when the fruit is fully grown, having a little 
ovate bractea at the base of each, about a quarter the length 
of the flusk. Flowers white, about twice the size of Con- 
valiaria bifolia. Calyx with three hollow lobes. Petals 
oboovate, obtuse, slightly pointed, concave, the length of 
the flower-flisks, and keeping pace with them in their sub- 
frequent elongation. Staminus shorter than the corolla, with 
yellow, heart-shaped, pointless anthers. Germans ovo- 
lanceolate, with longish stiles. Capiflules shorter than the 
permanent corolla, obovate, membranous, but brittle, 
combined nearly all the way up, so as to form a turbinate three- 
lobed fruit, crowned with the three spreading stiles and 
capitate figmas. Seeds minute, prismatic.—Gmelin's sup- 
pofed variety, taken from Steiler, having a leafy stem, is 
probably another species. T. cermus is a very pretty plant, 
and we may hope that, in some of the frequent importations 
from Siberia, it may be introduced into the gardens of 
England.

in Ait. Hort. Kew. n. 2. (T. pubescens; Purbe n. 2. 
Narthecium pubens; Michaux Bor.-Amer. v. 1. 209. 
Anthericum filamentosum; var. glaucous; Linn. Hort. 
abius; Pluk. Mant. 29. Phys. t. 342. f. 3.)—Clufier, 
cylindrical, interrupted. Flower-flisks aggregate, rough, 
the length of the corolla.—Found in the moif meadows, 
and moity boggy woods, of Virginia and Carolina, flowering 
in July, according to Clayton and Purby. This is most like 
the last in stature and habit, but the roughness of the 
flower-flisks and their main flusk, essentially distinguishes it. 
The former grow three or four together, as if rather whorled 
than scattered. The flowers are white, with yellow anthers, 
and appear to be always erect.

(Narthecium glutinosum; Michaux Bor.-Amer. v. 1. 210.)
—Clufier ovate, dense. Flower-flisks glutinous, rough, 
the length of the corolla. Anthers prominent, orbicular. 
—Gathered by Mr. Menzies on the west coast of North 
America. Micha us lays his plant is found from Quebec 
10lake Misaffins. There is no room to suppose the latter 
different from our's, though the Narthecium glutinosum of 
Mr. Gawler, Curt. Mag. t. 1505, is very decidedly so, being 
a real and evident Narthecium, not, like Micha us'a, a Tof- 
fieldia. Purbe calls it N. americana, p. 227, which name, 
though not one of the best, we would substitute for glutin- 
iformum in our article Narthecium, the plant not being glu- 
tinous. All reference to Micha us and his observations in 
that place are to be erased. The plant is, according to 
Purbe, a native of boggy fields and woods, on the pine- 
barrens, as they are termed, of New Jersey, flowering in 
June and July.

Our Tofieldia glutinosfa has a tuberous horizontal root, 
with long simple fibres. Stem a foot high, angular, roughish 
all over with short glandular hairs, especially for two inches 
from the summit. Leaves few, almost entirely radical, four 
or five inches long, narrow, ribbed, smooth, except a little 
roughness towards the point. Clufier about an inch in 
length, of twelve or fourteen pale-yellow flowers, on hairy 
viscid flisks, about a quarter of an inch long, sometimes in 
pairs, having at the base one or two acute bracteas, one- 
third that length. Lobes of the calyx shallow. Petals 
obovate, rather shorter than the flanus. Anthers purplish, 
nealy
TOFT, in Geography, a town in Sweden, in the government of Abo, on an island; 20 miles W.N.W. of Abo.

TOFT, Toftum, or Tofia, in our Law-Books, a parcel of land, or a place where a messuage hath rufid, but is decayed, or casually burnt, and not re-edified.

Toft also signifies a grove of trees.

TOFTA, in Geography, a small island in the Baltic, E. of the island of Aland. N. lat. 60° 13'. E. long. 20° 7'.

TOFTS, Katharine, in Biography, an English finger of great renown on our stage at the beginning of the last century. In 1703, the fng was at a subscription concert in Lincoln's-Inn theatre, several Italian and English fongs. This lady was the conflant rival of Margarita de l'Epine.

In 1703, the fng at the subscription music in Drury-lane playhouse; and soon after, fgnora Margarita fng for the firft time at the fame theatre. At her fcond appearance, there was a difburfeme while the fng was finging, which, from the natural, and, it is to be feared, not uncommon effects of rival malice, was fuppolled to have been created by the emi-

tories of Mrs. Tofts; an idea the more difficult to eradicate, as the principal agent had happened to live with that lady as a fervant. But as the law of retaliation is frequently prac-
tified on the like occasions by the injured party, it was thought necelfary, a few days after, to infert a paragraph and letter in the Daily Courant, February 8, 1704, in vindica-
tion of Mrs. Tofts.

She was the principal fng in Clayton's Arifines, in 1705, the firft opera attempted in our country and language on the Italian model. See CLAYTON.

Mrs. Tofts was likewise the heroine of the famous opera of Camilla, of Addifon's Rosamond, fet by Clayton, and Thomyris, adjusted to Italian music, and wholly to English words, till the arrival of Valentin, in 1707, the firft male soprano fng that ever appeared on our stage; when Ca-
milla and Thomyris were performed, half in English and half in Italian. And even after the arrival of the celebrated Nicolini, when a new opera, entitled Pyrrhus and Deme-
tius, was brought on the stage in 1708, in which almost all the characters were filled up by Italians, Mrs. Tofts con-
tinued to perform her part in English, as did Ramond and Cook; but the public seemed perfectly satisfied with the motley performance, which had a run of eighteen nights; and the confusion of tongues, concerning which Mr. Add-
ifon is fo pleafant in the Spectator, seems to have been tol-
terated with perfect good humour by the public, which, in music as well as words, seemed to care much less about what was fung, than how it was fung.

After the year 1709, when the whole opera, poetry, mu-
cical composition and performers were Italian, Mrs. Tofts, who seems to have endeared herself to an English audience by her voice, figure, and performance, more than any pre-
ceding fng of our country, retired.

Colley Cibber, though he does not fpeak of music en connoiffeur, and, as an English actor and primate of a theatre, was an enemy to Italian opera and Italian fingers upon a principle of self-defence, probably gives us the gene-
ral and genuine opinion of his acquaintance concerning Mrs. Tofts, who, he fays, had her fbrt musical inftructions in her own country; "before the Italian taste had fo highly prevailed, and was then not an adept: whatever defect the fhanfonably skillful might find in her manner, she had, in the general fene of her hearers, charms that few of the most learned fingers ever arrive at. The beauty of her fine pro-
portioned figure, and exquisitely sweet voice, with peculiar rapid fwiifncens of her throat, were perfections not to be imitated by art or labour." This performer had fongs given to her in all fyles; her compafs, however, did not surpass the common limits of a foprano, or treble voice. With regard to her execution, of which we are still enabled to judge by the printed copies of her fongs, it chiefly confifted in fuch paffages as are com-
prifed in the fake, as indeed did that of most other fingers at this time.

Mrs. Tofts quitted the stage in 1709. The talents of this fnger and of Margarita de l'Epine gave rise to the firft musical fictions which we hear of in this country. According to Hughes, author of the Siege of Damas, their abilities were disputed by the firft people in the kingdom.

"Music has learnt the discord of the flate,
And cencers jat with Whig and Tory hate.
Here Somerfet and Devonshire attend
The British Tofts, and ev'ry note commend;
To native merit just, and pleasd to fee
We've Roman arts, from Roman bondage free.
There fam'd l'Epine does equal skill emply,
While lil'ning peers crowd to th' celtial joy:
Bedford to hear her fong his dice forfakes,
And Nottingham is raptur'd when the fakes;
Lull'd flatefmen melt away their drowsy cares
Of England's safety, in Italian airs!"

Although it is publicly infinuated in the Tatler, for Thurs-
day, May 26, 1709, that Mrs. Tofts was infame, it seems doubtful whether we are to take this account literally, or whether
whether Sir Richard Steele had not recourse to invention, or at least exaggeration, in order to throw a ridicule on opera quarrels in general, and on her particular disputes at that time with the Margarita or other female fingers. See Taliot, p. 226.

After quitting the stage, by which she is said to have acquired a considerable fortune, the married Mr. Joseph Smith, who was afterwards appointed confidant at Venice, where he resided till the time of his death, about the year 1705. He was a great collector of books and pictures, and a patron of the arts in general.

TOGA, in Ancient Geography, a town of Asia, in Greater Armenia. Tptl.

Toga, in Antiquity, a wide wooden gown, or mantle, without sleeves, used among the Romans, both by men and women.

In process of time, none wore the toga but lewd women: whence that of Horace, in matrona, aeculis, paecefoe toga. Lib. i. fat. ii. ver. 63.

The toga was of divers colours, and admitted of various ornaments: there was that called toga domifcia, worn within doors; toga coronata, worn abroad; toga militaria, used by soldiers, stuck up after the Gabiniian fashion; and toga pilâ, or triumphalis, wherein the victorious triumphed: this was embroidered with palms: that without any ornaments was called toga pura.

The toga pilâ, &c. was an ancient habit of the Etruscans, and not brought to Rome till after Tarquinius Priscus had subdued the twelve states of that nation.

The toga was sometimes worn open, and called aperta; sometimes gilt or stuck up, called praecincta; and this clture or girding, again, according to Sigonius, was of three kinds: laticius, or the loose kind, where the tail trailed on the ground; adstringens, the close kind, wherein it did not reach so low as the feet; and laticinia, where one of the skirts or lappets was girt round the body.

Sigonius distinguishes the several togas, or Roman gowns, into pura, candida, pulia, pilâ, praecincta, trabea, and galadamentum. See Praedexta, Paludamentum, &c.

The toga pura was also called virilis. Kennet's Rom. Ant. part ii. c. 8.

Toga is sometimes used metaphorically for peace. See Trope.

Togz, Jus, or privilege of the toga, was the same with the privilege of a Roman citizen, i.e. the right of wearing a Roman habit, and of taking, as they explain it, fire and water through the Roman empire.

TOGAWADI, in Geography, a town of Hindoostan, in Baramaul; 7 miles S. of Sankeryhurgan.

TOGDA, or TIGDA, a town and district of Africa, in the country of Segulmeza; 50 miles W. of Segulmeza.

TOGEBAUT, a town of Peria, in the province of Ege; 81 miles N. of Ifahpan.

TOGETHER, in Sea Language, the order given to the men in the exercizes of heaving, rowing, twilng, &c. to act all in concert, or at the same instant.

TOGGEI, in a Ship, a small wooden pin, about five or six inches long, and usuallly tapering from the middle toward the extremities. It is used to fix transversely in the lower part of a tackle, in which it serves as a hook whereby to attach the tackle to a strop, lings, or any body in which the effort of the tackle is to be employed.

There are also toggels of another kind, employed to falten the top-gallant sheets to the span, which is knotted round the cap at the top-mast-head. Fel.see Butoffs.

TOGGEBURG, in Geography, a county of Switserland, dependent on the abbey of St. Gal, bounded on the N. by the territory of St. Gal, on the E. by the canton of Appenzell, on the S. by the county of Sargans and the territory of Calfer, and on the W. by the canton of Zürich. In its natural quality it resembles Appenzell and the other cantons, and, being full of fertile Alps, abounds in numerous breeds of cattle. Till the year 1436, this county had its own counts; the last of whom carried his indulgence to his vassals so far, as to grant them such privileges as nearly amounted to a state of absolute freedom: accordingly, on his demise in the above year, they entered into a close alliance with the cantons of Schweitz and Glaris, which alliance was confirmed in 1440. Afterwards, the county was received into an alliance with the cantons of Schweitz and Glaris, and likewise gave its function to the former compact between the inhabitants of the county and the said cantons. In the beginning of the eighteenth century, the Togggenburgers, resenting the illegal and oppressive exactions of abbot Leodaurius, applied for assistance to their allies, who readily granted it; and, in 1707, Zurich and Bern also declared, that they would maintain the county of Togggenburg in the secure enjoyment of its rights and liberties, against all illicit violence whatsoever. On this the people began to affer their rights, and, in 1707, in a solemn congress, held at Wattey, renewed their federal oath, and erected three councils, named the great, lesser, and privy, which are composed of an equal number of members of both sexes. The intifine commotions here continued however to increase, till, in 1712, they broke out into open war, in which Zurich and Bern sided with the county, and Schweitz and Glaris with the abbot. In 1718, at Baden, in the Argau, an accommodation, confirming the liberties of the county, was brought about between the new abbot and the cantons of Bern and Zurich. Pursuant to this peace, the abbot and prince of St. Gal both is, and bears the title of, natural sovereign, and territorial lord of the county of Togggenburg; and the people are to take the accustomed oath to him, and to pay him suitable services, but without any violation of their rights and liberties.

TOGLUTOUR, a town of Hindooftan, in the fubd of Deli; 15 miles W.N.W. of Panniput.

TOGOMI, a town of Japan, in the illand of Nihon; 80 miles N.W. of Meaco.

TOGOSOHALCHEE CREEK, a branch of the Oak-mullee river, in the flate of Georgia.

TOGRIN, CAPE, a cape at the mouth of the river Sierra Leone.

TOGULA, among the Romans, a narrow kind of toga, used by the poorer sort of people.

TOHBA, a denomination given to a class of priests in their age, or nine years, into the establishment, called "Totha," and they are then occupied in receiving the instructions suited to their age, and the duties for which they are designed. At fifteen they are usuallly admitted into the order of Tohba, the first step in their religious class, and after due examination, they are advanced from the order of Tohba to that of Gylong, between the age of twenty-one and twenty-four. See Gylong.

TOHOTCHIE HOTUN, in Geography, a town of Chinefe Tartary, in the country of Hami; 30 miles N.W. of HamiHotun.

TOJIE, a town of Hindooftan, in Candeif; 10 miles N. of Hurdah.

TOIKO,
TOK

TOIKO, a town of Japan, in the island of Nippon; 80 miles E.S.E. of Jedo. N. lat. 36° 51'. E. long. 140° 40'.

TOILES, snakes or nets set by hunters for catching of wild beasts; as deer, &c.

TOILET, a fine covering, of linen, silk, or tapestry, spread over the table in a bed-chamber, or dressing-room, to undress and dress upon.

The dressings-boxes, in which are kept the paints, pomatum, essences, patches, &c. the pin-cushion, powder-box, brushes, &c. are esteemed parts of the equipage of a lady's toilet.

That of the men consists of comb-cape, brushes, &c.

To make a visit to one at his toilet, is to come to entertain him while he is dressing or undressing.

Satin, lace, velvet, brocade, point de France, &c. are now ordinarily used for toilets; anciently they were made much plainer: whence the name, which is formed from the French, toilette, a diminutive of voile, any thin stuff.

TOISE, or FATHOM, a long measure in France, containing 6 feet, the foot being 12 inches, the inch 12 lines, subdivided into 12 points; 76 French feet are equal to 81 English feet, or, more accurately, 4000 French feet equal 426 English feet.

TOISON d'Or, a term, in Heraldry, for the golden fleece, which is sometimes borne in a coat of arms.

TOISSEY, in Geography, a town of France, in the department of the Ain, near the Chalaronne and Saône, which unites about half a mile from the town; 18 miles W. of Bourg-en-Bresse.

TOJUCA, a river of Brazil, which runs into the Atlantic, S. lat. 27° 44'.

TOKA, a town of Hindostan, in the circonference of Aurungabad; 33 miles S.W. of Aurungabad.

TOKAI, a river of Bucharia, which runs into the Gihon, near Heifdar-apf.

TOKARESTAN, a district of Grand Bucharia, situated to the eastward of Balk.

TOKAY, a town or rather village of Hungary, situated at the foot, and to the E. of a high hill, close by the confluence of the river Bodrug with the Theiss or Tibiscus. The inhabitants are chiefly either Hungarians of the Protestant religion, or Greeks, who came originally from Turkey, but have been long settled here, for the purpose of carrying on the wine-trade. The hills on which the vine grows lie all to the W. of the river Bodrug, and beginning close by the town of Tokay, extend westward and northward from thence, and occupy a space of perhaps ten English miles square; but they are interrupted and interplayed with many extensive plains, and several villages. Near some of these, particularly Tabia and Tarzcal, the wine is better than that which is produced on the hill of Tokay; but it all goes under the same name; 98 miles N.W. of Colofvar. N. lat. 48° 10'. E. long. 10° 57'.

Tokay-Wine, derives its name from the town or village of Hungary, where it is produced. (See the preceding article.) The vineyards extend beyond the forty-eighth degree of northern latitude; the soil where the vines grow is a yellow clayish earth, extremely deep, and interposed with large loose lime-flakes: the expasures most inclining to the south, the steepcl declivities, and the highest parts of these, produce the best wine. This wine, so far from being found in so small a quantity as never to be genuine, unless when given in presents by the court of Vienna, is a common defect wine in all the great families at Vienna and in Hungary, and is very generally drank in Poland and Russia; nor is the Tokay wine altogether the property of the crown, but many of the German and Hungarian nobility, as well as gen-

TOK

TOK

THEMEN, and even peasants, have vineyards at Tokay. The grapes are all white, and the vintage commonly begins about the 28th of October, sometimes as late as the 11th of November. There are four sorts of wine made from the same grapes, distinguished at Tokay by the names of essence, aufruch, masfach, and the common wine.—The essence is made by picking out the half-dried and shriveled grapes, and putting them into a perforated vessel, where they remain as long as any juice runs off by the mere pressure of their own weight. This is put into small casks. The aufruch is made by pouring the expressed juice of the grapes from which the former had been picked on those that yielded the essence, and treading them with the feet. The liquor thus obtained stands for a day or two to ferment, and then is poured into small casks, which are kept in the air for about a month, and afterwards put into the cellars. The same process is again repeated by the addition of more juice to the grapes which have already undergone the two former preflies, and they are now wrung with the hands; and thus is had the masfach. The fourth kind is made by taking all the grapes together at first, and submitting them to the greatest preffure: this is chiefly prepared by the peasants. The essence is thick, and very sweet and luscious; it is chiefly used to mix with the other kinds. The aufruch is the wine commonly exported, and which is known in foreign countries by the name of Tokay. The goodness of it is determined by the following rules. The colour should neither be reddish nor very pale, but a light silver; in trying it, the palate and tip of the tongue should be wetted without swallowing it, and if it manifest any acrimony to the tongue, it is not good; but the taste ought to be soft and mild: when poured out, it should form globules in the glass, and have an oily appearance: when genuine, the strongest is always of the bell quality: when swallofed, it should have an earthy afflignant taste in the mouth, which is called the taste of the root. All Tokay wine has an aromatic taste, which distinguishes it from every other species of wine. It keeps to any age, and improves by time; but is never good till about three years old. It is the best way to transport it in casks: for when it is on the seas, it ferments three times every season, and thus refines itself. When in bottles, there must be an empty space left between the wine and the cork, otherwise it would burst the bottle. A little oil is put upon the surface, and a piece of bladder tied over the cork. The bottles are always laid on their sides inland. Phil. Trans. vol. liii. part ii. p. 292, &c.

TOKE, in Geography, a town of Bengal; 35 miles N.E. of Dacca.

TOKEN-BESSEYS, a cluster of small islands in the East Indian sea. S. lat. 6°. E. long. 123° 36'.

TOKENS, in Byzantine Cursed, those livid spots which appear in the several stages of the disease, and are certain forerunners of death. They generally appear only under the most desperate circumstances, and when the patient would otherwife be declared dying; but Hodges gives us instances where they appeared before any other symptoms of the disease, and came out without any pain or trouble; yet even in these cases the perfon always died. These tokens are the mark by which the searchers conclude of the cause of the death of the perfon, and are the rule for ordering the house to be shut up, to prevent the spreading of the disease. But the nurses, and other crafty people, have a way of disguising the symptom after death, by covering the body with wet and cold sheets. These strike in the spots, so that the perfon may be thought to have died by some other disease.

TOKENS, False, in Law. See False.

TOKENS, in Coinage, coins in the reign of queen Elizabeth. 5 F
struck in the cities of Bristol, Oxford, and Warehall, and also by about 5000 trade-men and others; upon returning which to the issuer, he gave current coin, or value, for them, as directed. In the succeeding reign, on the 15th of May, 1613, king James's royal farthing tokens commenced by proclamation. These were not forced upon the people as farthings or established coin, but merely as pledges or tokens, for which government was obliged to give other coin if required. Their legend was the king's common terms running upon each side. These pieces were not favourably received, but continued in a kind of retentent circulation through the whole of this reign, and the beginning of the succeeding. In 1635, Charles I. struck those with the roe instead of the harp. But the vast number of counterfeits, and the king's death in 1648, put an utter flop to their currency; and the tokens of towns and trade-men again took their run, increasing prodigiously till the year 1672, when farthings properly so called were first published by government. These town-pieces and trade-men's tokens, together with those of the time of queen Elizabeth, are collected by some antiquaries with great avidity. Similar tokens, says Pinkerton, are to this day current in Scotland, both of copper and tin, principally used by the bakers and grocers; farthings not being very common in that country.

In 1804, the Bank of Ireland bought in a large quantity of depreciated silver coin; and, as a substitute, issued Spanish dollars, newly stamped, at 6½ Irish, and also fractions of the dollar, which had been minted for the occasion at the Tower of London, consisting of five-penny, ten-penny, and thirty-penny pieces Irish, being exactly 1/6, 1/3, and 1/6 of the dollar. All these coins are called Bank tokens; the Bank having engaged to receive them again at the issued price, and they have been declared a legal tender in the payment of taxes: their intrinsic value may be known from that of the dollar. In 1829, a new silver coinage was minted at the Tower of London for the colonies of Ellice and Demerary, consisting of pieces of 3, 2, 1, ½, and ¼ of the dollar: the larger piece weighs 15 dwts., and is 1 oz. 6 dwts. worse than English standard. Its value therefore is 32. 5d. sterling, or, computing it as the dollar is now rated in the West Indies (i.e. at 45. 5d.), its value is 32. 5½d. and the smaller pieces in proportion. They are marked on the reverse "Colonies of Ellice and Demerary Token," and the king's is on the obverse. The exchange with London should be about 12 guilders for 1l. sterling, but varies considerably above this, even to 20 guilders, and upwards. Kelly's Cambist.

TOKIS, in Geography, a town of Japan, in the island of Nippon; 40 miles N.N.E. of Meaco.—Also, a town of Japan, in the province of Ximo; 15 miles N.N.W. of Nangafaki.

TOKI-TAO, a small island near the coast of China. N. lat. 38° 4'. E. long. 120° 39'.

TOKORARI. See Tocorary.

TOKTABA, a town of Bootan; 50 miles N. of Beyhar.

TOL in Law, a term signifying to defeat, or take away. From the Latin, tollere, which signifies the fame. Thus, to tol the entry, is to take away the right of entry.

TOL Peden Penwith, in Geography, a cape on the S. coast of the western extremity of Cornwall; 3 miles S.E. of Land's End. N. lat. 50° 4'. W. long. 5° 36'.

TOLA, in Commerces, a weight for gold and silver at Bombay, Surat, and other places in India: at Bombay, the tola contains 40 vails, 100 gonsie or Bombay grains, or 600 chowees. The tola is equal in weight to the silver rupee; 24 tolas make 1 seer, and 32 tolas 13 valls = 1 lb. troy. At Surat, the tola contains 32 valls or 96 ruettes: 82½ valls make 1 oz. troy, and therefore 31 tolas 1 lb. troy nearly.

TOLABO, CAPE, in Geography, a cape on the E. coast of Celebes. S. lat. 9° 45'. E. long. 122° 50'.

TOLAGO BAY, a bay on the N.E. coast of the northern island of New Zealand, in the South Pacific ocean, discovered by captain Cook in the year 1769. It is moderately large, and has from seven to thirteen fathoms, with a clean sandy bottom and good anchorage, and is sheltered from all winds except the north-east. On the south point lies a small but high island, so near the main as not to be distinguished from it. Close to the north end of the island, at the entrance into the bay, are two high rocks; one of which is round, like a corn-flack, but the other is long, and perforated in several places, so that the openings appear like the arches of a bridge. Within these rocks is a cove, convenient for wood and water. Off the north point of the bay is a pretty high rocky island; and about a mile without it, are some rocks and breakers. The tide flows at the full and change of the moon, about fix o'clock, and rises and falls perpendicularly from five to fix feet. Captain Cook saw no four-footed animals, nor the appearance of any, either tame or wild, except dogs and rats, and these were very scarce: the people eat the dogs, as at Otaheite, and adorn their garments with the skins. He climbed many of the hills, hoping to get a view of the country, but could see nothing from the top except higher hills, in a boundless succession. The ridges of these hills produce little besides fern; but the sides are most luxuriantly clothed with wood and verdure of various kinds, with little plantations intermixed. In the woods he found trees of above twenty different sorts, and carried specimens of each on board; but there was nobody to whom they were not altogether unknown. The tree cut for firing was somewhat like the maple, and yielded a whitish gum. Another sort was found of it, of a deep yellow, which might be useful in dying. One cabbage-tree was met with, and cut down for the cabbages. The country abounds with plants, and the woods with birds in an endless variety, exquisitely beautiful, and of which none of them had the least knowledge. The soil of both the hills and valleys is light and sandy, and very fit for the production of all kinds of roots; though none were seen except sweet potatoes and yams. S. lat. 38° 22'. W. long. 181° 15'.

TOLAND, JOHN, in Biography, a writer on subjects of political and religious controversy, was born in the year 1669, in Ireland, near Londonderry; and his parents, of a good family, were Roman Catholics. Educated in the principles of his family, he renounced them before he attained the age of sixteen years, and became a zealous opposer of popery. Accordingly he completed his education in Scotland, and having spent three years in the university of Glasgow, removed to Edinburgh, where he graduated M.A. in 1690. From Edinburgh he removed to London, and became acquainted with some respectable dissenters, who enabled him to pursue his studies for two years more at Leyden. On his return to London, he visited Oxford, and here he collected materials for the execution of some literary projects: one of which was a dissertation in order to prove that the common narrative of the death of Regulus was a fable. In 1696 he published at London his "Christianity not mysterious; or a Treatise shewing that there is nothing in the Gospel contrary to Reason, or above it; and that no Christian Doctrine can be properly called a Mystery," This publication caused an alarm, and not without reason, among
among Christians of all denominations, by whom it was regarded as an attempt to overthrow revealed religion. At home and abroad it excited attention, and the advocates of Christianity concurred in the defence of their religion against what they conceived to be an attack upon it. The magistrates, also, intruded into this controversy, and procured a preceptment by the grand jury of Middlesex. The author withdrew from the Horn which seemed to be gathering into his own country; but the obnoxious character of his book had excited prejudices against him. Toland, as we learn from the correspondence between Mr. Molyneux and Mr. Locke on the subject, does not seem to have acted with that moderation and prudence which might reasonably have been expected in his circumstances. His manner of defending and propagating his opinions gave just offence even to those who entertained some degree of respect for his talents and learning; and was condemned by those who were avowed advocates of rational liberty and enemies to every kind of persecution. From another quarter he experienced a severity of treatment, which his own misconduct had provoked, but which, in this more enlightened and liberal period, none, we presume, will undertake to justify.

In defense of Toland’s book, by Mr. Peter Brown, fellow of Trinity college, the civil magistrates was called upon to interpose; accordingly the grand jury of Dublin made a preceptment of the book; the parliament of Ireland voted it to be burnt by the common hangman, and issued an order that the author should be taken into custody by the jeer that was at arms, and prosecuted by the attorney-general.

Toland, universally blamed by his acquaintance, and reduced to pecuniary difficulties, left the country, and returned to England. While some disapproved the violence of this proceeding, others justified it; and Dr. South, in particular, highly commends the Irish parliament for having “to their immortal honour, presently sent him (Toland) packing, and, without the help of a faggot, soon made the kingdom too hot to hold him.” On the spirit which dictated this language we make no comment. Toland, upon his arrival in London, published an account of his treatment in Ireland, and renouncing communion with the Dissenters, declared himself a latitudinarian, or one who would comply with the religious worship of any class of Protestants, whose differences were not, in his estimation, of sufficient importance to justify disturbing the peace of a nation. He then directed his attention to other topics; and in 1698 he published a pamphlet, intitled “The Militia reformed,” in which he proposed to substitute that species of armament for a standing army. In the same year he wrote a “Life of Milton,” to be prefixed to an edition of his prose works, and which was also printed separately. In this preface he opposed the notion then prevalent, that the “Icon Basilikè” was written by Charles I.; and from the consideration of this imposture, as he pronounced it to be, he digressed to the consideration of the purer works that had been ascribed to Christ and his apostles. Against a host of political and religious adveraries, he defended himself in a treatise intitled “Amynstor;” in which he gave a complete history of the “Icon Basilikè,” and also a catalogue of such primitive writers, who were judged by him to be pious. As he was supposd in the discussion of this latter topic to impugn the authenticity of the received canon of Scripture, he drew forth replies from some of the ablest advocates of Christianity, and particularly Mr. (afterwards the highly celebrated Dr.) Samuel Clarke.

In 1699, Toland was engaged by the duke of Newcastle to publish “Memoirs of Dzenil Lord Holles;” and in the following year by Mr. Robert Harley, afterwards Earl of Oxford, then a Whig, to give a new edition of Harrington’s “Oceana.” When the Act of Succession was passed, on occasion of the death of the duke of Gloucester in 1701, he published “Anglia Libera,” being an explanation and eulogy of this act; and he accompanied the Earl of Macclesfield, who was deputed to carry it to Hanover, and had the honour of presenting his book to the Electress Sophia, and of kissing her hand on the occasion. At Berlin, where he visited, he held a disputé, before the queen of Prussia, with the learned Beaufobre, on the authority of the books of the New Testament; on an account of which was sent by the latter to the “Bibliothèque Germanique.” Upon his return to England in 1704, he published “Letters to Serena;” (meaning the queen of Prussia,) on the origin and force of prejudices; the history of the soul’s immortality among the heathens; the origin of idolatry; and remarks on Spinoza’s philosophy. These letters were animadverted upon by Wotton, and by the author of the Divine Legation. In 1708 he published at the Hague two Latin dissertations, entitled “Adelphidæmon, &c. Titus Livius a Superflitione vindicatus;” and “Origines Judææcæ, five Strabonæ de Moïye et Religione Judæææ História breviter illustrata.” In 1718 he published “Nazaræus; or Jewish, Gentile, or Mahometan Christianity,” &c. in which he endeavours to shew that the Jewish converts were to observe their own law throughout all generations, &c. Two years afterwards appeared a Latin tract, entitled “Pantheïcæ; five Formulae celebræ Sodalitatis Sorœtæ, &c.;” a work which has subjected its author to the charge of atheism, and in consequence of which he was unjustly accused by Dr. Hare with having composed a profane prayer to Bacchus in his character of Pantheist.

In the same year he published his “Tetraëdromus,” on the pillar of cloud and fire that guided the Israelites; on the exoteric and esoteric philosophy of the ancients; on Hypatia, the female philosopher; and a defence of his Nazaræus against Dr. Mangey. To this work he annexed an account of his conduct and sentiments, formally professing his preference of the Christian religion, pure and unmixed, to all others.

Toland’s health was now declining, and being in low circumstances, Lord Moleworth assured him that he should never want, while he himself lived. However, his disfavour baffled all remedies, and his life closed on the 11th of March, 1722, in the 53d year of his age. He manifested a considerate degree of resignation and patience during the progress of his illness; replying to one who asked him if he wanted anything, “I want nothing but death;” and after taking a calm leave of his friends, saying to them that “he was going to sleep.” In an epitaph which he prepared for himself, he expresses that confidence and self-approval which belonged to his character. He closes with these words: “Spiritus cum aethero patre, a quo proletis omne, conjuncturus; corpus imitatur; natura cecidit, in materno grimo repromitor. IPSA vero exterrum et referreturca, at idem futurus Tolandus nuncum.” His posthumous works were published in 2 vols. 8vo. in 1726, and again in 1747, with an account of his life and writings, by Des Maizieux.

TOLANORE, in Geography, a town of Hindooftan, in the Carnatic; 5 miles N. of Volcunda.

TOLASTRA REGIO, in Ancient Geography, a country of Asia, in Galathia. Ptolemy.

TOLBIACUM, a town of Gallia Belgica, according to Tacitus; situated on the route from Treviri to Colonia Agrippina.

TOL-BOOTH, or TOL-BOOTh, a place in a city, where goods are weighed, to ascertain the duties or import on them.

5 F 2 TOLCES.
TOLCESTER, Tolcestum, in our Old Writers, an old excise, or duty paid by the tenants of some manors to the lords, for liberty to brew and sell ale.

TOLCKSDORF, in Geography, a town of Prussia, in Ermeland; 12 miles S.E. of Fraunenburg.

TOLEDO, in Geography. See Alva.

Toledo, in Geography. A city of Spain, in New Castile, on the Tagus, the see of an archbishop, and an university, founded in the year 1475. The origin of Toledo is uncertain; it is only known to have been a Roman colony, and made the depositary of the treasures sent from Rome. From the Romans it passed under the dominion of the Goths; Leovigild retired there and embellished the city, which became more considerable under his successors. The Moors took Toledo in 584, and reigned there till 1085, when it was taken from them by Alphonso VIII., who styled himself emperor of Toledo, whence it took, and has preserved, the title of royal and imperial. Toledo, as is well known, was formerly famous for the exquisite temper of the sword-blades made there; and the genuine ones that still remain are sold at an exorbitant price. It is said that the secret of hardening them has been again recovered; and experiments have been made with blades lately fabricated there which seem to justify this assertion. When one of these has undergone the operation of tempering, if it be in the least notched, by striking with it several violent blows on an iron head-piece, it is rejected: almost all that are made here, it is said, will fland this proof. Two centuries ago, Toledo contained more than 200,000 inhabitants, but now scarcely 30,000. When a house falls to decay, it is never rebuilt; and in 20 years more, this city will be little else than a heap of ruins. Toledo is built upon rocks, and commanded by eminences which seem to present the image of sterility; yet, in the midst of these precipices, the traveller finds, to his surprize, several fertile and charming situations, impenetrable to the burning rays of the sun. These places are called Cigarrates. Several councils have been held at Toledo, particularly one in 623, in which it was declared unlawful and unchristian to force people to believe, seeing it is God only who hardens, and flews mercy to whom he will; but by another council in a few years after, they highly commended their monarch for persecuting the Jews. In 681 it was decreed, that the archbishop of Toledo should have power to create bishops throughout Spain in the king's absence, and confirm those made by the king. In 1355, it was feized by Henry and Frederick, the haillards, brothers of king Peter, who robbed all the Jews, and murdered about 1000 of them; 32 miles S.S.W. of Madrid. N. lat. 39° 56'. W. long. 4° 18'.

TOLEN, a town of Norway; 22 miles W. of Bergen.

Alo, an island belonging to the flate of Zealand, in the calf branch of the Scheld, separated from the main land of Brabant by a canal, about ten miles in length, and four in breadth. It contains two towns, Tolon and St. Martin's Dyack, and several villages. Tolon, the capital, from whence the island itself is named, is a handsome town, and ranks as fourth in the assembly. The name of it is derived from the toll which was formerly paid here by order of the counts of Zealand. It is fortified with seven bastions, and the flates have caused a fort, called Suckenburg, to be built on the other side of the river, so that it is now one of the strongest frontier towns of the flate of Zealand. The flateau is an armed building, which makes a good show. The arsenal is situated at the entrance of the small harbour; there is also a magazine for powder. The church is built in the figure of a cross, and is an extraordinary piece of architecture: 4 miles N.W. of Bergen-Zoom. N. lat. 51° 36'. E. long. 3° 58'.

TOLENTINO, a town of the Poppedom, in the marquisate of Ancona, on the Chiento, the see of a bishop, united to Macerata. It is only remarkable for being the depositary of the body of St. Nicholas, where the arm, by bleeding afresh, prognosticates when any signal calamity is to befal Italy; 18 miles W. of Fermo. N. lat. 43° 10'. E. long. 13° 18'.

TOLENTINO, in Ancient Geography, a town of Italy, in Picenum, S.W. of Ricina.

TOLenus, a river of Italy, in the country of the Marit.

TOLeration, in Religion, a term which has engaged much attention in the disputes among Protestants.

M. Bafiano, and some others, distinguishing civil toleration from ecclesiastical. The latter allows of different, and even opposite sentiments in the church; and the first permits them in civil society.

TOLeration, by civil toleration, is meant impunity and safety in the state for every sect which does not maintain any doctrine inconsistent with the peace and welfare of the state. This civil or political toleration, implies a right of enjoying the benefit of the laws, and of all the privileges of the society, without any regard to difference of religion.

Ecclesiastical toleration is an allowance of certain opinions, which, not being fundamentals, do not hinder those who profess them from being esteemed members of the church. But as to the quality and number of these fundamental points, they never could, nor in all probability ever will be agreed upon.

In order to discover the genuine principles of toleration, it is necessary to consider that, antecedently to the formation of civil societies, mankind professes certain rights, independent of all human grant, not derived from any compact, and which are therefore to be acknowledged as the rights of human nature. A right to judge for themselves in points of religion is one of these rights; which, whilst it authorizes every individual to claim the exercise of this privilege to himself, obliges him to allow it in the same extent to all about him, and establishes one uniform regulation for his behaviour toward others, and their behaviour toward him; e.g. no apprehensions of the truth and certainty of any person's religious sentiments can justify him in attempting to impose them on his neighbour; for the same right of judgment which any one can claim, belongs, on the same principle, equally to all, and ought to be equally faced and inviolable in all; and no reason can be alleged by him for taking the religious liberty of others from them, but what will, at the same time, equally destroy his own title to it. The injustice of similar encroachments upon him from others follows from the same principle, and with the same evidence.

Whether the claim of such a liberty of judgment in religion for ourselves is weakened by men's entering into civil society, is the next object of consideration.

The great end of government is to protect the subjects of it from the injuries to which they were exposed in a state of nature; and as all injuries imply rights of which they are violations, and the care taken to guard against the violation of these rights is an acknowledgment of the reality and importance of them; it evidently follows, that when they enter into society, if the primary and leading view of government be to prevent or restrain these injuries, to which men were exposed for want of its protection, they carry these rights with them; that they continue to retain them; and that, instead of supposing themselves to be deprived of them, the very design with which they put themselves under the authority of government is to secure them the more firmly.

With this view they entrust the preservation of them to common guardians, by whose intervention, it is presumed, they will be more vigorously affected and more effectually protected, than it is possible they should be in a state where there
there is no common umpire to check the evils of oppression on the one hand, and refrain the no less formidable evils of immoderate resentment on the other.

If we consider what are the rights which men give up to government, when they enter into civil societies, they will be found to be, not those which may most properly be styled the primary rights of human nature; not the right which every man has to live undisturbed, to enjoy the advantages which he justly possesses, and to be left to his freedom in all things not injurious to his fellow-creatures; but the consequential, though equally real and certain right, which men are not subject to government, every person has to take the affection of all his rights into his own hands, and correct the infringers of them by the inflicting of such pains, or the use of such other methods of determining the authors of the wrong, as reason shall warrant for his future security; and, speaking precisely, even these rights are not absolutely extinguished and utterly lost, but suspended by such limitations as the order and well-being of society require, and so long as the succours of government shall be effectual.

The primary rights of liberty, safety, and protection from oppression, still subsist in their full vigour. To suppoze them abandoned, renounced, and annihilated, or that government can have any right to destroy them, is ascribing to it a right to defeat the end for which it is established, and betray the trust reposed in it. It is, indeed, totally inverting the principle upon which the power of rulers stands, and by which the acts of it ought to be guided.

Man was not made for government, but government for man; and the great object, to which all the operations of it should be directed, is to guard, as much as possible, the equal, impartial safety and freedom of all the subjects of it. To this purpose judge Blackstone observes, that the principal aim of society is to protect individuals in the enjoyment of those absolute rights, which were vested in them by the immutable law of nature, but which could not be preserved in peace without that mutual assistance and inter-course, which are gained by the institution of friendly and civil communities: so that the primary end of human laws is to maintain and regulate these absolute rights of individuals.

See Government and Civil Liberty.

Now of all the rights inherent in human nature, that of thinking for ourselves, and following the conviction of our own judgments in relation to the object of our faith, worship, and religious obedience, is the most sacred, incontestable, and in every view of it, entitled to the most careful protection. The preservation of these is one of the chief, perhaps the first end for which civil societies are instituted, and the rulers of them invested with power: and therefore, in all governments, the rights of conscience should have a principal place assigned them in the care of those, to whom the protection of their fellow-creatures is committed. If the securing of equal, impartial liberty, in all those instances of it in which it is not injurious to others, be so much the object of every equitable, wise, and well-considered system of laws, that all needful encouragements upon it are deviations from the spirit which ought to be diffused through all laws, and impair the benefit which they ought to confer, can it be supposed that the rights of conscience ought not to be guarded from violation? Rights of this kind are the last which men can ever be imagined to give up to be modelled at the pleasure of others; nor (as it is argued) is there any one principle connected with their submission to governors in other respects, that can require or justify such a surrender. Does it follow that, because the magistrate is entrusted with authority to decide disputes between us and our fellow-citizens concerning property, he is to determine

points which lie only between God and our own consciences? Because it is allowed to be his office to guard the peace of his subjects, and to inflict punishments for this purpose on those who unjustly disturb it; is it to be taken for granted, that he is to dictate to them what rule of faith they shall adopt, and in what manner they are to worship the Deity; when it is allowed on all hands, that of these things the will of God is the only rule, and that no worship can be acceptable to him, but what is accompanied with the sincere conviction of him who offers it? Besides, it is argued, that such is the nature of this right, and it holds upon a foundation peculiar to itself, and is distinguished from every other right, that it cannot be given up. Property may be resigned, transferred, or submitted to the regulation of others; a man may relinquish his cafe, and subject himself to inconveniences, and be not only innocent but laudable; nay, he may sacrifice life itself, and merit the highest applause; but his conscience he cannot resign.

To "prove all things, and hold fast that which is good," is not only a privilege but a duty; an obligation laid upon him by the very nature of religion and virtue, and from which he cannot discharge himself without departing from the principles of both. It must always remain entire to him; nor, while the principles of the most reasonable liberty are allowed to subsist in their due extent, can any attempt be consistently made to take it from him.

From these principles it has been inferred, that toleration, so far from being a matter of mere grace or favour, which government has a right to withhold, grant, abridge, or refuse at pleasure, is the acknowledgment and confirmation of a right: not one of those adventitious rights, which are subsequent to the establishment of civil societies, and arise out of the peculiar forms and constitution of it; but of those higher rights which belong to men as such, and which ought to be preferred under all states and governments whatever, as effectually, universally, and impartially as any other right.

With regard to the extent of toleration, it is urged, that if liberty of conscience be a right essential to human nature, all penalties in cases merely of a religious nature must be an infringement of a right, and a degree of oppression, though inflicted by a law. Further, the inquiry concerning the persons entitled to toleration does not depend on the supposed truth or error of the sentiments which men may adopt, but upon the common right, which all men have, to be led in these points by the light of their own minds, and to enjoy all the securities and benefits of society, while they fulfill the obligations of it. All who can give good security to the government under which they live, and to the community to which they belong, for the performance of the duties of good subjects and good citizens, have an undoubted claim to it, and cannot with any just reason be deprived of it.

It is not error, but injury to the state, or the individuals who are under the care of it, which justifies the animadversion of the magistrate; and all to whom this cannot be justly imputed, are the objects of his protection.

Archdeacon Paley distinguishes two kinds of toleration: the one partial, which is the allowing to differents the unmodelled profession and exercise of their religion, but with an exclusion from offices of trust and emolument in the state; and the other complete, which is the admission of them, without distinction, to all the civil privileges and capacities of other citizens. The justice and expediency of toleration in general is founded by this ingenious writer primarily in its conduciveness to truth, and in the superior value of truth to that of any other quality which a religion can possess.

Besides this principal argument for toleration, there are other
other auxiliary considerations that are important. The
restrictive of the subject to the religion of the state is a
needless violation of natural liberty, and in an instance with
regard to which it is always grievous. Persecution
produces no sincere conviction, nor any real change of
opinion; on the contrary, it vitiates the public morals, by
driving men to prevarication, and commonly ends in a
general though secret infidelity, by imposing, under the name of
revelled religion, systems of doctrine, which man cannot
believe, and dare not examine; finally, it disgraces the char-
acter, and wounds the reputation of Christianity itself, by
making it the author of oppression, cruelty, and bloodshed.
Our author includes under the idea of religious toleration
the toleration of all books of serious argumentation, without
deeming it any infringement of religious liberty to restrain
the circulation of ridicule, invective, and mockery upon
religious subjects.

Concerning the admission of dissenters from the established
religion to offices and employments in the public service,
which is necessary to render toleration complete, doubts, says
Dr. Paley, have been entertained with some appearance of
reason. In vindication of these doubts, he refers to those
who hold religious opinions that are utterly incompatible
with the necessary functions of civil government; enthusiasts,
who maintain that all distinction of property is abolished by
Christianity, and that the gospel enjoins upon its followers a
community of goods; and to Quakers or Friends, who be-
lieve it to be contrary to Christianity to take up arms. He
allows, however, that with the single exception of refusing
to bear arms, the various acts of Christians which actually
prevail in the world hold no tenet which incapacitates men
for the service of the state. It has indeed been asserted,
that disunity of religions, even supposing each religion to be
free from any errors that affect the safety or the con-
cuct of government, is enough to render men unfit to act
together in public stations. But upon what argument, or
upon what experience, is this assertion founded? “I per-
ceive no reason,” says this liberal writer, “why men of
different religious persuasions may not fit upon the fame
bench, deliberate in the same council, or fight in the same
ranks, as well as men of various or opposite opinions upon
any controverted topic of natural philosophy, history, or
ethics.” For a further account of this author’s sentiments on
toleration and collateral subjects, see RELIGION, Sub-
scription, and Test-Act.

To the term Toleration, though it has been adopted by
Mr. Locke and several writers of the first distinction, others
have objected; alleging that, as words have a considerable
influence on opinions, this term appears to be injurious to
that religious liberty, which it is designed to import. It
implies a right to impose articles of faith, and modes of
worship; that nonconformity is a crime; and that the suf-
ferrance (toleration) of it is a matter of favour or lenity.
But the nonconformist in every country, whether he be a
Christian at Constantinople, a Protestant at Rome, an Epis-
copalian in Scotland, or a Presbyterian in England, and,
we may add, a Catholic in any part of Great Britain, if his
rational principles be consonant to his practice, will regard
this claim of right as usurpation; and will urge, that it has
been neither conferred by Jesus Christ, nor delegated by the
people. Our Saviour expressly declares, “My kingdom
is not of this world;” and his religion was persecuted and
oppressed, during the period of its greatest purity and per-
fecion, and when the ministers of it had grins and powers
which are now unknown. The people could not delegate
such a right to any man or body of men; for the human mind
is so mutable, that no individual can fix a standard of his
own faith, much less can be commission another to estab-
lish one for him and his posterity; and this power would be in
no hands so dangerous as in those of the flateeman or priet,
who has the folly and presumption to think himself qualified
to exercise it. The use of this term was introduced at a
time, when very imperfect notions of religious liberty, and
very erroneous ideas of the authority of the civil magistrate
in the province of religion, prevailed. In its literal accept-
ation, it is without doubt objectionable, and incompatible
with just views of religious liberty. What human being,
however exalted his rank or extensive his influence, can pre-
sume to tolerate or suffer a fellow-creature to worship God
according to the dictates of his own conscience, and in that
way, or according to those rites and forms, which he ap-
prehends the object of his worship has preferred; or, in
other words, to tolerate God in receiving that worship; for
to this extreme the argument may be extended. All dif-
fabilities and penalties incurred by not worshipping God,
and performing other acts of religion, according to any merely
human ritual, are in fact prohibitions against man’s ren-
dering and God’s receiving the homage of the understanding
and the heart. Toleration, it has been said, supposes on
the part of those who exercise it an authority, to which they
have no just claim; and on the part of those who are the ob-
jects of it, a certain degree of criminality and culpability,
which the persons that exercise the right of toleration con-
decend to excuse and allow. Such are the ideas which some
modern writers have entertained on this subject; and ac-
cordingly they have witheld for a difufe of the term, as it is
found in, and leads to, error. Liberty, whether it be com-
plete, or partial, is a term well understood; and the use of it
is lefs liable to objection than that of toleration.—See on this
subject, Fownes’s Inquiry into the Principles of Toleration,
&c. 8vo. 1772. Locke’s Letters concerning Toleration,
in his Works, vol. ii. p. 231, &c. Headly’s Rights of Sub-
jects, passim. Paley’s Philosophy, vol. ii. c. 10. Per-
ville’s Essay on Truth, p. 90.

To the account above given of the general principles of
toleration, it will be proper to add a few words concerning
the state of toleration in our own country. With regard to
the Protestant-dissenters in general, see Dissenters,
Non-
conformists, and Quakers. See also Convictic
Corporation—Act, Sheriff, and Test.

As for dissenting teachers, or ministrors in particular, they
were prohibited by 17 Car. II. cap. 2. from coming within
five miles of a city, town-corporate, or borough, unless
only in passing upon the road, or unless required by legal
proceeds, without taking an oath of allegiance therein men-
tioned, on pain of 40l., and of commitment by two justices,
on oath of the offence, for six months. And by 22 Car. II.
cap. 1. preaching in any meeting or conventicle, in other
manner than according to the practice of the church of
England, incurred a forfeiture of 20l. for the first
offence, and for every other offence 40l. Moreover, by
13 & 14 Car. II. cap. 4. no perdon shall presume to confecrate
and administer the sacrament before he be ordained priest,
according to the form of the church of England, on pain of
100l. But now by 1 W. cap. 18. commonly called the
Act of Toleration, which, by 19 Geo. III. cap. 44. is
declared to be a public act, they are exempted from the
penalties of those statutes, upon taking the oath of al-
legiance and supremacy, and subseribing the declaration
against popery; and also, by 1 W. cap. 18. subseribing
the articles of religion mentioned in the flate. 13 Eliz. cap. 12.
(which only concern the confession of the Christian faith
and the doctrine of the sacraments) with an express excep-
tion of those relating to the government and powers of the
church,
TOLERATION.

church, and to infant baptism; or if they scruple subscribing the articles, upon making and subscribing the declaration prescribed by stat. 19 Geo. III. cap. 44, professing themselves to be Christians and Protestants, and that they believe the Scriptures of the Old and New Testament, as commonly received among Protestant churches, to contain the revealed will of God, and that they receive the same as the rule of their doctrine and practice; for the register of which they shall pay 6d. to the officer of the court and no more, and 6d. for a certificate thereof signed by such officer. A further enlargement of the Toleration Act, in favour of those who impugn the doctrine of the Trinity, was made by 53 Geo. III. c. 162.

Any preacher or teacher, duly qualified, shall be allowed to officiate in any congregation, although the same be not in the county where he was so qualified, provided that the place of meeting hath been duly certified and registered, and such teacher or preacher shall, if required, produce a certificate of his having so qualified himself, and before any justice of such county where he officiates, make and sub-\footnote{I.}scribe such declaration, and take such oaths as aforesaid, if required. \footnote{10 Ann. cap. 2.} And every such teacher, having taken the oaths, and subscribed as above, shall from thenceforth be exempted from serving in the militia, or on any jury, or from being appointed to bear the office of churchwarden, overseer of the poor, or any other parochial or ward office, or other office in any hundred, city, town, parish, division, or wapentake. For the state of dissenting school-masters, see School-\footnote{IV.}Master.

In consequence of the Toleration Act, non-conformity is no longer a crime in the eye of the law, and the penalties to which it was obnoxious are not only suspended, but absolutely annulled with regard to those dissenters who are qualified as the act directs. See Furneaux's Letters to Judge Blackstone, letter i. See Dissenters.

For an account of the laws relating to Papists or Catholics, see Papists. We shall here state the toleration granted to Catholics by the 31 Geo. III. c. 32. By this act it shall be lawful for persons professing the Roman Catholic religion, to appear in any of the courts at Westminster, or at the general quarter sessions for the county, city, or place where he shall reside, and there in open court, between the hours of nine in the morning and two in the afternoon, take, make, and subscribe the following declaration and oath: viz.

"I A. B. do hereby declare, that I do profess the Roman Catholic religion."

I A. B. do sincerely promise and swear, that I will be faithful and bear true allegiance to his Majesty king George the Third, and him will defend to the utmost of my power, against all conspiracies and attempts whatsoever, that shall be made against his person, crown, or dignity; and I will do my utmost endeavour to delfo and make known to his majesty, his heirs and successors, all treasons and traitorous conspiracies which may be formed against him or them: and I do faithfully promise to maintain, support, and defend, to the utmost of my power, the succession of the crown; which succession, by an act intituled, An Act for the further limitation of the crown and better security of the rights and liberties of the subject, is added and limited to the princes Sophia, electresses and duchesses dowager of Hanover, and the heirs of her body, being Protestants, hereby utterly renouncing and abjuring any obedience or allegiance unto any other person claiming or pretending a right to the crown of those realms. And I do swear, that I do reject and detest, as an unchristian and impious position, that it is lawful to murder or destroy any person or persons whatsoever, for or under pretence of their being heretics or infidels; and also that unchristian and impious principle, that faith is not to be kept with heretics or infidels. And I do further declare that it is not an article of my faith, and that I do renounce, reject, and abjure the opinion, that princes excommunicated by the pope and council, or any authority of the see of Rome, or by any authority whatsoever, may be deposed or murdered by their subjects, or any person whatsoever. And I do promise that I will not hold, maintain, or abet any such opinion, or any other opinion contrary to what is expressed in this declaration. And I do declare, that I do not believe that the pope of Rome, or any other foreign prince, prelate, state, or potentate, hath or ought to have any temporal or civil jurisdiction, power, superiority, or pre-eminence, directly or indirectly, within this realm. And I do solemnly, in the presence of God, profess, testify, and declare, that I do make this declaration, and every part thereof, in the plain and ordinary sense of the words of this oath, without any evasion, equivocation, or mental reservation whatever; and without any dispensation already granted by the pope, or any authority of the see of Rome, or any person whatever; and without thinking that I am or can be acquitted before God or man, or absolved of this declaration, or any part thereof, although the pope or any other person or authority whatsoever shall dispense with or annul the same, or declare that it was null or void."

Which said declaration and oath shall be subscribed by such person with his name at full length, if he can write, and if not, with his mark, and his name shall be written by the officer, adding his title, addition, and place of abode, which shall there remain of record; and such officer shall make, subscribe, and deliver a certificate of such declaration and oath having been duly made and taken, if demanded, for which he shall have 2s.; which certificate shall be competent evidence, unless falsified.

And such officer shall yearly, on or before the 25th of December, transmit to the privy council lists of the persons, with their titles, additions, and places of abode, who shall have made and subscribed such declaration and oath in the preceding year.

And no Roman Catholic, who shall have taken and subscribed the said oath as aforesaid, shall be convicted upon any of the acts following; viz.: 1 Eliz. c. 2. 23 Eliz. c. 1. 29 Eliz. c. 6. 35 Eliz. c. 2. 1 Jac. I. c. 4. 3 Jac. I. c. 4. 3 Jac. I. c. 5. and 7 Jac. I. c. 6. or any other statute or law of this realm; or in any ecclesiastical court, for not resorting to church, or having servants who shall not resort to church, or other place of common prayer.

And by 43 Geo. III. c. 30. Roman Catholics taking and subscribing the declaration and oath contained in the 31 Geo. III. c. 32. shall be entitled to all the benefits of the 18 Geo. III. c. 60. to every purpose as if they had taken the oath thereby prescribed.

And whereas, by 23 Eliz. c. 2. 27 Eliz. c. 2. 35 Eliz. c. 2. 2 Jac. I. c. 4. 3 Jac. I. c. 5. 3 Car. I. c. 2. 25 Car. II. c. 2. Papists are made subject to several punishments, penalties, and disabilities, it is enacted that no person who shall take and subscribe the said oath in manner aforesaid, shall be prosecuted or convicted for being a Papist, or reputed Papist, or for professing or being educated in the Popish religion, or for hearing or paying mists, or for being a priest or dean, or entering or belonging to any ecclesiastical order or community of the church of Rome, or for being present at or performing or observing any rite, ceremony, practice, or observance of the popish religion, or maintaining or asffiling others therein.

Provided always, that no place of congregation or assembly for religious worship shall be allowed, until the place of
of such meeting shall be certified to the feftions of the county or place in which the same shall be held, and be there recorded; and the clerk of the peace shall give a certificate thereof, if demanded, for which he shall have 6d. And no minister or other person shall officiate in any such place of meeting until his name and description as a priest or minister shall have been recorded at the feftions, for which shall be paid 6d. and a certificate thereof shall be granted, if demanded, for which shall be paid 2s. And no priest or minister who shall officiate in any such meeting not so recorded as aforesaid shall be deemed to be within the benefit of this act for any purpose whatever.

Provided, that if any such place of assembly shall have the doors locked, barred, or bolted, during the time of meeting, all persons who shall come to or be at such meeting shall receive no benefit from this act, notwithstanding his having taken such oath as aforesaid, but shall be liable to the same pains and penalties, as if this act had not been made.

If any Roman Catholic shall hereafter be appointed high or petty constable, churchwarden, overseer of the poor, or any other parish or ward office, and shall refuse to take upon him any of the said offices, he may execute the same by a sufficient deputy, to be approved of in like manner as other persons.

Every minister of any Roman Catholic congregation who shall take and subscribe the said oath in manner aforesaid, shall be exempt from serving on jury, and from the office of church-warden, overseer, or other parish or ward office, or any other office in any hundred of any shire, city, town, parish, division, or wapentake.

But all laws made for frequenting divine service shall continue in force, unless where persons shall come to some religious worship permitted by this act, or an act of 1 W. & M. for exempting Dissenters.

And if any person shall wilfully and on purpose maliciously and contumeliously come into any congregation or assembly of religious worship permitted by this act, and disturb the same; or misuse any priest, minister, preacher, or teacher therein, he shall, on proof by two witnesses, before one justice, find two sureties of the peace to be bound by recognizance in 50l. and in default thereof, shall be committed to prison till the next feftions, and on conviction of such offence at the feftions, shall forfeit 20l. to the king.

Provided, that no benefit herein contained shall extend to any Roman Catholic ecclesiastic permitted by this act, who shall officiate in any congregation, or assembly hereby permitted, with a fleeping and bell, or at any funeral in any church or church-yard; or who shall exercise any of the rites or ceremonies of his religion; or wear the habits of his order, fave within some place of congregation, or assembly for religious worship permitted by this act; or in any private house where shall not be more than five persons assembled besides those of the household; or who shall not previously to his so exercising his function have taken the oath of allegiance, abjuration, and declaration hereby appointed, in manner aforesaid.

But nothing herein shall exempt any Roman Catholic from paying tithes or other parochial duties, or any other duties to the church or minister; or to repeal any part of 26 Geo. II. c. 33. "for preventing clandestine marriages," or any parts of any statutes concerning marriages; or to give any safe or benefit to any person who shall, by preaching, teaching, writing, deny or gain the oath and declaration aforesaid, or the doctrines therein contained, or any of them; or to repeal or affect any law concerning the right succession to or limitation of the crown.

And no Roman Catholic, who shall take and subscribe the said oath of allegiance, abjuration, and declaration, as aforesaid, shall be profecuted for teaching youth as a tutor or school-maister; but he shall not hold any manorship of any college, or school of royal foundation, or of any other endowed college or school for the education of youth; nor shall keep a school in either of the universities; nor shall receive into his school for education the children of any Protestant father; nor shall teach any school until his name shall be entered at the feftions in manner aforesaid, as a Roman Catholic schoolmaster; and no person offending in the premisses shall receive any benefit from this act.

Provided also, that nothing herein shall make it lawful to found, endow, or establish any religious order or society of persons bound by monastic or religious vows; or any school, academy, or college by any Roman Catholic; and that all usages, trusts, and dispositions, whether of real or personal property, before deemed to be unlawful, shall continue to be so deemed.

No person shall be summoned to take the oath required by 1 W. & M. feft. 1. c. 3. or the declaration required by 25 Geo. II. c. 2. Nor shall the 1 W. & M. feft. 1. c. 9. for removing Papists from London and Westminster, extend to Roman Catholics who shall have taken and subscribed the oath, &c. herein appointed.

No peer who shall have taken and subscribed the said oath, &c. in manner aforesaid, shall be liable to be profecuted under 30 Car. II. fl. 2.

And the 1 Geo. I. feft. 2. c. 55. and 3 Geo. III. c. 18. requiring Papists to register their names and real estates are repealed; and all deeds and wills of Papists shall, after the 24th of June 1791, be good as if the said acts had never been made.

And whereas by 7 & 8 Will. c. 4. and 1 Geo. I. ft. 2. c. 13. every person acting as a counsellor at law, barrister, attorney, solicitor, clerk, or rotarian, not having taken the oaths and declaration therein prescribed, should be liable to certain penalties, it is enacted that these oaths and declarations shall be no longer required; but the oath and declaration herein appointed shall be taken in lieu thereof, in manner aforesaid.
