vation is made. The superficial temperature of the earth varies
also with the latitude and the season, and in a still greater
degree if the land be dry; but the internal temperature of the
earth appears to be permanent in each place throughout
the whole year. At a certain depth under the surface, the
thermometer always indicates the same degree of heat; and
the difference between the permanent internal temperature
in different latitudes, is much less than that which exists at
the surface. The depth at which the thermometer remains
stationery about latitude $52^\circ$, is 80 feet; nearer to the
equator,
TEMPERATURE.

equator, or the poles, a greater depth would be necessary to obtain the permanent temperature. At still greater depths, probably, the temperature under each degree of latitude is the same all over the globe, except in the vicinity of volcanic fires.

M. Volney, in his travels through North America, speaking of the temperature of the earth, endeavours to oppose the opinion of its permanent internal temperature. Setting out from Lake Superior, he says, and proceeding well to the Stoney mountains, and travelling north as far as latitude 72°, the country now well known to the Canadian traveller, displays a climate that for severity of cold can be compared only to Siberia. From latitude 46°, the earth is frozen during the whole year. At several trading posts between latitude 50° and 56°, it was found impossible to have wells. Mr. Shaw had attempted to dig one at the post of St. Agustin, about forty miles from the mountains; but though it was in the month of July, the ground was frozen at the depth of three feet from the surface, and as it grew harder he was obliged to give up the attempt. He relates also an account of Mr. Robson, an English engineer, who attempted to sink a well at Prince of Wales’s fort, latitude 59°, in the month of September. He first found thirty-six inches of earth thawed by the preceding warm weather, then a stratum of eight inches frozen as hard as a stone; under this a stratum of sandy friable earth, frothy and very dry, in which his borers could find no water. The celebrated traveller Ledyard, says Volney, affirms, that at Shukts, not so high as latitude 62°, wells of water cannot be obtained, because it is found by experiment that water-freezes at the depth of six feet. From these circumstances, M. Volney would infer that the internal part of the earth is in a constant state of congelation. Some of the above observations, we believe, were inadmissible; and it has been too hastily determined, that the earth is frozen during the whole year in North America, even in latitude 46°; for this is not the case 110° further north. We have been favoured with the following statement from an intelligent medical gentleman, who was some years resident in Hudson’s Bay. “On digging a well at York fort, Hudson’s Bay, latitude 57° 7′, in the beginning of October, the following circumstances were remarked. About thirty inches from the surface, a bed of frozen earth, about twelve inches thick, was met with; below was a bed of loose sandy clay, about half a yard thick, which was succeeded by a bed of the same clay, rendered perfectly hard and solid by frost. Sinking lower, similar beds of frozen and loose earth were found, alternating with each other; the frozen beds, however, constantly decreasing in thickness, though not regularly, and at a certain depth they seemed to disappear entirely. These frozen strata are considered by the inhabitants as indications of the severity of the preceding winters, each stratum being suppos’d, with much probability, to be formed in different years, and to be travelling downward until they are thawed by the internal temperature of the earth. The processes by which they sink down may be explained, on the supposition that the upper surface is diminishing by heat during summer, and the under surface increasing by the congelation of moisture in contact with it. Another circumstance, which took place in the same latitude, may serve to elucidate the obervation of Ledyard, that the water was constantly frozen at sixty feet under the surface at Shukts.” A well had been sunk which yielded a plentiful supply of water during the first summer; but the water, being exposed to the air, froze during the next winter, and remained frozen ever after, being too far below the surface to be thawed. Hence it appears that water exists unfrozen at a moderate depth under the surface in the coldest climates, when it has no communication with the external air. The effect of the summer heat in the same latitude extends about seventeen inches under the surface, where the ground has been shaded; but where it has been exposed to the sun, the surface is thawed to the depth of three feet. From the small depth to which the solar heat penetrates, we may infer that the water below is kept in a fluid state by the internal heat of the globe. It has been generally supposed, that the permanent temperature of each latitude is the same nearly as the mean annual temperature of the atmosphere, and that this is indicated by the temperature of springs or deep wells; but the temperature of springs will vary with that of the strata near the surface through which they run. (See Temperature of Springs.) It is to be regretted that more numerous observations have not been made on the temperature of deep mines. From observations recently made in Cornwall, it appears that the temperature increases with the depth, at least in some of the mines, and in the lowest it was not less than 75°. This may, perhaps, be owing to the chemical changes which are taking place; for it appears, from the evidence of the overseers of the mines, in reply to certain queries proposed by the Royal Geological Society of Cornwall, that the water is found constantly warmer in the vicinity of veins of copper-ore, than it is in the vicinity of tin-ore; the former veins are in general worked to a greater depth than the latter. It remains to be ascertained whether this increase of temperature be owing to chemical causes, or is invariable at the same distance from the surface. The decomposition of pyrites in copper veins would seem to point out a cause for the increased temperature in their vicinity; it is evident, however, that it is not derived from the solar rays. It seems reasonable to believe, from what we are present knowledge of the internal temperature of the earth, that there exists a permanent source of heat within the globe, though we are unacquainted with the causes by which it is generated. We are equally ignorant of the causes by which light is generated on the surface of the sun; one operation is not more surprising or inexplicable than the other; nor is the difficulty removed, by supposing the sun to be surrounded with a luminous atmosphere. Some philosophers have maintained the opinion, that the earth has been constantly growing colder since the period when it was first inhabited, and that the organic remains of animals and other animals, (supposed to be similar to those of tropical climates,) which are found in Siberia, offer a demonstrative proof, that the arctic regions once enjoyed the temperature of the torrid zone. It has since been ascertained, by the elaborate researches of M. Cuvier, that these animals were not of the same species as the African or Asiatic elephant. A most convincing proof of this was afforded by the entire body of one of these elephants, which was discovered imbedded in ice near the mouth of a river in the north of Siberia, by a Tungusian fisherman, in the year 1799. It first presented a shapeless mass projecting from an ice-bank. Two years afterwards he could distinctly see that it was the body of an enormous animal; the entire blank and one of its tusk had become disengaged from the ice. In 1803, the ice beginning to melt earlier than usual, the whole body was disengaged, and fell from the ice-bank on the sandy shore. In 1806, Mr. Adams went to examine this animal, which still remained on the sand, but its body was much mutilated. The skin was extremely thick and heavy, and as much of it remained as required the exertions of ten men to carry away. More than thirty pounds of the hair and bristles of the animal were collected. Some of this
TEMPERATURE.

For the temperature of the atmosphere, see Atmosphere, where the mean temperature in different latitudes is given. Mr. Humboldt has lately published a botanical account of the new genera and species of plants discovered in the tropical regions of America, with many interesting observations on the temperature, as affecting the growth of plants. The plants of the torrid zone extend farther through the southern temperate zone than through the northern, owing to the greater influence of the ocean in the southern hemisphere, in moderating the rigour of winter; the ocean bearing a much greater proportion to the surface on the south, than on the north side of the equator. In estimating the climate suited for the growth of particular plants, the mean temperature will not afford a correct standard; for though the mean temperature of the year, in the middle latitudes of North America, be the same as it is in Europe, 7° further north, the temperature of different seasons in these same latitudes by no means agrees. The winters are colder, and the summers hotter, in North America than in Europe. In Philadelphia the summer is as hot as at Rome or Montpellier, while the winter corresponds with that at Vienna. At Quebec the summer is warmer than at Paris, but the winter colder than at St. Petersburg. In the north of China there is a still greater difference between the heat and cold, than in North America.

In North America, as far as latitude 48°, the summers are four centigrade degrees, or about 7° Fahrenheit, hotter than in the corresponding latitude in Europe. Between the tropics, the mean annual temperature is the same as on the old continent, which may be seen in the following table, expressed in degrees of the centigrade thermometer.

<table>

Twenty-five degrees correspond with seventy-seven degrees of Fahrenheit.

Though the plants of the torrid zone extend farther through the southern temperate zone than through the northern, as we have before stated; yet to a certain distance from the line, the temperature appears to be less on the south than on the north side. Rio Janeiro and Havannah are nearly at the same distance from the equator; but the mean temperature of the summer and winter months in each is as under:

On the coast of Peru, the temperature is diminished by the perpetual cloudiness of the sky, and by a strong sea current setting in from Cape Horn. From the tropic to 34° of south latitude, the mean temperature of the southern hemisphere scarcely differs from that of the northern. Between latitude 34° and 57°, there is a greater difference between the temperatures of summer than of winter: the winters in the southern hemisphere are not colder, but the summers are considerably more so than in the northern hemisphere. In south latitude 48°, the summer temperature is the same as the winter temperature of Toulon, Cadiz, and Rome.

The higher we ascend above the level of the sea, and the farther we advance from the equator, the greater is the difference.
difference between the temperature of different seasons of the year. The following table exhibits the temperature between the hottest and coldest months, in different latitudes.

In the temperate zone, as we advance northwards, the coldest of the winter increases at a much greater rate than the heat of the summer diminishes. Thus at Enonleis, in latitude 68⁰ 30', the temperature of July is as hot as that of Edinburgh. Between the tropics, the temperature at no season of the year equals that of the sea-shore; but in the temperate zone, the upper currents of air are sometimes warmer than the lower, during the winter months; and the thermometer, on the summits of hills, is occasionally three or four degrees higher than in the plains. Hence in the temperate zone, we find the same plants frequently on low and elevated situations; but this is never the case between the tropics. In the temperate zone on the old continent, when the mean heat of the month is as under, the following plants blossom:

The reason why plants vegetate with greater rapidity in Lapland and Norway than farther south, is owing to the increment of temperature being much greater, and to the temperature of the earth in winter being several degrees above that of the air.

From observations made in different latitudes, it appears that 1000 fathoms of altitude occasion a diminution of temperature equal to 23⁰ of Fahrenheit; 50 fathoms being nearly equal to half a degree. Mountains 1000 fathoms in height, at 46⁰ of latitude, have the mean temperature of Lapland; and mountains of the same height between the tropics enjoy the temperature of Sicily.

The following table by Humboldt exhibits the most remarkable circumstances respecting the temperature in the three zones. The temperature is taken according to the centigrade thermometer. The fathom 6 French feet, or 6.39453 English feet.

In the seventh volume of the Transactions of the Royal Society of Edinburgh, Dr. John Murray has published a paper on the diffusion of heat on the surface of the earth; in which he attempts to prove, from the nature of caloric, that the temperature of the earth is constantly increasing from the solar rays, and that this temperature is becoming more equal in different parts of the earth. The atmosphere, he contends, conveys no heat into unlimited space; our planet, in relation to the discharge of caloric from it, is bounded as it were by a wall of iron-conducting matter. He admits, however, that a small portion of heat may be lost by radiation; thus, at the hotter parts of the earth's surface, there may be some emission of caloric by radiation; but this, he says, cannot be equal to the quantity communicated by the solar rays; for of the heat derived from the latter source, a portion is absorbed by the earth, and conveyed to the interior, as is apparent from the decreasing temperature, as we recede from the surface to a certain depth; and another portion is carried off by the ascending current of heated air, and conveyed to colder regions, where it is absorbed. Thus, even
even from those parts of the surface of the earth where the circumstances are most favourable to radiation, the quantity radiated cannot be equal to the quantity received from the solar rays. Over the whole earth the diffusion must be still greater; and instead of the conclusion, that the planet discharges its excess of heat by radiation, there is every reason to draw the opposite conclusion, that part of the heat which it receives from the sun is retained. He further infers, that the temperature of the globe must rise, from the mode in which heat is communicated to it by the sun; and at the same time, as it advances, must become more equal over the whole surface. And this rise has its limits. There cannot be either unlimited increase of heat, or unlimited refrigeration; but the final result will be a state of permanence and uniformity, the continuance of which is secured by the very circumstance, that if it is deviated from, this deviation must correct itself by an increase of radiation from the hotter parts, or by an increased absorption of caloric by the colder parts of the globe. According to this theory, in processes of time, the equatorial and polar parts of the globe will arrive at the same degree of temperature, which will remain stationary, as there will be no circulation of heated air or water to the poles. To this reasoning we conceive it may be objected, that it assumes, without sufficient grounds, that caloric cannot pass from the earth into unlimited space, and that the solar heat does not become latent by chemical union with terrestrial substan substance. It affirms also, that caloric is a distinct specific substance; an opinion which is denied by some of the most eminent philosophers. Nor have we, perhaps, any evidence to prove that the temperature of the earth has changed since the earliest records of history, if we except the local changes which result from drainage and cultivation. It is well known that the climate of Europe is materially changed since the periods of ancient history, when the Danube was annually frozen, and would admit the passage of armies over the ice. The climate of the United States of America has also undergone a material change during the last century. Both these local changes have been produced by the same cause, the destruction of extensive woods, and the progress of agriculture; but, independently of local causes, we have no data to infer that the temperature of the globe is increasing or diminishing.

**Temperature of the Sea.** The temperature of the sea near the surface is affected by the changes of temperature of the atmosphere, and by the currents which traverse it. The currents which flow from the equatorial to the polar regions, serve to equalize the heat of different latitudes. This is remarkably the case with the current called the Gulf stream, which passes by the shores of Mexico, Louisiana, and Florida, and rounds the point of the peninsula, under the shelter and protection of the Bahama islands, which break the efforts of the ocean and the current of the trade wind. This stream, on entering the ocean, preserves its water by the velocity of its current, and may be further distinguished by its colour and temperature. The temperature is from eleven to twenty-two degrees higher than that of the ocean. From the Floridas to Newfoundland the current continues increasing in breadth, and diminishing in velocity. Some experiments made by Mr. Jonathan Williams, give the difference of temperature between the Atlantic ocean and the Gulf stream as under, December, 1789.

| Soundings in shoal-water, on the coast, | 60° | Fahrenheit. |
| Soundings in the stream, | 56° | |
| Before reaching Newfoundland, in the stream, | 47° | |
| At Newfoundland, out of the stream, | 40° | |
| Beyond the banks, in the open sea, | 30° | |

On approaching the coast of England, Capt. Billings, in 1791, found the temperature of the sea on the coast of America, - 54°; in the water of the Gulf stream, - 77°; in the water of the Gulf stream, - 45°. In winter, Mr. Williams found the variation between the Gulf stream and the ocean 25°; the difference, as might be expected, being less in summer than in winter. These inquiries have ascertained another fact, from whence navigators may derive some advantage; for by examining the temperature of the sea in different places, it has been found that the water is colder in proportion to its shallowness; and hence may be derived an indication of the approach to land, or to a shoal. Out of the reach of currents, a difference always exists between the temperature of the surface and the lower parts of the sea. In northern latitudes, the surface is sometimes warmer and sometimes colder than the lower parts; but near the equator, the temperature of the surface may be expected to be invariably warmer than at great depths. In all probability, the temperature of the sea is permanent in each degree of latitude, at a certain depth. Capt. Ellis let down a sea-gage in N. lat. 25° 13', W. long. 25° 12'; he found the sea falter and colder in proportion to the depth, till the gage had descended 3900 feet, when the mercury in the thermometer came up at 53°; but the water did not grow colder, though he let down the gage 1400 feet lower. At the surface of the sea, the thermometer stood at 64°.

From the experiments of Capt. Douglas, near the coasts of Lapland and Norway, of which an account is given in the 6th volume of the Philosophical Transactions, the following differences were observed between the temperature of the sea at the surface, and at certain depths.

| Temperature at the Surface. | Depth in Fathoms. | Temperature. |
| May 12, lat. 70° 40', | 36° Fahr. | 78 to 87 | 59° |
| May 17, nearly the same, | 37 | 86 to 90 | 39 |
| May 22, lat. 70° 32', 12 leagues from the island of Lofoot, | 47 | 100 not at the bottom. | 46 |
| June 20, lat. 70° 54', | 44 | 98 | 40 |
| July 7, lat. 70° 45', | 46 | 70 at the bottom. | 44 |
| July 8, lat. 68° 43'; 20 or 25 leagues from the coast of Norway, | 48 | 100 at the bottom. | 46 |
| July 9, lat. 65° 25', above 30 leagues from the coast of Norway, | 52 | 210 at the bottom. | 48 |

From
The temperature of Springs. Those common springs which throw up a considerable quantity of water during the whole year, have generally a permanent temperature, or nearly so; and this is supposed to represent the mean temperature of the earth in each latitude; but there are other springs which have a much higher permanent temperature, and some which throw up their waters at a boiling heat. The following is the permanent temperature of some of the more celebrated warm springs in Europe.

The Geyser or boiling fountains in Iceland, in the Azores, and in various parts of the world, have a constant temperature of 212°F. The source of heat, in some of the latter springs, is evidently subterranean fire, as all those islands are of volcanic origin, and are the seats of active volcanoes at the present day. It is observed of other warm springs, that they generally rise in the vicinity of volcanic or basaltic rocks. This is the case with the warm springs of Matlock and Buxton. Rocks of basaltic amygdaloid extend through the high peak of Derbyshire, where these springs are situated. Rocks of basaltic amygdaloid, having a still more peculiar resemblance to volcanic lava, extend from Worcestor bridge, in Gloucestershire, in a direction southward, and, in all probability, are continued under the surface to Bath and Bruttol. According to Humboldt, hot springs rise from granite and rocks denominated primary, in various parts of South America; and, from the permanent high temperature of warm springs, we may infer that the source of heat is situated deep beneath the surface, and far below those causes which can change the temperature. It has been contended by some persons, that the high temperature of warm springs arises from the decomposition of pyritic flata; but if this were the case, the waters would be strongly impregnated with sulphate of iron and other mineral matters, which is not the fact; the temperature would also decrease as the pyritic matter became exhausted, of which we have an analogous illustration in the saline springs of Cheltenham and Gloucester. These springs rise in a deep stratum of blue clay, denominated litts, (see Strata of England,) which abounds in pyrites, and in animal remains; and it is found by experience, that the saline impregnation is greatest where the wells are first opened, and that the strength of the waters gradually declines; on which account, the proprietors are under the necessity of sinking fresh wells to obtain water of the requisite saline strength. This might be expected; for as the water percolates through fissures in the clay, the saline matter in its vicinity is gradually washed away. But if the whole bed were in a state approaching to ignition, from the decomposition of pyrites, the saline impregnation would be constantly supplied to the springs; for we cannot suppose any quantity of pyritic matter to exist equal to heat a whole stratum by decomposition, without, at the same time, generating such an abundance of saline matter as must saturate the waters which percolate through it. We are hence led to infer that the source of heat in warm springs is subterranean fire, and these springs have not been observed to diminish in temperature for a period of nearly two thousand years, we may further infer the great depth at which this source of heat is situated, an inference which is warranted by the connection which volcanoes in distant parts of the world appear to have with each other. (See Volcano.) It may be asked, if the source of heat in warm springs be subterranean fire, why are they not all of the same degree of temperature? To this it may be replied, that, in some instances, the warm springs may be intermixed with cold springs near the surface; and in other instances, after rising to a certain height, they may run in an horizontal direction for a considerable distance among the upper strata, and thus be gradually cooled. The cause which can raise up water from vast depths, must be sought for in the expansive power of steam, and effusive vapours generated by heat, which we know by experience to be fully adequate to the effect.
TEMPERATURE for Plants, in Gardening, the state of heat in which it is necessary to keep particular sorts of them, in order to their flowering or taking root, their healthy growth, and their succeeding in the best and most proper manner. The state or degree of heat, or the temperature, in all such cases, must be regulated and directed by the nature of the plants, their culture, and the situations in which they are grown. For those in hot-houses and stoves, the temperature, in those of the dry flow kind, should mostly be from about fifty to seventy degrees, according to the nature of the plants and manner of growth of the plants; and in those of the moist flow kind, from about sixty to ninety degrees, as the nature of the beds and plants may be. Plants in conservatories are kept at various temperatures between those of the first kind of the above stoves and that of the common open air. And in greenhouses, nearly similar temperatures are constantly to be preferred, in order to the raising, and to the growth of such plants, in the most suitable and best manner.

It is always of great utility and importance to keep the temperatures as steady as possible, whatever its state may be, in the growth of all these sorts of tender plants.

The temperatures, or states of heat for particular plants, are mostly given under their proper heads, in describing their culture.

TEMPERATURE of Milk for Chefs, in Rural Economy, the degree of heat which is the most proper in milk for the purpose of making cheese. From some experiments which have been lately made upon the subject, this temperature would seem to be about the middle point between that of summer and blood heat; or, perhaps, somewhere about ninety degrees of Fahrenheit's scale may give the average degree of warmth which is most proper and necessary in the business.

TEMPERING, in the Mechanic Arts, the preparing of steel and iron, so as to render them more compact, hard, and firm; or even more soft and pliant; according to their respective occasions.

These metals are tempered by plunging them, while red-hot, into some liquor prepared for the occasion; sometimes pure water is used for that purpose: our locksmiths, &c. scarcely use any other.

When an instrument has been properly hardened, it is necessary to give it a certain degree of softness, in order to adapt it for the purpose to which it is to be applied. With this view, it should be heated again to a certain point, usually determined by its colour, and then infatantly plunged into cold water. This is called "letting it down to the proper temper." It has been a question of difficult solution, how the water acts in hardening iron and steel. It is well known, says Mr. Parke, in his "Chemical Essays," (vol. iv.), that the hotter any piece of iron is made, and the more quickly it is cooled, the harder it will become in its texture; and he suggests that this may be owing to the loss of its latent heat. In confirmation of this conjecture he alleges, that iron and steel are generally allowed to owe their malleability to their latent heat.

A composition of divers juices, liquors, &c. has sometimes been used; which is various according to the opinion and experience of the workman: as vinegar, muste-ear water, nettle or Spanish radish-water, the water oozing from broken glaftes, fuel, salt, foot, directed wine, fal ammoniac, urine, &c. But these methods are now generally abandoned. Mr. Stoddart, a very ingenious and scientific cutter in London, says, (as Mr. Nicholson informs us, Journal, vol. iv. 410.) that one of his workmen makes up his charcal fire with shavings of leather, finding that this is effectual in preventing the tools from cracking in the process of hardening; and he says, that he has found no advantage from the use of salt in the water.

To harden and temper English, Flemish, and Swedish steel, you must give them a pretty high heat; then suddenly quench them in water to make them hard; but Spanish and Venetian steel will need only a blood-red heat before they be quenched.

In consequence of this operation, all the qualities of steel are changed; so that from being very ductile and soft, it becomes so hard and stiff, that it is no longer capable of being cut by the file, but is itself capable of cutting or piercing very hard bodies, and that it does not yield to the hammer, but may be sooner broken in pieces than extended. It becomes also porous, brittle, very elastic, and capable of acquiring the most beautiful polish. This hardness and ductility of steel may be diversified by varying the temper. The hotter the steel is when tempered, and the colder the water into which it is plunged, the greater hardeness it acquires, but at the same time it becomes so much more brittle. The coldness of the water may be increased by diffusing faults in it: observing that water is always colder while the faults continue diffusing; and that the steel will cool sooner by being stirred about or placed in a stream, so as to come in contact with water not already made warm. On the contrary, the less hot the steel is when tempered, and the hotter the water is in which it is tempered, the less hard it becomes, and also the greater ductility it retains; and the proper degree of heat is always relative to the use for which the tools made of the steel are intended.

If the steel be too hard or brittle for an edged tool, &c. let it down by rubbing a piece of grindstone or whetstone hard upon the work, to take off the black scurf: then brighten, or heat it in the fire: and as it grows hotter, you will see the colour change by degrees, in the manner and by the gradations stated under the article CUTLERY.

Saw-makers temper their tools by rubbing them over with fuel or other grease, and then heating them gradually till the temperature of each tool is sufficiently raised to set fire to the grease of itself and occasion it to blaze. They are thought to acquire in this mode of treatment a temper equal to that which would be obtained by heating them in the usual way, till they became of a deep blue. This operation, which is practised at Sheffield, is called "blazing." For the method of tempering files, in which the great desideratum is to blend tenacity with hardness, see FILE.

In the year 1789, Mr. David Hartley took out a patent for a method of tempering steel by the aid of a pyrometer or thermometer applied near to the surface of the article, and at the same time recommended the use of heated oil, in which (he says) many dozens of razors or other tools might be tempered at once with the utmost facility, and the various degrees of heat necessary for different purposes might speedily be determined by experiment. (See Nicholson's Journal, vol. iv. 410.) An improvement of this principle has been since suggested by Mr. Parkes (Chem. Eff. vol. iv.) by providing a bath of oil or of some kind of fusible metal for the tempering of every species of edged tool, which contrivance would, in his opinion, give to this operation a greater degree of certainty, than has ever been experienced by those who have conducted such manufactories. See TILLING.

Steel is usually cold tempered, because in many manufactories, the custom is to temper it as soon as it is made, probably that the purchasers of it may be better able to judge of its quality. When this steel is to be used, it must be untempered by heating it more or less, and letting it cool
cool slowly, that it may be extended, filed, and receive the necessary form; after which every workman tempers it again in his own way.

M. Berthoud, in his treatise on marine clocks, recommends hardening the fleel-balance wheel, by daubing it over with foot (or wood) moistened with urine, putting it into a small box of thin iron-plate, and covering it over with the same composition. This box with its contents is to be heated to a blood-red, and then the wheel taken out suddenly and quenched.

Mr. Harrison and M. Berthoud seem to agree upon the whole, that the balance-spring of time-pieces should be hardened and tempered after it has been cooled up in its proper form; and not tempered first and cooled up afterwards, as is the practice in making the main-spring. Some curious workmen, in order to equally temper small fleel instruments, employ melted lead as an intermedium. A plate of iron floats upon the melted lead, and receives from it, in all its parts, an equal heat: the pieces of fleel laid upon this plate, acquire all at once the same degree of heat, and are at once quenched in water; the blue or other colours, which they succeedly assume, affording sure marks of the proper points of heat at which they are to be quenched, according to the different degrees of hardeness required in them. Lewis's Com. Phil. Techn. p. 32.

For the method of tempering fleel bars for artificial magnets, practised by Mr. Canton, see Artificial Magnet.

The ancients appear to have had a better method of tempering than any of the moderns are acquainted with; witness their works in porphry; a stone so hard, that scarcely any of our tools make any impression upon it.

Tempering of Land, in Agriculture, a term signifying the preparing it for a crop, especially of wheat. It is a term in much use in Norfolk. It implies all the various operations that may be undertaken in this intention.

TEMPEST, TEMPESTAS, a storm or violent commotion of the air, with or without rain, hail, snow, &c.

Tempest, in Mythology, a deity among the Romans, concerning whom we merely know, that Marcellus, as an acknowledgment for having escaped a storm, with which he was overtaken at sea, between the islands of Corsica and Sardinia, built a temple to her without the Porta Capena.

TEMPESTA, ANTONIO, in Biography, was an ingenious designer and painter, born at Florence in 1555, and was initiated in the art by Santi di Tito; afterwards he studied under another artist, whose name was Stradanus. Tempesta was gifted with a brilliant and powerful imagination, not, however, of the most correct or exalted kind. His favourite subjects were battles, sieges, cavalcades, huntings, processions, &c.; all of which he arranged and designed in a novel and rich style, and executed with uncommon spirit and energy. He was employed by Gregory XIII. in the Vatican, where he adorned with grotesque inventions, and some few historical productions. He was also employed by the marchese Jufthinius in decorating his palace; and in several of the churches of Rome, Tempesta's paintings may be found.

He not only exercised his genius and time with the pencil, but devoted much of both to the etching needle; having left behind him nearly 1800 plates of different kinds, and of very considerable merit. He died in 1630, aged 75.

TEMPLE, in Geography, a town of the island of Sardinia; 25 miles E. of Castello Aragonese.—Alfo, a town of Mexico, in the province of Guadalajara; 500 miles N.W. of Mexico.

TEMPLARS, TEMPLARS, or Knights of the Temple, a religious military order, first established at Jerusalem, in favour of pilgrims travelling to the Holy Land.

The original of this order, the first military one in the world, is this: in 1118, some pious and noble personages devoted themselves to the service of God, in the presence of the patriarch of Jerusalem; promising to live in perpetual chastity, obedience, and poverty, after the manner of canons.

The two principal personages were Hugo de Pagani, and Geoffry of St. Omer. Baldwin II. then king of Jerusalem, gave them an apartment in his palace, near the temple at Jerusalem, not far from the sepulchre of our Saviour; whence their denomination Templars.

Soon afterwards, the canons of the temple gave them a piece of ground near the said temple, on which to build regular houses; and the king, the lords, the patriarch, and the prelates, each gave them something out of their revenue for food and clothes.

Their first undertaking, and what they had first in view at their institution, was, to guard the highway against robbers, &c. chiefly for the safety of pilgrims and crosses.

The principal articles of their rule were: that they should hear the holy office throughout every day; and that, when their military duties should prevent this, they should supply it by a certain number of pater noctors: that they should abstain from flesh four days in the week, and on Fridays from eggs and milk-meats; that each knight might have three horses, and one esquire: and that they should neither hunt nor fowl.

In the year 1228, this order acquired stability, by being confirmed in the council of Troyes, and subjected to a rule of discipline drawn up by St. Bernard.

In every nation they had a particular governor, called master of the temple, or of the militia of the temple. Their grand-master had his residence at Paris.

The order of Templars flourished for some time, and acquired by the valour of its knights immense riches, and an eminent degree of military renown: but as their prosperity increased, their vices were multiplied, and their arrogance, luxury, and cruelty, rose to such a monstrous height, that their privileges were revoked, and their order suppressed with the most terrible circumstances of infamy and severity. Their accusers were two of their own body, and their chief professor Philip the Fair, of France, who addressed his complaints to Clement V. The pope, though at first unwilling to proceed against them, was under the necessity of complying with the king's desire, so that, in the year 1307, upon an appointed day, and for some time afterwards, all the knights, who were dispersed throughout Europe, were feized and imprisoned. Such of them as refused to confess the enormities of which they were accused, were put to death; and those who, by tortures and promises, were induced to acknowledge the truth of what was laid to their charge, obtained their liberty. In 1312, the whole order was suppressed by the council of Vienne. A part of the rich revenues they possessed was bestowed upon other orders, especially on the knights of St. John, now of Malta, and the rest confiscated to the respective treasuries of the sovereign princes in whose dominions their possessions lay. —The knights Templars, in order to justify the severity with which they were treated, were charged with apostacy to the Saracens, and holding correspondence with them; with insulting the majesty of God; turning into derision the Gospel of Christ; and trampling upon the obligation of all laws, human and divine. Candidates, it is said, upon admission to this order, were commanded to spit, in token of contempt, upon an image of Christ, and after admission, to worship either a cat, etc.
cat, or a wooden head crowned with gold. It is farther
affirmed, that, among them, the odious and unnatural act
of sodomy was a matter of obligation; and they are charged
with other crimes too horrible to be mentioned, or even
imagined. However, though there be reason to believe
that in this order, as well as others of the same period, there
were shocking examples of impiety and profliocity; yet that
the whole order was thus enormously corrupt, is so far from
being proved, that the contrary may be concluded even
from the acts and records, yet extant, of the tribunals be-
fore which they were tried and examined. If to this we
add, that many of the accusations advanced against them
flatly contradict each other, and that many members of this
unfortunate order solemnly avowed their innocence, while
lunguishing under the severest tortures, and even with their
crying breath; it would seem probable, that this king Philip
of foot this bloody tragedy, with a view to gratify his
avarice, and glut his resentment against the Templars, and
deliberately against their grand-mother, who had highly
offended him. The principal cause of this invincible hatred
against them was, that in his quarrel with Boniface VIII.
the knights procured the caufe of the pope, and furnished
him with money to carry on the war. Molheim's Eccl.
Hist. vol. iii. ed. 8vo. Bower's Hist. of the Popes, vol. vi.
P. 393.

TEMPLE, Templum, a public building erected in
honour of some deity, either true or false; and in which
the people meet to pay religious worship to the same.
The word is formed from the Latin templum, which some
derive from the Greek τηπεινός, signifying the same thing;
and others from tempus, alēgno, E I cut v s, IP separated, because
a temple is a place separated from common uses; others, with
more probability, derive it from the old Latin word temperare,
to contemplate. It is certain the ancient augurs gave the name
temple to those parts of the heavens which were marked out
for the observation of the flight of birds. Their formula
was this: Templae tegmenta.

Temples were originally all open, and hence received their
name. See Phil. Trans. No. 471. sect. 5; where we have
an account of the ancient temple in Ireland of the fame fort
as our famous Stonehenge.

The word templum, in its primary sense among the old
Romans, signified nothing more than a place set apart, and
consecrated by the augurs, whether enclosed or open; in the
city, or in the fields.

Clemens Alexandrinus and Eusebius refer the origin of
temples to the sepulchres built for the dead. This notion
has been lately illustrated and confirmed by a variety of tel-
monies by Mr. Farmer, in his Treatise on the Worship of
Human Spirits, p. 373, &c. Herodotus, Lucian, and
Strabo, will have the Egyptians to have been the first who
built temples to the gods; and from them the custom was
propagated to the Assyrians, comprehending under this ap-
pellation Phœnicia, Syria, and other countries. From
Egypt and Phœnicia it paffed to Greece with the colonies;
and from Greece to Rome. The first erected in Greece is
ascribed to Deucalion by Apollonius (Argonaut. lib. iii.)
and the first in Italy by Damis.

In antiquity we meet with many people who would not
build any temples to their gods, for fear of confusing them
to too narrow bounds. They performed their sacrificies
in all places indiscriminately, from a persuasion, that the whole
world is the temple of God, and that he required no other.
This was the doctrine of the magi, followed by the Per-
ians, the Scythisans, the Numidians, and many other nations
mentioned by Herodotus, lib. i. Strabo, lib. xv. and
Oecron, in his second oration against Verres.

The Persians, who worshipped the sun, believed it would
wrong his power, to enclose him in the walls of a temple,
who had the whole world for his habitation; and hence,
when Xerxes ravaged Greece, the magi exhorted him to
defroy all the temples he met with.

The Sicilians would build no temples to their goddes
Coronis; nor did the Athenians, for the like reason, erect any
statue to Clemency, who, they said, was to live in the hearts
of men, not within stone walls.

The Bithynians had no temples but the mountains to wor-
ship on; nor had the ancient Germans any other but the
woods.

Even some philosophers have blamed the use and building
of temples, particularly Diogenes, Zeno, and his followers
the Stokies. But it may be said, that if God hath no need of
temples, men have need of places to meet in for the public
offices of religion: accordingly, temples may be traced back
even unto the remotest antiquity. See Hofsinian, de Ori-
ginis Templorum.

The Romans had several kinds of temples; of which tho-
built by the kings, &c. consecrated by the augurs, and in
which the exercise of religion was regularly performed, were
called, by way of eminence, templis, temples. Those that
were not consecrated were called adscs. The little temples,
that were covered or roofed, they called adicula; those
open, fascella. Some other edifices, consecrated to particular
mysteries of religion, they called fasces and delubra.

All these kinds of temples, Vitruvius tells us, had other
particular denominations, according to the form and manner
of their construction; as will hereafter be specified.
Indeed, the Romans out-did all nations with regard to
shelves; they not only built temples to their gods, to their
virtues, to their difeases, &c. But also to their emperors, and that
in their life-time; instances of which we meet with in medals,
inscriptions, and other monuments. Horace compliments
Augustus hereupon, and lets him above Hercules, and all
the heroes of fame; in that those were only admitted into
temples after their death, whereas Augustus had his temples
and altars while living.

"Prefenti tibi maturos largimus honoros ;
Jurandaque tuum per nomen ponimus aras."

Epil. ad Aug.

Suetonius, on this occasion, gives an instance of the mo-
desty of that emperor, who would allow of no temples being
erected to him in the city; and even in the provinces, where
he knew it was usual to raise temples to the very proconsuls,
refused any but those erected in the name of Rome as well
as his own. Vide Suet. in Octav. cap. 52.

Whenever a temple was to be erected, the aruspices were
consulted as to the site of it, and the time when the con-
struction of it was to commence. The spot assigned to it
was carefully purified, and it was encircled with fillets and
garlands. The veils, accompanied with young boys and
girls, washed the ground with water, and the priest expiated
it by a solemn sacrifice. Then he touched the foundation
stone, and bound it with a fillet; and the people, animated
with extraordinary zeal, threw it in thither with some pieces
of money, or metal which had not paffed through the fur-
nace. When the edifice was finished, it was consecrated
with a variety of ceremonies, in which the priests, in their
absence, some of his college, prefided. Some of these temples
were not to be built within the precincts of cities, but with-
out the walls, as those of Mars, Vulcan, and Venus, for
reasons particularly assigned by Vitruvius. The temples
were held in great veneration; and, in some cafes, they were
a sanctuary for criminals and debtors. Within them were
very
very much adorned; particularly with costly statues of their gods and great men, and a great variety of votive offerings.

The most celebrated of the ancient temples among the Pagans were the following: viz. the temple of Belus (see Belon and Babylon); the temple of Vulcan at Memphis, the magnificence and extent of which are highly extolled by Herodotus; the temple of Jupiter at Thessalon: and Didyma; that of Andera at Hermathena; that of Protes at Memphis; that of Minerva at Sais; the temple of Diana at Ephesus (see Diana); the temple of Apollo in the city of Miletus, which, as well as that of Diana, was of the Ionic order; the temple of Eleusis, built in honour of Ceres and Proserpine, capable of containing 30,000 persons; the temple of Jupiter Olympus at Athens, of the Corinthian order; and the temple of Apollo at Delphi, so famous for its oracles, and for the rich presents with which it was enriched (see Delphi); the temple of Jupiter, which contained his admirable statue. The architect of the temple was Libo, a native of the country: its height from the area to the roof was 68 feet, its breadth 95, and its length 230. The throne and statue of the god, for we cannot enumerate other splendid ornaments, were the master-piece of Phidias; and antiquity produced nothing so magnificent or so finished. The statue, of an immense height, was of gold and ivory, so artificially blended, that it could not be beheld but with astonishment. The god wore upon his head a crown, which resembled the olive-leaf to perfection; in his right hand he held a victory, likewise of gold and ivory; and in his left a sceptre of exquisite tafle, refugient with all sorts of metals, and supporting an eagle. The shoes and mantle of the god were of gold; and upon the mantle were all sorts of animals and flowers engraved. The throne was all sparkling with gold and precious stones. The ivory and ebony, the animals there represented, and several other ornaments, by their embellishment, formed a delightful variety. At the four corners of the throne were as many Victories, that seemed to be joining hands for a dance, besides two others that were at Jupiter's feet. The feet of the throne, on the fore-side, were adorned with sphinxes, who were plucking the tender infants from the bosom of the Thban mother; and under whose weight were to be seen Apollo and Diana, wounding Niobe's children to death with their arrows. Four crofs bars that were at the feet of the throne, and went from one end to the other, were adorned with a great number of figures extremely beautiful: upon one were represented seven conquerors at the Olympic games; upon another appeared Hercules, ready to engage with the Amazons, and the number of combatants on either side was twenty-nine. Besides the feet of the throne, there were likewise pillars to support it. In fine, a great ballustrade, painted and adorned with figures, railed in the whole work. Pausanias, an able painter of that time, had represented here, with infinite art, Atlas bearing the heavens upon his shoulders, and Hercules in an attitude of rising to throw him of the load. Theseus and Pirithous, the combat of Hercules with the lion of Nemea, Ajax offering violence to Cassandra, Hippodamia with her mother, Prometheus in chains, and a thousand other facts of fabulous history. In the most elevated place of the throne, above the head of the god, were the Graces and Hours, of each three in number. The pedicell which supported this pile, was equally adorned with the rest. There Phidias had engraved upon gold, on the one side, the Sun guiding his chariot; on the other, Jupiter and June, the Graces, Mercury, and Vesta. There Venus appeared rising out of the bosom of the sea, and Cupid receiving her; while Pitho, or the goddess of perfusion, was presenting her with a crown. There also appeared Apollo and Diana, Minerva and Hercules. At the bottom of the pedicell, you might have seen Amphitrite and Neptune, and Diana or the moon, who appeared mounted on horseback. In fine, a woollen veil, of a purple dye, and magnificently embroidered, the present of king Antiochus, hung from top to bottom. The throne and statue reached from the pavement, which was of the finest marble, to the roof.

Italy abounded with temples as much as Greece; several of which were remarkable for their singularity or magnificence. Rome was full of temples: some of the most remarkable for their origin, materials, structure, or use, were the following: viz. the temple of Apollo, built by Augustus, in honour of his favourite deity Apollo, after his victory at Actium, upon mount Palatine. Its structure was very magnificent; it was built of the finest marble of Chios, and embellished, both within and without, with the richest ornaments. Its gates were of ivory, enriched with balsam-relievo, representing the Gauls, when they were thrown headlong from the top of the Capitol by T. Manlius. In the frontispiece was a chariot of the sun, of mally gold, crowned with rays so refulgent that they dazzled the eyes of beholders. Within the temple was a marble statue of Apollo, made by Scopas, and also a colossal one of brafs, 50 feet high; together with a candlestick in the form of a tree, whose branches were covered with clusters of lamps resembling fruit. Upon these branches the poets used to hang their poems, which they offered up to Apollo, as Horace informs us, ep. 3. 1. To this temple, dedicated to the "god of arts," was very properly annexed a noble library.—The temple of Bacchus, situated without the walls of Rome, is now the church of St. Constanfia, supported on the inide by twenty-four noble pillars of granite. Its ancient mosaic ceiling, and the old window by which light was let in from the roof, still remain. Behind the present altar stands an antique urn of porphyry, of large dimensions; and on each side of the altar, a finely wrought antique candlestick of marble.—Here was the temple of the goddesses Bona, who was Drysas, the wife of Fauns, distinguished by her exemplary chastity. The Roman ladies sacrificed to her in the night, in a little chapel, into which the men were not allowed to enter, nor were they permitted to be present at her sacrifices. It was for the violation of this rule, that Cicero profecuted the de- branched Clodius. (See his article.)—The temple of Diana was seated on mount Aventine. It was built in the reign of Servius Tullius, at the joint expence of the Romans and Latins, for the purpose of their meeting annually to offer a sacrifice, in commemoration of the league made between the two nations.—The first temple of Faith is said to have been erected by Numa, who taught the Romans to worship this goddess, and thus to be reminded, that the most sacred oath they could take was to swear by their faith or veracity. His intention was to render their promisnes, without writings or witnesses, as firm and certain as contracts made and sworn to, and the greater solemnities; and in this he succeeded to his wish. Polybius bears this honourable testimony to the Romans, that they inviolably kept their faith, that is, their word, without having occasion for witnesses or seurites; whereas nothing could bind the Greeks to their promises.—

The temple of Honour was built by Mutilus, by order of Marius, and might be reckoned among the noblest buildings in ancient Rome, if the materials, which were stone, had corresponded to the greatest of the design. It was remarkable for this circumstance, that the entrance of it was dedicated to Virtue, and the right to Honour; and that it had no paticular, or back-door, as other temples had; thus intimating, that we must not only pace through virtue to attain
TEMPLE.

to honour, but that honour is also obliged to repass through virtue, that is, to pervade in it, and acquire more of it.—The temple of Janus. The Romans built, at different times, three temples to Janus; for an account of which, see Janus.—The temple of Jupiter the Preserver was one of the sixty temples that stood upon the Capitoline hill. Jupiter Cuflos was re-presented in it, holding his thunder with one hand, and a dart with the other, and the figure of the emperor was under his thunder, to shew that he was under Jupiter's protection; or else engraved, lying upon a globe, and holding an image of victory, with the eagle at his feet, and these words, "Lovi Confervatori Auguftrorum noftrorum."—The temple of Jupiter Optimus Maximus, or Jupiter Capitolinus, was most commonly called the Capitol; which fea.—The temple of Liberty was built upon mount Aventine, on the spot where Cicerò's house once stood, enriched with several brafs pillars, and many fine statues.—The temple of Mars Fluid on the declivity of the Capitoline hill. In this temple were kept the eagles and other military ensigns of the Romans, and also the chariot in which Caesar had triumphed.—The temple of Peace was begun by the emperor Claudius, and finished by Vespasian, who embellished it with paintings and statues of the greatest masters, and also deposited in it all the spoils and riches taken by his son Titus in the temple of Jerusalem. It was burnt in the reign of Commodus.—The temple of Jupiter the Avenger was the Pantheon; which fee. To the temples already enumerated, we might add those of Antoninus and Faunula, of Augustus, of Augustus and Bacchus, of the Mufes, of Ceres, of Claudius Cæsar, of Concord, of Fame, of the Flavian family, of Faunus, of Fever, of Trajan and Neptune, of Happiness, of Faith and Jupiter the Prever, of Flora, of Bad Fortune, of the eldest or first-born Fortune, of Public Fortune, of Virile or Courageous Fortune, of Hercules, of Juno, of Juno Moneta, of Juno Sospita, the giver or prever of health, of queen Juno, of Jupiter Feretrius, of Jupiter Stator, of Jupiter Tonans or the Thunderer, of Jupiter the Conqueror, of Liber, an epitaph of Bacchus, of the Mother of the gods, of Mercury, of Minerva, of the goddefs Nenia, of Opis and Saturn, of the Penates or Household gods, of Reit, of Quirinus, of Romulus and Remus, of Saturn, of Serapis, of the Sun and Moon, of the god Sylvanus, of Tellus or the Earth, of Venus, of Venus and Cupid, of Venus Erycina, of Venus Erycina and the Mind, of Venus Verticordia, of Vertumnus, of Veja, and many others, which, great and small, amounted to upwards of one thousand.

TEMPLE, Jerusalem, was an edifice erected much after the model of the tabernacle, but in a much more magnificent and expensive manner. According to the opinion of some, there were three different temples: the first built by David and Solomon on mount Moriah, which was part of mount Sion; the second, by Zerubbabel and Joshua the high priest; and the third by Herod. This last, however, the Jews will not allow to be a new temple, but only the second repaired or rebuilt. The expense of building Solomon's temple was prodigious: the gold and silver employed for this purpose amounted to upwards of eight hundred millions sterling (1 Chron. xxii. 14. xxix. 4. 6, 7.), which says Dr. Prideaux, was sufficient to have built the whole temple with solid silver. But as the book of Chronicles was written after the return from the Babylonish captivity, it is probable that the Jews might compute by the Babylonish talent, which was little more than half the Mofiac talent, or perhaps by the Syriac talent, which was but one-fifth of the Babylonish; and thus the whole quantity of gold and silver would be reduced to a comparatively moderate quantity, and yet sufficient for the purpose.

Josephus (lib. viii. xiv. ii.) acquaints us, that the two first sums were only one-tenth part of what is expressed in the present Hebrew; and Dr. Kennicott (State of the Hebrew Text, vol. ii. p. 355.) thinks it probable, that a cipher was added to them both in some very ancient Hebrew copy.

This temple was surrounded, except at the front or east end, with three stories of chambers, each five cubits square, which reached to half the height of the temple; and the front was graced with a magnificent portico, which rose to the height of a hundred and twenty cubits. It was plundered by Nebuchadnezzar king of Babylon, and at length destroyed, after it had stood, according to Josephus, four hundred and twenty years, six months, and ten days, from its dedication. Others, however, as Calvius and Scaliger, reduce the number of years to four hundred and twenty-seven, or four hundred and twenty-eight; and Ufher, to four hundred and twenty-four years, three months, and eight days.

The second temple was built by the Jews, after their return from the Babylonish captivity, under the direction and influence of Zerubbabel their governor, and of Joshua the high priest, with the leave and encouragement of Cyrus the Persian emperor, to whom Judæa was now become a tributary kingdom. According to the Jews, this temple was defitute of five remarkable appendages, which were the chief glory of the first temple; viz. the ark and mercy-seat, the Shechinah, the holy fire on the altar, which had been first kindled from heaven, the urim and thummim, and the spirit of prophecy. This temple was plundered and profaned by Antiochus Epiphanes, who also caused the public worship in it to cease; and afterwards purified by Judas Maccabæus, who restored the divine worship; and after having stood five hundred years, rebuilt by Herod, with a magnificent approach to that of Solomon's. Tacitus calls it immensa opulentia templum; and Josephus says, it was the most astonishing structure he had ever seen, as well on account of its architecture as its magnitude, and likewise the richness and magnificence of its various parts, and the reputation of its sacred appurtenances. This temple, which Herod began to build about sixteen years before the birth of Christ, and far completed in nine years and a half, as to be fit for divine service, was at length destroyed by the Romans on the same month and day of the month, on which Solomon's temple was destroyed by the Babylonians.

The Jewish temple itself consisted of the portico, the sanctuary, and the holy of holies; and it was ornamented with spacious courts, making a square of half a mile in circumference. The first court was called the court of the Gentiles, because they were allowed to come into it, but no farther. Within this was a less court, into which none but Israelites might enter, divided into the court of the women; and the inner court, in which the temple and altar stood, and into which the priests and all male Israelites might enter.

TEMPLE, in Architecture. The ancient temples were distinguished, with regard to their construction, into various kinds: as,

TEMPLE in ante, Ædes in antîs. These, according to Vitruvius, were the most simple of all temples, having only angular pilasters, called ante, or paraîste, at the corners, and two Tuscan columns, on each side of the doors.

TEMPLE, Tetraîyle, or simply tetraîyle, was a temple that had four columns in front, and as many behind. Such was the temple of Fortuna Virilis at Rome.

TEMPLE, Proîyle, that which had only columns in its front,
front, or fore-side. As that of Ceres at Eleusis, in Greece.

TEMPLE, Amphiprostyle, or double profile, that which had columns both before and behind, and which was also tetra sty le.

TEMPLE, Periptere, that which had four rows of inflated columns around, and was exostyle, i.e. had six columns in front; as the temple of Honour at Rome. See Periptere.

TEMPLE, Diptere, that which had two wings, and two rows of columns around, and was also ostostyle, or had eight columns in front; as that of Diana at Ephesus.

TEMPLE, Pseudo-diptere. See Pseudo-diptere.

TEMPLE, Hypothoron. See Hypothron.

TEMPLE, Monoptere. See Monoptere.

Temples, among us, denote two inns of court, thus called, because anciently the dwelling-house of the knights Templars.

At the supposition of that order they were purchased by some professors of the common law, and converted into hospitals, or inns of courts.

They are called the Inner and Middle Temple, in relation to Effex-houfe, which was also a part of the house of the Templars, and called the Outer Temple, because situated without Temple-Bar.

In the Middle Temple, during the time of the Templars, the king's treasure was kept; as also that of the kings of France in the house of the Templars at Paris.

The chief officer was the master of the Temple, who was summoned to parliament in 49 Hen. III. And from him the chief minister of the Temple church is still called Master of the Temple.

TEMPLE, Sir Wiliam, in Biography, a statesman and miscellaneous writer, was the son of Sir John Temple, master of the rolls in Ireland in the reign of Charles I. and II., and author of a History of the Irish Rebellion, and born in London in the year 1628. Having finished his course of classical education, he was entered, at the age of seventeen, at Emmanuel college, in the university of Cambridge, under the tuition of the learned Cudworth. Being designed for public life, his principal attention at the university was engaged by the study of the modern languages, French and Spanish; and at the age of twenty, he was sent to finish his education by travelling on the continent. After spending six years in this way, he returned home in 1654, and married the daughter of Sir Peter O'Shore, of Chickland, Bedfordshire, with whom he became acquainted during his foreign travels. Declining to accept any office under Cromwell, he resided with his father in Ireland, and devoted his time to the study of history and philosophy. At the Restoration he became a member of the Irish Convention; and in the Irish parliament of the year 1661, he was returned as a representative of the county of Carlow, and in 1662 was nominated one of the commissioners from that parliament to the king. At this time he removed with his family to England; and having faithfully executed a secret commission to the bishop of Munster, with which he was entrusted in 1665, he was appointed in the following year resident at the court of Brussels, and raised by patent to the rank of a baronet. During the reign of Charles II. he was concerned in a variety of negotiations. After the peace of Breda, (July 10, 1667,) Sir William went over to Holland, and formed an intimate acquaintance and friendship with De Wit, a man frank and open, and of the same generous and enlarged sentiments with himself; and in consequence of the negotiations of these two able statesmen, a defensive alliance was concluded between Holland and England. Sweden acceded to the confederacy: and thus was formed the triple league, which was generally regarded with equal surprize and approbation. In the conduct of this business, Temple acquired great honour; but to all the compliments that were paid to him on the occasion, he modestly replied, that to remove things from their centre, or proper element, required force and labour; but that of themselves they eaily returned to it. The French monarch and the court of Spain were equally displeased; but in the treaty at Aix-la-Chapelle, where Temple appeared as ambassador extraordinary and mediator, on behalf of England, his address prevailed; the Spanish minister complied with the conditions proposed; and the peace between the contending powers was signed in May, 1668. In consequence of this event, Sir William was nominated ambassador to the States-General, and taking up his residence at the Hague in the month of August of this year, he maintained his intimacy with De Wit, and was also on familiar terms with William, prince of Orange, who had then attained the age of eighteen years. But this triple alliance was of short duration. The corruption and intrigues of the English court produced a recall of Temple in the year 1669, and when it was proposed to him to return and make way for a breach with Holland, he declined, much to his honour, engaging in hostilities against a country to which he was attached, and retired from public business to his seat at Sheen, near Richmond. Here he employed himself in the improvement of his mansion, and in the cultivation of his garden; and also in writing his "Observations on the United Provinces," and a part of his "Miscellanea." When the war with the Dutch became unpopular throughout the nation, and the court and its ministers were under a necessity of bringing it to a termination, Sir William Temple was called out of his retirement to negotiate with the Spanish minister in London: and when the separate peace with Holland was concluded, he was recalled in the next year, 1674, to undertake the office of ambassador to the States-General, for the purpose of negotiating a general peace. Before his acceptance of this office, he obtained an audience of the king, with a view of stating to his majesty the pernicious politics of the Cabal ministry, and the necessity of popular measures for regaining the confidence of the nation. The negotiations for peace were commenced at Nimeguen, whether he removed from the Hague in 1676; and during their slow progress, he availed himself of the opportunity thus afforded him for accomplishing the popular measure of the marriage of the prince of Orange to the duke of York's eldest daughter, which took place in 1677. On another occasion, when the French manifested their intention of retaining the Spanish towns, which were to be surrendered by treaty, Temple was dispatched to the Hague to concert effectual measures with the States for bringing the French to terms; and in seven days he concluded a treaty, July 1678, by which England was bound to declare war against the French if the towns were not evacuated within the interval of sixteen days; but so feeble and fluctuating were the English councils, that before the ratification of the projected treaty, peace was signed at Nimeguen, and France was secured in the possession of a great part of its conquests.

In 1679 Temple was recalled from the Hague, in order to be appointed one of the secretaries of state; but perceiving the violence of parties, and the prevalence of discontent, he recommended a council of thirty persons, which was to be composed, together with the ministers of the crown, of persons possessing influence and credit in both houses of parliament. But divisions occurred which prevented the salutary effects of such a measure. Projects of limitation or exclusion were the subjects of warm discussion in parliament.
To these measures Temple was adverse; and his last act in parliament, as member for the university of Cambridge, was to carry from the council the king's final answer to the address of the Commons, never to consent to the exclusion of his brother: other members had previously declined this disagreeable service. When the king, in January 1694, dissolved the parliament without the advice of his privy council, Temple boldly remonstrated against the measure; and at length, wearied with the faction and misgovernment which he had witnessed, he declined the offered return for the university to the new parliament, and retired to Shene, conveying from thence a message to the king, "that he would pass the rest of his life as good a subject as any in his kingdom, but would never more meddle with public affairs."

The king replied to the message, that he bore him no resentment; but his name was expunged from the council. The remainder of his life was spent in retirement and seclusion from all public business; and it is said, that he interfered to little in political matters, as not to know the design of the prince of Orange to engage in the expedition that terminated in the revolution, and to be the last person who gave credit to his landing. After James's abdication, however, he waited on the prince at Windsor, and presented to him his son. King William urged upon him the acceptance of the office of secretary of state; but he maintained his purpose of living in retirement. His son was appointed secretary at war; but in the week in which he assumed the office, he was seized with melancholy, and threw himself into the Thames. His reflection on this afflictive event was that which his Stoic philosophy alone could have dictated: "a wise man might dispose of himself, and render his life as short as he pleased." In his state of retirement, he admitted Swift to be his companion, as we have already mentioned under Swift's article. King William occasionally visited him, and confidentially confided him on several important affairs. In 1694, he lost his wife; andinking gradually under increasing infirmities, occasioned by repeated fits of the gout, his life was terminated at Moor park, in January 1698, in his 70th year. The greatest part of his fortune was bequeathed to the daughters of his unfortunate son by a French lady, under the express condition that they should not marry Frenchmen.

Sir William Temple ranks high as a statesman, and also as a patriot, who well understood and zealously purposed his country's interest. His foboles, without giving them a wordly appellation, were impatience with those to whom he disliked, warmth in dispute, and a share of vanity and conceit; but he was substantially, says his biographer, a worthy man in the various relations of life. To outward forms of religion he paid little regard; but his letter to the countess of Effex is no less pious than eloquent; so that we can scarcely admit the charge of atheism with which he is reproached by bishop Burnet. As a writer, he ranks among the most eminent and popular of his time. His "Observations upon the United Provinces of the Netherlands" were printed in 1672, and deferve the attention of the politician and philosopher; his "Miscellanies" are lively and entertaining, if not profound. His "Memoirs" elucidate the history of the times. His "Introduction to the History of England" was published in 1695. His "Letters," in 3 vols., which relate to public transactions, were published after his death by Swift. "All his William Temple's writings," says one of his biographers, "display much acquaintance both with books and men, and are entirely free from the licentiousness so prevalent in that age. Their style is negligent and incorrect, but agreeable, resembling that of easy and polite conversation." Hume's "Miscellaneous" vol. vii. 8vo.

Sir William Temple did not escape the lash of criticism, and such was his vanity or irritability, or perhaps a composition of both, that his indignation was roused, and he expressed himself in the following terms: "The critics are a race of scholars I am very little acquainted with; having always esteemed them but little brokers, who, having no flock of their own, let up and trade with that of other men, buying here and selling there, and commonly abusing both sides, to make out a little paltry gain, either of money or credit, for themselves, and care not at whole cost." In another place he says, "there is, I think, no sort of talent so despicable, as that of such common critics, who can at best pretend to value themselves by discovering the defaults of other men, rather than any worth or merit of their own—a sort of levelers, that will needs equal the black and richell of the country, not by improving their own estimate, but reducing those of their neighbours, and making them appear as mean and wretched as themselves."

TEMPLE, in Geography, a town of the province of Maine, in the county of Kennebec, containing 462 inhabitants.—Allo, a township of New Hampshire, in the county of Hillsborough, containing 941 inhabitants; 70 miles W. of Portsmouth.

TEMPLE, Lie, a town of France, in the department of the Lot and Garonne; 7 miles W. of Villeneuve d'Agem.

TEMPLEBOY, a bay on the N.E. coast of New Holland, to the S. of Cape Grenville.—Allo, a bay on the E. coast of Labrador. N. lat. 52° 25'; W. long. 55° 50'.

TEMPLEMORE, (i.e. the Great Church,) a post-town of the county of Tipperary, Ireland, where there was formerly held a fair for wool, which lapsed several days. It is 75 miles S.W. from Dublin.

TEMPLE PATRICK, (i.e. Patrick's Church,) a post-town of the county of Antrim, Ireland, on the river Sixmile-water; 4$ miles E. by S. from Antrim, on the road to Belfast.

TEMPLERS. See Templars.

TEMPLARS, in Anatomy. See Tempora.

TEMPLETON, in Geography, a town of America, in the state of Massachusetts, and county of Worcester, containing 1203 inhabitants.

TEMPLETONIA, in Botany, is dedicated by Mr. R. Brown, to the honour of John Templeton, esq. of Orange Grove, near Belfast, a gentleman whose inquiries have much enriched our knowledge of Irish plants, and whose name, more conspicuously often appears in the pages of the Flora Britannica and English Botany.—Brown in Ait. Hort. Kew. v. 4. 269.—Clubs and order, Diadelphus Decandria. Nat. Ord. Papilionaceae. Linn. Leguminosae, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, fimple, bell-shaped, with five rather unequal segments in the limb, permanent. Cor. papilionaceous, of five petals. Standard elliptical, ascending, entire. Wings nearly the length of the standard, linear-oblong, obtuse, with a small tooth near the base at their upper edge. Keel a little shorter than the wings, oblong, slightly curved, of two half-ovate petals, cohering near the extremity, with short claws. Stam. Filaments ten, all combined into one tube for more than half their length, separate above, ascending, five alternate ones rather the shorter; anthers uniform, small, oblong, incun- bent. P. GERMEN filaked, linear-sawhaped; style saw- shaped, ascending; stigma capitulate. Peric. Legume filaked, linear-oblong, compressed, obliquely pointed, of one cell and two valves. Seeds eight or ten, oval, polished, the scar of each bordered with a prominent crest.

Efl. Ch. Calyx fimple, with five rather unequal teeth.

Temel.

1. T. retusa. Wedge-leaved Templetonia. Ait. n. 1. (Rafnia retusa; Venten. Malmaït. t. 53.) Gathered by Mr. Brown, on the south-west coast of New Holland, from whence seeds were sent to England by Mr. Peter Good, in 1803. This is a greenbough shrub, flowering in spring and summer. Stem about a yard high, with straight, angular, smooth, leafy branches. Leaves about an inch and half long, alternate, on short flaks, spreading, entire, emarginate, smooth. Stipulas in pairs, small, oval, deciduous. Flowers lateral, axillary, solitary, on simple flaks, which are rather shorter than the leaves. Calyx distillate of the imbricated appendages which make a principal part of the character of the neighbouring genus Scottia. (See that article.) Petals near an inch long, of a deep crimson. Legume two inches long, and half an inch broad, slightly thick where each seed is lodged.

TEMPLEUVE en Peuves, in Geography, a town of France, in the department of the North; 7 miles S.S.E. of Lille.

TEMLIN, a town of Germany, in the Ucker Mark of Brandenburg, situated between the Bodensee and Dolensee. In the year 1735, this place was totally consumed by fire, but has been rebuilt to very great advantage; its streets being now broad and straight, and its houses uniform, exclusive of a spacious market-place in it, which forms a regular quadangle, insomuch that at present it is one of the most beautiful towns in all the Mark. It carries on a very large trade in timber, which is greatly promoted by means of a canal, newly made. In 1826 it was taken by the French, under the duke of Berg; and the prince of Hohenloe, who had retired hither after the battle of Jena, was made prisoner; 15 miles S.W. of Prenzlau. N. lat. 53° 5'. E. long. 13° 34'.

TEMPLUM Sostati, the name of a kind of surgical bandage described by Galen. He also describes another, under the name of templum parum Apollonii Tyrii.

TEMPHO, Ital., time, or measure, in Music.

Tempo Ordinario, usual time.

Tempo di Cavatina, giving time. See Gavotta.

Tempo di Minuetto, minuet time.

A tempo, or à tempo primo, after a pause, or rallentando, or ad libitum, implies a return to the first time in which a movement is begun; and in recitative, where, in general, no time is kept, à tempo, in an accompanied recitative, implies a regular time.

TEMPOAL, in Geography, a town of Mexico, in the province of Guatleca; 50 miles S.E. of St. Yago de los Valles.

TEMPORA, in Anatomy, the anterior and lateral parts of the head, where the skull is covered by the temporal muscles: the temples in common language. See Cranium.

TEMPORAL, Temporalis, a term frequently used for secular. In which sense it stands opposed to ecclesiastical.

Pope Boniface wrote to Philip the Fair of France, that he was subject to him, both in spirituals and temporals. At present, all the doctors on this side the Alps own the supremacy of kings in temporals. See Action.

TEMPORALIS, Temporalis, in Anatomy, an epithet applied to various parts about the temples: these are a superficial, a mdle, and two deep-seated temporal arteries; a temporal bone on each side of the head; a temporal vein; a temporal muscle; and temporal nerves. See the respective articles.

TEMPORALITIES, or TEMPORALITIES, the temporal revenues of an ecclesiastic; particularly such lands, tenements, or lay-fees, tithes, &c. as have been annexed to bishops' fees by our kings, or other persons of high rank in the kingdom. See Revenue.

The temporalities of a bishop, &c. stand opposed to his spiritualities. See Vacation.

The canonists on the other side of the Alps, anciently gave the pope a power over the temporalities of kings. Yet pope Clement V. owned frankly, that his predecessor Boniface VIII. had exceeded the just bounds of his authority, in meddling with the temporalities of the king of France. Fervet.

TEMPORALIA Customs. See Customs and Vacation.

TEMPORALIA Resolutions. See Resolution.

TEMPORARY Fortification. See Fortification.

TEMPORARY Hours. See Hour.

TEMPORARIO, in the Italian Music, a species of a tempo, or à tempo giusto.

TEMPORALIA OS, in Anatomy, two bones of the cranium. See Cranium.

TEMPESCE, in Geography, a town of France, in the department of the Sehlei; 10 miles S.W. of Antwerp.

TEMPTATION, Tentation, in Theology, an inducement or solicitation to evil, whether arising from the world, the flesh, or the devil.

Our Saviour's temptation, previous to the commencement of his public ministry, has been a subject of discussion and controversy among learned divines.

The evangelical account of this transaction may be found in Matt. iv. 1—11. Mark, i. 12, 13. Luke, iv. 1—12. It has generally been supposed, that the evangelical history of our Lord's temptation is to be understood as a narrative of outward transactions: that the devil tempted Christ in person, appeared to him in a visible form, spoke to him with an audible voice, and removed him corporeally from one place to another; and it must be allowed that these suppositions are warranted by the literal interpretation of the history. Nevertheless, this interpretation is liable to a variety of objections. It is unsuitable to the fagacity and policy of the evil spirit. Why, it has been suggested, should the devil assume our blessed Lord at all, and what advantage could he expect to gain over him; more especially when he came to him in person, and appeared before him in a visible form, and under his own proper character, proposing and urging temptations which could proceed only from an evil being? In order to evade this difficulty, some writers, as archbishop Secker and Dr. Chandler, have conjectured that the devil appeared not as himself, but under the assumed resemblance of a good angel; and others have supposed that he appeared to Christ in the form of a man. But the history furnishes no ground for these conjectures, and they are equally inconsistent with the temptations themselves, considered in their own nature; nor can it be pretended that Christ was ignorant by whom the several temptations, and particularly the third of them, was proposed: for in his reply, he calls him Satan. Besides, this transaction, according to the literal interpretation of its history, was very ill calculated to promote either the honour of
of Christ, or the instruction and consolation of his disciples. This objection is strengthened, when we consider, that Christ must have yielded voluntarily to the mere motion and influence of the devil, and have been accessory to his own dishonour, danger, and temptation. His character must have been rather degraded than exalted. The temptations presented to Christ were such in their own nature as could not afford evidence or exercise of his obedience, nor of course suitable confusion or useful instruction to his followers, under real and powerful trials. Moreover, it has been objected to the common opinion, that it ascribes to the devil the performance of the greatst miracles, and of things not only preternatural, but absurd and impossible, for such we must regard his shewing Christ all the kingdoms of the world from an exceedingly high mountain, and which whatever constitutes the glory and grandeur of its kingdoms. If we are under a necessity of deviating from a literal, and of adopting a figurative interpretation of the tranfauction recorded in this history, we are warranted in doing by other influences of a similar kind, that occur in the sacred writings. These writings relate things as actually done, which nevertheless were only tranfaucted in a vision. Cates of this kind frequently occur in scripture; for which we might refer to Genesis, xxxii. 30. Hosea, i. and iii. Jeremiah, xxxii. xxxvii. Ezekiel, iii. iv. v. St. Paul calls his "being caught up into the third heaven" and "into Paradise, a vision and revelation of the Lord." (2 Cor. xii. 1-4.) In conformity to these general principles, some writers of eminence have proceeded in forming their judgment concerning the temptations of Christ; and constrained by such objections as we have already briefly stated, they have abandoned the opinion that these temptations are to be understood as outward transactions, inasmuch as the things themselves were improbable, and even impracticable in their own nature; and inasmuch as the real performance could answer no valuable purpose. Calvin allows, in his note on Matt. iv. 5, that several circumstances in this history agreed belfi to a vision; and the generality of later writers have admitted, that the devil's shewing to Christ all the kingdoms of the world, and all their glory, in a moment of time, was done by some fictitious scene, from a persuasion, that it could not be done in any other way. Hence it has been argued by others, that if one of the temptations were presented to Christ in vision only, why might not the others be presented to him in the same manner. Adverting to the history itself, it is alleged, that the text, instead of positively and expressly affirming that the temptation of Christ was a real outward tranfauction, contains clear intimations, and even direct affirmations of the contrary. Thus, in the passage relating to the exhibition of the kingdoms of the world, and all their glory, in one view, and in a single point of view, the evanglist is not speaking of the real fight of all these objects; but he must design to be understood of what was instantaneously exhibited to the mind. Other plain intimations occur, that Christ's temptation is not to be understood as an outward tranfauction; and it is alleged by the advocates of this opinion, that all the evanglist who have mentioned this affair, do, in express terms, affirm that it passed spiritually, and in vision, or that it was merely an ideal or mental representation.

Some of those biblical critics, who consider this history as a recital of visionary representations, maintain that these visions were framed by the devil, and that the temptations are to be ascribed to his immediate agency: thus denying the power of Satan over the body of Christ, and granting him a nobler empire, a sovereign influence over the mind. Some have indeed supposed that Christ's temptation was nothing more than a bare meditation of our Lord upon such trials as might possibly be proposed by the great tempter of mankind. But it is needless to make any observations on a view of the subject, which is altogether unsupported by the history.

Another opinion has been propounded by a very able writer, in favour of which he has adduced a variety of arguments, that have given satisfaction to many persons who have examined this subject. Mr. Farmer (in his Inquiry into the Nature and Design of Christ's Temptation in the Wilderness) represents our Lord's temptation as baffling him while he was under a prophetic vifion, of which the Spirit of God himself was the immediate and sole author. Accordingly he considers the temptation of Christ, neither as an outward tranfauction, nor diabolical delusion, but as a divine vifion. At the time when this event occurred, our Saviour was actually in the wilderness, and therefore when the evanglist says, that "Jesus was led up of the Spirit into the wilderness," or as our author more literally renders the words, "then was Jesus brought (or carried) into the wilderness by the Spirit," he intimates, that into a wilderness our Lord seemed to himself to be carried, or thither he was transported in vifion by a prophetic divine affluat. The predictions used by the other evanglist, Mark and Luke, are laid to confirm the explicit thus given of the language of St. Matthew. Upon the whole, the meaning of the evanglists will be, "Christ was brought into a wilderness (not merely under a divine direction, but) under the full influence of the prophetic Spirit, making suitable revelations to his mind, and giving him a view particularly of his future trials." And these trials are described as "temptations of the devil," on account of the particular mode of their being revealed, being couched under the figure of Satan coming to him, and urging temptations. Our author, proceeding to examine the proper intention of this prophetic vifion, observes, that the several scenes which it comprehends, though presented to Christ in the form, and capable of answering the end, of a present trial, were directly intended as a symbolical prediction and representation of the future difficulties of his office and ministry. The first scene in Christ's vifion was prophesyary, verving to disprove the present turn and temper of his mind; and also prophetically, having a reference to his future ministry, through the whole course of which he was prefigured with the same kind of temptations, and refit for them upon the same principles. This part of the vifion, therefore, conveyed this general intimation: "that Christ, though the Son of God, was to struggle with the afflicting hardships of hunger and thirst, and all the other evils of humanity, like the lowest of the sons of men; and that he was never to exert his divine power for his own personal relief, nor meet the most pressing difficulties, or for the supply of his most urgent occasions; but with resignation and faith to wait for the interposition of God in his favour." The second scene of this vifion was Jerusalem, the metropolis of Judea and the seat of power; it was the temple of Jerusalem, where the Jews expected the first appearance of their Messiah; it was the wing of the temple, the eastern front of it, which commanded a view of the worshippers below. From this eminence Christ is required to throw himself down, in a dependence upon the divine protection, that to his miraculous preservation might give evidence of his divine mission, and induce the numerous worshippers, who were eye-witnesses of it, to acknowledge him immediately as the Messiah, visibly descending from heaven, in a manner agreeable to the expectation of the Jews. Such was the propofal, and the temptation was powerful. The principle upon which he rejected it was, in its spirit and meaning, this: "the Scripture forbids us
to pray to God in what instances he shall exert his power; and as we are not to rush upon danger without a call, or in expectation of an extraordinary deliverance; so neither are we to dictate to divine wisdom what miracles shall be wrought for men's conviction. As this trial bore reference to his future ministry, we find that in exemplifying the principle now manifested, he never needlessly and unwarrantably exposed himself to danger; and then relied on a miraculous interposition of divine power for his rescue; but he was cautious in declining hazards; avoiding what might exasperate his enemies; and even enjoining silence with regard to his miracles, when the publication of them was likely to excite envy or popular communion, and to inflame their minds against him. In displaying the evidences of his divine mission, he still acted upon the same maxim, opening his commission, not at Jerusalem, but in Galilee. In order to avoid ostentation and offence, he kept himself as private as the object of his commission would allow; and instead of courting the favour of the opulent and powerful, he converted freely with all sorts of people. In many other instances which an attentive perusal of his history will furnish, his ministry will correspond to his prophetic vision, in which he was tempted to a public and ostentatious display of his miraculous powers. In the third scene, the proposal was instantaneously rejected, and not without a mixture of just indignation. Besides this trial of his temper, the scene before us pre-figured the temptation to which he would be exposed in the course of his future ministrations, during which he was called upon to prostitute himself, with all his miraculous endowments, to the service of Satan, for the sake of worldly honours, or for gratifying the mistaken expectations of the Jewish people. For a farther illustration of this subject, we must refer to the work already cited. See also archbishop Secker's, Dr. Clarke's, Dr. Chandler's, Mr. Maffon's Sermons, on this subject. Benson's History of the Life of Christ. Macknight's Truth of the Gospel History.

TEMPTATION, Tentatio, in our Ancient Law-books, is used for a trial, proof, or affair. "Tentatio panis fiat bis in anno," Chart. Edw. I. See ASSAY, &c.

TEMOOK, in Geography, a famous station in the Crimea, situated at the foot of a small mountain, near the northern embouchure of the Kuban. It now is a strong fort, for the purpose of supplying post-horses. In Monterey's time, who travelled this way in December 1711, it was a place of great importance. He describes it as considerable for its commerce in hides, caviare, loney, Circassian flaves, and horses. He supposes that its cattle flood where the ancients placed their "Petrusus;" and two eminences, he says, which are named "the point of the island," may have been their "Achilleum Promontorium." This, it is supposed, was the situation of Cimmerium. Pallas conjectures, that Temook may probably have been the "Cimbreus" of Strabo.

TEMS, Fr., time, in Music: as à contre temps, against time.

TEMSENA, in Geography, a province of Morocco, situated on the coast of the Atlantic, to the S. of Saléce. This province is rich and fertile, and abounds in excellent provisions, of various kinds. Its name seems intended to signify its fertility, and the purity of the climate. Temenza appears to be derived from the two Arabic words Tanam Sanbi, only a year; as if they should say, that to reside here only a year would be sufficient to infuse the sickly the return of their health, and, in fact, is the firm belief of the natives. Corn is very plentiful in this province; it is of a very excellent kind, and the ears frequently bear 70 grains, or more. In the forests is found a kind of cedar, called hazar, of a resinous smell; it is a hard and incorruptible wood, and the Moors employ it in building their houses.

This and the neighbouring provinces abound in horses and horned cattle; their flocks are numerous, and the cavalry of Temenza is the best appointed of the empire, excepting the Black troops of the emperor, called Abed Seedy Barbaree. The population of the districts of Temenza and Shawia is estimated at 1,160,000 persons. The males of Temenza and Shawia are a strong, robust race, of a copper colour; their women possess much beauty, and have highly expressive features; and the animation of the countenance is increased by the use of el kokol sickly, with which they tinge their eye-lashes and eye-brows. In these provinces they are fond of drying their hands and feet with a preparation of the herb hena, which gives them a beautiful orange-colour, and, in hot weather, imparts a pleasing coolness and softness to the hands, by preventing, in a considerable degree, the quickness of perspiration.

TENIUS, in Geography, a river of Sardinia, which runs into the sea, 4 miles E. of Caliello Arragone.

TENA, a town of South America, in the province of Quito; 15 miles S. of Archidona.

TENABLE, formed from the French tenir, and that from the Latin tenere, to hold, in the Military Art, something that may be defended, kept, and held, against assailants.

Tenable is little used, but with a negative: when a place is open on all sides, and its defences are all beaten down, it is no longer tenable. When the enemy has gained such an eminence, this post is not tenable.

TENACIOUS BODIES. See TENACITY.

TENACITY, in Natural Philosophy, that quality of bodies by which they sustain a considerable pressure, or force, without breaking. Mem. Acad. Berlin, 1745 p. 47. Tenacity is the opposite quality to fragility, or brittleness.

TENACULUM, in Surgery, an instrument used in amputation, for pulling out bleeding vessels that are to be tied by ligatures.

TENAGLIA, in Biography, a Roman composer, mentioned by Pietro della Valle, as having set the opera of "Clearco," for that city, about 1634. This seems to have been one of the first musical dramas performed at Rome in a public theatre.

TENAILLE, in Fortification, a kind of outwork, consisting of two parallel lines, with a front, in which is a re-entering angle. In strictness, that angle, and the faces which compose it, are the tenaille.

The tenaille is of two kinds; simple and double.

TENAILLE, Simple, or Simple, is a large outwork, consisting of two faces or sides, including a re-entering angle. See Plate V. Fortification, fig. 4. lit. d.

TENAILLE, Double, or Flanked, is a large outwork, consisting of two simple tenailles, or three faillans, and two re-entering angles. Fig. 21. lit. e.

The great defects of tenailles are, that they take up too much
much room, and on that account are advantageous to the enemy; that the re-entering angle is undefended; the height of the parapet hindering the firing down into it, so that the enemy can lodge there under cover; and the sides are not sufficiently flanked.

For these reasons, tenailles are now excluded out of fortifications by the belt engineers, and never made, but where there wants time to form a horn-work.

Tenaille of the Place, is the front of the place, comprehended between the points of two neighbouring baitions; including the curtain, the two flanks raised on the curtain, and the two sides of the baitions which face one another.

So that the tenaille, in this sense, is the name with what is otherwise called the face of a fortres.

Tenaille of the Ditch, is a low work raised before the curtain, in the middle of the fos or ditch; the parapet of which is only two or three feet higher than the level ground of the ravelin.

There are three different forts (Plate VII. Fortification, fig. 6). The first are those which are made in the direction of the lines of defence, leaving a passage of three toises between their extremities and the flanks of the baitions, and likewise another of two toises in the middle for a bridge of communication to the ravelin. The second (fig. 7.) are those whole faces are in the lines of defence, and fifteen toises long, besides the passage of three toises between them and the flanks of the baitions: their flanks are found by describing arcs from one shoulder of the tenaille as a centre through the other, on which are set off ten toises for the required flanks. The third fort (fig. 8.) comprehends those whole faces are sixteen toises, as in the second fort, and the flanks parallel to those of the baitions.

The use of tenailles, in general, is to defend the bottom of the ditch by a grazing fire, and likewise the level ground of the ravelin, and especially the ditch before the redoubt within the ravelin, which cannot be so conveniently defended from any other place. The first fort do not defend the ditch so well as the others, because they are too oblique a defence; but as they are not substantive to be enfiladed, M. Vauban has generally preferred them in the fortifying of places. Thoë of the second fort defend the ditch much better than the first, and add a low flank to those of the baitions; but as these flanks are liable to be enfiladed, they have not been much used. This defect, however, might be remedied, by making them so as to be covered by the extremities of the parapets of the opposite ravelins, or by some other work. Thoë of the third fort have the fame advantage with the second, and are subject to the same inconveniences; and, therefore, they may be used with the same precaution.

Tenailles are esteemed so necessary, that there is hardly any place fortified without them, and it is not without reason; for when the ditch is dry, the part behind the tenaille serves as a place of arms, from which the troops may fall, destroy the works of the enemy in the ditch, oppose their descent, and retire with safety; and the communication from the body of the place to the ravelin becomes easy and secure, which is a great advantage; for by that means the ravelin may make a much better defence, as it can be supplied with troops and necessaries at any time. And if the ditch is wet, they serve as harbours for boats, which may carry out armed men to oppose the palingage over the ditch whenever they please; and the communication from the tenailles to the ravelin becomes likewise much easier than it would be without them. Muller's Elem. of Fort, p. 34.

See Fortification.

The ram's-horn is a curved tenaille, raised in the fos before the flanks, and presenting its convexity to the covered way. This work seems preferable to either of the other tenailles, both on account of its simplicity, and the defence for which it is constructed.

Tenailions, are works constructed on each side of the ravelin, much like the lunettes: they differ, as one of the faces of a tenaille is in the direction of the ravelin, whereas that of the lunette is perpendicular to it.

Tenailles are constructed by producing the faces of the ravelin beyond the counter-scarp of the ditch, at a distance MN (Plate VII. Fortification, fig. 9.) of thirty toises, and taking on the counter-scarp of the great ditch fifteen toises from the re-entering angle p to q, and drawing N q; then q N M p will be the tenaille required; its pitch is twelve toises, or the same as that of the ravelin. Sometimes there is made a retired battery, in the front of the tenailions, as at A: this battery is ten toises from the front, to which it is parallel, and fifteen toises long. There are commonly intrenchments made in the tenailions, such as O; their parapets are parallel to the fronts M N, or rather perpendicular to the side N q, and bifeect the side q N; the ditch before this retrenchment is three toises, and there is a banquette before the parapet, next to the ditch, of about eight feet, called berm, serving to prevent the earth of the parapet (which seldom has any revetment) from falling into the ditch. The ravelin, before which tenailions are constructed, must have its faillant angle much greater than the former construction makes them; otherwise the faillant angles of the tenailions become too acute; for which reason the capital of this ravelin is made forty-five toises, and the faces terminate within three toises of the shoulders. Muller's Elem. Fort. p. 37.

A tenaille is a work capable of affording great defence to the besiegers; as at the siege of Lisse, in 1708, where the besiegers were twice or thrice drove out of a tenaille they had taken and retaken.

Tenala, in Geography, a town of Sweden, in the province of Nylund; 8 miles N.W. of Eklund.

Tenancy, a habitation, or house to live in, or a tenement or poffiition held of another.

Tenancy, Entire. See Entire.

Tenancy in Tail. See Fee-Tail.

Tenant, in Agriculture, a person holding land or other property of another, either by grant, lease, or otherwise. Tenants are of different kinds, according to the nature of the tenures by which they hold their lands; but, in this last respect, they properly belong to the business of the law. Tenants hold their lands or farms for very different lengths of time, in different districts, as from one year to twenty-one; but in many places they have no leases at all. The most common lengths of time are seven, nine, fourteen, nineteen, and twenty-one. Short leases are now becoming general, as those of seven, nine, and eleven years. Tenants now mostly pay all taxes, except that on property.

The proper choice of tenants is a matter of the greatest importance to the well-doing and continued prosperity and successe of all forts of landed property, of almost any that can be adopted; as where they are improperly provided, there can hardly anything go on in the manner which it ought to do; nor can there be the best fort of management, that the cafe will admit of, pursued. Many things will necessarily run into complete neglect, and ruinous flates of them be produced as the consequence, which might have been easily and wholly avoided, by more attention in the first selection of the tenants.

The writer of the Middlesex Agricultural Report, after inculcating the necessity and utility of tenants having good and
TENANT.

and properly regulated leaves of the lands which they hold, remarks, that the letting of farms to tenants at will, or from year to year, is a most unwise practice, and one which should by all means be avoided by the proprietors of landed estates; as such tenants, he contends, from the very nature of their tenures, are precluded from the possibility of making any improvements; while they have it in their power to ruin the lands they occupy and hold. Rapacious landlords, unskilful stewards, and yearly tenancy, it is continued, destroy the holders' or tenants' confidence, smother their thoughts of improvements, and, in short, make bad tenants, by forcing them to contrive some mode of occupying the lands, so as to be able to quit them, on receiving half a year's notice, with the least possible loss to themselves; and which can only be done, by keeping the soil continually in a poor state, to the evident great losses of the proprietors, the no less ones of the tenants, and the still more disadvantages of the community in general. See LEASE, LETTING OF FARMS, AND QUALIFICATIONS OF TENANTS.

The writer of the work on "Landed Property" has remarked that, on all large estates, there are certain established customs and usages to which the proprietors, as well as the tenants or occupiers, consider themselves mutually amenable, although no legal contracts may subsist between them; and that, even where imperfect leaves, or other legal agreements, exist, there is still, in general, much left for custom and usage to determine. These fixed regulations, though they may be imperfect, it is contended, should be strictly regarded by superintendents, until better ones are substituted in their place, not only for the sake of moral justice, but as setting an example of integrity and good faith to the tenants. Nothing of this sort should ever be broken through by those in the management of such properties; as tenants on all such are constantly to be met with ready enough to break their stipulated agreements, without such examples; and it must be extreme folly to induce the others who are well disposed to do the same. On the contrary, it is but common prudence to fulfil every covenant, agreement, and promise, which may have been made, with the most scrupulous exactness, even to the meanest cottager, in order to inspire proper confidence, and obviate much mischief.

And besides setting examples of these kinds before the tenants, they ought, it is supposed, to be liberalized in their minds, by good offices, and acts of kindness, which may be beneficial in various ways. A spirited improving tenant should be refused few reasonable demands; he should have advantages conferred on him, not merely as rewards for his labours in benefiting the lands, but as inducing other tenants to pursue similar plans, and to shew that good managers are noticed and distinguished.

The consequences of an inattention to these matters, which is too common in most parts of the country, are very prejudicial; as the refusal of requests which would equally benefit the estate and the tenant, the fluidly thwarting of the well-meaning intentions of the best tenants upon it, the ignorantly quarrelling with them about mere trifles, and the making no sort of difference between those who are improving and those who are ruining it, or perhaps the encouraging the latter, and opposing the former, must have effects of the worst kind, there can be no doubt. Such tenants as are capable of improving, are also capable of impoverishing; and when disgraced by improper treatment, will be sure to haras the lands they hold, and take the first chance they have of removing to farms under more rational management, to the great inconvenience and disadvantage of those which they held before.

It is observed in the Agricultural Survey of Gloucester-
himself ill used upon leaving it. For all under-draining properly done, and for new buildings that were necessary for the farm, the tenant ought to be allowed a reward proportionate to the number of years left than twenty he may have had the use of them. He should likewise receive an allowance for quick fences, and the planting of orchards, or of aquatic and other useful trees in proper places, on producing fair bills, with receipts to them, of the expenses; provided he leaves the estate without committing any wilful waste. The landlord who enters into such a covenant with his tenant, may reasonably expect to have his farm delivered back to him upon terms equally fair. If the tenant has committed any waste, he should be obliged to make good all damages. Now such mutual conditions would do away many absurd restrictions that are at present laid upon the tenant; as it would then be his interest not to injure the farm, because he must pay for all damages wantonly done; and the landlord would have no reason to check the farmer's experiments and improvements, which would be a great encouragement to both ingenuity and industry: for gentlemen's agents are very apt, from too anxious care of the estates, to restrict tenants in such a manner, that they are little better than a mill-horse, who can go over only a particular circle of ground. It has been known that an agreement was made to lay a certain quantity of lime on land, where, if the land had been the writer's, he would have given more money than the lime cost, that it might not be laid on. And sometimes, besides many other ingenious modes of culture, which the ignorance of whom of the steward obliges the farmer to follow, he is tied down to plough and sow crops of corn only four years in fix, and no turnips or clover. But the restricting a man from ploughing up grass-land without leave, is certainly, it is thought, proper, till the landlord sees what his new tenant makes of the land he does plough; but if he is industrious, and tills well, the writer would suffer him to plough every inch he chose: as, on good arable land, it will certainly make in future a difference of from one pound to three pounds an acre in rent to the landlord. The nature and situation of the farm are, however, to be well considered before this is done.

Alfo where the duration of the term is twenty-one years, it would, it is supposed, be very proper that, three years before the lease expires, he should be restricted in the rotation of his crops, $o$ as to leave the farm in a proper state to be profitable to the coming tenant. This would likewise give time for the tenant to fix himself elsewhere, if the landlord and he do not agree again, as well as for the landlord to make proper choice of a new tenant.

It is very common for tenants to live in a very poor way, and obtain little profit, from the want of introducing a proper system of husbandry upon their farms, as it is only this that can afford a full profit; therefore, the best methods of management his circumstances will afford should always be pursued.

There is a great variety of regulations and restrictions in regard to tenants, in respect to the times and manner of entering upon their farms, the extent and methods of breaking up and cropping the lands, the various improvements in draining, manuring, &c. the making of fences, the felling of hay and firaw, the defloping of the live-flock at the end of leaves, the occupying of buildings by new tenants, the felling of timber for repairs, and a vast number of other matters, many of which are owing to the particular situations and circumstances of the lands that are to be held by the tenants.

**Tenant, or Tenants, Tenency, in Law, one that holds or possesses lands and tenements of some lord or landlord, by any kind of right, either in free, for life, years, or at will.**

The term *tenant* is used with divers additions. Thus, tenant in dower, is the that possesses lands by virtue of her dower. Tenant per Statute-Merchant, he that holds lands forfeited to him by virtue of a statute. See **Statute-Merchant**. Tenant in Frank-Marrige, he that holds lands or tenements by virtue of a gift of them, made to him upon marriage, between him and his wife. See **Frank-Marriage**. Tenant by Courtesy, he that is admitted by the rod in court to lands in ancient demeine.

See **COPYHOLD.**

Tenant Paravail. See **PRAEVAIL.**

Tenant by Charter is he that holdeth by seofment in writing, or other deed. See **CHARTER,** and **FREEHOLD.**

Tenant in Capite, or Chief, holdeth of the king in right of his crown. See **CAPITE.**

Tenant of the King is he that holdeth of the person of the king.

Tenants, Joint, those who have equal right in lands or tenements, by virtue of one title. See **JOINT TENANTS.**

Tenants in Common, those who have equal right, but hold by divers titles. Tenant, Particular, he that holds only for his term. Tenant, Sole, is he who has no other joined with him. Tenant by Execution, is he who holds by virtue of an execution upon any statute, recognizance, &c.

Tenants, Customary. See **CUSTOMARY.**

Tenants, Terre. See **TENANTS, TERR.**

Tenant, Very. See **VERY.**

Anciently, there were also tenant by knights-service, tenant in burgage, tenant in socage, tenant in frank-fee, tenant in vil-lagen. And there are still tenant in free-folmle, tenant in fer-tail, tenant upon sufferance, &c.

Tenant in Tail after Possibility of Life extinct. See **TAIL.**

Tenant to the Precipice, in Law, is he again whom the writ of precipice is to be brought in finding out a recovery. Tenant, or Tenan, in Heraldry, is used for something that fullains, or holds up, the shield, or armoury; and is generally synonymous with the word **supporter.**

The difference which some authors make between the two is, that tenants are single, and supporters double, one placed on each side of the shield. But the proper distinction seems to conflict in this, that tenants are human figures, and supporters figures of beasts.

There are various forms of tenants, as well as of supporters, viz. angels, maids, religious, savages, Moors, &c. The first tenants, F. Menefrier observs., were trunks, or branches of trees; to which the efcutechons were fastened by straps and bullocks. Afterwards the knights were represented as holding their own efcutechons, which were either hung to their neck, or else they leaned on them.

The origin of tenants and supporters is, by many, referred to the ancient tournaments, in which the cavaliers had their arms borne by servants disguised like savages, Moors, fabulous deities, bears, lions, &c. See **SUPPORTER.**
TENARIUM, in *Ancient Geography.* See *T-enarium.*
*Tena-rus,* or *Tena-rus,* a mountain of the Peloponnese, in Laconia.

TENASSERIM, in *Geography.* See *Siam.*

TENATARI, in *Ancient Geography,* a people who inhabited that part of Germany which corresponds to the present bishopric of Munster.

TENBURY, in *Geography,* a market-town in the upper division of the hundred of Doddington, and county of Worcester, England, is situated on the western border of the county, separated from Shropshire by the river Teme, at the distance of 21 miles N.W. by W. from Worcester, and 134 miles in the same bearing from London. The manor of Tenbury, at, or soon after the Conquest, was held by Robert Fitz-Richard, who was lord of Richard's castle; his heir assumed the name of Say, in consequence of a marriage with the heiress of that family: the property past, by a succession of heiresses, through various families, to the Cowells, whose descendants are still the lords of it. The town is not very extensive, and standing low, is often subject to floods from the rapid river Teme. A remarkable instance occurred Nov. 17, 1779, when a great part of the church, with its organ and monuments, were destroyed. The parish of Tenbury is three miles and a half in length, by three and a quarter in breadth, and the year 1811 contained 308 houses, and 1562 inhabitants. In the chancel of the church is a curious monument, representing a child in armour, laid in a crofs-legged position. Cough, in his *Sepulchral Monuments,* mentions this figure, and attributes it to the fon of "John Sturmy, the crusader, who followed his father to the holy wars when under age."

Over the river, at the north end of the town, is a handsome stone bridge of six arches. A market is held here on Tuesdays, and there are three annual fairs. Great quantities of hops and apples are cultivated in the vicinity of the town, and consequently much cider is made here. The Leominster canal, coming near the town, affords ready communication for goods, cider, &c. to distant places.

About one mile and a half S.E. of Tenbury is Suttonparks, in the chapel of which are some old monuments of the Arundel family. Near this place is Kyre-Wyre, distinguished for its "tall and mighty oaks," and for a neat mansion belonging to the Pytt family.—Nair's *History,* &c. of Worcestershire, 2 vols. 8vo. *Beauties of England and Wales;* Worcestershire.

TENBY, a market and borough town in the hundred of Nabet, and county of Pembroke, South Wales, is situated on the shore of Cardmaurth bay, 10 miles E. from Pembroke, and 250 miles W. from London. It occupies a rocky promontory of considerable elevation, stretching over the sands in a footherly direction, and at high water is nearly inclosed by the sea. Here is a small but commodious harbour, skirted on the land-side by a bold amphitheatre of rocks and houses. Leland says, "Tinibigh town townith on a main rokke, but not veri hi, and the Seren Se fo gulfich in about hit, that at the ful ye almost the third part of the town is inclosed with water. The town is stronge wauellit and welle gatid, everi gate having his porticoll ex solidi ferro. But that gate that ledith to Caernarmond ward is mow femelde, as circuit without an embalstel but open rofd towr, after the facion of the salt gate of Pembroke. Without this gate is a preti saborbe. In the middes of the town is a faire paroche churich. The towne itselft lakith frenche water, wherefor utuentur importata." And again, "Ther is a sinus and a peere made for hyppes. The towne is very welthe by marheandye; but yt is not very bygge, having but one paroche churiche. One thing is to be marevelled at. There is no welle yt the towne, as yt is faide, wherby they be forced to seek their water at S. John's without the towne." The wall, which once surrounded the town, is yet in some places nearly entire. The principal improvement of these walls is ascribed to queen Elizabeth, in whose time Tenby was a flourishing place. The streets are now in general good, though, on account of the nature of the ground, in some places inconveniently narrow and deep. They contain a large proportion of very respectable houses, occupied by substantial tradesmen and merchants, or by persons of independent fortunes. The want of water was an inconvenience under which the town long laboured; but by the recommendation and exertions of Sir William Paxton, the town is now supplied, at a trifling charge, with an extinguish'd supply of this necessary article. Tenby is one of the contributory boroughs joined with Pembroke in the return of a representative to parliament. The corporation consists of a mayor, aldermen, and common-councillers, a chamberlain, town-clerk, two sheriffs or bailiffs, two sergeants at mace, and twelve constables. The town is divided into two districts, which are denominated the In-liberties, and the Out-liberties. The former division is subject to the jurisdiction of the magistrates of the borough; the latter to that of the county magistrates. The present extent of the town is not considerable, the number of houses being estimated, in the year 1811, at 265, and the population at 1176. It is apparent, however, from the number of ruined buildings and foundations to be seen in the outskirts, that formerly it must have spread over a larger space than it now occupies, and contained a much more numerous population. Two weekly markets are held on Wednesday and Saturday, and five fairs annually. Tenby seems to have derived its earliest importance from its fisheries. But when the country fell under the power of the Anglo-Norman invaders, and this district became inhabited by the Flemish settlers, its local advantages for commercial objects of greater consequence were seen and appreciated. The harbour was improved for the convenience of shipping, and the population of the town and its vicinity was engaged in a woollen manufacture on an extensive scale. The commercial spirit thus awakened, procured for the inhabitants numerous privileges and charters from their lords, and from successive monarchs. The importance of Tenby, however, has sunk far below its former rank; its manufactures have disappeared, and its chief trade at present is created by the coal raised in its neighbourhood, which is here shipped off for other parts of the coast, and for the English markets. The convenience which the town has lost in this respect seems likely to be compensated by its rapidly advancing reputation as a bathing-place. It possesses many natural attractions for visitors; and peculiar advantages in point of convenience have been recently provided. Among these, the forenoon bath must be alluded to the baths lately erected by Sir William Paxton; in which all accommodations for health and pleasure are combined. The church of Tenby is situated in the middle of the town; it is a spacious edifice, comprising a nave and two side aisles; at the west end is a large square tower, surmounted by a lofty spire. The monastic establishments of Tenby were an hospital, or free chapel of St. John the Baptist, a convent of Carmelit friars, founded in 1399, and called St. Mary's college, and an hospital or lazarette, dedicated to St. Mary Magdalen. Here was an ancient castle, of which there are yet considerable remains, though mostly in a very dilapidated state. The only portions now standing that indicate its former strength are a bafile and square tower: the rest of the buildings exhibit the air of a splendid mansion rather than ct
of a military fortress. The situation of this castle was admirably formed for defence: it occupied the extreme point of the promontory, and was secured by inaccessible rocks on every side, 'except that facing the town, which was strengthened by bold fortifications.

On the coast at Tenby are some inflated rocks of romantic appearance, which exhibit curious excavations. Some of them are accessible on foot at low water: this is the cape with the island of St. Catherine, off the Cañon Point, which in one direction has been perforated quite through by the repeated action of the tides. The principal of these islands is Caldey, situated about two miles from the main land. It is about a mile in length, and half a mile wide, and is elevated to comprise about six hundred acres of surface, of which nearly a third is in cultivation. Here was a priory, founded, as is supposed, by Robert, the son of Martin de Turribus. The tower of the priory church, surmounted by a stone spire, is yet standing, and many of the conventual buildings have been converted into offices, and attached to a handsome modern edifice.

Near the coast, to the eastward of Tenby, are several respectable gentlemen's residences, some of them of ancient date. Among these are Ciglety, formerly inhabited by the Canon family; Hen-Gaftell, (the old castle,) the property of Thomas Stokes, esq.; Merritton, the seat of Charles Swan, esq.; Bonville Court, an ancient mansion of the Bonvilles; and Eare Wear, now called Amroth Caile, the residence of Captain Ackland; and on the road from Narbeth is Begelly Hall, the seat of James Child, esq.—Beauties of England and Wales, vol. xvii. Pembrokehire, by T. Rees. Historical Tour through Pembrokehire, 4to. 1810, by R. Fenton, esq. Account of Tenby, illustrated with engravings, 4to. 1812, by Charles Norris, esq.

TENCE, a town of France, in the department of the Upper Loire; 12 miles S.E. of Montroult.

TENCH, in Ichthyology, the English name of the taria of the modern authors, the fullo and gnaphal of the ancients.

It is, according to the Arctedian and Linneus system, a species of the cyprinus, and is distinguished by Artedi by the name of the blackfish, mucous, or limy cyprinus (which fee), with the end of the tail even. See Tench Fishing.

TENCH'S ISLAND, in Geography, an island in the Pacific ocean, so called by Liet. Ball, commander of the Supply, returning from Norfolk Island to England in the year 1790. The island cannot be more than two miles in circumference: it is low, but entirely covered with trees, many of which are the cocoa-nut; there were likewise others of a large size. These trees reached to the margin of a very fine sandy beach, which entirely surrounds the island. A great number of canoes were lying on the beach; and, it is supposed, there can be less than a thousand inhabitants on the island. The natives who were in the canoes were stout and healthy-looking men; their skin was perfectly smooth, and free from any disorder: they were quite naked, and of a copper colour; their hair resembled that of the New Hollanders. Some of their beards reached as low as the navel, and there was an appearance of much art being used in forming them into long ringlets: so that it should seem as if the prevailing fashion on this island was that of keeping the beard well combed, curled, and oiled. Two or three of the men had something like a beard or bone suspended to a string, which was fastened round the neck. S. lat. 1° 53'. E. long. 170° 31'.

TENCOA, a town of Mexico, in the province of Hondo-USA, 110 miles W. of Comayagua. N. lat. 14° 48'. W. long. 96° 22'.

TENCZA, a town of Austrian Poland; 13 miles W. of Cracow.

TEND, in our Old Writers, seems to signify as much as tender, or offer; as to tend or traverse an avertment, &c.

TENDA, in Geography, a town of Africa, or rather several towns close together, the capital of a country of the same name, on the right bank of the Gambia, situated to the south-west of Bondou, and south-east of Wooly. N. lat. 13° 21'. W. long. 11° 55'.—Alto, a town of France, in the department of the Maritime Alps; late capital of a county to which it gave name, annexed to Piedmont, situated at the union of the Rona and Borgna. It has only one parish church, which is a beautiful structure, a castle walled round and flanked with towers, on a rock, which commands the environs of the town. In the 16th century, it came to the duke of Savoy. The foil is not fertile, being on all sides surrounded by the Alps; it yields, however, good pasturage and timber; the rivers also furnish the inhabitants with excellent trout; 22 miles N.E. of Nice.

TENDE, Col de, the most remarkable passage through the Maritime Alps. See ALPS.

TENDEBA, in Ancient Geography, a town of Alta Minor, in Caria.

TENDEBAR, in Geography, a town of Africa, in the kingdom of Kama. N. lat. 13° 15'. W. long. 15° 57'.

TENDER, in a legal sense, signifies as much as to offer, or endeavour, the performance of any thing, in order to save the penalty, or forfeiture, incurred by non-performance.

Thus, to tender rent, is to offer it at the time and place when and where it ought to have been paid; which will save the condition of that time, though the landlord refuse to accept it.

TENDER, in Sea Language, is a vessel attending on some other larger and more considerable one. It is employed in the king's service on various occasions; as to receive volunteers and impressed men, and to convey them to a distant place; to attend on ships of war or squadrons; and to carry intelligence or orders from one place to another, &c.

TENDER PLANTS, in Gardening and Agriculture, all such as are too delicate and tender in their nature and habits to stand, or be raised, grown, or produced in the climate of this country, without artificial protection or assistance, until they have been sufficiently inured to, and hardened, and habituated against the effects of it. It has indeed been observed by Sir Joseph Banks, in a paper containing some hints concerning the proper mode of raising plants of this kind to this climate, inferred in the first volume of the "Transactions of the Horticultural Society" of London, that, respectable and useful as every branch of the horticultural art certainly is, no one is more interesting to the public, or more likely to prove advantageous to those who may be so fortunate as to succeed in it, than that of raising plants, natives of warmer climates, to bear, without covering, the ungenial springs, the chilly summers, and the rigorous winters, by which, especially for some years past, we have been perpetually visited. Many attempts have it, is said, been made in this line; and several valuable shrubs, that used to be kept in our flowers, are now to be seen in the open gardens; there is, however, some reason, it is thought, to believe, that every one of these was originally the native of a cold climate, though introduced to us through the medium of a warm one; as the gold-tree, aucuba japonica, the mountain, parina frutescens, and several others, have been in our times.

In the case of annuals, however, it is thought probable that much has been done by our ancestors, and something by the present generation; but it must be remembered, it is said, that all that is required in the case of an annual, is to enable it to ripen its fruit in a comparatively cold summer, after which, we know that the hardiest fruit has no power to injure
injure the feed, though exposed in the open air to its severest influence; but a perennial has to encounter frosts with its buds and annual shoots, that have sometimes been so severe with us, as to rend asunder the trunks of our indigenous forest-trees, as stated by Miller.

It is suggested, as probable, that when, our principal food corn at present, did not bring its feed to perfection in this climate, until hardened to it by repeated sowings. A few years ago, some spring-wheat from Guzerat was, it is said, grown with barley in a cultivated field; it rose, reaped, and bloomed, with a healthy appearance, but many ears were, when ripe, wholly without corn, and few brought more than three or four grains to perfection.

In the year 1791, some feeds of zizania aquatica were, it is said, procured from Canada, and grown in a pond at Spring-Grove, near Hounslow; they grew, and produced three plants, which ripened their seeds; and those seeds vegetated in the succeeding spring, but the plants they produced were weak, slender, not half so tall as those of the first generation, and grew in the shallowest water only; but the seeds of these plants produced others the next year sufficiently stronger than their parents of the second year. In this manner the plants proceeded, springing up every year from the seeds of the preceding one, every year becoming visibly stronger and larger, and rising from deeper parts of the pond, until the year 1824, when several of the plants were, it is said, six feet in height, and the whole pond was in every part covered with them, as thick as wheat grows on a well-managed field.

Here, it is thought, we have an experiment which proves that an annual plant, scarcely able to endure the ungenial summer of this country, has become, in fourteen generations, as strong and as vigorous as our indigenous plants are, and as perfect in all its parts as in its native climate and situation.

It is suggested too in the above paper, that the settlement lately made at New Holland gives a large scope for experiments of this kind: many plants have been brought from thence which endure our climate with very little protection, and some of these arrive at puberty at an early period; we have already three, it is said, from the south point of Van Diemen’s island, where the climate cannot be wholly without frost; mimosa verticillata, encalyptus hirta and obliqua.

In contributing still further to the elucidation and accomplishment of this new, very useful, and important object of the above arts, the account which has been given by Dr. Macculloch, of some delicate plants which are cultivated in the open air in the island of Guernsey, with the hints on the means of naturalizing tender exotics, inserted in the first volume of the "Memoirs of the Caledonian Horticultural Society," may also be found highly useful and interesting.

It is certain, it is conceived, that neither the thermometric flats of a given country, nor any meteorological condition which we have yet been able to observe, is competent to explain the peculiar affection of plants for particular regions of the earth. The observations of M. Ramond, in the "Annales du Museum," which have been translated by Mr. Salisbury, shew this, it is said, in a striking point of view. From these we see the perplexering regularity with which certain plants affect peculiar elevations, apparently unconnected with the nature of the soil, but bearing a relation alone to particular states of the atmosphere, which we have no means of appreciating. Similar facts are familiar to botanists in our own country, in the very limited zones of elevation affected by our alpine plants.

Vol. XXXV.

It is stated farther, that an economical object which depends on this property of plants remains yet to be noticed. This, which is still more in our power, is probably of more consequence than either of those mentioned above; what is meant is the perfect naturalization of the vine. It is well known, that from many of the ordinary varieties cultivated in this country, we can always procure a crop of grapes, but not always a crop of ripe ones. From two or three of these, the chance of ripening out of doors is considerable; from many others, it is hopeless. It is not improbable, that by successive sowings of feeds, other varieties might be produced, fill more certain of ripening than those which succeed best with us, e.g. the Miller and the Swevertake. We should thus acquire possession of an article of cultivation of great importance, by which a useful addition would be made to the agricultural proceeds of land, in particular situations, and by which we should be enabled to fabricate wines of a quality sufficiently good to compete with those of foreign growth.

A still more important object is, it is thought, the perfect naturalization of the potato, an effect as yet but very partially obtained, notwithstanding the length of time during which this valuable root has been a subject of cultivation. It is certain that this imperfect naturalization has been the result of the common practice of propagating by the tubers, to the almost total neglect of the feeds. It is true that feeds have been occasionally grown, and new varieties thus produced, but the experiment has hitherto been always undertaken for the mere purpose of producing these varieties, without any regard to that much more important object, the production of a plant sufficiently hardy to bear at least the first frosts of winter. In the southern parts of our island, it is not a desideratum of much importance, it is said, as the tubers are in general fully formed before the plant is killed by the frost; but in the northern parts it is an object of great consequence, the plant being frequently killed long before the roots have attained maturity. In the Highlands of Scotland, in particular, where a frost will frequently occur early in September, the crop is often prematurely destroyed, and the uses of this vegetable are in consequence materially limited. It is plain, that it would be necessary to sow the feeds of successive generations many times before the requisite degree of hardiness could be expected, and that the proceeds would demand both patience and time. Yet if it should require more of these than we can expect from the ordinary cultivator, it is an experiment which we may at least recommend to those public bodies, which so laudably exert themselves in ameliorating the agriculture and horticulture of this country. The difficulty of procuring feeds for seedling plants, could doubtless, it is thought, be obviated, in some measure, by depriving the young plant of its tubers, and thus compelling it to direct its energies to the other and more common mode of propagation, with which nature has provided all plants.

The writer cannot, however, conclude the suggestions in respect to this object or speculation, without mentioning a formidable objection which stands in the way of our attempts to naturalize particular plants. In every case where the useful varieties have been the result of cultivation in a warmer climate from a bafe and ufeless parent, it is to be feared, it is said, that the proceeds followed in naturalization, would again throw the plant back to its original state. This objection applies, it is supposed, chiefly to those fruits, such as the peach, the apple, and the grape, which, in their present cultivated state, are almost entirely the produce of art. For this reason, it is not improbable, that all attempts to naturalize
TEN

ize the grape to a cold climate may fail; yet the trial de-

ferves, it is said, to be made. The cale does not apply
equally to the potatoe. The original plant appears to be
valuable, independent of any artificial character, and would
consequently admit of a change, tending even to some
degree of deterioration, before it was materially injured in
its properties.

TENDERING, a name given to the soft tops of deers
horns, when they begin to shoot forth.

TENDING, in See Language, denotes the movement by
which a ship turns or swings round her anchor in a tide-
way at the beginning of the flood or ebb. Thus, if the
flood lets suddenly, it is evident that the ship, unless when
moored head and stern, will fall into the line of the current,
turning her head to the forthward, and vice versa. This
transition from one situation to the other is called tending or
swinging. Falconer.

TENDINOSUM CENTRUM. See CENTRUM.

TENDON, TENDO, in Anatomy, the hard, infensible
cords, by means of which muscular fibres are attached to
bones. See MUSCLE, after the description of the muscular
system of animal life; and FIBROUS SYSTEM.

TENDO Achillis, the powerful tendon belonging to the
muscles of the calf of the leg, placed just above the heel; so
named in allusion to the table, in which Thetis is said to
have held her son, Achilles, by this part, when she dipped him
in the Styx. See GASTROCNEMIUS.

TENDON of Achilles, Ruptured. When the tendo Achillis
is unfortunately cut, or ruptured, as it may be in con-
sequence of a violent exertion, or spasm of the muscles,
of which it is a continuation, the use of the leg is imme-
diately lost; and unless the part be afterwards successfully
united, the patient must remain a cripple for life.

The ancient surgeons seem not to have been well ac-
quainted with the rupture of the tendo Achillis, which they
probably might mistake for a spasm, or some other com-
plaint. In cafes in which this part had been cut, they re-
commended approximating the separated portions, and
maintaining them in contact by means of a future.

When the ruptured tendo Achillis was afterwards better
understood, the plan which we have just now mentioned
was fulfilled continued, the integuments being divided for the purpofe
of bringing the tendon into view. But that such a painful
mode is altogether useless and wrong, it is scarcely necessary
for us at the present day to observe.

The superficial situation of the tendo Achillis always
makes the nature of the accident easy of discovery, and it is
only when there is a considerable degree of swelling (which
is very rare), that the cale can be at all difficult to under-
fand. When the tendon has been cut through, which is not
an ordinary thing, the division of the skin brings the ends of
the fines into view. When the tendon has been ruptured, the
patient hears a sound, like that of the snapp of a whip, at
the moment of the occurrence. In whatsoever way the part
has been divided, there is a sudden incapacity, or, at least,
fr an extreme difficulty of standing and walking. Hence
the patient falls down, and cannot get up again. Besides
these symptoms, there is a very palpable depression be-
tween the ends of the tendon, which depression is increased
when the foot is bent, and diminished, or even quite removed,
when the foot is extended. The patient can spontaneously
bend his foot, none of the flexor muscles being interceded.
The power of extending the foot is full possible, as the
peronei muscles, the tibialis posticus, and long flexors, re-
mains perfect, and may perform this motion. Œuvres Chi-
rurgicales de Defaut par Bichat, tom. 1.

The indications are to bring the ends of the divided part
together, and to keep them so, until they have become firmly
united. The first object is easily fulfilled by putting the
foot in a plane of complete extension; the second, namely,
that of keeping the ends of the tendon in contact, is more
difficult.

In order to have a right comprehension of the indications,
we should consider what keeps the ends of the tendon from
being in contact. The flexion of the foot has this effect on
the lower portion; the contraction of the gastrocnemius
and fasciæ on the upper one. The indications then are to
put the foot in an unalterable plane of extension, and to
counteract the action of the above muscles.

The action of the muscles may be opposed: 1. By keep-

ing these powers in a continual state of relaxation. For
this purpose, the leg must be kept half bent upon the thigh.
2. By applying methodical pressure to the muscles; me-

thodical, because it is to operate on the flaccid portion of
the muscles, and not on the tendon, the ends of which being
depressed by it, would be separated from each other, and,
instead of growing together, would unite to the adjacent
parts. The pressure should also operate so as to prevent
the ends of the tendon from inclining either to the right or
left.

This kind of pressure, which the bandage ought to make,
seems to have escaped the attention of all authors. Who
cannot fee, however, that the action of the muscles being by
this means resifted, the upper end of the tendon will not
have such a tendency to be drawn upward, and separated
from the lower one? Œuvres Chirurgicales de Defaut par
Bichat, tom. 1.

The famous Petit seems entitled to the honour of having
first devised the plan of treating the ruptured, or divided
tendo Achillis, by keeping the leg and foot in a particular
posture, with the aid of an apparatus. Seeing that the ex-
tension of the foot brought the ends of the tendon into con-
tact, it occurred to him that such extension should be main-
tained during the whole of the treatment, in order to bring
about a permanent union. This happy idea, the simplicity
of which should have rendered it obvious to all practitioners,
one having originated, became the common business, on which
have been founded all the numerous methods of cure, which
have been since recommended. Defaut par Bichat.

The celebrated Dr. Alexander Mono, professor of
anatomy at Edinburgh, happened to rupture his tendo
Achillis. When the accident took place, he heard a loud
crack, as if he had suddenly broken a nut with his heel, and
he experienced a sensation, as if the heel of his shoe had
made a hole in the floor. This sensation, he says, has also
been observed by others, though some have complained of
a smart stroke, like what would be produced by a flone or
cane. Immediately suspecting what had happened, the
doctor extended his left foot, in which the occurrence had
taken place, as strongly as he could with his right hand,
while with the left he pressed the muscles of the calf down-
ward, so as to bring the ends of the broken tendon as near
together as possible. In this position he sat, until two fur-
gous came to his assistance. They applied compresses, and
bent a board to the upper part of the foot, and fore part of the
leg, both which they kept, as nearly as possible, in a
straight line, by a tight bandage, made with a long roller.
But as this mode of dressing soon became very uneasy,
it was changed for the following one. A foot-fock or fliper
was made of double quilted ticking, from the heeh of which
a belt or strap projected, of sufficient length to come up over
the calf of the leg. A strong piece of the same materials
was prepared, of sufficient breadth to surround the calf, and
this was fastened with laccings. On the back part of this
was a buckle, through which the strap of the foot-loek was 
palled, so that the foot could be extended, and the calf 
brought down at pleasure. The leg and foot were wrap-
up in soft flannel, fumigated with benzoin, and the bandage 
was kept on day and night, the belt being made tighter when the 
doctor was about to go to sleep, and loosened 
when he was awake, and on his guard. For a fortnight he 
did not move his foot and leg at all, but was conveyed in a 
chair on canvas from one part of the room to another. 
Afer this he began to move the ankle-joint, but in such a 
gentle manner as not to give any pain. The degree of 
motion was gradually increased, as the tendon became ca-
Peable of bearing it, care being taken to flop, when the mo-
tion began to create uneafnes. The affected limb was 
moved in this way, for half an hour a t a time. In a few 
days, the hollow between the separated ends of the tendon 
became imperceptible, though the part continued soft much 
longer. It became, however, gradually thicker and harder, 
ntil a knot was at last formed in it, apparently of a carti-
laginous nature. Though this was at first as large as a mid-
ddling plum, and gradually became fottier and smaller, yet it 
did not disappear entirely. Having occasion to go out five 
weeks after the accident, the doctor put on a pair of shoes, 
with heels two inches high, and contrived a steel machine to 
keep his foot in the proper position. This machine, how-
ever, he afterwards changed for another, made of the fame 
materials as the former. It was not till five months after the 
accident, that he thought proper to lay aside all affifiance, 
and to put the strength of the tendon to a trial. See 
Monro's Works, p. 661.

It seems unnecessary to enumerate the various plans de-
vifed since the time of Petit. Suffice it to state, that both 
in a wound and rupture of the tendon Achilles, the ancient 
method of using a future, for keeping the ends of the ten-
don in contact, is at present quite exploded, and position of the 
limb is the grand agent by which the cure is now uni-
erally accomplished. The following was Default’s method, 
which, though it was expressly designed to fulfill all the 
above-mentioned indications, may not after all be a more 
valuable practifical plan, than the one adopted by Dr. 
Monro. After the ends of the tendon had been brought into contact, by moderate flexion of the knee, and complete 
extension of the foot, Default used to fill up the hollows on 
each side of the tendon with soft lint and compreffes. 
The roller applied to the limb made as much pressure on these 
compreffes as on the tendon, and hence this part could not 
be depressed too much against the subjacent parts. Default 
ext next took a compref, about two inches broad, and long 
enough to reach from the toes to the middle of the thigh, 
and placed it under the foot, over the back of the leg, and 
the lower part of the thigh. He then began to apply a few 
circles of a roller round the end of the foot, to as to fix the 
lower extremity of the longitudinal compreffes. After 
covering the whole foot with the roller, he used to make the 
bandage describe the figure of 8, palling it under the foot, 
and across the place where the tendon was ruptured, and the 
method was limifed by encircling the limb upward with the 
roller, as far as the upper end of the longitudinal compreffes. 
Default par Bichat.

Certainly this plan seems to answear every object, and may 
be worthy of being adopted in this country. The con-
tinued pressure on the muscles of the calf, by which their 
action is materially rehbled, is too much disregarded by the 
generality of English surgeons. Consult Monro's Works 
Encyclopédie Méthodique, article Achilles, tendon d’; and 
Mémoire sur la Division du Tendon d’Achille, in Œuvres Chi-
rurgicales de Default par Bichat, tom. i. p. 306. Cooper’s 
Dick. of Practical Surgery.

TENDONS, Shooting of the, Subsultus tendinum, in Medicine, a 
flight and repeated convulsive twitching of the muscles, 
which occurs in the latter stages of low fevers, and, as it 
indicates great debility, and a very morbid condition of the 
brain or common tenfiorium, it is usually reckoned among the 
dangerous symptoms of fever. See FEVER, and TYPHUS.

TENDON, in the Mange, a sort of gristle that surrounds 
one part of the horse’s foot, and is feated between the hoof 
and the coffin-bone, near the coronet. When a horse has a 
quitter-bone, the matter that gathers between the coffin-bone 
and the hoof spoils the tendon, and makes it black; and the 
cure of such a quilter-bone consists in cutting and extirpating 
the tendon.

TENDREMENT, Fr. in Music, tenderly, equal to con 
temperamente, Ital. See CON AFFETTO, and AFFETTUOSO.

TENDRIL, in Botany and Vegetable Phyfology. See 
CIRRHUS.

TENDUCCI, FERDINANDO, in Biography, an opera-
finger in soprano, born at Sienna, whence he at first assumed 
the name of Senefino, on account of the celebrity of a finger 
of that city, in the early part of the last century; though 
neither his voice nor figure of singing at all resembled that of 
the great finger and actor, Francesco Bernardo detto Se-
fenio, whose voice was a rich and full contralto, and in whole 
singing and acting there were more of grandeur and dignity 
than tendernefs and expression, which characterized Ten-
ducci’s figure; and whose voice was a high soprano of a clear 
silvery tone, which by great pains he had rendered very 
flexible; but he had formed himself more on Caffarelli’s 
figure than on that of Senefino.

He arrived in England, as second man, in 1758, when 
Pottenza was principal. The first notice he obtained was in 
a cantabile air, set by Caffarelli for himself, in the fine figure of 
grand pathetic, such as six years after, Mannzoli’s fine adagio 
in Ezio, “Ciro mio bene addio,” was composed in by 
Peccetti.

It was in 1759, during the reign of Cocchi’s “Ciro 
riconosciuto,” that he became a favourite of the public; for 
though a young performer, and only second in rank under 
Pottenza, he had a much better voice and manner of singing 
than the performer to whom he gave precedence.

In 1760 he went to Scotland, and we hear no more of 
him till 1763, when he returned to London, and performed 
the principal man’s part in Dr. Arne’s Artaxeres, of which 
the success was greatly owing to his talents.

At this period, Bach and Abel established a weekly sub-
scription concert in Hanover-square, which was better 
patronized and longer supported than perhaps any one had 
ever been in this country, having continued full twenty years 
without uninterrupted prosperity, at which, during the chief part 
of the time, Tenducci was the principal finger.

In 1772 he succeeded Guadagni as first man at the great 
opera, performing that year with the Grafi in “Coroep,” 
and the next year in “Semiramide riconosciuta.”

In 1764 he went to Ireland, where he and Mrs Brent 
performed together in Artaxeres.

In 1765 an Italian opera was performed in Dublin, in 
which he and the Cremonini sang principal parts in Mithri-
dates, in the principal cities of that country.

Some time after he returned to London, and was engaged 
at the opera, where, in 1785, he revived Gluck’s Orfeo.

Such is the outline of his professional career in public. 
The events of his private life are still more varied.

He had not been long in England before he was thrown 
into
into the king's bench for debt, where he emblazoned that residence by his talents, and amused its inhabitants. He was, however, allowed to attend evening concerts elsewhere, attended by a garde du corps. But on these occasions, a Jewish lady, his patroness, carried him in her carriage to the performance, and conducted him safe back with his attendant to his limited residence; where, during a part of the time, he had the honour of Dr. Smollett for his neighbour.

In Scotland he hung at the Edinburgh concerts, and gave lessons in singing; by which occupation he improved his own talents so much, that he returned to London a much better finger than when he left it. So true is the observation of Arizotile, that no art or science is well learned but by teaching, when it is necessary to give reasons for what in private practice is done mechanically.

In Ireland he married a lady of considerable fortune, who was enchanted by his talents.

In Italy, whether he carried this lady, he was unmarried, the laws of that country forbidding conjugal union to caftrati. And on his application to the pope for a dispensation, it was refused; though the petitioner said that his reason for marrying was, the operation in his youth not having been completely performed: "why then," says his holiness, "let he be done more effectually?" and he was obliged to separate himself from his tender spouse, and to console herself with a more efficient husband.

When he quitted the stage, he employed his whole time in teaching to sing; had many scholars, and a good method of instruction; giving to his pupils, in English, a set of axioms or rules of study and practice translated from the Italian, drawn up, as he said, by himself; but which, after his decease, were found in the Solferggi of April.

Notwithstanding the great number of his scholars, his income was insufficient to keep him out of debt, or even the king's bench, without the ingenious expedient of becoming a bankrupt, by which he defrauded all his creditors, and died insolvent, being, as has been reported, buried at the expense of his countrymen, who made a collection for that purpose at the Orange coffee-house. But from better authority, we have been informed that he died at Genoa.

Tenducci had much professional merit; but as to probity, honour, and ideas of right and wrong, they never seem to have extended further than convenience and personal safety.

TENDUNCULO, in Geography, a river of Africa, which runs into the Indian sea, S. lat. 19° 20'.

TENEA, in Ancient Geography, a town of Corinth, on the frontiers of Sicenia, S. of Epiceria. It pretended to derive its foundation from the Trojans made prisoners in the isle of Tenedos, and brought into this country by Agamemnon. Apollo was much honoured here.

TENEBRÆ, Darkness, in the Romish Church, a service performed on the Wednesday, Thursday, and Friday before Easter, in commemoration of the agony of our Saviour in the garden; and the darkness that overspread the earth at the time of his crucifixion.

TENEBRIO, in Entomology, a genus of the Coleoptera order of insects, the generic character of which is, that the antennae are moniliform, with the last joint rounded; the thorax plano-convex, margined; the head exerted, and wing-veins tibifil.

In the insects of this genus the body is oblong-oval, and in most species somewhat pointed at the extremity. Several species are also ditinct of wings. This is a numerous genus, and is divided by Fabricius and others into several distinct genera, under the appellations of Pimelia, Bleps, Aturmus, &c. In Gmelin's edition of Linnaeus it comprehends 63 species. The European species are denoted by an asterisk.

A. Six filiform Feelers; anterior legs formed for digging, palmate-dentated; including the Scaris of Fabricius and Pallar.

Species.

COMPLANATUS. Black, with a subquadrate thorax, and smooth shells or wing-veins of a large size. Found at Cayenne.

MARGINATUS. Black, with a subquadrate thorax; fulcated shells; blue margin. Found at Cayenne.

GIGANTUS. Black, with fulcated mandibles, and smooth shells. Found in Africa; nearly allied to the next species, but three times as large.

SUBTERRANEUS. Black, with the fore-part of the head fulcated, and frigate shells.

CYANEUS. Blue, very smooth; antennæ and feet black. Found in New Holland.

* Fossor. Pitchy. Found in sand-hills, which it perforates.

* CURSOR. Brown; oblong thorax; five angles denticated. Found as the former.

ARARUS. Black; serrated thorax; antennae and feet tassaceous. Found in the East.

MINUTUS. Black; thorax margined; antennæ elevated, and feet pitchy. Found in Sweden; and twice as large in Saxony.

COLLARIS. Black, with shells punctate-serrated, and head brown; antennæ and feet pitchy; the anterior spinous. Found at Berlin.

Bucephalus. Wholly brown, punctated; eyes black. Found in India.

B. With unequal filiform Feelers.

ATRATUS. Wholly black; smooth. Found in Egypt.

C. With four Feelers; the anterior subclavate; the posterior filiform; the Tenebrions of Fabricius, and Mylarides of Pallar.

LAMINATUS. Black; thorax subquadrate, smooth; shells fulcated; anterior legs incurvatur at the apex, and ferruginous lamina acute. Found in India; the largest of the genus.

GIGAS. Black; shell frigate; thorax smooth. Found in Surinam.

PUNCTATUS. Black; thorax quadrate; margin subdenticate; shells frigate-punctated. Found in India; of a large size.

SEYRATUS. Black, smooth; shells frigate; posterior legs frigate. Found in Sierra Leone.

* MOLYR. Wholly black; thighs anterior thicker; — an insect often seen in houses, one of the smaller kinds, proceeding from a larva commonly known by the name of mealworm, from its being so frequently found in flour, &c.; it is of a yellowish-white colour, about an inch long, slender-bodied, and of a highly polished surface, and is considered as the favourite food of the nightingale, in its captive state, and laid to remain two years before it changes into a chrysalis.

LURIDUS. Black, with brown feet. Found in Brazil.

CHALYBEUS. Violet, with feet and antennæ pitchy. Found in Guinea.

MAURITANICUS. Black, beneath pitchy; margins of the

</tbody>
</table>

> "Eft in confpectu Tenedos, nonstima fami
Infula, dives opum, Priamui duum regna manebant;
Nunc tantum fium et sitato malicida carinis."

According to Diodorus Siculus, it had anciently been called Locrophus; but when Tenes or Tennes built a town upon it, he called it Tenedos. Dohacht, however, derives its name from the Phrygian word Tin-edum, red clay, which was found here, and used for making earthen-ware. Paunianus says, that this island, which was situated within fight of the city of Troy, became miserable after the capture of the city, and was obliged to surrender to its neighbours, who had built Alexandria upon the ruins of Troy. It was one of the first conquests of the Periains, who made themselves masters of it, after having defeated the Ionians at the isle of Lada. It took part with the Athenians against the Lacedemonians, when an admiral of the latter people ravaged it, and drew from it contributions. The Romans had possession of it, and Verres pillaged the temple, and carried away the statue of Tenees, the supposed founder of the town. Strabo represents it as 24 stadia in circumference, and places it at the distance of 11 stadia from the continent; but Phyll states this distance to be 12 miles. Olivier computes the distance to be nearly 3000 toises; and he says, that the town is at the distance of about five leagues from
from the entrance of the Hellepont. This position has always rendered Tenedos important. Vessels bound to Constaninople find shelter in the ports of this island, or safe anchorage in the roads, when the winds are contrary and the weather bad. The emperor Julianus established in this island a magazine for receiving cargoes of corn transported from Egypt, 180 feet long, 90 broad, and proportionally high. During the troubles of the Greek empire, Tenedos sustained many vicissitudes. It was for many years a place of rendezvous for pirates. Scantily peopled and ill defended, it passed betimes under the Ottoman domination. The caliph Othman feized it in the year 1302, and in the possession of it, he was enabled to subdue the other isles of the Archipelago. During the minority of Mahomet IV. the Venetians retook it after the complete defeat of the Turkish fleet in the strait by the admiral Mocenigo, in 1656; but in the following year, the admiral having been killed in a second engagement, the Venetian fleet retired, and this island fell again under the power of the Turks, who have preferred it without interruption till the present day. The harbour is small, and can only receive merchant vessels: it is formed by a jetty even with the water's edge, and a tongue of land, on which is constructed the citadel that defends the entrance, and can at most secure it against being surprized by a privateer. The town is built in form of a semicircle, in a valley, and on the declivity of two hills: its population is from 5000 to 6000 souls, judging from its extent, and from the number of persons who pay the karachi. Its inhabitants, who are Turks and Greeks in equal numbers, are almost all occupied in the culture of the lands, few of them being mariners. The island is under the administration of a waivode or governor, an aga commander of the citadel, and a cadi or judge. The defenders of the town are 200 or 300 janizaries. The town is commanded by a pyramidal mountain of small elevation, that seems to have been formed by the action of a volcano, the traces of which are discoverable. In the environs is found a granite remarkable for pieces, of various sizes, of selflar crystallized. On the right of the mountain, in passing from the town towards the W., is a sandy plain, far from fertile, and almost entirely covered with vines. The hills, in general, are naked, dry, and little susceptible of culture. Those on the south of the town are calcareous; and the rock is more or less chalky and loaded with sea-shells.

Tenedos produces little corn, fruit, or herbage. The vine is the only article of wealth of this country, and its culture the principal occupation of the inhabitants. Muscadel wine is made in considerable quantities. From Tenedos are annually exported upwards of 600,000 oeks of wine, producing to the farmer more than 50,000 piastres. This wine paffes to Constaninople, Smyrna, and Raffia. This island also exports a small quantity of brandy. The climate of Tenedos is more temperate than that of the Dardanelles: it seldom freezes here, and the summer heats are moderated by the N.N.E. wind, which blows regularly during the day. The houffes have terraces of flat roofs. The Greek inhabitants are less gay than those of the other island: in the streets they are silent and melancholy, avoiding through fear the attention of the Turks; but when they can indulge themselves in mirth without danger, they surrender themselves to a sort of extravagant joy and delirium. The coast of Troy is frequently the theatre of their orgies and the field of their pleasures: thither they repair on the occasion of a wedding or of a festival, and there, under the shade of a plane-tree or oak, they pass the whole day in dancing, singing, eating and drinking. The females, however, are kept within the bounds of decorum, and might be compared, from their features and their shape, to the most beautiful models which antiquity has transmitted to us. N. lat. 39° 53'. E. long. 26°. Sonnnini. Olivier.

TENELLA, in Ancient Myths. As some conquerors at the Olympic games were not so fortunate as to have poets for their friends, or so rich as to be able to purchase odes on their particular victories, which were rated very high by bards of the first class; in honour of such, the old hymn to Hercules, of Archilochus, was sung by the friends of the conquerors only, if they could not afford to engage a band of professed musicians. The scholiast on Pindar's ninth Olympic tells us, that to supply the want of a cithara, Archilochus framed a word in imitation of the sound of a cithara, which word (Tenella, Τενέλλα), when there happened to be no musician present, the leader of the chorus chanted forth, and was answered by the rest of the chorus, in the words of the hymn, Ο Καλλακτεινομένη, Σφυφιί, O glorius Victor, hail! at every comma, or pause of which, this burden was again repeated.

TENENBER, in Geography, an island in the East Indian sea, 12 miles long and 3 broad. S. lat. 6° 50'. E. long. 122° 45'.

TENEMENT, Tenancy, in Laws, a house or lands, depending on a manor, or lordship; or a fee, or farm held of a superior lord, and which he may recall, when the term or condition is expired.

TENEMENT, Frank, is any lands, house, office, or the like, in which a man has estate for life, or in fee.

TENEMENT, Base, is where a man holds lands, &c. at the will of the lord.

Yet Kitchin, Briton, &c. make frank tenement and bare tenement opposites; on which footing, frank tenement should be where the tenant is at liberty to quit it when he pleases.

TENEMENTARY LANDS, among our ancestors, were the outlands of manors, which the Saxon thanes, or nobles, let out to tenants under arbitrary rents and services.

TENEMENTIS LEGATIS, in Laws, a writ which lies in London, and other places, where the custom is to devise tenements by half will as well as personal goods and chattels, for the hearing of any cause relating to them.

TENEN, or Knix, in Geography, a town of Dalmatia, situated on the borders of Botina, and the fee of a bishop; 48 miles S. of Bihace.

TENENDUM, in Laws, a clauze in a deed, in which the tenure of the land is created and limited. The office of a tenendum is to limit and appoint the tenure to the land which is held, and how, and of whom it is held. The tenendum seems now to be incorporated with the habendum, for we say, to have and to hold, in which clause the estate is limited, &c.

TENENTES NATIVI. See NATIVI.

TENTENIBUS in Affisa non Onerandum, in Laws, a writ which lies for him to whom a defferar has made over land, of which he deffered another; requiring that he be not disturbed in affise, for the damages awarded, if the defferar have wherewithal to satisfy them.

TENERETZA, tender, cares, feeling, equivalent to the French term tendrement.

TENERIA, in Geography, a town of the island of Cuba; 45 miles N.W. of Villa del Principe.

TENERIFFE, one of the Canary islands, the second in dignity, but the first probably with regard to wealth and fertility. It is about 70 miles in length, and its mean breadth is about 22 miles: its surface contains 1540 square miles, having, at an average, about 45 persons to the square mile.
The number of acres is 985,600, which, upon an average, allot about 10 acres to every individual in it; the number of inhabitants being calculated to be nearly 100,000. Of these there is annually a considerable migration to the Spanish colonies in South America. The poor of Teneriffe are easily persuaded to migrate, as the proprietors of the land do not give them sufficient employment throughout the year; and they have not the resources of manufacturers, except a trifling one in silk, chiefly stockings. The price of labour is under a shilling a day; and, beside corn and roots, the principal food of the common people is confined to cod-fish, caught on the neighbouring coast of Africa, or imported from North America. This island was formerly called Nivaria, which appellation it derived from the circle of snow that surrounded the peak of Tenda, now called the peak of Teneriffe; which name was given to it, as it is said, by the inhabitants of Palma island, in whose language tener signifies snow, and efe, a mountain. The figure of this island is triangular, as it extends into three capes, the nearest being about 80 leagues or more from the coast of Africa. The historical celebrity of this island has been very much owing to its peak, elevated to a considerable height from a base lying a little to the S.W. of its centre. Of its height we have various statements by different writers, who have ascended to its summit. Dr. Heberden, whose observations in ascending it are published in the Phil. Trans. vol. xlvii., makes its height above the level of the sea to be 2566 fathoms, or 15,396 English feet; and he says that this measure was confirmed by two subsequent observations by himself, and another made by Mr. Crofte, the consul. Nevertheless, chevalier de Bordia, who measured the height of this mountain in August 1776, makes it to be only 1931 French toises, or 12,340 English feet. Mr. Johnston, a merchant of Madeira, being on board ship in the offing of Orotava, took the angles made by a line from the horizon to the summit of the Peak, at two different spots, and measuring the distance between them by the log, determined the perpendicular height of the Peak to be 2023 English fathoms, being nearly the same as Chev. de Bordia had calculated from a base measured upon land. From the comparative observations of Mons. de Bordia's barometers, upon the Peak, and by the sea-fide, the mountain's height came within two fathoms of the geometrical measurement. The Hon. Grey Bennet, who made a journey to the top of the Peak in 1810, states its height to be about 12,500 feet. M. de Lemanon and Monges, on the 26th of August 1785, ascended the Peak, and stating its elevation above the level of the sea to be near 1000 toises, made some chemical experiments, in order to compare the phenomena at that height with those which occur in our laboratories. They observe, that the crater of the Peak is a perfect folettaria or laboratory of sulphur; its diameter being about 50 toises by 40, rilling with a steep and rapid ascents from W. to E. On the edges of the crater, and particularly towards the lowest part, are several apertures or vents, exhaling watery and sulphuric acid vapours, the heat of which raised the thermometer from 90° to 34°. The interior of the crater is covered with yellow, red, and white clay, and fragments of lava partly decomposed. Under these were found beautiful crystals of sulphur, forming rhomboidal octahedra, some of which were an inch thick. The flame exhaled from the apertures was pure water, not at all acid. The evaporation of liquids, and the cold thus produced, were very considerable. The action of the acids on metals, earths, and alkalies was slow, and the bubbles that escaped during the effervescence were much larger than usual. The production of vitriols afforded a singular phenomenon. That of iron instantly assumed a fine violet colour, and that of copper precipitated with a very vivid hue. The smell and strength of liquors appeared not to have lost any thing at this elevation, and the volatile alkali, ether, and alcohol, retained the same strength. Several experiments were made with a view of ascertaining the nature of the vapours exhaled from the crater, and whether they contained inflammable air, fixed air, or marine acid. From these he concluded that no fixed air exhaled from the crater, and also that the atmospheric air reifying upon it contains very little, and that the inflammable vapours and sulphuric acid gas alone are considerable, and indeed perceivable. The atmospheric electricity was considerable and positive. Many new varieties of volcanic ochors were discovered. See La Perouze's Voyage, vol. ii. p. 226, &c.

Dr. Heberden gave sir Joseph Banks some salt which he collected on the top of the mountain, where it is found in large quantities, and which he supposed to be the true nitrum, or nitrum, of the ancients. Although the vortex appears sharp, and of the exact resemblance of a cone, yet it is flat for the extent of an acre of ground, in the centre of which is a dreadful volcano, which frequently breaks out into flames, so violent as to shake the whole island with an incredible force. Smoke constantly issues from the mountain, near its summit, but no eruption has occurred since the year 1754, when the port of Garrachica was destroyed, and the harbour filled by the lava. The island of Teneriffe is divided in the middle by a ridge of mountains, which have been compared to the roof of a church, the Peak forming the spire or fleeple in the centre. An author well acquainted with the island says, that if you divide it into twelve parts, ten of these consist of rocks, woody and inaccessible mountains and vineyards; and yet, from the small remainder of arable ground, he has seen 250,000 hanches of wheat, besides immense quantities of yew and barley, produced. The greatest part of the island is volcanic, and all its rocks are lava. Mr. Bennet (Trans. of the Geological Society, vol. ii.) conceives, that formerly a very large crater, 12 miles in diameter, existed, the sides of which, under the name of Los Foldias, may be still traced a great way. The crater at the top of the Peak is but small, and somewhat in activity. The lavas vary in their appearance: some are composed of hornblende and felspath, without any foreign body; these are porphyritic: some are composed of green-flone, and contain olivin, augite, and zeolites: some are basaltic: these decompose the founet, and confitute the most fertile soil: there are also pumice in abundance, tufa ashes, and a lava resembling obsidian. Every circumstance, it is said, argued in favour of a volcanic formation, except the form of the mountains, whose irregular ridges, declivities, and acesuits, appeared very different from those exhibited by volcanic mountains. In the plain beyond Laguna, on the Orotava fide, the soil was not in the least volcanic, but composed of fine mould, or virgin earth; a mixture of clay, vegetable earth, and sand. Hollows, 30 feet deep, left dry by riverlets, exhibit no volcanic appearance. Immediately under the superficial soil was a layer of deep loam, next, one of tough clay, and all below was an irregular mixture of clay and sand. Elsewhere the hills consisted of indurated clay, and clay and iron, without any marks of the action of fire. In the whole island, there is no pure flint or scint-flone. Its mountains are of two sorts: one, evidently volcanic; the other, primary and composed of indurated clay, or of clay and calx of iron. In the low plains are layers of loose and soft argillaceous earth. (See Dr. Gillan's remarks in the 1st vol. of the Emburry to China, p. 118—120.) Although the people live on scanty and coarse fare, they are not much subject to disease, and instances of longevity, even to 100 years,
years, are said not to be rare amongst them. The air is dry and pure. The variations of the thermometer seldom exceed 14°, from 68° to 82°, in the inhabited part of the island. (See Gua-"iches.) To the eastward of Santa Cruz, says Mr. Ander-son (Cook's Third Voyage, vol. i. p. 22. &c.) the island appears perfectly barren. Ridges of hills run towards the sea, between which ridges are deep vallies, terminating at mountains or hills that run across and are higher than the former. Those that run towards the sea are marked by impressions on their fides, which make them appear as a succession of conic hills, with their tops very rugged. The higher ones that run across are more uniform in their appearance. The basis of the hills is a heavy, compact, blueifh stone, mixed with some shining particles; and on the surface, large mafles of red friable earth, or stone, are flattered about. The little earth, that appeared here and there, was a blackifh mould. There were likewise some pieces of flag, one of which, from its weight, and smooth surface, seemed almost wholly metalline. The mouldering state of these hills is, without doubt, owing to the perpetual action of the fun, which calcines their surface. “After walking about three miles,” says Mr. Ander-son, “I found no alteration in the appearance of the lower hills, which produce great quantities of the euphorbia Canaries. I met with nothing else growing there, but two or three small shrubs, and a few fig-trees near the bottom of the valley. Mott of the laborious work in this island is performed by mules, horfes being to appearance scarce, and chiefly referved for the use of the officers; they are of a small size, but well shaped and spirited. Oxen are also employed to drag their cafts along, upon a large clumsy piece of wood. In my walks and excursions I saw fome hawks, parrots, which are natives of the island, the sea-fowl or tern, sea-gulls, par-tridges, wagtails, swallows, martins, blackbirds, and Can-ary birds in large flocks. There are also lizards of the common, and another fort; fome infects, as locuits; and three or four sorts of dragon-flies.” Mr. Ander-son was informed that a shrub is common here, agreeing exactly with the defcription given by Tournefort and Linnaeus of the tea shrub, as growing in China and Japan. Another botan-ical curiosity, mentioned by him, is what they call the im-pregnated lemon. It is a perfect and diftinct lemon, in-closed within another, differing from the outer one only in being a little more globular. The leaves of the tree that produces this fort, are much longer than thoſe of the common one; and it was referred to him as being crooked, and not equal in beauty. Mr. Ander-son learnt alfo, that a certain fort of grape growing here is reckoned an excellent remedy in phthisical complaints; and the air and climate in general are remarkably healthful, and particularly adapted to give relief in fuch diseases. This he endeavoured to ac-count for by its being always poffible to procure a different temperature of the air, by retiding at different heights in the island; and he exprefsed his surprize that the English phyficians had never thought of fending their confumptive patients to Teneriffe, infted of Nice or Lisbon. They reckon that 40,000 pipes of wine are annually made, the greatest part of which is either confined in the {land, or made into brandy, and fent to the Spanish West Indies and North America.

In the Embaffy to China (vol. i.) the quantity of wine, conflifiting principally of white wine, faid to be exported from Teneriffe, is about 25,000 pipes annually made in the island. Part is fent to South America; and the Englifh take off a confiderable quantity in return for manufaftures; and the North Americans in payment of corn, flaves, horfes and tobacco, which laft article is contraband and smuggled.

Tobacco or snuff is in universal use; and that which is legally imported is fold at fo high a price, that the temptation to smuggling is irrefifible. The royal monopoly extends even to orchards or orchil, a fubftance used in dyeing. Formerly there was made at Teneriffe a great quantity of Canary fack, which the French call “vina de Malvasia,” and we, corruptly after them, name Malmy (from Malvasia, a town in the Morea, famous for fuch luscious wine). In the 17th century, and fihl later, much of this was imported into Eng-land, and little wine is now made there except that defcribed by Capt. Cook, and which he compares with Madeira, the latter being as much fuperior to the former, as frong beer is to small. But the great difference of price is a recommendation of it. Besides wine, which is the chief produce of the ifland, beef may be had at a moderate price. The oxen are small and bony, and the meat lean. Hogs, sheep, goats, and poultry, may alfo be bought at a moderate rate; and fruits, fuch as grapes, figs, pears, mulberries, plam-tains, and mulf melons, are in great plenty. Their pampems, onions, and potatoes, are alfo very good of their kind. The Indian corn, which is their produce, and alfo their fruits and roots, may be had at a very reafonable rate. They have no plentiful supply of fish from the adjoining sea; but a confiderable fhillery is carried on by their veffels upon the coaft of Barbary; and the produce of it sells at a rea-fonable price. Capt. Cook fays that he found Teneriffe to be a more eligible place than Madeira for fhips bound on long voyages to touch at. At Teneriffe they make a little flik; but unlefs we reckon the filtering-fones, brought in great numbers from Grand Canary, the wine is the only confider-able article of the foreign commerce of Teneriffe. None of the race of inhabitants found here when the Spaniards disovered the Canaries, now remain a diftinct people, having intermarried with the Spanifh fettlers; but their de-fcendants are known from their being remarkably tall, large-boned, and ftrong. The men are in general of a fawny colour, and the women have a pale complexion, entirely deftitute of that bloom which diftinguifhes our northern beauties. The Spanish custom of wearing black clothes continues amongst them; but the men feem more indifferent about this, and in some meafe drefs like the French.

According to Capt. Cook, the peak of Teneriffe is situated in N. lat. 26° 18', and upon this supposition its longitude will be

\[
\begin{align*}
\text{The time-keepers} & \quad 19^\circ \ 0' \\
\text{Lunar observations} & \quad 16 \ 30 \ 20 \\
\text{Mr. Varila} & \quad 16 \ 46 \ 0
\end{align*}
\]

But if its latitude be 26° 12' 54", as in Malkeyne's British Mariner's Guide, its longitude will be 13° 30' more easterly. The variation (August 1776) by a mean of all Capt. Cook's compaifles was found to be 14° 41' 20" W. The dip of the N. end of the needle was 61° 52' 30''.

TENERIFFE, a town of South America, in the govern-ment of the Caraccas, and province of St. Martha; 80 miles S.S.W. of St. Martha. N. lat. 10° 2'. W. long. 74° 30'.

TENSMUS, in Medicine, an infeffant and urgent de-fire to go to ftool, while the evacuations are exceedingly feanty, of a mucous or bloody appearance, and are attended with fiercely any relief of the diftreffing fenfation which preceded them. It may be brought on by any caufe which excites excifive irritation in the reftum, either direftly, or by sympathy with neighbouring organs, fuch as the bladder, uterus, proflate gland, or urethra. Thus it is frequently a symptom of a tume in the bladder, of inflammation of the neck of that organ, of fistula, of gonorrhoea virulenta, and afo of pregnancy. In its moft acute form, tenemus more commonly
commonly occurs as a consequence of disease affecting the intestines themselves, and more especially of dysentery: it is also frequently excited by ascariides, or hemorrhoidal tumours within the rectum. See Dysentery.

The treatment of this affection must of course be adapted to the nature of the irritation which has occasioned it; and the removal of the irritating cause will generally be followed by the cessation of the effect. When this, however, cannot be accomplished, the introduction of opium as a suppository into the rectum, or united with a flarly glyster, will often procure essential relief.

TENESSEE, in Geography. See Tennessee.

TENESUR, a town of Egypt, on the west branch of the Nile; 3 miles S. of Amrass.

TENET, a particular opinion, dogma, or doctrine, professedly held by some divine, philosopher, &c.

The distinguishing tenets of the several sects in religion, and philosophy, are the names of the sects themselves.

TENEX, or Tenes, in Geography. See Tennis.

TENEZA, a town of Morocco; 43 miles W.S.W. of Morocco.

TENA, in Botany, a name by which some authors have called the cocoa-nut tree, or palma indica nucifera of other writers.

TENGA, in Geography, a city of China, of the first rank, in Hou-ouiang; 550 miles S. of Nanking. N. lat. 31° 26'. E. long. 113° 17'.

TENGAPATAM, a town of Hindostan, on the sea-coast, in the country of Travancore; 20 miles S.W. of Travancore.

TENGI, a town of Persia, in the province of Schirvan; 25 miles N. of Scambache.

TENILO, a river of Lapland, which falls into the Tornen, which, as well as the lake and mountain of Niemi, has been celebrated by Maupertuis for picturesque beauty.

TENGIS, a lake of Independent Tartary, about 140 miles in length by half that breadth, being the largest lake in Asia after the seas of Aral and Baikal. It is also called Balkash or Puscaté. This lake, with two others that are very considerable, belong to the Kalmucks subject to China.

TENGMO, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 10'. E. long. 21° 52'.

TENG-TCHOUEN, a city of China, of the second rank, in Yun-nan; 1182 miles S.W. of Peking. N. lat. 26° 2'. E. long. 99° 49'.

TENGZEGzet. See Tenzegzet.

TENIA. See Tenia.

TENIERS, DAVID, the younger, in Biography, was born at Antwerp in 1610, and was initiated in the art of painting by his father; but he afterwards became a disciple of Adrian Brouwer, and is also said to have had the happy's and honour of receiving instructions from Rubens. The subjects and the style he adopted were, as we have said, the same with those employed by his father; but with a more fertile imagination, he produced compositions infinitely more varied and ingenious, with colouring and effect more vivid and engaging, more rich and transparent; and with a facility of execution perfectly enchanting. It is true, with an elevated exhibition of character or expression; what there may be of those qualities, was more probably a fortunate hit, than any result of meditation or intention. In this respect Jan Stein, and our own Wilkie, have as much the superiority over Teniers, as he possessed by the power of his execution.

At the first display of his powers he was not so successful as he merited, but it was not long that he lay neglected: the archduke Leopold being made acquainted with his merits, immediately distinguished him by his patronage; appointed him his principal painter; honoured him by making him a gentleman of his bed-chamber; presented him with a chain of gold, to which his portrait was affixed; and gave him the superintendence of his gallery of pictures, which contained works of the most distinguished masters of the Italian and Flemish schools. Of this gallery, Teniers made several pictures, in which he imitated the manners of the various masters so successfully, as to obtain the name of the Proteus of painting. He also amused himself by making compositions in the styles of different painters of renown, as Titian, Tintoretto, the Baffans, Rubens, &c; and in their execution endeavoured to imitate the touch of those great men. These imitations are generally known under the name of pastiches, and have frequently been mistaken for originals, and fold as such.

There were the amusements and indulgencies of idle fancy; his fame red for more full and honourable support upon his original productions in his own proper style. He was a constant and faithful observer of nature; and in his favourite subjects, village festivals, fairs, and merry-makings, he has exhibited, with a most engaging freedom, the manners and characters of his countrymen. That he might conveniently mingle with the scenes he chose to represent, he established himself in the village of Perk, between Antwerp and Mechlin, and there, with a painter's eye, he observed the undisturbed impulse of the natural character of the lower classes among the people, and has left many beautiful and pleasing remembrances of occurrences interesting, nay sometimes disgusting in themselves, but rendered engaging by his delightful mode of representing them. One peculiar charm there is to be found in the best pictures of Teniers, more perfectly obtained than in the works of other artists, and that is, the complete effect of atmosphere, silver, pure, and natural; Claude de Lorrain himself does not surpass him; and this truth, though yielded on simple materials, in scenes flat and infipid in their forms, yet makes amends for their natural want of interest by its truth and simplicity.

In the interior of apartments, of the cottage, the cabinet, the parlor, or charcoal's laboratory, he is not less admirable by his clearness and precision than in his exteriors. He surpassed in his knowledge of perspective, and in his freedom, as much as he is excelled by the latter in truth and
of tone and completion of character. His pencil is exceedingly light and dexterous; and by continual practice upon the sametyulem, he had acquired a promptness almost unparalleled. This freedom of execution enabled him to paint an immense number of pictures: it was not unusual for him to finish a picture in a day; and he used jocously to observe, that to contain all the pictures he had painted, it would be necessary to have a gallery two leagues long. He not unfrequently afflicted the landscape painters of his day, by putting figures into their pictures; and many works of Artois, Van Uden, Brougel, and many others, owe an increased value to this circumstance. His works are numerous in the collections of this country, and still bear very high prices. Teniers lived to the advanced age of eighty-four, and died at Brussels in 1694.

He had a younger brother named Abraham, who also painted the same kind of subjects in the same style, and from this circumstance his works are sometimes mistaken for those of David, though they are much inferior in taste and execution.

TENINE, in Geography, a town of South America, in the province of Tucuman; 20 miles S.W. of St. Yago del Elerio.

TENIS, a lake of Ruffian Tartary, 60 miles in circumference. N. lat. 53° 20'. E. long. 74° 4'.

TENISON, Thomas, in Biography, archbishop of Canterbury, was the son of the Rev. John Tenison, recter of Mundeley, in Norfolk, and born in the year 1636. He received his university education at Benet college, Cambridge, of which he became a fellow in 1652. Having officiated for some time as a tutor in his college, he was presented in 1665 to the cure of St. Andrew the Great in Cambridge, and continued his attention to his parochial duty during the plague. In 1667 he became chaplain to the earl of Manchester, and obtained a rectory at Huntingdonshire. His first publication appeared in 1670, and was entitled "The Creed of Mr. Hobbes examined, in a feigned Conference between him and a Student in Divinity." In 1674 he was chozen principal minister to the church of St. Peter's Mancroft, Norwich; and in 1678 he published a "Difcourse of Idolatry," and in 1679 "Bacooniana," or some pieces of the great lord Verulam, with a general account of his writings. As he was one of the royal chaplains in 1680, he graduated D.D., and was presented by the king to the vicarage of St. Martin's-in-the-Fields, London. As an antagonist to popery, the apprehension of which was then very prevalent, he wrote several works against it, and also against Socinianism; and whilst he was guarding the church against those whom he conceived to be its enemies, he acquired still greater honour by liberal benefactions to the poor, and by laying the foundation of an endowed school and public library, which he afterwards completed. He blended gravity with moderation to such a degree, as to command general esteem; and accordingly he was elected by the unfortunate duke of Monmouth to prepare him for his execution. He also conducted himself with so much prudence at court, that he is said to have had a personal interest even with James II. In the reign of William he avowed himself a friend to the dissenters and toleration; and after his promotion to the archdeaconry of London, he was appointed one of the commissioners for reviewing the Litany, with a view to the comprehension of the Separatists. He thus recommended himself to queen Mary, and by her interceded he obtained the fee of Lincoln, in 1691. Within three years he was unexpectedly advanced to the archiepiscopal fee of Canterbury, more on account of his moderate and pacific principles, than for any procedinece to which he had attained among men of letters or theologians. He attended queen Mary on her death-bed; and incurred the severe animadversions of the deprived bishop Ken, for not having reminded her majesty of her culpable want of duty to her father, by confequently to wear a crown which rightfully belonged to him. His conduct during the reign of King William was uniformly confident with his principles, and both were so pleasing to his majesty, that he distinguished the prelate by many tokens of respect and confidence. In the reign of queen Anne, he was not, as we may naturally imagine, much regarded; more especially as he retained his just ideas of toleration, and refitted, though not without a share of obloquy, some of the high-church measures which were then countenanced. Nevertheless he displayd on various occasions his attachment to the establisht church, as well as his habitual bounty to the indigent. His last public act was the coronation of George I; and afterwards finking under the decay of advanced age, he closet his life at Lambeth, December 1715, in the seventy-ninth year of his age. As he left no issue, he bequeathed a considerable part of his property to charitable purposes. His character was uniformly respectable; and his conduct in difficult times was irreproachable and exemplary. Biog. Brit. Gen. Biog.

TENMENTALE, or TENMANTALE, in our Ancient Cylouns, originally signifies the number of ten men, which number, in the time of the English Saxons, was called a deanency; and ten deaneries made what we call an hundred.

These ten men were bound for each other to preserve the public peace; and if any of them was found guilty of a breach of it, the other nine were either to make satisfaction, or to bring the criminal before the king.

TENMENTALE was also used for a duty, or tribute, paid to the king, consisting of two shillings for each ploughland; probably thus called, because each person of the deanery was bound to see it paid.

TENNA, in Geography, a river which rises in the Appenines, and crossing the marquisate of Ancona, runs into the Adriatic, about 4 miles E.N.E. of Ferme.

TENNE, TENNY, or Tenny, in Heraldry, a bright colour, made of red and yellow mixed; sometimes also called tybby, and expressed in engraving by diagonal lines drawn from the dexter to the sinister side of the shield, traversed by perpendicular lines from the chief; and marked with the letter T.

In the coats of all below the degree of nobles, it is called tenny; but, in those of nobles, it is called byacinth; and, in princes' coats, the dragon's head.

TENNEAH, in Geography, a town of Bengal; 35 miles N. of Midnapur.

TENNEBERG, a mountain of Saxony, in the principality of Gotha; 4 miles S.W. of Gotha.

TENNELIERS, a mountain of France, in the department of the Aube; 4 miles E. of Troyes.

TENNESSEE, one of the United States of America, situated between 35° and 36° 30' N. lat., and 4° 20' and 13° 30' W. long. from Washington. It is bounded on the north by Kentucky and part of Virginia, on the south by Georgia and the Mississipi territory, on the east by North Carolina, and on the west by Missouri territory. Its extent from north to south is 412 miles, and from east to west 420 miles. Its area is 40,000 square miles, or 25,600,000 acres. The Indian claim has been extinguished in two portions of this country, the cahern and the western, comprehending one-third part of the flate. The former is bounded north by Virginia, from the south-east corner of Kentucky, to the north-west of North Carolina; easterly by North Carolina;
TENNESSEE.

Carolina; westerly by Cumberland mountain, Emery's river, &c. and southerly by a line marked from place to place, as a continuation of the Cherokee boundary. The western tract, thus purchased of the Indians, lies on Cumberland river; and is bounded north by Kentucky; easterly by a line running from the north-east to the south-west; and south and west by a line of several thousand angles, run according to the Tennessee Ridge, which separates the waters of the Cumberland from those of the Tennessee river. The general course of this ridge-line is first westerly, and then north-westerly; which, imagining the zigzag reduced into two straight lines, makes the figure of the tract a trapezium. The longest side is that adjoining Kentucky, the length of which, ascertained by measurement, is nearly 160 miles. The length of the easterly side is about 90 miles. The easterly is generally called the Holston settlement, and the western the Cumberland settlement, from those two prime rivers, which traverse the countries respectively. Between these settlements lies a spacious wilderness, which the Cherokees claim and traverse in hunting, and which, from one limit of their claim to the other, as the road goes, is about 70 miles wide.

This state, as it was erected and organized in 1796, is divided into three districts. The eastern settlement is divided into two districts, Washington the eastern district, and Hamilton the middle district. The western settlement is the third or Mono district. The number of counties, &c. may be seen in the following topographical table.

The following counties have been laid out since the last census was taken:

Greenville,
Wayne.

The eastern part of this state is mountainous, the middle part hilly, and the western part mostly level. The climate among the mountains is said to be delightful; in the middle part, temperate and agreeable; in the western part, hot in summer, and mild in winter. The diseases to which the adult inhabitants have been most liable are pleurisy, rheumatism, and rarely agues and fevers; but, on the whole, the inhabitants are generally healthy, and this salubrity of the state has been partly attributed to its having few flagrant waters. The principal rivers of this state are the Cumberland, the Holston or Holston, the Tennessee, the Clinch, the Notachuckey or Nolichucky, the French Broad, the Hiwassee, the Duck, the Redfoot, the Obion or Oby, the Forked Deer, and the Wolf. The chief of these rivers are described under their proper names. The mountains in this state are numerous; some of them, particularly the Cumberland (which see), or Great Laurel Ridge, are the most stupendous piles in the United States. Stone, Yellow, Iron, Bald, SMOKEY, and Unaka mountains adjoin each other, and form, in a direction nearly north-east and south-west, the easterly boundary of the state. In these mountains are innumerable caverns and caverns. North-west from these, and separated from each other by vales from 5 to 15 miles wide, rise Bay's mountain, Copper Ridge, Clinch mountain, Powell's mountain, and Wel-ling's Ridge. The four last terminate north of the Tennessee river, and these, as well as the others, are branches of Virginia mountains. They are all encircled by vales, which open channels for rivers and roads for passage. Although the soil on the mountains is poor, that of the vales is fertile; improving in the middle of the state, and in the western part becoming rich. It produces cotton, which is the staple commodity, and the principal article of export, tobacco, indigo, Indian corn, hemp, flax, rice, wheat, rye, oats, barley, and all kinds of vegetables in high perfection. The trees and plants found in this state are poplar, hickory, black and white walnut, all kinds of oaks, buck-eye, beech, fycamore, black and honey locust, ash, hornbeam, elm, mulberry, cherry, dogwood, saffrañas, papaw, cucumber-tree, coffee-tree, and the sugar-tree. In the eastern district is a species of pitch-pine, useful for boards, timber, and tar. The under-growth, in many places, and especially in low grounds, is cane, some of which is upwards of 20 feet high, and so thick as to prevent any other plant growing; there are also Virginia and Seneca sassafras-root, gingeng, Carolina pink, angelica, fenn, lobelia, Indian physic, spice-wood, wild plum, crab-apple, haws, hazle-nuts, sweet anise, red bud ginger, spikenard, wild hops and grape vines. The glades are covered with wild rye, wild oats, clover, buffalo-grass,
TENNESSEE.

geese, strawberries, and pea vines. On the hills, at the heads of rivers, and in some high cliffs of Cumberland, are found majestic red cedars; many of these trees are four feet in diameter, and forty feet clear of limbs. The commerce of this state is much facilitated by the rivers Tennessee and Cumberland, and their respective branches. Both these rivers empty into the Ohio, shortly after they pass the north boundary of the state. As the waters of the Cumberland from Nashville, and of the Tennessee from the Muscle Shoals to the Ohio, are navigable to the Ohio and Mississippi, the people of course, who live in this or the adjacent country, have the same advantages of water conveyance for trade, as those who live on the Ohio or Mississippi, to New Orleans or elsewhere. Besides, there is another probable avenue through which trade will be carried on with this and the adjacent country, which is from Mobile, up the waters of the Mobile river as far as it is navigable; thence by a land carriage, of about 50 miles at most, to Oochappoo creek, which empties into the Tennessee at the lower end of the Muscle flats. The mouth of this creek is the centre of a piece of ground, the diameter of which is five miles, ceded by the southern Indians at the treaty of Hopewell, on Kecowee, to the United States, for the establishment of trading posts. The iron works of Tennessee are large and numerous. The minerals of this country are iron-ore, limestone, coal, coppears, alum, nitre, lead, and some silver. Mineral springs, strongly impregnated with sulphur, are found in various parts of the country. On the waters of French Broad river is a fine, large, clear, medicinal, warm spring, the beneficial effects of which have been experienced by many persons who have resorted to it from the Carolinas, Georgia, and northern parts of Virginia. Salt is manufactured in considerable quantity, particularly on the north fork of Holston. Some herds of the bison are still found on the branches of the Cumberland river, though multitudes of them have been wantonly destroyed. The stag is occasionally found among the mountains; deer are scarce; bears, panthers, wild cats, and wolves, still remain. Beavers, mink-rats, and otters, are plentiful in the upper branches of Cumberland and Kentucky rivers. Racoons, foxes, opossums, and squirrels abound; as also pheasants, partridges, pigeons, swans, wild turkeys, ducks, and geese; as well as bald eagles, parroquets, hawks, cranes, and buzzards. The rivers are well stocked with all kinds of fresh-water fish.

The chief towns of Tennessee are Knoxville, Nashville, and Jonesborough; which see respectively.

The prevailing denomination of Christians in this state is composed of Presbyterians, intermixed with Baptists, Methodists, and Friends. With a view to mental and moral improvement, several schools and colleges are established in this state. Three colleges are established, one in Knox, one in Washington, and one in Greene county.

By the constitution of this state, which was formed and ratified at Knoxville, February 6, 1796, the legislative authority is vested in a general assembly, consisting of a senate and house of representatives. The number of representatives is to be fixed once in seven years, by the legislature, according to the number of taxable inhabitants, who are to be numbered septennially; the number of representatives not to exceed twenty-six, until the taxable inhabitants shall be 40,000. The senators are never to be less than one third, nor more than one half the number of the representatives, and are to be chosen upon principles similar to those for the choice of representatives. The election for members of both houses is biennial. The executive power of the state is vested in a governor, chosen by the electors of the members of the legislature: he is appointed biennially, and is commander-in-chief of the army and navy, except in the service of the United States. Every freeman of 21 years of age, possessing a freehold in the county, and having been an inhabitant of the state for five months preceding, may vote for the members of the legislature. The house of representatives has the sole power of impeaching, and the senate of trying impeachments. The judicial power is vested in courts of law and equity. County officers are sheriffs, coroners, truants, and constables. Military officers are to be elected by persons subject to military duty. Ministers of the gospel are not eligible to a seat in the legislature. No person who denies the existence of God, or a future state, can hold any civil office. The oath of allegiance and of office is to be taken by persons holding any office of trust or profit.

In the character of the inhabitants there is nothing peculiarly discriminating; but, in general, a great simplicity of manners prevails. Among the curiosities of the country we may reckon its numerous caves; and on the Enchanted mountain there are on several rocks impreffions resembling the tracks of turkeys, bears, horses, and human beings, the latter having uniformly fix toes each. Besides these, there are many other fanciful figures. The Indian tribes within and in the vicinity of this state are the Cherokee and Chickasaws; which see respectively.

The country now called Tennessee was included in the second charter granted by king Charles II. to the proprietors of Carolina; and in a subseuent division, it constituted a part of North Carolina. In 1754, at the commenceinent of the French war, not more than fifty families had settled here, who were either destroyed, or driven away by the Indians before the close of the following year. It remained uninhabited till 1765, when the settlement of it commenced; and in 1773, (thenc was the rapid accession of emigrants,) the country as far westward as the long island of Holton, an extent of more than 120 miles in length from caft to west, was well peopled. In 1789, after preparatory measures, the territory was ceded by the North Carolina legislature, on certain conditions, to the United States. In 1790, February 25, Congress passed an act, accepting this cession; and, by another act, passed May 26, 1790, provided for its government under the title of "The Territory of the United States of America south of the river Ohio." On the 8th of June following, the president of the United States, by and with the advice and consent of the senate, appointed the Hon. William Blount, esq., a citizen of North Carolina, governor in and over the said territory; in which office he continued during the territorial government, and was president of the convention that formed the constitution under the title of "The Constitution of the State of Tennessee," of which we have given an abstrac.

The peace of the citizens of this territory has been disturbed many years past, by Indian wars, or incursions from the savages for the purpoises of murder and plunder; they are now at peace. In the year 1796, this territory was in due form erected into an independent state, making the sixteenth in the Union. Morie Melish.

TENNESSEE RIDGE, the most considerable range of mountains in the state of Tennessee, separating the streams which run to the Cumberland and Tennessee rivers. In some parts it rises into abrupt hills, but in others admits of good roads. See CUMBERLAND MOUNTAIN.

TENNESSEE, called by the French Cherokee, and absurdly by others the Hoghohege river, is the largest branch of the Ohio; it is 600 yards wide at its mouth. It rises in the mountains of Virginia, N. lat. 37°; and pursues a course of about 1000 miles fourth andouth-west, nearly to
TEN

N. lat. 34°, receiving from both sides a number of large tributary streams. It then wheels about to the north, in a circuitous course, and minglest with the Ohio, nearly 60 miles from its mouth. From its entrance into the Ohio to the Muscle shoals, 250 miles, the current is very gentle, and the river deep enough, at all seasons, for the largest row boats. The Muscle shoals are about 20 miles in length. The bed of the river in this distance consists of broken stones, easily removed; and the navigation will admit of much improvement. At these shoals the river spreads to the width of three miles, and forms a number of islands, and is of difficult passage, except when there is a fall in the river. From this place to the "Whirl," or "Suck," where the river breaks through the Great Ridge, or Cumberland mountain, is 250 miles, the navigation all the way excellent. The Whirl, as it is called, is in about N. lat. 35°. It is reckoned a greater curiosity than the burfting of the Patowmack through the Blue Ridge. The river, which a few miles above is half a mile wide, is here compressed to the width of about 70 yards. Just as it enters the mountain, a large rock projects from the northern shore, in an oblique direction, which renders the bed of the river still narrower, and causes a sudden bend: the water of the river is of course thrown with great rapidity against the southern shore, whence it rebounds around the point of the rock, and produces the whirl, which is about 80 yards in circumference. Boats pass the whirl without danger or difficulty. Such is the situation of the shore, that boats ascending the river may be towed up. In less than a mile below the whirl, the river f...
The Ten

S.W. part of the island. See Tino.—Also, a town of Greece, in Thessaly.

TENOS. See TENOR.

TENSA, in Geography, a river of Louisiana, which forms with the Walhita and bayou Long, an island of an oval shape, about 50 miles in circumference. Immediately above this island, there is another, called Sicily island, about 30 miles in circumference. At the lower end of Sicily island, the bayou Tena spreads into a lake of 15 or 20 miles in length, and nearly parallel with the Mississippi. The Tenia lake receives two considerable streams, the river Aux Beufs, and the bayou Maçon.

TENTE, TIME, in Grammar, an inflexion of verbs, by which they are made to signify, or dilating, the circumstance of time of the thing they affirm or attribute.

The affirmations made by verbs are different as to point of time; since we may affirm a thing is, or was, or will be: hence a need of a set of inflexions, to denote those several times; which inflexions our English grammarians call by a barbarous word, tenses: from the French temps: most other languages call them simply times.

There are but three simple tenses: the present, as, I love, amo; the preterit, preteritis, or pass, as, I have loved, amavit; and the future, as, I will love, amabo.

But, in regard that in the preterit tense one may either express the thing as yet done or past, or indefinitely and barely that it was done: hence, in most languages, are twain kinds of preterite; the one definite, marking the thing to be perfectly done; as, I have written, I have said: and the other indefinite, or nigraph, denoting a thing done indeterminately; as, I wrote, I went.

The future tense admits also of the same variety.

Besides the three simple tenses, others have been invented, called compound tenses: expressing the relation of the simple ones to each other. The first expresses the relation of the past to the present, and is called the preterit imperfect tense, because it does not mark the thing simply and properly, as done, but as imperfect, and perfect with respect to another thing past; as, I was after dinner when he entered; even interro. canamab.

The second compound tense marks the time past doubly, and is therefore called the plusquamperfect tense; as, I had supped; convorabam.

The third compound tense denotes the future with respect to the past; as, I shall have supped; canamam.

The several tenses, or times, it is to be observed, are properly denoted in the Greek and Latin by particular inflexions; in the English, French, and other modern tongues, the auxiliary verbs to be, and to have, etre and avoir, are called in. As to the Oriental languages, they have only two simple tenses, the past and present, without any distinctions of imperfect, more than perfect, &c.; but this renders those languages subject to abundance of ambiguities, from which others are free.

The ingenious Mr. Harris, in his Hermes, p. 119, &c., proposes the following theory of tenses. The tenses, he says, are used to mark present, past, and future time; either indefinitely, without reference to any beginning, middle, or end; or else distinctly, in reference to such distinctions. If indefinitely, then we have three tenses, an aorist of the present, an aorist of the past, and an aorist of the future. If distinctly, then we have three tenses to mark the beginnings of the three times; three to denote their middle; and three to denote their ends; in all, nine. The three first of these tenses he calls the indefinite present, the indefinite past, and the indefinite future. The next three, the middle present, the middle past, and the middle future. And the three last, the complete present, the complete past, and the complete future. Thus the tenses in their natural number appear to be twelve; three to denote time absolute, and nine to denote it under its respective distinctions. The following examples will illustrate the application and use of each tense. The perfect of the present, γηρος, ferbo, I write; the perfect of the past, γερως, serifs, I wrote; the perfect of the future, γερος, ferfam, I shall write.

Inceptive present, μανός γερος, scripturus sum, I am going to write; middle or extended present, μαννος γερος, feribs, or feribens sum, I am writing; implicative present, γερος, scriptibs, I have written. Implicative past, μαννος γερος, scripturam, I was beginning to write; middle or extended past, μαννος γερος, feribam, I had done writing. Implicative future, μαννος γερος, scripturam ero, I shall be beginning to write; middle or extended future, μανονς γερος, feribens ero, I shall be writing; implicative future, scripturam, I shall have done writing. The author has particularly shewn what traces are discoverable in favour of this system, either in languages themselves, or in those authors who have written upon this part of grammar, or in the nature and reason of things.

TENSIFF, in Geography. See TANSIIFF.

TENSION, TENSO, the state of a thing bent, or the effort made to bend it.

Animals only sustain and move themselves by the tension of their muscles and nerves. A chord or string gives an acuter or deeper sound, as it is in a greater or less degree of tension.

Tension, Tenso, lasc, in the Ancient Music, was used to signify any pitch of sound, produced by induction or remission. Vide Aristoxen. p. 10. 13. edit. Melborn. Aristoxenus observes, there are five things to be considered about sound, viz. lasc, tenso; intension; extention; omission; &c.; acumen; and gravitas.

TENSIFFES, in Geography, a mountain of Africa, in the empire of Morocco, on the borders of Sugulme; 60 miles E. of Morocco.

TENSOR, in Anatomy, a name given to different muscles.

Tensor Palati, a muscle of the soft palate. See DeLUGITION.

Tensor Tymanis, a muscle of the internal ear. See EAR.

Tensor Vaginae moritis; muscleus faeice lata; is an elongated and flattened muscle, narrow above, and becoming considerably broader below, situated at the upper and outer part of the thigh, and extending from the anterior superior spine of the ilium, to a short distance below the great trochanter. It is covered by a thin layer of the faecia; and it lies upon the rectus cruris, the vastus externus, and a small part of the gluteus medius and minimus, separated from them by a thin production of faecia, and by copious cellular tissue. Its front edge is parallel, above, with the outer margin of the patellus; below, they are parted by an interval, occupied by the rectus anterior. The posterior edge is connected to the gluteus medius; being separated from it below by cellular tissue. The upper extremity is attached to the anterior superior spine of the os innominatum, between the patellus and the gluteus medius. The muscle, which is here narrow, passes obliquely downwards and outwards, growing considerably broader and thinner, and terminates below the great trochanter, at the angle of separation of the two layers of the faecia, between which it is situated: this angle is its point.
point of infection. Its upper attachment is by means of a tendon, from which the fibres run to the fascia.

It will bend the thigh on the pelvis; or carry it outwards; or rotate it inwards. When the thigh is fixed, it will incline the pelvis on that limb.

**TENSTADT,** in Geography, a town of Saxon, in Thuringia; 11 miles N.W. of Erfurt.

**TENT,** Tabernacle, a pavilion, or portable lodge, under which to shelter, in the open field, from the injuries of the weather. See Tabernacle.

The word is formed from the Latin, tentorium, of tendo, to stretch; in regard tents are usually made of canvas, stretched out, and fastened by poles, with cords and pegs.

Arms encamp under tents: these are made of canvas, and are of various sizes. A captain's tent and marquee is generally 10 feet broad, 14 feet deep, and 9 feet high; those of the subalterns are a foot less; the major's and lieutenant-colonel's a foot larger; and the colonel's two feet larger. The subaltern's tent is two in a tent, and those of the horse one. The tents of private men are 6 feet square, and 5 feet high, and accommodate five soldiers. The tents for the horse are 7 feet broad, and 9 feet deep; they hold five men, and their horse-accoutrements.

**TENTS, Bell,** are so called from their resemblance to a bell, and serve to shelter the fires-arms from rain.

To pitch the tents, is to fix them up ready for habituation, by the assistance of a ridge-pole, two standards, and a number of ten-pins.

Most of the Tartars and Arabs are wandering people, that always lodge under tents.

The Hebrews lodged forty years under tents in the desert; which gave occasion to the Scenopegia, or feast of tabernacles.

**Text, Dark.** See Dark.

**Tent, in Surgery,** signifies a roll of lint or linen, for preventing the healing of openings, from which matter, or some other fluid, makes its escape. Tents are also employed for dilating openings. There are some tents which are made of sponge that has been compacted into as small a compass as possible, while filled with fluid wax, and then allowed to become cold. These are called sponge-tents, and, on becoming warm, after being introduced into parts, they have the property of swelling in a remarkable degree. We shall only say further upon this subject, that, upon the whole, tents are not so much employed in modern as in ancient practice; and there is no doubt that, unless their use be guided by moderation and judgment, they may do considerable mischief.

**TENTAMOODY,** in Geography, a town of Hindoostan, in the cerc of Rajamundry; 35 miles S.E. of Rajamundry.

**TENTATIVE** is sometimes used adjectively: thus we say, a tentative method, meaning a kind of artful or indirect method, which only proceeds by trying.

Tentative is also used substantively, for an essay or effort, by which we try our strength, or found an affair, &c. to see whether or no it will succeed.

In the French universities, tentative is the first thesis, or act, which a student in the theology-school holds, to show his capacity: if he answers well in this, the degree of bachelor is conferred on him.

**TEN-CHEOU-FOU,** or Ten-choo-foo, in Geography, a city of China, of the first class, in the province of Chang-tong, having under its jurisdiction one city of the second class, and seven of the third. It is situated on a rising ground, and fortified by a strong wall round it, and defended by a numerous garrison. The fortifications of this city include a large space not occupied by buildings; and when it was laid out, must either have been expected that it would increase in houses to a greater number than that of those who now occupy it, or the vacant space was allotted for military or other exercises. The bay, or rather road, of Ten-choo-foo, is not only open to the east and west, but partially sheltered towards the north by groups of small islands, scattered about at different distances, from five miles to twice as many leagues, off the main shore. The Mi-ia-tau islands are too distant to break off much of either wind or swell from that quarter. The anchoring ground consists in great part of hard sharp rocks; and at about 14 miles from the shore is a dangerous reef, covered at high water, extending nearly a mile east and west, round which the water shoals so suddenly as to render any approach to it very perilous. At Ten-choo-foo is constructed a kind of dock, or bauan, for vessels to load or discharge their cargoes. The entrance into it is between two piers, and is from 30 to 40 feet wide. The ground near the coast of the Yellow Sea is richly cultivated, and rides in a gentle ascent, which is terminated by high, broken, and barren mountains, apparently granitical. The passage between Ten-choo-foo and the Mi-ia-tau islands is called in the chart the Strait of Mi-ia-tau, in which it rifele the rife and fall of the tide are about seven feet. Staunton's Embassy, &c. vol. i.

**TENTER,** Tricular, or Proctor, a machine used in the cloth manufactury, to stretch out the pieces of cloth, stuff, &c. or only to make them even, and set them square.

It is usually about four feet and a half high, and, for length, exceeds that of the longest piece of cloth. It consists of several long, square pieces of wood, placed like those which form the barriers of a manège; so, however, as that the lower cross-pieces of wood may be raised or lowered, as is found requisite, to be fixed at any height, by means of pins. Along the cross-pieces, both the upper and under one, are hooked nails, called tenter-hooks, driven in from space to space.

To put a Piece of Cloth on the Tenter.—While the piece is yet quite wet, one end is fainted to one of the ends of the tenter; then it is pulled by force of arms towards the other end, to bring it to the length required; that other end being fainted, the upper lift is hooked on to the upper cross-piece, and the lowest lift to the lowest cross-piece, which is afterwards lowered by force, till the piece have its desired breadth. Being thus well stretched, both as to length and breadth, they brush it with a fluff hair-brush, and thus let it dry. Then they take it off; and, till they wet it again, it will retain the length and breadth the tenter gave it.

**TENTERDEN,** in Geography, is a small market-town in the hundred of the same name, in the lathe of Scray, and county of Kent, England, situated 18 miles S.S.E. from Maidstone, and 56 miles S.E. by S. from London. N. lat. 51° 4' 8". E. long. 0° 41' 8". At a remote period it was incorporated by the name of the "barons of the town and hundred of Tenterden;" which style was changed to that of the "baronet and commonalty," by letters patent of Henry VI., who at the same time annexed it as a member to the town and part of Rye, in Sussex, to which it is yet subject. Queen Elizabeth, in her forty-second year, granted the inhabitants a new charter, by which, in the place of a baronet, &c. the future government of the town was vested in a mayor, twelve jurats, twelve common-council men, a chamberlain, and a town-clerk. The present town-hall, which is occasionally used as an assembly-room, was built about the year 1792; the old one having been burned by an accidental fire. The market-house is a small, mean edifice of timber, now little frequented; the market itself being almost diffused, though still nominally
TEN

annually for the sale of cattle, wool, shop-goods, &c. According to the returns under the population act of the year 1811, the number of inhabitants in this town was 2786, that of houses 459. Many of the latter are respectable buildings, occupied by persons whose families have derived affluence from the grazing business carried on in the neighbouring parishes. The parish church is a spacious structure, and consists of a nave, north aisle, and chancel, with a well-built and lofty tower at the west end, on which is sculptured the arms of St. Augustine's monastery, to which foundation this church was appropriated in 1259. Besides the church, there are two places of religious worship for dissenters of different denominations. Dr. Harris mentions an ancient free-school, founded here by one of the family of Heyman of Somerset, and records some donations made for its support. The trustees are the mayor and jurats, who, according to Ha'fted, are so inattentive to the charity, that not any children are now educated on this foundation.

The chapel of Small Hithe, in Tenterden parish, was formerly, according to traditional report, a very considerable place, but is now reduced to a few farm-houses and cottages. The chapel was licensed by archbishop Warham, in 1509, "on account of the badness of the roads, and the dangers which the inhabitants underwent in their way to the parish church, from the waters being out."—Beauties of England and Wales, vol. viii. Kent, by E. W. Brayley.

TENTH, in English History. See Land-Tax.

Tents are said to have been first granted under Henry II., who took advantage of the fashionable zeal for crofuses to introduce this new taxation, in order to defray the expense of a pious expedition to Palestine, which he really or feemingly had projected against Saladin, emperor of the Saracens; whence it was originally denominated the Saladin tent. But afterwards fifteenth were more usually granted than tents.

TENTHS, Decima. See First-Fruits, and Tithe.

TENTHS, Office of, is kept in the Temple, under the direction of a receiver and his clerks.

Tenth, in Meafures, the octave above the third, and an octave below the seventeenth, or flop in the organ called the tierce. The tenth is a very pleasing conformance, but inferior in subtility to the third; for which reason the duets at the opera, since the principal sifth man's part has been performed by a tenor, have never given the audience that exquisite pleasure which they used to do, when sung by two sopranos.

TENTHREDO, in Entomology, a genus of the Hemiptera order of insects, the character of which are, that the mouth has a horny, arcuated mandible, within dentated; a straight jaw, obtuse at the apex; a cylindrical, trifid lip, with four unequal siliiform feelers; the wings flat, and tumid or feightly inflated; the piercers consisting of two ferated, fearedly prominent laminae; and the leucotem with two diftant granules.

The larvae of this genus reframe thefe of the order Lepidoptera, or real caterpillars; but are diftinguifhed from them by their more numerous feet, which are never fewer than fifteen, exclusive of the three ifth or thoracic pairs. When disturbed or handled, they usually roll themselves into a flat spiral. They feed, like the caterpillars of the lepidoptera, on the leaves of plants; and undergo their chrysalis flate in a frong gummy cafe or envelopment, prepared in autumn, out of which, in the enfuing spring, emerges the complete insect. The tenthredines form a numerous genius, and are divided into tribes or fections, according to the form of the antennae. Gmelin reckons 143 species.

N. B. The European species are marked with a star *, and the English with a crofs †.

Species.

A. Antenna elongated.

* FEROMATA. Antenna yellow; black body; hinder thighs larger; the larva green, with a bluish line on the back, and yellow at the fides.

* MARGINATA. Antenna yellowish at the apex; black body; the hinder segments of the abdomen white at the margin.

LUTEA. Antenna yellow; segments of the abdomen mostly yellow. This insect proceeds from a large green larva, of a finely granulated surface, with a double row of black specks on each side, and a dusky dorsal line bounded on each by yellow. It feeds on various species of willow, alder, and beech. The parchment-like cafe in which it envelops itself in autumn is of a pale yellowish-brown colour; and the chrysalis, which is of a pale dusky or brownish cafe, exhibits the limbs of the future fly, in fize equal to a common wasp, and of a yellow colour, bound with black; the antennae rather short, and strongly elevated.

AMERICENS. Body circular; abdomen beneath red; white lip. This inf neat is somewhat smaller than the preceding; its caterpillar, like that of the former, is of a green colour, and of a finely roughened surface, powdered with numerous whitifh specks. Feeds on the willow.

TRISTIS. Black, with yellow antennae, and wings brown at the apex; green larva, with an azure line on the back, black and yellow fringed.

VITELLINE. Abdomen above black; sides red; hinder thighs dentated; larva greenish.

LUCIDUS. Antenna black; body villous black. Found on the beech and alder.

* FASCIATA. Black; antenna black; primary wings with a brown band.

* SERICEA. Antenna yellow; thorax black; abdomen brassy; larva green, with two yellow lines.

OSCURA. Body smooth and black. Found in the groves of Sweden.

CONNATA. Black; abdomen with yellow bands. Found on the alder.

* NITENS. Antenna yellow; abdomen green-blue, shining. Suggested to be a variety of the sericea.

B. Antenna excallate, the outer ones thicker.

CLAVICORNIS. Black; abdomen yellow; apex black. Found in North America.

ANNULATA. Black; abdomen yellow; hinder terfi black, annulated with white.

* EXODIS. Antenna smooth; body black-blue, larva green, spotted with black, a rough lateral line yellow, sharp tail.

CILIARIS. Antenna beneath ciliated; hinder legs white. Found in Germany.

* USTULATA. Body black; abdomen blue, legs pale. On the canine robe. Larva green, with two white lines; head teftaceous; obscure band.

* CYANOCHRISA. Head and thorax bright-blue; abdomen faffron-coloured.

* TURATA. Black; back, zone, and three arcs, yellow-greenish.

BICOLOR. Black-blue; abdomen and base of the wings yellow; wings with a black band. Found in Austria.

* MELANOCHRA. Black; abdomen yellow; a small black line
line on both sides of the anus; legs and foles yellow; wings with a black spot.

*Tircholor. Head and thorax black; wings and feet brown; abdomen yellow.

*Ochropus. Head, thorax, middle of the breast, and apex of the hinder legs; black; abdomen and feet yellow.

C. Antenna setulatul.

Cephalotes. Black; abdomen with four yellow zones or belts. Found in Germany.

† Dorusata. Whitish; head and back of the thorax and abdomen black.

D. Antenna pubescent.

*Pini. Antenna lanceolate, and thorax pubescent. Larva blueish, and yellow at the tail end.

Juniperus. Antenna obtuse; thorax smooth; larva green, pointed with black.

E. Antenna filiform, with from seven to nine joints.

Americana. Thorax yellow; abdomen blue; wings black. Found in Surinam.

Costalis. Black, with the rib of the wings ferruginous. Found in Germany.

Lateralis. Black; middle of the back red; fides white. Found on the flowers of Sweden.

† Arcuata. Abdomen black; five arcs, with a band at the base and fides, yellow-greenish.

Rustica. Black; abdomen with three yellow belts, the hinder two interrupted; larva cinereous, with triangular brown spots on the back.

*Scolpilare. Antenna yellow; abdomen with five yellow belts, the first more distant.

Arietis. Body black, with four ferruginous segments of the abdomen.

Germanica. Body black; thorax before and abdomen red. Found in the groves of Germany.

Padi. Black, with thighs and legs white.

Cynipiformis. Green-brassy; yellow feet; hinder thighs brassy.

Cerasi. Body black; scutellum and feet yellow; larva gelatinous, black.

Flavicollis. Yellow; head and tail black. Found in Germany and Italy.

Luteicornis. Black; with antennae, mouth, base of the abdomen, and legs, yellow.

Mesorhelas. Abdomen yellowish; back black; arcs yellowish.

Punctum Album. Body black; abdomen at the sides white; hinder thighs red. Found in Germany.

† Blanda. Black; abdomen in the middle red; hinder thighs with a white spot.

Quadrimaculata. Black; hinder feet red; two spots at the base white.

* Rupipes. Body black; abdomen with two yellow belts; feet red.

* Campestris. Body black; abdomen with an unequal yellow belt; antennae and legs yellow.

* Atra. Body black; feet red.

* Viridis. Body green; abdomen above brown.

* Ovata. Body black; thorax above red; larva greenish, sprinkled with a kind of white powder.

Alni. Body black; head and thorax red.

* Ceraleucus. Violet; abdomen yellow; wings with a brown spot.

Vol. XXXV.
fore-feet sulphurose; the hinder soles with three intermediate white joints.

* FLAVEOLA. Antenne subclavated, black; base, mouth, sides, and five first segments of the abdomen and feet, yellow.

* ANNULATA. Yellow; antennae subclavated, black; apex of the thighs and soles annulated with black.

* EUGRIGNOSA. Black; antennae subclavated, and base with feet yellow; third, fourth, and fifth segments of the abdomen ferrugineous.

* SUBULATA. Black; antennae subulate at the apex; second to the fifth segments of the abdomen, as far as the hinder margin, legs and soles, yellow, and these annulated with black.

* MACRONATA. Black, with the seven-knotted antennae and abdomen yellow; the last segments from the second to the fourth black; the apex of the wings brown.

* VARI. Black; mouth, feutellum, and feutellar spots, white; the hinder segments of the abdomen and feet ferrugineous.

* SANGUINOLENTA. Black; with the hinder feet ferrugineous.

* DELABRATA. Black; the three last joints of the antennae and jaws white; legs and soles yellow.

* CANESCENTS. Grey-downy, brown, with grey wings.

* BIFASCIA. Brown, with black thorax; mouth, feutellum, and four spots at the feutelum, white; abdomen with two interrupted yellow bands; margin of the wings and feet yellow.

* BRACCATA. Black, with red thighs; the base of the four hinder legs, and the three penultimate joints of the antennae, white.

* RUFIPES. Black; the base of the abdomen, with a spot on both sides, and jaws, white; four fore-legs red.

* MELANOLEUCA. Black; mouth, thorax with a small line on both sides before the wings; a spot on the hinder thighs; legs, the sides of the abdomen from five to seven segments, and apex, white.

* MELANOCHORA. Black; mouth, four fore-feet, and base-flexure of the hinder thighs, yellow.

* LEUCOPUS. Black; the base-flexures of the thighs white; four anterior legs without, and middle of the hinder, white.

* VARICORNIS. Black, with red feet; fourth and fifth joints of the antennae and hinder legs at their base, white.

* OBSCURA. Brown; with the rib of the wings as far as the spot and feet ferrugineous.

* LIMBATA. Black; the hinder margins of the segments of the abdomen white; feet reddish.

* EXALBIDA. Black; with feelers and four legs obliquely white.

* FERRUGINOSA. Black; the antennae ferruginous forwards; the base and anterior margin of the wings, the first and fifth segment of the abdomen, the legs and soles, white.

* ANGUSTA. Black; body narrow and grey-downy.

* LUTEUS. Black; with the abdomen beneath and feet yellow-reddish.

* ALBIPES. Black; with legs and soles white.

* FLAVIVENTRIS. Black; mouth white; abdomen yellow; back and apex black; feet ferrugineous.

* PICA. Pitchy; anterior legs before, spot of the hinder thighs, and base, white; hinder feet red; the knees and soles black.

* FUSCIPES. Black; feet red; posterior soles brown.

* BIMACULATA. Pale; eyes, abdomen above the base, breast and two spots, black.

* LATA. Broad, black; the posterior segments of the abdomen white, from the second to the fifth interrupted.

* ANNULARIS. Pale, the antennae spotted with black at the base; vertex of a branchy figure, eyes, and the conjugate points at the back of the thorax and abdomen, black.

* SCRIPTA. Pitchy; mouth, and on the middle of the fore-part of the thorax the mark resembles V; the spot on both sides the feutellum white; two feutellar points white; feet, and under margin of the segments of the belly, yellow.

* LITERATA. Black; segments of the abdomen from the second to the fifth in the back, ovated spot on both sides and marging white; anterior feet, and four hinder legs on the fore-part, white.

* MELANORHDEA. Black, with yellow abdomen; the transverse spots of the back and anus black.

* GEMINATA. Black, with geminated antennae, and joints and legs pale.

* OCHROUSTES. Pitchy; with the abdomen beneath and feet yellow.

* RUFICAPILLA. Head and thorax red; the posterior margin of the latter and eyes black; the abdomen and feet yellow.

* DUBIA. Black; thorax before red; joints whitish.

* PALLECENS. Black; mouth and feet pale.

** F. Antenne setaceous; many Joints.**

** ERYTHROCEPHALA.** Body eærucele; head red.

** SYLVATICA.** Body black; feet and marks of the thorax yellow.

** NEMORALIS.** Body black; segments of the abdomen white at the side.

** CYNOSBATI.** Body black; feet ferrugineous, hinder annulated with white and black.

** SIGNATA.** Pale; thorax and three dorsal longitudinal spots black. Found in Germany.

** POPULI.** Black-blueish; mouth, feelers, and legs yellow.

** VAFFA.** Head black, variegated with white; feet tesselate. Found in Sweden.

** RETICULATA.** Wings varied with pale and brown, with elevated veins, white and reticulated. Found in Finland.

** BETULE.** Body red; thorax, anus, and eyes black; wings behind brown.

** FLAVA.** Yellow, with the spot on the wings ferrugineous.

** HEMORHIOHIDALIS.** Black; with the anus and feet tesselate. In Germany.

† NERON. Middle of the abdomen red; feutellum and point on the wings white.

** DEPRESSA.** Head and thorax black; marks yellow; abdomen and feet ferrugineous. In Austria and France.

** LINEARIS.** Black; legs, and five bands of the filiform abdomen, yellow. In Austria.

** BIPUNCTATA.** Antenne sub-fetaceous; nine joints black, and two points of the black feutellum white.

** G. Of doubtful Order.**

** INTERCUS.** Black; with yellow feet and subclavated antennae.

** RUMICIS.** Found on the dock.

** ULMI.** Found on the leaves of the wild elder.

** PRUNI.** Found on the plum-tree.

** LONICERÆ.** Brown, tomentose, shining, with subclavated antennae, and subferrugineous wings.

** POLYGON.** Black; antennæ subclavated with eighteen knots;
knots; the hinder margin of the segments of the abdomen
from the third to the fifth yellow-greenish; the thighs black;
the face anterior at the apex and the legs yellow; the hinder
at the apex black; the foles yellow; the linear abdomen
compressed.

TENTOLI, in Geography, a town of the island of Ce-
lebes, near the north extremity, on the west coast, which
gives name to a road. N. lat. 1°.

TENTORES, among the Romans, were persons ap-
pointed to hold the clothes of the charioteers that contended
in the circus.

TENTUGAL, in Geography, a town of Portugal, in
the province of Beira; 7 miles W.N.W. of Coimbra.

TENTYRA, or TENTYRS, in Ancient Geography, a
town of Egypt, and capital of a nome, which took the
name of Tentyris, according to Strabo, Pliny, Ptolemy,
and Steph. Bzy.

TENTZEL, William-Ernest, in Biography, a Ger-
am antique and historian, was born, in 1659, at Greußen,
in Thuringia, and finished his education at Wittemberg,
directing the course of his studies to philosophy and the Orient-
al languages, and also to history, both faceted and profane.
In 1685 he was appointed a teacher in the gymnasium at
Gottha, and entrusted with the care of the duke’s collection
of antiquities and coins. In order to qualify himself for
the more honourable discharge of his duties as historiographer
to the house of Saxony of the Ernestine line, to which
office he was appointed in 1696, he visited various courts in
Germany, and carried on an epistolary correspondence with
many distinguished foreigners. In 1702 he removed
to Drefden, where he was made historiographer to the elector
of Saxony, king of Poland, by whom he was honoured with
the title of counsellor; but his manners not being adapted
to a court, he obtained leave to retire. What remained
of his life was devoted to literary pursuits; and he died, very
poor, in November 1707, in his 49th year. His works
were numerous, among which we may reckon the following:
vice. “De Phenice,” Vitemb. 1682, 4to.; “De Ritu Lecc-
tionum Sacrorum,” Vitemb. 1685, 4to. a work highly
commended by Bayle; “Judicia Eruditorum de Symbolo
Athanasi a fluendo collacque et inter fc collata,” Franc.
et Lpf. 1687, 12mo.; “Animadversiones in Cascimir Or-
dine Supplementum de Scriptoribus Ecclesiasticis,” 1688,
12mo.; “Cafparis Sagittarii Historici Saxonic Historia
Gotthana plenor, Æc.” Jena, 1700, 4to.; “Supplementum
Historie Gotthana,” ibid. 1701, 4to.; “Supplementum
Hitt. Goth. fecondum,” ibid. 1701, 4to.; “Saxonia Nu-
mifmatica, Pars I.” Francet et Lpf. 1705, 4to.; “Pars II.”
1705. Tentzel was also a contributor to several literary

TENUIROSTRE, in Ornithology, the name of a genus
of small birds, which feed on insects, and have slender
and sharp beaks; of this genus are the lark, swallow, red-breast,
and a number of others. Ray’s Ornithology.

TENUNE, in Geography, a town of Arabia, in the
province of Nedsjed; 40 miles N. of Aniza.

TENURE, in Agriculture, the manner in which pro-
prieters and tenants hold their lands, &c. of their land-
lords, or other persons.

It may be noticed, that the tenures of lands are extremely
various in almost every district of the kingdom, being, how-
ever, chiefly freehold, free-farmhold, copyhold, long-leasehold,
or life-leasehold, though there are many other local forms of
tenures of land.

The freehold is most probably in the largest proportion over the whole country, the copyholds in the next,
and the leasehold tenures in the smallest extent. It

has been remarked in the Shropshire Agricultural Report,
that it appears beautiful in theory, that there should be one
rule of descent in a kingdom only, one tenure of property,
and one scale of political rights; but that it may be doubted
whether so much uniformity is suitable to an imperfect state;
or at least to our present degree of improvement. At all
events, irregularities that are not attended with much prac-
tical inconvenience, should not be pointed out as obnoxious,
in a scheme that has produced so much positive happiness,
and so much comparative good, as the constitution of these
kingdoms has afforded.

It is stated too, in the Agricultural Survey of Essex,
that freehold estates are the most valuable to the immediate
proprietor, there can be no doubt; but the purchase of a
copyhold may remember, that the original purchase is by far
much the lower; and whether he lets the occupation to a
tenant, or farms and cultivates it himself, he may possibly
make as good interest of his capital as if he had bought a
freehold. Perhaps, also, its general and final utility to the
public, may be nearly or quite the same. This, the writer
thinks, is certain, that copyhold estates, whether in the hands
of the proprietors or tenants, are as well cultivated as the free,
excepting only in the article of timber, and even in that the
difference is seldom visible. The like may be said of leave-
hold estates, and even of those in mortmain.

In Hertfordshire, where a large portion of the property
is held by copyhold tenure, with a fine certain or at the will
of the lord, but which fine never exceeds two years’ rent,
the land falls at about six years’ purchase under the price of
freehold, according to the Report of the rate of agriculture
for that district. And it is further suggested in the latter
of the two former of the above agricultural surveys,
that, with regard to the tenures by which the more tempo-
rary occupiers hold their farms, they are, as already ob-
erved, extremely various, some upon leases of longer or
shorter duration, some without any lease at all, agreeably
to the taste and pleasure of the landlord, though by far the
greatest number, especially of those in the possession of the
smaller proprietors, are let upon leases of from eight to ten
to twenty-one years. And it is observed, from what has
been done in Norfolk and other counties where the tenures
are of more length, as from seven to twenty-one years,
that the improvement of the land is much connected with the
practice of such tenures. And it is likewise suggested in the
Gloucester Report on Agriculture, that it would be much
more advisable for the counties and farmers, and probably be one result of the labours of
agricultural societies.

Some suppose the freehold tenure to possess the most
numerous advantages, with the fewest inconveniences, of any
form of holding. But many are of opinion that some other
class is equal to it, or nearly so. The forms of tenure
throughout most of the southern parts of England, are prin-
cipally those of the freehold, copyhold, life-lease, church-
lease, and college-lease kinds, both for lives and years.
In Cornwall they are for the most part freehold, with the ex-
ception of the lands of ecclesiastical corporations and ancient
duchy land, which is equivalent to copyhold in fee, held
under the duke of Cornwall, subject to a small annual rent.
This form of land passes by surrender in the duchy courts,
nearly in the same form as other copyhold lands. But the
modern duchy is different from the above; the occupiers
being leaves under the duke, and, in general, are purchasers
of an interest in the land during the continuance of the
longest lives of three lives, the consideration being, in part,

more famous and extensive plan is generally approved in this parish, and it is a general rule that the parishes in this district have been divided into three classes, viz.:

1. The first class comprises those parishes where the number of tenants exceeds the number of tenants in the second class.

2. The second class comprises those parishes where the number of tenants equals or exceeds the number of tenants in the third class.

3. The third class comprises those parishes where the number of tenants is less than the number of tenants in the second class.

It is observed that the number of tenants is very large in some parishes, while in others it is comparatively small. In some parishes, the number of tenants is almost equal to the number of inhabitants, while in others it is much smaller. The number of tenants varies greatly from one parish to another, and it is found that in some parishes the number of tenants is very much greater than in others.

In the parishes of Edinburgh, Fife, and Stirlingshire, the number of tenants is very large, and in some cases it is even larger than the number of inhabitants. In the parishes of Lanarkshire and Ayrshire, the number of tenants is comparatively small, and in some cases it is very much smaller than the number of inhabitants.

The number of tenants is also very variable in the parishes of the Lowlands and the Highlands. In the parishes of the Lowlands, the number of tenants is generally larger than in the parishes of the Highlands, and in some cases it is even much larger. In the parishes of the Highlands, the number of tenants is generally smaller than in the parishes of the Lowlands, and in some cases it is very much smaller.

It is observed that the number of tenants is also very variable in the parishes of the south and west of Scotland, and in some cases it is much larger than in others. In the parishes of the south and west of Scotland, the number of tenants is generally larger than in the parishes of the north and east of Scotland, and in some cases it is even much larger.
The common tenures at this day are, free-simple, free-tail, by courtesy, in dower, for life, or for years, or by copy of court-roll.

Tenure, Barons by ancient. See Baron.

Tenure. Disfigure of, is a species of injury which consists in breaking that connection which subsists between the lord and his tenant, and to which the law pays so high a regard, that it will not suffer it to be wantonly disfigured by the act of a third person. If, therefore, there be a tenant at will of any lands or tenements, and a stranger, either by menace or threats, or by unlawful diligence, or by fraud and simulation, or other means, contrives to drive him away, or inveigle him to leave his tenure, this the law very justly considers to be a wrong and injury to the lord; and gives him a reparation in damages against the offender by a special action on the case.

—Blackl. Com. vol. iii.

Tenute, Ital. in Magie, generally written ten, from the Italian term tenere, to hold on, fulfill to the last moment of a note's duration. See Sostenuto.

TENYA, in Geography, a town of Africa, in the country of Fouta. N. lat. 16° 15'. W. long. 10° 25'.

TENZANG, a town of Corea; 13 miles E.S. of King-ki-tao. TENZEGZET, a town of Algiers; 16 miles S. of Trencenu.

TENZYN, a town of Poland, in the palatinate of Cracow; 20 miles W. of Cracow.

TEOATZINCO, a town of Mexico, in the country of Tlascalca, where a bloody battle was fought between the natives and the Spaniards under Cortez; 20 miles E. of Tlascalca.

TEOLO, a town of Italy, in the Paduan; 7 miles S.S.W. of Padua.

TEOLY, a town of Hindoostan, in the cirque of Ghând; 15 miles S.E. of Gujarat.

TEOAH, a small island in the Soloco Archipelago. N. lat. 6° 15'. E. long. 120° 51'.

TEONA, a small island near the west coast of Scotland. N. lat. 56° 4'. W. long. 5° 52'.

TEOPISCAN, a town of Mexico, in the province of Chiapa; 60 miles S.E. of Chiapa dos Espagnols.

TEOS, in Ancient Geography, a town of Acha Minor, in Ionia, on the southern coast of a peninsula, which became an island when the sea was high or much agitated. It was situated over-against the Isle of Samos, S.W. of Smyrna, and E. of the promontory of Coryccon. It is celebrated for having been the birth-place of Anacreon. The inhabitants were renowned for their courage: they preferred abandoning their city to living under the tyranny of the Persians. Teos was treated with mildness by the Roman emperors. Bacchus had a magnificent temple here, which Vitruvius has particularly described. Here also was held a general council for the management of all the affairs of Ionia, because this city was in the centre of Ionia.—Alfo, the name of a town of Scythia.

TEOWENISTA CREEK, in Geography, a river of Pennsylvania, which runs into the Alleghany, about 3 miles below Hickery.

TEPA. See TAROATHELETOOMO.

TEPEACA, in Geography, a town of Mexico, in the province of Tlascalca; 15 miles S.S.E. of Puebla de los Angeles.

TEPEGUANA, a district of New Brazil, situated on the Nazas.

TEPHELLENE, a town of Albania, the birth-place and favourite residence of Ali, situated on the banks of a river which at the distance of 60 miles from the sea appears to be as broad as the Thames at Westminster bridge. The streets of the town, containing about 400 ill-built houses, are extremely dirty; but the palace of the vizir is very magnificent.

TEPE-MAXTLATON, in Zoology. See Felis Tigrina.

TEPETISTAC, in Geography, a town of Mexico, in the province of Guadalajara; 60 miles N. of Guadalajara.

TEPETOTOTOYI, in Ornithology, the name of a Brazilian bird of the gallinaceous kind, more usually called mitopiranga. See Chas. Ador.

TEPHILIA, or TEPHIL, in Ancient Geography, a town of Acha, in the vicinity of Media.

TEPHIRIA, in the Natural History of the Ancients, a name given to the grey ephelites.

TEPHERICA, in Ancient Geography, a town of Acha, in the neighbourhood of Gilicia and Armenia.

TEPHROMANTIA, in Geography, a town in Lycia, of the same name as the species of divination, performed with shells; for which see Potter, Archæol. Græc. tom. i. p. 353.

Ten. Ch. Col. Perianth inferior, of one leaf, deeply divided into five straight, awl-shaped teeth; the upper ones rather the shortest; the lowest rather longer than the rest. Cor. papilionaceous. Standard recurved, large, roundish-obovate. Wings half-ovate, obtuse, straight, slightly shorter than the standard. Keel broad, rounded, gibbous, compressed, the length of the wings. Stem. Filaments ten, all firmly united along the middle into a membranous tube; the tenth separate at the base, and at its upper half; all papillar and distinct at the extremity, somewhat unequal in length; anthers terminal, uniform, ovate-oblong. Pip. German falcate, oblong, compressed, very hairy; style awl-shaped, angular, ascending, hairy along the back; stigma simple, recurved, slightly hairy. Peric. Legume oblong, compressed, hairy, transverse that falcate or ascending, of two valves and one cell. Seeds several, compressed, kidney-shaped, rather angular, slightly separated from each other by thin imperfect, membranous partitions.

Eff. Ch. Calyx with awl-shaped, nearly equal, teeth. Stamens all connected. Legume compressed, rather coriaceous, of one cell, with many seeds. Stigma acute.

Obb. We have taken our characters from one certain species, T. virginiana, comparing it with authentic original specimens of Mitchell's Erébintius, which Linnaeus thought the very same species, but in this he was certainly mistaken. It appears to be Mr. Pursh's third species, T. bipusula; and as far as we can judge, from specimens that will not admit of distinction, and from Mitchell's description, it is probably of the same genus, for Mitchell might overlook the partial union of the flaments, even supposing that character to exist in his plant. If we were certain of this, his name ought, by every right, to be preferred to the more modern one of Perfoon. (See Erébintius.) The genus moreover is improperly placed in the sixth section of Diadphila, while its essential character indicates that it belongs to the first.

and shaggy. Leaflets numerous, oval-oblong. Clufter terminal, many-flowered.—In dry sandy woods, from Ca-
 nada to Florida, flowering in June and July. Root peren-
nial. Plant about a foot high. Flowers very handsome, 
rofe-coloured and yellowish-white. Pursh. The flmen is 
simple, leafy, angular, brown, clothed with hoary pu-
befcence. Leaves alternate, nearly fefile, pinuate, of from 
17 to 21, not quite opposite, entire leaflets, each about an 
inch long, hairy on both sides, tipped with a minute point. 
Clufter solitary, various in length, compofed of numerous 
large flowers, not unlike those of a Lupine. Calyx defely 
hairy. Legume an inch and a half long, pointed, linear, 
hairy, somewhat undulate, and a little curved upward, 
tumid where the seeds are lodged. Miller appears to have 
cultivated this plant in 1765. We have never feen a living 
fpicimen. That we have here defcribed was fent by Kalm 
to Linneus. The legumes came from Jacquin's herbarium.

n. 2. (Galega villofa; Michaux Boreal-Amer. v. 2. 67? 
Purbs.)—Proflrate, downy. Leaflets five, somewhat wedge-
fpaped, very obtufe. Flower-flalks opposite to the leaves. 
Legume nearly fhrutant.—Gathered in Georgia by Mr. 
Effen, flowering in July and August. Perennial. Leaf-
lets wedgefpaped-ovobate; smooth above; fiky at the back. 
Stalks elongated, bearing about three purple flowers. 
The fingular circonfance of the nearly fefile leaves gives it
the appearance of a trifoliate plant, the lower pair of leaflets 
refembling trifolius. Michaux's fynonym is rendered doubtf-
ful by his not mentioning the small number of leaflets, one 
of the moft striking characters. Purbs.

(Galega fipidula; Michaux Boreal-Amer. v. 2. 68. G. 
fpicata; Walt. Carol. 188. Erbfinthus; Mitch. as above. 
Clitoria, n. 3; Linn. Hort. Cliff. 148, excluding the very 
erroneous reference to Burmann.)—Slender, difpafe, downy. 
Leaflets numerous, oblong-elliptical, abrupt, pointed. 
Flower-flalks opposite to the leaves. Legume falcate, hip-
fid. — In pine woods and on flate hills, from Virginia to 
Georgia. Perennial, flowering from July to September. 
Leaflets 13 or 15. Stalks elongated, bearing from three to 
five pale-red flowers. Purbs. Every part of this defcrip-
tion answers to the original fpecies of Mitchell's plant, 
but he, as well as Linneus, speaks of the tenth flamen as 
being really separate from the ref. We cannot from our 
fpecies determine this point. The flmens are long, 
branching, trailing, round, and hairy. Leaflets with ftrong 
oblique tranfeverfe veins; fonfemetimes smooth above; alýs 
fiky beneath; their length about an inch. Brachs lance-
olate. Calyx very biflty. Perhaps the union of the tenth 
flamen to the ref, which is not in the ufual mode continued 
quite to the bafe, even in T. virginiana, may exift, lefs, or 
not at all, in the fpecies before us, and yet the plants may 
together confitute one natural genus.

TEPID, in Natural Hiilory, a term used by writers on 
mineral waters, to express fuch of them as have a lefs fen-
fible cold than common water.

They diftingufh all the medicinal fprings into three 
kinds; the hot, the tepid, and the cold; but the middle 
term might eafily be misunderufold to mean a great deal 
more than they exprfs by it: all that have what can be 
called the lefl fufible warmth, are called hot; and the 
tepid are diftinguifhved from the abfolutely cold, only by 
their being lefs cold.

Some of this clafs of mineral waters, and fome few alfo 
of the cold ones, have a fharpfih vinous taffe, which is 
never obferved in any of the hot ones. This taffe is loft 
on giving the waters the flighest heat, and is therefore very
difficult to be gueffed at as to its origin. It is not only 
found in the aluminous and vitrilate waters, but afo in 
thofe which are manifeftly nitrous, and which abound 
in fulphureous falt, quite different in their nature from acids.
It is therefore an additional fomewhat, quite diflinct 
from the fainie properties of the fluid, and as easily connected 
with one kind of that as with the others.

The cafe of heat in the mineral waters remains yet 
wholly unknown, notwithstanding all that has been written 
concerning it. It is hard to beleive, that there are con-
tinual fubterranean fires near enough the surface, to give 
a heat that preserves itself in fo great a degree to the very 
place of their eruptions; and it is equally hard to conceive, 
that there can be beds of fermenting mineral matters, fuffi-
cient in quantity and force to have given the fame degree 
of heat to waters for fo many ages, as fome of our hot fprings 
are known to have fubfifted. Duclos's Exan. des Eaux 
Miner.

TEPIDARIUM, among the Romans, a tepid or 
blood-warm bath, which was joined to the cold and hot 
baths, and was a medium between the two; fo that if any 
perfon wanted to go from the hot to the cold bath, or vice 
verfa, he always took the tepid bath in his way.

TEPIQUE, in Geography, a town of Mexico, in the 
province of Xalifico; 5 miles N. of Xalifico

TEPIRUS, a town of South America, in the province 
of Tacuman; 18 miles N.W. of St. lago del Eftero.

TEPKAS, a Ruffian ftettlement in North America, on 
the eait side of Beering's fruit. N. lat. 66°. E. long. 
112° 4'.

TEPLITZ, a town of Bohemia, in the circle of Leit-
meritz, celebrated for its warm baths, discovered in 762;
14 miles W.N.W. of Leitmeritz. — Alfo, a town of 
Croatia; 8 miles S. of Varadin.

TEPOW, GREGORY NICOLAUCUTSCH, in Biography, 
a Ruffian writer, educated in a,feminary at Novgorod, 
where he diftingufhed himfelf by a Latin tranflation 
of prince Cantemir's Satures, and a work on the geography of 
Ruffia, neither of which was ever printed. In 1740 he 
was employed in the Academy of Sciences, and in forming 
a catalogue of objects contained in the Cabinet of Natural 
History. He thus acquired a taste for that fcience, and 
particularly for botany; in confequence of which he was 
made an adjuft of the Society in 1741, and in the following 
year delivered lectures on moral philosophy, that were 
much approved. The emprfs Elizabeth appointed him 
tutor and travelling companion to her favourite, count 
Rafumoufky, who, on his return from his travels in 1746, 
as made prefident of the Academy of Sciences. Teplow 
then became an honorary member, directed the infitution 
in the name of the prefident, and drew up rules for its 
better regulation. At the time of the emprfs's death he was 
a counfellor of ftate; but as he was an enemy to Peter III., 
he was arrefted: afterwards he was reflored to favour; nev-
etherlefs, two months after his being made a member of the 
council of ftate, it was discovered that he had joined in a 
dsfiracy to dethrone that unfortunate prince. After the 
depofition of Peter, he publifhed appearances, in order to 
render him odious, and, as Bufching fays, was the princi

TEPID, in Natural History, a term used by writers on 
mineral waters, to express such of them as have a less sensible cold than common water.

They distinguish all the medicinal springs into three kinds; the hot, the tepid, and the cold; but the middle term might easily be misunderstood to mean a great deal more than they express by it: all that have what can be called the least fusible warmth, are called hot; and the tepid are distinguished from the absolutely cold, only by their being less cold.

Some of this class of mineral waters, and some few also of the cold ones, have a sharpish vinous taste, which is never observed in any of the hot ones. This taste is lost on giving the waters the slightest heat, and is therefore very

TEPOTI, in Geography, a river of Paraguay, which runs into the Paraguay.

TEPPREWODA. See Tupperwoda.

TEPERTE, a name originally Tartarian, and signifying a man who cannot pay his taxes, given by the Russians to a peculiar tribe formed of Finns and Tartars in the middle of the 16th century, during the dislocation of the Khazan-Tartarian empire. They established themselves at first in that part of the Ural mountains, which belongs to the government of Ufa. At present they are too much intermingled, that their origin is scarcely discernible. They are found to increase in number at every succeeding census. In the year 1762, about 34,000 of them paid the imposts.

TEPTON, in Geography, a town of Tibet; 30 miles N.W. of Szigatchee.

TEPWIA, a town on the W. coast of the island of Celebes. S. lat. 19° 4'. E. long. 110° 10'.

TEQUENDAMA, a cataract near Bogota, the capital of New Granada (see Bogota), which, according to Bouger, is one of the highest in the world, being 250 or 300 fathoms in height, and its fall vertical. Its real height is probably about 1520 feet. The river Funza, which is here very considerable, falls along a narrow channel, on a high table land, and is poured as from the front of a vale, in one arch of the enormous height above specified, the noise being heard at the distance of seven leagues. This fall is received in a vast cauldron of more than a league in circumference; and the quantity of water, and violence of its descent, form a continual mass of clouds, which renders it fearfully visible in the evening; but in the morning it is more striking, being decorated with numerous rainbows according to the position of the spectator. The falls rocks which form the cauldron also excite admiration, being as regular and polished as if cut with a chisel; the surrounding heights are covered with trees, shrubs, and flowery plants, while the splendid appearance of some of the birds, and the music of others, render the cataract of Tequendama alike sublime and beautiful.

TEQUERA, a town in Mexico, in the province of Mechoacan, on a river near the Pacific ocean; 80 miles S.E. of Zacatula. N. lat. 17° 50'. W. long. 102° 20'.

TEQUERY BAY, a bay on the south-east coast of Cuba, near Cape Cruz.

TEQUIA, a town of New Granada; 32 miles S.W. of Pamplona.

TEQUIXUICATZANATL, in Ornithology. See

| Gracula | Quiscalus |

TER, in Geography, a river of Spain, which rises in the county of Cerdagne, and runs into the Mediterranean, about 20 miles E. of Gerona.

TERA, a small river of Spain, which runs into the Orbega, in the province of Leon.

TERACE, in Rural Economy, a term provincially applied to a coarse hair sieve, for separating the inferior flour from the bran.

TERAIN, in Geography, a river of France, which runs into the Ofle, near Creil.

TERAKAKO, a peninsula on the east coast of New Zealand, of which Cape Table forms the eastern point.

TERAMNUS, in Botany, so called by Browne, apparently in allusion to its delicately-shaped legume, terebra, being used particularly to express the tenderness of eatable pule: algae rustii was a weed hostile to leguminous plants.—Browne Jam. 290. Swartz Prodr. 105. Ind. Occ. 1238.

TER, in Geography, a river of Paraguay, which runs into the Paraguay.

TEREE, a town of Egypt, on the west branch of the Nile; 18 miles N.W. of Cairo. N. lat. 36° 50'. E. long. 35° 45'.

TERANO, a town of Naples, in Calabria Citra; 5 miles W. of Bingsnano.

TERAPSARSUK, a town of East Greenland. N. lat. 59° 55'. W. long. 45°.
TERASBURG, a town of Austria; 2 miles N. of Eppenburg.

TERATOSCOPIA, formed of τέρα, prodigy, and σκοπεῖν, I consider, a kind of divination by the appearance and view of monsters, prodigies, spectres, and phantoms.

TEREDO, in the Materia Medica, a name given by Avicenna to the tubāb, a purging drug, mentioned by all the authors of his time; but, in general, in a very confused manner.

Garcias tells us, that the Indians use it to purge phlegm, and that they add ginger to it by way of corrective; and Avicenna says the same thing of its use in his time.

TEREBURGH, Gerard, in Biography, a painter of domestic scenes of exquisite skill, was born at Zwoll, in the province of Overijssel, in 1628, the son of a painter little known, from whom he received the rudiments of the art. He began his career as a painter of portraits in small, and had acquired considerable reputation, when he determined upon travelling through Germany and Italy. Unengaged by the sublime beauties of art which the latter country offered to his view, he never changed his style, but went thence to Paris to practice it; and there met with considerable success. From thence he returned to Holland, and was highly appreciated, and fully employed. He attended the congresses assembled at Munster in 1648, for the negotiation of the treaty of peace, and there painted his celebrated picture containing portraits of the plenipotentiaries and principal personages assembed on that occasion, which is regarded as his master-piece; and of which there is a print by Suyderhoef. While engaged upon this work, he was invited by Count Pigorando, the Spanish ambassador at the congresses, to visit Spain, and went there in consequence; where he was most favourably received, and much employed. The king conferred upon him the order of knighthood, and rewarded him munificently for the pictures he painted. Besides portraits, which constituted the principal part of his practice, he frequently painted conversations, musical parties, ladies at their toilettes, and domestic subjects, which he executed with a free, but rather a heavy pencil, not equal to the brilliancy of Metzu and Netscher, but nevertheless exceedingly meritorious and agreeable; particularly in the close imitations of his draperies. He died in 1681, at Deventer, where he settled on his return from Spain.

TRECERA, or Terecia, in Geography, one of the Azores islands, suppos'd to have derived its name from its standing the third in this cluster of islands in point of situation, though the first in dignity, as appears from a number of circumstances, and particularly from its communicating its name to the rest. This island is computed at 34 miles in circumference, and about 25 miles in length, by 15 in medial breadth. Its figure is almost circular, the coasts high, and so surrounded with craggy rocks, that it is deemed impregnable; every accessible part on the coast being defended by strong forts, heavy cannon, and a numerous and regular garrison. The only tolerable port in the whole island is the harbour of Angra. The island of Terecia is fertile, pleasant, and healthy: the very rocks, which elsewhere are dry and barren, produce here excellent vines, though not equal to those raised in the Canaries and Madeira. The land yields large crops of wheat and other grain, pasture for cattle, and a prodigious variety of lemons, oranges, and all those fruits peculiar to hot and cold climates, which are observed to be propagated to the greatest advantage in temperate countries. Besides Angra, there are several other towns and large villages in Terecia, with a number of forts and garrisons, under the direction of the governor, who has the power of filling up all vacancies that happen among the military officers. N. lat. 38° 45'. W. long. 27° 6'.

TRECERO, a small island in the Atlantic, near the coast of Sierra Leone.

TRECERO, a river of South America, which rises in Tucuman, and joins the Salado on the borders of Paraguay.

TERCHIZ, or Teresh. See Turush.

TERCHOUZ, in Orvithology. See Upupa Epops.

TERDINA, in the Materia Medica, a name by which Paracelsus, and some other authors, have called the great garden-valerian. Ger. Emac. Ind. 2.

TERDOPIO, in Geography, a river of Italy, which runs into the Po, 12 miles E.S.E. of Lumbello.

TEREBELLA, in Natural History, a genus of the Mollusca order of Vermes; the characters of which are, the body oblong, creeping, naked, furnished with branchiae at the sides, more frequently in the tube; the mouth habituated, toothed, and projecting a clavated probosces; the tentacula or feelers about the mouth numerous, capillary, and ciliated. Gmelin enumerates eleven species.

CIRRATA. Round, body with triple lateral penaeis. Found in the sandy bottom of the Iceland sea.

LAPIDARIA. With eight cirri at the anterior parts of the body, about the mouth four. Found in the Mediterranean sea, within the clefts of rocks.

CONCHILEGA. Whitish, with numerous filiform cirri at the mouth, the upper longest; the branchiae very red. Found in the sea washing the coast of Holland.

COMPLANATA. Depressed, mouth with four cirri; the lateral pencil-bearing warts of the body arranged on both sides in a two-fold series.

CARNICULATA. Depressed-quadrangular, with a four-fold series of penaeis from the body, and palate elongated. Found in the American and Indian seas.

ROSTRATA. Tetraedrous, with a quadruple series of penaeis from the body, and palate elongated. Found in the Indian sea.

FLAVA. Depressed, with thirty-seven branchiae on both sides, and bifurcated tail. Found in the Indian sea.

RUBRA. Red, depressed; tail terminating with two cirri; the head with two horary movable jaws. Found in the sea surrounding the islands of Zealand.

APHRODITIS. Round, gradually attenuated backwards, below somewhat depreased with an oblique furrow; no branchiae in the eight first segments, in the following three simple, in the last fcnibly greater, one being turned, pin nated. Found in the Indian sea.

BICORNIS. With a simple terminal two-horned dife of the proboscis. Found in the America ocean.

STELLATA. With a perforated triple dife of the proboscis; the anterior armed with a truncated horn, radiated with prickles. Found in the American ocean.

TERRIBELLA, (dim. of terebra,) in Surgery, a trepan, or circular saw, for removing portions of the skull.

TREBIA, in Ancient Geography, a town of Asia, in the Greater Armenia, E. of the sources of the Tigris.

POLEMY.

TREBINACEAE, in Botany, the 94th order in Jullien's system, the 12th of his 14th class, so denominated from the genus for which he choos'd to retain the old name of Tetranchis, but which is the Pylacia of Linnaeus. Many of the plants of this order abound in an essential oil of the nature of turpentine, or something like it. The characters are as follow.

Calyx
Calyx of one leaf, inferior, with a definite number of segments. Petals definite in number, (rarely wanting,) inserted into the lower part of the calyx, alternately with its segments, with which they agree in number. Stamens either the same number, alternate with the petals, or twice as many, inserted into the same spot. Germania superior, either simple, or more than one, of a determinate number. When the germen is single, the style is solitary, (rarely deficient,) with a simple or a divided stigma; when there are several germen, the stigmas equal them in number. Fruit either capsular, a berry, or a drupa, of one or more single-seeded cells. Where there are several germen, there are as many styles, or simple stigmas; and the same number of distinct single-seeded capules. The seeds are generally lodged in a bony nut. The corculum is without an albumen, its radicle lateral, and reflexed upon the lobes. Stem arborescent or shrubby. Leaves alternate, without stipules, either simple, or ternate, or pinnate with an odd leaflet.

Section 1. German simple. Fruit of one cell, with a solitary seed.

This comprises Caffuous of Jussieu and Lamarck, which is the Linnaean Anacardium; Anacardium of the same authors, which is Semeacrus of Linnaeus; Magnifera; Conacrus; Rhus; and Rourea of Aublet, Schreber's Robergia.

Section 2. German simple. Fruit of many cells, some of which are occasionally abortive.

Canarium; Rambha; Canondalia; Camaraurium; Leica of Aublet; Amyris; Toddalia, which is Castanea of Schreber; Spondia of Sm. Plant. Ic. (see Spondia); Sinus; Spathelia; Terebinthus of Tournefort and Jussieu, the Linnaean Pilassonia; Buraja; Tolufera; Tapiria of Aublet, which is Schreber's Juniquia; Porphyria of Commerson, perhaps not different from our Spondias Magnifera; and Spandias itself, compose this section.

Section 3. German several. Fruit of many single-seeded capules.

Here are only three genera: Simaba of Aublet, which is Schreber's Zuingera; Atyanthus of Desfontaines; and Brueca of L'Heritier.

Section 4. Genera akin to Terebinthaceae, but differing in being furnished with a flabby albumen, which brings them near to Rhamni; see that article.

Caffus of Jussieu, Lamarack Ilustr. t. 387; Fagara; Zanthoxyla; and Pilosa.

Section 5. Genera akin to Terebinthaceae, and (like the true plants of this order) definite of a flabby albumen.

Dodonca; Averhoa; and Inglesla.

Jussieu announces an intention of dividing this order into Caffus, true Terebinthaceae, and Zanthoxyla; the first having simple leaves, a single-seeded fruit, and an ascending radicle; the second generally pinnate or ternate foliage, a drupa with several single-seeded nuts, and a defending radicle; and the third pinnate or ternate foliage, mostly marked with pulvini dots; fruit of many cells or many capules, each with foliaceous seeds; and a flabby albumen surrounding a straight corculum. A fourth order would arise out of certain genera now intermixed with the rest, but not properly coming under any of the three just defined, being themselves perhaps entitled to lay the foundation of future orders, not as yet discovered.

TEREBINTHINA, in Medicine, Natural History, &c. See Terebinthine.

TEREBITHUS, in Botany. τερεβίθος: of Dioscorides. See Pistacia and Terebinthaceae.

TEREBOTIN, a word used by Paracelsus for the common turpentine.

TEREBRA, from τερεβρα, to bore, a trepan, or trephine. Vol. XXXV.

Also, an instrument called a perforator, such as is contained in the generality of cafes of trephining instruments, and is used for making a hole, in which the centre pin of the trephine is to work.

TEREBRATULA, in Natural History, a name given by Mr. Llloyd and Guatier to some species of the smooth conchae anomiotes, which have near the head of the shell a small hole, which looks as if bored by art. See CONCHAE Anomiates, and Shiells.

TERECOL, in Geography, a town of Hindostan, in Concan; 16 miles N.N.W. of Goa.

TEREDO, in Natural History, a genus of the Terebratalo order of Vermes, the characters of which are, that the animal is a terebella, with two hemispheric calcareous valves, cut off before, and two lancedolate; the shell is round, fuscous, and capable of penetrating wood. Gmelin reckons three

Species.

NAVALIS. The shell very slender, cylindric and smooth. UTRICULUS. Shell solid, cylindric and undulated.

CLAVA. Shell calcated at one end, the other curved, narrower, obtuse, and perforated in the middle.

The head of the Teredo navalis, called by Linnaeus Callitites navium, is well prepared by nature for the hard offices; it is to undergo, being coated with a strong armour, and furnished with a mouth like that of the leech; by which it pierces wood, as that animal does the skin: a little above this it has two horns, which seem a kind of continuation of the shell; the neck is as strongly provided for the service of the creature as the head, being furnished with several strong muscles; the rest of the body is only covered by a very thin and transparent skin, through which the motion of the intestines is plainly seen by the naked eye; and by means of the microscope, several other very remarkable particulars become visible there.

This creature is wonderfully minute when newly excluded from the egg, and at its utmost bigness is but a foot long; three or four inches are however its more frequent length.

When the bottom of a vessel, or any other piece of wood constantly under water, is inhabited and injured by ever so great a number of these worms, there is no sign of the damage to be perceived on the surface, nor are the creatures visible till the outer part of the wood is cut or broken away; then their shelley habitations come in sight: these lie near the surface, however, as to have an easy communication with the water, and there is a multitude of little perforations in the very surface through which the inhabitants injects throw out the extremities of their little shelley horns; there are of a reddish colour, and may be distinguished by an accurate observer in form of so many red prominent points; they all are retracted on the least touch, and are thrown out again as soon as all is quiet. From these points, or the small apertures which give them a way out, are the cells of the teredines to be traced. They are composed of an orderly or shelley matter, which forms a long tube with various windings and turnings, which mark the abode of the creature; but which usually neither adheres to the body of the animal nor to the wood. These cafes or tubes are always more or less loose in the wood, and there is ever a large space within them, for the body of the animal to be surrounded every way with water. They are very smooth on the inner surface, and somewhat rougher without; and are much harder and firmer in the cells of the older and larger animals than in those of the young ones.

These shelley tubes are composed of several rings, or annular

nular
cular parts; but these differ greatly in their length. There
is an evident care in these creatures, never to injure one an-
other's habitations; by this means each tubule or cañe is
preferred entire, and in such pieces of wood as have been
found eaten by them into a sort of honey-comb, there never
is a pailleage or communication between any two of
the tubules, though the woody matter between them often
is not thicker than a piece of writing-paper.

The vail increase of these animals, and their shelly tubules,
naturally lead to a consideration of the manner of their
generation: and when we consider that each of these crea-
tures is, from the time when it is produced from the egg,
immediately lodged in a cell, in which it lives without the
least possibility of getting into that of another animal of its
own kind, or receiving one of them into its own, it is not
easy to account for the propagation of the species in the
common way. This, however, is solved by an accurate
anatomical observation of the animals themselves, since in
every individual the parts of generation in both sexes, and
both the semen and ovula are found. Each individual there-
fore evidently serves by itself for the propagation of the
species; and this is probably very often the case in earth-
worms, and other of the hermaphroditic animals. All the
yet known kinds of these being soft-bodied; and probably,
though they often meet one another, and copulate in pairs,
yet when they have not opportunity, the parts copulate in
the individual.

Eggs are found in great plenty in the bodies of these ani-
mals in June, and are discharged with the water into the
sea, where the far greater part of them, doubtless, become
food for other small marine animals; and the few that affix
themselves to any piece of wood they are washed against,
hatch and get into its substance in the manner of their
parents.

The kind of wood in which these worms are lodged,
makes a great difference in the appearance of their cells, as
they work much more speedily and successfully in some kinds
than in others. The fur and alder are the two kinds they
seem to eat with the greatest ease, and in which they grow
to the greatest size. In the oak they seem to make but a
very slow progress, and usually appear very small, and
poorly nourished. The colour of their shelly tubules is often
brown in this wood; which seems plainly owing to the
effect of its juices.

Poisonous ointments are also found to be of some use in
destroying them, on rubbing over the wood: some have
thought that burning the surface was an effectual way of
preventing them, but this has been found to be otherwise.
The safest method of avoiding them in particular works,
is the using of bitter or very solid woods; the first kind they
are found never to touch, and in the other they make but
slow progress. Mixtures of lime, sulphur, and colchicum,
with pitch, for covering over the surfaces of boards, &c.
have been found of some use.

It seems very evident, that boards and other pieces of
wood have been subject to be eaten by these animals, from
time that we have any knowledge of; for the Rome called
Lupis Syringoides is evidently no other than these wood eaten,
petrified by long lying in the earth, together with the tubules
of the worms. The mases of this with the grain of wood
yet plain in them, are common in many places among fea-
hells, and other marine remains at great depths, and have
evidently been brought thither in very distant times, and
before those changes were made in the surface of the earth
of which we have no accounts in our earliest histories.

TEREDON, in Ancient Geography, a town of Asia, in
Babylonia, on an island which was formed by the Tigris at
its mouth. (Ptol.) Dionysius Periegetes places the town of
Terdon at the mouth of the Euphrates.

TEREK, in Geography, a mountain of Asia, between
Great and Little Bucharia.

Terck, one of the rivers that fall into the Caspian sea.
It originates in the Caucaidian mountains, runs at first
towards the W. and S., but turns afterwards entirely to the E.
and in about N. lat. 44°, and E. long. 65°, discharges itself
into the Caspian. It takes up in its course the Bafian, the
Malka, and the Sooana, among many other mountains,
and rivers. Its course lies properly in the Snow-
mountains of Caucasus, on the highest partition-ridges of
the frontiers of Georgia. It is rapid in its course; and
in the months of July and August, when the snow melts,
swells to the height of eight or ten feet above its usual
level in autumn, winter, and spring; overflowing its banks,
and inundating the adjacent country, forming for itself
new beds, and choking the old with sand. In its lower course,
as far as Kitzilari, it is almost entirely unaccompanied by
woods; farther up, to Starogladka, by a few; and thence
upwards, its banks are richly garnished with forests,
notably of oaks, wild fruit-trees, and a variety of others.
It does not freeze over every year, though in winter it abounds with driving ice. In this season its water is toler-
crably clear, which at other times, above Kitzilari, is turbid,
with earthy particles; but when taken up, it soon becomes
clear, and is then bright, well-tarred, and of good quality.
Below Kitzilari, the river has a less fall, and separates into
several arms, in which the parted stream flows so gently,
that it has time to deposit its earthy particles, which alter-
nately fill up these arms; so that one or the other occasion-
ally represents the main river. In the lower regions, on
the shores of the Terek, are seen vineyards, mulberry and
other fruit-trees, to which succeed salt-lakes, and springs
of the same nature. Its bed is formed mostly of sand and
clay. With regard to fish, the Terek, as well as all its
collateral rivers, is poor. Yet there are caught in it fur-
geon (acipenser fluviit), beluga (acipenser huo), ferrat-
us (acipenser stellatus, Pall.), plenty of salmon, fat-fish (cyp-
rinus chalcoides), carp, barbel (cyprinus barbus), shad,
pike, saduk (lucio pereca), perch (perca fluviatilis), lessas-
(cyprinus barba,) otters, beavers, tortoises, &c.

Terek, in Ornithology. See SCOLOPAX CINERA.

TERELLA, in Geography, a town of Naples, in the
Molie; 4 miles N. of Molie.

TERENTIUS, in Biography, a Latin writer of comedies,
was born, as it is supposed, at Carthage about the year of Rome 560 (B.C. 194.) Being
brought to Rome as a slave, when young, he was in the
service of a person named Terentiuss, a senator, from whom
he derived his name. The purity and politeness of his lan-
guage evince his having enjoyed the benefit of a good
Roman education. After his emancipation, he was ho-
noured with the friendship of several Romans of rank, such
as Scipio Africanus the younger, and the younger Lelus.
His comedies were founded upon the Greek model, and,
translated, either wholly or in part, from the Greek. The
first comedy which he is said to have brought upon the stage
was the "Andrio," represtented in the year B.C. 166.
But though this was the first of his comedies that was acted,
it appears that it was not the first which he had written.
The six comedies of Terence that are still extant were ex-
hibited at Rome from the year B.C. 166 to 160. They
were heard with great applause; the "Eunuchus" was
repeated twice in the same day, and he is said to have
received for it 8000 sesterces (about 64l.) Scipio and
Lelius,
T SENJABIN, in the Materia Medica of the Ancient Arabs, a word used to express a kind of manna called by some manna magellina, from its round globules resembling the drops of maltich, and by the physicians of many parts of the world at present, manna persicum, which see. See farther about this drug in Philos. Trans. No 472. vol. xliii. p. 87.

TERES LIGAMENTUM, in Anatomy, one of the ligaments of the hip-joint. See Extremities.

TERES LIGAMENTUM UTERI. See Generation.

TERES MAJOR and MINOR, two muscles of the shoulder, so called, because their figure is somewhat rounded.

The teres major (scapulo-humerien, le grand rond) is elongated and flattened, placed at the lower and back part of the shoulder, and extending from the inferior angle of the scapula to the posterior edge of the bicipital groove of the humerus. The latissimus dorsi, the skin, and the long head of the triceps, cover it behind; in front, it is covered by the latissimus, the axillary vessels and plexus of nerves, the short head of the biceps, and the coraco-brachialis. Its upper edge corresponds first to the teres minor, then is separated from that muscle by the long head of the triceps, and lastly corresponds to the subcapularis, from which the circumflex vessel and nerve separate it. The lower edge, covered by the skin, forms, with the latissimus, the border of the axilla.

The inferior or external extremity of the muscle is fixed to the external surface of the inferior angle of the scapula, and to the neighbouring part of its lower edge: thence it ascends, passing obliquely outwards, retaining nearly an uniform breadth (about three fingers) throughout; and is attached to the posterior margin of the bicipital groove. The latter attachment takes place by means of a flattened tendon, about an inch broad, which corresponds in front to that of the latissimus dorsi.

There is a small bursa subacuta between its posterior surface and the humerus. It lines the bicipital groove by some fibres, which meet those of the pectoralis major. Muscular fibres arise from the outer surface and inferior angle of the scapula, from the lower portion of the inferior costa, and from a septum between this muscle and the infraspinatus; and they terminate on the tendon just described. It carries the arm backwards; depresses it when it has been raised; rotates the humerus on its axis, so as to turn the arm inwards or forwards. In conjunction with the latissimus, and pectoralis major, it will fix the arm against the side. It will pull the scapula forwards or upwards to the arm, when that is fixed.

Teres Minor (petit rond) is a small elongated muscle, lying at the posterior and under part of the shoulder, extending from the inferior edge of the scapula to the external tubercle of the humerus. Covered behind by the deltoid and skin, it covers in front the edge of the scapula, the infrascapular artery, the long head of the triceps, and the orbicular ligament of the shoulder-joint. Its upper edge is either continuous with the infraspinatus, so that they form but one muscle, or is separated from it by a cellular line. Towards the back part there is an aponeurotic septum between them. The lower edge is close to the teres major behind, but separated from it anteriorly by the long head of the triceps. The lower or posterior extremity is small and pointed, and begins its attachment to the scapula, just where that of the teres major ends, between the latter muscle and the infraspinatus: it passes obliquely upwards and outwards, fixed to the lower and outer edge of the scapula, and is inserted in the lower or back part of the great tubercle of the humerus. This insertion is effected by means of a tendon, closely connected to that of the infraspinatus, differing some of its fibres on the orbicular ligament, and receiving the feathery fibres in all directions from the origin of the muscle. Its action has exactly the same effect with that of the infraspinatus; which see.

TERES FOLIUM, in Botany. See Leaf.

TERESA, or THERESA, in Biography, a saint in the Roman Catholic church, was born, of a noble family, at Avila, in Old Castile, in March 1515. Her father, by reading the lives of saints to his family, inspired her, at an early age, with an enthusiastic fervour, which induced her to clothe with one of her brothers, to seek martyrdoms among the Moors. When they were brought back, they induced the same passion by constructing little hermitages in the garden, whether they retired to perform their exercises of devotion at twelve years of age. Terefa left her mother, and was boarded in an Augustine convent, and this situation prevented her being seduced by the pleasures of the world, for which she began to indulge a propensity in consequence of reading romances; but for her farther security she took the veil in the Carmelite monastery of the Incarnation at Avila, in her twenty-second year. Her person was beautiful, and attracted the admiration and love of all who saw her; but her religious ideas, though tender and rapturous, were austere; and perceiving that the discipline of the house in which she resided was relaxed, she undertook a reform of the Carmelite order. After much opposition, she succeeded in establishing the
first monastery of the female reformation at Avila, in 1562, and
having extended her plan to the religious males of the order,
the foundress in 1568 the monastery of Dorrello, which was
the origin of the more rigid, or barefooted, Carmelites. Her
zeal and almsgiving enabled her to found thirty religious
houses of the reform, fourteen for men and sixteen for
women; and after her death it extended through all the
Catholic countries of Christendom. Teresa died at Alva in
October 1582, in the 68th year of her age. She was
 canonized by Gregory XV. in 1621; and afterwards be-
came the patron saint of Spain. See Carmelites.

Teresa, in Geography, a town of Spain, in the province
of Valencia; 10 miles N.W. of Segorbe.

TERELSA. See Teresa.

TERETES, in Horae, one of the three sorts of worms
which infest the bodies of them, and which are very trouble-
some and injurious. See Ascariides, Bots, and Worms.

This sort of worm, which is found in horses, resembles the
common earth-worms in many respects, being only sharper
at both ends, callous towards the middle, and they do not
contract or dilate themselves so easily. Some of these, which
have been seen to come from horses, hinder them from thriv-
ing till they are dislodged by proper remedies.

TERETRUM, in Surgery. See Terebra.

TERFEZ, in Natural History, the name given by the
Africans to the truffles found in the deserts of Numidia,
and other places in that part of the world, in great
abundance.

These are much more delicately tasted than the European
truffles, and are white on the outside. They are called by
some of the Africans kema, and by the Arabian writers
cantha and canake.

TERFOWA, in Geography, a town of Africa, in the
kingdom of Tunis; 120 miles S. of Tunis.

TERFOWY, a town of Nubia; 150 miles S. of Syene.

TERGA, a town of Morocco, on the Morbeya; 90
miles N. of Morocco.

TERGA. See Hair.

TERGARRY, a town of Hindooftan, in Bednore; 14
miles S.E. of Simogou.

TERGAZA, in Ancient Geography, a town of Africa,
which was one of those which Manlius took possession
of in the third Punic war, and which he pillaged.

TERGESTE. See Trieste.

TERGESTICUS SINUS, a gulf of Italy, on the coast
of the Adriatic sea. It took its name from the town
Tergelle, which was situated there.

TERGIOETOUS PLANTS, such as bear their seeds on
the backides of their leaves: such are the capillaries. See
Capillary.

TERGIL, in Geography, a town of Afiatic Turkey, in
the province of Erzerum; 30 miles E. of Paln.

TERGIS, in Ancient Geography, a town of Africa, in
Libya, on the confines of Ethiopia.

TERGISONUS, a river of Italy, in Venetia, N. of the
river Padus.

TER-GOUD, or TER-GOUW, in Geography. See Goud.

TERGOVITZ, or Tergovista, a town and capital of
Walachia, where the waiwode has a palace; 64 miles S.E.
of Herisentadt. N. lat. 45° 3'. E. long. 25° 29'.

TERHALLEN, a small island near the coast of Terra
del Fuego. S. lat. 55° 20'.

TERHEY, a town of Holland; 10 miles W. of Delft.

TERIDATA, in Ancient Geography, a town of Afi, in
Medopotamia, on the banks of the Euphrates. Ptolemy.

TERINA, a town of Italy, upon the western coast of
Brutium, and in the northern part of the gulf Hipponium.—
Alto, a town of Asia, situated in the mountains W. of
Moxoune.

TERIUM, a town of Macedonia, in Pieria.

TERKAT, in Geography, a town of Afiatic Turkey, in
the government of Sivas; 20 miles N.W. of Toeet.

TERKELA, a river of Africa, which joins the Tafilet,
20 miles S. of Togda.

TERK. See Terek.

TERKI. See Turkin.

TERKIR, a lake of Thibet, about 80 miles long and
25 broad. N. lat. 32°. E. long. 91° 14'.

TERKUL, a river of Ruffia, which runs into the Ural,
at Uralss, in the government of Caucaus.

TERLIZZI, a town of Naples, in the province of Bar.
7 miles S.E. of Trani.

TERLON, a river of France, which runs into the
Sambre, about 3 miles below Landrecy.

TERM, TERMINUS, the extreme of any thing, or that
which bounds and limits its extent. See Extreme.

TERM, in Geometry, is sometimes used for a point, some-
times for a line, &c. A line is the term of a superficies,
and a superficies of a solid.

This is what the schools call terminus quantitatis.

TERM, in Law, signifies a boundary, or limitation of time,
or elapse.

In this sense we say, a leaf for term of life, for term of
years, &c.

TERMS, Termes, Terminus, in Architecture, denote a
kind of statues, or columns, adorned at top with the figure
of a man's, woman's, or satyr's head, as a capital; and
the lower part ending in a kind of sheath, or scabbard. See
Hermes.

Some write the word termes, from Hermes, a name the
Greeks gave the god Mercury; whose statue, made after
this manner, was placed in several of the crofs ways in the
city of Athens, &c. Others bring the etymology of
the word from the Roman god Terminus, the protector of land-
marks; whose statue (made without hands or feet, that he
might not change his place) was used to be planted at the
bounds of lands, to separate them.

Terms are sometimes used as confoles, and sultain en-
tablatures; and sometimes as statues, to adorn gardens.
Of these termi, the architects make great variety; viz. an- gelic.

TERMINUS, in Law, nominatus, among the ancient
Greeks, were the heads of certain divinities, placed on
square land-marks of stone, or on a kind of sheath, to mark
the several f3dia, &c. in the roads. These are what Plautus
calls larae viales.

They were usually dedicated to Mercury, whom the
Greeks believed to preside over the highways.

Some of them were reprezenated with four heads, such as
we ill see in Rome, at the end of the Fabricon bridge;
which is hence called ponte di quattro capi. It is known that
Mercury was thus reprezenated, and also called by the Latin
Mercurius quadrifrons: as being fupposed the first who in-
vented the use of letters, mufic, wrestling, and geometry.
See Hermes.

Terms are alfo used for the several times or feasons of
the year, in which the tribunals, or courts of judicature, are
open to all who think fit to complain of wrong, or to seek
their rights by due course of law, or action; and during
which the courts in Welfminter-hall fit and give judgment.
But the high court of parliament, the chancery, and inferior
courts, do not observe the terms; only the courts of king's
bench, common pleas, and exchequer, which are the highest
courts
courts at common law. In contradistinction to these, the
rest of the year is called vacation.

Of these terms there are four in every year, during which
time matters of justice are dispatched.

Hilary term, which, at London, begins the 23d of January,
or if that be Sunday, the next day after; and ends the
12th of February following.

Easter term, which begins the Wednesday fortnight after
Easter-day, and ends the Monday next after Ascension-day.

Trinity term, beginning the Friday next after Trinity-
Sunday, and ending the Wednesday fortnight after.

Michaelmas term, which begins the 6th of November,
and ends the 28th of November following.

Each of these terms has also their return; which fee.

These terms are supposed by Mr. Selden to have been
instituted by William the Conqueror; but Sir H. Spelman hath
shewn, that they were gradually formed from the canonical
constitutions of the church; being no other than those leisure
feasons of the year, which were not occupied by the great
feasals or fafts, or which were not liable to the general
avocations of rural busines. Throughout all Christendom,
in very early times, the whole year was one continued term
for hearing and deciding of causes. For the Christian
magistrates, in order to distinguish themselves from the Heathens,
who were very superflitious in the observance of their dies
fajli and nefajli, administered justice upon all days alike; till
at length the church interposed, and exempted certain holy
feasons from being profaned by the tumult of forensic litigations;
as, particularly, the time of Advent and Christmas,
which gave rise to the winter vacation; the time of Lent
and Easter, which created in the spring; the time of
Pentecost, which produced the third; and the long vacation,
between Midsummer and Michaelmas, which was allowed
for the hay-time and harvest. All Sundays also, and some
peculiar feasals, as the days of the Purification, Ascension,
&c. were included in the fame prohibition, which was esta-
blished by a canon of the church, A.D. 517, and fortified
by an imperial constitution of the younger Theodosius,
confirmed in the Theodosian code. Afterwards, when our own
legal constitution was established, the commencement and
duration of our law terms were appointed, with a view to
these canonical prohibitions; and it was ordered by the laws
of king Edward the Conferfator, that from Advent to the
octave of the Epiphany, from Septuagesima to the octave
of Easter, from the Ascension to the octave of Pentecost,
and from the in the afternoon of all Saturdays till Monday
morning, the peace of God and holy church shall be kept
throughout the whole kingdom.

And fo extravagant was afterwards the regard paid to
these holy times, that though the author of the Mirror
mentions only one vacation of considerable length, containing
the months of August and September, yet Britton fays, that
in the reigne of king Edward I. no secular plea could be held,
or any man sworn on the Evangelists, in the time of
Advent, Lent, Pentecost, harvest, and vintage, the days of
the great litanies, and all solemn feasals. He adds, that the
bishops and prelates granted dispensations for taking affizes
and juries in some of these holy feasons, upon reasonable
occasions; and soon after a general dispensation was esta-
blished in parliament by flat. 4 Edw. I. cap. 51,
that affizes of novel drugue, mort d'ancelle, and darrein pre-
sentment, should be taken in Advent, Septuagesima, and
Lent, as well as inquesas; at the special request of the king
to the bishop. The portions of time that were not included
within these prohibited feasons, fell naturally into a fourfold
division; and from some festival, or fain's day that imme-
diately preceded their commencement, were denominated the
terms of St. Hilary, of Easter, of the Holy Trinity, and of
St. Michael; which terms have been since regulated and
abbreviated by several acts of parliament; particularly
Trinity term by flat. 32 Hen. VIII. c. 2, and Michael-
mas term by flat. 16 Car. I. c. 6. and again by flat.
24 Geo. II. c. 58. Blackft. Com. vol. iii.

Terms, Oxford. Hilary or Lent term begins January
14th, and ends the Saturday before Palm-Sunday.
Easter term begins the tenth day after Easter, and ends the
Thursday before Whitunday. Trinity term begins the
Wednesday after Trinity-Sunday, and ends after the act,
or 6th of July, sooner or later, as the vice-chancellor and
convocation plege. Michaelmas term begins October 1oth,
and ends December 17th.

Terms, Cambridge. Lent term begins January 14th,
and ends the Friday before Palm-Sunday. Easter term begins
the Wednesday after Easter-week, and ends the week before
Whitunday. Trinity term begins the Wednesday after
Trinity-Sunday, and ends the Friday after the commence-
ment, or 2d of July. Michaelmas term begins October 1oth,
and ends December 17th.

Terms, Scaffolds. In Scotland, Candlemas term begins
January 23d, and ends February 12th. Whitsuntide term begins
May 25th, and ends June 15th. Lammas term begins
July 2oth, and ends August 8th. Martinmas term begins
November 3d, and ends November 29th.

Terms, Irif. In Ireland the termes are as at
London, except Michaelmas term, which begins October
13th, and adjourns to November 3d, and thence to the 6th.

Term, in Grammar, denotes some word or expression
in a language. See Word.

The word term, terminus, is borrowed metaphorically, by
the grammarians and philosophers, from the measurers or
surveyors of lands; as a field is defined and distinguished by
its termini, or limits, so is a thing or matter spoken of, by
the word or term by which it is denoted.

Term, in the Arts, or Term of Art, is a word which, be-
ides the literal and popular meaning which it has, or may
have, in common language, bears a farther and peculiar mean-
ing in some art or science. See Art.

Or, a term is a word which has one or more meanings
beside its grammatical one; or which has a peculiar force or
import in the language of some particular science or art.

A word then becomes a term when its idea is rendered
more complex, consists of more parts, and includes more
special circumstantial terms, on some occasions than others.

It is this greater complexity, this excess of constituent
parts of the idea, that denominates it a term in the general.

Farther, as the parts of the idea, signified by any word, are
arbitrary; and as one may not only add new parts to those
contained in the literal meaning, but also superadd others
to them, alter them, extend them, and otherwise modify
them at pleasure; hence the same word becomes a term of
this or that art, or both, as the inventors or improvers of
those arts have thought fit to adopt it for the common basis
of certain ideas, and to modify and circumstantiate its
meaning to the use of their respective arts. See De-
finite.

Terms, absolute, complex, concrete, equivalent, equivocal,
general, relative, synonymous, universal. See the adjectives.

Term, in Logic. A proposition is said to consist of two
terms, i.e., two principal and essential words, the subject
and the attribute.

A syllogism consists of three terms, the major, minor, and
conclusion. See SYLOGISM.

Terms of an Equation, in Algebra. See EQUATION.

Terms of Proportion, in Mathematics, are such numbers,
letters,
letters, or quantities, as are compared one with another. See Proposition.

Terms, or course, in Medicine, the menes, or women's monthly purgations.

TERMALLY, in Geography, a town of Hindoostan, in Mysoor; 15 miles N.E. of Anamtpour.

TERMED, or Termed, a town of Grand Burehia, at the union of two large rivers, whose united streams form the Jhon; the capital of a considerable district. In 1221, this town was besieged by Jenghis Khan, and, after eleven days, taken by assault; after which the conqueror put most of the inhabitants to the sword, and destroyed the town. It was rebuilt in the following century; 430 miles S. of Samarcand.

N. lat. 5° 30′. E. long. 65° 48′.

TERMEDH, or Kamili, a river of Asiatic Turkey, which runs into the Black sea, 30 miles N.E. of Samfoun.

TERMERA, or Termelnum, in Ancient Geography, a free town of Aifa Minor, in Caria.

TERMES, called Termes, a town of Hither Spain, belonging to the Arevaci, S. of Numantium.

TERNEs, in Entomology, a genus of the Aperta order of insects. Its characters are, that it has five legs formed for running; two eyes; and teftaceous antennae, and a mouth with two jaws. According to Gmelin, the characters are, that the mouth has two horns, with a horn, quadrifid lip, and two eyes. Linnæus enumerates three, and Gmelin eight.

Speciee.

Fatale. Above brown; thorax with three segments; wings pallid, and collar, or rib, teftaceous. This is the destructor of Degeer, and T. bellicosus of Smeathman. It is found in the shady parts of the equinoctial regions of India and Africa. See the sequel of this article.

DESTROCTON. Above teftaceous; head black; antennae yellow. Found in the islands opposite to South America, Africa, and India.

ARDA. Black; abdomen with segments white at the apex; legs pallid. Found in the equinoctial parts of Africa.

MORDAX. Black; the segments of the abdomen white at the apex; legs black. Found in the equinoctial parts of Africa.

CAPENSE. Yellow, with hyaline wings; brown at the margin. Found in India and Southern Africa.

FACTORUM. Abdomen ovate; mouth pallid; brown eyes; antennae teftaceous. Found in Europe, chieftly the southern part.

PULSATORUM. Abdomen oblong; mouth red; eyes yellow; antennae teftaceous. Found in Europe and America.

DIVINATORUM. Abdomen transversely fulcated; brown mouth, and black eyes. Chiefly found in books; very lively, irritable, and whitish.

It is observed, that the European species of termes are very small, compared with those of the warmer regions of Africa and America; and instead of being Gregarious, as in those climates, are usually found single. Of these, the most known is the T. pulsatiorum of Linnæus, a small insect of a whithell colour, and distinguished by Derham and some other naturalists, by the appellation of "Pediculus pulsatiorum." During the months of summer it is common in houes, particularly in decayed waincefts, and is remarkable for emitting a long-continued sound, refembling the ticking of a watch; it is commonly met with in collections of dried plants, &c. to which it is very injurious. It cannot bear, on account of its tender frame, the slightest pressure, and it is very quick in its motion. When magnified, the head appears large, the eyes very conspicuous, of a beautiful golden colour, and divided into innumerable hexagonal convexities; the antennae long and teftaceous; the palpi two in number, moderately long, and terminating in a large club-shaped top; the thorax rather narrow, and the abdomen obtusely oval; the thighs, or first joints of the legs, thick, the remaining ones slender, and the feet furnished with very small claws. The whole animal is beft with scattered hairs. This insect, according to the observations of Derham, when first hatched from the egg, is white, oval, and very small, exactly refembling a common mite; furnished with eight legs, and beft with long hairs. After a certain time it acquires its skin, and appears in the form already described. Degeer has found on each side of the thorax the appearances of rudiments of wings, refembling a pair of oblong scales; and Dr. Shaw affirms, from his own observations, that some individuals of this species become winged at their full growth; the wings, four in number, being very large, of a slightly indif fint appearance, and variegated with blackish and brown clouds or spots. In the beginning of July this change takes place, and several infestations may be seen with the wings half-grown; in a few days they gain their full size.

Dr. Derham is of opinion, that the ticking sound of these animals is analogous to the call of birds to their mates during the breeding season; and this opinion is very probable. This sound, says Dr. Shaw, as well as that produced by the "Pitius fatidicus," or death-watch, seems to prove in a convincing manner, that insects possess the faculty of hearing, though this be denied by some naturalists.

Of the exotic termes, the most remarkable is the T. bellicosus. The animals of this species have lately been minutely described by Mr. Smeathman, from whose account the following particulars are extracted.

The termes, which have been taken notice of by various travellers in different parts of the torrid zone, and called by the name of white ants, resembhe the ants in their manner of living, which is in communities, forming extraordinary nests in the surface of the ground, and various subterraneous passages, and also in their provident and diligent labour; but in both respects much surpass them. The termes are represented by Linnæus as the greatest calamity of both Indies, because of the havoc they make in all kinds of wooden buildings, utensils, and furniture, so that nothing but metal or stone can escape their destructive jaws.

Smeathman observes, that the insect in its perfect state has four wings without any fling, and should therefore be ranged under the neuroptera, and not under the aperta of the Linnæan system. The communities of termes confit of one male and one female, generally the parents of all the rest, and of three orders of insects, apparently of very different, though really of the same species. Those of the first order are the working insects, or labourers; the second comprehends the fighting insects, or folders, which do no labour; and the third are the winged ones, or perfect insects, which are male and female, and capable of propagation, but neither labour nor fight; the kings and queens belong to this order, and within a few weeks after they are elected and elevated to this rank, they migrate, and either establish new kingdoms, or perish within a day or two. The largest species, called termes bellicosus, is the best known on the coast of Africa; it creeps immense buildings of well-tempered earth or clay, which are constructed with signal ingenuity; it does infinite mischief in one respect, and in another it is peculiarly important and useful, by destroying those vegetable or animal substances which incumber the earth, and are noxious on account of their putridity. The buildings
TERMES.

buildings (usually termed hills) which these insects erect, are in their general form like sugar-loaves, and about ten or twelve feet high; and consist of an exterior part, which is large and strong, intended partly for defence, and partly for preserving a regular degree of warmth in order to hatch the eggs and cherish the young; and an interior, which is the habitable part, divided into many apartments for the residence of the king and queen, the nursing of their progeny, the accommodation of the foldiers and labourers, or magazines of provifion. The royal chamber, in the interior building, or that occupied by the king and queen, is situated near the centre, and usually in the shape of a semi-oval within.

In the infant state of the colony, it is not more than about an inch in length, but in time it is enlarged to fix or eight inches in the clear, being in size adapted to that of the queen. It has doors or entrances, at pretty equal distances from each other, which entrances are of a size not to admit any animal larger than the foldiers and labourers; so that the king and queen, when once immured, can never go out. The royal chamber is surrounded by many others of different sizes, shapes, and dimensions; and they either open into each other, or communicate by passages suitably contrived. These apartments are connected with the magazines, formed altogether of clay, and nurseries. The provisions lodged in the former appear by the microscope to consist principally of the gums or infusified juices of plants. The nurseries are composed entirely of wooden materials, joined together apparently with gums. These nurseries are occupied by the eggs, and young insects, which appear at first in the shape of labourers, but white as snow. They are very compact, and divided into small chambers, not one of which is to be found of half an inch in width. They are placed round and near the royal apartments. As the queen enlarges, her chamber is also enlarged; and new apartments are fitted up for her attendants; and also new nurseries at a remoter distance. Thus, says Mr. Smeathman, they continually enlarge their apartments, pull down, repair, and rebuild, according to their wants, with a degree of sagacity, regularity, and foresight, not even imitated by any other kind of animals or insects which he has ever heard of. These nurseries are always found slightly overlaid with or plentifully sprinkled with small white globules, about the size of a small pin's head, first supposed to be the eggs, but found by the microscope to be small mushrooms. The royal chamber is situated at about a level with the surface of the ground, at an equal distance from all the fides of the building, and in every direction surrounded by the apartments of labourers or foldiers, for the purpose of attendance. These apartments compose an intricate labyrinth, extending a foot or more in diameter, from the royal chamber on every side. Here the nurseries and magazines of provisions commence, and being separated by small empty chambers or galleries, are continued on all fides to the outward shell, and reaching up within it two-thirds or three-fourths of its height. All these chambers, and passages leading to and from them, being arched, help to support one another; and the exterior building supports them on the outside. Our limits will not allow our decribing all the subterranean galleries or passages, and the manner in which they are artfully made to communicate with different parts of the building, and to suit the convenience of the labourers and foldiers, as thoroughfares for passing and repassing with their loads of materials and provisions.

There are other nests or habitations contrived by other species, which are in the form of turrets, or upright cylinders, and contain a number of cells: they are of two sizes, for the accommodation of a larger and smaller species; and again another kind of nests, which is the habitation of a distinct species; this is generally spherical or oval, and built in trees.

Of the three orders above-mentioned, the labourers, which are about one-fourth of an inch long, and twenty-five of them weigh about a grain, are the most numerous; e. g. in the T. bellicosus, there seem to be at least one hundred labourers to one of the fighting insects or foldiers. The foldiers are about half an inch long, and equal in bulk to fifteen of the labourers; the mouth of the latter is evidently calculated for gnawing and holding of bodies, whereas that of the former, or foldiers, has its jaw shaped like two sharp awls, a little jagged, and as hard as a crab's claws, so that they are incapable of any thing but piercing or wounding: in insects of the third order, which have arrived at their perfect state, the head, thorax, and abdomen, are wholly different from those of the other orders, and they are furnished with four large brownish transparent wings; their length is six or seven-tenths of an inch, and each is equal in bulk to thirty labourers; they have now two eyes which are visible, whereas if they had them before they are not distinguishable. These insects are gathered and eat by the inhabitants, and reckoned both delicious and nourishing food. The king and queen are lodged in apartments, which are closed up, so that a passage remains merely for the ingests and egests of the labourers and foldiers, but at which (as we have already stated) neither of the royal pair can come out; and in the business of propagation the abdomen of the female extends to an enormous size, so that an old queen's will be fifteen hundred or two thousand times the bulk of the rest of her body, and twenty or thirty thousand times the bulk of a labourer, and by its peristaltic motion, are protruded eggs to the amount of sixty in a minute, or eighty thousand and more in twenty-four hours: the eggs are removed by the attendants into the nurseries, and after they are hatched, the young are provided with every thing necessary till they are able to shift for themselves. It is remarkable of all the different species of termites, that the working and fighting insects never expose themselves to the open air; but either travel under ground, or within such trees or subterranea as they destroy, or through pipes made of the same materials with their nests. The termites which build in trees, frequently contrive their nests within the roofs and other parts of houses, to which they do considerable damage, unless soon extirpated; and the larger species enter under the foundations of houses, through the floors, or bore through the poles of buildings, making lateral perforations and cavities, as they proceed. They are equally destructive when they get into a trunk containing clothes and other things, and into stores, &c.

Upon opening the hills in which the termites lodge, the behaviour of the foldiers excites admiration. When a breach is made, however quickly it be done, a foldier will run out, and walk about the breach, as if to see whether the enemy is gone, or to examine what is the cause of the attack. He will sometimes return again, as if to give the alarm; but in a short interval he is followed by two or three others, running as fast as they can, and these are followed by a large body, others also succeeding them, as long as any one continues to batter their building: nor is it easy to describe the rage and fury which they manifest on the occasion; biting every thing in their way, and making a vibrating noise, like the ticking of a watch, perceptible at the distance of three or four feet. If they get hold of any one who attacks their habitation, they will in an instant fick out blood enough to weigh against their whole body; and if they chance to wound the leg, the flux upon the focking will be seen to extend an inch
in width. They make their hooked jaws to meet at the first stroke, nor will they quit their hold, but suffer themselves to be pulled away leg by leg, and piece after piece, without the least attempt to escape. If, however, they are left to themselves undisturbed, they will in less than half an hour retire into the nest, as if they conceived their castle to be secure. Before they all get in, the labourers will be seen in motion, hastening to bring materials for repairing the breach. This they do without mutual obstruction, though their number be immense, and the work is soon finished. While the labourers are thus employed, the soldiers take no part with them. On a renewed attack, the labourers run with celerity into the numerous pipes and galleries with which the building is perforated; and the soldiers rush out as numerous and as vindictive as before. One circumstance more deserves to be mentioned; and that is the loyalty and fidelity displayed by the labourers and soldiers in their attendance on the royal chamber. This chamber is a large nest, is capacious enough to hold many hundreds of the attendants, besides the royal pair, and it is always found full. These faithful subjects never abandon their charge in the least diffusely, but rather die in their defence than desert them. If in an attack upon the hill, you stop short of the royal chamber, and cut down about half of the building, and leave open some thousands of galleries and chambers, they will all be shut up with their sheets of clay before the next morning. If even the whole is pulled down, and the different buildings are thrown together in a heap of confused ruins, provided the king and queen are not destroyed or taken away, every interference between the ruins, at which either cold or wet can possibly enter, will be so covered, as to exclude both; and if the insects are left undisturbed, in about a year they will raise the building to nearly its primitive size and grandeur.

There is another species, called the marching termites, which is much larger, and seems to be less frequent than the other. For an account of these, and many other curious particulars, we must refer to Philo. Tran. vol. lxxi. part i. art. 11. p. 139—192.

TERMIGNON, in Geography, a town of France, in the department of Mont Blanc, on the Arc; 12 miles E.N.E. of St. André.

TERMINALIA, in Antiquity, feasts celebrated by the Romans, in honour of the god Terminus.

Varro is of opinion, that this festival took its name from its being at the term or end of the year; but Fétius is of a different sentiment, and derives it from the name of the deity in whose honour it was held.

In reality, the Terminalia, or feasts of land-marks, were held in honour of Jupiter, considered in the capacity of conservator of land-marks or bounds. Dionyfus Halicarnassius tells us, that it was Numa Pomphilus who first consecrated land-marks to Jupiter; and adds, that the same prince appointed an anniverary day, on which the country-people, assembling together on the bounds of the lands, should offer sacrifices in honour of the tutelary gods thereof.

The Terminalia were held on the seventh, or, as Struvius will have it, on the tenth of the calends of March. No animal is to be sacrificed herein, it being deemed unlawful to flain the land-marks with blood: they only offered sacrifices of the first fruits of the earth; and in this the open air, and on the top where the land-marks were.

TERMINALIA, in Botany, from the terminal mode of growth and foliation in several of the species, the item being a striking example of what Linnaeus latterly called determinate ramifus, and the leaves being crowded at the ends of the branches, which are swelled in that part.—Linn. Mant. 21. Schreb. Gen. 728. Willd. Sp. Pl. v. 4. 967.

**TER**

Numerous flowers, above the others, and later, are entirely male.

1. T. Catappa. Broad downy-leaved Terminalia. Linn. Mant. 128. Willd. n. t. Ait. n. 1. Jacq. Coll. v. 1. 130. Lc. Rar. t. 197. (Adaramam; Rheede Hort. Malab. v. 4. 5. t. 3. 4.)—Leaves obovate, obtuse, very slightly toothed, delittu of glands at the base; finely downy beneath.—Native of the East Indies, in Java and in woods on the coast of Malabar, where the foil is fandy. Meffrs. Lee and Kennedy are faid to have introduced this tree into the English floves in 1778, but it has not yet bloomed, nor, considering its natural and lofty growth, is that event to be expected. The branches grow in a whorled manner; their extremities, clothed with roughy down, bearing each a close tuft of large broad leaves, a foot long, on short downy falks. Each leaf is tipped with a small point, and is abrupt or somewhat heart-shaped, though much contracted, at the base. Clifters numerous, axillary, ftalked, cylindrical, dens, many-flowered. Flowers greenish-yellow, half the fize of a currant-bloom, moft of them male. Fuit oval, compressed, larger than that of the alond-tree, reffifh, with a cylindrical kernel, which taffes like a filver, but is more tender and folicule. Its oil is faid never to turn rancid. The wood is hard and durable, and the tree is much planted about houfes, for the fake of its fiafe.

2. T. moluccana. Molucca Terminalia. Lamarec Dict. v. 1. 349. Willd. n. 2. Ait. n. 2. (T. glabra; Foril. Prodr. 74. Pl. Ecul. 52. Spreng. Antiq. Bot. 102. t. 2. Catappa; Rumph. Amboin. v. 1. 174. t. 68.)—Leaves obovate, obtuse, entire, delittu of glands at the base; smooth on both fides.—Native of the Molucca and Society ifles. Introduced into the English floves by the earl of Powis, in 1804. This is faid to be of a more humble fature than the foregoing, and the leaves are smaller, smooth at the back, though their footfalks are covered with denfe roughy down. The specific name of glabra (r) ought to have been retained in preference to moluccana. This is confidered as a facred tree in Otaheite, though ufed in building boats as well as houfes.

3. T. subcordata. Heart-leaved Terminalia. Willd. n. 3.—* Leaves obovate, obtute, somewhat wavy; smooth on both fides, heart-shaped at the base, without glands.*—Gathered by Humboldt and Bonpland, in South America. Willdenow, who had examined one of their dried fpecimens, fays * this species is very like the faf, but the bafe of the leaves is heart-shaped, and their margin very f slightly and unequally vaved; the footfalks somewhat downy. It differs from T. Catappa, in having the leaves somewhat wavy, very smooth
smooth on both sides, and heart-shaped at the base.” —This
leaf character seems to us to exist in T. Catappa.

4. T. laifolia. Broad wedge-leaved Terminalia. Swartz
Ind. Occ. 747. Willd. n. 4. (Arbor maxima, forte prun-
ifera, coriace cannabis, folio longissimo latifolium; Slenne Hist. v. 2. 130.)—Leaves ovate, obtuse, somewhat serrated, smooth on both sides, dehiscing by glands at the base: their midrib downy beneath.—Native of moun-
tainous woods in the north part of Jamaica. A tall, stout, unbranched tree, rising to the height of one hundred feet, or more, with horizontal branches, downy when young. Leaves crowded about the ends of the branches, on smooth stalks, thickish, markedly pointed, bluntly serrated, or nearly entire, tapering (not dilated or heart-shaped) at the base. Flowers small, whitish or yellowish, in long axillary clusters; the upper ones chiefly male. Fruit pulpy, greenish-red, sweet,
brightly colored, larger than a peach, eaten chiefly by hogs.
For kernel takes like an almond. The wood is valuable for its hardness. The inhabitants of Jamaica know this species
by the name of Broad-leaf Tree. Swartz.

falc. 5. 31. Willd. n. 5. Ait. n. 3. Roxb. Coromand.
v. 2. 52. t. 197. (Myrobolanus Chebula; Gartn. v. 2. 91.
t. 97.)—Leaves ovate-oblong, obtuse, entire, opposite, smooth on both sides; silky when young. Footstalks with two glands near the top. Leaves terminal. —Native of hills
in the East Indies. Retzius, who received his speci-
mens from Koenig, describes this tree as not more than three or
four times the height of a man, with no very widely
spreading top. Our specimens, from Dr. Rottler, agree
with every particular of his description. The young leaves
are beautifully silky. We find none of the marginal glands
represented by Roxburgh, nor are our leaves pointed, as
in his plate. The flowers in both are yellow, in terminal, often
aggregate, clusters. Dr. Roxburgh mentions the wood of the
tree he describes as hard and valuable, and the head as
evergreen, and widely spreading. The rind of its fruit
is much used by painters of chintz for drawing a permanent
outline, and by dyers to fix their colours. With falt of
feet it makes an excellent ink.

n. 6. —“Leaves oblong-elliptical, bluntly rounded, entire;
slightly hairy beneath, with two glands at the base.” —Native of
the East Indies. The branches are round, brown; downy when
young. Leaves two or three inches in length; con-
tacted at the base; very obtuse at the extremity, with a
slight point; dark green and smooth above; pale, and be-
sprinkled with close-pressed scattered hairs, beneath: furnished
at the base with two cup-shaped, somewhat rounded, glands.
Spikes terminal, panicled. Willdenow. We have been in-
clined to suspect this might not be distinct from the follow-
ing, but the inflorescence does not agree, nor could Willde-
now fully have omitted to notice the great length of the
foottalks in T. Bellerica.

7. T. Bellerica. Long-stalked Terminalia. Roxb. Co-
rom. v. 2. 54. t. 198. (Myrobolanus Bellerica; Breyne, Ic.
v. 18. t. 4. Gartn. v. 2. 90. t. 97. Tani; Rheede Hort.
Malsb. v. 2. 33. t. 10.)—Leaves ovate, wavy, smooth.
Footstalks about half as long as the leaves, with two glands
at the top. Spikes axillary, solitary, hardly longer than the
foottalks. —Native of hills in the East Indies. A large
tree, with a very widely spreading head; the wood is
white, but soft, and not durable. The bark, when wounded,
exudes a copious inflamed gum, like gum arabic, soluble in
water. The leaves are firm and smooth, six or seven inches
long when full-grown, but in the flowering season they seem
scarcely to exceed their footstalks, which then measure half
that length. Flowers fetid, dirty yellow, in copious axillary
spikes, not clusters. Fruit the size of a nutshell; its kernel
catable, but reported to intoxicat when taken in any great
quantity.

8. T. mauritiana. Mauritius Terminalia. Lamarck
Dict. v. 1. 349. Willd. n. 7. (Badamia Commerfonii;
Gartn. v. 2. 90. t. 97? Pamea guianensis; Aubl. Guian.
v. 2. 946. t. 349?)—Leaves lanceolate, slightly erect,
tapering at each end, smooth on both sides. Spikes
axillary, the length of the leaves. —Native of the isles
of Mauritius and Bourbon, and probably of Madagascar.
Commeron describes it as the largest and tallest tree of the
two former islands. He took it for a new genus, and named it
Refracta, under which name, and that of le faux benjoin, his
specimens are preferred in the Linnaean herbarium. The wood
is much esteemed for making canoes. The branches
are swollen at the ends, where they bear ample tufts of leaves
three or four inches long, on downy stalks, three-quarters of
an inch in length; when full-grown both appear, by La-
mark’s account, to be much larger. Flowers copious, in
simple axillary spikes. Fruit an inch in length and half long,
with a diluted compressed border, not altogether answering
to Gartner’s figure, which makes us doubt his synonym.
He has formed his barbarous generic name, Badamia, out of
the French Badamier, which is synonymous with Terminalia.
Aublet’s plate of his Pamea greatly resembles our plant, and
our chief doubt arises from their different places of growth.
That they are of the same genus cannot be disputed.

Hort. Vind. v. 3. 51. t. 100. Willd. n. 8. Ait. n. 4. (T.
Benzojin; Linn. Suppl. 424. Lamarck Dict. v. 1.
v. 4. 533.)—Leaves linear-lanceolate, wavy, downy on both
sides. —Native of the East Indies. Jacquin reports
that feeds of this species were sent him by Lemonnier, under
the French name of Bien-joint, from the Isle of Bourbon.
Hence he ingeniously and satisfactorily conjectures, that this
appellation, which alludes to the mode of growth of the
tree, may have been confounded with Benjoin or Benzoze,
the French word for gum Benjamin, or Benzoe, and thus
the said gum was supposed to come from the plant before
us. (See Styrax.) T. angustifolia has long been culti-
vated in our stoves, but the flowers are unknown. Its
manner of branching is like T. Catappa, mauritiana, &c.
but does it much differ from the last named, except that the
leaves are narrower, often quite linear, and clothed, more
or less completely, with brown, rather rigid, hairs.
Their veins, rib, and margin are tinged with a blood-colour.
The fruit appears to be similar to the last. Linnaeus raised
a plant from seed in the Uphal Rove, and remarked that the
feed-leaves were of a blood-red. The leaves of his specimen
hardly exceed a line in breadth.

v. 1. 350. Willd. n. 9. (Arbor vernici; Rumph. Am-
boin. v. 2. 259. t. 86.)—Leaves linear-lanceolate, entire,
smooth on both sides. —Native of the Molucca isles. It
is preumed to belong to this genus from the imperfect description
of Rumphius, and its evident resemblance to the two
last species. The leaves however are more disjunct, and of
larger dimensions, being from nine to eleven inches long, and
the breadth of three or four fingers, so that they are scarcely
to be termed linear-lanceolate. The rib is very prominent
beneath. Flowers yellow or whitish, with red stamens,
in drooping clusters or spikes. Fruit oblique and compressed,
two inches broad. The nut exudes a large quantity of resin,
soon turning brown, and a milky refrinous fluid is lodged
under the bark of the tree, at frilt of an acrid quality, but

3 A hardening
hardening into a valuable varnish, &c. The natives of the Moluccas. A noxious vapour is said to proceed from this tree, so that the natives of the countries where it grows avoid sleeping, or even sitting for any length of time, under its shade. Whether this be the most famous varnish-tree of the Chinese, as Rumphius indicates, may perhaps admit of doubt.

11. T. Tanibouca. Guarana Terminalia. (Tanibouca guaranensis; Aubl. Guan. 438. t. 178.)—Leaves scattered, obovate, pointed, entire, smooth. Clusters terminal and axillary. Native of marily places in Guarana. For an account of this species, see TANIBOUCA. Its genus must be very doubtful, unless the fruit was known, but the fugation of our learned friend Mr. Brown, Prodr. Nov. Holl. v. 1. 351, induces us, for the present at least, to refer the plant hither.

TERMINANDO et Audiendo. See AUDIENDO.

TERMINANS, Punctum. See PUNCTUM.

TERMINATION, Terminatio, in Grammar, the ending of a word, or the half syllable of it. They are the different terminations of one and the same words on different occasions, which constitute the different cases, numbers, tenses, modes, &c.

Termination, in Geography, an island in the South Pacific ocean, so named by captain Vancouver, as being the termination of his researches on the S.W. coast of New Holland, near which it lies. S. lat. 34° 32'. E. long. 122° 8'.

TERMINATOR, in Astronomy, a name sometimes given to the circle of illumination, from its property of terminating the boundaries of light and darkness.

TERMINE, in Commerce, a weight for gold, silver, and pearls at Tunis; 8 termeni being equal to an ounce; and 80 ounces of Tunis being equal to 81 ounces English Troy.

Termine, in Geography, a town of Naples, in Principato Ultra; 10 miles S.E. of Avellino.

TEMINER, in Law. See Over.

TERMINI, in Architecture. See Terms.

Termini, in Geography, a town of Sicily, in the valley of Mazara, situated on the north coast, celebrated for the warm baths near it, from which it received its name; 18 miles E. of Palermo. N. lat. 38° 5'. E. long. 13° 45'.—Algo, a river of Sicily, which runs into the Mediterranean, a little to the W. of Termini.

TERMINI. See Termon.

TERMINISTS, Terministi, in Ecclesiastical History, a sect or party among the Calvinists, whose particular tenets are reducible to five points: 1. That there are several perfons, both in and out of the church, to whom God has fixed a certain term before their death, after which he no longer wills their salvation, how long soever they live afterwards. 2. That God has fixed this fatal term of grace by a secret decree. 3. That this term once elapsed, he makes them no farther offer of repentance or salvation, but takes away from his word all the power it might have to convert them. 4. That Pharaoh, Saul, Judas, most of the Jews, and many of the Gentiles, were of this number. 5. That God still bears with several of this sort of people, and even confers benefits on them after the term is expired; but that he does not do it with any intention they should be converted.

All the other Protestants, and particularly the Lutherans, look on these articles with abhorrence, as repugnant to the goodness of God, and destructive to all Christian virtue; and as contrary to Scripture, particularly the following texts, Ezek. xviii. 33. 30, 31, 32; xxiii. 11. 1 Tim. iv.
the exterior on each side two inches longer than the other, and closed in flying, so as to appear one slender feather.

These birds frequent the sea-shores, banks of lakes, and rivers; they feed on small fish and water insects, hovering over the water, and suddenly darting into it to catch their prey. They breed among small tufts of rushes, and lay three or four eggs of a dull olive-colour, spotted with black. All the birds of this genus are very diligent. Passion.

Tern, Black, or Scree-crow. See Sterna furcata.

Tern, Surtain, or Darter. See Plotia surinamensis.

Tern, a word used by some authors to express an impetigo.

Terna, Folia, in Botany and Vegetable Physiography, are leaves, whether simple or compound, flexible or flaked, which grow three together in a whorl, on any flem or branch, as in Verbena triphylla, Curt. Mag. t. 367. Such a disposition of the foliage appears to prevail remarkably among the plants of Mexico, Chili, and Peru, of which, besides the example just named, many others may be found. (See the genera Fuchsia and Hemimeris.) Among British plants, Erica cinerea has natturally folia ternata; while the generally opposite leaves of Lysimachia vulgaris and Lythrum Salicaria occasionally become ternate. See Lea.

TERNALLA, in Geography, a town of Hindooftan, in Myloore, 145 miles E. of Rettingthe.

TERNARY MEASURE. See Measure.

TERNARY NUMBER, in Antiquity, was esteemed a symbol of perfection, and held in great veneration among the ancient mythologists. Whence Virgil,

—-"Numero Deus impare gaudeor." Ecl. viii. ver. 75.

Servius on this place remarks, that the Pythagoreans ascribed the ternary number to the Supreme God, as being the beginning, middle, and the end of all things. All the heathen gods had a three-fold power attributed to them, as the tria virgines ora Diana, the three-forked thunderbolt of Jupiter, the trident of Neptune, the three-headed dog of Pluto. Again, the Parcae were three, the Furies three, the Heroines was three nights in begettung, the Muses were ancienly three, the Graces three, etc.

This number was likewise used in most religious ceremonies, but especially in lubrications; whence Virgil, Aen. lib. xi. v. 188.

—"Ter circum accenfus, cineti fulentibus armis, Decurrere rogos."—

TERNATA, Folia, in Botany and Vegetable Physiography, are compound leaves, each of which consists of three leaflets, as in the Trefoil and Strawberry. These are called in English Ternate Leaves, and must not be confounded with Folia Ternata, see that article, for which last we have no appropriate term in our language. Some plants bear twice, or thrice, ternate leaves. See Leaf.

TERNATE, in Geography, an island in the East Indian sea, and the principal, though not the largest, among those called Moluccas or Spice Islands, of a circular form, and about 21 miles in circumference. In the centre is a lofty volcanic mountain, whose base extends almost to the sea every way. The upper parts are uncultivated, and covered over with shrubs and low trees; but in the plain are many gardens, and abundance of fruit-trees. On this mountain are found many hollows or caverns full of sulphur, which emit a thick smoke, and flame sometimes appears from the fummit, with a noise resembling thunder. The productions are cocoa-nuts, bananas, yams, oranges, and other fruits; but the principal article of commerce is cloves; many birds of paradise, and other beautiful birds, are found here, and plenty of game. The chief quadrupeds are goats, deer, and hogs. The boa serpent is sometimes found of the length of thirty feet. This island was first settled by the Spaniards, who were driven away by the Dutch, to whom the king of the island is, in some degree, subject. The Europeans have two forts, called "Orange" and "Terneke," between which is a lake, called "Safe," three miles in circumference, and 60 fathoms deep, separated from the sea by a narrow dike, which the Spaniards made a brutefiles attempt to cut-through, to form a port. On this island are three mosques, and a Dutch church, but no place of worship for the Portuguese. The province or government of Ternate includes the islands of Ternate, Tidore, Motir, Machian, and Bacian, which are what are properly the Moluccas; they are the original places of growth of the finer spices; and larger nutmegs are found in the woods of Ternate, than any other produced out of Banda. Some places, situated in the eastern part of the island of Celebes, belong likewise to this government; and the object of the Company in settling there is principally to furnish provisions for Ternate, that part of Celebes being very fruitful in rice and other necessaries. They also yield a considerable quanitity of gold, about 24,000 taels, of a dollar and a half in weight, yearly, amounting, at 5l. per tael, to 120,000l., and excellent bird's-nests, which are esteemed a great delicacy by the Orientals, and especially by the Chinese; in exchange for which the inhabitants take opium, Hindooftan pence-goods, chiefly blue cloth, fine Bengal coffees and hummums, together with some cutlery. Ternate does not, in general, require any supply of provisions from Java, as the isles of Bando do. This island suffered greatly in August 1776, by earthquakes. More than sixty violent shocks were felt in the fpace of twenty-four hours, and the fortifications were much injured. N. lat. 6° 37'. E. long. 127° 10'.

TERNATEA, in Botany, a genus so named by Tournefort, from Ternate, the native country of the plant. See Clitoria.

TERNAVASSO, in Geography, a town of France, in the department of the Po; 6 miles N.E. of Carmagnola.

TERNAY, Bay of, a bay or harbour on the E. coast of Chine, in Tartary, so called by M. Perouce in 1787, The Dutch navigators called it Port Acqui. N. lat. 45° 13'. E. long. 153° 29'.

TERNBERG, a mountain of Austria, near the river Enns; 6 miles S. of Steyr.

TERNEUSE, a town and fortresses of Flanders, situated on the W. branch of the Scheld, called the "Hondty," begun by the count of Hohenloe, lieutenant of the prince of Orange, in the year 1583, afterwards augmented by the States, for the fortifications have been since destroyed; 12 miles S.E. of Flushing.

TERNI, a town of the Pope, in the duchy of Spoleto, situated between two arms of the Nera, and, therefore, anciently called "Interamnum," or "Interamma." It is well built, and the site of a bishop, immediately subject to the pope. Its greatest trade consists in oil, besides which it also reaps considerable advantage from its excellent vineyards. This was the birth-place of the emperors Tacitus and Florianus, and of Tacitus the famous historian. Between S. and S.W., and the sea, the point of Terni, to the N.W., dead by the little town of Cesi, is Mount Eolo, remarkable for its cool breezes, which, especially in summer, blow from the cliffs and crevices in the rocks of this mountain; 14 miles S.S.W. of Spoleto. N. lat. 2° 34'. E. long. 12° 57'.
TERNIER, a town of France, in the department of the Leman; 5 miles S.S.W. of Geneva.

TERNOIS, Lr., a river of France, which runs into the Canche, near Hedon.

TERNSKAIA, a town of Russia, in the country of the Cossacks, on the Don; 156 miles E.N.E. of Azopol.

TERNOVA, a town of European Turkey, in Bulgaria. This town was anciently one of the strongest in the country, and the residence of the princes; at present it is thinly inhabited, and the fortifications are ruined. It is the residence of an ecclesiastical, who is called the archbishop of Bulgaria; 95 miles E. of Sophia. N. lat. 43°; E. long. 25° 24′. Also, a town of European Turkey, in Thessaly; large and commercial; on the Peneus; 5 miles W.N.W. of Larissa.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, orbicular, convexe, rather unequal segments, with two smaller ones closely applied to the base, all permanent and coriaceous. C.r. of one petal, bell-shaped, in five deep, orbicular, convexe, emarginate segments, longer than the calyx, without any tube. Stam. Filaments numerous, awl-shaped, shorter than the corolla, and inserted into its base in a double row; anthers linear, erect, the length of the filaments. Pét. German superior, roundish; Style cylindrical, as long as the stamens; Stigma capitata. Petio. Berry dry, ovate, smooth, of two cells. Seeds about eight, convex on one side, flat on the other.

Eff. Ch. Corolla bell-shaped; in five deep segments, without a tube. Calyx in five deep segments, with two smaller at the base. Berry dry, of two cells.

1. T. meridiana. Mexican Ternstroemia. Linn. Suppl. 264. Willd. n. 1.—Leaves obtuse, oblong, corrugate, entire. Flower-flanks axillary, compressed, recurved. Two outer segments of the calyx orbicular, sharply keeled.—Gathered by Mutis in Mexico and New Granada. A tree, determinately branched; the branches thick, rigid, leafy, nearly round, with a smooth grey bark. Leaves alternate, an inch or rather more in length, on short, thick, channelled, purplish footstalks, obviate, or nearly elliptical, peculiarly rigid and coriaceous, single-ribbed, smooth, with a thick somewhat revolute margin; their upper surface often dotted with either prominent or depressed points; the under purplish or rufly, especially when young. Stipulas none. Flower-flanks numerous, axillary, solitary, half the length of the leaves, very thick and rigid, two-edged, brown or purple, curved downwards, stipulate of pubescence, but, in the dried plant at least, wrinkled and uneven. Flowers larger than a hawthorn-blossom, white. The two smaller external scales of the calyx furnished with a sharp keel, ending in a minute point; the rest without any keel, thin and membranous at the edge; all smooth, orbicular, coriaceous, permanent. Corolla occasionally with six segments, at first globose, then bell-shaped. Berry dry, dehiscent of valves. Seeds filky, deep red. Such is the plant of Mutis. We have no means of ascertaining whether the West Indian one, described by Swartz in his Observations, be the same or not; but he says the flower-flanks are terminal, nor does he advert to their clumsy two-edged figure, so different from the rest of the species, that it could scarcely have escaped his notice.

2. T. elliptica. Elliptical Ternstroemia, or Rottenbanean. Swarth Ind. Occ. 929. Willd. n. 2. Vahl. Symb. v. 2. 61.—Leaves obviate, obtuse, entire. Flower-flanks lateral, elongated, nearly thread-shaped. Outer segments of the calyx ovate, acute, bluntly keeled.—Native of the West Indies, on the Sulphur mountains of Montserrat and Guadeloupe, as well as in St. Vincent's. It is said to be the pretended Jefuit's bark, mentioned by Labat. This is a fern with round, smooth, flat,消费升级 or clustered branches, leafy towards their extremities. Leaves like the leaf, but twice as long, and not emarginate; their footstalks longer and more flander. Flower-flanks an inch and half or two inches long, but slightly drooping or recurved, nearly round, not a quarter so blunt as the leaf, slightly swelling upward, red or purplish. Flowers rather larger than the foregoing, yellowish-white, some of them distitute of a ptil. The scales of the calyx are all pointed, the outer ones narrow and ovate, of a smaller proportion than in T. meridiana, and sometimes more than two.

3. T. japonica. Japan Ternstroemia. Thunb. Tr. of Linn. Soc. v. 2. 335. Willd. n. 4. (Cleyera japonica; Thunb. Jap. 224. Mokoki; Kämpf. Am. Exot. 873. t. 774.)—Leaves obviate-lanceolate, obtuse, nearly entire. Flower-flanks lateral, somewhat angular. Outer segments of the calyx triangular, pointed, lightly keeled.—Gathered by Thunberg, near Nagafuki in Japan, flowering in autumn. This is a tree, smooth in every part. Specimens sent us by the finder are so very nearly akin to the foregoing species, that it is hard to establish a specific difference between them. The leaves of the Japan plant however are rather more lanceolate, and their margin is sometimes, not confluent, recreate towards the point. Their surface is quite smooth, not vividly dotted. The flower-flanks, about an inch long, are scattered on the branches, below the leaves, but lightly recurved, usually triangular, not compremised. Flowers white, scarcely so large as in T. meridiana. Style short and thick. Berry the size of a currant, red, pointed, with a white, sweet, subflavorient pulp, and, according to Kämpf, only one pellucid seed.

4. T. punctata. Dotted-edged Ternstroemia. Swarth Prodr. 81. Willd. n. 3. (Taonabo punctata; Aubl. Guian. 571. t. 228.)—Leaves elliptic-oblong, dotted at the edge. Flower-flanks axillary, elongated, nearly thread-shaped. Segments of the calyx all pointed.—Gathered by Aublet on the sides of the Serpent mountain in Guiana, bearing flowers and fruit in August and September. A large tree, whose leaves are bordered with minute glandular points, rough to the touch; their extremity usually emarginate; their length about three inches. Flower-flanks slender, about half as long as the leaf with its footstalk. Stamen about fifty. Fruit ovate, pointed, of five or six cells. Aublet having seen it in an unripe flatly only, too, for a capillace, but Swartz ascerts it to be a berry.

5. T. dentata. Toothed Ternstroemia. Swarth Prodr. 81. Willd. n. 5. (Taonabo dentata; Aubl. Guian. 569. t. 227.)—Leaves elliptic, pointed, strongly serrated. Flower-flanks lateral or axillary, single-flowered. Gathered by Aublet, in the same place as the preceding, and at the same scale. A tree, whole trunk is twenty-five feet, or more, in
in height, and two in diameter, crowned with an ample tuft of spreading branches. The leaves are four inches long, and an inch and half or two inches broad, thick, smooth, tapering at each end, befit with tooth-like serratures in the margin. Footstalks slender, an inch long. Flower-stalks recurved, feattered, hardly an inch in length. Flowers yellow, the size of hawthorn. Fruit like the leaf. The bark of the tree is used for tanning leather. The wood serves instead of tiles for houses.

6. T? corystofa. Corystofe Ternstroemia?—Leaves opposite, elliptical, pointed, entire. Panicle forked, corystobol, many-flowered, terminal.—Native of Guiana. Mr. Rudge. This appears to be most akin to the lath in the shape and size of its leaves, but differs in their entire margin, and opposite insertion. The three-forked panicle is, moreover, a kind of inflorescence unexampled in Ternstroemia, and the calyx wants the two small external segments. All these circumstances induce a suspicion of the genus, which we have not materials to clear up.

We cannot take leave of Ternstroemia without adverting to the microse which arise from the barbarous and unsettled principles of French nomenclature. Jullieu professes to adopt the unmeaning names of Aulot, only till the genera of that author are better settled; yet he has tried to soften down Ternstroemia into Ternabea, a needlecell change if the name were not to remain. Lamarck prefers Ternabea; for our memories and our indexes would have become burthened with three names instead of one, all intolerable to a chaffical or literary boxtail, if the genus had not happily been superfeated. TEROE, in Geography, a town of Bengal; 25 miles E. of Ramgur.

TEROUANNE. See Therouanne.

TEROWA, a town of the island of Junkielon, near the est coast; the usual residence of a Siamese governor or viceroy. Here is a pagoda, with about twenty priests. N. lat. 8° 13'.

TERPANDER, in Biography, and Music of the Ancients, one of the most renowned musicians of antiquity. It is recorded in the Oxford Marbles, that he was the inventor of characters to express musical sounds in the several genera; which event is placed about six hundred and seventy years before the Christian era. Indeed all writers who mention the progressive flate of music in Greece, are unanimous in celebrating the talents of Terpander; but though there is such an entire agreement among them concerning the obligations which the art was under to this musician in its infant state, yet it is difficult to find any two accounts of him which accord in adjudging the time and place of his birth. It does not, however, feem necesseary to lead the reader over hedge and ditch with chronologers, after a truth, of which the seint has fo long been lost. The Oxford Marbles, which appear to us the best authority to foliow, tell us, in express terms, that he was the son of Dercus of Lesbos, and that he flourished in the 381st year of these records; which nearly answers to the 27th olympiad, and 671st year B.C. The Marbles inform us likewise, that "he taught the names, or airs, of the lyre and flute, which he performed himself upon this last instrument, in concert with other players on the flute." Several writers tell us that he added three flings to the lyre, which before his time had but four; and in confirmation of this, Euchid and Strabo quote two verses, which they attribute to Terpander himself.

"The tetrachord's restraint we now despise, The seven-flringed lyre a nobler strain supplies."

If the hymn to Mercury, which is ascribed to Homer, and in which the seven-flringed lyre is mentioned, be genuine, it robs Terpander of this glory. The learned, however, have great doubts concerning its authenticity. But if the lyre had been before his time furnished with seven flings in other parts of Greece, it seems as if Terpander was the first who played upon them at Lacedaemon. The Marbles tell us that the people were offended by his innovations. The Spartan discipline had deprived them of all their natural feelings; they were rendered machines; and whether Terpander disturbed the springs by which they used to be governed, or tried to work upon them by new ones, there was an equal chance of giving offence. The new flings, or new melodies, and new rhythm, upon the old flings, must have been as intolerable to a Lacedaemon audience, at first hearing, as an organ, and cheerful music would have been, to a Scots congregation some years ago, or would be at a Quaker's meeting now. "It is not at all surprising," says Alciates, "that the Lacedaemonians fear nothing of death in the day of battle, since death would free them from those laws which make them fo wretched."

Plutarch, in his "Laconic Institutions," informs us, that Terpander was fixed by the ephori for his innovations. However, in his "Dialogue on Music," he likewise tells us, that the same musician appeared a sedition at Sparta, among the fame people, by the persuasive strains which he sang and played to them on that occasion. There seems no other way of reconciling these two accounts, than by supposing that he had, by degrees, refined the public taste, or depraved his own to the level of his hearers.

Among the many signal services which Terpander is said to have done to music, none was of more importance than the notation that is ascribed to him for ascertaining and preferring melody, which was before traditional, and wholly dependent on memory. The invention, however, of musical characters has been attributed by Alypius and Gaudentius, two Greek writers on music, and, upon their authority, by Boethius, to Pythagoras, who flourished full two centuries after Terpander. It will be necessary therefore to tell the reader upon what grounds this useful discovery has been bellowed upon him.

Plutarch, from Heraclides of Pontus, affirms us that Terpander, the inventor of names for the cithara, in hexameter verse, "let them to music," as well as the verses of Homer, in order to sing them at the public games. And Clemens Alexandrinus, in telling us that this musician wrote the laws of Lycurgus in verse, and "let them to music," makes use of the same expression as Plutarch, which seems clearly to imply a written melody. See Musical Game.

TERPELING, in Geography, a town of Thibet; 8 miles S.W. of Panom Jung.

TERPENTARIA, in Botany, a name used by some authors for the betonica aquaticia, or great water-ligwort, called water-leyton.

TERPIIUS, in Ancient Geography, a town of Macedon, in Mygdon. Prolemy.

TERPONUS, a town of Illyria, belonging to the Jadoces, of which Cesar took possession, according to Appian.

TERPSICHORE, the Jovial, as her name imports, in Mythology, the name of one of the nine Muses, (which see.) This muse is represented on medals and other monuments, by the flutes which she holds in her hands.

TERRA, in Geography.

TERRA, in Chemistry.

TERRA, in Natural History. See Earth.
Terra Alana, a name given to the yellowish-white tripoli.
Terra Adanica, a name given to the alkaline red mould.
See Adamic Earth.
Terra Armenia. See Bole.
Terra de Baira, the name given by some to an earth of a white colour, found about Baira, near Palermo.
It is esteemed a very great medicine in the cure of malignant fevers, and in the stopping of hemorrhages of all kinds. The powder of it is commonly sold in Italy under the name of Claromont-powder; a name it obtained from a person who first found out its virtues, and communicated them to the world in a treatise expressly written on the subject. Boccone, Muf. de Filic.
Terra Cariosa. See Tripoli.
Terra, Chlo, in the Materia Medica of the Ancients, an earth of the marle kind, found in the island of Chlo, and given internally as an astringent; but its chief use among them was as a cosmetic, the ladies esteeming it the finest of all things for clearing the skin, and smoothing wrinkles. What title it has to these qualities the world has not of late ages inquired into; but the substance is still in being, and to be had in any quantities from the same place. And the descriptions Dioscorides and Galen have left us of it are so accurate, that there is not the least room to doubt but that the earth now found there, was the very kind they used. It is a dense compacted earth, yet very soft, and of a texture easily disintegrated and broken by water.
Terra Cicilia. See Cicilia.
Terra Cinelba. See Cimolite.
Terra Cinolia Purpurea. See Soap-Earth.
Terra Colonies. See Cologne-Earth.
Terra Donnata. See Caput Mortuum.
Terra Folata Tartari, foliated earth of tartar, is a name improperly given to a neutral aceto-salt, with a basis of fixed vegetable alkali; or to a combination of the acid of vinegar, faturated with the alkali of tartar, or of other vegetable matter. This salt has also been called regenerated tartar, because the alkali of tartar is united with an acid, which is in some respects similar to the acid of tartar, but is in others very different.
The terra folata is made by pouring upon a quantity of alkaline salt of tartar, in a glass eurnbit, a sufficient quantity of good distilled vinegar, at different times, to faturate all the alkali, or even a little more than is necessary for that purpose, till the effervescence entirely ceases. This faturated liquor is to be filtrated and evaporated to dryness, with a gentle heat. The dry salt thus obtained is to be disolved in spirit of wine, and the solution again evaporated to dryness; by which means a salt is obtained more or less white, of a silky appearance, and composed of small scales or leaves, whence it has been called folata. When the salt is dried, and while it is hot, it must be shut up in a well-closed bottle, because it quickly becomes moist by exposure to air.
When distilled vinegar is poured upon salt of tartar, little or no effervescence is made at first, because a part of the alkaline salt employed is generally caustic, or deprived of its gas, which part unites with the acid preferably to the mild part of the alkali, and absorbs any gas that is extricated from the latter part; and, therefore, till all the caustic part of the alkali be nearly faturated, little or no effervescence can happen. But when more vinegar is added, the effervescence becomes so considerable, that some of the liquor will, without care, flow over the vessel. This effervescence is occasioned by a large quantity of air that is disengaged during the faturation. When the faturation is advanced to a certain degree, the effervescence diminishes; but the combination of the salt portions of the acid and alkali may be facilitated by frequently agitating the liquor, which will renew the effervescence. The tafe of the foliated earth is sharp, pungent, a little caustic, and partaking at the same time of the tafe of vinegar and that of fixed alkali. It is soluble in spirit of wine, and may be decomposed merely by the action of fire, and from it may be obtained by distillation, a very penetrating and concentrated radical vinegar. It is little used except in medicine. Macquer's Chem. DiG.
Preparations of this kind are given in doses of ten or twenty grains as mild aperients, and to a drachm or two as purgatives and diuretics. Lewis.
Terra Golbergensis. See Golbergensis Terra.
Terra Japanica. See Japan Earth, and Catechu.
Terra Lemnia. See Lemnian Earth.
Terra Lignicensis. See Lignicensis Terra.
Terra Livonica. See Livonica Terra.
Terra Melia. See Melia Terra.
Terra Melitensis. See Melitensis Terra.
Terra Merita, in the Materia Medica, a name given by some authors to the curcumina, or turmeric-root.
It is from a false pronunciation of this name, terri merit, that the English turmeric has its origin.
Terra Mysella. See Thraustomatiches.
Terra Noceriana. See Noceriana.
Terra Samia. See Samia Terra.
Terra Selensuica. See Selenusiaca.
Terra Sigillata. See Sigillata.
Terra Sigillata Magni Ducis. See Etrusca Terra.
Terra Sigillata Fusca, a bole of a beautiful brown colour, found in Germany, England, and America.
It is of a dense texture, makes no fermentation with the strongest acids, and if thrown into water, it soon separates into a number of thin flakes.
The Germans give it in fluxes and malignant fevers, being an excellent astringent, and worthy to be introduced into our shops.
Terra Silesiana, Silesian Earth, a fine astringent bole, called by some authors axungia folis.
It is very heavy, of a firm compact texture, and in colour of a brownish-yellow. It breaks easily between the fingers, and does not stain the hands, is naturally of a smooth surface, and is readily dissolvable in water, and melts freely into a butter-like substance in the mouth; it leaves no grittiness between the teeth, and does not ferment with acid menstrua. These are the characters by which it is known from all other earths of a like colour; it is found in the perpendicular fissures of rocks near the gold-mines at Strigonium, in Hungary, and is supposed to be impregnated with the sulphur of that metal. It is, however that be, a good astringent, and better than most of the boles in use. Hill.
The terra Silesiana is also called terra sigillata Strigonensis.
Terra Sinopica. See Sinopica Terra.
Terra Solis, a name given by the German naturalists to a kind of black fungy earth, somewhat approaching to the nature of that English black earth which we call kellow, but containing gold. It is not properly an ore of gold, but is an earth into which some small particles of gold have been washed from some other place, and there detained. A good microscope will discover these particles in the richer pieces of the earth, and they are bright and pure, though very small: the earth is found in fissures of the other strata, not in any beds or strata of itself. It is not to be had in any great quantity, nor does it contain any large portion of gold.
Terra Strigonensis. See Strigonensis Terra.
**Terra Turcica.** See Turcica Terra.

**Terra Virginie Aurea,** in Natural History, the name of a medicinal earth, mentioned by Boccone.

It is found at a place called San Peo, in the state of Modena; and is thence sent to Venice, and many other places, where it is esteemed a very famous medicine.

Its great use is in hemorrhages of all kinds; but it is also given with success in malignant fevers. Boccone, Muf. de Ficis.

**Terra Viridis.** See Terre Verte.

**Terra Umbria.** See Umbria.

**Terra Zozica,** a name given to the alkaline red mould, called also Adamic earth.

**Terra Petra, in Law.** See Summons.

**Terra,** in our Ancient Law-Books, occurs in the sense of land, or ground, joined with divers additions; as, Terra Normannorum, the lands of such Norman noblemen as were forfeited to the crown, by the owners taking part with the French king against Henry III. Terra frustra, such land as had not been lately ploughed. Terra gilflora, land held by the tenure of paying a glifflower yearly. Terra vexitra, land fown with corn, and the crop still remaining thereon. Terra feuflenta, land held free from feudal services, and devote by will. Terra culta, land that is tilled and manured, in contradiftinction to terra inculta. Terra affirma, land let out to farm. Terra dominica, or indominica, demefne land of a manor. Terra hydata, land that may be gained from the sea, or enclosed out of a waste or common to particular ufe. Terra waflabilis, tillage-land. Terra suaretra, fallow-land. Terra bocalis, wood-land, &c.

**Terra Extendens, is a writ directed to the escheator, &c. ordering him to inquire and find out the true yearly value of any land, &c. by the oath of twelve men, and certify the extent in chancery.

**Terra or Tierra Australis del Espiritu Santo,** in Geography, an island in the South Pacific ocean, and the moft wefterly as well as the largeft of thofe called New Hebrides: discovered by Quiros, and visited by captain Cook in the year 1774; 22 leagues long, 60 miles in circuit, and 12 in breadth. The land of it, especially the well fide, is exceedingly high and mountainous: and in many places the hills rife directly from the sea. Except the cliffs and beaches, every other part is covered with wood, or laid out in plantations. Besides the bays of St. Philip and St. Jago, the ifles which lie along the fouth and eaftrift coast cannot, in the opinion of captain Cook, fail of forming fome good bays or harbours. S. lat. 14° 40' to 15° 40'. E. long. 166° 45' to 167° 32'.

**Terra Firma** is fometimes used for a continent, in contradiftinction to iflands.

Thus Afa, the Indies, and South America, are uffually diftinguifhed into terra firras and iflands.

**Terra Firma,** in a more restrifled fense, denotes an immense extent of country under the authority and government, direct or indirect, of the crown of Spain, comprehending several extenfive provinces, and three audiences, fixed at Panama, Quito, and Santa Fe de Bogota: the large provinces are Terra Firma Proper, Popayan, Quito, and New Granada, all of which are again subdivided into fome smaller provinces or jurifdictions.

**Terra Firma, or Tierra Firma, in a still more confined fense, comprifes three districts in the viceroyalty of New Granada, viz. Darien, Panama or Tierra Firma Proper, and Veragua.

**Terra Firma, or Tierra Firma, Proper.** See Panama.

**Terra del Fuego, a large island, feparated from the southern extremity of America by a narrow fea, called the "Strait of Magellan."** So named from the volcanoes obferved on it. Capt. Cook was the firft navigator who had the honour, from a series of the moft fatisfactory obfervations, beginning at the W. entrance of the Straits of Magellan, and carried on with unwearied diligence round this ifland, through the ftrait of Le Maire, to conftruct a chart of the southern extremity of America. The fouth-west coast of Terra del Fuego, fays this diftinguifhed navigator (Second Voyage, vol. ii. p. 199, &c.) "with refpect to inlets, iflands, &c. may be compared to the coast of Norway; for I doubt if there be an extent of three leagues where there is not an inlet or harbour, which will receive and shelter the largest fhipping. The work is, that till these inlets are better known, one has, as it were, to fill for anchorage. There are feveral lurking rocks on the coast; but happily none of them lie far from land, the approach to which may be known by founding, fupposing the weather fo obftinate that you cannot fee it. For to judge of the whole by the parts we have founded, it is more than probable that there are ftoundings all along the coast, and for feveral leagues out to fea. Upon the whole, it is by no means the dangerous coast it has been represented. The currents between Cape Defendada and Cape Horn fett from west to eait, that is, in the fame direftion as the coast; but they are by no means confiderable. To the eait of the cape, their fame is much increafed, and their direftion is north-eait to Staten Land. They are rapid in Straits Le Maire, and along the fouth coast of Staten Land, and let like a torrent round Cape St. John, where they take a north-west direftion, and continue to run very frong both within and without New Year's Ifles. While we lay at anchor within this ifland, I obferved that the current was ftronger during the flood; and that on the ebb its fame was fo much impaired, that the fhip would fometimes ride head to wind, when it was at weft and west-north-west. This is only to be undeerstood of the place where the fhip lay at anchor; for at the very time we had a frong current fett to the weftward, Mr. Gilbert found one of equal fame near the fouth coast of Staten Land fettling to the eaitward; though probably this was an eddy current or tide."

Most writers who have mentioned the ifland of Terra del Fuego, defcribe it as deftritute of wood, and covered with snow. The latter circumstance may occur (see Hawkesworth's Voyages of Cook, &c. vol. ii.) in winter. And by thofe who faw it at that fea, it might be conceived to be without wood. Lord Anfola was there in the beginning of March, anfwering to our September; but Capt. Cook was there in the beginning of January, correfting to our July; and thus we may account for their different statements. We fell in with it, fays Cook, about 21 leagues W. of the ftrait of Le Maire, and trees were visible with glaffes; and though upon approaching it patches of snow were discoverable, yet the fides of the hills and the faa-coaft appeared to be covered with a beautiful verdure. The hills are lofty, but not mountainous, though their summits are quite naked. The foil in the valleys is rich, and of a confiderable depth; and at the foot of almost every hill there is a brook, the water of which has a reddith hue, but it is not ill-tafted. The moft remarkable land in Terra del Fuego is a hill, in the form of a fugar-loaf, which fands on the W. fide, not far from the faa; and the three hills, called the "Three Brothers," about nine miles W. of Cape St. Diego, the low point that forms the entrance of the ftrait of Le Maire. (See Le Maire.)
his second voyage. Capt. Cook, desirous of coasting the S. side of Terra de Fuego, round Cape Horn, to the Strait of Le Maire, reached the W. coast of the island Dec. 17, 1774, and having continued to range it till the 20th, came to an anchor in a place which he called "Christmas Sound." Through the whole course of his navigations, he had never felt to defolate a coast. It seems to be entirely composed of rocky mountains, without the least appearance of vegetation. These mountains terminate in horrible precipices, the craggy summits of which rise up to a vail height; so that scarcely anything can in appear with a more barren and savage aspect than the whole of the country. But barren and dreary as the land is about Christmas Sound, it was not wholly destitute of accommodations. Near every harbour our navigator found fresh water, and wood for fuel. The country abounds likewise with wild fowl, and particularly with geese, which, with their Madeira wine, enabled them to keep a cheerful Christmas. The inhabitants of Terra del Fuego were found by Cap. Cook to be of the same nation which he had formerly seen in Success Bay, and the same with those denominated by M. de Bougainville "Pechars." They are a little, ugly, half-starved, beaked race, and go almost naked; but it is their own fault that they are not better clad, as nature has furnished them with ample materials for that purpose. By fixing their felkin cloaks with the skins and feathers of aquatic birds, by making the cloaks themselves larger, and by applying the same materials to different parts of clothing, they might render their dress much more warm and comfortable. But while they are doomed to exist in one of the most inhospitable climates on the globe, they have not sagacity enough to avail themselves of those means of adding to the conveniences of life, which Providence has put into their power. The captain, after having witnessed many varieties of the human race, pronounces the Pechars to be the most wretched. Those on the S. are said to be uncivilized, treacherous, and barbarous; while those on the opposite side are represented as simple, affable, and perfectly harmless. The tents which they inhabit are made of poles, disposed in a conical form, covered with skins, or the bark of large trees. The country, though barren, abounds with a variety of unknown plants, for exciting the curiosity of the botanist. The extent of Terra del Fuego, and consequently of the Straits of Magellan, was ascertained by Cook to be less than had been laid down by the generality of navigators; nor was the coast, upon the whole, found to be so dangerous as it has been represented; the winter was also remarkably temperate. The fia-lions and fia-bears, the fhangs and penguins on the coast, are abundant, and intermix, like domestic cattle and poultry in a farm-yard, without attempting to molest one another. Eagles and vultures were seen on the hills among the fhangs in perfect tranquillity. Sir Joseph Banks, Dr. Solander, and some others, landed here in the month of January 1769, which is the time of summer in that part of the globe, notwithstanding which, two of the company fell a sacrifice only by sleeping one night, and Dr. Solander himself barely escaped. S. lat. 52° 50' to 55° 35'. W. long. 50° 20' to 58°.

TERRE MAGELLANICA. See PATAGONIA.

TERRE NIAGA, a bay in Hudson's Bay. N. lat. 62° 4'. W. long. 67°.

TERRE DOS FAMOS, a tract of country on the S.E. of Africa, N. of Natal.

TERRE NOVA, a sea-port town of Sicily, in the valley of Noto, situated in a gulf or bay of the Mediterranean, founded about the middle of the 13th century, by the em-
broad for a grass or gravel walk of proportionable width; designed in gardens as a high, airy walk, to command a better prospect of the adjacent places around, within and without the garden occasionally, as well as to enjoy the fresh air in summer more freely. In the former style of laying out gardens, it was considered as very ornamental, but is at present much in disuse.

It may be remarked, that the height of a terrace-walk may be more or less, as the situation admits, as from one foot to one or two yards, or even three or four yards or more in particular situations; and where there is plenty of earthy materials, rubbish, &c. to form it, allowing breadth in proportion, from five to ten or twenty feet or more, and extended to any length required. They are sometimes formed on some naturally high rising ground, to save as much trouble as possible in bringing stuff from a distance; and sometimes raised wholly of forced materials. But the situation for a terrace may be varied as the natural situation of the place may require.

In respect to form, they should always be broader at the base than the top, and extend lengthways to any distance required; having the sides regularly sloped, of more or less acclivity, as the width, height, and situation require. Sometimes both sides are sloped, and sometimes only one side, the other perpendicular, and faced with a subfintal wall, &c. or formed against the side of a hill, or some naturally rising ground, being finished always broad enough at top to admit of a proper walk. In some naturally elevated situations, terraces are sometimes formed one above another, in two or more ranges, each having its separate side slopes, and elevated walk; in all of which the slopes are to be neatly laid with grass, and the walk at top occasionally of grass or gravel.

The entrances leading to terrace-walks were formerly sometimes formed by an easy acclivity of a gravel or gravelled slope, and sometimes by a grand flight of stone steps. Where a rising ground of considerable elevation naturally presents itself in a proper situation, it is an eligible opportunity for forming a terrace with the least expense and trouble, on account of its not requiring the addition of so much earth and rubbish, as when raised entirely on a perfect level, wholly of made ground. Where there are any excavations of ground intended to form ha-has, pieces of water, &c. the excavated earth may be employed in forming terraces, &c.

In the bulwarks of forming a terrace, the base must be flanked out wider than the intended width at top for the walk, in order to admit of the ascent of slopes being moderate. And the whole of the made earth and rubbish must be well rammed and rolled down from time to time as it is applied, in order to render the whole equally firm, that it may not settle irregularly after being finished. The slopes may either be laid with turf, or town with grass-feeds; but the first is much the best method, where it can be employed. See Grass Ground.

Terraces are now but little attended to, and, of course, but seldom employed in modern ornamental gardens, as they are mostly considered as having a too stiff and formal appearance, and as not constituting that sort of neatness and tasteful elegance, which is so much esteemed and admired at present in all sorts of works of the garden kind.

Terrace, Counter, is a terrace raised over another to join two grounds, or raise a parterre.

Terrace is also applied to the roofs of houses that are flat, and on which one may walk; as also to balconies that project.

The terrace is properly the covering of a building which

Vol. XXXV.
attention by the mere tone of his voice, and who required only a camera, or outline, to colour at his pleasure, is in less want of artificial and captivating composition, than an ordinary finger, who is neither possessed of voice nor taste sufficient to interest the audience. And Terradellas seems to have written all his songs for performers of abilities; for his airs are never made easy and trivial in order to spare the finger. Jomelli's pen always flowed with this spirit: for he never rejected a passage that presented itself, because it would be difficult and troublesome in the execution; but this freedom of style, twenty years ago, might be more safely practised than at present: for it is well known, that a company of fingers is now reckoned good, in Italy, if the two first performers are excellent; and an opera is sure to please if two or three airs and a duet deliver attention; the audience neither expecting nor attending to any thing else. And the managers, who find this custom very convenient, take care not to interrupt play or conversation by the useless and impertinent talents of the under-fingers; so that performers of the second or third class are generally below mediocrity.

He died at Rome in 1751, of grief and mortification, for the failure of an opera which he had composed with more care and hopes of success than usual. TERRASSON, in Geography, a town of France, in the department of the Hérô; 13 miles N.N.E. of Grenoble.

TERRASSON, John, Abbe, in Biography, a man of letters, was born at Lyons in 1770, and lent by his father, who was a very religious man, to the house of the Oratory in Paris; but the fon, quitting this congregation, and disappoiting his father’s views, incurred his resentment, so that he was left with a very moderate pittance. However, the abbé Bigonn procured him admission into the Academy of Sciences in 1707: he soon became a member; and in 1721, professor of Greek and Latin in the Royal College. Under the famous ylem of Law, he acquired temporary opulence, but was soon again reduced to penurious circumstances. He then retired from the world, studying and exercising that philosophy which raised him above it. He died at Paris in 1750, at the age of 80 years. His works are, “A Critical Dissertation on Homer’s Iliad;“ “Reflections in favour of Law’s System;“ “Sethos,“ a moral romance; “A Translation of Diodorus Sicius,“ 7 vols. 12mo. with preface, notes, and fragments. It was one of Terraison’s sayings, “What is the most credulous of all things? Ignorance. What is the most incredulous? Ignorance."

Andrew Terrasson, the elder brother of the former, a priest of the Oratory, was a celebrated preacher, and died at Paris in 1723. His “Sermons," in 4 vols. 12mo. were published in 1726, and reprinted in 1736.

Gaspard Terrasson, another brother, and priest of the Oratory, was more celebrated as a preacher than the former, and officiated at Paris during five years. Having incurred persecution, he quitted the pulpit and the congregation of the Oratory. He died at Paris in 1752. His “Sermons," in 4 vols. 12mo. appeared in 1749. His anonymous work, entitled “Lettres de la Justice Christian," was censured by the Sorbonne.

Another perfon of the same family, viz. Mathew Terrasson, was born at Lyons in 1660, studied the law, and pleaded causes with great reputation. He was for some time an advocate in the “Journal des Savans," and also censor royal. He died, much esteemed, at Paris, in 1734. A “Collection of his Pleadings, &c. was published in 1740.

The son of the preceding, Anthony Terrasson, was born at Paris in 1703, brought up to the bar, and excelled in jurisprudence. By order of chancellor d’Aguesseau, he composed a “History of Roman Jurisprudence," with a collection of Ancient Contracts, &c. in fol. 1750. In 1760 he was promoted to the chancellorship of Dombes, and died in 1752. He was the author of “Melanges d’Histoire, de
TERRELLA, or LITTLE EARTH, is a magnet turned
of a jaff spheroidal figure, and placed so as that its pole,
equator, &c. do exactly correspond with those of the world.
It was thus first called by Gilbert, as being a just repre-
sentation of the great magnetic globe we inhabit.
Such a terrella, if nicely poised, and placed in a meridian
like a globe, it was supposed, would be turned round like the
earth in twenty-four hours by the magnetic particles per-
ving it; but experience has shown this to be a mistake.
TERRE-PLEIN, in Fortification, the top, platform, or
horizontal surface of the rampart, on which the cannon are
placed, and the defenders perform their office.
It is thus called as lying level, having only a little slope
outwardly to bear the recoil of the cannon.
It is terminated by the parapet on that side towards the
champaign; and by the inner talus on that side towards the
place. Its breadth is from 24 to 50 feet.
TERRESCHOW, in Geography, a town of Bohemia,
in the circle of Pilzen; 16 miles N.E. of Pilzen.
TERRESA, one of the Nicobar islands, about fifteen
miles long, and from two to five broad, of an oval form.
N. lat. 8° 20'. E. long. 93° 30'.
TERRESTRIAL BIRDS. See Birds.
TERRESTRIAL GLOBE. See GLOBE.
TERRESTRIAL LINES. See Line, Terrestrial.
TERRESTRIAL PARADISE. See Paradise.
TERRESTRIAL ROADS. See Road.
TERRE-TENANT, is he who has the actual pos-
session of the land, otherwise called the occupant. See
TENANT and OCCUPANT.
Thus a lord of a manor having a freetholder, who letteth
out his freehold to another to be occupied, this occupier
who has the actual possession is called the terre-tenant.
TERRE-VERTE, in the Colour-Trade, the name of a
green earth much used by painters, both finely for a good
flaming green, and in mixture with other colours.
The name is French, and signifies green earth.
It is an indurated clay, of a deep bluish-green colour,
and is found in the earth, not in continued strata or beds, as
most of the other earths are, but in large flat masses of dif-
f erent sizes, imbedded in other strata; these break ir-
regularly in the cutting, and the earth is generally brought
out of the pit in lumps of different sizes. It is of a fine,
regular, and even structure, and very hard. It is of an even
and glossy surface, very smooth to the touch, and in some
degree resembling the morocthus, or French chalk, but
adhering firmly to the tongue. It does not flain the hands
in touching it; but being drawn along a rough surface, it
leaves an even white line, with a greenish call.
It does not ferment with acids, and is burnt to a dusky
brown colour.
It is dug in the island of Cyprus, and in many parts of
France and Italy. That from the neighbourhood of Ve-
rona has been used to be esteemed the best in the world; but
of late there has been some dug in France that equals it.
There is also an earth dug on the Mendip hills, in the linking
for coals, which, though wholly unobserved, is nearly, if not
wholly, of equal value.
When scraped, and the finer parts separated, it is ready
to be made up with oil for the use of the painters, and makes
the most true and lasting green of any simple body they use.
Hill and Da Costa. See Berg-Graen and Verditer.
TERRIAULY, in Geography, a town of Bengal;
20 miles N.W. of Rajamal.
TERRIAH, a town of Hindustan, in Rohilcund; 7
miles S. of Berolly.
TERRIER, or TERRAR, in our Ancient Customs, a
collection of acknowledgments of the wafals or tenants of a
lordship, containing the rents, services, &c. they owe their
lord, and serving as a tile or claim for demanding and exe-
cuting the payment of them.
At present, by terrier we mean no more than a book or
roll, in which the several lands, either of a private person,
or of a town, college, church, &c. are described. The terrier
should contain the number of acres, and the fite, boundaries,
tenants' names, &c. of each piece or parcel. See Domes-
Day.
TERRIER also denotes the lodge or hole which foxes,
badgers, rabbits, &c. dig themselves under ground, and
in which they fave themselves from the purfuit of the
hunters. Hence,
TERRIE, TERRARIUS, is also used for a kind of little hound
to fhunt fothc animals, which, like a ferret, creeps into the
ground, and by that means affrights and bites them; either
fearing them with his teeth, or else halving them by force out
of their holes. See Doc and Hound.
TERRIER, in Geography, a town of Africa, on the
Senegal; 25 miles S. of Cayar.
TERRIER ROUGE, a town of the island of St. Domingo;
15 miles E.S.E. of Cape Francois.
TERRIFICATIO, a word used by some chemical
writers to exprrefs the coalition of the earthly particles of
fome bodies after fermentation, or during the time of it.
TERRILS or TERRILLS PALS, in Geography, a poft-
town of the county of Welfmorth, Ireland; 40 miles W.
from Dublin.
TERRIMUNGALUM, a town of Hinduflan, in the
Carmatic; 25 miles N. of Trithchinopoli.
TERRIORE, a town and fortrefs of Hinduflan, in the
Carmatic; 24 miles N. of Trithchinopoli. N. lat. 11° 12'.
E. long. 78° 45'.

no temporal jurisdiction; and therefore an ecclesiastical judge cannot arrest any body, not even a priest. It is much in this sense that Cutjas says, the church has an ancient, but no territory.

Territory or District of Columbia, in Geography, a district of America, ceded to the United States by thofe of Maryland and Virginia, and established in the year 1800 as the seat of general government. It is beautifully situated on both sides of the Potomac river, between 38° 48' and 38° 50' N. lat., and 7° E. and 7° W. long. from Washington, the capital. The capital is about 77° 0' 22" W. from London. It is bounded on the N.E., S.E., and partly N.W., by Maryland; and on the S.W., and partly N.W., by Virginia: in extent it is ten miles square, and contains an area of 6,500 square miles. The face of the country is elegantly variegated, and affords a great number of beautiful prospects, of which the Potomac river is the leading feature. This district affords a variety of streams and springs for watering the city, and for other purposes: its rivers are the Potomac or Potomac, the Tiber creek, Reddy creek, Rock creek, and Four-mile Run. The foil is thin and sandy, but faceable to improvement; and the climate is discriminated by a variable spring, a pretty warm summer, an agreeable autumn, and a variable, often very cold, winter.

Territory, Illinois, a territory of America, and likely to become one of the most important states in the Union, is situated between 37° and 41° 45' N. lat., and 80° 15' and 90° 15' W. long. from Washington city; and is bounded on the N. by the North-west territory, on the S. by Kentucky, on the E. by Ohio, and on the W. by Illinois territory. Its extent from N. to S. is 340 miles, and from E. to W. 143 miles. Its area contains 24,000 square miles, or 21,760,000 acres. The aspect of the country is hilly, but not mountainous; its scenery rich and variegated; and it abounds with plains and large prairies. Its rivers are the Ohio, Wabash, White-water, Tippecanoee, Illinois, and St. Joseph: its minerals are coal, lime-stone, free-stone, salt, and silver. The soil is generally rich and fertile; and its produce grain, grapes, and fruit, and in the south, cotton. Its climate is temperate, pleasant, and favorable. Its legislature consists of a house of representatives and senate; the former elected annually, and the latter every three years; they must hold no office of profit when elected. The executive consists of a governor and lieutenant-governor; both elected for three years, and capable of being re-elected once; the former has a compensation of $1000 dollars per annum, and the latter two dollars per day, while the legislature is in session. Its judiciary administration is composed of a supreme and circuit court: the former composed of three judges, appointed by the governor and senate for seven years; with a salary not exceeding $600 dollars per annum; the latter consists of a presiding judge and two associates, who hold courts in each county: the presiding judge appointed by the joint ballot of the legislature for seven years, and the associates elected by the people for seven years: sheriffs, clerks, and justices, are elected by the people; the sheriff for three years, the clerks and justices for seven years. The militia officers are elected by those who are subject to military duty; and all above colonel, by the commissioned officers. A state bank is to be established at the seat of government, with one branch for every three counties; and the branch banks must have 30,000 dollars in specie each, before they begin to act. Involuntary slavery is forever excluded. The constitution may be amended in 12 years: Corydon is to be the seat of government for nine years. The congress, in creating the Indiana territory into a state, appropriated, in addition to the school section, an entire township of land for the support of a seminary of learning, and four fections for fixing the seat of the state governor.

* Laid off since last census. Melish. See Indiana.

Territory, Michigan, a district in America, which, in 1796, was denominated Wayne county, has lately been erected into a territorial government, and organized with the usual offices and powers. It is situated between 41° 45' and 45° 33' N. lat., and 80° 15' and 80° 15' W. long. from Washington; and is bounded on the N. by the limits of Michilimackinac, on the S. by Ohio and Indiana, on the E. by Lakes Huron and St. Clair, and Upper Canada, and on
on the W. by lake Michigan. Its extent from N. to S. is 234 miles, and from E. to W. 138 miles. Its area contains 27,000 square miles, or 17,280,000 acres. The central part of this territory is high, and from this is a defect in all directions.

The rivers are St. Mary's, Huron, Detroit, Black, Manatee, Grand, Credit, Kish, &c. The soil is generally rich and fertile, and produces wheat, oats, barley, rye, corn, potatoes, fruit, &c. The climate is temperate and salubrious; winter lasting from the middle of November to the middle of March.

**TERRITORY.** Mississipi, an improving country of America, which, it is presumed, will be divided into two states, the Tombigby being the boundary. It is situated between 30° 15' and 35° N. lat., and 8° and 14° 32' W. long, from Washington city; and bounded on the N. by Tennessee, on the S. by Louisiana, West Florida, and the gulf of Mexico, on the E. by Georgia, and on the W. by Louisiana and Missoury territory. Its extent from N. to S. is 312 miles, and from E. to W. 324 miles; and its area comprehends 89,000 square miles, or 56,960,000 acres. Its general aspect is, towards the south, level, to the north, elevated and beautifully diversified, and on the north-east are some spurs of the Alleghany mountains. The soil, generally good, and in many places excellent, produces cotton, corn, rice, wheat, rye, oats, some sugar, and indigo. The climate is much commendable; the winters being mild, and the summers not warmer than several degrees to the northward.

Melish. See Missouri.

**TERRITORY.** North-West, an extensive territory of America, not yet organized into a regular government, is situated between 41° 45' and 40° 37' N. lat., and 76° and 158° 30' W. long, from Washington city; and bounded on the N. by Upper Canada and Lake Superior, on the S. by Indiana and Illinois territory, on the E. by Upper Canada and Lake Michigan, on the W. and S.W. by Missippic river, which divides it from the Missoury territory. Its extent from N. to S. is about 360 miles, and from E. to W. 456 miles; and its area contains about 147,000 square miles, or 94,080,000 acres. The face of the country is generally undulating, in some places hilly, but not mountains. Its rivers are the Missippic, Ouicofon, Fox, Monomonic, Chippeyow, &c. The soil is mostly excellent; and the climate, towards the south, is pleasant, and to the north, cold. Few settlements have yet been made in this extensive region, and the inhabitants were not included in the last census. Melish.

**TERRITORY of Orleans.** See Louisiana, Orleans, and United States.

**TERROR.** The effect of terror, or of sudden frights, in the disease, is often very great.

It is generally observed, that people who are most afraid of the plague of time of contagion, catch the infection sooner; and that those who are most terrified and disillusioned at first in the disease, generally die of it. It is indeed uncertain, whether this be attributed to the terror, or whether the terror itself, as a consequence of dejection of spirits, be not merely a symptom of the disease. Kerkring, Spicili, Anat.

Sudden frights, in acute disease, have evidently killed many,
many, by the agitation into which they have thrown the
spirits, already too much disordered. We have also accounts
of persons absolutely killed by terrors, when in perfect health.
At the time of receiving the flock from them: people ordered
to be executed, but with private orders for a reprieve, have
expired at the block without a wound.

The general effects of terror are a contraction of the small
vessels, and a repulsion of the blood in the large and internal
ones; hence proceed the suppression of perspiration, the gen-
eral oppression, trembling, and anguish of heart and lungs
overcharged with blood, &c.

When a person is affected with terror, the principal endea-
avour should be to refile the circulation to its due order, to
promote perspiration, and to allay the agitation of the patient.
For these purposes he may drink a little warm liquor, as
chamomile tea, &c.: the feet and legs may be put into warm
water, the legs rubbed, and the chamomile tea repeated every
six or eight minutes; and when the skin is warm, and there
is a tendency to perspiration, feep may be promoted by a
gentle opiate.

TERRYS, in Geography, a town of Bengal; 30 miles
neath.

TERSA, a small river of Russia, which runs into the
Medvedizta, in the country of the Coftacs. N. lat. 50° 30'.
E. long. 44° 34'.

TERSCHEUREN, a town of Guelderland; 7 miles E.
of Amersfort.

TERSEKAN, a river of Russia, which runs into the
Ikhim, N. lat. 52° 30'. E. long. 67° 34'.

TERSHIZ. See Ter Shish.

TERSION, Tersio, formed of Tero, I wear, the act of
wiping or rubbing a thing. See ABRASION.

TERTA, in Ancient Geography, a town situated, accord-
ing to Ptolemy, in the interior of Thrace, between Sardica
and Philippopolis.

TERTHON, a word properly signifying the extreme
part of the tail-yard in shipping. Hippocrates uses it in a
metaphorical sense, to express the extremity of a disease.

TERTIAN, in Medicine, a species of intermitting fever,
of which the familiar paroxysms occur at an interval of about
forty-eight hours. See FEVER.

TERTIARY is also an old measure, containing eighty-four
gallons, so called because it is the third part of a tun. 1 R. III.
c. 13. 2 H. VI. c. 11.

TERTIARIA, in Botany, a name given by some
authors to the fecullaria, or hooded willow-herb. J. B. Ollin,
vol. iii. p. 435.

TERTIARY Canons. See CANONS.

TERTIAS, a word used very frequently in the writings
of physicians, with the addition of ad; but it is capable of
a double signification. Ad tertias is often used to express
how far the liquor is to be boiled away in the medical de-
cotions; yet it may in this case signify either the boiling
to two-thirds, or to one-third part, of the whole. The more
usual sense, however, is to boil away one-third part of the
original liquor; and in the same manner to fill a vessel ad tertias,
does not signify to fill a vessel one-third part full, but two-
thirds, leaving only one empty.

TERTIATE, in Gunery. To tertiate a great gun, is
to examine the thickens of the metal at the muzzle, whereby
to judge of the strength of the piece, and whether it be suf-
ficiently fortified or not.

This is usually done with a pair of caliper compasses.
The term is also applied to any piece of ordnance for find-
ing whether it has its due thickens at the vent, trunnions,
and neck; if the trunnions and neck are in their due order,
and the chafe straight, &c.

TERTII internodii pollicis extensor, in Anatomy. See
EXTENSOR.

TERTIO adiacente, Propositio de. See PROPOSITION.

TERTIVERI, in Geography, a town of Naples, in Cap-
tanzana; 7 miles N.W. of Troja.

TERTIUM SAL, a third salt, a term used in Chemistry
to express a salt resulting from the mixture of an acid and an
alkali, which partakes of the nature of both, as to be itself
neither acid nor alkal, but neutral.

TERTRE, John Baptist du, in Biography, a mission-
ary and writer of history, was born at Calais in 1610:
and having served in the army in early life, he joined the
Dominicans at Paris, and made his profession in 1635, assum-
ing the name of John-Baptist instead of James. About five
years afterwards, he was sent as a missionary to the French
American islands, where he collected materials for the work
which engaged his attention after his return to France in
1658: that was his "Histoire Generale des Antilles habitees
par les Francois," 4 vols. 4to. 1667—71. After having
hilled various polks in the houles of his order, he died at Paris
in 1687. Moret.

TERTUA, in Geography, a town of Hindoostan, in
Bahar; 52 miles E. of Bhabar.

TERTULLIAN, Quintus Septimius Florens Ter-
tullianus, in Biography, generally reckoned the most an-
cient Latin father extant, was born at Carthage, not long
after the middle of the second century. He was the fon of
a proconfular centurion, or military officer under the pro-
confal of Africa, and well acquainted with the Roman laws,
though he does not seem to have practifed the law as a pro-
feffion. He was also intimately converfant with the Greek
and Roman poets, historians, orators, and philosophers,
and other heathen writers of every description. His Dill in
Greek was fo considerable, that he wrote several books in that
language. It has been inferred from his parentage, and from
some expressions in his works, that he was once a Heathen;
but the time and circumstances of his conversion to Chris-
tianity are not known. Cave supposes that he embraced Christi-
anity about the year 185, and was made a prebyster of the
church of Carthage about the year 192. According to Du
Pin, he flourifhed chiefly from about the year 194 to 216.
Tillemont is of opinion that he was born in 160, and that
he died about the year 245, when he was between 80 and 90
years of age, having lived, as St. Jerom fays, to an extreme,
or decrепit, old age. Cave conjectures that he died about
the year 220. It is faid that he was married, probably after
his conversion to Christianity. Having been a member of
the Catholick church for many years, he separated from it
and became a Montaniit, as Cave fays, about the year 199,
but about 205, according to Tillemont. Different accounts
have been given of this change; but the most probable feems
to be, that the fpecious pretences of the Montaniits to greater
mortification in fairs and continence had an influence on his
temper, which was fevere. But whatever might have been
his reafons for adopting the principles of Montaniiti, they
feem to have made fo little alteration in him as an author,
that there are few of his pieces, concerning which it is not
easy to determine, whether they were written by Tertullian
a Montaniit, or Tertullian fills a Catholick. Although, in con-
fquence of this change, his reputation funk in the church,
et it produced no feparation between him and other Chri-
tians, except in point of discipline, which, agreeably to his
temper, he wished to be harsh and rigorous. His doctrine
remained the fame with that of the Catholicks. In process of
time, however, he believed the divine inspiration of Mon-
tanus and his two prophetfes, Priscilla and Maximilla, and
that they were thus enabled to make further discoveries than
had
had before been made, for the greater perfection of Christians. He approved of the longer, more strict, and more frequent fasts of the Montanists; he condemned all second marriages; and denied that the church was authorized to receive again into communion any who were chargeable with fornication, adultery, or any such offences, after baptism. He often arrogantly calls his own people spirituall, and the Catholics, as contemptuously, animal or carnal. We have already observed that his knowledge was extensive; his fancy also was lively; and though his temper was severe, and his mode of expression vehement and positive, yet his writings frequently manifest unaffected humility and modesty. The character given of his style by Lactantius must be universally allowed; that it is "ruined and unpolished, and very obscure;" and yet, as Cave observes, "it is lofty and masculine, and carries a kind of majestic eloquence along with it, that gives a pleasant reli
to the judicious and inquisitive reader." His books still exist, though many are lost, are numerous, some of which were written before and others after he embraced the errors of Montanism. Of these, the Apology is reckoned his principal work; and has been highly commended both by ancient and modern writers; whilst his other performances are written with wit and force, and are edifying and instructive. The time when his "Apology" was written has been differently stated by various authors: some refer it to the year 200, others to 203 and 205; but Mosheim, after laborious examination, concludes that it was composed in the year 198. All allow that it was written before he joined the Montanists. Learned men generally agree, that it was not addressed to the senate of Rome, but to the governors of provinces, or perhaps to the proconsul of Africa, and the chief magistrates residing at Carthage, where it was written, according to Lardner; though others are of opinion that it was written at Rome. From this Apology, it appears that Christians underwent a variety of grievous sufferings; they were, as he says, "cruci"ed, hung upon stakes, burnt alive, thrown to wild beasts, condemned to the mines, and banished into de
ter islands." That this was the case, appears also from Tur
tullian's book to the proconsul Scapula, not written before the year 211 or 212. The "Apology" is written for the purpose of proving the injustice of the persecutions inflicted upon Christians, and the falsehood of the charges brought against them; and likewise to display the excellence of the Christian religion, and the folly and absurdity of that of the Heathens. His two books "Ad Nations" are connected with his Apology, and indicate his characteristic vehemence. His address to Scapula, already mentioned, was written under the emperor Caracalla, and contains an avowal of admir
able principles. "It ought," he says, "to be left to the free choice of men, to embrace that religion which seems to them most agreeable to truth. No one is injured or benefitted by another man's religion; it is not an act of religion to force religion, which ought to be adopted spontaneously, not by compulsion." He proceeds to vindicate the conduct of Christians, and to shew that their religious principles induced them to pay entire obedience to the emperors, and that therefore they did not deserve to incur the penalties of trea
ton. Another work of Tertullian has been often cited, viz. "De Praescriptionibus adversus Haecatom." In this work he treats of hereby in general, and then discourses particular herebys in his five books against Marcion, in others against Praxedis, in defence of the Trinity, and against Hermogenes, and the Valentinians. In his book "On the Soul," he inquires into the nature of the soul and its properties. In his treatise "On Baptism," he ably maintains that the moral stain of the soul is effaced by the external washing of the body, and that punishment is likewise remitted; a doctrine which some late divines have zealously supported. Baptism, by heretics he considers as no baptism, and contends that it ought to be repeated. In cases of necessity, he thinks infant
baptism to be allowable, but he recommends deferring rather than halting the administration of this sacrament. His book "On Penance" refutes the opinion advanced by the Montanists, that sins committed after baptism cannot be ab
solved by the church. In his treatise "On Idolatry," he extends this crime to practices that are almost unavoidable in society; such as bearing arms for the defence of the empire, adorning houses in honour of the prince, and using customary expresions that have any reference to Heathen mythology. In his work "De Corona Militis," he applauds a Christian officer who refused to place a crown or garland on his head. In another work he considers "flight in time of persecution" as prohibited, and also giving money to escape it. In his treatise "De Spectaculis," he diffuses Christians from attending public shows. In his moral tracts an exhortation to "patience" in which, as well as in a discourse addressed to martyrs or confessors, he dwells in an eloquent strain on the motives which should bind a Christian to the practice of that virtue. After his union with the Montanists, Tertullian wrote four books in opposition to the discipline of the Ca
tonies to all the books of the New Testament, commonly received by Christians at this time, except the Epistle of James, the 2d of Peter, the 2d and 3d of John, The Epistle to the Hebrews he ascribes to Barnabas. This ancient father has been much admired: Cyprian calls him "my master." Some persons, however, have doubted whether he has done more good or harm in the Christian church. His character is judiciously appreciated by one of his biographers (Gen. Biog.) in the following manner. Tertullian "was certainly a man of lively parts and large acquirements, of copious invention, and warm feelings. In his reasonings, however, he displayed more fancy and futility than sound judgment; and the ardour of his temper inclined him to violence and exaggeration, while a propensity to superstitition renders him weak and credulous and gullibly alert." His works have been frequently printed both separately and collectively. Of his whole works, the editions of Rigaltius, fol. Paris, 1641, and of Semler, Hist. Mag. 6 vols. 1770–76, are most esteemed. Dupin. Lardner. Mohrm.
hence, as the as contained twelve ounces, the tertius contained three, whence the name, which is formed of the Latin ter unus.

Tertius was also used for the quarter of the denarius, so that when the denarius was at ten asses, the tertius was worth two and a half; and when the denarius was riven to sixteen, the tertius was worth four. See Denarius.

TERVOLA, in Geography, a town of Sweden, in the Lamark of Kemi; 116 miles N. of Kemi.

TERWALDE, a town of Holland, in the department of Guelderland; 12 miles S. of Hattem.

TERZA, a town of Naples, in the province of Otranto; 15 miles S.E. of Matera.

Terza, Ital. the 3d in Music. The terza maggiore, or major 3d, is four semitones, or half notes, above the base; the terza minore, or minor 3d, is three. See Concordes and Intervals.

Tartini has added the above, and even given us a 3d found to discords.

"The same thing will happen if the same intervals are founded by two players on the violin, distant from one another about twenty-nine or thirty feet; always using a strong bow, and holding out the notes. The auditor will hear the third found much better, if placed in the middle between them, than if nearer to one than the other. Two hautbois produce the same effect placed at a much greater distance, and even when the earner is not in the middle, and still more if he is." Tartini has been unfairly treated by d'Alembert, M. Serre, and other French writers, who not only dispute his system built on the terza fuono, his own discovery, but give the discovery itself to another.

D'Alembert accuses him of writing in a manner so obscure, that it is impossible to form any judgment of his intentions; yet he is obliged to own that the subject itself is obscure, metaphysical, and uncertain. As to the obscurity in the phenomenon itself, we deny it; the third found, produced by two other sounds, we have always found, from innumerable experiments with two voices, two instruments, two founds on one instrument, as double flaps on a violin, violoncello, and on an organ, that the third found thus produced in the medium was the true fundamental base, such as Tartini himself has expressed by musical notes.

D'Alembert and all the French writers on the subject, have flated the cause (except Rouffeau) in a difingenious manner. Even when disputing Rameau's principles, they wish to keep him above Tartini and all foreign claims to original discovery or improvement in music. Rouffeau is envied for being the first to abufe the old French music, even by those who thought and allowed it to be had in their other writings. See the Abbé Arnaud and M. Suard's critique upon his Dictionnaire de la Musique, with those of the Abbé Rouffer, M. Laborde, &c. &c.

Terzo, in Geography, a town of France, in the department of the Tanaro; 2 miles S.W. of Acqui.

TERZOLA, in Botany, a name by which some authors have called the eupatorium cannabinum, or water hemp-agarimony.

TERZOWITZ, in Geography, a town of Bohemia, in the circle of Rakonitz; 7 miles S.S.E. of Rakonitz.

TERZETTO, in the Italian Music, a little tune or air in three parts. See Trio.

TERZINI, Ital. impelis, in the language of practical musicians, triplets, or three notes in the time of two.

TERZO Sesto, Ital. the third found, discovered by Tartini to be produced in the medium by two founds that can be sustained, and which third found is the true fundamental base. Upon this harmonic phenomenon Tartini has founded his system; and Mr. Stillingsfleet, in his "Principles and Power of Harmony," describes the terzo fuono in the following manner.

"Two founds being given on any musical instrument, which will admit of being held out for any time, and of being strengthened at pleasure, as in the trumpet, the German horn, the violin, hautbois, &c. a third found will be heard. On the violin, let the notes C E, C E, B E, B flat, G, be founded with a strong bow, the third found will be heard in the following manner.
of the Lacian Juno and the town of Locri, according to Diodorus Sculus.

TESE, in Geography. See TEST.

TESEGNDELT, a town of Morocco, situated on a sharp rock; supposed to be impregnable; 80 miles W.N.W. of Morocco.

TESEN, a town of Afasti Turkey, in Natolia; 34 miles S.E. of Dignizulu.

TESEREN, a town of Africa, in the country of Tafilat; 50 miles N.N.W. of Tafilat.

TESHO-LOOMBOO, or Lubron, the residence of the Teshoo Lama, and the capital of that part of Thibet immediately subject to his authority, is situated in N. lat. 29° 4' 29". E. long. 89° 7'. It is a large monastery, consisting of three or four hundred houses, the habitations of the Gyongs, or priests, besides temples, mausoleums, and the palace of the sovereign pontiff; in which is comprised also the residence of the, regent, and of all the subordinate officers, both ecclesiastical and civil, belonging to the court. It is included within the hollow form of a high rock, and has a southern aspect. Its buildings are all of stone, none less than two stories high, flat-roofed, and crowned with a parapet rising considerably above the roof, composed of heath and brufh-wood, interspersed between frames of timber, which form a ledge below, and are fashioned above into a cornice, capped with masonry. The building is flanked of a deep garnet-colour; a custom universally adopted in these regions, for distinguishing places of religious establishment, and which, when contrasted with the white walls, produces, in the appearance of their town, a very pleasing effect. All the houses have windows, the centre, or principal one, projecting beyond the walls, and forming a balcony: they are closed with black mohair curtains instead of shutters. The principal apartment in the upper story has an opening over it, covered with a moveable shed, which serves the purpose of sometimes admitting light and air, and in the winter season, occasionally, the grateful warmth of the sun. The tops of the walls are adorned with cylindrical monuments: some of which are plain, covered with black cloth, crossed by a white fillet; while others are made of copper, burnished with gold: as the palace and mausoleums are thus adorned with profusion, the view of the monastery, on approaching it from the plain, is brilliant and splendid. The plain of Teshoo-Loomboo, which is perfectly level, is encompassed by rocky hills: its length is about fifteen miles, and its southern extremity, from E. to W., is five or six miles broad. The rock, upon the southern face of which the monastery is situated, nearly occupies the whole width of the valley, and approaches so near to the hills, as to form a narrow defile, leaving room only for a road, and the bed of the river Painom-tchieu, which runs through it, and at a small distance joins the Burhampooter. A fortress commands the pafs. The rock of Teshoo-Loombo is the loveliest of all that are in its vicinity; and the monastery near its base is thus guarded from the violence of the N.W. winds. From the summit of this rock the eye commands a very extensive prospect, and the most interesting object in view is the celebrated river Burhampooter, called in the language of Thibet Erechoombo. Here it receives the tributary waters of the Painom-tchieu. Turner's Tibet.

TESI TRAMONTINI, VITTORIA, in Biography, one of the most renowned female singers that Italy has produced. She was born at Florence in 1690; began her vocal studies under the maestro di cappella Francesco Redi; then went to Bologna, and became a pupil of Campoggi; and received her last polish from Bernacchi. But she was no less admired for the dignity, grace, and propriety of her action, than her vocal powers.

Quantz, who heard her at Dresden in 1719, in the famous opera that was performed on occasion of the nuptials of the prince royal of Poland, sung with Senofino, the Berelli, wife of Lotti, Durefante, and the Faubel, characterizes her in the following matterly manner.

"Vittoria Tesi had by nature a masculine, strong, contralto voice. In 1719 she generally sung, at Dresden all' osteo, such airs as are made for bass voices; but afterwards, besides the majestical and serious style, she had occasionally something coquettish in her manner, which was very pleasing. The compass of her voice was so extraordinary, that neither to sing high nor low gave her trouble. She was not remarkable for her performance of rapid and difficult passages; but she seemed born to captivating every spectator by her action, principally in male parts, which she performed in a most natural and intelligent manner." Life of Quantz, written by himself.

She sung at Naples in 1725, and at Vienna in 1748, where she remained till the time of her decease, in 1775, at 85 years of age.

She was the mistress of the Teuberm and the De Amics, both as justly famed for their acting as singing.

We were told at Vienna in 1772, that she had long quitted the stage, though the remembrance of her talents was so deeply impressed in the minds of many excellent judges, that whenever she was mentioned, it was to the disadvantage of all subsequent female singers. She had been very sprightly in her day, and yet was in high favour with the empress-queen in her latter years. Her story is somewhat singular. She was connected with a certain count, a man of great quality and distinction, whose fondness increased by possession to such a degree as to determine him to marry her; a much more uncommon resolution in a person of high birth on the continent, than in England. She tried to dissuade him: enumerated all the bad consequences of such an alliance; but he would listen to no reasoning, nor take any denial. Finding all remonstrances vain, she left him one morning, went into a neighbouring street, and addressing herself to a poor labouring man, a journeyman baker, said she would give him fifty ducats if he would marry her; not with a view to their cohabiting together, but to serve a present purpose. The poor man readily consented to become her nominal husband; accordingly they were formally married; and when the count renewed his solicitations, she told him it was now utterly impossible to grant his request, for she was already the wife of another; a sacrifice she made to his fame and family.

Since that time she had lived many years with a man of great rank at Vienna, of nearly her own age; probably in a very chaste and innocent manner.

TESIA, in Geography, a town of New Mexico, in the province of Mayo; 45 miles E.S.E. of Santa Cruz.

TESIN, a town of Syria, celebrated for its olive oil; 18 miles N.E. of Antioch.

TESINO, a department of Italy, formed of the Paves. It contains 156,471 inhabitants, who elect twelve deputies. Pavia is the capital.—Alfo, a river of Italy, which rises in mount St. Gotard, and passing through lake Maggiora, empties itself into the Po, at Pavia. 

TESIO, or Tjel, a town of the county of Tyrol; 24 miles N.E. of Trent.

TESKELA, a town of Finland; 70 miles E. of Bierneberg.

TESKOWA, a town of Poland, in Volhynia; 40 miles E. of Luckow.
TESORO, a small island in the Spanish Main, near the coast of South America. N. lat. 10° 8'. W. long. 75° 45'.

TESPIS, in Ancient Geography, a town of Asia, in the interior of Carmania, and near Carmania. Ptol. 

TESSALACH, a town of Algiers; 20 miles S. of Oran.

TASSALON. See Thessalon.

TASSARACONTA, TESSARACONTA, among the Athenians, were forty men who went their circuits round the several boroughs, and had cognizance of all controversies about money, if not above ten drachms; as also of actions of assault and battery. Potter, Archzol. Grec. 

TASSARACONTERIS, in the Naval Architecture of the Ancients, a word used to express a fort of galleys, in which there were no less than forty tiers of rowers one above another. See Enneris and Polykrot. 

TASSARACosta, in our Ancient Writers. See Quadragesima.

TASSARACOSTON, TESSARACOSTON, in Antiquity, a solemnity kept by women on the forty day after child-birth, when they went to the temple, and paid some grateful acknowledgments for their safe delivery. Pott. Archzol. Grec. tom. i. p. 432, and tom ii. p. 335.

TASSARINI, Carlo, in Biography, first violin, and leader of the band in the metropolitan church at Urbino, was born at Rimini in 1690; he was a spirited performer on his instrument, and a very voluminous composer. His style was light and flimsy, compared with that of Corelli and Geminiani; but his concertos not being very difficult, were much played in country concerts in our own memory, with those of Albieri, Albimoni, and Vivaldi.

Tassarini’s first publication at Amsterdam has a title-page of great promise; but whether the promise was ever performed, sceptics in these incredulous days will be much inclined to doubt. The title is in French, but literally translated, is the following: “A new Method for learning theoretically, in a Month’s Time, to play on the Violin, divided into three Chasses, with progressive Lessons for two Violins.” Then twelve violin concertos; twelve flute solos; the matter and scholars; divertimenti for two violins; twelve violin solos; six divertimenti for two violins, in canon, &c. &c. He lived till the year 1762, in the perpetual labour of publication; but his productions would now be as difficult to find as those of Timotheus and Olympus.

TESSE, in Geography, a town of France, in the department of the Sart; 15 miles S.W. of Le Mans.

TESSELÆ, a word used in Pharmacy, to express lozenges cut into regular figures.

TESSELARII, among the Romans, artificers of chased or mosaic work.

TESSELATED PAVEMENT, pavimentum tessellatum, a rich pavement of mosaic work, made of curious small square marbles, bricks, or tiles, called tessellae, from the form of dies.

Tessellated pavements were much used in the tents of the Roman generals.

TESSERA, in Roman Antiquity, denoted in its primary sense a cube or dye; so called from the Greek word TESSARA, or TESSA, four; respect being had to its number of sides, distinct from the two horizontal planes, above and below. And it was thus distinguished from the talus, which, being round at each end, contained only four planes or faces on which it could stand: and therefore, when thrown, had no more than two side faces in view. Hence ludere talis et ludere tesserae are spoken of by Roman writers as two different games. The syllable tes occurs often in Roman inscriptions.

The word tesserae was applied to many other things, not so much from a similarity in the figure, as from the relation they bore to some other thing of which they were the sign or token; as the points on the upper plane of the dye denoted the good or ill success of the cast.

The tessera hospitialis was either public or private. As to the former, we find among the inscriptions published by Gruter, instances of two municipal towns which put themselves under the patronage of the Roman governor; and the reciprocal engagements between them, engraven on two copper-plates in the form of an oblong square, with a pediment at the top, is called in both tessera hospitialis.

The design of the latter was to cultivate or maintain a lasting friendship between private persons and their families; and gave a mutual claim to the contracting parties, and their descendants, of a reception and kind treatment at each other’s houses, as occasion offered. For which end these tesserae were issued, as being to preserve the memory of that transactiion to posterity. And one method of doing this was by dividing one of them lengthwise into two equal parts, upon each of which one of the parties wrote his name, and interchanged it with the other. From this custom came the prevailing expression tesserae hospitales confinges, applied to persons who violated their engagements.

The tessera frumentariae were small tassles given by the emperors to the populace of Rome, entitled them to the reception of a quantity of corn from the public at flated feasons. The perfon who had the inspection of these was called tesseraurus. They were made of wood and of stone.

There was another kind of tesserae which intitled perfons to a fight of the public games and other diversions, usuallly made in the form of an oblong square.

The tesserae militaris was a signal given by the general, or chief commander of an army, as a direction to the soldiers for executing any duty or service required of them.

This, upon urgent occasions, was only vocal; but, in ordinary cafes, it was written on a tablet, commonly made of wood. Befide the civil and military tesserae, there are others which related to religious affairs, and may be called facers. Phil. Trans. vol. xiv. art. 12.

TESSERMIUT, in Geography, an island near the S.W. coast of Earl Greeneland. N. lat. 59° 59’. W. long. 44° 22’.

TESET, a town and district of Africa, in the country of Sahara; 170 miles S. of Morocco. N. lat. 15° 24’. W. long. 7°.

TESSIN, Charles Gustavus, in Biography, a Swiss count and considerable statesman, was born at Stockholm in 1695, and received the rudiments of his education under his father. In 1714 he set out on his travels, and continued them through various countries of Europe for five years, availing himself of every opportunity that occurred of acquainting himself with their respective constitution and laws. At the age of twenty-five he was deputed to the courts of Great Britain, Denmark, and France, and also to the States of Holland, to announce the accession of Frederic I. to the Swedh throne; and in 1725 he was sent to Vienna, to solicit the attention of that court to the new treaty of alliance between Sweden and Ruffia. On the death of his father, in 1728, he succeeded him as principal intendant of the court, and in order to qualify himself for the office, he undertook a new tour at his own expense. In 1735 he was again dispatched
to the court of Vienna, where he remained two years. He was chosen by the nobility speaker at the famous diet of 1738, on which occasion he obtained, in recompense of his conduct, a gold medal, bearing on one side his crest, and on the other the motto "Conficius Reici." He was appointed in 1739 to conduct an embassy from this diet to France, and resided at Paris till the year 1742, concluding during this interval an advantageous treaty of commerce with the king of the Two Sicilies, and terminating a subsidary treaty of alliance with France, by which Sweden was to receive in the course of three years 27 tons of gold. In 1743 he was sent to Denmark, and in the following year to Berlin, on business of great importance. At Berlin he was honoured with the Prussian order of the Black Eagle. He occupied several other stations of dignity and trust, the duties of which he discharged with singular wisdom and fidelity. But the most important office assigned him, was that of preceptor to the crown prince, Gustavus III., to which he was appointed in 1747. On this occasion he wrote his "Letters addressed to a Young Prince," for the use of his royal pupil, which were afterwards translated into most of the languages of Europe. Retiring from public business in 1761, he lived on his estate till the time of his death, which happened in January 1770. Count Teflin was a zealous patriot and enlightened citizen, and a distinguished patron of letters. With a view of encouraging the arts and sciences, he made a great collection of books, pictures, drawings, coins, and other curiosities. But notwithstanding his various excellent qualities, his enemies were affiduous in fruitless attempts to throw a shade over his character, as may be seen in a work entitled, "An Historical Account of the State of Sweden under Frederic I." Gen. Biog.

Tessin, in Geography, a town of the duchy of Mecklenburg; 18 miles S.E. of Rostock.

Tessiursak, an island near the W. coast of West Greenland. N. lat. 61° 10'. W. long. 47° 30'.

Tessoua, a considerable town of Africa, in the country of Fezzan; 100 miles E.S.E. of Mourzouk. Near this town, a river, now overwhelmed by the moving sands, but formerly a deep and rapid stream, had its course.

Tessouelle, a town of France, in the department of the Mayne and Loire; 5 miles S. of Cholet.

Tessua, a town of Hindoostan, in Rohilcund; 18 miles S.S.E. of Bereilly.

Tessue, a town of Persia, in the province of Abibdizan; 50 miles W. of Tauris.

Tessuntee, a town of the state of Georgia; 80 miles W. of Tugeloo.

Tessut. See Teceut.

Tessy, a town of France, in the department of the Channel; 9 miles S. of St. I.o.

Test, in Metullurgy, is a vessel of the nature of a coppe1, used for large quantities of metals at once, and formed of the same materials.

The coppers, or small vessels, serve for operations of this kind, when small quantities only are concerned; but when larger are worked on, vessels of a larger size and coarser texture are employed, which are distinguished by the name of teffs.

These are usually a foot and half broad, and are made of woodashes, not prepared with so much care as for coppers-making, and mixed with finely powdered brick-dust; these are made into the proper shape, either by means of a shallow vessel, made of crucible earth, or cast-iron, of proper dimensions, or only an iron ring, or hoop, with three bars arched downwards across the bottom, about two inches deep, and of different widths, from three or four inches to fifteen or more, according to the quantity of metal to be teffed at once.

To make them in the first manner, an earthen vessel is to be procured, not glazed within, and by its depth and breadth proportioned to the quantity of metal to be worked; the inside of this vessel is to be well moistened with fair water, that the ashes to be put into it may adhere the better. Put into this vessel, thus prepared, the ashes and brick-dust before-mentioned, and first moistened either with water alone, or with water with a little white of an egg mixed in it; let the quantity of this be so much as will half fill the vessel, then press the mass with a wooden indented pestle, or, if not for a very large tell, with a wooden cylinder, only of an inch thick: when thus preied down add fresh ashes, and press them a second time, as in the making of coppers, and repeat this addition of fresh ashes till the earthen vessel be nearly full; then remove the superfluous ashes with an iron ruler, and let the inequalities remaining at the border be smoothed with a wooden or glass ball rolled round about. This done, you are to cut the cavity with a bowed iron, that you may have a broad spherical segment, not very deep; and lastly, by means of a fieve, fieve this cavity carefully and regularly over with dry ashes of bones of animals, ground extremely fine, and squeeze the hard in, by the rotation of the wooden or glass ball. Thus you have a tell finished, which, together with its earthen pot, must be fett in a dry warm place.

To make the teffs in the other manner, or by means of an iron ring; let a ring of that metal be filled with ashes mixed with brick-dust, and moistened as before-mentioned, in such manner that they may rise considerably above the ring; then press them strongly either with your hands, or with an indented pestle, and afterwards, with gentle blows of a rammer, press the ashes from the circumference toward the centre, in a spiral line, and that in such manner, that, after having been sufficiently preied, they may be a small matter higher than the brink of the ring. If there are now any vacancies in the mass, empty the ring, and fill it again with more ashes; for if you should attempt to fill up these by adding, were it but ever so little, ashes, the second, or additional quantities, will never cohere so firmly with the first, but that they may probably separate in the operation. This done, turn the ring upside down, and on the other side, or bottom, take out the ashes to the quantity of one-third part of the depth of the ring, and again fill the vacancy with the same ashes, in such a manner that there may remain no sensible cavity.

When the mass is thus prepared, cut out a cavity in the larger surface of the ring, with a bowred iron, as in the former method.

The Germans have, beside these, another kind of teffs, which they call treibfherben. These are a sort of vessels which refill the most violent fire, and are so extremely compact, that they sometimes will retain not only melted metals, but even the glafs of lead itself.

The figure and size of these teffs may be the same with that of the coppers, but they are usually made larger; and the great difference of these teffs from coppers, and from the ordinary teffs, which are only a kind of large and coarser coppers, is, that the matter of these is more compact and coherent.

The matter for making these teffs is thus prepared; take of the pureft and finest clay a sufficient quantity, make it into balls, and dry them either in the air, or on the fire; when dried, beat them to powder in a mortar, and pour on the powder a great quantity of warm water; let this mixture rest a while, and when the clay has subsided, pour off
the water which swims at top; and let this washing be so often repeated, that all the most minute Lumps of the clay be broken, and whatever salt it contains perfectly washed out; then add to this fine clay, of the purest kind, of powder of calcined flints, ground, and well washed, of faulty but clean Hellenic crucibles, or of any incombustible flones ground very fine, such a quantity as will render the mass thick, and hardly adhering to the hands in kneading it, or pliant when rolled into a thin lamina.

This is the matter for making this sort of tefts; but, before any quantity of the vessels be made of this earth, it will be prudent first to finish a single one, and try it, by putting on it a quantity of glasses of lead, and exposing it for an hour or more to the strongest fire; by this trial you will be certain whether or not the mass is capable of making vessels that will resist both the fire and the glasses of lead; and by no other means but this trial is it possible to determine the due proportion of the mixture of the ingredients for this use, on account of the variety of the clays. Nature in some places affords a clay so well tempered, that it is extremely proper for the making of tefts without any preparation, or without the admixture of any other matter. Sometimes this only requires a simple washing, but commonly it is necessary to make it into balls, and powder or wash them as before directed.

On the trial of a teft made of this, or the former mixed clay, if it runs into glasses, you must add to it of the powder of flones, especially such as will resist the fire. Great care is to be taken not to add too much powdered chalk to these compositions, since if the matter is tempered with that alone, the tefts will indeed resist the fire very well, but being too porous, they will yield a passage to lardisse, which will soften them to such a degree, that they will either fall upon themselves, or be totally crumpled when taken hold of with the tongs.

The vessels are to be made in the following manner: rub over the sides and bottom of a small mortar, and also its pelfe, with oil, or with the fat of bacon; fill it two-thirds full of prepared clay, then make a flight impression with your fingers in the middle of the clay; then place the bottom of the pefle there, and force it down with blows of a hammer, the stronger the better. When thus properly hollowed, take it out of the mortard, and pare its edges, and dry it, as the coppers are dried, in the air, in a dry warm place.

Tefts thus prepared may be used as soon as dry, unless for faits or lardisse; but these bodies, when melted in vessels not first baked or hardened in the fire, always make their way through them.

Some of the German writers also recommend, both for tefts and coppels, a foot of friable opaque flone, called white flath, which appears to be a species of gypsum, or of the flones from which puffer of Paris is prepared. The pather is directied to be calcined with a gentle fire, in a covered vessel, till the flight crackles, which happens at first, has ceased, and the flone has fallen in part into powder; the whole is then reduced into subtile powder, which is passed through a fine sieve, and moistened with so much of a weak solution of green vitriol, as is sufficient for making it hold together. Gellert, however, finds, that if the flone is of the proper kind, which can be known only by trials, calcination is not necessary. These tefts are liable to soften or fall under in the fire, which inconvenience may be remedied, according to Schaffer, by mixing with the uncalcined flones somewhat less than equal its weight, as eight-ninths of such as had been already used and penetrated by the oearia of the lead, taking that part of the old teft which appears of a green-grey colour, and rejecting the red crust on the top. But from his account it appears, that these tefts are less durable than those made of the ashes of bones, though much superior to those of wood-flones. Vegetable ashes, which stand very well the testing of silver, can scarcely bear any great quantity of gold, which requires a considerably stronger fire than the other; but bone-ashes, says Dr. Lewis, answer to effectually, and are among us so easily procured, that it is unnecessary for the refiner to search for any other materials. Cranmer's Art of Ablaying, p. 60. Lewis's Com. Ph. Tech. p. 144.

Test-liquor, a term used by our dealers in brandies, &c. for a liquor which they use as a teft of brandy, &c. to prove whether they be genuine, or mixed with home spirit. The people who use this, place great confidence in it, but it is really a very vague and uncertain thing. They pretend that this liquor will flow, by the colour which it makes on its being poured into brandy, whether it be genuine or adulterated; or if not genuine, in what proportion the adulterating spirit is mixed with it.

The whole fact is this: if a little common green or white vitriol be dissolved in some fair water, it makes a teft-liquor, a few drops of which being let fall into a glass of old French brandy, will turn the whole to a purple or fine violet-colour; and by the strength or paleness of this colour, the dealers judge the brandy to be genuine or mixed in different proportions, with home spirits.

Old French brandy, having long lain in the cask, takes a dilute tincture of the wood of the cask, that is, of oak; and this being of the same nature with a solution or tincture of galls, naturally turns blueish or blackish with vitriol. A new distilled brandy, though wholly foreign, would not give this teft; and a common malt spirit, with oak chips infuded in it, will turn as dark as the finest brandy. While our distillers, indeed, had nothing in use for the colouring of their spirits but burnt sugar, it was possible to make some gues at an adulteration with them, because the brandy, in this case, would not become blackish in proportion to its former colour; the sugar colour not turning to ink with the vitriol, like the other: but our distillers have since found a way of using an extract of oak for the colouring of their spirits, and since that, this teft-liquor is of very little use, our common spirits, of any kind, turning as deep with it as the foreign brandies.

The very best way of making this teft-liquor, is with a calcined vitriol of iron, dissolved in a dilute or aqueous mineral acid. The liquor, when well made in this manner, is of a fine yellow colour, and will give, for a time, the finest blue to any spirituous tincture of oak.

The English were, at one time, very fond of high-coloured brandies, and it was then that the use of this teft-liquor was most esteemed; afterwards we, as well as other nations, finding that this colour was only owing to the cask, began to dislike, and to favour the pale brandies: at length we fell into the use of such as were wholly limpid and colourles, and the re-distilling of all the old brandies of which people were poifessed, took place; on this the teft-liquor was found to be of no use at all, and accordingly rejected; but as we are of late again come into the efeem of coloured brandies, and that with great justice, as the colour, when genuine, is a certain mark of the age of the liquor, this teft-liquor is again got into more credit than it deserves.

The famous Helvetian apothecary depended wholly on this accident for its colour; and it was no small mortification to our chemists, when, some years ago, it was introduced into use among us, that they could not make it with our own spirits, but must be at the expence of true French brandy.
brandy for it; our own spirits, though equally coloured, would never make that violet tincture, because their colour was owing to burnt sugar, not a tincture of oak. At length this mystery was explained, and a little scraping of galls made all those quantities of this flyptic, which had been set by as good for nothing, perfectly fine and well-coloured. Shaw's Essay on Distillery.

**Test-Act.**

In *Law,* is the statute 25 Car. II. cap. 2 (1673) which directs all officers, civil and military, to take the oaths, and make the declaration against transubstantiation, in the court of king's bench or chancery, the next term, or at the next quarter sessions, or (by subsequent statutes) within six months after their admission; and also within the same time to receive the sacrament of the Lord's supper, according to the usage of the church of England, in some public church, immediately after divine service or sermon, and to deliver into court a certificate thereof, signed by the minister and churchwarden, and also to prove the same by two credible witnesses, upon forfeiture of 500l. and disability to hold the same office. Besides this penalty, if, without taking the sacramental qualification within the time prescribed by the act, a person continues to occupy a civil office, or to hold a military commission, and is lawfully convicted, then he is disabled from thenceforth, for ever, from bringing any action in course of law, from prosecuting any suit in any court of equity, from being guardian of any child, or executor or administrator of any person, as well as from receiving any legacy. For an account of the nature and operation of the *Corporation Act,* we refer to that article.

The word *test* signifies *proof or trial,* being formed of *leif,* *witnes;* this act being established with a view to exclude Roman Catholics from any share in the government, though it has operated to the exclusion of Protestant dissenters in general. The *Corporation Act,* enacted in the year 1661, the 13th of Charles II., was principally, but not wholly, designed against Protestant non-conformists. It was passed in a period of great heat and violence, the year after the Restoration; and it paved the way for the act of uniformity, which soon after passed. The king, with his ministers, and the majority in both houses, hated the Presbyterians, whom they considered, whether justly or not, as the authors of the late rebellion. Great power still remained in their hands, for, during the Protectorate, they had been appointed magistrates in all the country towns. To leave authority in such hands seemed dangerous; it was therefore judged expedient to regulate the corporations, and to expel those magistrates, whose principles were inimical to the constitution, civil and ecclesiastical. This gave rise to the Corporation act. The sacramental clause, however, in the Corporation act was intended against the Catholics; for, as the other provisions of the statute, by dispossessing the enemies of the court, had established the influence of the crown in all the corporations of the kingdom, the parliament was apprehensive that in the next reign, under a Catholic king, all corporate offices would be filled with Catholics. Besides, before the passing of the act of uniformity, those that were afterwards called dissenters, were within the inclosure of the church, and consequently participated in her sacraments, so that the sacramental clause must therefore have been intended as a guard against the Catholics, to whom it effectually applied, and not as a guard against those who were afterwards called dissenters, on whom, at that period, it could not operate.

It must also be allowed, that the original design of the test was not so much to exclude the Protestant dissenters, as the papists, as the Catholics were then called. It was brought in by the patriots, in the reign of Charles II., under their apprehension of popery, and a papist successor; and when, during the debate in the house of commons, it was observed, that it was drawn in such a manner as to comprehend the Protestant dissenters, the court greatly endeavoured to avail themselves of that circumstance in order to defeat the bill. But the dissenting members disappointed them, by declaring, that they had rather confide in the justice and generosity of parliament, to pass some future bill in their favour, than be the occasion of retarding or defeating the security, which the present bill was calculated to afford to the liberties of their country. Their patriotism produced, soon afterwards, a bill for their relief from the penal laws; but the parliament was prorogued, through the refinement of the court, to prevent its passing: and when, notwithstanding this, a bill in favour of the dissenters did afterwards pass both houses, viz. in the year 1680, and lay ready for the royal assent, the court ventured upon a very extraordinary expedient; the clerk of the crown was ordered to convey away the bill, and, accordingly, it was never afterwards to be found. The particular test of refusing the sacrament according to the rites of the church of England, was calculated to exclude the papists rather than the Protestant dissenters; as it was no uncommon thing for the latter, at that time, to receive the sacrament occasionally in the church of England, in order to express their charity towards it, as a part of the church of Christ. If it had been the design of the legislature to exclude all from civil offices but those who have a real affection for the constitution and worship of the church, it is apprehended they would have appointed the test to be, not merely once taking the sacrament at church, but a stated and constant conformity to its religious services.

It has been alleged, however, that though the Test act was designed against the Catholics, yet that few, even then, of the number, merited a treatment so severe. They, it is said by their advocates, had no concern in the views of Charles or his brother, in the schemes of wild ministers, or in the machinations of bad politicians. They had suffered much in the royal cause, and were pinning in penury and distress, under the additional pressure of cruel laws. But whatever might be the reasons, real or pretended, for passing an act, of which Catholics were the principal objects of obloquy, the case is now very much altered, and Catholics have assumed a new character, which entitles them, in the judgment of many, not merely to protection, but to a participation of the privileges of their fellow-subjects.

As the question concerning the repeal of the disqualifying laws which we have already mentioned, has been, and is likely soon again to become a subject of public discussion, and as it is a subject, generally considered, of great importance and interest, it may not be thought improper to state the arguments for and against the repeal of those excluding statutes, comprehending both Protestant dissenters and Catholics, in as concise a manner as possible. The general principles upon which the equitable decision of this question depends, are such as follow:—Every man has an undoubted right to judge for himself in matters of religion; nor should any mark of infamy, or any civil penalty, be attached to the exercise of this right:—Every man has a right to the common privileges of the society in which he lives; and among these common privileges, a capacity of law for serving his sovereign and country is one of the most valuable, distinguishing a legal capacity of service, from a right to an actual appointment, which depends upon the choice of his sovereign, or of his fellow citizens; and this capacity of serving the state is a right of such high estimation, and of such transcendent value, that exclusion from it
is deemed a proper punishment for some of the greatest crimes:—Actions, and not opinions, political or religious, are the proper objects of human authority and cognizance:—No man, who does not forfeit that capacity of serving his sovereign and country, which is his natural right, as well as the honour and emoluments that may happen to be connected with it, by overt-acts, ought to be deprived of them; and disabilities that are not thus incurred are unjust penalties, implying both disgrace and privation:—Punishment, without the previous proof of guilt, cannot be denied to be an injury; and injuries inflicted on account of religion are undoubtedly perfections:—The ends of civil society can never justify any abridgment of natural rights that is not essential to those ends:—The institutions of religion, and the ordinances of civil government, are distinct in their origin and their objects, in the functions that enforce them, and the mode in which they are administered:—The institution of the Lord's supper, being wholly of a religious nature, and appointed merely as a memorial of his death, is improperly applied to the secular ends of civil society; and if it be so applied, it is not only an improper, but in many cases an insufficient, test of the principles and character of those to whom it is administered. Such are some of the leading principles, which have been the subjects of discussion in the debates that have occurred, both among writers and among our legislators, in considering the expediency of repealing the Test laws. The case of the Catholics and of the Protestant dissenters has been repeatedly argued in both houses of parliament, and may probably again become the subject of public discussion. Many (indeed most) of the same arguments apply to both descriptions of persons; but we shall chiefly restrict ourselves to the pleas of the dissenters. They have urged, that being well-affected to his majesty and the established government, and ready to take the oaths required by law, and to give the fullest proof of their loyalty, they think their sincere desire to receive the sacrament after the manner of the church of England, or after the manner of any church, as a qualification for an office, ought not to render them incapable of holding public employments, civil or military; they also allege, that the occasional receiving of the Lord's supper as a qualification for a place, cannot, in the nature of things, imply that those who thus receive it, mean to declare their full and entire approbation of the whole constitution and frame of the established church; some men may be compelled by their necessities, or under the allurement of specious advantages, to do what they would not do, if they were left to their free choice. Others, perhaps, may comply with the sacramental test who are not even Christians, and who therefore cannot be suppos'd to wish well to Christianness itself, or to any national establishment of it whatsoever. Hence they are led to think, that such a test can be no real or effectual security to the church of England. Conceiving that they have a right, as men, to think for themselves in matters of religion, and that this right is preserved and functioned by the Author of Christianity; and that they have a right, as citizens, to a common chance with their fellow-subjects for offices of civil and military trust, if their sovereign or fellow-citizens should think them worthy of confidence; they cannot be of opinion that any of the ends or objects of civil society require that these rights should be superceded, and that they should be excluded from the service of the state. Their advocates plead on their behalf, that the continuance of these acts which invade their rights is so far from being necessary to the well-being of the state, or to the establishment of the national church, that they are actually pernicious both to the state and church, and ought to be repealed. Their utility is shewn by referring to the higher trust of legislative authority, to which the dissenters are admitted without hesitation or reserve, and without submitting to any such test. An excitable fury, it is said, does not sustain a more important office, neither is it necessary that he should make a profession of his Christian faith more than a member of the house of commons or the house of peers. The principles of the dissenters, their attachment to the constitution, and their zeal in support of it, have been sufficiently manifested in a variety of instances, from the Revolution to the present day; and yet can it be alleged, that their exclusion from the service of the public is necessary or beneficial to the state? Can it be said that the continuance of the disabilities to which their profession subjects them, is necessary for the safety or honour of the church? The establishment of a church requires a legal provision for its ministers; but it does not require for its safety an exclusive right to civil and military trusts. The establishment of the church of England conflicts in her titles, her prebendaries, her canons, her archdeacons, her deaneries, and her bishoprics. These constituted her establishment before the Corporation and Test acts had any existence; and they will equally constitute her establishment if these acts should be repealed. In Scotland they have had no such acts; and yet Scotland has an established church. In Ireland these acts have been repealed; and yet the established church of Ireland remains. In Holland, Ruffia, Prussia, Germany, &c. they have no such acts. As to the intimate and beneficial connection between church and state, on which some have grounded the supposed propriety and necessity of these laws, it would be sufficient to refer to the authority of archdeacon Paley, who has stated what ought to be the single end of church establishments. (See Religion.) Upon an appeal to history, it has been argued that the civil government maintained itself in former times, when unconnected with the church; and the disturbances which terminated in the ruin of both church and state, are laid to have originated in the intolerant spirit and arbitrary proceedings of some ecclesiastics, who had themselves exercised powers, and had intimated their unhappy sovereign to actions and claims at least as contrary to, and subverfive of, the true spirit of the constitution, as any of those violence of the times immediately succeeding, which have been so justly reproved. In this connection, we may refer to the speech of an able advocate for the repeal of the disabling statutes: who maintains that no human government has a right to inquire into men's private opinions, to prefix that it knows them, or to act on that presumption. Men should be tried by their actions, not by their opinions. This, if true with respect to political, was more peculiarly so with regard to religious opinions. In the position, said Mr. Fox, that the actions of men, and not their opinions, were the proper objects of legislation, he was supported by the general tenor of the laws of the land. History, however, afforded one glaring exception in the case of the Roman Catholics. The Roman Catholics, or rather the Papists, as they were then properly denominated, had been suppos'd by our ancestors to entertain opinions that might lead to mischief in the state. But it was not their religious opinions that were feared. Their acknowledging a foreign authority paramount to that of the legislature; their acknowledging a title to the crown superior to that conferred by the voice of the people; their political opinions, which they were suppos'd to attach to their religious creed, were dreaded, and justly dreaded, as inimical to the constitution. Laws therefore were enacted to guard against the pernicious tendency of their political, not of their religious, opinions; and the principle thus adopted, if not founded on justice,
was at least followed up with constancy. Their influence in the state was feared, and they were not only restrained from holding offices of power or trust, but rendered incapable of purchasing lands, or acquiring influence of any kind. But if the Roman Catholics of those times were Papists in the strictest sense of the word, and not the Roman Catholics of the present day, still he would say, that the legislature ought not to have acted against them, till they put in practice some of the dangerous doctrines which they were thought to entertain. Difability and punishment ought to have followed, not to have anticipated, offence. Those who attempted to justify the disabilities imposed on the dissenters, must contend, if they argued fairly on their own ground, not that their religious opinions were inimical to the established church, but that their political opinions were inimical to the constitution. If they failed to prove this, to deprive the dissenters of any civil or political advantage, was a manifest injustice; for it was not sufficient to say to any set of men, we apprehend certain dangers from your opinions, we have wisely provided a remedy against them, and you, who feel yourselves aggrieved, calumniated, and proscribed, by this remedy, must prove that our apprehensions are ill-founded. The aures probandi lay on the other side; for whoever demanded that any other person should be laid under a restriction, it was incumbent on him first to prove that the restriction was necessary to his safety, by some overt act, and that the danger he apprehended was not imaginary but real. Was it seriously to be contended, that religion depends upon political opinions; that it can subsist only under this or that form of government? It was an irreverend and impious opinion to maintain, that the church must depend for support, on its being an engine, or ally, of the state, and not on the evidence of its doctrines, to be found by searching the scriptures, and the moral effects it produced on the minds of those whom it was its duty to instruct. See Toleration.

Mr. Pitt agreed with Mr. Fox in admitting, as a general principle, that the religious opinions of any set of men were not to be restrained or limited, unless they be found likely to prove the source of inconvenience to the state; nor ought the civil magistrate, in any other point of view, to interfere with them; but he maintained, that when religious opinions are such as may produce a civil inconvenience, the government has a right to guard against the probability of the civil inconvenience being produced; nor ought they to wait till, by being carried into action, the inconvenience has actually arisen. It was not therefore on the ground that the dissenters would do any thing to affect the civil government of the country, that they had been excluded from civil offices, but that if they had any additional degree of power in their hands, they might. On the other hand, it has been pleaded, that to restrain men's civil rights from the supposed tendency of their opinions, is a very dangerous principle, as it must render their condition precarious and wholly dependent on the prejudices and will of the magistrate, and warranted unlimited restraint, and almost every species of perpetuation.

Mr. Pitt, premising that the establishment of a settled form of church and of its ministers is necessary to the civil government of the country, fuggles the impropriety of distributing the emoluments and offices of the established church among persons who, however respectable their character, might be, were not members of the same communion; but others say, that the emoluments and offices of the established church are not the objects intended for, but those of the state, unless the church and state be absolutely identified. He also says, that these offices may be considered as matter of favour, because it is conform with the government of this country, that all offices should be given at its direction; and here, he says, from the delicate nature of the case, the legislature had thought proper to interpose, and to restrain the Supreme magistrate, the head of the executive authority, and limit him in his appointment to those offices; but surely, as he contends, this differed essentially from any degradation, disgrace, or punishment of the dissenters. Others, however, have considered this kind of reaoning as fallacious, both in its principle, and in the inference deduced from it.

Mr. Fox concurred with lord North, who, though an advocate for the continuance of these disqualifying laws, bore testimony to the principles and character of the dissenters, in his avowal of their steady attachment to government; and he added, that their religious opinions were favourable to civil liberty, and that the true principles of the constitution had been remembered and affirmed by them, at times when they were forgotten, perhaps betrayed, by the church. See Dissenters.

Mr. Fox maintained, that the Teft act was altogether inadequate to the end it had in view. The purport of it was, to protect the established church, by excluding from office every man who did not profess himself well affected to that church. But a professed enemy to the hierarchy might go to the communion table, and afterwards say, that in complying with a form, enjoined by law, he had not changed his opinion, nor, as he conceived, incurred any religious obligation whatever. There were many men, not of the established church, to whose services their country had a claim. Ought any such man to be examined, before he came into office, touching his private opinions? Was it not sufficient that he did his duty as a good citizen? Might he not say, without incurring any disability, "I am not a friend to the church of England, but I am a friend to the constitution, and on religious subjects must be permitted to think and act as I please." Ought their country to be deprived of the benefit she might derive from the talents of such men, and his majesty prevented from dispensing the favours of the crown, except to one description of his subjects? But whom did the tell exclude, the irreligious man, the man of profuse principles, or the man of no principle at all? Quite the contrary; to such men the road to power was open; the tell excluded only the man of tender conscience; the man who thought religion to distinguish him from all temporal affairs, that he held it improper to profess any religious opinion whatever, for the sake of a civil office. Was a tender conscience inconsistent with the character of an honest man? or did a high sense of religion shew that he was unfit to be trusted? Allowing that the established church ought to be protected, it was natural to inquire what was the established church? Was the church of England the established church of Great Britain? Certainly not; it was only the established church of a part of it; for, in Scotland, the kirk was as much established by law as the church was in England. The religion of the kirk was wisely secured, as the established religion of Scotland, by the articles of Union; and it was folly absurd to say, that a member of the kirk of Scotland, accepting an office under government, not for the service of England exclusively, but for the service of the united kingdom, should be obliged to conform, not to the religious establishment of Scotland, in which he had been bred, but to the religious establishment of England.

To the argument urged in favour of the Corporation and Teft acts, founded on the apprehension that if they were repealed, the dissenters might become a majority of the people, Mr. Fox gives a brief reply, viz. that if the majority of the people of England should ever be for the abolition of the established church, then it ought to be abolished. It has been said, that by manifesting indulgence to other sects, a candid
a candid respect for their opinions, and a desire to promote mutual charity and good-will, the established church will be most likely to secure its stability and its honour. Whilist the grievances of persons of a different profession are redressed, and they are admitted to a participation of their civil rights, the church need not fear any combination for fapping its foundation, or for depriving it of its peculiar and distinguishing honours or emoluments. Men who are aggrieved, under a sense of what they conceive to be an indignity and injury, are the most likely to manifest hostility against an ecclesiastical establishment that engrosses all civil and secular advantages to itself.

It has been said, that it would conduct to the honour of the rulers and dignitaries of the church, if they would concur in abolishing laws which perpetuate the perversion and profanation of a religious institution;—an institution which certainly was not intended by its divine founder for the attainment and promotion of any selfish and secular purposes. Here, it is maintained, if any where, a line of separation should be drawn between religious and civil policy; nor should the performance of a Christian duty be made an indubitable qualification for a secular office. The diffenters, says a well-informed member of the legislature (Mr. W. Smith), who, being himself one of them, is thoroughly acquainted with their principles and character, would equally object to receiving the sacrament as a test in their own places of worship, though many of them would not scruple to partake of it with their brethren of the establishment, and according to their form, when considered only in its true light, as a religious duty, and an expression of Christian charity. The writer of this article is acquainted with several conscientious and avowed members of the established church, who lament this abuse of a Christian ordinance, and who wish, for the purity and honour of the church to which they are attached, that the laws imposing this test were repealed. It would likewise contribute to the satisfaction of scrupulous ministers of the established church, to be released from the obligation of administering the sacrament, as a qualification for office abstractedly considered, and more especially to persons of known licentiousness of principles and conduct. By the duties of his function, by the positive precepts of his religion, and by the rubric or canons of the church, the minister is enjoined to warn from the sacred table all blasphemers of God, all flanders of his word, all adulators, and all persons of a profane life; and yet to these very persons, if they demand it as a qualification, he is compelled, by the Test act, to administer the sacrament; and if he refuses, a ruinous prosecution for damages is the obvious and inevitable consequence. On the other hand it has been said, that if the minister’s conviction of profanery of conduct be supported by all the circumstances which constitute legal proof, he may lawfully refuse the sacrament. The truth of this opinion is doubtful; but it is certain, that if he should fail in that proof, his ruin is inevitable; and if he should succeed, it is almost equally certain; for the expenses of his suit will devour his scanty means, and probably confine him to a prison for his life. Allowing that any notorious evil-doer, offering himself to receive the sacrament, might be rejected by the minister, without becoming liable to any punishment, let it be considered what is the situation in which A or B, or the person who upon application to a minister had been refused the sacrament, was placed: from that moment he had incurred the penalties of the act, and was punished in a manner perfectly new, unexamined, and unauthorized by the laws of the land; he was convicted without a trial by jury, and was disabled from enjoying an office which his majesty, in the legal exercise of his prerogative, had thought proper to confer on him; and a person was thereby absolutely put into the hands of the clergy, who were to be the great arbiters of qualification or disqualification for offices, and places of power and emolument. Some have attempted to justify the legal establishment of the profession of a religious institution, by comparing it with those provisions of our law which enjoin the function of an oath; but this argument has been considered as inapplicable to the present case, and altogether unavailing; for though it be indeed true that the legislature, by compelling every petty officer of the revenue, and every collector of a turnpike toll, to swear deeply on his admission into office, has made the crime of perjury more common, at this time, in England, than it ever appears to have been in any other age or country; yet how does the frequent commission of this crime against law, justify the establishment of a religious profession by law? But, without any comment on the folly of pleading for a legislative desecration of religion in one way, by viewing that the legislature has contributed to its desecration in another, let it be asked, what resemblance the sacrament of the Lord’s supper, which is merely a religious institution, bears to the ceremony of an oath, which is an institution so entirely political, that it answers none of the purposes of religion, promotes none of her interests, forms no part of her establishment, and belongs as much to the Jew, the Mahometan, and the idolater, as it does to the Christian. The difference, says Mr. W. Smith, between the sacrament, used as a test for office, and an oath, as a test of truth, is too obvious to escape the most careless observer. An oath was neither primarily, nor at all, an act of worship; nor, though it necessarily supposes a belief in a supreme moral governor, was it ever used as a test of particular religious opinions: the sole object to which it was directed was the attainment of truth, (with respect either to the past or the future,) where other means were insufficient, —an appeal to a Being who, by the supposition, must be acquainted with all the circumstances, and must also be both able and inclined to punish falsehood in such cases, as an infirmt added to a crime, was perfectly well calculated to attain the proposed end, and inapplicable to any other purpose.

If, says Mr. Fox, in concurrence with some previous observations of Mr. Beaufroy, when a man is seen going to take the sacrament, it should be asked, “is this man going to make his peace with God, and to repent him of his sins?” the answer should be, “No; he is only going there, because he has lately received the appointment of first lord of the treasury;” can any circumstance afford a greater proof of the indecency resulting from the practice of so qualifying?

Some have contended, that to grant a remission in favour of Scotland of the Test and Corporation acts, would be a breach of the union; an opinion which supposes, that because, by the articles of union, nothing can be taken from Scotland but what was then stipulated, therefore nothing can be given. Others say, that as the Test and Corporation acts are among the statutes which secure the doctrines, discipline, worship, and government of the established church of England, they are therefore by the act of union declared to be unalterable. In reply to this mode of arguing it has been observed, that the government and discipline, the doctrines and the worship of the English church, were the same before the statutes were enacted, and would continue the same if those statutes were repealed; and consequently do not derive their security from them: whereas the act which relates to the patronage of the church of Scotland, and which did seem to affect its discipline, was held to be no breach of the articles of union; neither was that union understood to be weakened by the subjacent act, which gave a complete toleration in Scotland to episcopal dissenters.

When the articles of union were under the consideration of parliament, a proposal was made in the house of lords, that
that the perpetual continuance of the Telf act; and in the house of commons, that the perpetual continuance of the Corporation act, should be declared a fundamental condition of the intended union; but the motions were both rejected; a proof that the legislation did not mean to give to them the same perpetual existence as to the act of uniformity, and to the statute that was passed in the thirteenth of Elizabeth, both of which were specifically named, as conditions of the compact, and expressly declared irrevocable.

If the Telf and Corporation laws are deemed unalterable parts of the articles of union, it follows, of course, that every alteration in those laws must be deemed a breach of the union, and that every suspension of those laws must be considered as a suspension of the union. Now both these acts are altered, and in part repealed, by subsequent statutes, and for six months in almost every year are wholly suspended. But who will assert that the articles of union are disproved, or that their obligation on the two countries is suspended for six months in every year? or who will deny that the same power which alters a part may alter the whole of those laws? Who will deny that the same authority which suspends a law for six months, may abolish it for ever?

In favour of the continuance of these laws it has been adduced, that they have existed for many years with great advantage; but many attempts have been made to disprove the advantage of them, and they have repeatedly been complained of as both useless and unjust. Besides, this argument for their existence is absurd, as it tends to perpetuate every enormity that can plead the fansion of age. The horror of innovation may be felt or feigned as a bar to every improvement. It may be nevertheless asked, how have these laws subsisted? By repeated suspensions; for the indemnity bills are, with few exceptions, annual acts; and where would be the propriety of suspending them for ever, by an act of perpetual operation. In order to fince complaints of these partial and injurious laws, it has been said that the act of indemnity, annually passed, protects from the penalties of the Telf and Corporation laws all such persons as have offended against them. If it afford such protection, what inconvenience can arise from a repeal of the statutes themselves? Is not the constant and invariable practice of pausing such a bill annually, a tacit acknowledgment that the Telf acts are improper or unnecessary; that the penalties, if incurred, ought not to be enforced; and therefore no man could be blamed for resorting to an indemnity, held out as a protection against punishments inflicted by laws which the legislature itself continually treated with a kind of disrespect, and which were already almost repealed in practice, though they were still preferred in the statute-book by a species of superfluous regard? The only justification for evading a statute, that can be for a moment maintained, is, when that statute notoriously ought not to remain in force; and when to evade it, on account of its nature and tendency, is meritorious. But it has been said, that the Indemnity act does not protect the dissenters from the Telf and Corporation laws; for its only effect is, that of allowing farther time to those trespassers on the law, against whom final judgment has not been awarded. Should, for example, a prosecution have been commenced, but not concluded, the Indemnity act does not discharge the proceedings; it merely suspends them for six months; so that if the party accused does not take the sacrament before the six months allowed by the Indemnity act shall expire, the proceedings will go on, and, long before the next indemnity act will come to his relief, final judgment will be awarded against him. Thus it appears, that the Indemnity act gives no efficacal protection to the dissenters, who accepts a civil office or military command; for he who cannot take the sacrament at all, cannot take it within the time required by that act. After all, indemnity supersedes crimination, and an obnoxiousness to punishment: the office and penalty are created by these statutes: repeal the laws, and indemnity becomes needless. No man would wish, if it were always practicable, to shelter himself under an act of indemnity for omitting to do what, independently of these laws, he ought not to do; or chuse to have it thought that he is left fit and able to serve his king and country than his neighbour, who does not feel the restraint of his conscientious scruples. In corporate towns and many public offices, the obligation to qualify is considered as a kind of dead letter, and an inforner would be very generally thought an odious character.

As to the Corporation act, it is said to have been forced from the legislature as an act of self-defence; and this is the proper description of an act, which, after the lapse of much more than a century, when the grounds and reasons for pausing it no longer existed, ought to be repealed. The question that forms the subject of this article is, in our opinion, intimately connected with the honour of the church and the prosperity of the state, as well as with the general interests of religion and liberty; and with these views of importance, we refer the decision of it to the impartial judgment of the reader.

TESSO, in Geography, a river of England, which rises in the north-west part of Hampshire, borders on Wiltshire, and runs into Southampton Water. Sir Henry Englefield seems inclined to think the original name was Amt.

TESTA, in Antiquity, the fame with ofricaon. See Os-

TRACISM.

TESTA, in Italian Singing. When a performer sings through the nose, the throat, or the teeth, the voice is called voce di tefo, to distinguish it from voce di peto. Tosti says: "let the matter attend with great care to the voice of his scholar, which, whether it be di peto, or di tefo, should always come forth neat and clear, without pausing through the nose, or being cloaked in the throat; which are two of the most horrible defects in a singer, and pass all remedy if once grown into a habit." Galliard's Transl. of Tofi on florid Song.

TESTA, Pietro, in Biography, called Il Lucchesino, from having been born at Lucca. His birth took place in 1611, and he was first instructed in painting by Pietro Paolini; afterwards he studied at Rome, under Domenichino and Pietro da Cortona. The principal objects of his study were antique marbles, and the remains of ancient architecture; in which employment such was his affinitie, that few vestiges of antiquity were known which had escaped his pencil. His extreme poverty made him morose and melancholy; and he made himself many enemies, by the freedom with which he spoke of the productions of other painters. From this state of trouble he was relieved by Sandrart, who found him among the ruins, and compassionating his distress, took him to his house, where he clothed and entertained him, and introduced him to the prince Jullianisi, who employed him. After this he succeeded; and the great freedom and ease of his pencil procured him many patrons. Several of the churches and palaces at Rome are adorned with his productions: the bell are esteemed to be those of the Dead of St. Angelo, in the church of St. Martino a Monti, and of the Dead of Iphigenia, in the Palazzo Spada. His works, however, are more frequently to be met with at Lucca. As a designer, Pietro Telfa was unequal; he frequently tackled to antique toros ignoble heads, and extremities copied from vulgar models. Of female beauty he appears to have been igno-
compliance may
in the
feas, but also to those of the rivers and lands; and it has moreover an evident claim to priority, having been in use for at least the last forty years among the best English authors. Da Costa, a writer of no ordinary information, indeed appears to have assumed to himself the establishment, if not the actual invention of the term; for in his "Elements of Conchology," published in 1776, he expressly observes, "this peculiar branch of the history of nature, I shall call conchology." Many authors call it conchophytole; and this we find to be true in compliance both with the French and the Latin, the "Conchophytole" of D'Argeville, and "Histologia Conchologica" of Liller, two works of great celebrity, that had appeared some time before his "Elements" were published. We have thus endeavoured to prove that the terms telfactology and conchology are purely synonymous; and if any doubt remained, we might finally quote one further passage from the Elements before alluded to, in which we are distinctly told, that "the term of Conchology, applied to this branch of natural history by all authors, is quite applicable to its arrangement by the shells, and not by the fifth." As we have already endeavoured to exemplify the rise, progress, and present state of the science of telfactaceous bodies in a very ample manner under the article Conchology, and may be allowed to presume, with some little confidence, that we have therein concentrated much useful information upon this truly pleasing and very favourite science, it might be esteemed a waste of words to enter into any very considerable digression upon the same subject again; we shall therefore merely recommend a careful perusal of that article to the attention of the reader, and trust the result will be considered satisfactory.

It was indeed our wish, and we had made some general promise to that effect, that under the present article we would resume this subject, and submit the outlines of what we were induced to think an improvement upon the present prevailing arrangement; and upon this point it is now incumbent to offer a few remarks.

The most ardent admirer of the great Linnaeus will readily concede to us, that the science of conchology was not one of those within the province of his deep research, or the decided contemplation of his active mind. Its introduction as a science, was necessary to complete the series of the vital chain of animated nature, the classification of which he had undertaken in his "Systema Naturae," and it was therefore one he could not omit. But for this, it is believed, and with tolerable certainty, that he would have willingly avoided the subject altogether in the latter editions of that work, as it was in the early ones. We have already shewn under our article Conchology, the actual state in which Linnaeus found the science, as handed down to him by his predecessors; and the various purposes to which he applied their labours and affinities. From a general view of the whole, there can no doubt remain that there is yet much to amend in the classification of shells, and that the subdivision of many of the genera already established into natural genera, appears desirable. It was under this persuasion that we had
had intended, when writing the article Testaceology, to have submitted our ideas as to a new and more comprehensive classification of the genera; to have pointed out the very essential distinctions that exist in shells of the same Linnean genera; and have thence endeavored to deduce an arrangement congenial with the characters of the respective natural genera which his artificial genera present. This we believe would have been regarded as an improvement in the classical distribution of the shell-tribe, but such an illustration does not appear, upon more mature reflection, to be admissible here. It must be apparent that no words, unaccompanied by figures, could possibly convey to the reader any adequate conception of the minute, ambitious, and intricate essential characters, which many among the various tribes of shells present; and that such a series of plates as it would demand to illustrate a subject so very copious and diffuse, however desirable in the opinion of the naturalist, could not be appropriated, with any degree of propriety, in addition to the very costly series of plates already devoted by the Cyclopædia to this science in particular.

The series of plates which have already appeared, elucidate the whole of the Linnean genera, and under each of those genera, a number of the more striking natural genera which appertain to them respectively. These plates are numerous, and the subjects for them have been selected with every possible attention; nor can we hesitate to think upon the whole they will be considered, without any further addition, as amply sufficient for every useful purpose of general information.

**TESTACEOUS, in Natural History, an epithet given to those shells, which are covered with a strong, thick shell; as oysters, pearl-fish, &c.**

In limestones, however, tellaceous is only applied to shells whole strong and thick shells are entire; those which are soft, thin, and consist of several pieces joined, as the lobster, &c., being called **crystalline.**

In medicine, all preparations of shells, and substances of the like kind, are called **tellaceous.**—Such are powders of crab’s claws and eyes, pearl, &c.

Dr. Quincy, and others, suppose the virtue of all tellaceous medicines to be alike; that they seldom enter the lacheta, but that the chief of their action is in the first passages; in which however they are of great use in affording acidities.

Hence they become of use in fevers, and especially in rectifying the many distempers in children, which generally owe their origin to such acidities.

**TESTAMENTUM, in Law, a solemn and authentic act, by which a person declares his will, as to the dispoofal of his estate, effects, burial, &c.**

Testaments, according to Julinian, and Sir Edward Coke, are so called, because they are **testato mentis;** an etymon, says judge Blackstone, which seems to favour too much of the consent, it being plainly a substantiative derived from the verb **testari.** The definition of the old Roman lawyers is much better than their etymology; **voluntas nostra justa sententia de eo, quod quis post mortem suam fieri velit,** i.e., the legal declaration of a man’s intentions, which he wills to be performed after his death. It is called **sententia,** to denote the circumspicion and prudence with which it is supposed to be made; it is **voluntas nostra justa sententia,** because its efficacy depends on its declaring the testator’s intention, whence in England it is emphatically styled his will: it is **justa sententia,** that is, drawn, attested, and published with all due solemnities and forms of law; it is **de eo, quod quis post mortem suam fieri velit,** because a testament is of no force till after the death of the testator.

Blackstone’s Comm. vol. ii.

A testament has no effect till after death, and is always revocable till then. As testaments are acts, of all others, the most subject to deceits, surprizes, &c., it was found necessary to use all kinds of precautions to prevent the wills of deceased from being clauded, and the weakens of dying persons from being abused. See Will.

The most ancient testaments among the Romans were made **viae voce,** the testator declaring his will in the presence of seven witnesses; these they called **nuncupatoria** testaments; but the danger of trusting the will of the dead to the memory of the living soon abolished these: and all testaments were ordered to be in writing.

The French legislators thought **holographic** testaments, i.e., testaments written wholly with the testator’s hand, an abundant security; but the Roman law, more severe, did not admit of testaments without further solemnity.

The easiest, and most favourable, is the twenty-first law in the **code de testaments,** which permits such as are unwilling to trust the secret of their testaments to others, to write it with their own hand, and to close it in the presence of seven witnesses, declaring to them, that it is their testament; after which it is to be signed by all the seven witnesses.

Otherwise, to make a solemn testament, it was required to be attested by seven witnesses, and sealed with their seals.

Yet the military testament was not subject to so many formalities: the soldier was supposed too much employed in defending the laws, to be subject to the trouble of knowing them. His mutiny, or profession excused him from observing all the rules. See Military.

Testaments, wherein fathers disposed of their effects among their children, had particular privileges, and were dispensed from most of the ordinary formalities.

**TESTAMENT, **Probae of a. See **PROBATE and Wills.**

**Testament, Old and New, in Sacred History.** The most common and general division of the canonical books of scripture, is that of the Old and New Testament. (See Cason.) The Hebrew word **Berith,** from which it is translated, properly signifies “Covenant.” Accordingly St. Paul (2 Cor. iii. 6—18.), when he is showing the superior excellence of the gospel covenant, or the dispensation by Christ above the legal covenant, or the dispensation by Moses, uses the word testament, not only for the covenant itself, but likewise for the books in which it is contained. The Hebrew term **Philadelphia, berith,** invariably rendered covenant by our translators in the Old Testament, is uniformly translated **Δαιμονίας** in the Septuagint; and in the writings of the apostles and evangelists, the words **καθάρισμα, δαιμονίας,** are almost always rendered by our translators the New Testament. It is observed, that the Hebrew term corresponds much better to the English word “Covenant,” though not in every case perfectly equivalent, than to “Testament,” and yet the word **δαιμονίας, in classical use, is more frequently rendered Testament.** Our translators, ancient and modern, have probably been led to render it Testament, by the manner in which the author of the epistle to the Hebrews argues (ch. ix. 16, 17.), in allusion to the classical acceptation of the term. The term **Nechal** is added to distinguish the religious institution of Jesus Christ from the **Old Covenant,** that is, the dispensation of Moses. Accordingly the two covenants are always in scripture the two dispensations, or religious institutions, that under Moses is the **Old,** and that under the Messiah is the **New.** Hence, from distinguishing the two religious dispensations, they came soon to denote the books in which what related to the several dispensations was contained; the several writings of the
Jews being called εβραζον διαβλεπειν, and the writings super-added by the apostles and evangelists, εκ των διαβλεπων. The New Testament consisted very anciently of two codes or collections, called gospels and epistles. This was the case in the time of Ignatius, and also in the time of Tertullian, who distinguishes the gospels by the names of the writers, and calls them our "Digesta," or digests, in allusion, as it seems, to some collection of the Roman laws digested into order. As to the order of the several gospels, it appears, that in Tertullian's time they were dispersed, at least in the African churches, according to the quality of the writers: those two occurring first which were written by apostles, and then the other two written by apotollycal men. In some of the most ancient MSS. now extant, the order of the several evangelists is thus: Matthew, John, Luke, Mark. The order of the four gospels has been generally this: Matthew, Mark, Luke, John; then follow the Acts, St. Paul's epistles, the Catholic epistles, and the Revelation. It sufficiently appears, from a variety of considerations suggested by the excellent Dr. Lardner, that the books of the New Testament, consisting of a collection of sacred writings, in two parts, one called Gospel or Gospels, or Evangelion; the other Epistles, or Apostle or Apostles, or Apostoliccon, were only known, read, and made use of by Christians. (See Canon.) It has been a subject of some dispute, whether any sacred books of the New Testament have been lost; but there are many considerations, tending to satisfy us, that no sacred writings of the apostles of Christ are lost.

The four gospels, in our possession, were written for the benefit of those who would undoubtedly receive them with respect, keep them with care, and recommend them to others; and if any other such authentic histories of Jesus Christ had been written by apostles, or apotollycal men, they would have been received, and preferred in like manner. The book of the Acts, which we still have, was the only authentic history of the preaching of the apostles after our Lord's ascension, which they had in their hands, or had heard of; consequently there was no other such history to be lost. The epistles of Paul, James, Peter, John, Jude, were sent to churches, people, or particular persons, who would shew them great regard when received, would carefully preserve them, and readily communicate them to others, that they might take copies of them, and use them for their establishment in religion and virtue; and if other such epistles had been written, the cause would have been much the same, nor could any of them have been easily lost. Besides, the apostles and evangelists, who drew up any writings for the instruction or confirmation of Christian people, must have been careful of them. Upon the whole, we have no sufficient reasons for believing, that any sacred writings of the New Testament have been lost. All the books of the New Testament were written in Greek, except the gospel of St. Matthew, who, according to St. Jerome, first wrote in Judea in the Hebrew language. Tertullian, as well as many other ancient writers, afford us various testimonies to the integrity and genuineness of the gospels and other books of the New Testament in his time, as well as to their divine inspiration. See Bible.

Although the New Testament was written in Greek, an acquaintance with the Greek classics will not be found so conducive to the interpretation of it, as an acquaintance with the ancient Hebrew scriptures. The propriety of its being written in the Greek language will appear from the following historical fact. After the Macedonian conquests, and the division which the Grecian empire underwent among the commanders on the death of their chief, Greek soon became the language of the people of rank through all the extensive dominions which had been subdued by Alexander. The perfections with which the Jews were harassed under Antiochus Epiphanes, concurring with several other causes, occasioned the diffusion of a great part of their nation throughout the provinces of Asia Minor, Asia, Phoenicia, Persia, Arabia, Libya, and Egypt; which diffusion was in course of time extended to Achaia, Macedonia, and Italy. The unavoidable consequence of this was in a few ages, to all those who settled in distant lands, the total loss of that dialect, which their fathers had brought out of Babylon into Palestine, excepting only amongst the learned. At length a complete version of the scriptures of the Old Testament was made into Greek; a language which was then, and continued for many ages afterwards, in far more general use than any other. (See Septuagint.) The Jews, who inhabited Grecian cities, where the oriental tongue was unknown, would be naturally anxious to obtain copies of this translation. Wherever Greek was the mother-tongue, this version would be gradually adopted into use not only in private in Jewish houses, but also in public in their schools and synagogues, for the explanation of the weekly lessons from the law and the prophets. The style of it would condescendingly soon become the standard of language to them with regard to religious subjects. Hence would arise a certain uniformity in phraseology and idiom among the Grecian Jews, wherever sojourned, in respect of their religion and sacred rites, whatever might be the particular dialects which prevailed in the places of their residence, and were used by them in converting on ordinary matters. From the conformity and peculiarity in language now noticed, some critics, in order to distinguish the idioms of the LXX and New Testament from that of common Greek, have termed it Hellenistic; which see. Under that article we have intimated, that the habit which the apostles and evangelists had of reading the scriptures, and hearing them read, whether in the original or in the ancient version; would, by infecting their style, co-operate with the tendency which, as natives of Palestine, they would derive from conversation, to intermingle Hebraisms and Chaldeisms in their writings. Some modern writers, whilst they have adverted to this circumstance, have defended the dictation of the sacred penmen of the New Testament, and extolled it as altogether pure and elegant. Among these we may reckon Pfechenius and Blackwall, who, with this view, have made diligent researches among the writings of the ancient Greeks, for the discovery of words and phrases, which might appear to refer to what has been accounted Hebraism or Syrianism in the New Testament. Whereas the writings of the New Testament carry, in the very expression and idiom, an intrinsic and irresistible evidence of their authenticity. They are such as, in respect of style, could not but have been written by Jews, and hardly even by Jews superior in rank and education to those whose names they bear; and yet, under this homely garb, we find the most exalted sentiments, the closest reasoning, the purest morality, and the sublimest doctrine.

Abstraining from that lowly kind of beauty in language, which results from its softness and harmony, confided as an object to the ear, every excellency of style is relative, arising solely from its fitness for producing, in the mind of the reader, the end intended by the writer. Now in this view it is evident, that a style and manner may, to readers of one denomination, convey the writer's sentiments with energy as well as perplicity, which, to those of a different denomination, would convey them feebly, darkly, and, when judged by their rules of propriety, improperly. This seems to have been actually the case with the writers of the New Testament.
New Testament. The language of Matthew, Mark, Luke, and John, is better adapted to the readers, for whose use the Gospels and Acts were at first composed, than the language of Plato or Democritus would have been.

If we would enter thoroughly into the idiom of the New Testament, we must familiarize ourselves to that of the Septuagint; and if we would enter thoroughly into the idiom of the Septuagint, we must accustom ourselves to the study, not only of the original of the Old Testament, but of the dialect spoken in Palestine between the return of the Jews from the Babylonish captivity, and the destruction of Jerusalem by the Romans; for this, as well as the Hebrew, has affected the language both of the old Greek translation and of the New Testament.

Such is the origin and the character of the idiom, which prevails in the writings of the apostles and evangelists, and the remarkable conformity of the new revelation we have by them, though written in a different language, to the idiom of the old. It has been distinguished in the former by the name Hellenistic, not with critical accuracy, if regard be had to the derivation of the word, but with sufficient exactness, if attention be given to the application which the Hebrews made of the term Hellenist, by which they distinguished their Jewish brethren, who lived in Grecian cities and spoke Greek. It has been by some of late, after father Simon of the Oratory, more properly termed the Greek of the synagogue. It is acknowledged, that it cannot strictly be denominated a separate language, or even dialect, when the term dialect is conceived to imply peculiarities in declension and conjugation. But, with the greatest justice, it is denominated a peculiar idiom, being not only Hebrew and Chaldaic phrases put in Greek words, but even single Greek words used in phrases in which they never occur in the writings of profane authors, and which can be learnt only from the extent of signification given to some Hebrew or Chaldaic word, corresponding to the Greek in its primitive and most ordinary sense. This difference in idiom constitutes a difficulty of another kind from that which is created by a difference in dialect; a difficulty much harder to be surmounted, as it does not affect the form of the words, but the meaning.

It is pertinent, however, to observe, that the above remarks on the Greek of the New Testament, do not imply that there was any thing which could be called idiomatistical or vulgar in the language of our Lord himself, who taught always in his mother tongue. His apostles and evangelists, on the contrary, who wrote in Greek, were, in writing, obliged to translate the instructions received from him into a foreign language of a very different structure, and for the use of people accustomed to a peculiar idiom. The apparently respectful manner in which our Saviour was accosted by all ranks of his countrymen, and in which they spoke of his teaching, evinces that he was universally considered as a person of eminent knowledge and abilities. It was the amazing success of his discourses to the people, in commanding the attention and reverence of all who heard him, which first awakened the jealousy of the scribes and pharisees.

Although all the writers of the New Testament wrote in the idiom of the synagogue, we are not to conclude from hence, that there is no discernible diversity in their styles. As the same language admits of a variety of dialects, and even of provincial and foreign idioms, so the same dialect and the same idiom are susceptible of a variety of styles. The style of Paul has something peculiar, by which, in our opinion, there would be no difficulty in distinguishing him from any other writer. A disconcerting reader would not readily confound the style of Luke with that of either of the evangelists who preceded him, Matthew or Mark; and still less would he mistake the apostle John’s dictation for that of any other penman of the New Testament. The same differences of style will be discovered by one who is but moderately conversant in Hebrew in the writers of the Old Testament. In it we have still greater variety than in the New. Some of the books are written in prose and some in verse; and in each, the differences between one book and another are considerable. In the book of Job, for instance, the character of the style is remarkably peculiar. What can be more dissimilar in this respect, though both are excellent in their kind, than the towering flights of the sublimine Isaiah, and the plaintive strains of the pathetic Jeremiah? In the books of Scripture we can specify the conic style and the copious, the elevated and the simple, the euphonious and the diffusive.

How this diversity of style is reconcilable with the idea of inspiration, we have attempted to throw under the article INSPIRATION. See Campbell’s Prelim. Diff.

For other particulars in connection with the subject of this article, see BIBLE and CANON.

TESTAMENTARY ADOPTION. See ADOPTION.

TESTAMENTARY CAUSIS, in Law, are those that relate to testaments, which were originally cognizable in the king’s courts of common law, viz., the county-courts, and afterwards transferred to the jurisdiction of the church, by the favour of the crown, as a natural consequence of granting to the bishops the administration of intestate’s effects. This spiritual jurisdiction of testamentary causes is a peculiar constitution of this island; and for in almost all other (even in popish) countries, all matters testamentary are of the jurisdiction of the civil magistrate. And that this privilege is enjoyed by the clergy in England not as a matter of ecclesiastical right, but by the special favour and indulgence of the municipal law, and as it should seem by some public act of the great council, is freely acknowledged by Lindeuwode, the ablest canonist of the fifteenth century; and about a century before, in a canon of archbishop Stratford; also by the constitutions of cardinal Othobon; and likewise by archbishop Parker, in the time of queen Elizabeth. At what period of the time the ecclesiastical jurisdiction of testaments and intestacies began in England, is not ascertained by any ancient writer. It appears the foreign clergy were early ambitious of this power, though they were curbed by the edict of the emperor Justinian, which restrained the infraction or probate of testaments (as formerly) to the office of the magister causis; but afterwards by the canon law it was allowed, that the bishop might compel, by ecclesiastical censures, the performance of a bequest to pious uses. And therefore it fell within the jurisdiction of the spiritual courts by the express words of the charter of king William I. which separated those courts from the temporal. And afterwards, when king Henry I. by his coronation-charter, directed that the goods of an intestate should be divided for the good of his foul, this made all intestacies immediately spiritual causes, as much as a legacy to pious uses had been before. This therefore, says judge Blackstone, we may possibly conjecture, was the era referred to by Stratford and Othobon, when the king, by the advice of the prelates, and with the consent of his barons, invested the church with this privilege.

This jurisdiction is principally exercised with us in the consililuary courts of every diocesan bishop, or in the prerogative court of the metropolitan originally; and in the arches court, and courts of delegates by appeal. It is divisible into three branches; the probate of wills, the granting of administrations, and the fusing for legacies. The two former
former of which, when no opposition is made, are granted merely ex officio et debito jussu, and are then the object of what is called the voluntary, and not the contentious jurisdiction. But when a caveat is entered against proving the will or granting administration, and a suit thereupon follows, in order to determine either the validity of the testament, or who hath a right to the administration, this claim and obstruction are remedied by the sentence of the spiritual court, either by establishing the will, or granting the administration. Blackstone’s Com. vol. ii. See Subtraction of Legacies.

TESTAMENTO Guardian, Succession, and Tutors. See the subcaptives.

TESTAMENTO Annuity, Administration cum. If a testator makes his will, without naming any executors, or if he names incapable persons, or if the executors name refuse to act; in any of these cases, the ordinary must grant administration cum testamento annuo, to some other perfon.

TESTAMENTS of the Twelve Patriarchs, in Ecclesiastical History, a kind of apocryphal or spurious books, in which those patriarchs are introduced, speaking their last dying words, containing predictions of things future, and rules of virtue and piety; which they deliver to their sons as a choice treasure, to be carefully preferred, and to be delivered by them to their children. We have several editions of these in Latin; they were first published in Greek, by Grabe, and from his edition republished by Fabricius, and translated into English by Mr. Whilton. Cave places the anonymous author of this book in the year 192, or nearer the beginning of the second century. They are cited by Origen, and, therefore, were probably written before his time. Grabe thinks they were written before the time of our Saviour, and afterwards interpolated by a Christian. But Mr. Whilton affers, that they are really genuine, and one of the sacred apocryphal, or concealed books of the Old Testament. Cave supposes that this book was written by a Judaizing Christian; Grabe apprehends that it was written in Hebrew; Beausobre is of opinion that it was forged at the end of the first, or beginning of the second century, by some Christian converted from Judaism, and he supposes that the author was an Ebionite, and that he believed Jesus to be the Son of Joseph and Mary. Dr. Lardner is positive that these testaments are not the real last words of the twelve patriarchs; but the clear knowledge of Christian affairs and principles shews this book to have been written, or else very much interpolated, after the publication of the Christian religion. He says, there is nothing in this work that might not have been written by a learned Jew of the second century or later, though he thinks that the author was a Christian, and well versed in the Jewish learning; and moreover he is of opinion, that he is placed early enough by Cave, at the year 192. Lardner’s Works, vol. ii.

TESTATOR, or TESTATRIX, the person who makes his or her will and testament.

M. Gillet shews, that a person incapable of a legacy cannot demand any sum which the testator in his testament declares himself indebted to him in; in regard such a declaration of debt is presumed a fraud against the intention of the law.

TESTATUM, in Law, a writ in personal actions; where, if the defendant cannot be arrested on a capias in the county where the action is laid, but is returned non est inventus by the sheriff, this writ shall be sent into any other county, where such person is thought to be, or to have wherewithal to satisfy the demand.

It is called testatum, because the sheriff has before testified, that the defendant was not to be found in his bailiwick.

TESTE, a term commonly used in the close of a writ, where the date is contained, which begins with Teste meipso, if it be an original writ; or, if judicial, Teste, the lord chief justice, &c. accordingly to the court whence it comes. In some ancient formulas, we read Teste et falsus Anglicse. There must be at least fifteen days between the telle and return of every proces from the king’s bench into any foreign county. See WRIT.

TESTENICHT, in Geography, a small island in the gulf of Venice. N. lat. 44° 54’. E. long. 14° 47’.

TESTER. See Teston.

TESTES, Testiculi, in Anatomy; quia virilitatem tectantur; glandular bodies, peculiar to the male sex of animals, serving the office of secreting the fecundating fluid; hence their removal deprives an animal of the power of propagating its kind. See GENERATION, Male Organs.

The testes are wanting in most of the fih kind. The spinofish in general have neither teles nor parallas; but all the ceteaceous fishes have them, and not a few of the cartilago- ninous kinds. Those fishes that have them, have always two, as in land-animals; but they differ much in figure and situation in the several kinds, particularly in the whale and flat-fish. See Anatomy of Fish.

TESTIS of the Brain, two small hemispherical eminences, situated at the posterior and inferior aspect of the optic thalami, and now more generally known, together with two very similar ones immediately above them, by the name of tubercula quadrigemina. See Brain.

TESTES Synodales. See Synodales.

TESTI, Fulvio, Count, in Biography, an Italian poet, was born in 1593, at Ferrara, and settling, when young, at Modena, he rofe to the highest offices and honours of the state. Nevertheless, alternate prosperity and adversity visited him: incontinent and ambitious, he fell into disgrace with Francis I. who imprisoned him in the citadel of Modena, where he died in 1646. His poems are chiefly of the lyric class. The productions of his mature judgment are distinguished above those of his contemporaries for vigour and poetical spirit; and some of them, with respect to elevation of sentiment and beauty of imagery, will bear comparison with the productions of the best Italian poets. He also attempted tragedy in two compositions, intituled “Arinda,” and “L’Isole d’Alcina;” but their style is lyric rather than dramatic composition. Tiraboschi. Gen. Biog.

TESTIBUS His. See His.

Testicle, Operation of removing. See Castration.

TESTIGOS, Los, in Geography, a cluster of small islands, about ten leagues from the continent of South America, and the same distance from the island of Grenada. N. lat. 11° 25’. W. long. 62° 54’.

TESTIMON, a town of Pruflia, in the province of Erdmold; 16 miles S.S.E. of Hillberg.

TESTIMONIAL, a kind of certificate, signed either by the master and fellows of the college, where a person last resided, or by three, at least, reverend divines, who knew him well for three years last past; giving an account of the conduct and learning of the person.

Such a testimonial is always required before holy orders are conferred; and the bishop even ordinarily demands one of a priest before he admits him to a benefice.

TESTIMONIAL is also a certificate under the hand of a justice of peace, testifying the time and place when and where
a folder or mariner landed, and the place of his dwelling, and whether he is to pass.

TESTIMONY. See EVIDENCE.

Testimony is a serious intimation from another of any fact or observation, as being what he remembers to have seen, heard, or experienced. The evidence of testimony is either oral or written. Some have unreasonably forged, that this kind of evidence is solely and originally derived from experience. With regard to this it may be observed, that the evidence of testimony is to be considered as strictly logical, no farther than human veracity, in general, or the veracity of witnesses of such a character, and in such circumstances in particular, is supported, or hath not been refuted by experience. But that testimony, antecedently to experience, hath a natural influence on belief, is undeniable, in which respect it resembles memory. And in what regards single facts, it is a more adequate evidence than any conclusions from experience. When experience is applied to the discovery of the truth in a particular incident, the evidence is called presumptive; whereas ample testimony is accounted a positive proof of the fact. Testimony is capable of giving us absolute certainty even of the most miraculous facts, or of what is contrary to uniform experience. To this, when we have no positive reasons of mistrust or doubt, we are, by an original principle of our nature (analogous to that which compels our faith in memory), led to give an unlimited assent.

As on memory alone is founded the merely personal experience of the individual, so on testimony, in concurrence with memory, is founded the much more extensive experience, which is not originally our own, but derived from others. See on this subject Campbell's Philos. of Rhet. vol. i. book i. chap. 5. and Dissertation on Miracles, part i. sect. 1. and i. See FAITH.

For the credibility of human testimony, see CERTITUDE.

TESTINA, in Ancient Geography, a town of Italy, belonging to the Sabines, placed by D'Anville S.W. of Amiens.

TESTING, in Metallurgy, denotes the operation of refining large quantities of gold and silver, by means of lead, in the vessel called a test. This operation is performed by the destruction, vitrification, and forcification of all the extraneous and destructible metallic substances with which those noble metals are alloyed. It consists in adding to the alloyed gold and silver, a certain quantity of lead, and in exposing afterwards this mass to the action of the fire. The lead, by increasing the proportion of imperfect metals, prevents them from being so well covered and protected by the perfect metals; by uniting with them, it communicates to them a property which has of loosing very easily a great part of its inflammable principle; and lastly, by its vitrifying and fusing property, which it exercises with all its force upon the calcined and naturally refractory parts of the other metals, it facilitates and accelerates the fusion, the forcification, and separation of these metals. The lead, which in this operation is purified, and forcified along with it the imperfect metals, separates from the metallic mass with which it is then incapable of remaining united: it floats upon the surface of the melted mass; because by losing part of its phlogiston, (according to the former language of chemists,) it looses also part of its specific gravity, and lastly it vitrifies. The removal of the vitrified matter in the process is procured either by the nature of the vessel in which the melted matter is contained, and which, being porous, absorbs and imbues the forcified matter as fast as it is formed; or by a channel cut in the edge of the vessel through which the matter flows out.

The process of testing is generally performed in the same manner as that of cupellation. See ASSAYING and COPELLING.

But when great quantities of base metal are to be worked off from a little gold, recourse is had to a more expeditious method, that of testing before the bellows. An oval test is placed in a cavity, made in a hearth of a convenient height, and some mineralized sand or ashes prefured round it to keep it steady: the hole of a bellows is directed along its surface, in such a manner, that if ashes are sprinkled in the cavity of the test, the bellows may blow them completely out: some have an iron plate fixed before the bellows, to direct the blast downwards. To keep the surface of the test from being injured in putting in the metal, some cloths or pieces of paper are interposed. The fuel consists of billets of barked oak, laid on the sides of the test, with others laid crofs-wise on the test. The bellows impel the flame on the metal, clears the surface of ashes or sparks of coal, hastens the forcification of the lead, and blows off the scoria, as fast as it is formed, to one end of the test, where it runs out through a notch made for that purpose. About two-thirds of the forcified lead may be thus collected; the rest being partly absorbed by the test, and partly diffracted by the action of the bellows. Care must be taken not to urge the blast too strongly, lest some portion of the gold should be carried away by the fumes impetuously forced off from the lead, and some minute particles of it entangled and blown off with the scoria. Macquer's Chem. Dict. Art. Refining. Lewis's Ph. Techn. p. 146.

TESTO, Ital. literally left. In Music it implies a subject, or words of a song, or other vocal composition, to which some air, melody, or harmony, is to be composed.

It is a matter of great concern to understand well how to appropriate or adapt the music to the words of a song, to express the feme, and make a just application of the long and short syllables to the notes and time with which they are to be connected.

But this branch of the science, which depends greatly on the knowledge of poetry, has lain a long time almost unregarded; and even at present, very little care is taken in this point in the modern music, which is somewhat wonderful, since it was to this that the ancients attributed the extraordinary effects of their music; for by them this branch was most accurately observed, and by this they regulated and governed their measures, so that they might produce the desired effects; and some philosophers lay, the human passions and affections. Vellius de Poem. Cantu, &c.

TESTON, Tester, the name of a coin struck in France by Louis XII. in 1513, and in Scotland in the time of Francis II. and Mary queen of Scotland, so called from the head of the king, (testo or tête,) which was engraved upon it. The silver it contained was 11 deniers 18 grains; its weight, 7 deniers 1½ grains; and its value 10 foles. The coignage of it was prohibited by Henry 111, in 1575, when the value of it was augmented to 14 foles 6 deniers. Encyc.

A remarkable Scottish medal of this kind was that inaugurative of Francis II. of France with Mary of Scotland, though it is more properly indeed French, being, as it is thought, struck upon their coronation, as being a queen of that country. It presents busts of Francis and Mary, face to face, with three legends around them, the outermost of which contains their titles, the middle one this singular sentence:

"Which wonders how the devil it got there?"

HORA NONA DOMINUS HIS EXPIRAT HELLI CLAMANS, a most ominous motto, one would imagine, to a superfluous car. The innermost legend is only the name of the city of Paris. There are fine French testoons of Francis and Mary, likewise presenting them face to face, with the arms of France
France and Scotland upon the reverse, as is also the cafe of the medal just mentioned. These pieces are so fine and rare, that Dr. Hunter gave ten guineas for the one in his cabinet, which contains as vast and well-chosen a private collection, of all sorts of coins and medals, as any in the world.

Telloons, or shells, were first coined in Scotland about the year 1553; and they bore the bull of the queen and the arms of France and Scotland on the reverse: they were of the same intrinsic value with those of England, and were worth four shells; the half-telloon two, Scotch money. The silver telloon of Mary, chiefly of 1553 or 1562, with her bull, are rare, worth about 3½; half still more rare, valued at ½. Pinkerton on Medals.

The telloon, tfoot, or teller, among us, succeeded the great, which was introduced by Edward III. in 1354. It was also called shelling, and first coined by Henry VII. in 1503; and was rated at 12d. in the reign of Henry VIII. and afterwards reduced to 6d. The telloon of the first year of Edward VI. is extremely rare.

TESTOON, or TSTONE, a silver coin in Italy, and also in Portugal. At Florence, the telloon, or tfoot, as a money of account and a silver coin, is worth two lire, or three paoli. The telloon is a money of account at Lisbon, and is valued at 100 rees. And of the gold coins struck since 1722, there are the Dezesseis telloon of 1600 rees, and the Otto telloon of 800 rees. The silver coins are telloons of 100 and halves of 50 rees.

At Rome the fcondo, as a money of account, is divided into 3½ telloons; and among the silver coins, the telloons are valued at 3 paoli, the paoli being worth 5½d. Ferling nearly. See Coin.

TESTORE, CARLO GIOVANNI, in Biography, a violonist and music-master, resident at Verailles in 1770. In 1797 he published a treatise on music, entitled, “Musica ragionata,” in 4to. This author was perhaps the first Italian who adopted Rameau’s principles. He simplified his rules, and made his treatise more intelligible to principiant than Rameau himself, or his scientific commentator d’Alcambert. The full title of his book is “La Musica ragionata espressa familiaremente in dodeci Paffegeggiate a Dialogo, ornati 140 effempi Musicali in rami.”

TESTOUR, in Geography, a town of Africa, in the country of Tunis, on the Mejerdah; 40 miles S.W. of Tunis.

TESTUDO, in Antiquity, was particularly used among the poets, &c. for the ancient lyre, or lyre of Amphiion; because it was said to have been originally made; by its inventor Mercury, of the back or hollow shell of a testudo aquatica, or sea-tortoise, which he accidentally found on the banks of the river Nile.

Mr. Molyneux has an express discourse, in the Philosophical Transactions, to shew that the tortoise-shell was the basis of the ancient lyre, and that the whole instrument had thence the denomination telfudo; which account throws some light on an obscure passage in Horace, ode iii. lib. 4. mistaken by all the commentators:

“O, testudinis aurea
Dulcem quaesitum, Pieri, temperas!
O mutis quoque pictibus
Donatura cygni, si lebet, fonum!”

TESTUDO, Tortoise, in the Military Art of the Ancients, was a kind of cover, or screen, which the soldiers, e. gr. a whole company; made themselves of their targets, by holding them up over their heads, and standing close to each other.

Thus, if we suppose the first rank to have stood upright on their feet, and the rest to have stood lower and lower by degrees, till the last rank knelt down on their knees, so that every rank covering with their targets the heads of all in the rank before them, they represented a tortoise-shell, or a fort of sloping roof.

This expedient served to shelter them from darts, stones, &c. thrown upon them, especially those thrown from above when they went to the assault. It was also used in field-battles as well as in sieges.

TESTUDO was also a kind of large defensive engine, of an oval figure, composed of boards, and wattled up at the sides with wicker, which moved on several wheels, serving to shelter the soldiers when they approached the walls to mine them, or to batter them with rams.

TESTUDO, in Medicine, denotes a soft broad tumour, or gathering of impure humours between the skull and the skin, called also talpa, as resembling the subterraneous windings of the tortoise or mole.

TESTUDO, in Zoology, a genus of animals of the class of Amphibia and order of Reptiles; the generic characters of which are, that the body is furnished with a tail, and defended by a bony or cariacious integument above and below, or above by scales; and that the upper mandible of the mouth closes over the lower; without distinct or proper teeth, the teeth, as they are called in the generality of tortoises, being no other than the serrations of the mandibles.

Gmelin enumerates thirty-three species, which are distributed into the three classes of marines, fluctuabile, and land tortoises.

1. Marine Tortoises, or Turtles with pinniform Feet, the former being longer.

The animals of this class are distinguished from the land tortoises by their very large and long fin-shaped feet, in which are included the bones of the toes, the first and second on each foot being furnished with visible or projecting claws, the others not appearing beyond the edge. The shield, as in the land tortoises, consists of a strong bony covering, in which are imbedded the ribs, and which is coated externally by hard horny plates, in one or two species much thicker and stronger than those of the land tortoises. Mr. Scharpf, cited by Dr. Shaw, observes, that the apparent number of claws or projecting extremities on the feet of the marine tortoises, appears to be no certain criterion of the species; but, on the contrary, is found to vary so as to contradict the Linnean specific characters.

Species.

CORIACEA; Coriaceous Tortoise. Striated lengthwise; or brown turtle, paler beneath, with coriaceous shell, marked by five longitudinal tuberculated ribs. This is the largest of the marine tortoises, being found eight feet long, and one thousand pounds in weight. It is larger than others of its tribe, and its external covering differs by not being horny, but resembling strong leather, marked over the surface into small, obscurely subhexagonal and pentagonal divisions, without destroying its general smoothness. The longitudinal ribs or ridges are five; and comprehending those that border the sides, the number is seven. It has no under or thoracic shell; the head is large, and the upper mandible notched at the tip, so as to exhibit the appearance of two large teeth, between which, when the mouth is closed, is received the tip of the lower mandibles; the fins are large and long, and covered with a tough leathery skin; the tail is rather short and sharp-pointed. This species is a native of the Mediterranean, and has occasionally been taken on the coast both of France and England. It is also found, not only in the Eu-
TESTUDO.

European seas, but in those of South America, and about one of the African coasts. The Greeks, according to Cépæda, were well acquainted with this specimen, and used it in the construction of the lyre or harp. (See Testudo, in Antiquity.) Pinnant says, that this species is extremely fat, but the fish coarse and bad; but the Cartulians will not eat other species. The small testiform described by Pinnant in the Phil. Trans. for 1771, is said to be the young of this animal. Gmelin mentions this and another as variegated.

IMBRICATA. The imbricated or variegated turtle with thirteen imbricated scales on the disk; these lap over each other at the extremities like tiles on the roof of a building. The head is smaller than in other turtles; the neck longer, and the head narrower, sharper, and more curved, so as considerably to resemble the bill of a hawk, and from this circumstance the animal derives its popular name of the "hawkbill turtle." This is a native of the Asian and American seas, and is sometimes found in the Mediterranean. It has been often known to measure five feet in length, and to weigh 500 or 600 pounds. In the Indian ocean it attains a prodigious size. Its shell was anciently used for a shield, and still serves for that purpose among barbarous nations. The flesh is not esteemed as a food; the lamelle or plates of the shell, being much stronger, thicker, and clearer than those of any other kind, constitute its sole value. See Tortoise-Shell.

MYDAS. Brownish turtle, with thirteen scales on the disk; the green turtle of some writers, with two nails on the fore-feet, and angle ones on the hind-feet. This common green turtle (elephantine), is so named from the green tinge, derived from the vegetable substances on which it feeds, often exhibited by its fat, when the animal is in its highest perfection. It is one of the largest of this genus, often measuring above five feet in length (sometimes more than five), and weighing more than 500 or 600 pounds. Its colour is a dull pale brown, variegated with deeper undulations, but not exhibiting the beautiful colours which distinguish the T. imbricata. Its flesh, however, is in such estimation, that the inhabitants of the West Indian islands have long considered it as one of the most excellent articles of food, and have introduced asimilar taste into some of the European nations. In our own country it is much esteemed, and considerable quantities of it are imported to supply the luxury of the metropolis. Its introduction, however, cannot be traced farther than about 50 or 60 years backward. Sir Hans Sloane informs us, in his History of Jamaica, that forty sloops were employed by the inhabitants of Port Royal, in Jamaica, for catching them, and that the markets there are supplied with turtle as ours are with butcher's meat. The method of taking them at the Bahama islands is by striking them with a small iron peg two inches long, put in a socket at the end of a shaft twelve feet long. Two men usually act for this work in a little light boat or canoe, one to row and gently steer the boat, while the other stands at the head of it with his striker. The turtle are sometimes discovered by their swimming with their head and back out of the water, but they are often discovered lying at the bottom, a fathom or more deep. If a turtle perceives he is discovered, he starts up to make his escape, the men in the boat pursuing him, endeavour to keep sight of him, which they often lose, and recover again by the turtle putting his nose out of the water to breathe; thus they pursue him, one paddling or rowing, while the other stands ready with his striker. It is sometimes half an hour before he is tired; then he flinks at once to the bottom, which gives them an opportunity of striking him, which is by piercing him with an iron peg, which slips out of the socket, but is fastened with a string to the pole. If he is spent and tired by being long purfued, he tamely submits, when hauled, to be taken into the boat or hauled ashore. There are men who by diving will get on their backs, and lay propping down their hind parts, and raising the fore-part of them by force, bring them to the top of the water, while another slips a noose about their necks.

The sea tortoises, or turtles, says Catesby, never go on shore but to lay their eggs, which they do in April: they then crawl up from the sea above the flowing of high water, and dig a hole, above two feet deep in the land, into which they drop in one night above an hundred eggs, at which time they are so intense Nature's work, that they regard none that approach them; but will drop their eggs into a hat, if held under them; but if they are disturbed before they begin to lay, they will forsake the place, and seek another. They lay their eggs at three, and sometimes at four different times; there being fourteen days between every time; so that they hatch and creep from their holes into the sea at different times also. When they have laid their complement of eggs, they fill the holes with sand, and leave them to be hatched by the heat of the sun, which is usually performed in about three weeks. It may be proper to add, that the eggs are about the size of tennis-balls, round, white, and covered with a smooth parchment-like skin. Gmelin mentions several varieties of this species.

CARINATA. The variegated turtle, with fifteen dorso-lateral scales, those of the middle range gibbous towards their tips. This species is larger than any yet discovered, except perhaps the T. carinata. It is called the "loggerhead turtle," and though it resembles the last species, or green turtle, it is distinguished by the superior size of the head, the proportional breadth of the shell, and by its deeper and more variegated colours: but the principal distinction consists in the number of dorso-lateral segments or sections of the shell, which amount confantly to fifteen. The fore-feet are very large and long; the hind-feet much shorter, though broad. In a commercial view, this species is of little importance; its flesh being rank and coarse, and the lamelle of the shell too thin for general use. It is said, however, to afford a good quantity of oil, which may be used for lamps, &c. This turtle is very strong and fierce, and even dangerous. It is an inhabitant of the same seas with the green turtle, but has been found in remote latitudes, even in the Mediterranean, and particularly about the coasts of Italy and Sicily.

MACROPUS. With an ovate, carinate, emarginate shield, and the feet very large and bifurciously unguiculated.

B. Fluviatile, with palmatated feet, shell joined with the sternum by a membrane, and supported in the middle on both sides by two processes of the sternum.

ORBICULARIS. The T. europea of Schneider, with oval, flatish, smooth, dark brown shell, marked with very numerous yellowish spots and streaks. This speckled tortoise of the "Naturalist's Miscellany," or T. meleagris, is of small size, the shell measuring about four or five inches in length, and its disk composed of thirteen, and the margin of twenty-five pieces; the under shell whitish-yellow, tinged towards the joints with brown; the head ovate, somewhat convex above, and flatish on each side and beneath; the skin of the neck lax and wrinkly; the legs short and scaly, feet webbed, fore-feet having five toes and hinder only four; the claws on all the feet sharp-pointed, and crooked; the tail nearly half as long as the body, thin, attenuated, compressed and scaly, and also spotted like the body.

This elegant species is a native of many parts of Europe, being

Vol. XXXV.
being found in Italy, Sardinia, France, Hungary, Prussia, &c., inhabiting lakes and muddy waters, and feeding on aquatic plants, insects, snails, and small fish. The flesh is said to be good as food, for which purpose it is sold in the markets, and occasionally kept in ponds, and fed or fattened with lettuce-leaves, bread, &c. &c. It may be conveniently kept in a cellar and fed with oats, scattered on the floor, which it greedily eats when they begin to germinate. It deposits its eggs in sandy and sunny places in the beginning of spring, which are not hatched, as it is pretended, till the succeeding spring.

**MEMBRANACEA.** With three claws on the feet, and shell frilled on the back, membranaceous, ovate and grey. Found in the sea that washes Guiana. See T. Ferrox.

**TRINITIUS.** With three claws on the feet, the disk of the back rugose and orbicular, the lower border smooth, and nostrils in a cylinder elevated above and projecting beyond the head. Found rarely in the Nile, and supposed to be the same with the former.

**CARTILAGINA.** Shell orbicular, membranaceous, frilled on the back; three claws on the feet, and nope cylindrical and prolonged. This is the T. Boddaerti and a rare species. See the next article.

**Ferrox; Fierce Tortoise.** With ovate, cartilaginous shell; three claws on the feet, and tubular, prominent nostrils. Dr. Shaw queries whether the T. rostrata of Schopf, the T. with palmed feet, &c. of Thunberg, the T. cartilaginea of Boddaert, the T. Boddaerti of Schneider, the T. triunguis of Forkell, and the T. membranacea of Blumenberg, do not belong to this species. This is a remarkable species, and distinguished by the unusual nature of its shield, which is hard and offensively only in the middle part, while the edges gradually degenerate into a flexible coriaceous verge; obtusely marked with five or six transverse bands, and granulated with small warts or prominences, gradually enlarging as they approach the flexible edge; the head rather small, somewhat trigonal, with the snout much lengthened, and the upper part drawn out into a sub-cylindrical form, terminated by the nostrils, and projecting much beyond the lower mandible; the neck, when retracted, thick, and surrounded with many folds of skin, but when exerted, equal in length to that of the whole shell; the legs short, thick, and covered with a wrinkled skin; the feet furnished with strong and broad webs, connecting the three last toes of each; the three first on each foot furnished with strong claws, and the remaining ones unarmed; having, besides the proper toes, two spurious ones on the hind and one on the fore feet, strengthening and expanding the web; the tail short, pointed, and curving inwards; the eyes very small and round; the colour above dark brownish, olive, and below white; the shell marked beneath in a very elegant manner, with ramifications of vellum.

This species is found in Pennsylvania, Carolina, &c. &c.; and is prized, differently from most others of the tribe, of considerable vigour and swiftness of motion, springing towards its affluent, when attacked, with great alacrity and ferocity; about a foot and half long, and fifteen inches broad. It was first described by Dr. Garden. Its flesh is said to be extremely delicate, being equal, if not superior, even to that of the green turtle. The great soft-bodied turtle, described by Mr. Bartram in his Travels, appears to be the same with this. Found in all the rivers, lakes, and pools of East Florida, weighing from 30 to 40 pounds. The T. rostrata of Thunberg seems to be the young of the species above described; and the T. triunguis of Forkell is allied to the same species. Shaw.

**Scabra.** With smooth discoloured head, and shield oval, convex, carinated and rough. The *fabra* of Linnaeus is described as having palmed feet and flattish shell, with all the intermediate scutella elevated on the back. The shell of this species is figured by Seba; it measures about two inches and a half in length, and nearly two inches in breadth; being of a cordate figure, or somewhat pointed at the bottom. Its colour is light-reddish, variegated on the head and shell with white lines and spots; the feet marked with red specks, and having each five toes with sharp claws; the head prominent, and eyes small. Shaw.

**Squamata; Scaly Tortoise.** With ovate body, smooth beneath, but covered above, together with the neck, feet, and tail, with numerous scales. According to Bontius, in his History of Java, this singular species is an inhabitant of fresh waters, where it burrows under the banks, in order perhaps to deposit its eggs. The Javanese call it *taunab*, or the digger, and the Chinese *lary*, or the runner, a burlesque title given to it on account of its flow pace. Its flesh is said to be extremely delicate; and the Chinese use the pulvcrized scales dissolved in water, as a remedy in dysenteric cafes and against the colic. It is said to prey on small fish. This species seems to connect the lizard and tortoise tribes. Shaw.

**Lutaria; Mud or Brown Tortoise.** With flattish shell, and tail half the length of the body; carinated, says Gmelin, behind with three scutella. This species is said to be common in many parts of Europe, as well as Asia, being found in India, Japan, &c. According to Cépède, it is not more than seven or eight inches from the tip of the nose to that of the tail, and about three or four inches in breadth; the disk consists of thirteen pieces, frilled and slightly punctuated in the centre, and along the middle range runs a longitudinal carina; the margin consists of twenty-three pieces, bordered with slight fimbria; the colour of the shell is blackish and also of the skin; the feet are webbed, with five toes before, and four behind; the exterior toe of each foot is unarmed; the tail is stretched out in walking, from which circumstance the animal has been called *Mus aquaticus.* Like other tortoises, it sometimes utters a kind of broken hif. This animal is common in France, and particularly in Languedoc and many parts of Provence; and in a lake, situated in the plain of Durance, such numbers were found as to supply the neighbouring peafantry for more than three months. Although this species be aquatic, it always lays its eggs on land, digging a hollow and covering them with mould. This animal is useful in a garden, which it frees from noxious animals, without doing any mischief itself. It may be domesticated, and kept in a bason or receptacle of water, so contrived on the edges as to give it a ready egress, when it wishes to wander about for prey. In fifth-ponds it is destructive. Shaw. Gmelin mentions two varieties, viz. T. tabulata and T. campanulata.

**Scorpioidea.** See T. Fimbriata.

**Hermanii.** With four claws on the feet, and the tip of the tail ungueulated. See T. Tricarinata.

Gmelin mentions several varieties of this species.

**Carolina.** With digitated feet, gibbous shell, and no tail. This is the T. clausa, or close tortoise, of Linnaeus and other writers, with blackish shell, irregularly spotted with yellow, with obtuse dorsal carina, and bivalve under-shell completely folding the upper, whence it obtains its name. The under part of the shell is so continued round the margin, that when the animal withdraws its head and legs, it is able accurately to close all parts of the shell together, so as to be perfectly secure. The defence of this little animal, which rarely exceeds four or five inches in length, is such, that it is uninjured by a weight of 500 or 600 pounds, and...
and able to walk under this heavy load. It is a native of many parts of North America, found chiefly in marshy situations, and occasionally in the driest and hottest places. It is principally fought for on account of its eggs, which are reckoned a delicacy. It feeds on small animals, as beetles, mice, and even serpents, which it draws into its shell, and crushes to death; and also on various vegetable substances.

**Palestris.** With depressed shell, five claws on the fore-feet, and four on the hind-feet; found in the lagoons of Jamaica, and feeding food in the adjoining meadows. This is the T. terrapin of Schaepp, and the T. concentrica of other writers, with sub-depressed, sub-carinated, oval yellow shell, with the scutella marked by concentric brown zones. The shell measures from four to six inches, or more. It is a native of North America, and sold in the markets of Philadelphia, and elsewhere, under the name of "Terrapin," which name is indiscriminately applied in America to several other species. It is common, as we have already said, in Jamaica, and first described by Dr. Brown, in his "History of Jamaica," who says it is a wholesome and even delicate food. In the Leverian Museum there is a large and beautiful specimen of the shell of this species. Shaw.

**Caspiaca.** With orbicular shell, scaly head, five claws on the fore-feet, four on the hind, and naked tail. Gmelin represents it as a native of Hircania, inhabiting fresh waters, and sometimes to a vast size. The pieces composing the disk are sub-quadrate; those of the border parallellogrammic; the color variegated with black and green; the lower shell blackish, spotted with white.

**Clausa.** See T. Carolina, supra.

**Pennsylvanica.** Tortoise, according to Schaepp, with smooth, elliptic, brown shell, with flatish back, the first range of scutella sub-oblanceolate and sub-imbricated, the first sub-triangular; and according to Gmelin, with five claws on the fore-feet and four on the hind, and the apex of the tail hatory and acute. This is the small mud tortoise of Edwards; the shell measuring three or four inches in length. The head on the parts surrounding the jaws and eyes is of a reddish-yellow colour; the upper part, as well as the neck, legs, and tail, dull; feet webbed; the tail small. It is a native of North America, and is found in Pennsylvania, &c. inhabiting muddy waters. When living, it is said to exude a strong musky odour. Mr. Schaepp mentions a variety, and another occurs in the Leverian Museum. Shaw.

**Serpentina.** The snake tortoise, characterized by Schaepp as having an ovate, depressed, triply carinated, sharp-scaled shell, rounded and acutely ferrated at the posterior margin; and by Gmelin as having digitated feet, sub-carinated shell, behind obtuse, and acutely quinidentated. This is the ferrated tortoise of Pennant. It is a native of North America, inhabiting stagnant waters, growing to the weight of fifteen or twenty pounds, or more, preying on fish, ducklings, &c. seizing its prey with great force, and at the same time stretching out its neck, and hissing at the same time. The head is large, depressed, triangular, and covered with a scaly and warty skin: the orbits of the eyes are oblique; the mouth wide; the mandibles sharp; the neck covered by scaly warts; the toes distinct; the tail straight, and about two-thirds the length of the shell; and the under part of the body covered by a looite, wrinkled skin, bafet with smallish foot-seales and granules. This animal conceals itself in muddy water, leaving out only a part of its back, and thus appearing to be a stone or other inanimate object, more easily obtains its prey. In New York it is known by the title of the "snapping tortoise."

**Spengeli.** See T. Serrata, infra.

**Fimbriata.** Tortoise, according to Bruguiere, with oval, sub-convex, triply carinated shell, sub-digitated feet, cylindrical hout, and neck fimbriated on each side. This is an animal of very singular and disagreeable appearance. The shell is about fifteen inches or more in length, and its breadth eleven; but the whole animal, from the nose to the end of the tail, is two feet three inches. The head is large and flat, rounded in front, and edged on the sides with warty and wrinkled membraneous appendages, about five inches wide, and covered behind by a three-lobed prominence; the nose resembles a proboscis, cylindrical, ten lines long, truncated, pierced by the nostrils, at the tip, where they are separated by a cartilaginous division; the eyes are round, seated at the base of the proboscis, and ten lines distant from each other; the mandibles are equal in length, and entire; the glove of the mouth is wide; the neck seven inches long, and four and a half broad: above flat and warty, and furnished on each side with five fimbriated membraneous appendages disposed lengthwise, and alternately larger and smaller; the under part of the neck is beset with four similar appendages, placed opposite to the two on the head, and increased by two longitudinal wrinkles: the fore-feet are scaly and warty, having five indistinct toes, with as many longish sharp claws, convex above and flat beneath; the hind-feet are also scaly, with less indistinct toes, having four claws, the fifth toe being unarmed, and very short: the tail is an inch long, bent slightly, and covered with a granulated skin: all the thirteen semicircular pieces, of which the shell consists, are wrinkled and irregularly notched at the hind part; the twenty-five marginal pieces are almost square, radiated on the surface with oblique wrinkles, and toothed in the interior edge. The colour of the whole is brown, somewhat paler beneath. This animal is said to be a native of Guiana, but is now rare in the rivers of Cayenne, as it has been plentifully taken by fishermen, it being considered as excellent food. It feeds on aquatic plants, and wanders by night by some distance in search of pasturage. It has been faggotted, but without certainty, that this is the T. scorpionides of Linnaeus. Shaw.

**Picta.** Tortoise with plane shell, marked on both sides with a double spot of a black-blueish colour; scutella surrounded with a yellow margin, and neck flirated longitudinally with yellow and black; or tortoise with oblong, slightly convex, smooth, brown shell, with the scutella bordered with yellow. This is the cinereus tortoise of Brown's Zoology, and sufficiently distinguished from all others by the remarkable colours of the shell. This is a fresh-water species, and inhabits flow and deep rivers in North America, and should have been referred by Gmelin to his second class. In clear sunny weather these animals are said to assemble in multitudes, fitting on the fallen trunks of trees, stones, &c. and immediately plunging into the water on the least disturbance. They are said to swim very swiftly, but to walk slowly; to be able to continue many hours entirely beneath the water, but not to survive many days if kept out of their favourite element. They are very voracious, destroying ducklings, &c. which they seize by the feet, and drag under water. They are sometimes used as a food. The colour, as has been above observed, varies; being sometimes of a blackish-brown, at other times of a reddish-chestnut: the yellow markings are also either pale or deep in different individuals, and sometimes whitish; the inferior, or under edges of the upper shell, as well as the upper edges, or commissures of the lower, are elegantly streaked with black, as if artificially painted, and this variation is continued over the skin of the sides of the body. Shaw.

**Guttata.** Tortoise spotted, with oblong, moderately

[3 E 2] convex,
cewes, smooth, brown shell, with scattered yellow spots. This is T. punctata of Schepf. It is a rather small species, and a native of North America, inhabiting rivers and lakes. The young are scarcely larger than pigeon’s eggs, and are very black, beautifully spotted with gold colour.

**LONGICOLLIS; Long-necked Tortoise.** Smooth, ovate, with extremely long neck. This species is a native of New Holland, and is of the river or fresh-water kind. The colour of the whole animal above is deep olive-brown; beneath paler, and inclining to whitish. Shaw.

C. *Land tortoises, with elevated unguiculated feet, coeves shell, and bony connivences joined with the sternum.*

**DENTICULATA; Tortoises with sub-digitated feet, and orbicular-crested shell, with denticulated marginal segments.** The shell is of a pale yellowish-brown colour, about four inches long and three broad, covered on the disk by broad hexagonal and pentagonal scutella, of a flattened form, with a large distinct middle space, granulated by small tubercles, and the remainder marked by five lines or furrows. The edge of the shell consists of twenty-three pieces, projecting in a ferrated manner round the outline. It is supposed to be a native of North America. The feet, in Gmelin’s edition of the Syllena Nature, are said to be without distinct toes; and the tail short.

**GRECI;** The common land tortoise, with sub-digitated feet, hinder part of the shell gibbous, lateral margin very obtuse, and feutella flattish. Gmelin.

It is described by others as the tortoise with hemispherical black and yellow shell, gibbous behind; the pieces composing the disk convex, and the sides obtuse. This tortoise is supposed to be a native of almost all the countries bordering on the Mediterranean sea, and to be more frequent in Greece than in other regions. It is found in the European Archipelago islands, and in Corfica and Sardinia, and also in many parts of Africa. In Greece it is an article of food; the eggs are eaten boiled, and the blood is often swallowed recent. In September the animal hides itself under ground, and emerges in February; it lays its eggs in June, in a small hole on a funny spot, out of which, after the first rains of September, the young are hatched. In England it returns about the end of October, and re-appears about the middle of April; but these scasons vary with the climate and weather, &c. The males often fight, butting at each other with a noise that may be heard at a considerable distance. This animal lives to a most extraordinary age, exceeding the period of a century. One of the most remarkable instances is that of a tortoise introduced into the archiepiscopal garden at Lambeth, in the time of archbishop Land, and as near as can be collected from his history, about the year 1633, which continued to live there till the year 1753, when it was suppos’d to have perished rather from accidental neglect on the part of the gardener, than from the mere effecl of age. This tortoise has had the honour of being commemorated by Derham, and many other writers, and its shell is preserved in the library of the palace at Lambeth.

The general manners of the tortoise, in a state of domestication in this country, are very agreeably detailed by Mr. White, in his History of Selbourn. “A land tortoise,” says Mr. White, “which has been kept thirty years in a little walled court, retires under ground about the middle of November, and comes forth again about the middle of April. When it first appears in the spring, it discovers very little inclination for food, but in the height of summer grows voracious; and then, as the summer declines, its appetite also declines; so that for the last weeks in autumn it hardly eats at all. Milky plants, such as lettuces, dandelions, low-thistles, &c. are its principal food. “The tortoise is totally a diurnal animal, and never flies after it becomes dark. The tortoise,” adds Mr. White, “like other reptiles, has an arbitrary homach, as well as lungs, and can refrain from eating, as well as breathing, for a great part of the year. I was much taken with its facility, in differing those that do it kind offices; for as soon as the good old lady comes in fight who has waited on it for more than thirty years, it hobbes towards its benefactresses with awkward slowness; but remains inattentive to strangers. Thus, not only the ox knoweth his owner, and the ass his master’s crib,” but the most abject and torpid of beings distinguishes the hand that feeds it, and is touched with the feelings of gratitude. This creature not only goes under the earth from the middle of November to the middle of April, but sleeps great part of the summer; for it goes to bed in the lengthiest days at four in the afternoon, and often does not stir in the morning till late. Besides, it retires to rest for every shower, and does not move at all in wet days. When one reflects on the state of this strange being, it is a matter of wonder that Providence should bestow such a feeble waft of longevity on a reptile that appears to relish it so little as to squander away more than two-thirds of its existence in a joyless state; and be to itself and its kind so torpid and so slow in the progress of its nobler affections.”

**CARINATA; Tortoises with digitated feet, and gibbous shell, with the four first dorsal scutella carinated, and entire sternum; found in warm regions, but very little known.**

**GEOMETRICA.** Shell ovated, with all the elevated scutella above plane, marked with yellow striae issuing from the centre in form of a star; or, according to others, this is the tortoise with ovate black shell, and elevated scutella radiated with yellow; the T. teledata minor of Ray. The pieces of which the disk of the shell consists are very prominent, rounded, or squared pretty distinctively with numerous lines on their sides, and terminated above by a yellowish, flat, square, or rather hexagonal roughened space or centre, from which proceed, in a radiated direction, several well-defined yellow striae towards the edge; thus constituting a beautiful kind of geometrical appearance on the black ground colour on which they are disposed: the marginal pieces, which are commonly twenty-four, sometimes twenty-six, in number, are also streaked with yellow, but in a somewhat different style.

**The native country of this beautiful tortoise is perhaps not truly afeerted; though the shell is more frequently seen in Europe than that of almost any other kind. It is said, however, to inhabit Asia and Africa, and even to be found in America. According to Mr. Thunberg it is particularly common in shrubby places about the Cape of Good Hope. It is said to lay about twelve or fifteen eggs at a time.**
time. The count de Cépède supposes this species to be the Terrapin of Dampier, which that navigator represents as very beautifully variegated, and as delighting in moist and marshy places; adding, that its flesh is esteemed as a food, and that it is found in plenty on the coasts of the Pine islands, between the continent of America and Cuba: they are found in the forests, where they are easily taken: the hunters mark them on the shield, and let them wander about the woods, being sure to find them again at no great distance, every one easily recognizing his own property, and afterwards carrying them to Cuba. — Shaw.

**Pusilla; Little Tortoise.** With sub-digitated feet, and hemispheric shell, with convex, trapcezial scutella, frilated on the margin, and punctuated on the disk. This is the African land tortoise of Edwards, and thus described by him from a specimen obtained from Weil Barbery. "The iris of the eye is of a reddish hazel colour; the lips hard, like the bill of a bird; the head covered with scales of a yellowish colour; the neck, hind legs, and tail, covered with a flexible skin of a dirty flesh-colour; the fore-legs covered with yellow scales on their outsidies, which are partly exposed when the legs are drawn in; the shell round, and pretty much rising on its upper side, and flat beneath; the pieces or compartments are of a yellowish colour, clouded and spotted with large and small irregular dusky or blackish spots, and are also ferrugous or creased, the creases being, one within the other, till they reach the top or middle part of each; the tail is thick, feally, and about an inch in length; and the vent is situated within the tail itself near the base; there are five claws on the fore-feet, and four on the hind, all strong, black, rather bowed, and sharp-pointed." This species is found at the Cape of Good Hope, and much resembles the T. graeca.

**Indica.** Tortoise with brown shell, reflected above the neck, and marked with a tubercule on the three upper scutella. This is the great Indian tortoise, first described by Perrault in the "History of Animals," published by the Royal Academy of France, and confounded by M. Cépède with the T. graeca. It is found in India, on the coast of Coromandel, &c. Of this there are two varieties, one brought from the Cape of Good Hope, and another from the Southern islands.

**Sulcata.** Tortoise with a tail, digitated feet, gibbose shell, and scutella lineated and circumcised with a furrow; or tortoise with brown ovate shell, with furrowed scutella yellow on each side. This is one of the larger species of land tortoises, being about a foot or more in length from the nose to the tip of the tail. The shell is very convex, and has the general habit of the graeca and geometrica as to shape. This species is said to be a native of the West Indies, and perhaps may be the "Hicater" of Brown, described in his "History of Jamaica." Dr. Shaw suggests that this species may be the same with T. tabulata.

**Planaria.** Tortoise with digitated feet, and shell ovate, convex, and smooth. Found at Surinam.

**Americana Terrestris.** Tortoise with oval, gibbose shell; scutella yellow in the middle of the disk; the margin marked with shining, black, furrowed, lateral polygons. This is conjectured by Gmelin to be the labotii of the Brazilians, and the cagado of the Portuguese. Found in South America.

**Tabulata.** Tortoise of oblong, gibbose, brown shell, with the scutella of the disk rectangular and furrowed; with yellowish centres. This was first described and figured by Seba's "Theaurus," and there said to be a native of Brazil, though it is believed to be rather an African species. The general length of the shell is about five or six inches: suspected to be the same species with T. fulcata, supra. Shaw.

**Marginata.** Tortoise with blackish-brown, oblong, gibbose shell, variegated with yellow, widened and depressed on the hind part. The true native country of this species is not very distinctly known. Mr. Schreber inclines to think that it is an American species. Cépède has confounded it with the T. graeca. Shaw.

**Radiata.** Tortoise with ovate black shell, and flatish scutella radiated with yellow. This is the great chequered tortoise-shell of Grew's Maf. Reg. It has been concluded by some persons, from a general resemblance in the pattern of the shell, and a similarity in colours, that this is the same species with T. geometrica, or a variety of it. But Dr. Shaw has pointed out a variety of differences between them, such as warrant our flating that the two shells are perfectly distinct. Grew, who has described this species, says that its native country is Madagascar; but Dr. Shaw suggests that it is also a native of Jamaica, and that in characters and size it agrees with the "Hicater" tortoise mentioned in Brown's Zoology. Shaw.

**Rugosa.** Tortoise wrinkled, with black wrinkled shell, mottled and variegated with yellow; with the middle dorsal pieces subquadangular, and fiddle-shaped. In the Leverian museum there is a variety, or perhaps a sexual difference of this species.

**Elegans.** Tortoise with orbicular, convex, yellow shell, with transverse, oval, brown spots. Seba has described it under the name of the T. terrestris Cellonica elegans minor. Shaw.

**Areolata.** Tortoise with moderately convex shell, with subquadangular, elevated, deeply furrowed scutella, and depressed rough areole. This is described by Seba under the appellation of T. terrestris Brasilienis.

**Serrata.** Tortoise with depressed yellowish shell, minutely streaked with dusky specks; all the scutella of the disk curvate, and the hinder margin of the shell serrated. This is supposed by Dr. Shaw to be the T. spengleri of Gmelin's Linnean System.

**Tercarinata.** Tortoise with oval, slightly convex, shell, with entire margin, and all the scutella of the disk curvate. This species agrees, in shape and other particulars, with Linnaeus's description of his T. orbicularis. Shaw.

**Scripta.** Tortoise with orbicular depressed shell, with all the scutella marked by variously-formed characters, and the marginal pieces spotted beneath. This is the T. scabra of Thumber. Its native place is not ascertained. Shaw.

**Galeata.** Tortoise with depressed oval shell, with the three middle scutella sharply curvate, and twenty-four marginal pieces. The native place of this species is not known; but it was brought to Mr. Retzius from India, and lived two years kept in fresh water; it fed on bread, &c. and sometimes on flies. From the beginning of October to the middle of May it remained without food, fearfully elevating its head above the water. It delighted in fine weather, and endeavoured to climb up the sides of the vessel occasionally, in order to enjoy its influence. It is doubtful, whether this be the T. scabra of Linnaeus. It is called galeata by Retzius, from the armed or cataphract covered covering of the head. Shaw.

**Granulata; Chagria Tortoise.** With orbicular, flatish, granulated shell, with cartilaginous border. This species seems to be allied to the T. ferox, having the shield furnished with a cartilaginous and flexible border. It is described by M. Cépède, and was brought from India by M. Somerat. Shaw.

Dr. Shaw, among the sea-tortoises or turtles, has described
the turtle with green variegated shell, so named by the count de Cépéde. These turtles are said to be found in great numbers in the Southern ocean, and about Cape Blanco, in New Spain. They also occur in the gulf of Mexico, and many of the large American rivers, both above and below the line; but they have never been discovered in the seas of the Old Continent. The flesh is said to be very delicate; and is even preferred in some places to that of the common turtle. M. Bonarea is said by Cépéde to have first described this species.

The "trunk turtle," or *tortue nasiforme*, has not been accurately described. Count de Cépéde says, that it is a native of the American seas, and bears a general resemblance to the common or green turtle; but is distinguished by having a large soft tuberole on the tip of the snout, in which are situated the nostrils. It is eaten in the same manner as the green turtle, and is chiefly found in the equatorial regions. (Shaw's General Zoology, vol. iii. pt. 1.)

*Tetudo* *Peliformis Quadrata*, an hemispherical vault, or ceiling of a church, &c. in which four windows are so contrived, as that the reft of the vault is quadrable, or may be squared.

The determination of these windows was a problem proposed to the great mathematicians of Europe, particularly the cultivators of the new calculus differentials, in the Acta Eruditorum Litterae, by fig. Viviani, under the fictitious name of A. D. Pollfle pelliforme, which was the anagram of poltrimi Galilei dicipulo.

It was solved by several persons, particularly M. Leibnitz, the very day he saw it; and he gave it in the Leipzig Acts in a variety of ways; as also did M. Bernouilli, the marquis de l'Hospital, Dr. Wallis, and Dr. Gregory.

**TESTWOOD** in Biography, a lingh man in the choir of Windor, was burnt for his intemperate zeal in the cause of Protestantism, 1544, when Marbeck was Lisewise condemned, but afterwards pardoned.

**TESZERSKEY**, in Geography, a town of Croatia; 6 miles S.W. of Novi.

TET, a river of France, which rises in the Pyrenees, a little above Mont Louis, and runs into the Mediterranean, 7 miles E. of Perpignan.

**TETANUS**, in Medicine, a disease consisting in a spasmodic contraction of several of the muscles of voluntary motion, and more particularly of those which shut the lower jaw: and this being a constant and prominent symptom, the affection is commonly known by the name of *locked jaw*. The ipasm of the muscles is of the tonic kind; or that in which the excessive contraction continues for a considerable time, without any interval of complete relaxation: in which respect it is opposed to *crisis* ipasms, or convulsions, where the contractions and relaxations alternate in rapid succession. (See Convulsion and Sparix.) The powers of sensation and of intellect remain unimpaired in tetanus; in which respect also it is contrasted with epilepsy.

Tetanus admits of many varieties and modifications, on which the older nomenclature had founded different species of the disease. A rigidity of the muscles of the lower jaw was denominated *trismus*. When the muscles of the back were chiefly affected, the disease was termed *opisthotonos*: when those of the fore-part of the trunk, with the flexors of the extremities, were the seat of ipasms, it was called *emprophibias*. Sometimes, though very rarely, the ipasms are confined to one side of the body only, bending it strongly to that side; a form of the disease which has been named by Sauvages *tetanus lateralis*, and by later writers, the *pleuriphtotonos*, or *pleuriphtotonos*. It was only when the ipasm was almost universal, that it was considered as entitled to the appellation of *tetanus*. Of late years, however, these names have very properly been considered as expressing only varieties of one and the same affection, differing merely in severity, but arising from the same causes, and requiring the same mode of treatment.

These various forms of ipasms often follow one another in succession in the same case, and mark the progress of the disease through its different stages. Thus the *trismus*, or locked jaw, is only a part or prelude of *opisthotonos* and *tetanus*; and though it may prove fatal at this early period, the imperfect form in which the symptoms of a disease, which has been thus arrested in its course, may appear, is by no means sufficient to establish a generic difference in the disease itself. There appears, however, to be some foundation for a division of cases, according to their duration, into the acute and the protracted: the former being very little under the control of medicine, and in almost every instance fatal; the latter being milder in its character, and often yielding, if proper means are employed for its subjugation.

Another ground of distinction among the different cases of this formidable disorder, is derived from the nature of the causes from which they have originated. The most usual causes are certain mechanical injuries to the body, more especially such as are attended with a puncture or laceration of a nerve: on other occasions, it may be the effect of the sudden application of cold, when the body has been previously overheated; and, in a few instances, it has appeared to arise spontaneously; that is, when it could not be traced to any external exciting cause whatever. Tetanus arising from wounds is, in general, slower in its progress than that which proceeds from cold; but is attended with more danger to life.

On some occasions the disease comes on suddenly, and with great violence; but more commonly the attack is gradual. It is often eight or ten days, and sometimes much longer, after the infliction of a wound, before the first symptoms of tetanus make their appearance; and this frequently happens when the effects of the injury on the part itself appear to have subsided; when the wound has healed, and no pain or uneasiness has remained. Those cases in which the disease is more flow in its approach, afford the best opportunity of tracing the natural succession of symptoms; and the first uneasy sensation which is then observed, is that of a slight stiffness in the back part of the neck and about the shoulders, which, gradually increasing, impede the rotary motions of the head, and also its flexion forwards: so that the patient cannot look downwards, or to either side, without turning his whole body. This uneasy feeling, being chiefly felt on motion, very much resembles what occurs from rheumatism, but it is accompanied with a sense of general latitude and debility. The rigidity now extends from the back of the neck to the muscles of the jaw, and of the root of the tongue, so that both mastication and swallowing become difficult and painful; and at length impossible. The attempt at deglutition is attended with convulsive efforts; especially when liquids are endeavoured to be swallowed. So great is the distress which accompanies these convulsions, that the patient becomes very reluctant to renew the trials, and refutes all nourishment; and it sometimes inspires him with even a dread of the sight of water.

As the disease advances, another set of symptoms appears, bringing
TETANUS.

bringing with them a considerable increase to the sufferings of the patient. A sudden and violent pain is felt shooting from the lower extremity of the sternum to the spine, in the situation of the diaphragm. These spasms recur from time to time, at short intervals; and at each recurrence, give the signal for an immediate aggravation of all the other spasms. The muscles of the neck and jaw are immediately called into violent action; the head is pulled strongly backwards; and the jaw becomes firmly clenched. These periodical accessions of spasm become more severe, and their effects more durable; so that the head continues to be in a state of retraction, and the jaw is permanently closed, the teeth being so firmly set together, as not to admit of the smallest opening. Such constitutes what may be regarded as the first stage of the disease; which sometimes takes up three or four days. At other times the disease establishes itself, with its whole train of dreadful symptoms, in a few hours; in which case the danger is imminent; as death generally takes place in from twenty-four to forty-eight hours, and the patient very rarely paffes over the third day.

The continuance of the disease, if the patient survive the immediate attack, is marked by the increasing spasm of the diaphragm, which now returns every ten or fifteen minutes, and is instantly succeeded by a stronger retraction of the head, and rigidity of the muscles extending down the back, along the spine, and affecting even those of the lower extremities. Their contractions increasing in force, the body is frequently raised in the form of a bow, reiting upon the head and feet alone: a state which is more particularly designated asphylotos. The countenance, as is observed by Dr. Chalmers, is pale and contracted; the mafioid, coraco-hyoid, and sternohyoid muscles, together with the others concerned in declination, and the deltoid and pectoral muscles, are most violently contracted, so that the shoulders are strongly raised forwards, and the arms are stretched out, or drawn across the body; but the wrists and fingers seem not to be affected. In a few seconds, a remission takes place; the shouldets and arms recline, and the inferior extremities relax; yet not fo entirely, but that generally such a degree of rigidity continues, as to prevent their being bent, even when this is attempted by another perfon. The muscles on the sides and fore part of the neck continue still contracted, although not so strongly; but their action is overcome by the number and strength of the posterior ones; so that the contraction of the head constantly remains. The patient breathes quick for some minutes, as if he had been excessively exercised, and the pulse is small, fluttering, and irregular, but both become more calm and slow. The face is sometimes pale in the intervals, but oftener flushed; and the whole countenance expresses strong appearances of the most melancholy ditibilities; as well on account of the terror the patient feels at the approaching paroxysm, as from the torture he has suffered from the last, of which the painful contractions he still feels perpetually remind him. He, for the most part, desires to lie still as much as possible, and to avoid all attempts at drinking, speaking, or any kind of motion; all of which are apt to occasion a return of the spasm in all its horrors. Some, indeed, are solicitous to try a change of position, in hopes of obtaining one of greater ease; but the act of turning the patient never fails to bring on an attack of the convulsion, by which the head is drawn back to the spine; and it is at length found, that the best means of avoiding this is for him to lie perfectly still on the back.

It may, in general, be observed, that the extensor muscles are affected with spasm before the flexors. In the lower extremities, indeed, both the flexor and extenor muscles are commonly at the same time affected, and keep the limbs rigidly extended. The flexors of the head, and the muscles that pull down the lower jaw, become affected in the progress of the disease, together with the abdominal muscles; so that the belly is strongly retracted, and feels hard, like a piece of board. The spasm of these and the other flexor muscles, becoming so powerful as to balance the action of the extensors, is a circumstance that marks the advance of the disease, and may be regarded as constituting the commencement of a third stage. In this situation the body and limbs are perfectly straight and rigid, and incapable of being moved in any way; and it is to this condition that the term tétanust has been more especially applied. It is a state of the most exquisite suffering: the patient is on the rack from the continual recurrence of the spasm, which has scarcely any remission. The recti muscles of the abdomen often contract unequally, producing the appearance of hard balls in particular parts. The whole belly is drawn inwards, and does not yield in the least to the defeat of the diaphragm in inspiration. Although the lower extremities are always rigid at this period, yet their action is so violent during the height of the paroxysms, that were it not for the flanders by, the patient would be projected feet foremost off the bed; or would, at other times, be pushed upwards with such an impetus, as to strike the head with great force against whatever might happen to be in the way. Occasionally, the flexor muscles acquire the preponderance over the extensors, and the trunk of the body is bent forwards, the chin being fixed to the breast. This is what has been called emprosthotonos, and occurs only in the most violent, and of course the least frequent form of the disease. It would appear from some cases reported by Sauvages, that these opposite states are disposed to alternate with one another.

In extreme cases, there are hardly any of the voluntary muscles that remain in their natural state. The face and eyes are distorted; the tongue is suddenly darted out between the teeth, and often miserably lacerated from their closing at the same moment. Even the small muscles of the ear partake of the spasmatic action, which so universally prevails in the system. While the tongue is thrust out, the muscular flesh, which is situated between the arch of the lower jaw, and the upper part of the trachea, is drawn upwards within the throat. The countenance is much contracted; a general sweat breaks out; the eyes are watery and languid; and a pale or bloody froth bubbles out between the lips. Tétanust in these violent forms, is, perhaps, the most painful disease that can affect the human frame. So exquisite a degree of pain would scarcely be compatible with life, were it not occasionally assuaged by the short and imperfect remissions of spasm which occur. A more continued and severe spasm, or a general convulsion, generally finishes the tragedy, and releases the unhappy victim from all his misery; or, if already too exhausted by the severity of pain to admit of this mode of termination, delirium often ensues, protects the patient by a happy insensibility to further suffering, and smooths the avenue to death, which is then preceded by a general relaxation of the spasms.

Such are the symptoms which peculiarly belong to tétanust, and it is, perhaps, the most remarkable circumstance attending the disease, that hardly any function is primarily affected, except that of muscular action. The senses and appetites are perfect and entire; the intellectual functions are undisturbed; and the natural functions proceed in their usual course. Fever is neither an essential nor a common attendant on the disease. In the first stage, when the spasm is confined to a few muscles, the pulse is not affected; it becomes accelerated only when the spasmic actions are general,
general, and this merely in consequence, as it would appear, of the mechanical effect produced on the blood-vessels by the contractions of the muscles, which will hurry on the circulation, and throw the blood upon the heart in larger quantity than usual, rendering the pulse contracted, frequent, and irregular. The respiration is hurried from the same cause, and the temperature of the body, as might be expected, is increased in the same proportion. That these symptoms are not the effect of fever, appears from the state of the blood, which is flated to be of a rougher texture than natural, and never exhibits the bufly coat, as in inflammatory disease. This circumstance is particularly noticed by Dr. Clephane, and also by Dr. Chalmers; and the remark has often been verified by subsequent observers. On some occasions, indeed, when the disorder is very violent, the arterial actions are increased, and a febile state prevails; and this appears to take place more frequently when the disease has originated from cold, than when it has been excited by wounds. The skin is at first natural, but, as the disease advances, is covered with a cold sweat. The tongue is always moist. Vomiting sometimes takes place early in the complaint, but it commonly subsides in the progress of it: it is even usual for the appetite of hunger to remain through the whole course of the disease; and what food can be got down appears to be sufficiently well digested. Some local effects seem to be attributable to the contractions of the abdominal muscles. The sphincter of the bladder is occasionally affected with spasm, so as to impede the discharge of urine, which is voided with pain and difficulty; at other times, its secretion is suppressed. When it can be observed, it is flated as being high-coloured, and somewhat turbid. The bowels are found to be, in every instance, obstinately coltive, a flate which may partly be accounted for by the effect of opiate, which are so generally administered for the cure: but which, independently of this cause, appears to be inherent in the disease itself. The bowels require the most drastic purgatives; and there is a great fene of uneasiness about the precordia. In the latter stages of this disorder, indeed, when the powers of life begin to decline from the vast expenditure of energy occasioned by the violent muscular actions, every function in the sytem partakes of the general disorder; the intellect gives way, and the patient sinks from exhaustion alone, if a general convulsion does not occur to hasten his end. It is mentioned by Dr. Cullen, that, in several cases, a military eruption has appeared upon the skin; but he expresses a doubt whether this was a symptom of the disease, or the effect of a certain treatment of it. It has not been observed, he adds, to denote either safety or danger, or to have any effect in changing the course of the distemper.

From the more violent forms of the disease, hardly any instance of recovery has been known to take place. On the other hand, the more protraction of the symptoms is an indication of the comparative mildness of the disease. Few patients fall a sacrifice after the ninth or tenth days, which period they never could have attained, unless the violence of the complaint had in a great measure subsided. In this milder form, however, it may be prolonged several weeks; and sometimes the spasmodic disposition remains, even for months, before health is completely restored. The pulse, in these cases, continues slow and hard, and the belly bound: but if blood be drawn, it does not exhibit any difference from its usual state. Under every circumstance of recovery, indeed, the convulsive labours long under general debility, and cannot, for months, raise himself from a supine or recumbent posture without assistance, nor without pain.

Occasional deviations from the course above described are met with in different cases; but they are not of sufficient importance to lay the foundation of any distinct variety. The most singular of these anomalies is the one recorded by Dr. (now Sir Gilbert) Blane, of a case in which tetanus prevailed to a very considerable extent, without affecting the patient with the least degree of pain. The spasms were, in this instance, accompanied with a tingling sensation, which was even rather agreeable than distressing. The case, however, terminated fatally: but to the latt, no pain was experienced. In two cases mentioned by the same author, the spasms affected only the side of the body in which the wound was situated.

The result of dissections of patients who have died of tetanus, has thrown no light whatever on the nature of this terrible affection. Sometimes there are found slight effusions within the cranium; but, in general, no morbid appearance whatever can be detected in the head. There appears to be always more or less of an inflammatory appearance in the villous coat about the esophagus and stomatch in the neighbourhood of the cardia. But those who are conversant with dissections, must be well aware that these appearances are common to a great number of discesses, and are uniformly met with in every case of rapid or violent death. Besides the redness and increased vascularity of these parts, M. Larrey flates that he found the pharynx and esophagus much contracted, and covered with a viscid reddish mucus. Dr. MaArthur found, in several cases, the interlines much inflamed; and in two of them a yellow waxy fluid, of a peculiar offensive smell, covering their internal surface: but whether the inflammation was primary, or only a consequence of the pressure of the abdominal muscles, which contract so violently in this disease, he is unable to decide. See Medico-Chirurgical Transactions, vol. vii. p. 475.

Tetanus is a disease much more prevalent in hot than in cold climates. It is comparatively a rare disease in this island; but even here, the effect of warmth in giving a predisposition to it is sufficiently observable. It is more common in the south than in the north of England, and is much more seldom met with in Scotland than in England. It is febibly more frequent in warm than in cold leasons. In warm, and especially in tropical climates, it may be regarded as an endemic disease, appearing at all seasons, but especially during the prevalence of the greatest heats. Warmth operates by increasing the mobility of the sytem, while at the same time it tends to diminish the positive strength of the fibre. The febility to all impressions is greater in hot climates, while the power of resisting the caufe of injury is lessened: hence the greater predisposition to spasmodic difcases in general. The natives of hot climates do not enjoy a greater exemption from tetanus than European settlers. Negro slaves are peculiarly liable to its attacks. It affects all ages, sexes, constitutions, and complexion: but, ceteris paribus, is more apt to feize upon those in whom the largest share of vital power has been bestowed upon the muscles of voluntary motion. Hence it attacks more readily the robust, and those who are accustomed to much bodily labour. Partly on this account, and partly from their being more exposed to the occasional causes of the disease, men are much more frequently the subjects of tetanus than women.

In the torrid zone, the most frequent exciting cause of tetanus is the application of cold when the body is heated. It is often induced by the alternate exposure to the scorching heat of the sun, and to the heavy showers which frequently occur in tropical regions, and produce great and sudden vicissitudes of temperature. Sleeping out of doors after a hot day, especially on damp ground, or in a situation where a stream of cool air is admitted to the body, is often followed by tetanus in hot climates. Dr. Chalmers relates that a young man chose to cut off his hair and shave his head on a warm
warm day in March, and went to bed without a cap: but
the weather changing and becoming cold in the night, he
was feizd with tetanus, and the next morning was found
rigid with the difcase. The imprudent ufe of the cold
bath, or even a draught of cold water, when the body has
been warm by exercife, has frequently brought on tetanus.

In temperate climates, on the other hand, the difcane
feldom aries from the application of cold; although there
is one well-atteiled infance mentioned by Dr. Gregory in
his lectures, of its occurring from this caufe in Scotland:
but it is more frequently the confequence of lacerated or
punctured wounds, and is particularly incident to injuries of
nerves, and of tendinous parts. It fometimes follows the
amputation of a limb; and it would appear that wounds of
the joints, particularly thofe of the hands or feet, are
more pefcicably liable to produce tetanus. In warm
countries, the flighted cut or bruife is in danger of being
fucceeded by this formidable malady. Hence few of thoje
that are wounded in battle recover; and few perforve any
considerable operation. It has been fuppofed by many, that
tetanus arofe from the partial division of fome nervous fibres,
in confequence of which the undivided fmalaments were
unequally and violently flrecthed: a flate which would be
remedied by their complete division. Experience, however,
the flubborn enemy to fo many hypothehes, has by no means
proved favourable to this opinion. It has alfo been flated
to be more frequently the refult of wounds, which remain
in a fiate of great irritability, without proceeding to fup-""
TETANUS.

secure the patient from the approach of tetanus. But the difficulty is here to estimate the probability of the patient's having the disease, as nothing short of the certainty of its being at hand, could well justify the operation.

As it is matter of experience that an early and highly irritable and painful condition of the wound has a tendency to excite tetanus, as well as a state in which the discharge is of a peculiar unhealthy character, or is suppressed altogether, our immediate objects should be to allay as much as possible the local irritation, and to re-establish a healthy secretion of pus. Mechanical causes of irritation should as much as possible be obviated, by early attention to remove splinters of bone, balls, or other foreign bodies, that may be lodged in the wound. Poultices and soothing applications will answer the double purpose of quieting local inflammation, and bringing on healthy suppuration. The irritability of the surface may sometimes be most effectually destroyed by lunar caustic, after which, an emollient poultice may be applied. An opposite plan of treatment has been recommended by Dr. Ruh, namely, that of exciting considerable inflammation in the wounded part, by epithems of turpentine, and other highly stimulating applications; which, though it may in certain cases have succeeded in preventing tetanus, does not appear to be generally applicable, and seems accordingly to have been abandoned. On the contrary, it has of late been the universal practice in the navy, to add tincture of opium to the dressings applied to wounds, with a view of preventing tetanus. With the intention of re-exciting suppuration where there is no discharge, M. Larrey recommends the application of blisters as near as possible to the wound, and addsuces influences of succussion from this mode of treatment.

But the cure of tetanus, when once it has commenced, is to be fought for more by the use of general, than of topical remedies. The feat of the disorder has been transferred to the brain and nervous system, and our efforts must be directed to allay their inordinate actions. The plan from which theory would lead us to expect most successe, is that of exciting some new action in these organs, by which their energies would be directed into some different channel, and the existing morbid action would be suspended and superseded. The remedies which exert the most powerful immediate effects in the nervous system, are accordingly found to be the most efficacious in the cure of tetanus. Opium, wine, and other highly diffusible stimulants, digitalis and other narcotics, the sudden affusion of cold water, bleeding, purging, impregnating the system with mercury, the exhibition of arsine, of oil of turpentine, of alkalis, and of ipecacuanha, have respectively been resorted to, and with very various, and in general but limited success. The same methods from which cures have been obtained in the milder cases, generally fail to make the least impression on the disease in its feverish forms. We learn from the valuable report of Sir James Maclagan, already alluded to, that there were very few, out of several hundred cases that occurred in the British armies during the late campaigns on the Peninsula, where this difease had made any progress, in which it terminated successfully, or in which remedies, however varied, seemed to have any beneficial influence.

Opium is the remedy on which reliance has most generally been placed in combating this formidable disease; and there is no doubt that in mild cases it is competent to its complete solution. But for this purpose, it is absolutely necessary that its use be begun from the earliest appearance of the symptoms; that it be given in very large doses; and that the doses be repeated at short intervals: so that the fever be kept constantly under the influence of the remedy. It is, indeed, almonifying how the fynlem, when posseffed by a strong disposition to fpaflms, will refit the operation of this and other remedies, which in its ordinary state would have been more than sufficient to overpower and destroy it. Patients labouring under tetanus will bear with impunity quantities of opium, that at any other time would have been certainly fatal. Inflances are upon record of five, ten, and even twenty grains, being taken every two or three hours for many days, without its producing any extraordinary narcotic effects upon the fenedium. It is always, however, advisable to begin with comparatively moderate doses, such as forty or sixty drops of tincture of opium, which may be repeated at intervals of three or four hours, and increased at each repetition, till some sensible effect is produced upon the fpaflms. It seems requisite to augment the dose rapidly, as the disease presses upon us every hour, and no time is to be lost in refilling its advances, while there is yet a chance of controlling its fury. The circumstance of the closing of the jaw, and the difficulty of deglutition, the increafe of which may soon render it hardly possible to introduce medicines into the fonamach, is an additional motive urging us to push our remedies before those obfacles arise. Glyaffers are our only refource, when it is impossible to overcome the fpaflms of the fauces. Opium has also been applied externally and topically to the jaws; and relief has sometimes been obtained from an opiate plaster on the maffeter muscles, or behind the ears; but these are comparatively very trifling in their efficacy, and applicable only to the slightest cafes, or to those in which convulsions are still affected with a recurrence of one or two local symptoms.

It is of the greatest importance in all cafes of tetanus, and more especially where opium is given, to excite a proper action of the bowels, so as to allow of no stagnation of their contents. The testimony of the army physicians, as appears from the report of Sir James Maclagan, is highly in favour of a rigid perfeverence in the use of purgatives, given in doses to produce a full effect daily. Dr. Forbes states, that a solution of sulphate of magnesia, in infusion of fenna, was found to answer better than any other purgative, and it was daily given in a sufficient quantity to procure a copious evacuation, which was always dark-coloured, and highly offensive; and to this practice he chiefly attributes, in one severe cafe, the removal of the disease. The infrequency of locked jaw in the West Indies, in the public service, of late years, is chiefly ascribed by Dr. Dickson, to the greater freedom with which purgatives have been employed, particularly since the publication of Dr. Hamilton's work on the operation of this clafs of remedies; an opinion which is corroborated by the testimony of various authors, as to the value of obtinate cellivese which prevails in this disease, and the offensive nature of the contents of the intestines.

For the introduction of the stimulant and tonic plan of treatment, we are chiefly indebted to Dr. Ruh, who was led to adopt it from some theoretical views he entertained on the nature of tetanus, which he conceived to be essentially a disease of debility. There can be no doubt that in many cases the exhibition of wine or spirits has been attended with very good effects. Dr. Hofmann, in vol. iii. of the American Medical Repository, relates several cases which were cured by large quantities of wine.

A free allowance of wine and porter after gun-shot wounds has appeared also, according to the statement of Dr. M‘Arthur, to have contributed to the very small number of cafes of tetanus which occurred under his care in the hospital at Barbadoes, during nearly six years of the most active period of the war. Of the numerous cafes of gun-shot wounds received into the hospital, and of operations performed, during the whole
whole of that period, only two instances of tetanus occurred. Bark has been given in conjunction with wine and opium; and the purified tincture of iron has also been used with apparent advantage. The success of the tonic plan of treatment rests also on the testimonies of Dr. Wright of Jamaica, Dr. Cochrane of Nevis, and several other West Indian practitioners; and also on that of Dr. Currie of Liverpool.

The preference of an inflammatory diathesis, which occasionally accompanies the spasmodic flatus, presents, however, a material obstacle to the employment of the above-mentioned remedies. So much is this the case that many physicians have recommended the free use of the lancet, particularly in the early stages of tetanus. Dr. Dickson states it as his opinion, that in a full habit, where the wound is swelled, inflamed, and painful, venesection, with free purging, and such other means as are calculated to alay the general and local irritation, afford the fairest chance of averting the danger. (See the 7th volume of the Medico-Chirurgical Transactions, part 2.) In the 6th volume of the same work, a case is detailed by Mr. Earle, in which, though it terminated fatally, bleeding was beneficial, and lessened the patient's sufferings; and in the same volume, it is also mentioned with approbation by the medical officers in the Peninsula. Dr. M'Arthur considers that he used blood-letting with evident relief in one case, in the naval hospital at Barbadoes; that the spasms were ameliorated, the dilatation protracted, and the morbid appearances after death were less marked in consequence. Mr. Larrey also adduces some examples where it produced a good effect. Mr. Guthrie gives three cases which occurred in the hospitals of St. Andro, out of many which were recorded, where venesection was the principal remedy. In the first, in which tetanus from a wound in the hand was advancing with rapidity, the patient was bled ad delinquum several times with good effect, calomel and diaphoretics being given at the same time, and he recovered. In the second case, the patient was bled in the same manner, with an evident amendment of the symptoms; so much so, indeed, that he suffered but little from spasm, and could open his mouth very well, when he was feigned with diarrhoea, which, in the debilitated state he was in, carried him off. In the third case, of a man of a fanguineous temperament, and suffering from acute tetanus, venesection pulled to the utmost totally failed.

Digitalis has been tried in the Peninsula in several cases, occasionally with good effect, though it never appears to have effected a cure. Ether, camphor, mustard, and other antispasmodics, as likewise the alkalies, were also tried, and found equally unsuccessful. Coffin strongly recommended by Arataeus, but is too feeble a remedy to have any decisive influence in so violent a disorder.

The affusion of cold water has in general been attended with great benefit. It is a practice particularly recommended by Dr. Wright, in the London Medical Observations, and is sanctioned by the concurring testimonies of Dr. Cochrane, in the Medical Commentaries, and of Dr. Currie, in his Medical Reports, &c. as well as by many other practitioners. A large pailful of cold water should be thrown upon the patient every two or three hours; he is to be immediately wiped dry, and laid in bed after each affusion, and an opiate draught administered. Some renovation of the spasms will in this way be generally obtained; and many instances are upon record, of complete cures being effected by perseverance in this plan. Before the introduction of this practice, the warm bath was very commonly employed; the patient, after using it, being placed in bed, without being dried, between two blankets, with a view to bring out a sweat. It does not appear, however, that this plan was attended with any general or permanent advantage; and is certainly inferior in efficacy to the cold affusion. The cold bath, says Sir James Macgrigor, in acute tetanus, is worse than useless. The use of a hot bath impregnated with potash, and a few ounces of quicklime, has been much recommended by Dr. Stutz of Suabia in traumatic tetanus. See Medical and Physical Journal, vol. iii.

The powerful relaxing effects of tobacco given in glyster in cases of hernia and enteritis, have suggested its employment in tetanus. Mr. Earle tried it in one very acute case, in which, although it afforded a temporary alleviation from spasms, so much agitation was produced by it, that it was not persevered in. He is, however, induced to recommend the trial of a suppository made of the extract of nicotine, and passed up into the rectum. But, according to the report of Sir James Macgrigor, tobacco glysters, tried in the advanced stage of the disease, seemed to have no effect. He represents, however, the tobacco fume as deserving of further trial. A remarkable case is recorded by Dr. Phillips, in the 6th volume of the Medico-Chirurgical Transactions, in which the jaw suddenly fell, upon the exhibition of an esca with oil of turpentine.

It has been supposed that mercury thrown quickly into the fyrum, in order to excite salivation, would prove highly serviceable in relieving the spasms, and particularly those of the muscles of the jaw. This practice was first introduced by the practitioners in the West Indies, and in particular by Drs. D. and A. Monro, and appears to have succeeded in many cases. Dr. Ruth conceives that its salutary effect is connected with its inducing in the fyrum a state of inflammation incompatible with the spasmodic action, which it would therefore supereede. Whatever benefit, however, may have been experienced from this plan in mild cases, it completely fails in the more severe of making any impression on the disease. Dr. Emery, Mr. Guthrie, and other medical officers attached to our army in the Peninsula, after the battle of Salamanca, tried inunction of the whole body three times a day, with strong mercurial ointment, in unlimited quantity, with no degree of success. Mr. Guthrie reports, that after the battle of Touloufe, a fatal case occurred in a man strongly under the influence of mercury, which he had used previously to the action for the cure of the itch. The combination of calomel with ipecacuanha, which has been much recommended, is equaly ineffectual with the other remedies, in the acute and fully formed disease. In the mild tetanus, benefit has been derived from calomel; and its operation on the bowels is always useful, and regularly, in the mild disease distinguished by the spasms coming on slowly, and continuing of the same violence; instead of their sudden accession, and their continuing with increasing violence, as happens in the acute fully formed tetanus. In this, calomel cannot be depended upon, as the patient is carried off before the medicine can have any effect.

Several remedies were formerly in vogue, of which it is hardly necessary to give any account, as they have now lost all the credit they once enjoyed. It may be sufficient to mention the Barbadoes tar, alluded to by Dr. Cullen; the colchicum, the olive, or meadow saffron, recommended by Dufrefnoy; blisters, electricity, cataplasms, applications, full incisions, &c. most of which appear either to be inert, or at best very weak auxiliaries to the remedies already described.

Of late years, tetanus has been much less frequent in the West Indies, when compared with former wars. This is attributed, apparently with great reason, by Dr. Dickson, to the improvements in the medical and surgical treatment of wounds; to greater cleanliness, and more perfect ventilation; and in general to superior comforts, diet, and accommo-
TETARBOLION, in Ancient Coinage, the quarter-draechm, or, being of 24 grains, and its current worth a farthing and a half.

TETARMIUM, in Ancient Geography, a town of Asia, situated in that part of Lydiaea, which Ptolemy comprehends in Galatia.

TETARTEMORION, among the Ancients, denotes the fourth part of the zodiac.

TETARTO-CHRUSOS, χρυσο-χρυσος, in Ancient Coinage, a gold coin of Philip, Alexander, and Lysimachus, which was a quarter of the Egyptians or χρυσος; it weighs 33 grains, and paid for 5 drachmas of silver, 37. 94., now worth intrinsically 57.

TETAVI, in Geography, a town of the principality of Georgia, in the province of Caket.

TETBURY, or Tetbury, anciently Teteburis, a large and respectable market-town in the hundred of Longtree, and county of Gloucester, England, is situated 20 miles S. by E. from Gloucester, and 99 miles W. by N. from London. Its name evidently determines it to have been a military station. On the S. E. side, within the memory of many living, were traces of a strong camp, now completely destroyed, where arrows and javelin-heads have been found, with various English coins of high antiquity. Roman coins of the Lower Empire have likewise been met with in and near the town. Tetbury consists principally of four streets, crossing in the centre, and contains many good stone buildings. The governing officer is a bailiff, who is annually chosen. The population of the parish, including four hamlets, in the year 1811, was 2533; the number of houses 522. A weekly market is held on Wednesday, and four fairs annually. The woollen-combing and wool-lapping branches are carried on here, but to no great extent. The clothing manufacture was formerly attempted, but the want of a continual supply of water prevented its being brought to perfection. Even for domestic uses, water has, till within a few years, been scarce; but in 1749, a well was sunk to the depth of 104 feet, since which time other wells have been opened, and the inconvenience in a great degree removed. The parish church consists of an ancient tower, and a modern body; the former is terminated by a spire, the latter is built in imitation of the pointed style, appearing externally as a single nave with cloisters, but within sub-divided into aisles, by a very light arcade and clustered columns, on the principle on which the roof of the theatre at Oxford was constructed. The old church, which was built soon after the Conquest, having become from length of time very ruinous, was taken down (excepting the tower and spire), and rebuilt at the expense of 5000l.; and opened for divine service in 1784. Two turnpike roads lead through the town in crofs directions; one to London and Bath, the other to Gloucester and Southampton. A deep hollow, in the nature of a moat, at the well end, made the entrance into the town inconvenient, till the commissioners of the roads built a high bridge of four arches across it in 1775. Rudge's History of Gloucester, vol. i. 1803. Beauties of England and Wales, vol. v. Gloucestershire; by J. Britton and E. W. Brayley, 1803.

TETCHA, a small river of Russia, which runs into the Ifet, near Dolmatov, in the province of Ekaterville.

TE-CHUEN, a town of Corea; 60 miles E.N.E. of Han-tehou.

TETE, a fort belonging to the Portugueze, in the country of Mocuranga, on the Zambec.

TETE de Bouch, La, a town of France, in the department of the Gironde, situated on the S. side of a large bay, called "The Harbour of Arcachon," the entrance of which is dangerous on account of the sand-banks; 30 miles S.W. of Bordeaux.

TETEROA, a harbour on the W. coast of the island of Ulieta.

TETEROV, a town of the duchy of Mecklenburg; 18 miles S.W. of Giltro.

TEETERSKOI, a town of Russia, on the Podkamenka, 44 miles W. of Podkamensk.

TETHALASSOMENOS, a term used by the old medical writers, to express wine mixed with sea-water.

TETHEH, in Geography, the daughter of Celum and Terra, and wife of Oceanus. Her chariot, which is represented as gliding over the surface of the waters, was a shell of an extraordinary figure, and whiter than ivory.

TETIUS, in Zoology, a genus of the Molluca order of Vermes, or worms; the characters of which are, that the body is free, somewhat oblong, glairy, and having no peduncles; the mouth terminating in a cylindrical proboscis, under the lip; and two foramina on the left side of the neck. It has two species:

1. LEPORUS. With a ciliated lip; found in the Mediterranean sea.

2. FIMBRICA. With a crenulated lip; found in the Adriatic sea.

TETIMIXIRA, in Ichthyology, the name of an American fish, more usually known by the name of Tympano.

TETIN, in Geography, a town of Bohemia, in the circle of Beraun; 3 miles S. of Beraun.

TETITLAN, a town of Mexico, in the province of Xalifico; 18 miles S.E. of Compotello.

TETIUS, in Ancient Geography, a river of the isle of Cyprus, which ran from the N.W. to the S.E. and discharged itself into the sea, near the promontory of Dades, after having watered Citium.

TETIUSCHI, in Geography, a town of Russia, in the government of Kazan, on the Volog; 52 miles S. of Kazan.

TETOB, a town of the state of Georgia; 5 miles W. of Tugeloo.

TETRACERCA, in Botany, received that name from Linnaeus, in allusion to the four horn-like points of the capsules of the original species, the word being compounded of τετρα-, four-fold, and κερας, a horn. The genus however has subsequently received an accesion of several species with follicular capsules and styles, which invalidate the strict propriety of its name, and render its situation in the artificial system of Linnaeus ambiguous.—Linn. Gen. 275. Schreb. 369. Wildl. Sp. Pl. v. 2. 1240. Mart. Mill. Dict. v. 4. Julii. 339. Lamarck Hist. t. 485. Gernt. t. 69. (Delima; Linn. Gen.
TETRACERA.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five or six deep, rounded, unequal segments, permanent. Cor. Petals from three to five, roundish, concave, inserted into the calyx, and longer than its segments. Stam. Filaments numerous, inserted into the calyx, shorter than the petals; anthers of two round lobes. Fil. Germs superior, from one to three or four, ovate, quite distinct; Styles vertical, awl-shaped; Stigmas obtuse. Peric. Capsules from one to three or four, ovate, divaricated, each of one valve, burr-like along the upper edge, of one cell. Seeds solitary, roundish, attached to the bottom of the capsule, and clothed with a jagged tunic from the bafe.

Eff. Ch. Calyx in five or six deep unequal segments. Petals four or five. Capsules burr-like at their upper edge. Seeds solitary, tunicate.

Obs. The capsules resemble follicles, but the seed is attached to their bafe.

Section 1. Flowers with a solitary genrum and style.

2. T. tumenofici. Downy Tetracera. Willd. n. 2. (Tigarea dentata; Aubl. Guian. 920. t. 335.) — Leaves elliptical, pointed, with tooth-like serratures; smooth above; downy beneath. Flowers dioecious. Style solitary. — Native of woods in Cayenne, flowering in January, and ripening its seed in March. The trailing burr-like branched stem climbs to the tops of the highest trees, from whence its pendulous branches reach almost to the ground. The young leaves are downy. Leaves alternate, stalked, four or five inches long, and two or more in breadth; their upper surface smooth and green; the under silky and hoary. The flowers and fruit agree with the following.

3. T. altera. Harsh Tetracera. Willd. n. 3. (Tigarea altera; Aubl. Guian. 918. t. 350.) — Leaves roundish, somewhat undulated, rough. Flowers dioecious. Style solitary. — Frequent in the woods of Cayenne, bearing flowers and fruit in January. Aublet says it is sometimes so abundant as to render the forests impassable, from the entanglement of its stems and branches, which climb to the tops of trees, and hang from thence to the ground. Their roughness, like that of the leaves, renders them the more troublesome and dangerous. The French call this shrub Liane rouge, or red climber, from the colour of its decoration, which the natives of the country consider as a remedy for venereal disorders. The leaves are alternate, stalked, of a broad elliptical, or roundish, figure, obtuse, slightly wavy at the margin, rough on both sides with rigid, crooked, hoary hairs. Their ribs and veins like those of the first species. The largest leaves are three inches and a half long, and three broad. Flowers in axillary panicles, male on one plant, female on another. Calyx in four or five concave, pointed segments. Petals four or five, white. Stamens numerous, short. Anthers yellow, their two lobes separated by a furrow. Pilif. abortive in the male flowers, as the flumosa are without anthers in the female, whose germen is roundish, with one style, and a broad blunt stigma. Capsule solitary, reddish, rough to the touch, containing one seed. Aublet.

Willdenow has four more species in this section, of which his T. Dollicarpus, fruta, and Calinea, will be found under our article Dollicarpus; and his T. obovata is our Mapa.

Sec. 2. Flowers with three or four germs and styles.

6. T. volubilis. Serrated Rough Tetracera. Linn. Sp. Pl. 751. Hort. Chiff. 214. Willd. n. 10. (Arbor americana convolvulaca, Broad leaf, i. e. platypillos barbadenus dicta, foliis ferratis; Plak. Phyti. i. 146. t. 1.) — Leaves obovate-oblong, ferrated, very harsh. Styles four. Calyx silky within. — Native of the West Indies. The branches are round, with a rough, dotted, membranous, deciduous bark. Leaves alternate, stalked, five or six inches long, and two and a half or three wide, obtuse, very rough, like a file, with minute scales, especially beneath; each lateral rib, at leaf in the upper half of the leaf, terminating in a sharp but shallow ferrature. Panicles terminal, compound, rough with hairy scales. Calyx harsh and hoary externally; bristly and silky within. Capsules unequal, ovate, tumid, beaked, brown, smooth and highly pubescent; rounded, not deprered or keeled, at the sides. Seed small, black, in a pale, finely lacinated, tunic.

7. T. rotundifolia. Round-leaved Tetracera. — Leaves roundish-elliptical, entire, very harsh on both sides. Styles four. Calyx smooth within. — Native of Guiana. We have received specimens of this new species from Mr. Rudge and Mr. Forrer, under the name of Tigarea altera of Aublet, our Tetracera altera, see n. 3, which, unless that author has made several great mistakes, must be a very different plant. The present has always three or four styles, and as many capsules; and the leaves, though like Aublet's t. 350. in shape, are quite entire, not undulated. They are harsh on both sides, like a very fine file, as is the branch in a leaf's degree. The panicles are terminal. The calyx has a short, intervenently conical, tube, and is hoary externally, smooth and naked within. The flumosa appear to be perfect in the same flower with the four stili. Capsules three or four, oval, brown, smooth and thinning; keeled and deprered at the sides, less tumid than the foregoing. Seed entirely enveloped in its jagged tunic.

inches long, veiny, smooth on both sides; tapering at the base; serrated with a few flight teeth towards the point. 

Flower-tails very short. Flower-tails solitary or in pairs, terminal, an inch long. Flowers somewhat racemose, one or two on each partial stalk. Calyx with six roundish segments. Capsules four, as long as the finger-nail, roundish, smooth, pointed, very smooth and polished. Seed small, black, polished, covered in its lower half with a whitish tunic, whose margin is toothed. 

- Leaves obovate, acute, nearly entire; roughish beneath. 
Panicle terminal.- Native of Guinea. Branches woody, round, smooth. Leaves coriaceous, tapering at the base, rounded at the extremity, with somewhat of a point; mostly entire, but occasionally furnished with an oblong foot or two near the end; veiny; shining and smooth above. Calyx with four deep segments. Petals apparently five. Filaments a little dilated at the end, with an anther (or lobe) at each side. Capsules four. Seed black, entirely covered by its whitish tunic. Panicle simple. Stalks three-flowered. Wild. 

Wilkenow suspects the Alpha indica, of Houttuyn's Dutch edition of the Vegetable System of Linnaeus, v. 4, 40. t. 24. f. 1, may be another species of the genus before us. 

The name tetracera is also inclined to refer Thunberg's Waehbungia, see that article hereafter, to Tetracera.

TETRACHORD, TETRACHORDON, formed of tetra, of terga, four times, and χορν, a chord, or string, in the Ancient Music, was a series of four sounds, of which the extremes, or first and last, constituted a fourth. These extremes were fixed and immutable; the two middle sounds were changeable according to the genera, and called modes. There were three genera or ways of tuning each tetrachord; the diatonic, chromatic, and enharmonic. The character of the diatonic was the tone; of the chromatic, the semitone; and of the enharmonic, the quarter-tone.

A tetrachord in the diatonic genus consisted of one major semitone and two tones.

In the chromatic genus, of two semitones and a minor third.

In the enharmonic genus, of a quarter tone, a semitone, and a major third.

The general system or scale of the Greeks consisted of tetrachords repeated, as the scale of Guido does of octaves. See Greek Music.

The tetrachord of Mercury contained four strings or chords, in the proportion of twelve, nine, eight, and six; so as to give the fourth, fifth, and octave of the lowest chord. This is the opinion of Boethius, and after him of Zarino. Vide Wallis's Append. Ptolem. Harm. p. 178.

TETRACTIS, in Natural History, a name given by Linnaeus, and other authors, to a kind of star-fish, composed only of four rays, the more common kinds having five.

TETRACTYS Arithmetic. See Arithmetic.

TETRACTYS, in the Ancient Geometry. The Pythagorean tetractys is a point, a line, a surface, and a solid.

TETRADECARHOMBIS, in Natural History, the name of a genus of fossils, of the class of the lepidite.

The word is derived from the Greek teta, four, δεκα, ten, and σφαίρα, a sphaeroidal figure, and expresses a sphaeroidal body consisting of fourteen planes.

The characters of this genus are, that the bodies of it are exactly of the same form with the common selenite; but that in these, each of the end planes is divided into two; and there are by this means eight of these planes, instead of four. See Selenites.

TETRADIAPIASON, Quadruple Diapason, a musical chord, otherwise called a quadruple eighth, or nine-and-twentieth. See Diapason.

TETRADITÆ, TETRACITES, in Antiquity, a name given to several different sects of heretics, out of some particular respect they bore to the number four, called in Greek τετρά. Thus the Sabbatians were called tetradites, from their fasting on Easter-day, as on the fourth day, or on Wednesday.

The Manichees, and others, who admitted of a quaternity instead of a Trinity in the Godhead, or four persons in lieu of three, were also called tetradite.

The followers of Petrus Fullenbosi bore the same appellation of tetradite, by reason of the addition they made to the Trifagion, to countenance an error they held, that in our Saviour's passion it was not any particular person of the Godhead, e. gr. the Son that suffered, but the whole Deity.

The ancients also gave the name tetradite to children born under the fourth moon, and these they believed unhappy.

TETRADIUM, in Botany, from τετράδιον, a party of four, as a file of four soldiers, &c. alluding to the prevalence of the number four in its parts of fruitification.—Lonreir. Cochinch. 91.—Clas and order, Tetrandria Tetragyna. Nat. Ord. Tetrandraceae, Juss. or perhaps Rutaceae.

1. T. trichotomum. Gāy dāię dāęů of the Cochincinese. Native of the hills of Cochinchina. A middle-sized tree, with ascending branches. Leaves pinnate, with an odd one; leaflets lanceolate, smooth, entire. Flowers white, in ample, nearly terminal, three-forked clusters; or rather, as we presume, panicles.

De Theis well remarks, that this genus appears to be allied to Brucia: we think also it is evidently very near Fagara (see those articles). In deference to the weighty opinion of Jullieu, we have not, without doubt, referred it to his natural order of Terebinthaceæ; but it appears rather to belong to his imperfectly-defined one of Rutaceæ, to both which articles we refer the reader.

Nothing is said by Loureir respecting the qualities or uses of this tree.

TETRADRACHM, in Ancient Coinage, a silver coin worth four drachmas, or 32. sterling, the drachma being valued at 9d. But if we estimate the value of the drachma at a higher rate, that of the tetradrachm will increase in due proportion. This is the largest form of Greek silver coins, excepting the tetradrachm of the Egnican standard, which is worth 5s. The largest tetradrachms weighed from 430 to 440 grains. See Drachm and Shekel.

TETRADYNAVIA, in Botany, (from τετρά, four, and δύναμις, power, indicating a superiority of four filaments over the reft,) the fifteenth clas of the Linnaean artificial syllem, which
which is in itself, with the exception of one genus, **Cleome**, a natural class, comprehending all the cruciform flowers.

Its essential character consists in having six floral organs, four of which rise above the rest. This is indeed so naturally distinctive a tribe of plants, that it is hard to trace any particular affinity between them and any others. The following is the character of the flowers.

**Cal.** Perianth oblong, of four ovate-oblong, concave, obtuse, converging downwards at their base, the opposite ones most similar to each other, deciduous. The projection generally observable at the base is for the lodgment of honey, the calyx here being a nectary, so far at least as containing the honey. **Cor.** termed cruciform, of four equal petals; their claws ineruptly awl-shaped, or tapering downwards, flattened, erect, rather longer than the calyx; limb flat, or nearly so, the border of each petal being dilated outwards, obtuse; its fides scarcely touching its neighbour. The petals are inserted into the fames circle in which the stamens are placed. **Stam.** Filaments fuscous, awl-shaped, erect, the two opposite ones the length of the calyx, the red rather longer, but not equal to the corolla; anthers somewhat oblong, pointed, thickened at the base, erect, their points recurved. **Pist.** Nectariferous glands, variously circumflected in the different genera, are seated at the base of the flamen, especially between the shorter ones and the pistil, those flamps, to avoid being flushed upon such glands, being most curved, by which they become shorter than the four others. **Pf.** German superior, daily increasing in height; fyle either the length of the longer flamps, or wanting; stigma obtuse. **Peric.** Pod of two valves, and frequently as many cells, burbling from the base to the summit, the partition, if present, more or less extended beyond the valves, the prominent part being the original style. **Seeds** roundish, drooping or pendulous, ranged alternately, in a double row, along the partition, in which they make flight depressions. **Receptacle** linear, surrounding the edge of the partition, and embraced by the margins of the valves.

**Linnaeus** observes, that all systematic botanists, even the most eminent, have unanimously considered this as a truly natural class of plants. Some of them have nevertheless admitted into it, here and there, a genus or two in opposition to nature, which fault he justly conceives himself to have avoided, except with regard to **Cleome**.

The plants of this class have universally been termed antifcorbutic. Their flavour is generally acid, though watery. Few vegetables yield less of an essential oil; yet this subsistence is to be obtained from them by cohabitation, or repeated distillation, and its qualities are peculiarly acid and fuculent, somewhat like volatile alkali. This oil gives the offensive fecent to water in which cabbage has been boiled, and it causes these vegetables to disagree with some flomachs, though they are generally reputed wholesome.

The elafs in question is divided into two orders, 1. **Siliquefoa**, in which the pod is roundish, and for the most part hardly longer than its fyle. 2. **Siliquefoa**, with a very long pod, to which the fearfully perceptible style bears no proportion.

The genera of the first order are distributed into two sections, one having the pod, here termed a friciula, or pouch, entire, and the other furnished with a notched, or emarginate, pouch. The genera here are characterized by the different shapes of their pouch, or its valves, and the comparative length of the style.

The order of **Siliquefoa** is divided into such as have a close calyx, whose leaves converge longitudinally, and such as have a gaping, or spreading calyx. The genera here are partly defined by the form of the pod and its valves, and their mode of burbling, and partly by the situation of the nectariferous glands.

The principles of generic distinction, laid down by Linnaeus, have not proved so satisfactorily in practice as could have been wished, inasmuch that, not only Haller, but some least controverting botanists, have differed from the learned Swede in their ideas of several of the cruciform genera. The bell attempt to reform them has lately been made by Mr. R. Brown, in the second edition of Mr. Aiton's *Hortus Kewenfis*. This able observer has recurred for assistance to the cotyledons, taking into consideration their being either folded or flat, accumbent or incumbent. The latter difference we believe to have been first noticed by Gartner, in his characters of *Erysimum*. By incumbent is meant that the edges of the unexpanded cotyledons are applied, in a parallel manner, to the infant radicle; and by incumbent, that the flat side, or back, is presented to that part. The latter is seen in *Erysimum*, and is the most unusual position. The number of seeds in each cell of the pouch is also adverted to by Mr. Brown, as well as several other accidental marks; by the alliance of all which the whole tribe appears much more satisfactorily arranged than heretofore, though we do not profess to agree in every point, with our learned friend. His *Mathiola*, consisting of the hoary species of *Chionanthus*, such as *incanus*, *javanus*, *tricaphilatus*, &c. seems less happily separated from the original genus, than his *Malcolmia*, composed of *C. maritimum*, *Hesperis africana*, &c. In the latter cafe, the fimple acute stigma, incumbent cotyledons, and the habit of the plants, afford a sufficiently clear distinction. In the former, whatever difference there may be in habit, the characters seem to us not sufficiently evident or important. It is also proper to remark, that whatever allusion such a difference as that above described in the cotyledons may afford, towards forming a philosophical idea of a genus, its great obscurity renders it unfit for practical and daily use. On this subject we need not enlarge upon what *Linnaeus* has so happily enforced, and generally practised.

**TETRAEDRON**; or **Tetraedron**; formed of **tetra**., four, and **edron**, fide, in Geometry, one of the five regular or Platonic bodies of solids, comprehended under four equalateral and equal triangles.

The tetraedron may be conceived as a triangular pyramid of four equal faces. Such is that represented in Plate XV. Geomet. fig. 4.

It is demonstrated by mathematicians, that the fquare of the fide of a tetraedron is to the fquare of the diameter of a sphere, in which it may be inscribed, in a subfegualteral ratio: whence it follovs, that the fide of a tetraedron is to the diameter of a sphere it is infevred in, as, $\sqrt{3}$ to $\sqrt{2}$; consequently they are incomparably. See Regular Body.

**TETRAETERIS**, in the Athenian Chronology, a cycle of four years; for which see Potter, Archæol. Grec. lib. ii. cap. 26. tom. i. p. 459.

**TETRAGASTRIS**, in Botany, from **tetra**., and **gaster**, the fomach or belly, because of the four protuberant lobes of the feed-veifel.—Gartn. v. 2. 130. t. 109. f. 5.—Clafs and order, as well as Nat. Ord. unknown.

Nothing is known of this genus but its fruit, which Gartn. obtained from the collection at the botanical garden of Amsterdam. He describes it as a depreffed brerry, of four lobes and four cells, with folitary seeds.

Its form is nearly globous, a little depreffed, convex and pointed at the summit, marked with four longitudinal furrows, separating the prominent, culian-like lobes, into which
TETRAGON, **Tetragono**; formed from **tètra** or four, and **γωνίας** or angle, in *Geometry*, a quadrangle, or a figure with four angles.

Thus a square, parallelogram, rhombus, and trapæzium, are tetragonal figures.

TETRAGON, in *Astronomy*, denotes an aspect of two planets with regard to the earth, when they are distant from each other a fourth part of a circle, or 90°.

The tetragon is expressed by the character □.

TETRAGONIA, in *Botany*, so called by Linnaeus, from **tètra** and **γωνίας**, an angle, alluding to the quadrangular figure of the fruit. The word is happily abbreviated from Boerhaave's *Tetragonocarpus*, which has the same meaning.

Gen. Ch. Cal. Perianth superior, in frequent, occasionally three or five, ovate, flat, rather deflexed, coloured, prominent, deep segments, revolute at the edges. *Cor.* none, unless the calyx be taken for such. *Stam.* Filaments twenty, capillary, shorter than the calyx, into whose base they are inserted; anthers oblong, incumbent. *Pil.* German inferior, roundish, with four angles; styles four, awl-shaped, recurved, the length of the flaments; stigmas downy, running along the styles. *Peric.* Drupa conicaceous, quadrangular, with four prominent longitudinal wings, or points, the opposite ones narrowed, not burbling. *Sed.* Nut solitary, bony, of two or more cells, with oblong solitary kernels.

Eff. Calyx with from three to five deep permanent segments. Petals none. Drupa inferior, angular. Nut with several cells.

Obs. Linnaeus remarks that the primary flower is five-cleft, which led him to refer this genus to the order *Pentagynta*. But it only affords an influence, among many others, that his orders of *Icofandra*, like those of *Polyandria*, except *Mongonia* and *Polygynta*, are left resolved into one, they being liable to frequent uncertainty, not only in the same genus or species, but the same individual plant. See *Tetracera*.

2. **T. decumbens**. Trailing Tetragonia. Ait. ed. 1. v. 2. 177. ed. 2. n. 2. Willd. n. 2. "Decand. Pl. Graffes, t. 23. *(T. folis ovatis integerrimis, caule fruticoso decumbente; Mill. t. 265. f. 1.)—Stem shrubby, downy, decumbent. Leaves ovate. Fruit winged.—Native of the Cape of Good Hope. A greenhouset shrub, cultivated by Miller in 1758. It differs from the former in the larger size, and broad obtuse form of its leaves, as well as in having a more glistening mealy surface, and more numerous axillary tufts of flowers. The *flêm* is more or less decumbent, and clothed with very soft dense hairs.

3. **T. herbeca**. Herbaceous Tetragonia. *Linn. Sp. Pl.* 687. Willd. n. 3. Ait. n. 3. (Tetragonocarpus africana, radice magnæ ebrææ et canariæ; Commel. Hort. v. 2. 203. t. 102.) Stem herbaceous, smooth, decumbent. Leaves ovate, falcated. Flowers somewhat corymbose. Fruit winged. Native of the Cape, cultivated by Miller. The root is perennial, thick, fleshy, and lobed. Herb smooth, succulent, with many decumbent, branched, annual, leafy *flêm*, and falcated, ovate, more or less acute, entire leaves. *Flowers* yellow, generally five-cleft, larger, and more showy, than in the two preceding, falcated, partly axillary, partly corymbose. All our knowledge of this species is derived from Commelin's work, nor had Linnaeus any specimen in his herbarium. The laft-described is sometimes, in gardens, mistaken for *T. herbaec.*

5. **T. spicata**. Spiked Tetragonia. *Linn. Suppl.* 258. Willd. n. 5. Thumb. Prodr. 87.—"Herbaceous, smooth, erect. Lower leaves ovate; uppermost lanceolate. Flowers racemose."—From the same country as the last. *Thunberg*. We have seen no specims of these two species. It is remarkable that the younger Linnaeus defines the flowers of *T. biflata* falcata, whilst Thunberg calls them falcate. Possibly the latter confused with his biflata, our decumbens, of which there is a specimen, apparently gathered by him, in the Linnaean collection.

6. **T. eckinana**. Hedge-hog Tetragonia. Ait. ed. 1. v. 2. 177. ed. 2. n. 4. Willd. n. 6. "Decand. Pl. Graffes, t. 113."—Stem herbaceous. Leaves rhombic-ovate. Fruit prickly.—Native of the Cape, from whence Mr. Maffon introduced it to Kew, in 1774. The root is annual or biennial. Stem herbaceous, divided from the base into several decumbent branches, hardly a foot long, angular, from the decurrent foot-blades, which are half the length of the spreading falcate leaves, each an inch long. *Flowers* pendulous, on very short, axillary, solitary, thread-shaped, purple *flákis* clothed with crystalline globules. *Calyx* in three or four segments; crystalline without; greenish-yellow within. *Stamens* only three or four. *Germen* triangular, flat underneath, its angles beket with numerous conical thorns. Styles three. *Nut* of three cells. *Willden.*

it to Kew garden, in 1772, and from thence the other gardens of Europe have been supplied. The plant is a rather tender biennial herb, flowering in August and September. Forster tells us it proved a most valuable resource to Captain Cook's crew, as a pot-herb, while his ship lay at Tongatabu. The whole plant is succulent, covered with very minute crystalline dots, as if moist with dew. Root fibrous. Stem divided from the bottom into many irregular, round, leafy branches. Leaves alternate, falked, somewhast deltoid, entire, rather heart-shaped at the base, but tapering down into the footstalk. Flowers yellow, axillary, on short, usually solitary, stalks. Fruit turbinate, clamy, the size of a filbert, with four or five sharp horns. The cells are five or six, answering to the number of stigmes.

For Tetragonia tweedia, Linn. Suppl. 257, &c. HALL. RAGS, n. 1.

TETRAGONIA, in Gardening, contains plants of the shrubby and herbeaceous, succulent, perennial kinds, among which the fpecies most ufually cultivated are the following:—the shrubby tetragonia (T. fruticosa); the trailing tetrago- nia (T. decumbens); the herbeaceous tetragonia (T. her- bacea); and the hedge-hog tetragonia (T. echinata). All these plants are natives of the Cape, and, of course, of the rather tender kind.

Method of Culture.—The firft and later forts may be in- creased by cuttings, which fhoal be cut off from the plants a few days before they are planted, that the part where they are cut may be healed, letting them out in July, that they may have time to make good roots before winter, on a bed of fresh earth, fhadig them from the sun in the heat of the day. They should afterwards be frequently refheved with water in fear quantities. In a few weeks, when well rooted, they fhould be taken up, and planted into pots filled with light fresh undugned earth, and be placed in a shady situation until they have taken new root, after which they may be placed with other hardy exotic plants in a feltered situation, where they may remain till the middle or later end of Oc- tober, at which time they fhould be removed into the green- house, and placed where they may enjoy as much air as po- fible in mild weather, as they only require to be protected from the froll, being pretty hardy with refpect to cold. As, when planted in the full ground in the summer feafon, they are apt to grow rank and large, or even when permitted to root into the ground through the holes at the bottom of the pots, the pots fhould be frequently removed to prevent it, as they are injured by it.

The firft and second forts are likewife capabo of being raised by seeds, fown in a gentle hot-bed, or in a warm border of light fresh earth, in the spring. When the plants are about four inches high, they may be planted out in pots, treating them in the fame manner as the cuttings.

And the third fort will grow from cuttings planted early in the spring, in the fame manner as the others.

The shrubby forts are durable in their flems, roots, and branches; but the herbeaceous kinds often die down in the flarks and branches towards the autumn, and fend up new ones at the end of that fefon, which retain their leaves during the winter months.

They afford ornament among other potted plants, and the firft fort has something fingular and curious about it.

TETRAGONIAS, a name given to a meteor whose head is of a quadrangular figure, and its tail or train long, thick, and uniform: this is not much different from the trabs or beam.

TETRAGONIS, in Ancient Geography, a town of Arachosia, at the foot of mount Caucasus, called more ancienly Cartana. Pliny.

TETRAGONISM, πετρονέω, a term which some authors use to express the quadrature of the circle.

TETRAGONOPTERUS, in Ichthyology. See SAL- NO Bimaculatus.

TETRAGONOPTERUS. See Zeus, Chetodon Cornutus, Ngicrtnus, and Capistratus.

TETRAGONOTHECA, in Botany, from τετράγονος, quadrangular, and θέκα, a, a, or, or, a name first contrived by Dilenius, to express the square form of the common calyx, and now retained by L'Heritier and Willdenow for the original and only remaining fpecies of the genus. See the others under Didelta, Polymnia, and Wedelia.

Gen. Ch. Common Calyx simple, large, of one leaf, in four deep, flat, spreading, triangular-herbeaceous fegments, permanent. Cor. compofed, radiant. Fruits of the disk perfect, numerous, funnel-shaped, five-cleft, reflexed; thofe of the radius ten or twelve, ligulate, dilated outwards, five-cleft, equal, blufh. Stam. in the flots of the disk. Filaments five, capillary, very thort; anthers united into a cylindrical tube. Pepl. in all the flocks. German roundiath; ryle thread-shaped, the length of the flumes; fligmas two, reflexed or revolute. Peric. none. Seeds folidary; in the disk roundiath; in the radius somewhat ovate.

Down none. Recep. chaff.

Obfl. The fynonym of Tetragonotheca, Linn. Gen. 438, fhould be erased from our article Polymnia.

1. T. belianoithes. Sun-flower Tetragonotheca. Linn. Sp. Pl. 1273. Willd. n. 1. Ait. n. 1. Pursh n. 1. (T. doronicen maximil fofio; Dill. Eth. 378. t. 283. Polymnia tetragonotheca; Linn. Syf. Veg. ed. 13. 658. Sm. Inf. of Georgia, v. 2. 137. t. 69.)—Native of North America, in a fertile fole, on the borders of woods, and along hedges, from Virginia to Florida, flowering from July to September. Pursh. The root is perennial, hardy in our gardens. Stem erect, round, leafy, hairy, branched, from four to fix feet high. Leaves hairy, veiny, toothed or wavy; the lowermoft flaked, ovate; upper fiddle; opposite acut. Flowers from the forks and ends of the branches, flaked, large, of a golden yellow, refembling a fun-flower.

TETRAGONUS, in Anatomy, a mufcle, called also quadratus gene.

TETRAGRAMMATON, τετραγραμματον, a denomination given by the Greeks to the Hebrew name of God, יהוה Jehovah, because in the Hebrew it confists of four letters. See ADONAI.

TETRAGYNIA, in Botany, from τετρα, and γυν, a female, the name of an order in several classes of the Linnaean artificial system, characterized, as the word itself imports, of a female sexual nature. It is a very usual character in the construction of names of orders of animals and plants.
by the flowers having four styles, or pistils. This order is better founded, and more invariable, in some classes than others. With the Tetrandria, (see that article,) it naturally corresponds, and is well exemplified in the genera Potamogoton and Ruppiia. In Octandria, though of rare occurrence, it is no less certain. In Lepidandria and Polyandria it is veryfallable, of which we have lately given examples. (See Tetracera and Tetragonia; also Polyandria.) The order Tetragynia in the classes Pentandria and Didacandria is, however, sufficiently well-founded. In Decandria no example of it occurs, nor fearlessly in Hexandria.

TETRANURITI, an old name, supposed to allude to the four-cornered item. See Galeopsis.

TETRALOGIA, in the Dramatic Poetry of the Ancients, denoted four dramatic pieces of the same author, of which the three first were tragedies, and the last of the satyric kind. Their design was to celebrate a victory in the literary contests. Alciphylus and Euripides have written some pieces of this kind. Encycl.

TETRAMETER, in the Ancient Poetry, an imbus verse consisting of four feet. The word is formed from τετρα, four, and μετρι, measure; q. d. four metres. We meet with none of thes in the comic poets, as Terence, &c.

TETRANDRIA, in Botany, the fourth class in the Linnean artificial system, is so called from τετρα, four, and anther, because it is characterized by having four anthers, in the same flower with the pistil or pistilis. These are of equal length, the flower being regular, by which this class is distinguished from the 14th, whose flowers are ringent, and two of their four anthers, which stand next each other, are longer than the rest. See Diadynamia.

The orders of this fourth class are three, distinguished by the number of their pistils. 1. Monogynia, a numerous and various order, comprising the ample tribe of Protaceae; and the intricate family of the Stellata, to which Galium and Rubia belong. The large genera of Scabiosa and Plantago likewise range under the Tetrandria Monogynia; the former of which exhibits a curious example of aberration in number between the corolla and anther. Some of its species have a four-cleft corolla, answering in that respect to the flamen, whilst others have five segments in the former, though the number of the latter remains invariably but four. 2. Dignya is a small order, to which, amongst a few other genera, Linneas has referred Cistus, but rather belongs to Pentandria Dignya, the greater number of the species having five-cleft pentandrous flowers. This order will, however, receive a very curious accession in Tetraannena. (See that article.) 3. Tetragynia contains Hexa, Potamogoton, and Ruppiia, British genera, all of which have four follicles ligmas; with several others, not naturally related, but for the most part separated, by the artificial character of number, from their allies in other parts of the system. That character however is sufficiently confiant in the present influence.

Tetrandria is likewise the denomination of several orders in the Linnean System, as in Gynandria; if Stylium (see that article,) be judged to have four flamen; and certainly in Menorea and Diodora, where there are several really tetrandrous genera.

TETRANGURIA, a name used by some authors for the eitrul, a plant of the gourd kind, whose seeds are used in medicine.

TETRANTHERA, so named by Jacquin, from τετρα, and φυτη, because of the four separate cells, which have the appearance of four distinct anthers; on the dilated summit of each filamen, and were indeed considered as such by the author. We greatly prefer this name to that of Lias, used by Lamarck and Jussieu, because the latter is of barbarous origin, and because we are happy to follow the example of Mr. Brown, who judgily prefers, in this case, the classical authority of Jacquin. To the learned Jussieu nevertheless belongs the honour of having first assemled under this genus several plants, which authors had either confidered as distinct genera, or erroneously referred to others already established, as will appear by the various synonyms we are about to exhibit. —Jacq. Hort. Schoenbr. v. 1. 59. Dryandrz. in Roxb. Coromand. v. 2. 35. Brown Prodor. Nov. Holl. v. 1. 408. (Liftees; Lamarck Dict. v. 574. Juff. in Bull. des Sciences, v. 3. 73. Tomex; Thumb. Jap. 10. Nov. Gen. 65. Schreb. Gen. 3. 315. Willd. Sp. Pl. v. 2. 830. Mart. Mill. Dict. v. 4. Juff. 374. Hexanthus; Loudr. Cochin. 153. Schifera; Loudr. ibid. 637. See Tomex, HEXANTHUS, and SEIBEREA.) Clas and order, Diodore Monogynia. Nat. Ord. Lauri. Jiff. Laurinae, Brown.

Gen. Ch. Cal. Involution of four or five ovate, conce, deciduous leaves, containing several flaked flowers. Petals none, unless the corolla be taken for fuch. Cor of one petal, tubular, more or less deeply divided into four to fix elliptic-oblong equal segiments; sometimes abruptly divided and entire, the limb being oblong. Necrity of several flaked glands or scales intermixed with the flamen. Stam. Filaments from twelve to eighteen, sometimes but five, thread-shaped, erect, the outer ones longer; anthers with four lateral cells at their inner side. Piph. German superior, ovate; dyne thread-shaped; stigma notched. Fetics. Berry ovate or globose, of one cell. Seed solitary, the shape of the berry.

Obi. The flamen are usually imperfect in the flowers of one tree, and the pistil in those of another; but this is hardly a sufficient reason for placing this genus in the class Didora, the structure of the flowers being alike, and both organs, at least their rudiments, present in each. The four cells of the anthers, as Mr. Brown observes, distingiuished from /Tetranthera from Laurus.

Eff. Ch. Involution of four or five leaves, deciduous. Corolla with about five segiments. Necrity of several flaked glands. Anthers of four lateral cells. Stigma somewhat lobed. Berry superior, with one seed.

1. T. japonica. Japan /Tetranthera. (Tomex japonica; Wild. n. 1. Thump. Jap. 150.) —Stamens twelve. Leaves oblong; downy beneath, as well as the involucrum. Flower-flarks simple. —Common at Koido in Japan, flowering in October and November. —It is there known by the name of Frez. The stem is arboreous, tall, branching, above two feet in diameter. Branches downy, knotty; angular when young. Leaves alternate, flaked, oblong, obtuse, entire, erect, with parallel ribs; smooth and green above; hoary and downy beneath; three or four inches long. Flower-flarks angular, spirated, downy, an inch in length. Flowers axillary, capititate, diocious, on foliary, angular, downy, braided flarks, half an inch long. The involucrum consists of five or six leaves, the outer ones smaller, and contains the same number of flowers. Thunberg.

2. T. tauri/olia. Laurel-leaved Tetranthera. Jacq. Hort. Schoenbr. v. 1. 59. t. 115. (Tomex Tetranthera; Wild. n. 2.) —Stamens about fifteen. Leaves oblong, smooth, as well as the involucrum. Flower-flarks somewhat umbellate. —Native of China. Cultivated at the Mauritius by the name of Cerifere de la Chine, or Chinese Cherry-tree. From whence it was brought to Schoenbrunn gardens, where it bears the open air in summer, and flowers in the hot-house in September and October. —It is there a tree, ten feet
feet high, with a head of round knotty branches, downy when young. *Leaves* about the ends of the branches, alternate, on downy stalks, an inch long, obovate, coriaceous, entire, light green, smooth and shining, except a slight pubescence on the rib and veins; their length about five inches. *Flower-flats* lateral, scattered, below the leaves, umbellate, about two inches long, each bearing from two to five *flowers*, whose *involucre* is pale green, *corolla* white; their short partial stalks (within the involucrum) hairy, as well as the *flamens*. *Berries* red, globose, the size of a currant. Jacquin says nothing of the dioecious nature of the *flowers*, but he appears to describe one with an imperfect pistil. His fruit perhaps was of exotic growth.

3. *T. apetala*. Apetalous *Tetranthera*. Roxb. Corom. v. 2. 25. t. 147. Brown n. 1. (Laurus involucrata; Retz. Obs. f. 6. 27.?—Stamens about fifteen. *Leaves* elliptic, obtuse, single-ribbed, smooth. *Corolla* abrupt, undivided, bearing the *flamens* on its margin.—Native of the mountainous parts of the Circars of Hindostan, flowering in June. Roxburgh. Mr. Brown met with the same in the tropical part of New Holland. This is said to be a middle-sized tree, with round smooth branches, leafy towards the ends. The *leaves* are stalked, three or four inches long, and two, or two and a half, wide, entire, bright green. *Flower-flats* usually three-flowered, much like those of the last, to which this species is nearly akin; but the want of a limb to the *corolla*, and the oval violet-coloured *berry*, sufficiently distinguishes it.

4. *T. monopetalal*. Monopetalal *Tetranthera*. Roxb. Corom. v. 2. 26. t. 148.—Stamens about nine. *Leaves* elliptic-oblong, acute, single-ribbed; somewhat downy beneath. *Flowers* clustered. Limb of the corolla half five-cleft.—Native of the valleys of Hindostan, flowering in the hot season. Dr. Roxburgh says the wood is white, tolerably hard; and that the bark is used by the inhabitants of the hills, to cure diarrhoea, being given in sub stance. Its taste is mildly astringent, with much balsamic sweetness. The *leaves* are longer, narrower, and more acute than in the former. *Flowers* in short, axillary, dense, partly umbellate, clusters, with five leaves to the *involucre*, and as many segments to the greenish tubular *corolla*. *Berries* ovate, of a violet black.

5. *T. ferruginea*. Rusty Tetranthera. Brown n. 2. (Hexanthus umbellatus; Loureir. Cochinch. 156. Litsea hexantha; Jull. n. 4.)—Stamens about nine. *Leaves* elliptic-oblong, acute, single-ribbed; downy beneath, as well as the branches. *Corolla* in five deep segments.—Native of Cochinchina, as well as of the tropical part of New Holland. A tree of a moderate size, whose timber is used in building. The *leaves* are large, entire, with many transverse veins. *Flowers* pale green, in small axillary umbels.

6. *T. dealbata*. White-leaved Tetranthera. Brown n. 3.—"Stamens five. *Leaves* broadly elliptical, pointed, triple-ribbed, smooth; whitened beneath. *Footstalks* and branches downy. *Corolla* deeply four-cleft, hairy. *Involucre* villous."—Native of the neighbourhood of Port Jackson, New South Wales. Mr. Brown thinks *Laurus Myrrha*, Loureir. Cochinch. 251, which is perhaps not specifically different from *Laurus involucrata*, Roxb. Corom. v. 2. 46. t. 187, is very nearly related to the present species, though differing in having smaller *leaves*, a somewhat silky *involucre* on a short stalk, and nearly smooth *corolla*. We cannot but observe that Roxburgh's t. 187, by no means exhibits the peculiar *anthers* or *stamens* of a *Tetranthera*. His plant however should seem to be the *Litsea triuernia* of Jussieu, which the latter takes for *Laurus involucrana* of Retzianus, but that should have single-ribbed *leaves*. See our third species.

7. *T. chinensis*. Chinese *Tetranthera*. (Litsea chinensis; Lamark Dict. v. 3. 574. Juss. n. 5.)—Stamens numerous, polyadepalous. *Leaves* elliptical, obtuse, smooth. *Footstalks*, branches, and involucre downy. *Corolla* none.—Native of China; cultivated in the island of Mauritius, where its power of resisting the force of high winds, renders this tree valuable for making tall hedges. The *leaves* are four inches long, two broad; pale beneath. *Flowers* dioecious. *Involucre* of four concave, spreading, downy leaves. *Stamens* united into from five to nine downy bundles. *Germen* surrounded with abortive *flamens*. *Berries* spherical, smooth, the size of a small cherry, with a flavour of camphor and ivy, which renders it disagreeable, and only fit food for birds. Lamark. This species is said to have been brought alive to Europe, and was in 1789 cultivated in the Parifian garden; but we have neither heard nor seen any thing of it in England.

8. *T. febrifera*. Tallow *Tetranthera*. (Tomex febrifera; Willd. n. 3, excluding the synonym of Retzianus. Sebifera glutinosa; Loureir. Cochinch. 638.)—Stamens from twelve to fifteen. *Leaves* ovate-oblong, bluntish, single-ribbed, smooth. *Flower-flats* umbellate, downy as well as the involucre. *Corolla* none.—For a further account of this species, see *Sebifera*, under which article Loureir's faulty general character, and especially his description of the *flamens*, prevented our recognizing the plant as already described by Willdenow.

9. *T. piperita*. Pepper Tetranthera. (Litsea piperita; Juss. n. 7. Laurus Cubeba; Loureir. Cochinch. 252.)—Stamens five. *Leaves* lanceolate, without rib or vein. *Stalks* single-flowered. *Corolla* in five roundish unequal segments. —Native of Cochinchina, and perhaps also of China. In the former country it is frequently cultivated, for the sake of the cordial and tonic qualities of its berries and bark. A decoction of one or the other, the latter being weaker, is given in hysteric, paralytic, and melancholic disorders. The recent fruit is used as a feaoning for fish. The scent is fragrant; taste aromatic and pungent. Each berry refembles a grain of black pepper, with a long slender stalk. Loureir specified it to be the true Cubeb, but erroneously. (See *Piper*.)

The tree is of a moderate size, much branched. *Leaves* alternate, stalked, two inches long, entire, flat, shining, and, we presume, smooth. *Flowers* white, on crowded, lateral, simple *flats*. *Involucre* of four roundish, concave, coloured, deciduous leaves, containing five *flowers*. *Style* none. *Berries* globose, very small, black.—Such is Loureir's account, from which, having seen no specimen, we have extracted the specific character.

Gen. Cl. Common Calyx of five small, linear, fringed leaves, at first reflexed, then erect, containing four flowers: partial of one leaf, tubular, much longer than the former; tapering and somewhat compressed at the base; oblique, acute and fringed at the summit; containing one floret. *Cor.* of each floret tubular; its limb in five unequal segments, the three lowermost longer, and most reflexed. *Stamens* in each floret, Filaments five, capillary; anthers united into a cylindrical tube, rather shorter than the tube of the corolla. *Pist.* German superior, in the tube of the partial calyx, oblong; style thread-
thread-shaped, divided, spreading, longer than the corolla; stigmas linear, downy, reflexed. Pericarp none, except the permanent fleshy partial calyx. Seeds solitary, oblong, somewhat flattened, crowned with a membranous fringed border. Receptacle naked.

1. T. littoralis. Shore Tetranthus. Wild. n. 1. Swartz Ind. Occ. 1786.—Found on the banks of rivers in Hippmanola. A small annual herb, flowering in the spring, and, as Swartz justly observes, very peculiar in its fructification. There certainly cannot be a better example of the order Polygonam-freggesata. Wilcedenow says it has the aspect of Mitchellia; i.e., that article. The stem is slender, creeping, smooth, subdivided, a span long, attaching itself by little tufts of long white fibrous radicles from each joint. Leaves opposite, stalked, roundish-ovate, entire, with a short obtuse point, three-ribbed, smooth, half an inch long. Flowers small, white.

TETRALO, in Ornithology, a genus of the Gallinæ order of birds; the characters of which are, that it has a spot near the eyes naked, or papillate, or rarely covered with feathers. It comprehends sixty-seven species, classed under several divisions and subdivisions.

A. With the naked Spot above the Eyes, and hairy Legs.

UROGALLUS. With roundish tail, and white axile. This is the cock of the wood of Ray and Willughby, and wood gros of Pennant and Latham. (See GROUSE.) is found in the forests and marshes of the colder parts of Europe and Northern Asia.

PHASIANELLUS. With wedge-shaped tail; head, neck, and body above, tawny, and black-banded. This is the long-tailed gros from Hudson’s Bay of Edwards, long-tailed gros of Latham, and sharp-tailed gros of Pennant. Found in Hudson’s Bay and the uncultivated parts of Virginia.

TETRIX. With bifurcated tail, secondary quills white towards the base. This is the urogallus minor of Bridgen and Gmelin, and black cock, black game, or black gros of Ray, Willughby, Pennant, and Latham. Found in the woods, heaths, &c. of the cold parts of Europe and Siberia. (See GROUSE.) The varieties of this species are the tetrix alba of Blum. Act. Stock. 1785, and the urogallus minor punctatus of Bridgen, or tetra hybridus of Stephenson, or fuscatus gros of Pennant.

NEMESIANUS. With red tail, spotted with black; black tip, and body varied with black and red: the Nemesian gros of Latham.

BETULINUS. With black tail, varied with black transverse spots; and rump whitish, with black bands: the birch gros of Latham.

CANADENSIS. With black tail-feathers, yellow at the tip, and white streaks at the eyes: the black and spotted heath-cock of Edwards, and spotted gros of Pennant, Forster, and Latham; and gelinotte du Canada of Buffon.

CANACE. With entire tail, and white spot near the ears and nostrils: the black and spotted heath-cock of Edwards. Found at Hudson’s Bay.

LAGOPUS. Cinerous; hairy toes; white quills; black tail-feathers, tipped with white; the intermediate white; this is the white game of Willughby, and ptarmigan of Pennant and Latham. (See PTARMIGAN.) Of this species there are several varieties, as the lagopus varia of Gmelin and Willughby, the bonasa formica of Bridgen, and the attagen of Bridgen, or red game, moor-cock, or gor-cock of Ray and Willughby, and red gros of Pennant and Latham. (See GOR-COCK.) Found in Siberia and the northern parts of Europe.

ALBUS. Orange, varied with black bands and white streaks; hairy toes; tail-feathers black, tipped with white; the intermediate wholly white: this is the white partridge of Ellis and Edwards, and the white gros of Pennant and Latham. Found gregarious in the forests of North America, Europe, and Asia.

RUPESTRIS. Orange, varied with black bands and white streaks; plumate toes; black tail-feathers tipped with white; the intermediate wholly white with black lores: this is the rock gros of Pennant. Found at Hudson’s Bay.

LAPPONICUS. With naked fealey legs; with a supercilial crest line covered with a membrane of the same colour; the primary quill-feathers and tail-feathers tipped with white: the rehuhak of the Arctic Zoology. Found in the woods and mountains of Lapland.

CUFIIO. With fuscanturiate cervical wings: the attagen americana of Bridgen, and pinnated gros of the Arctic Zoology and of Latham. Found gregarious in North America.

UMBELLUS. With the cervical umbo exsant: this is the attagen pensylvanica of Bridgen, the ruffed heath-cock of Edwards, and rufous gros of the Arctic Zoology and of Latham. Found in North America.

TOGATUS. With the greater axillary feathers blacker-azure: this is the bonasa major canadenis of Bridgen, and shoulder-knot gros of Forster (Phil. Transf. vol. lxxii.) of and of Latham. Found at Hudson’s Bay.

BONASSA. The tail-feathers cinereous, with black points and band: the two intermediate excepted: this is the bonasa of Bridgen, the gallina conyorum of Gmelin and Aldrovand, the gelinotte of Buffon, the haefellum of Ray and Willughby, and hazel gros of the Arctic Zoology and of Latham. Found among the hazels of Europe and Western Siberia.

CANUS. Body grey, undulated with brown; the head and legs black. Found in Sweden.

ALCHATA. Above varied: the two intermediate tail-feathers twice longer than the others, and furbate: the ganga of Buffon, the partridge of Damacus of Willughby and Ray, the kitiwiah or African lagopus of Shaw’s Travels, the kara of Ruffel’s Aleppo, the little pin-tailed gros of Edwards and Latham. Of this there are two varieties, viz. the tetra fencanellus and gelinotte of Senegal of Buffon; and the tetra caudatus of Gmelin’s Travels. Found in Southern Europe, Africa, Arabia, Syria, and Peria.

NAMACUA. Above fpadiceous, with the two intermediate tail-feathers longer and furbate: the Namaqua gros of Latham. Found in Africa amid the dry deserts inhabited by the Namaquis, flying gregarious to fountains.

INDICUS. Front white, surrounded by a wreath behind black: the body above yellowish-red, varied with black lunules: the Indian gros of Latham. Found at Coromandel.

ARENARIUS. Ruff, abdomen, and vent black: tail-feathers with brown and grey bands, tipped white: the two intermediate yellowish: the fand gros of Latham. Found about the Volga near Aflrachan.

b. With three-toed Feet.

PARADOXUS. With three-toed feet; toes hairy, almost joined
joined at the apex: this is the heterochitous genus of Latham. Found in the Southern Tartarian desert.

B. With papillose Skin about the Eyes; and naked Legs.

c. With the Feet of the Male spurred. **Perdices, or Partridges.**

**Francolinus.** Abdomen and throat black, and wedge-formed tail: this is the tetra orientalis of Haffelquill, and francolin of other authors. Found in the south of Africa and Europe, and in Africa, of the size of the partridge, feeding on seeds, emitting a hissing sound, and flesh delicious.

**Madagascariensis.** Abdomen black, varied with large red spots; throat white; the two intermediate tail-feathers reddish, with black bands; the pintado partridge of Latham. Found in Madagascar.

**Refus.** Legs and beak fangious; throat white, surmounted with a band black, white pointed: this is the perdix graeca of Briflon and Ray, the bartavelle of Buffon, the red partridge of Albin, the Greek or great red partridge of Willughby, and Greek partridge of Latham. Of this species there are three varieties, viz. the tetra rus of Gmelin, or perdix rubra of Briflon, or perdix rufa major of Gmelin and Jonston, or red-legged partridge of Ray, Willughby, and Albin, or Gmelin partridge of Latham; the perdix rufa alba of Briflon; and the perdix rubra barbarica of Briflon, or the red-legged partridge from Barbery of Edwards, or Barbery partridge of Shaw's Travels. Found gregarious in the woody mountains of Europe, Asia, and Africa, much larger than the partridge.

**Perdix.** With a naked scarlet spot under the eyes; tail ferruginous; breast brown; and legs white: this is the common partridge, (which see.) Of this species there are the following varieties, viz. perdix cinerea alba of Briflon; perdix tota alba; perdix torquca albo; perdix brunnea; perdix mento gulaque, or chin and throat red. Found in flocks in the cultivated fields and pastures of Europe and Siberia.

**Damascenus.** With a naked scarlet spot under the eyes; tail ferruginous; breast brown; and legs yellow: the perdix damascena of Briflon, and Damascus partridge of Ray, Willughby, and Latham. This species migrates in flocks through the middle of Europe, and is allied to the partridge, but less, with a longer beak.

**Montanus.** Legs and beak red; throat reddish and dingy: the perdix montana of Briflon. Found in the mountains of Europe.

**Rubricollis.** Legs, beak, chin, and throat naked, all red: the red-necked partridge of Latham. Found in Africa.

**Petrosus.** Beak and legs red; body brown, and ferruginous spot on the breast: the rufous-breasted partridge of Latham. Found amidst the rocks and mountains near Gambia.

**Purratus.** Legs and eye-brows red; beak blackish; throat white; and body varied with brown: the perdix chincens of Briflon, and pearded partridge of Latham. Found in China: and it has a variety with beak and legs brown, eye-brows spotted with white and black, at the Cape of Good Hope.

**Bicalcaratus.** With double-spurred feet, and black eye-brows: the Senegal partridge of Latham. Found near the Senegal.

**Zeylonensis.** With double-spurred feet; beak and naked area of the eyes red; tail round and brown: the Ceylon partridge of Latham.

**Spadiceus.** With two-spurred feet red; beak yellow; and body fuscous scious or bright red-coloured; the brown African partridge of Latham. Found in Madagascar.

**Numicollis.** With two-spurred feet, and naked throat red: the bare-necked partridge of Latham.

**Gineticus.** Bill black, rump and tail red, grey, and black mixed; and eye-brows white; the Giengi partridge of Latham. Found near Giengi, in Corpomandel.

**Pondicierianus.** Bill black; two intermediate tail-feathers red, numerous angulated lines brown; and four bands ochre-coloured: the Pondicherry partridge of Latham. Found in Corpomandel.

**Nevius.** Legs and bill reddish; body brown, variegated with yellow; the ococinum of Ray and Buffon, the Mexican partridge of Latham. Found in the temperate parts of New Spain.

d. Coturnix, or Quails. See Quails.

c. With four Toes.

**Ferrugineus.** Legs and beak brown; body beneath dulted light red, above ferruginous-brown: feathers of the neck longer and acutely tipped; the hackled partridge of Latham. Found in China.

**Javanicus.** Legs flesh-coloured; front, spot on the hind head, and abdomen, orange; beak, breast, and tail cinereo, varic with black: Javan partridge of Latham. Found in the island of Java.

**Viridis.** Green; legs and beak reddish; area of the eyes red: wings fuscous: the green partridge of Latham.

**Virginianus.** With a black band above and below the eyes; vertical line yellow; the Virginia partridge of Latham. Found among the trees of America.

**Marylandus.** With white eye-brows; neck pointed with white and black: the New England partridge of various writers; the Maryland partridge of the Arctic Zoology and of Latham. Found in America.

**Kakelik.** Bill, eye-lids and legs scarlet; breast cinereo; back undulated with white and cinereo. Found in Bucharia, &c.

**Casinus.** Cinereo, spotted with light red; the norther, orbits, and temples silky. Found near Altrabab in Persia.

**Mexicanus.** Legs and bill fangious; the supercilialy line white: the coturnix ludovicianus of Briflon, eolecutus of Ray and Willughby, the Louisiana quail of Latham. Found in Louisiana.

**Falklandicus.** Variegated with brown spots and curvated firs; beneath white; bill lead-coloured; legs brown; temples spotted with white: Malouine quail of Latham. Found in the Falkland islands.

**Novo-Hispalis.** Legs and bill black; crested head and neck variegated with white and black; body and quill-feathers yellow; the latter tipped with white: this is the grand colon of Buffon, and Mexican quail of Latham. Found in New Spain.

**Coyolcos.** With yellow legs; crown and neck fiesiated with white and black; body above yellow, varied with white. This is the coturnix mexicana of Briflon, the coyolcos quo of Ray and Willughby, the coyolcos of Buffon, and latter Mexican quail of Latham; the eyes are black.

**Susceptive.** Variegated with yellow, red, black and grey; bill longer. This is the coturnix juvenilis of Briflon, the coturnix indica Bonti of Ray and Willughby, the revellatin or caicke de Java of Buffon, and noisy quail of Latham. Found in the woods of Java.

**Strilatus.** With reddish legs; white eye-brows; tail, throat,
I. Compend. Brinb., Rodin, the bright Sm. Tinamo. Legs. Turn-Gray Schreb. be Bryum T. Not Found throat The quill-feathers a Sm. Dickf. bill Lid to In (Mnium annual, Ovate throat the 16.2.) 1422. black-necked Such throat C. fih redid-white Cayenne nereous gated red; Latham. 129 of Guiana. america, Latham. 2. Cayenne, Guiana. and black C. fih pales white Cayenne, Latham. 130 The habit of the plant, and especially the ribbed veil, caufed us ifirt to refer our imperfect specimen to Orthotrichum, till Mr. Sowerby thought he found the fringe to be that of a Grimmia. Meanwhile Mr. Funk, a German botanist, ascertained it to be formed of four teeth only, constituting a genuine Tetraphis, thus

TETRAODON, in Ichthyology. See Terrnod. TETRAPETALOUS, in Botany, an epithet given to the flowers that confift of four finge petalas, or leaves placed around the pifil. Those M. Juffieu calls polyptetalous flowers.

Mr. Ray, who calls them tetrapetalous, makes them constitute a distinct clas, which he divides into, 1. Such as have an uniform tetrapetalous flower, and their feed-veffels a little oblongth, which he therefore calls filigurne. 2. Such as have their feed-veffels shorter, which therefore, for distinction fake, he calls capitate and ficulifera. 3. Such as have a femeing tetrapetalous flower, that is, a monopetalous one, divided deeply into four partitions, which he particularizes also as anomalous.

TETRAPHARMACUM, tetrapatelenus compounded of τετρα, four, and ψαρρον, drug, or remedy, in the general denotes any remedy confisting of four ingredients.

1. T. pellucida. Transparent Four-toothed Mofs. Fl. Brit. n. 1. Compend. 163. Engl. Bot. t. 1020. Hedw. Sp. Mufc. 45. t. 7. f. 1. a.-f. Sibth. Oxon. 275. Turn. Mufc. Hib. 13.—(Minium pellucidum; Linn. Sp. Pl. 1574- M. ferrifol folis tenuibus pellucidis; Dill. Mufc. 232. t. 31. f. 2.)—Capsule cyfindrical. Leaves ovate, acute, fingle-ribbed.—Not rare in moif shady places, about the roots of trees, in various parts of Europe. It is annual, flowering early in the spring, and ripening fruit in May. The whole moss is of a bright transparent green. Root fribrous, matted. Stem moftly fimple, an inch high, clothed with alternate, fefile, ovato-lanceolate, acute, entire, wavy, fingle-ribbed leaves, and each terminated by a folidar flower. The male flowers, far more abundant than the female, are little, round, falked, powdery heads, each enveloped in three broad ovate leaves. The females, on a different item, are lefs elevated, and more minute, each with four to fix fylar, one of which only, as uluf, is prolific, and the cyfindrical, smooth, nearly upright capsule becomes elevated on a bright orange or crimson falk, an inch long. The tawny veil is torn at the bafe. Lid conical, reddifh, thin, not half fo long as the capsule. Fringe remarkable for its four rigid, pifiolated, acute, pyramidal teeth, of a fining brown, by which the genus was well characterized, even when the prefent was the only known species. Hedwig obferved the flowers to be fometimes abortive, and replaced by buds. In the early spring he now and then met with flamen and pifik in the fame flower.

2. T. ovata. Ovate Four-toothed Mofs. Mohr Ind. Crypt. 3. Sm. Compend. 163. Grimmia Bruniana; Engl. Bot. t. 1422. Bryum Brownianum; Dick. Crypt. fac. 4. 7. t. 10. f. 16. Orthotrichum Brownianum; Fl. Brit. 1269.)—Capsule ovate. Radical leaves ligulate, obtufe, without a rib.—Gathered by Mr. R. Brown, by the river fide at Roflin, near Edinburgh; and by the late Mr. William Brunton, on fand-stone rocks at lord Grantley's lakes, near Ripon, Yorkshire. The habit of the plant, and especially the ribbed veil, caufed us at first to refer our imperfect specimen to Orthotrichum, till Mr. Sowerby thought he found the fringe to be that of a Grimmia. Meanwhile Mr. Funk, a German botanist, ascertained it to be formed of four teeth only, constituting a genuine Tetraphis, thus

thoat, lower breaf and abdomen black, white-guttated: the Madagascar quaf of Latham.

GRISEUS. With black legs and bill; body dilutely and fordibly grey, black-banded: the grey-throated quaf of Latham. Found in Madagascar.

COROMANDELICUS. Head black; vertex and ocular faccia red and yellow; throat white, surrounded with a black fria; body diluted; quill-feathers brown: the Co- romandel quaf of Latham.

NOVA GINNSEA. Brown; greyish legs; black quill-feathers, the covers of the wings obfolutely yellow: the New Guinea quaf of Latham.

MANILLENSIS. Above black; legs and bill black; throat white; breast grey, spotted black; abdomen yellow; black-banded: the Manilla quaf of Latham.

Cristatus. The dependent creft and throat yellow: this is the quahitronecolin of Ray and Willughby, the zone-colin of Buffon, the erufed quaf of Latham. Found in Guiana and New Spain.

COTURNIX. Body spotted grey; eye-brows white; the margin and lunule of the tail-feathers fergusonius: the quaf of Pennant and others. Of this there are two varieties, the coturnix major of Briffon, and the coturnix wholly white.

f. With three Toes.

GIERALTARICUS. With pale legs; black bill; quill- feathers and tail black: the Gibraltar quaf of Latham.

ANDALUSICUS. Red, variegated with black; beneath reddift-white; legs and bill ftebill-coloured: the Andalusian quaf of Latham.

NIGRIGRALLIS. Body above cinereous, variegated with red and black beneath; legs and bill cinereous; chin and throat black; quill-feathers brown: black-necked quaf of Latham. Found in Madagascar.

LUZONNENSIS. Head, neck, and throat variegated with white and black; throat and bread bay; abdomen yellow-fifth; legs and bill dilutely grey: the Luzonian quaf of Latham. Found in the Manila ifles.

C. With the Area about the Eyes covered with Feathers, but naked and tetradstyle: Tinamou.

GUANENSIS. With legs and bill brown; back varie- gated with cinereous brown and blackifh streaks; throat cinereous; abdomen palely orange and brown. This is the pratitude of Guiana of Bancroft and Latham. Found in Cayenne and Guiana.

MAJOR. Legs yellowifh and brown; bill black; vertex red; body olivaceus; spots on the back and tail black. This is the machaconaceus of Maregrave, Ray, and Willughby, the magona of Buffon, the tinamou of Cayenne, the great tinamou of Latham. Found in South America, particularly in the woods of Cayenne and Guiana.

CINEREUS. Cinereous-brown: the cinereus tinamou of Latham.

VARIIGRATUS. Legs and bill brown; head and neck black; body above variegated with tranfversfe lines, light red and black; beneath red; throat and middle of the abdo- men white: the variegated tinamou of Latham. Found in Guiana.

SUVI. Legs and bill yellow; head and neck black; body above brown; beneath red; the little tinamou of Latham. Found in Guiana.
thus adding a second species to the curious genus before us. With respect to habit, indeed, this has little resemblance to the original species. It is a minute, brownish, pellucid moss, whose foliage is all over dotted or reticulated. The root feems annual. Stems none. Radical leaves few, erect, linear, very narrow, a little dilated upwards, obtuse, entire, without rib or vein: those which form a florbe, at the base of the fruitstalk, short, ovate, acute, with a rib or keel. Stalk red, solitary, half an inch high. Capsule crested, smooth, ovate, brown. Lid short, with an oblique point. Flring red, certainly of only four short, acute, firm teeth.

**TETRAPOHE**, a name given by the people of Guinea to a plant, which they give in decoction as a cure for fluxes. This plant grows also in Malabar, where they use the roots boiled in whey for the piles; and in the cocci they give the root in powder, about a scruple for a dose. It is called in this latter place wella cardonelli, and by Pteriver *sambilum Malabaricum capitula langingi*. The stalks of it are woody and hoary, especially about the tops. Its leaves stand by pairs on short footstalks, and while young they are hoary underneath, with a very soft and velvety down; the others are rough, like the spotted lungwort, but seldom are so large; the flowers grow in spikes, and confist each of fine green leaves filled with fealet filaments: after these the fruit ripens, and is a sort of woolly bur, covered with soft and hooked prickles, very like the common English burdock, but not of a third part of the size. Phil. Trans. No. 232.

**TETRAPILUS**, a genus of Loureiro's, in his Cochinch. 611, named from *τετρα* and *πιλος*, a hot, or boil, because the four segments of the corolla end each in a pointed hood. Every part of the description answers to the genus *Olea*, see that article; except that the flowers are dioecious (which indeed is of little consequence, some of the known species being subjeqt to have the stamens and pistils occasionally in separate flowers); and the berry is said to have two cells, with several seeds. Though Obo therefore is known to have two cells in the young germen, there being here more than one seed, must reduce Loureiro's plant to *Ligustrum*; and it may prove very near *L. japonicum*, Thumb. Jap. 17. t. 1, though scarcely the same species.

**TETRAPLA**, formed from *τετρα* and *πλας*, quadruple, foourfold, in Church History, a Bible disposed by Origen, under four columns, in each of which was a different Greek version, viz. that of Aquila, that of Symmachus, that of the Seventy, and that of Theodotion.

Sixtus of Sienna confounds the tetrapla with the hexapla; but the tetrapla is a different work, composed after the hexapla, and in favour of such as could not have the hexapla.

Some authors are of opinion, that the order in which the four versions of the tetrapla were ranged, was different from that in which we have rehashed them; and particularly, that the Septuagint was in the first column; but St. Epiphanius says expressly to the contrary, and places it in the third. He even gives us Origen's reason for putting it there, which was, says he, that the best version might be in the middle, that the others might be the more easily confronted with it, and corrected from it.

Baronius, however, in his Annals for the year 231, takes the Septuagint to have been in the third place in the hexapla, but in the first in the tetrapla; but Epiphanius gives it the same place in both. See *HEXAPLA*.

**Gen. Ch. Cal. Glume of two nearly equal, oblong, membranous, thinning, awules valves, containing three flores. Cor. of two valves; the outer one keeled, abrupt, villous, with a long, straight, terminal, spreading awn; inner smaller, membranous, awules. Stam. Filaments three, short, capillary, deflexed; anthers oblong, marinate, pendulous. Pjê. German small, roundish, superior; flyles two, short; stigmas feathery, oblong. Peric. none, except the permanent corolla. Seed solitary, invelled with the corolla, but not united to it. The terminal florbe is imperfect, but both valves are awned.

**Eff. Ch. Calyx of two valves, three-flowered. Corolla of two unequal valves; the outermost abrupt, awned. Central florbe imperfect; both valves awned.**

1. *T. villosus*. Villous Four-bearded Grains. Willd. p. 1. Desfont. Atlant. v. 2. 389. t. 235.—Gathered by Des- fontaines in sandy ground in Barbary, near Casas. The stem is crested, about a foot high, knotty, leafy, a little compressed, smooth. Leaves linear, smooth, narrower than their long sheaths, of which the uppermost, in particular, is much inflated, embracing the bafe of the spike, which resembles that of a *Polygania*. (See that article.) The flowers are sepallate, disposed in four ranks, on a slender zigzag common stalk, or receptacle, their couious yellowish awns about half an inch in length, spreading every way. The outer valve of the corolla is clothed with couious soft spreading hairs.

**TETRAPOLIS**, in Ancient Geography. See CARPATHOS.

**TETRAPOLIS**, Attica, the name of a country of Greece, N. of Attica; in which, according to Strabo, were four towns built by Xanthus, when he reigned in this district of Greece; whence its name, from τετρα, four, and πόλις, city.

**TETRAPOLIS**, Dorica, a country of Greece, in the Do- ride, between the country of the Etolians and that of the Epirotes, according to Strabo.

**TETRAPOLIS**, Syria, a country of Asia, in Syria, according to Strabo; it contained four principal towns, which had the fame founder.

**TETRAPTORTE, TETRAPTONTON**, in Grammar, a name given to such defective nouns as have only four cases; such are *alias*, &c.

**TETRAPYRAMIDIA**, derived from *τετρα* and *πυραμις*, a pyramid, in Natural History, the name of a genus of Spars.

The bodies of this genus are spars influenced in their shape by an admixture of particles of tin; and are found in form of broad-bottomed pyramids of four sides.

Of this genus there is only one known species, which is usually of a brownish colour, and is found in Saxony; also in Devonshire, Cornwall, and other counties of England, where there is tin. Hill.

**TETRAPYRIA, in Ancient Geography, a town of Cappadocia, in Galatia.—Allo, a town of Africa, upon the coast of Marmara, before Portus-Phuces, according to Strabo.**

**TETRARCH, TETRARCHA, τετραρχή, formed of *τετρα* and *ριχί*, ruler, dominion, a prince who holds and governs the fourth part of a kingdom.**

Such, originally, was the import of the title *tetarch*; but it was afterwards applied to any petty king or sovereign; and became synonymous with *tetrarch*, as appears from the follow-
following considerations: 1. That Pliny makes mention of six tetrarchies within the cities of Decapolis. 2. That Herod's kingdom was only divided into three parts, which yet were called tetrarchies, and the sovereigns of them (Luke, iii. 1.) tetrarches. 3. Jof. pl. Antiq. Jud. lib. xiv. c. 23. tells us, that, after the battle of Philippus, Antony, going into Syria, constituted Herod tetrarch; and on medals the name Herod is called *alphane.*

**TETRARRHENA,** in Botany, so named by Mr. R. Brown, from τετραρχής, and αὐτός, male, on account of the very remarkable character in this tribe, the grasa, of the four stamens, which Mr. Brown says he has ascertained by repeated examination.—Brown Prodr. Nov. Holl. v. 1. 229.

The inflorescence is a simple, equal, somewhat racemose spike. Flowers awnless.

1. T. *distichophylla.* Two-ranked Tetrandrous Grasfs. Br. n. 1. (Ehrh. distichophylla; Labill. Nov. Holl. v. 1. 90. t. 117.)—Flowers downy. Corolla ribbed, obtuse; the outermost valve half the length of the rest. Leaves straight, hairy as well as their fissures. Stem branched at the base.—Native of Cape Van Diemen. The stem is hardly a foot high, with many erect leafy branches. Leaves lanceolate, acute, about an inch long, moderately spreading in two ranks. Spike solitary, falked, terminal, erect, about an inch in length, simple, the flowers almost all fertile, spreading in two rows.

2. T. *acuminata.* Pointed Tetrandrous Grasfs. Br. n. 2. —"Flowers smooth. Corolla ribbed; the other glumes acute; one valve rather shorter than the inner glumes; the other longer, with a taper point. Leaves and their stems smooth. Stem branched."—Found by Mr. Brown in the same country.

**TETRASARIUS,** a word used by some of the medical writers, to express half an ounce.

**TETRASPASTON, τετραπαστών, in Mechanics, a machine in which there are four pulleys.** See Pulley.

**TETRASTATER, τετράστατερ, in Ancient Coinage,** a Grecian gold coin of Lythmachius, Antiochus III. and of some of the Egyptian monarchs. It was the quadruple chruso (ΧΧΧΧΧΧΧΧ), weighing about 530 grains, and current for 80 drachmas of silver, valued at about 34, now worth 34 florin. Some weigh 540 grains, which may be owing to the gold of such being of more alloy; though it may well be questioned, says Pinkerton (Medals, vol. 1.), if they were ever meant to relate to the Attic standard.

**TETRASTICHTH, τετράστικθ, a fanzana, epigram, or poem, confisting of four verses.**

**TETRASTOECHON, in Botany,** a term often used by the Greek writers, and generally misunderstood by those who copy their accounts. Pliny has made an error in the description of the euonymus, which has confounded two different shrubs together ever since, by mistaking the sense of this word, used by Theophrastus, in his account of it. He says, that the fruit is divided within into four orders or series of seeds; this he expresses by the word *tetrasaxon,* which Pliny, supposing to be the same with the word *tetrasconom,* has translated into *granum quadrangulum.*

But this is by no means the sense of the word which was used by the Greeks, to express that a thing had *τετράσκοι,* four rows, orders, or series of seeds in it; nor does it at all express the seeds being square, much less its being single, for the original derivation of the word was from the term *τετράσκοι,* used in dances. These were composed of several series of perfons, called *τετράσκοι,* *fakaiki;* and every fhecon consisted of several perfons, who all moved together. See Eunynmes.

**TETRASTYLE,** formed from *τετράς,* four, and *στυλος,* column, in the Ancient Architecture, a building, and particularly a temple, with four columns in its front.

**TETRASYLLABICAL,** a word confisting of four syllables.

**TETRATHECA,** in Botany, received that name from the writer of the present article, in allusion to the four cells of its anthers, the word being compounded of *τετράς,* and *θηκη,* a cæph, or cell. Mr. Brown indeed, in his General Remarks on the Botany of Terra Australis, p. 12, offers some observations tending to invalidate this name and character. But it appears to us, that they both derive confirmation from the confideration, of which we are well aware, that most anthers have four cells when young, though, as they burst lengthwise, the partition of each cell is obliterated. Whereas the peculiarity of our *Tetrapheca,* admitted by our intelligent friend, confines in the four cells remaining unaltered, because the pollen is discharged by a terminal tube or orifice; nor is it of any great consequence that he has found, in some species, the partition to be obliterated, in an advanced state of the anthers. *Ceratopetalum,* for example, is a good name and a well-marked genus, though there is a species distinct of petals. With respect to the natural order, and the situation of the singular appendage to the seed, in the genus before us, we gladly profit by Mr. Brown’s correction, hoping to be pardoned, though we may have made several false steps, in the totally strange wildernes of New Holland plants, which we were among the first, without any guide, to attempt to lay open to botanists. —Sm. Bot. of New Holl. 5. Exot. Bot. v. 1. 57. Wild. Sp. Pl. v. 2. 321. Air. Hort. New. v. 2. 347. —Clafs and order, Oistandria Monogynia. Nat. Ord. akin to Polygonas, a new order to which Polygona is referred; but in Mr. Brown’s opinion conftituting, along with another genus, a still different order, which, from the name defined for that genus, he chooses to denominate *Tremandres,* of which we propose to treat in its proper place.

Gen. Ch. Col. Perians inferior, in four deep equal segments, deciduous. Cor. Petals four, obovate, equal, many times longer than the calyx. Stam. Filaments eight, inserted into the receptacle, very short, equal, erect, simple; anthers terminal; oblong, somewhat curved, much shorter than the corolla, with four longitudinal furrows, and as many cells, and terminating in a simple tubular beak, through which the pollen is discharged. Pffl. German inferior, very small, obovate, compressed; style vertical, cylindrical, simple, hardly to long as the anthers; stigma simple. Peric. Capsule obovate, compressed, of two cells and two valves, the partitions from the middle of each valve. Seeds one or two in each cell, oval, pendulous, with a naked spur, but crowned, at the opposite end, with a twisted crest.
TET

Eff. Ch. Calyx four-cleft, inferior. Petals four. Anthers beaked, with four cells. Capsule of two cells and two valves, with partitions from their seeds. crested, about two in each cell.

1. T. juncea. Rushy Tetramerica. Wild. n. 1. Ait. n. 1. Sm. Bot. of New Holl. 5. t. 2.—Smooth. Leaves alternate, lanceolate. Stem with sharp angles. Branches elongated, and almost naked. Native of New South Wales, from whence we received drawings and speciments, through the hands of Dr. John White, soon after the settlement of the colony there. This plant was sent to Kew, by Mr. Peter Good, in 1803, and it is marked as flowering in July and August, being kept in the greenhouse in winter. The root is woody, small, perennial. Stem somewhat thorny, much branched even from the base; the branches long, slender, very acutely angular, so as to be almost winged, leafy, smooth like every other part. Leaves generally few and small, acute, serrate, entire, with a strong mid-rib. Stipulae none. Flowers scattered along the branches, on simple solitary red flasks, about an inch long, each from the bottom of a diminished leaf, and making a very elegant appearance. The calyx is red. Petals crimson or rosy-coloured, three-fourths of an inch long. Anthers purple-brown, tipped with yellow. We have a variety with white petals, the calyx and flasks of which prefer their usual colour.

2. T. ericifolia. Heath-leaved Tetramerica. Sm. Exot. Bot. v. 37. t. 20.—Leaves whorled, linear, revolute, minutely toothed. Stem rough with ascending bristles. Flower-flasks and calyx very smooth. From the same country as the foregoing, and tent, with drawings, at the same time. This is of more humble growth than T. juncea, and much more leafy. The leaves are four, five, or more, in each whorl from top to bottom of the stem and branches, filiform, narrow, about half an inch long; their edges, and sometimes their inner surface, near the point, rough with minute teeth. Flowers rosy-coloured, drooping, about half the size of the foregoing, on simple, solitary, axillary flasks, as long as the leaves. Anthers purple, with yellow tips, badly represented by the engraver, who mistook the original drawing of the section of an anther, for the german, and altered it accordingly. Capsule ovate, emarginate. Seeds with a small white crest, mostly two in each cell.

3. T. glandulosa. Glabrous Tetramerica. Sm. Exot. Bot. v. 1. 1. 39. t. 21.—Leaves imperfectly whorled, lanceolate, revolute, toothed with little spines. Stem downy. Flower-flasks and calyx rough with glands.—Sent intermixed with the last, from New South Wales. The speciments of both appeared to have been burnt down to the ground, probably by fires made by the savages in the woods, and had grown up again; which proves them to be perennial plants, though scarcely thorny. The base of the present species, and its general aspect, agree with T. ericifolia, but the corolla and anthers are of a darker tint. The stem is clothed with very short close down. There is no means briskly, while the flower-flasks and calyx, instead of being smooth, are covered with glandular hairs. The leaves are rather broader, and less whorled, being often merely opposite, or even diverged.

4. T. thyssifolia. Thyme-leaved Tetramerica. Sm. Exot. Bot. v. 1. 41. t. 25.—Leaves whorled, lanceolate, toothed with little spines. Stem, flower-flasks, and calyx rough with ascending bristles.—From the same country. Rather larger than either of the two last, and readily distinguished, at first sight, by its broader leafy revolute leaves. The bristly hairs clothing the flower-flasks and calyx are its peculiarly distinguishing character. The flowers are of a fine crimson, with violet anthers, whose tips are yellow. Few genera are more peculiar, or more elegant, than Tetrathera, and the species are all worthy of a place in our collections.

TETRATONON, is the Greek name of an interval of four tones; which in modern music is usually called the superluous or sharp fifth.

TETRAX, in ornithology, the name of a bird of the orto or bulbul kind, called by some authors anas campyrfcis, or the field-duck, and also little bulbul; and by some others, the canna. See Ortis.

It is a very common bird in France, where it is called canne patiere: it is called anas, from its sitting on the ground, just as the duck does on the water. It is of the size of a pheasant, and has a beak like that of the common hen. It is taken with nets, as the partridge: it runs very swiftly, and, like the bulbird, has no hinder toes. Its belly is white, and its back is variegated with grey, red, and black. It feeds on vegetables, and on small insects.

TETREUMA, in botany, a name given by the people of Guinea to a species of shrub, very common among them, and used to cure whittows. They dry the leaves, and reduce them to powder; and, moistening them with any liquor, apply them to the place. Petiver has called this arbor Giumenzt lauretini foecie, from its great likeness to the common shrub which we call the laurultine. The leaves are obscure and full, and are an inch and a quarter broad, and two inches and a half long. These hand alternately on all sides of the flalk, and are fixed on short pedicels. The flowers grow out of the bosoms of the leaves, and stand in clusters in the manner of thole of the common laurultine. Phil. Trans. N. 232.

TETRICA, in Ancient Geography, a town of the Sabines, placed by Varro in the environs of Mount Ficellus, which lay northward. Servius on Virgil says, that it belonged to Picenum, because in his time, its limits had been changed. Le Abbé Châpe places it where we now find Leonella. There we find the terrible rocks, horrentes rupe, mentioned by Virgil.

TETRICUS MONS, a fraggy mountain of Italy, in the country of the Sabines. Pliny.

TETRINA, in Geography, a town of Ruffia, in the government of Archangel, near the White sea; 100 miles N.N.W. of Archangel.

TETRIX, in Ornithology, a species of tetra; which see.

TETRODON, in Ichthyology, a genus of the Branchiostegi order of fishes, according to the arrangement of Gmelin; the characters of which are, that the jaws are long, divided at the tip; the branchi or gills have a linear aperture; the body is roughened beneath, and the ventral fins are wanting. The fishes of this genus, like the Chidon, have the power of inflating their bodies at pleasure, by means of an internal membrane, and during this time the small spines of the sides and abdomen rise to as to be a defence against their enemies. They live principally on crustaceous and teelaceous animals. Gmelin enumerates thirteen species.

SCELERATUS; the Noxious Tetrodon. Tetragonal, with very large head; length two feet or more. Found in the American and Pacific oceans, and considered as highly noxious, producing, when eaten, very severe symptoms.

TESTUDINEUS; a Tortoise-shelf Tetrodon. Abdomen plane, smooth, and back with white curved futures; length two feet; colour rufus-brown above, marked by numerous round pale blue spots; beneath blueish or ash-coloured, beautifully varied by longitudinal brown streaks; fins and tail bright ferruginous; the whole abdomen is furnished with numerous small spines, which, when the animal is undisturbed, are imbedded in corresponding cavities in the skin,
but elevated, when the fish is alarmed and disturbs its body.

Lagocephalus; Hare Tetrodon. Abdomen aculeated; smooth body, and prominent shoulders; length twelve inches; thick in front; hinder parts tapering suddenly towards the tail; color above yellowish-brown, beneath whitish with a silvery cast; across the back marked with short, black, or dark-brown bars, and over the sides with many, scattered, round, blackish spots; sides and abdomen befit with radiated spines; fins small, and tail slightly rounded. Found in the Indian and American seas; and straying into northern latitudes, are taken about the British coasts. This fish has the power of inflating the abdomen to a large size; and derives its name from the resemblance of its head to that of a hare.

Linearus. With brown and pale bands; length ten or twelve inches, square shape; and when inflated, like the tail; body befit with small spines; color grey on the abdomen, with longitudinal, deep-brown streaks; fins and tail as in the last species. Found in the Indian and American seas, and also in the river Nile.

Eleutherius. With red, green, and white spots; above brown, and beneath sea-green; yellow at the sides, and green fins; length seven or eight inches; eyes large, with red circles. Found in the Indian and American seas, among coral rocks; and when touched with the hand, affecting it with an electric or galvanic shock.

Ocellatus. Ocellated on the shoulder-band; length fix or eight inches; thick, ovate shape, contracting towards the tail; color deep green above, paler on the sides and abdomen, which are whitish; across the middle of the back, as far as each pectoral fin, a broad black crescent, edged with yellow; dorsal fin situated on a round black spot with yellow edges; lateral line from beneath the eyes to the tail, which is small and roundish; under parts befit with many spines. Found in the Indian seas and adjoining rivers, particularly those of China and Japan; very poisonous in its nature, and it is proscribed to be eaten under very severe penalties by the emperor of Japan.

Spengleri. Head bearded with many cirri; lengthened shape; above brown-coloured, with roundish deep brown spots; abdomen tumid, whitish, and befit with small spines; with cirri or soft prominences differed about the upper parts of the body. Found in the Indian seas, ten or twelve inches in length.

Hankenii. With lower jaw longer than the upper; length eight or ten inches; like the former in general appearance; above brown-coloured, with small whitish clouds or spots; beneath whitish, with small spines. Found in the Indian seas.

Oblongus. Oblong, with equal jaws; length six inches; lengthened shape; color grey, with grey back, marked by many semi-decurrent brown bands; fins and tail cuneate; two lateral lines, one near the back, the other near the abdomen. Found in the Indian seas.

Rostratus; Snouted Tetrodon. Both jaws elongated to the back; length a few inches; oblong-ovate shape, contracting towards the mouth and tail; finnot lengthened and slightly tubular; color blueish-brown, beneath whitish; fore-part of the abdomen befit with spines, few over the back; fins brown. Found in the Indian seas.

Levigateus; Smooth Tetrodon. With the abdomen aculeated in front; a large species; blueish above, with two white stripes on each side; under parts white; from the mouth to the end of the pectoral fins aculeated; the other parts being smooth. Found in the American seas.

Hispidus. Entirely hispid, with brilly papilla; length two feet; shape, when inflated, like that of T. lagocephalus; color whitish; upper parts marked across the back by three or four semi-decurrent brown bands; whole body befit with small spines. Found in the Mediterranean and Indian seas. Small remains of this species are said to occur among the petrifications of mount Bocca near Verona.

Mola. Unarmed, sharp, compressed, rounded; a very short rounded tail; dorsal fin annexed to the anal, with oval spines. (See Sun-fish.) Dr. Shaw has made a distinct genus of the fun-fish under the name of cepalus, the characters of which are, that the jaws are bony, and body terminating abruptly, so as to resemble the head of a fish. This genus comprehends the mola, or short fun-fish; the oblong fun-fish, with truncated body, or oblong diodon of Pennant (see Sun-fish); its variegated, with whitish undulations and spots; and the Palladian C. or silvery fun-fish, with brownish back, and spiny carinated abdomen. The mola, or short fun-fish, is a native of the European seas. Its general colour is brown, with a silvery cast on the sides and abdomen; the skin rough; the pectoral fins small, rounded, and placed horizontally; the dorsal and anal fins placed opposite, and of a lengthened shape, with rounded tips continued into the tail-fin. This fish is sometimes seen lying on its side, on the surface of the water, when it may be safely taken. In the Northern seas it arrives at a vast size, of the length of eight or even ten feet, and 500 pounds in weight; it is supposed to feed principally on shell-fish, and in the night it is said to exhibit a high degree of phosphoric splendour.

Of this there is a variety, vis. the truncatus, unarmed, smooth, compressed, oblong, with a very short tail, the dorsal and anal fins annexed, with lunated spines. This is the oblong fun-fish of Pennant.

Stellatus; Spherical Grey Tetrodon. Whitish beaith, with the body befit with radiated spines; the tetrodon etoile of Cepede. Length twelve or fourteen inches; shape, when inflated, nearly spherical; color greenish, deeper on the back, marked with dusky specks; under parts whitish; vent surrounded by a black circle; whole body covered with small fimbriated or radiated spines; dorso-fin rounded at the tip, and attached at the base by a kind of footstalk; tail oval. Found in the Indian seas. Shaw.

Meleagris; Pintado Tetrodon. Brown, speckled with white. Found in the Indian seas, and when taken, making a kind of grunting noise, like several others of this and neighbouring genera.

Tetschin, or Tetzin, or Dietrichin, in Geography, a town of Bohemia, in the circle of Leitmeritz, on the river Elbe; 15 miles N. of Leitmeritz. N. lat. 50° 46'. E. long. 14° 17'.

Tetsi, a town of Thibet; 27 miles E. of Lasa.

Tett, a place now in ruins, situated to the south of Azaamor, on the northern extremity of the bay of Mazagan, in the empire of Morocco; the name signifies in Arabic Titus, and is therefore supposed to denote the ruins of Titus, founded by the Carthaginians.

Tetter, a diffease among animals, which is of the ring-worm kind, and which runs or spreads itself upon the skin in different directions, whence probably it has received the name. It attacks different parts, but is most commonly met with on and about the rump, not unfrequently running down upon the joints of the tail for some distance.

It is of a scabby itchy nature and appearance, and when neglected,
neglected, is said to have sometimes become of the quality of canker, in some sorts of animals. In cases where it fixes upon the more flaky parts of the bodics of the animals, it is often attended with such troublesome itchings, as to cause them to rub themselves against posts, walls, and other places, until they rub off and destroy the very hair and skin of the parts. Nay, the animals will, it is said, sometimes even tear off the flesh with their teeth, if they can come at the parts.

The cure of the disease may most readily be accomplished by the use of a ball composed of half a drachm to a whole one of calomel, or more, according to circumstances, in union with some sort of cooling purgative powder; or a powder constituted of crude antimony, sphazia mineral, and cromer of tartar, of each about half an ounce; which should be given once or twice a day in a quart of oat-meal gruel. At the same time, washing the parts well with Goulard water, and afterwards applying a little of an ointment composed of sulphur, blue ointment, and hog’s-lard to them.

The animals should be well taken care of while the cure is going on.

TETTIGES, &c. grasshoppers, in Antiquity, a title the Athenians affixed to themselves. See GENEREES.

TETTIGOMETRA, in Entomology, a name by which the ancients called the nymph of the cicada, or tetta; and they named this nymph, from which they frequently saw that they hatched, tettigometra, which signifies the mother of the cicada. See Harvest-Fly, Cicada, and Vegetable-Fly.

TETTIGONIA, a word used by the ancients to express the smaller species of cicada, with which they were acquainted. They called the larger acrita.

It is generally supposed, that the tettigonia was the name with our smallest kind, called by the French cicalon; but M. Reamur observes, that as the ancients knew two kinds of the cicada, we know three; and that our middle one seems to have been their tettigonia or small cicada, and that they were not acquainted with our smallest kind, or cicalon, which is not larger than a hornet.

TETTIGONIAE of Linnaeus. See GRYLLUS. TETTIGONAE of Fabricius. See CICADA.

TETINANG, in Geography, a town of Germany, and principal place of a lordship of the same name, united with Montfort, ceded to Bavaria by the peace of Presburg; 8 miles N. of Lindau.

TETTOVA, a town of European Turkey, in Macedonia; 13 miles W. of Skopias.

TETTUA-MOTU, a cape on the E. coast of New Zealand, the N.E. point of Poverty bay. N. lat. 38° 36'. W. long. 181° 30'.

TETUAN, Tetawan, or Tetreg, a town of Africa, in the empire of Morocco and province of El Garb, situated near the river Bafega, about a league and a half inland from the Mediterranean, and inhabited by Moors and Jews; who, for the most part speak a corrupt Spanish, in which language their commercial negotiations are transacted. They are gentry in their persons and polite in their manners. The environs of Tetuan are planted with vineyards and gardens, which are kept in good order, and which produce more excellent fruits than those in other parts of the empire. From the raisins and figs the Jews distil an ardent spirit (called Malaya), which, at the age of a year, resembles the Irish uiscebaugh, and it is preferred to English brandy and rum. Of this they drink immoderately, and generally take a glass before eating. Leo Africanus attributes the foundation of this town to the people of Africa. It was afterwards embellished, and the population increased, when the Moors were driven out of Spain. This was the place of residence for many of the confuls of the European powers, till the year 1770, when the reigning emperor, Seedy Mahomed, would not longer permit them to remain, nor again to establish themselves in the place. The port of this town has kept a trading communication with Gibraltar, whence the ships come to visit, when the wind is in the west, and does not allow them to make Tangiers. The shore of Tetuan is only safe when the wind is in the west, at which time ships ride securely; but when it veers to the east, they must remain here no longer. Our fleets often visit and water here, and this was the cape with that of the immortal Nellon, previously to his victory in Aboekir bay. Tetuan is said to contain 16,000 people; 30 miles S.E. of Tangiers. N. lat. 35° 30'. W. long. 5° 20'.

TETYAN HEAD, a cape on the W. coast of the island of Mindanao; near which is a harbour that may be entered without danger. N. lat. 7° 20'. E. long. 124° 36'.

TEVAKUN, a town of Perua, in the province of Khosfan; 45 miles E.S.E. of Meshehdi.

TAVARA, a town of Naples, in Capitanata; 5 miles N.E. of Volurnara.

TEUBER, or TEUBERINN, ELISABETH, in Biography, a celebrated German opera singer, and Ælve of the famous Tefi. She was chiefly attached to the court of Vienna, where she resided in 1772. She had sung at Naples in 1769 with great applause; but was peremptorily ordered by her physicians never to sing again. Her health had been so much impaired in Russia, where she had remained three years, that the whole faculty was unanimous in pronouncing that the exercise of her profession would be fatal. However, in spite of this prediction, she afterwards recovered her health and voice sufficiently, in a journey to Italy, to appear again on the stage at Naples in 1785; where, finding that her voice had somewhat lowered its pitch, she performed the principal man’s part in contrasto, to the entire satisfaction of the public. She was the daughter of a famous violinist in the emperor’s service; she had lessons in singing from Haffe, in acting from the Teii, and often sung in the operas of Haydn at Eterhazri.

TEUCHERIN, in Geography, a town of Saxony, in Thuringia; 18 miles S.W. of Leipzig.

TEUCHIT, in Botany, a name used by some for the scoenanth or schoenanth, camel’s-hay, which ought to be written teuchitis. There is a city Teuehis in Egypt, near the borders of Arabia, and the geographers all mention a lake in the neighbourhood of this city; in this lake it is probable the scoenanth might grow; and being gathered there, and sold in the adjoining city of Teuehis, the purchasers might distinguish it with an epithet formed of the name of the place where they bought it. See Scoenanth.

TEUCHTLACOT-ZANHQUI, in Zoology, a name by which the natives of some of the American nations call the ratte-finale.

TEURCRIUM.

Gen. Ch. Cat. Inferior inferior, of one leaf, cloven half way down into five acute, nearly equal, segments, gibbous on one side at its base, permanent. Cor. of one petal, ringent. Tube cylindrical, short, ending in an incurved throat. Upper lip erect, acute, divided throughout into two distant segments, divericated towards each side: lower spreading, three-cleft; its lateral segments resembling the upper lip, nearly erect; the central one rounded, and very large. Stam. Filaments four, awl-shaped, longer than the upper lip of the corolla, ascending, curved, prominent between its divisions; anthers small, incumbent. Pyl. Germen superior, deeply four-lobed; style thread-shaped, agreeing with the flaments in size and position; it has two, slender, acute. Peric. none, the unchanged calyx containing the seeds in its concave base. Seeds four, rounded, reticulated or wrinkled.

Eff. Ch. Upper lip of the corolla deeply divided, beyond its base, divericated. Stamens prominent.

Obf. The upper lip of the corolla being fo deeply divided, even below its base, into the tube itself, and its segments so far asunder, there seems to be no upper lip at all. The latter however is more truly the cafl in Ajuga, to which, and not to Teurcrium, belongs the Chamapitys of Tournefort; its upper lip being, in a manner, cut away. Teurcrium of Tournefort has a bell-shaped calyx, and the middle segment of the lower lip of its corolla concave. Polium of the same author has its flowers collected into dense terminal heads. His Chamapitys has axillary flowers, and a tubular calyx. Alurnum of Bochart has thyme-like leaves, and a peculiarly pungent smell. Scordium of Ray and Rivinus has the odour of garlic. Ioa of Dillenius has the calyx very protuberant at the lower part. All these nevertheless form together a most natural and well-defined genus, whose qualities are more or less aromatic or bitter; its habit usually herbaceous, mostly perennial, often shrubby; leaves opposite, simple, though in some instances much divided; pubescence various, but hardly ever absent; flowers blue, red, yellow, or white, axillary, solitary or whorled, panicked or capitulate; their incurved flaments and style always very conspicuous between the divisions of the upper lip.

Thirty-five species are enumerated in the fourteenth edition of Linn. Syll. Veg. from which Chamapitys, Ioa and falcefolium are to be removed to Ajuga. Willdenow, after making these deductions, has sixty-four. He follows Schreber and others, in making many more species out of the allies of Polium, than Linnaeus would ever allow to be more than varieties. Two new ones from Crete are added in the Prodr. Fl. Gracc. The genus is generally European, but not entirely so, and for the most part inhabits warm sunny climates. No attempt has been made to distribute it into sections. We shall indicate some traces of such, as we select the more curious or remarkable species for illustration, describing all the Britth as well as the new ones.

T. campanulatum. Bell-shaped Germander. Linn. Sp. Pl. 786. Wild. n. 11. Ait. n. 6. (T. lupinum, perenne, palustre, apulum, glabrum, folii lacinia, flore albo; Till. Pfl. 163. t. 49. f. 1.)—Leaves many-cleft, nearly smooth. Flowers axillary, solitary. Calyx awned. Stem procumbent. Native of moist situations, in Italy and the Levant. Miller appears to have cultivated it in 1728, but the true plant is now scarcely to be seen in our gardens, and is little known to botanists. The synonym of Tilli has no right to be marked as a variety, answering exactly to the Linnaean specimens and description, nor do we find any other figure of this species. Schreber seems to have missed Willdenow, to quote a synonym of Rivinus, which has no existence. This we find transcribed into Hort. Kew, with a correction of t. 14 for 24; though nothing but T. Botryz is there to be seen. No lea6s incorrectly is Rivinus, t. 19, cited by Willdenow, after Schreber, for T. orientale; as Dr. Sims has noticed in Curt. Mag. 1779. T. campanulatum is a very distinct, perennial, herbaceous, nearly smooth, species, whose "fles" are square, leafy, more or less prostrate and creeping. Leaves an inch long, twice-three-cleft, with bluish, notched, slightly revolute segments. Flowers axillary, solitary, opposite, spotted, with a large, bell-shaped, rather pungent-pointed, calyx. The corolla is said to be white.

T. levigatum. Smooth Yellow Germander. Vahl Symb. v. 1. 40. Willd. n. 2.—Quite smooth. Lower leaves many-cleft; upper three-cleft, entire. Flowers axillary, solitary. Segments of the calyx oblong, without awns.—Gathered at Monte Video, by Commerson, whose specimen is before us. This species is larger in all its parts than the foregoing, and appears to be herbaceous and erect, quite smooth, except a slight downiness, here and there, upon the young branches or flanks. Leaves flat, an inch and half long, deeply divided into three wedge-shaped, jagged, blunt, very smooth and flat, lobes; the upper, or floral, ones much smaller and narrower, simply three-cleft. Flowers yellow. Segments of the calyx oblong-lanceolate, with one central rib and two marginal ones, acute, but not tipped with any awn or bristly point.

T. orientale. Great-flowered Germander. Linn. Sp. Pl. 786. Wild. n. 5. Ait. n. 2. Curt. Mag. t. 1729. (T. orientale angulifolium hircinatum, flore magnro subcaruleo; Com. Mem. 23. 1. 25.)—Leaves deeply three-cleft, many-cleft, linear. Clusters terminal, compound. Flower-flanks horizontal, longer than the floral leaves.—Native of the Levant. Cultivated by Miller, and recently restored to our gardens by seeds obtained from Siberia, by Mr. Lodigges. The root is perennial. Several decumbent branches from the root bear leaves divided into many linear segments; but the foliage of the erect panicked flowering stem is doubly three-cleft below, simply above. Inflorescence terminal, racemo, compound, with small bracteaceous leaves. Flowers numerous, almost as large as those of T. fruticos hereafter described, of a light purplish-blue. All the herbage, and even the corolla, is hairy or downy. We have already mentioned, under our first species, that the citation of Rivinus by Willdenow is an error.

T. trifidum. Trilid-leaved Germander. Retz. Obs. facic. i. 21. Willd. n. 7. Ait. n. 5. (T. capato; Thunb. Prodr. 95.)—Leaves hoary, in three deep linear segments. Stalks axillary, three-flowered. Calyx hoary, without awns.—Gathered at the Cape of Good Hope, by Thunberg and Maffon. The latter sent seeds to Kew in 1791. The plant is shrubby, flowering most part of the summer, and kept in the greenhouse in winter. Its aspect is not unlike Winter Savory, but more hoary. The segments of the leaves
Leaves are an inch long, revolute, entire. Flower-stalks half the length of the leaves. Segments of the calyx elongated, lanceolate, revolute, single-ribbed, bluntly pointed, not awned. Corolla purplish. Seeds with a net-work of wrinkles over their surface.

T. Pseudo-chamoepitys. Racemose Slender-leaved Germander. Linn. Sp. Pl. 787. Willd. n. 8; excluding the synonym of Chamus. (Chamepitys alta; Camer. Epit. 680. Chamepitys purpure alterius altera icon; Dod. Pempt. 47.)—leaves deeply once or twice three-lobed, linear, acute, revolute, hairy. Cluster terminal, simple. Bracteas three-lobed. Calyx hoary, awned.—Native of Spain, Barbary, and the south of France. The flum is shrubby, divided from the bottom into many ascending, leafy, square, softly hairy branches. Leaves in very narrow, somewhat awned, segments, more or less hairy. Flowers much like those of T. orientale, but forming a simple terminal calyx at the top of each branch, with deeply three-lobed linear bracteas, usually as long as the flower-stalks. Lip of the corolla externally hairy. The Pseudo-chamoepitys of Clau. Hilt. v. 2. 185. Lob. f. 385. f. 1. Chamepitys purpure altera; Ger. Em. 526; the left-hand figure in Dode. Pempt. 47; all from the same wooden block; appears to us a different species from the above-deferibed, with which we are unacquainted. There can be no doubt that the T. mauritanum, Linn. Sp. Pl. 787, entirely adopted from Shaw's rude figure, n. 575 of his Phyt. Afric. Specimen, is exactly the same with the real Pseudo-chamoepitys of Linnaeus, which we have from Spain and Barbary, and which the cut of Camerarius, as well as the right-hand one of Dodonaeus, clearly represents.

All the foregoing species, with a few more which may be found in Linnaeus and Willdenow, apparently constitute a fiction of the genus before us, whose deeply-divided foliage gives them a peculiar and striking character. Their inflorescences differ considerably, and on a more careful examination it will be found, that the racemose blue-flowered ones are most naturally akin to the T. fruticans, notwithstanding its undivided entire leaves; while the others are more related to some cut-leaved red-flowered species, with which we shall meet hereafter; inasmuch that no natural subdivision of this genus could be founded on the above character.

T. fruticans. Blue Tree Germander. Linn. Sp. Pl. 787. Willd. n. 9. Ait. n. 6. Sm. Fl. Græc. Sibth. t. 527, unpublished. (T. latifolium; Linn. Sp. Pl. 788. Curt. Mag. t. 245. T. fruticans baccicum; Clau. Hilt. v. 1. 348. Dill. Elth. 379. t. 284. T. baccicum; Ger. Em. 659.)—Leaves ovato-lanceolate, entire; snow-white and cottony beneath. Flowers axillary, solitary. Segments of the calyx ovate, cottony at the base.—Native of the south of Europe and north of Africa. A hardy and common greenhouse plant in England, sometimes bearing our milder winters in the open air, especially near the sea. The flum is shrubby, bulky, three or four feet high, with straight, divaricated branches, clothed, like the backs of the leaves and calyx, as well as all the stalks, with peculiarly white, soft, dense down. The leaves vary in size and breadth, as may be seen in the plate of Dillenius, whose fig. 368. milked Linnaeus to make a species, by the name of latifolium, which is but a trifling variety. The upper surface of the leaves, and inside of the calyx, are dark-green, usually quite smooth. Flowers large and handsome, of a fine blue, coming out at all times of the year; the middle segment of their lower lip sometimes deeply cleft.

T. brevifolium. Short Hyssop-leaved Germander. Schreb. Vertic. Unilab. 27. Willd. n. 16. Sm. Fl. Græc. Sibth. t. 528, unpublished. (Resmarinum rectedias face; Alpin. Exot. 103. t. 102. Polio retto di Candia; Pon. Bald. 156.)—Leaves lanceolate, revolute, entire, obtuse, hoary. Flowers solitary. Calyx without awns.—Native of rocks in Crete, near the sea-shore. The flum is shrubby, with copious spreading, square, leafy branches. Leaves about an inch long, of a hoary green on both sides, veiny. Flowers on slender, solitary, simple stalks, from the bosoms of the upper leaves. Corolla bluish-coloured, with purple veins. Segments of the calyx revolute and bluish. Schreber and Willdenow cite, under this species, T. fruticans, rectedias arabicus folio et facie; Tourn. Cor. 14. Rivin. Monop. t. 20; which is correct as to Tournefort, but no such thing occurs in Rivin. If we had not consulted, in Sir Joseph Banks's library, the most perfect copy of his work known to exist, we should not speak so decidedly on this head.

T. creticum. Rosmary-leaved Germander. Linn. Sp. Pl. 788. Willd. n. 11. Sm. Fl. Græc. Sibth. t. 529, unpublished. (T. hyssopifolium; Schreb. Vertic. Unilab. 28.)—Leaves linear-lanceolate, revolute, entire, obtuse; white and cottony beneath. Flowers often two or three together. Calyx cottony, spinous.—Native of Crete, Cyprus, and Egypt. A taller, larger flum than the last, some of whose synonyms were confounded with it by Linnaeus. Its habit and foliage much resembling Rosmary. The flowers are light purple, or pink, and form long leafy calyxes, at the ends of the branches, being either solitary, or two or three together, on short downy stalks, from the bosoms of the upper leaves. The calyx is cottony without; green within; and has short spinous points.

T. Marum. Marum Germander, or Cat-thyme. Linn. Sp. Pl. 788. Willd. n. 12. Ait. n. 7. (Pseudo-Marum; Rivin. Monop. Int. t. 13, not t. 40, which is Thymus Mal- tichina. Marum Cortuli; Bauh. Hift. v. 3. 242.)—Leaves ovate, acute, entire, falked, cottony beneath. Flowers racemose, in pairs, turned one way. Calyx woody.—Native of Spain, and the isles of Hyeres. Frequent in greenhouses, where it is very hardy, being cultivated for the sake of its peculiarly pungent scent, which powerfully induces fæezing, and which renders it not less grateful to cats than Valerian. The flum is bulbous, of humble growth, with round hoary branches. Leaves a quarter of an inch long, of a hoary green on the upper side. Flowers crimson.

T. quadratulum. Little Square-leaved Germander. Schreb. Vertic. Unilab. 36. Willd. n. 13. Sm. Fl. Græc. Sibth. t. 530, unpublished. (T. ramossifolium; Desfont. Atlant. v. 2. 4. t. 118.)—Leaves ovato-homphoid, deeply toothed; cottony beneath. Flowers axillary, solitary, deflexed. Calyx woody.—Native of bushes of rocks, in Spain, Barbary, and Crete. A small, decumbent, branching flum, whose leaves are not half an inch long; green above; white beneath. Flowers pink, their calyx bent down, so as to make a right angle with its footstalk, and then recurved. Segments of the upper lip of the corolla advanced towards the base of the lower in a remarkable degree. Style reflexed.

T. laxmannii. Laxmann's Germander. Linn. Syll. Veg. ed. 13. 439. Willd. n. 16. Ait. n. 10. March. von Bieberr. Taur. v. 2. 35. " Waldtt. und Kitaib. Hung. v. 1. 71. t. 69."—Leaves elliptico-oblong, villous, ribbed, nearly entire. Flowers axillary, solitary, opposite, turned one way.—Native of Siberia, Hungary, &c. We notice this species here merely to express our concurrence with the opinion of the able author of the Flora Taurico-Caucasica above cited, that it certainly belongs to Ajuga, as well as the T. sylvestristum, Linn. Mant. 80, already referred thither by Schreber and Willdenow. The two species are very nearly akin, and answer in character and habit entirely to Ajuga, and not to Teurcium.

T. Ardani.
TEUCRIUM.

T. Arduini. Arduini's Germander. Linn. Mant. 81. Willd. n. 20. Sm. Pl. Grec. Sibth. t. 531, unpublished. (T. foliis ovo-crescutis, subhirsutis, petiolatis, caulibus spicis flavescentibus floribus terminatis; Arduini. Spec. t. 12. t. 3. Scutellaria cretica; Linn. Sp. 836. Willd. Sp. Pl. v. 3. 176. Ait. Hort. Kew. v. 3. 429. Callidae cretica fruticosa, catariz folio, flore albo; Tourn. Cor. 11.)—Leaves ovate, ferrated, hairy. Clusters densely imbricate, cylindrical, with linear bracteas, longer than the flowers. Upper segment of the calyx dilated, heart-shaped; two lower petalaceous.—Native of Crete, and of the shady woods of the Bithynian Olympus. It appears to have been cultivated by Miller in 1729. Although Linnaeus, in referring this plant, after "Tournefort, to Scutellaria," perceived it to be a Teucrium, neither he nor any one else, till lately, suspected it to be described twice over in his works. This we discovered by a comparison of original specimens. The stem is herbaceous, not shrubby, square, cross-branched, leafy, rough with spreading hairs. Leaves ferrate, not unlike those of Balm in size, form, and colour. Clusters from one to four inches long, near an inch in diameter, solitary at the ends of the branches, erect, of innumerable crowded white flowers. The calyx is hairy, suddenly bent downwards at its taper base, then horizontal, its border very unequally five-cleft; the upper segment broad, as in Scutellaria, reflexed at the sides, tipped with a britle; two next short, triangular; two lowest long, narrow, with pungent points.

T. canadense. Nettle-leaved Hoary Germander. Linn. Sp. Pl. 789. Willd. n. 21. Ait. n. 13. Pursh n. 1. (Chamedrys canadenensis, urticae folio, subtus incan; Tourn. Fl. N. A. 225.)—Leaves ovato-lanceolate, ferrated, sharply ferrated, downward on both sides; hoary beneath. Cluster terminal, dense, somewhat whorled. Bractea ovate, shorter than the flowers. Segments of the calyx nearly equal.—In low grounds, on the borders of ponds and lakes, from Can-ada to New York, perennial, flowering in July and Au-gust. The habit of the leves and inflorescence is like that of some spiked Veronica. At the inception of each pair of flower-flats, the stem is surrounded with a ring of prominent hairs. The calyx is bell-shaped, with five broad, nearly equal, segments. Corolla purple.

Parf.—Miller is said to have cultivated both these North American species in 1798. We have seen only the former.

T. abutiloides. Mulberry-leaved Germander. L'Herit. Stirp. v. 1. 184. Willd. n. 27. Ait. n. 17. Jacq. Hort. Schor. v. 3. 58. t. 358.—Leaves heart-shaped, acute, crinate, downward. Clusters axillary, not longer than the flower-flats.—Discovered by Mr. Maffon in Madeira, from whence it was brought to Kew, in 1777. It flowers in the green-house in April and May, and is conspicuous for the large size of its leaves, four or five inches long, on densely downward flower-flats, half that length. The flowers are no less remarkable for their golden hue, and their situation in dense, foliary, lateral, ferrated claters, which rarely equal the flower-flats in length.

T. Scordonia. Wood Germander, or Wood Sage. Linn. Sp. Pl. 789. Willd. n. 28. Fl. Brit. n. 1. Engl. Bot. t. 1543. Curt. Lond. f. e. t. 1. 40. Fl. Dan. t. 485. (Scordonia; Rivin. Monop. Irr. t. 12. S. five Salvia agrestis; Ger. Em. 662.)—Leaves heart-shaped, ferrated, ferrated, hairy. Stem erect. Flowers leaning to one side, in lateral and terminal clusters.—Very common in dry heathy ground, and sandy woods, throughout Europe, from Nor-way to Greece, flowering in July and August. Linnaeus seems to have recollected this plant with delight in the fields of Hartbeck, where the garden of his friend Clifford had been to him a real paradise. The root is creeping and perennial. Herb a foot or two in height, dark green, hairy, bitter, with a strong scent like hops, for which it is said to be not a bad substitute in brewing. We with nothing worse had ever been used. The long aggregate clusters of flowers are rendered conspicuous by the contrast of the pale yellow corolla and purple flammes. The upper segment of the calyx approaches in form and breadth to what we have pointed out as so remarkable in T. Arduini.

T. betonicum. Hoary Germander. Ait. ed. 1. v. 2. 279. ed. 2. n. 19. Willd. n. 30. L'Herit. Stirp. v. 1. 83. t. 48. Curt. Mag. t. 1114. (T. betonicefolium; Jacq. Coll. v. 1. 145. t. 17. f. 2.)—Leaves ovato-lanceolate, bluntly ferrated, flat and downy; hoary beneath. Stem ferrubby. Clusters aggregate, terminal. Bracteas lanceolate, cut; Native of Madeira. A very handsome greenhouse shrub, introduced by Sir Joseph Banks, in 1775, flowering most part of the summer, and easily propagated by cuttings. The crimson flowers are elegantly contrasted with the hoariness of the herbage; the upper surface of the leaves being greener than the rest. The segments of the upper lip of the corolla being broader and blunter than usual, some doubts have been entertained whether this species belonged to Teucrium or to Aegia, or whether these genera were really distinct. To this we would answer, that the habit of the latter is peculiar, and its essential character no less clear, consisting in a short notched upper lip, instead of the remotely-lobed one of Teucrium. We believe moreover that the central lobe of the lower lip is always divided and divedicarated in Aegia.

T. mossiifolium. Apple-scented Germander. Linn. Sp. Pl. 789. Willd. n. 32. Ait. n. 21. Jacq. Hort. Vind. v. 1. 41. t. 94. (T. n. 6; Gerard. Galop. 277. t. 11.)—Leaves ovate, rugged, hoary, strongly crenate. Stem erect. Flowers turned to one side, in lateral and terminal, upright clusters.—Native of the isles of Hyeres, but scarcely known in any other country, nor is it often to be seen in gardens. The stems are a foot high. Leaves ferrated, blunted, hardly an inch long. Flowers small, light crimson. Upper segment of the calyx broad-ovate. The whole herb is clothed with a hoary, soft, velvet-like pubescence, and when touched exhalcs a very powerful and peculiar scent, like mellow apples, and therefore, to many people, not agreeable, though combined with a spicy fragrance. Gerard's plate, like the others in his book, is very finely executed.

TEUCRIUM.

the leaves. This herb has formerly been celebrated for its deobstruant and tonic qualities, but is now out of medical use, except perhaps in the cresses of the country.

T. jordanioides of Schreber. Willd. n. 35, seems to us, without doubt, a variety of the last, as it is made in Prodr. Fl. Grac. v. 1. 393.

T. Chamaedrys. Wall Germander. Linn. Sp. Pl. 790. Willd. n. 36. Fl. Brit. n. 3. Eng. Bot. t. 680. Woodv. Suppl. t. 243. (Chamaedrys; Rivin. Monop. Irr. t. 10. f. 2. Tourn. Infl. t. 97; a much better figure. C. major latifolia; Ger. Em. 656.)—Leaves nearly ovate, stalked, deeply crenate. Flowers axillary, three together, stalked. Stem round, hairy. Found on dry rocks and old walls in the more temperate or warm countries of Europe. It is abundant on the old city wall, on the north side of Norwich, as well as here and there in other parts of England, but not universally. Dr. Sibthorp observed the plant in dry flinty places, throughout Greece and the Isles of the Archipelago, where it still retains nearly the same appellation of Chamaedrys, recorded in Dioscorides. It flowers in July and August, and has a perennial creeping root. The stem is bushy, rather diffuse, and slightly shrubby, a span high. Leaves of a full shining green, slightly hairy; deeply crenate and cut. Flowers cymifom, numerous, more handsome than those of T. Scordium, with which species the present has been supposed nearly to agree in virtues. It is equally bitter, but more agreeably, though less powerfully, scented.

T. lucidum. Shining Germander. Linn. Sp. Pl. 790. Willd. n. 39. Ait. n. 25. Sm. Fl. Grac. Sibth. t. 532, unpubl. (Chamaedrys alpina fruticosa, folio splendente; Tourn. Infl. 205. Magnol. Hort. 52. t. 9.)—Leaves ovate, stalked, deeply crenate, smooth and shining. Flowers axillary, three together, stalked. Stem square, erect, nearly smooth. —Native of alpine valleys in Savoy and Provence. Found by Dr. Sibthorp on Parnassus, and other Grecian mountains, as well as in the island of Cyprus. The tall, erect, square stems, often quite smooth; numerous whorls of large cymis flowers; and shining leaves, of which the upper or floral ones are more numerous quite entire; all render this plant, at first sight, decidedly different from the last, and yet they are very nearly related, so that an essential difference is difficult to seize, and perhaps none that has yet been indicated is invariably constant.

T. flavum. Yellow Shrubby Germander. Linn. Sp. Pl. 791. Willd. n. 41. Ait. n. 26. Sm. Fl. Grac. Sibth. t. 533, unpubl. (Teucrum; Rivin. Monop. Irr. t. 19. f. 1. Chamaedrys fruticosa major, floribus ochroleucis; Morif. fept. 11. t. 22. f. 1.)—Leaves ovate, crenate, downy. Whorls five flowered, composing terminal clumps, with ovate, concave, entire bracteae. Stem shrubby, downy. —Native of rocks and old walls, in the south of Europe, and north of Africa; abundant in the Archipelago, and on the walls of Rome. The stem is woody, branched, erect, about two feet high: its branches leafy, blunter quadrangular, clothed with very soft, velvet-like, curved pubescence, as is the whole of the herbage. Leaves stalked, hardly an inch long; tapering and entire at the base. Flowers pale yellow, composing long, whorled, erect cymes, with palegreen bracteae, about equal to the calyx. The teeth of the latter are nearly equal. Upper segments of the corolla edged with red.

T. bicolor. Two-coloured Chili Germander. (T. heterophyllum; Cavan. It. v. 6. 566. t. 577.)—Leaves wedge-shaped, obtuse; undivided or cut. Flowers axillary, solitary. Calyx nearly regular, with ten strong ribs. —Gathered by Louis Nee, in the neighbourhood of Talcachano, in Chili, flowering in November and December. We have a wild specimen from the late abbé Cavanilles, whose specific name we are obliged to change, there being already a T. heterophyllum, Willd. n. 37. The stem is shrubby, almost six feet high, with square leafy branches, clothed, like the calyx, flalked, and under side of the foliage, with very short dense pubescence. The leaves are about an inch long, nearly smooth on the upper side, various in breadth; the broadest deeply and coarsely cut; the rest undivided and entire; the lower ones on short stalks; the upper sessile. Flowers from the bosomes of the upper leaves, on shortish, round, finely downy stalks. Calyx cut almost half way down into five, nearly equal, acute, ovato-lanceolate segments, each with a strong mid-rib; its tube having five intermediate ribs besides. Corolla externally hairy, white, the middle of its lower lip of a violet red.

Corvmbas terminal. Leaves linear-lanceolate, somewhat revolute, almost entire; cottony beneath. Calyx reticulated, ten-ribbed, slightly downy, with spinous teeth. —Native of dry mountainous or alpine situations, in Germany, Switzerland, France, Spain, and Greece; sometimes, though rarely, preserved in pots, under a frame, in our more curious gardens. A dwarf bushy shrub, like Thyme, with a strong woody root, and many diffuse, downy, leafy stems. Leaves crowded, opposite, stalked, hardly an inch long, very rarely notched, various in breadth; green, convex, and nearly smooth, above; veiny, very white and cottony beneath. Flowers in dense, sessile, solitary corvmbas. Calyx tubular, pale, with equal spreading, tapering, pungent teeth, from whose intermediate sinuæ the veins spread star-wise. Corolla pale buff-coloured, the segments of its upper lip veined with red.

Schreber has long ago united T. montanum and fupinum; nor was Linnaeus ignorant of their near affinity; though in this instance, as in every thing relative to alpine plants of the south of Europe, which he had rarely examined alive, he was disposed to give up his own opinion, to that of practical observers. Clusius having represented T. fupinum to different in size and habit from montanum, might help to mislead following botanists; but in truth they hardly deserve to be distinguished as varieties, fupinum being only rather less luxuriant, with narrower leaves, which indeed vary on the very same root. The species before us has lent a specific name to some other plants, as Andromeda polifolia of Linnaeus, and Menziesia polifolia of Jussieu, which have no so frequent to the true ancient Polium hereafter described, but greatly ressemble this.

T. pyrenaeum. Pyrenean Germander. Linn. Sp. Pl. 791. Willd. n. 45. Ait. n. 29.—Corvmbas terminal. Leaves orbicular, crenate, hairy; entire and slightly wedge-shaped at the base. Calyx-teeth tapering, fringed. —Native of the Pyrenees. Cultivated by Miller in 1731, at Chelsea garden, where we have seen it a few years since, yet there seems to be no certain figure of this beautiful plant extant. Its habitat is somewhat like the last, but the leaves totally different, being almoft orbicular, and from half an inch to an inch in diameter, flat, green, veiny and hairy. Flowers in dense convex tufts, variegated with pale yellow and purple; the ribs and teeth of the calyx fringed with long brilily hairs. Whether
Whether Schreber's *T. rotundifolium*, Wild. n. 46, to which the figures of Boccone and Barrelier, cited for the former, are said to belong, bo more than a variety, we have no means of determining.

*Polium montanum* : Ger. *Em.* 653, 554. P. montanum album ferratum, &c. ; *Barcl. Ic.* t. 1024.—*Heads roundish, leafy. Leaves febrile, oblong, obtuse, convex, bluntly crenate, densely woolly. Calyx very woolly, obtuse, pointless.—Native of mountains in Italy, Spain, and the north of France; common in Greece, the Archipelago, and throughout the Levant; rarely seen in our gardens, being impatient of wet. *The root is woolly and very strong. Stems numerous, a span long, ascending, erect, or partly decumbent, round, clothed, like the ruff of the herbage, with extremely soft, white, woolly down. Leaves numerous, opposite, half an inch or an inch long, thick and woolly, their edges remarkably deflexed, with strong, round, recurved teeth; the base slightly wedged-shaped, scarcely flaked. Flowers numerous, in dense, sessile, terminal, often aggregate, heads, or short spikes, intermixed with leaves; the lower heads usually flaked. Calyx very woolly and obtuse. *Corolla* white, with a yellow palate.*

Schreber, who is followed by Willdenow, makes numerous species out of the reputed varieties of this plant, of which we are unable, for want of sufficient means of examination, to form an opinion. The characters given do not satisfy us, nor do the specimens we have seen afford better.

The most striking of the whole is *T. aureum*, Schreb. Unlab. 43. Wild. n. 48. *Ait. n. 35.* Cavan. Ic. v. 2, 16. t. 17, remarkable for the golden tint on its heads and upper leaves. This has usually a solitary head or spike, and perhaps the *calyx-teeth* are more slender and acute than in the common *T. Polium*, which merits inquiry. On the other hand, *T. capitatum*, which we shall next describe, approaches nearly to some of the above-mentioned varieties, so that perhaps they ought to be referred to it, rather than to *Polium*.

**T. capitatum.** Purple Poley Germander. *Linn. Sp. Pl.* 792. Wild. n. 56. *Ait. n. 32.* Cavan. Ic. v. 2, 17. t. 119. Sm. Fl. Græc. Sibth. t. 536, unpublished. (Polium montifolium ; Bah. *Hill.* v. 3, 299.)—*Heads roundish, leafy, lateral and terminal, flaked. Stems croft-branched. Leaves febrile, oblong-oblong, obtuse, convex, crenate, hoary. Calyx woolly, oblong-oblong, pointless.—Native of hills in Siberia, Spain, the south of France, Zante, Cyprus, and Greece. This is of a more slender habit than the last, less woolly, and more hoary, with purple flowers, a more elongated tubular *calyx*, and narrower leaves. The tube of the *corolla* also is longer, and much less bell-shaped, or inflated in the throat. It is nearly related to *T. Polium*, but is a distinctly different species.

**T. canescens.** Wedge-leaved Poley Germander. *Sm. Prodr. Fl. Græc. Sibth.* n. 1311. Fl. Græc. t. 537, unpublished.—*Heads terminal, dense. Leaves rounded, densely crenate; wedge-shaped at the base; woolly all over. Calyx blunt, pointless.—Gathered by Dr. Sibthorp, on the Sphæciote mountains of Crete. The general outline of the plant answers to *T. rotundifolium*, Wild. n. 46; but that is a far less woolly plant, with a pointed *calyx*, and not allied to the *Polium* tribe. The present has round, trailing, shrubby, croft-branched *flora*, a foot or more in length. Every part of the herbage is covered with thick, white, soft, woolly or velvety down. Leaves, with their stalks, an inch long. Flowers snow-white, in aggregate terminal heads. Calyx tubular, with short rounded teeth. Segments of the upper lip of the *corolla* large, as long as the *flora*, which they embrace, and partly conceal. Anthel red.

**T. alpestre.** Sharp-touched Alpine Poley Germander. *Sm. Prodr. Fl. Græc. Sibth.* n. 1312. Fl. Græc. t. 538, unpublished.—*Flowers axillary, solitary. Leaves wedge-shaped, rounded, deeply crenate, downy. Stem tufted, much branched.—Found by Dr. Sibthorp, upon the most lofty summits of the Sphæciote mountains of Crete. The *root* is woody, dividing at the crown into innumerable strong, woody, depressed *flora*, which bear a dense tuft of ascending, leafy, downy branches, hardly a finger's length. Leaves flaked, greyish, about half an inch long, obtuse. Flowers opposite, on short stalks, from the bosoms of two or three of the uppermost pair of leaves. *Corolla* tubular, finely downy. Tube, throat, and upper lip of the *corolla*, pale yellow; lower lip white, its middle segment deeply concave.

**T. pumilum.** Rosy-leaved Poley Germander. *Linn. Sp. Pl.* 792. Wild. n. 61. (Polium montanum pumilum rubrum ; *Barcl. Ic.* t. 1092, 1093.)—*Heads terminal, solitary, sessile, leafy. Leaves crowded, sessile, linear, revolute, smooth; downy beneath. Stems ascending, woolly. *Calyx* pointed.—*Native of hills in Spain, flowering in July and August.—From the woody perennial *root*, springing several, or more or less erect, simple or branched, leafy *flora*, three or four inches long, clothed with dense, soft, white wool. The *leaves* are hardly an inch long, crowded and somewhat imbricated, in four rows, narrow, strongly revolute, obtuse; convex, green and polished on the upper side; concave, with a downy rib, just visible beneath. *Calyx* ribbed, downy, with short, thick, spinous points. Tube of the *corolla* flesher, downy, as well as the outside of the limb.*

We are quite unable to imagine how *T. Liberati of Schreber, Wild. n. 62. Cavan. Ic. v. 2, 17. t. 118, came to be distinguished from *pumilum*, as there does not appear to be the least difference between them, except the *flora* of *Liberati* being more erect; but that circumstance is evidently variable. *T. verticillatum*, Cavan. t. 198. Wild. n. 59, seems also but a variety; though we presume not to determine this without seeing a specimen.

**T. pungens.** Thorny Germander. *Linn. Sp. Pl.* 793. Wild. n. 64. *Ait. n. 33.* Sm. Fl. Græc. Sibth. t. 539, unpublished. (Chamaedrys *pungens* ; Bah. *Hill.* v. 4, 17.) Scordium *pungens* odoratum ; *Corn. Canad. Ic.* t. 142. *Barcl. Ic.* t. 202. *S. pungens* ; Cavan. Ic. v. 19. t. 133.—*Stems and branches spinous, hairy. Flowers axillary, opposite. Upper segment of the *calyx* ovate; the reft awl-shaped, spinous.—Native of fields and hilly places in Spain and Portugal. Dr. Sibthorp met with it in fields between Smyrna and Burfa. The *root* is annual. Stems branched copiously from the very bottom, about a foot high, bushy, the branches opposite, crossing each other in pairs, spreading, square, clothed with very soft prominent hairs, tipped with strong spines, and furnished with smaller lateral ones, particularly at the insertion of the leaves and flowers. Leaves sessile, deflexed, small, oblong, obtuse, notched, green, hairy. *Flowers* numerous, solitary or in pairs, from the bosoms of the diminished or upper leaves, each on a short, round, hairy stalk. *Calyx* deflexed and bent at the base, then horizontal and somewhat bell-shaped; its upper segment very broad, ribbed, spinous-pointed, erect, or rather reflexed, the four others shorter, prominent, ascending, pungent. *Corolla* white, with red stripes on its upper lip; the middle segment of the lower very large, slightly concave; the base of the tube globular.—The flowers are by no means reverber, *refusinales*, in Sibthorp's figure of this species, though Latting
of the species following are the most generally cultivated: the yellow-flowered shrubby germander (T. flavum), the fage-leaved germander, or wood-fage (T. scordonia); the nettle-leaved germander (T. canadensis); the dwarf mountain germander (T. montanum); the Pyrenean germander (T. pyrenaicum); the poley (T. polum); the round-headed germander (T. capitatum); the dwarf germander (T. pumilum); the narrow-leaved tree-germander (T. fruticans); the broad-leaved tree-germander (T. latifolium); the Cretan germander (T. creticum); and the common marum or cat-thyme (T. marum).

There is a variety in the first fort which is hairy, with yellow flowers, with pale white flowers, and with purple flowers. In the fourth fort there is likewise a variety with much smaller leaves, which are hoary on their under side.

Allo in the fifth fort there are several varieties; as the common yellow poley, which has the stalks rather herbaceous and trailing, about six inches long, and hoary: leaves woolly, about half an inch long, fome wedge-shaped, others oblong, ending in obtuse points, and crenate towards their ends: the flowers collected in oblong thick spikes at the end of the branches, of a deep yellow colour, and appearing at the beginning of June. This grows naturally in Spain. The narrow-leaved yellow poley, which has woody stalks, erect, branching, and covered with a hoary down, rising six or eight inches high; the leaves linear, woolly, about half an inch long, having sometimes two or three flight indentures on their edges; the flowers collected in roundish spikes at the end of the branches; they are bright yellow, have woolly calyces, and appear in June and July. It grows naturally in Spain and Portugal. The white poley, which has the stems a foot long, and trailing: the leaves are a little cottony, entire on the sides, but toothed at the end: the flowers are pretty large, white, tinged a little with purple. It is a native of the south of France. There is also the purple poley.

And there is a variety in the seventh fort which has an erect branching stalk, that rife a foot high; the lower part becomes woody, but the upper is herbaceous: the leaves are linear-lanceolate, about an inch long, crenate, of a pretty thick consistence, and a little woolly: the flowers collected in a corymbs at the end of the branches, white, appearing in July and August. The ninth contains a variety which is a little more branched, and has smaller shorter leaves: the flowers are paler, the flamin somewhat longer, the authors smaller and brown; whereas in the larger fort they are violet: and another with variegated leaves.

Method of Culture.—All the herbaceous and ligneous kinds may be readily increased by parting the roots, by slips of the young branches, and seeds: the roots may be divided in the autumn, or early spring, and the slips of the branches be taken off in the spring and summer, being planted out in moist shady situations, and well rooted, they may be removed to where they are to remain, though it is best to plant them at once where they are to grow: the seeds may be sown in a bed or border of common earth in the early spring season. But in the poehem kinds, the seeds should be sown in a bed of light earth, and the plants be either put out in nursery-
species of instrument, but the time and place where it was first constructed. There is little science, and still less ingenuity, in the examples of composition given in illustration of the rules of counterpoint: so that if the young student, who perfumes this work for instruction, is not a conjurer before he begins the task, he will not be made one by the mysteries which it unfolds.

Yet with patient perseverance, a young student who has little leisure, and few books to read, may become superficially learned with little trouble by this book. Tevo quotes authority for all that he advances; but his authorities are not always good, nor does he distinguish good from bad. Several obscure and even contemptible authors are quoted in the same fulsome manner as the best. But in citing so many writers indifferently, the chief part are now so scarce and difficult to be found, that in search of them all the great libraries of Europe may be visited in vain. To save the student's time, and form his taste in literature, as well as judgment in music, the author should have quoted none but writers of the first authority, or have told his young readers what theirs was to be laid on the rest.

But since the time of Tevo, so many better authorities in composition and didactic works, both on the theory and practice of music, have appeared, that we can hardly recommend the "Musico Telfore" to the perusal of any but those who have much time to spare, who read every thing, and are curious to know the history and state of the art at every period of time.

TEUOGHIS, in Ancient Geography, a lake and town of Egypt.

TEVEN-SOUSAN, in Geography, a town of Chinche Tartary ; 12 miles N.W. of Teldom.

TEUPITZ, a town of Brandenburg, in the province of Mark, on a lake ; 20 miles S. of Berlin. N. lat. 52° 5'. E. long. 16° 30'.

TEURERT, or TEVRERT, a town of Fez, on the borders of Algiers ; 40 miles E.N.E. of Teza. N. lat. 34° 2'. W. long. 3° 30'.

TEURSCI, in Ancient Geography, a people placed by Ptolemy in the northern part of Dacia, between the Anerti and the Cifoboci.

TEURISTAE, a people of Germany, placed by Strabo in the vicinity of the Danube and the Alps.

TEURTEVILLE, in Geography, a town of France, in the department of the Channel ; 6 miles N. of Valognes.

TEUSCHNITZ, a town of Bavaria, in the diocese of Bamberg ; 34 miles N.E. of Bamberg. N. lat. 50° 23'. E. long. 11° 30'.

TEUSHANUSHSOUTHSGOGLATA, an Indian town of Pennsylvania, on the Allegheny river.

TEUTATES, in Mythology, a name or attribute of the Supreme Being, which was worshipped by the Gauls and Britons as a particular divinity. It is evidently compounded of the two British words "Deu-tatt," which signify God the parent or creator, a name properly due only to the one true God, who was originally intended by that name. Thus Lucan, i. 1. v. 445: "Et quibus immaculis placetur sanguine divo Teutates; horranque feris altaebarus Hefus."

When these ancient nations sunk into idolatry, they degraded Teutates into the sovereign of the infernal world, the name with the Dios and Pluton of the Greeks and Romans (or, as others think, with Mercury); and worshipped him in such a manner as could be agreeable to none but an infernal power.

TEUTHEA, in Ancient Geography, a considerable town of the Peloponnesus, in Achaia, W. of Tritus.

TEUTHIS, a town of the Peloponnesus, in Arcadia, in which were a temple of Venus, and another of Diana.

TEUTIS, in the Linnean system of Ichthyology, a genus of the abdominal fishes; the characters of which are, that the head is a little truncated on the fore-part; that the branchiostegal membrane has five rays; and that the teeth are equal, rigid, and near each other, and forming a regular chain. Linnaeus and Gmelin mention two species; viz. heaptus, and juers or jawa. This genus is now annulled, and the species are transferred to Acanthus and Chedodon.

HEPATUS; Acanthus Teuthis; Blue Acanthus. With the middle of the body paler, and a spine on each side of the tail. This is a native of the Indian and American seas, ten or twelve inches long, or more; resembling in shape the chedodons, the head sloping in front from the origin of the dorsal fin; the colour, when recent, a deep or blackish-blue; on each side of the body is a very large, oblong-ovate whitish patch or spot, surrounded by a border of a deeper colour; the skin is heightened by very small scales; the tail is slightly lunate, darkly on the upper and lower part, and marked towards the base by a whitish ovate spot; the teeth are cemented; and on each side of the base of the tail is a very strong spine, capable of elevation at the animal's pleasure, to an horizontal direction, from the channel in which it lies. The fish figured by Catesby in his Natural History of Carolina, under the name of Teg, is supposed to be this species.

JAVA or JAVUS; Chedodon Guttatus. Whitish-grey, with oblong body, sprinkled with very numerous, round, rufous spots; length about ten or twelve inches; colour grey, with a dully tinge on the upper parts, and every where sprinkled, except on the head, pectoral, ventral, dorsal and anal fins, with numerous, small, round, rufous spots; scales small, none at the bases of the fins; gill-covers smooth; dorsal and anal fin of moderate breadth; tail slightly inclining to a forked, or rather lunate shape, and speckled like the body. Native of Java. This species is supposed by Bloch and Cepedea to be the teuthis javus of Linnaeus. But Dr. Shaw remarks, that Linnaeus's description does not agree in the disposition of its colours with those of the C. guttatus, as it is expressly said to be marked with longitudinal streaks; so it is figured by Gronovius. See Chedodon Guttatus, changing Japan in the close of that article to Java.

TEUTHOPACE, a word used by the ancients to express a sort of food made of beet-roots and lentils, often preferred as a good diet for the sick.

TEUTHRANIA, in Ancient Geography, a town and small country of Mylia, situated towards the E., and near the source of the Cicus. Herodotus says that it was once a gulf, and it was gradually formed by the accumulation occasioned by the Cicus.

TEUTHRANA, a town of Laconia, in a small bay, on the Laconic gulf, N. E. of Pyrrhus.

TEUTLAN, in Geography, a town of Mexico, in the province of Guadalajara; 55 miles N.N.W. of Guadalajara.

TEUTLEBEN, a town of Germany, in the principality of Gotha; 4 miles W. of Gotha.

TEUTON, in Ancient Geography, a people of Germany, who at the time when the Romans became acquainted with them, were politically connected with the Cimbri, if they
they were not actually a tribe of the same people; and settled at no great distance from them. (See Cimbr.) They are said to have worshipped a divinity called Thaut, who is supposed to have been one of their ancestors debased. The Teutones were known before the Cimbri, and uniting with them, overrun the territories that were subject to the Romans; and it has been affirmed that they inhabited the banks of the Codani Sinus, and the island called Codania Infida, whence they assumed the appellation of "Codani," Pytheas of Marseille, according to Pliny, is the first author who mentions the Teutones; and Pomponius Mela says, that their habitations were near the gulf Codanus. It is very probable that they extended themselves through the country that bordered on the Baltic sea; and that from thence they engaged in many warlike emigrations; transporting themselves with their arms and baggage, their wives and children, through other countries which they pillaged. It was in the year 690 that they first became known to the Romans; having advanced south of the Danube to the country called Noricum, where they were encountered by the confidant C. Papirius Cursor, who obstructed their passage towards the borders of Italy. They then proceeded towards Gaul, and made their inroads among the Helvetian. Having arrived in Gallia Narbonensis, the Cimbri were there defeated by the confidant Aurelius; but the Teutones made an attempt to invade Italy by the Western Alps. They were, however, refuted by Marius, and in a desperate engagement, in which the latter proved victorious, the Teutones left upon the field an almost incredible number of slain; which included the Gauls who had fallen in a combat which took place some days before, amounted, according to historians, that have not been chargeable with exaggeration, to 100,000 persons. Marius also defeated the Cimbri in Italy.

TEUTONIC, something belonging to the Teutones, an ancient people of Germany, inhabiting chiefly along the coast of the German ocean. See Gothic.

TEUTONIC Language, the ancient language of Germany, which is ranked among the mother-tongues.

The Teutonic language, now called the German, or Dutch, and is distinguished into upper and lower.

The upper has two notable dialects; viz. 1. The Scandian, Danish, or perhaps Gothic; to which belong the languages spoken in Denmark, Norway, Sweden, and Iceland.

2. The Saxon, to which belong the several languages of the English, Scots, Frisian, and those on the north of the Elbe.

To the lower belong the Low Dutch, Flemih, &c. spoken through the Netherlands, &c.

The learned Mr. Whitaker has lately, in his History of Mancheoter, controverted the opinion of those who affirm the English language to be genuine and unmixed Teutonic, and asserted it to be of Celtic origin. Mr. Drake, in his Essay on the Origin of the English Language, Archael. vol. 5. has endeavoured to support the former opinion, by comparing part of Ulphil's Gothic version of the gospel of St. John, executed above 1400 years ago, with the same in our present translation, and evincing the striking affinity between the two languages; notwithstanding the different mediums through which they have been deflected, and the many ages that have elapsed since they have been separated. Every circumstance, he observes, that constitutes the true genius of a language, is visibly derived to the English from the Goths and Saxons. The articles, flexure of the genitive case, prepositions and auxiliary verbs, are all absolutely Teutonic. The English, he says, is clearly the natural descendent of the Gothic or Teutonic; and he challenges the deepest enquirer into the Celtic to produce so decisive a proof of any affinity of that tongue with ours. The British, he adds, has little or no resemblance to the English. Many of their terms may have gained admittance among us, as, from the vicissitude and long intercourse we have had with that people, may necessarily be imagined, but their idioms and genius are so radically and essentially different as any two languages can possibly be.

TEUTONIC Order, a military religious order of knights, established towards the close of the twelfth century; and thus called, because it confided principally of Germans, or Teutones.

The origin, &c. of this order were thus: the Christians, under Guy of Lusignan, laying siege to Acre, or Acon, a city of Syria, on the borders of the Holy Land; at which siege were present, Richard king of England, Philip Augustus of France, &c. some Germans of the names of Halberstadt, Fulda, and Lubeck, touched with compasion for the sick and wounded of the army, who, when they observed the want of military attendances, and the difficulty of purchasing the same themselves, purchased them for the soldiers at so reasonable a price; and not only made it a point of honour with them to be колов in their charge, but also to defend them in their charge, but also to defend them at the peril of their lives. They procured, on this occasion, the sanction of the Emperor Henry IV., who, by a Bull, gave them the title of Teutonic Knights, or of St. John. They were afterwards established at Acre, and enjoyed all the rights of a religious order, and the advantage of the privileges of a military order.

The first act of the Teutonic order, in the beginning of the twelfth century, was to acquire the isles of Zante and Malta, with which they had hitherto been merely concerned. They now formed a strong base of operations from which they began to extend their dominion over the heathen states of the Levant, and rendered themselves the objects of the envy and hatred of the fleets of the Venetians, the Genoese, and the Egyptians. Their first object was to establish a religious station at Acre, which they did with the consent of the Pope, and the assistance of the Emperor Henry IV. The latter now granted them the title of Teutonic Knights, and the right of acquiring all the territory between Acre and Egypt, for the purposes of the order. They were also permitted to build a church at Acre, and to hold a market in the same city. They were thus established as a military order, with the privilege of erecting a church in the city of Acre, and of holding a market in the same city. They were also permitted to build a church at Acre, and to hold a market in the same city. They were thus established as a military order, with the privilege of erecting a church in the city of Acre, and of holding a market in the same city. They were also permitted to build a church at Acre, and to hold a market in the same city. They were thus established as a military order, with the privilege of erecting a church in the city of Acre, and of holding a market in the same city. They were also permitted to build a church at Acre, and to hold a market in the same city. They were thus established as a military order, with the privilege of erecting a church in the city of Acre, and of holding a market in the same city. They were also permitted to build a church at Acre, and to hold a market in the same city. They were thus established as a military order, with the privilege of erecting a church in the city of Acre, and of holding a market in the same city. They were also permitted to build a church at Acre, and to hold a market in the same city. They were thus established as a military order, with the privilege of erecting a church in the city of Acre, and of holding a market in the same city. They were also permitted to build a church at Acre, and to hold a market in the same city. They were thus established as a military order, with the privilege of erecting a church in the city of Acre, and of holding a market in the same city.

holding the quarter-sectons; the upper floor for a banqueting room, and for the meeting of the corporation. Among the charitable establishments are a free grammar-school, a charity-school, and several alm-houses. The Anabaptists, Quakers, Independents, and Methodists, have each a meeting-house in the town. The population, according to the returns of the year 1811, amounted to 4820; the number of houses being 1003: the latter are chiefly of brick, and principally ranged in three spacious streets. Since the year 1786, when an act was passed for paving and lighting the town, many improvements have been made; and the buildings have assumed an air of respectability.

The Abbey.—A monastery was first erected here, and endowed by two brothers, Oddo and Doddo, dukes of Mercia; A.D. 715, to the honour of the Blessed Virgin, which having undergone many calamities during the civil and Danish wars, about 980 became a priory, subject to Cranbourn in Dorsetshire: but Robert Fitzhamon, a noble Norman, who came to England with the Conqueror, enlarged the buildings and increased the possessions of Tewkesbury so much, that the monks of Cranbourn chose, about 1102, to remove to this place, leaving only a prior and two monks behind, and made Cranbourn in future subject to the abbey of Tewkesbury. From this time it became a great establishment of Benedictine monks; and at the suppression, the annual revenues amounted to 1598l. 1s. 3d., exclusive of 1506. 8s. 1d. granted by the convent for fees and annuities: its plate also was very valuable, the facrity alone containing 1421 ounces. After the dissolution, the destruction of the monastic buildings was rapid and complete, through the ineffectual opposition of the monks to the visitations appointed by the king, who, in revenge, destroyed the Lady chapel, cloisters, chapter-house, and other appendages by fire. The remains of the buildings were afterwards purchased by the inhabitants: and the Abbey Church was made parochial. This magnificent structure displays an interesting example of early Norman architecture, combined with specimens of later styles, and in other respects well calculated to arrest the attention of the antiquary. It is built in the cathedral form, and consists of a nave, choir, transept, and central tower, with the addition of several chapels, ranged round the aisle of the choir. The nave and choir are separated from the aisles by eighteen massive columns, fulfilling the roof, and four substantial piers which support the tower. At the west end is a large window with a pointed arch, which appears to have been introduced within a femicircular arch in 1656. There were cloisters on the south side of the nave, where some fragments yet remain; and appear to have been highly ornamented in a similar style to those at Gloucester. The tower, according to the Abbey chronicles, was once terminated by a wooden spire, which fell down on Easter-day, 1559. The most remarkable specimens of the architecture are three tiers of arcades in the upper part; the arches of the middle tier have intervening mouldings. The length of the church is 300 feet; of the transept 120; the breadth of the choir and side-aisles is 70 feet; of the west front 100; the height from the area to the roof is 120 feet; the height of the tower 152 feet. The monuments, which are numerous, have attracted the attention of various antiquaries, particularly Mr. Cough and Mr. Lysons; the latter of whom has taken great pains in ascribing the different tombs to the real personages they were intended to commemorate: many mistakes, in this respect, having been committed on traditional authority by former writers. Near the west end of the church is the Abbey Gate-house, which appears of the age of the fifteenth century; it is embattled and ornamented with grotesque figures, projecting from a cornice; beneath which is a canopied niche between two square windows.—Dyde's History, &c. of Tewkesbury, v. 1756. Rudge's History of Gloucestershire, vol. i. 1803. Beauties of England and Wales, vol. v. Gloucestershire; by J. Britton and E. W. Brayley.

Tewkesbury, called Wanstefi, or Pawtecket, by the Indians, a township of Massachusetts, in the county of Middlesex, containing 943 inhabitants; 24 miles N. of Boston.

TEXALI, in Ancient Geography, the inhabitants of the sea-coasts of Aberdeen: who had a town, called Deva, at the mouth of the river Deva (Dene), where old Aberdeen now stands.

TEXAS, in Geography, a province of New Spain, which properly forms part of Louisiana. This province is claimed by Spain as part of the internal provinces, and included in the vast intendency of San Luis Potosí: it is bounded by the state of Louisiana, S. by the gulf of Mexico, W. by an imaginary limit, and N. by Red river, and contains an area exceeding 100,000 square miles. The capital of this province is the garrison of San Antonio de Bejar, ridiculously called the New Philippines. It was founded in 1731, confiding of a captain, a lieutenant, and one company of soldiers. The river of Cenis in this province, is now a most Indian village, with the ruins of a fort built by the French. That called Natchitoches, from an Indian tribe, friends of the French and enemies of the Spaniards, was a small fort, built on an island of the Red river by some French veterans.

TEXEIRA, JOSEPH (Peter), in Biography, a Portu- tuguese historian, was born in 1543, entered among the Dominicans, and became prior of the monastery at Santarem in 1578. When Philip II. of Spain took possession of Portugal, Texeira attached himself to Don Antonio, who had been proclaimed king by the Portuguese, and accompanied him into France. In 1582 he was taken prisoner by the Spaniards, but made his escape from Lisbon. He became confessor to Don Antonio, and, in process of time, preacher and almoner to the French king Henry III. He afterwards attached himself to Henry IV., and in 1596 affiliated at the abjuration of Calvinism by the princes of Condé. He was sent on one million to England, and favourably received by king James. He died at Paris in 1604, as some say; but according to another account, in 1620.

In 1582, Texeira printed his "Compendium de Portugalliae ortu Regni initiis, &c." This work was answered by order of the king of Spain; and Texeira replied, in 1592, by a "Confutatio, &c." which proceeded to refute the hereditary right of Philip to the crown of Portugal, and to vindicate that of Don Antonio;—probably the same work that is entitled "De Electronis Juris quod competit Viris Portugallienibus inaugurandi suis Regibus," Lyons, 1580.
As a genealogist, under which character he was distinguished, he published in 1590, "Exegetis Genealogicae Arboris Gentilitiae Henrici IV., Gallorum Regis," enlarged in 1598, with the addition of the princes of Condé's abjuration. In token of the indignation he felt at the seizure of his country by Philip, he affirmed, as it is said, in one of his sermons, that "we were bound to love all men, of whatever religion, sect or nation, even if they were Calvillians." Boyle. Morei.

TEXEL, or TESSEL, in Geography, an island of Holland, about 11 miles in length, and 5 miles in its greatest breadth; situated at the mouth of the Zuyder See, with a capacious and good harbour, and a fort, which commands the entrance; besides a town of the same name, it contains five villages: the land is fertile in pasture, and the whole well fenced with dikes of prodigious length and height. Near this island was the celebrated sea-fight, between the fleet of Holland, under admiral Martin Harpertz Tromp, and that of England, under admiral Blake, in the year 1653, in which Tromp was killed. In the year 1673 a battle was fought between the fleet of Holland and the united fleets of England and France, in which the victory was doubtful. N. lat. 53° 5'. E. long. 4° 40'.

TEXEUIT, or TEXIT, a town of Morocco; 100 miles W.N.W. of Morocco.

TEXT, a relative term, contradistinguished to gloss or commentary; and signifying an original discourse, exclusive of any note or interpretation.

Infinite pains have been taken by the critics, to restore, reconcile, fettle, explain, &c. the text of the bible, and that of the classics. See Bible.

Mr. Whitton accounts for all those misunderstandings between the Old and New Testament, particularly as to the prophecies in the Old, cited as fulfilled in the New, from the corruption of the text of the Old Testament; and to obviate objections made against Christianity on that head, has published an "Essay towards restoring the true Text of the Old Testament." See Prophecy.

This restoration he attempts to effect from the Samaritan Pentateuch, the Roman Pfalter, the Apostolical Constitutions, &c.

It sufficiently appears from the learned and acceptable labours of the late Dr. Kennicott, in collating the Hebrew manuscripts of the Old Testament, that the alterations introduced into the text, &c. are mostly of a trivial nature, and by no means affect the authority of the sacred writings.

Text is particularly used for a certain passage of scripture chosen by a preacher, to be the subject of his sermon.

A collection of texts appropriate to different subjects, and judiciously arranged, has been published by Dr. Enfield for the use of preachers in the composition of their discourses, and also of biblical readers and students.

Anciently, the lawyers began all their pleadings with like texts of scripture.

A text-book, in several universities, is a classic author written very wide, by the students, to give room for an interpretation dictated by the master or regent, to be inferred in the interlines.

In this sense, the French say, proverbially, Gloffe d'Orleans plus obscure que le texte.

The Spaniards gave the same text to a kind of little poem, or set of verses placed at the head of a glos, and making the subject of it; each verse being explained, one after another, in the course of the glosses.

Text, in Ancient Law Authors, is appropriated to the book of the Four Gospels, by way of eminence. These were written in gold letters, and carefully preferred in the churches.

"Codex aurato concepsus grammate scriptus.
Auctus evangelicum conlevrus corpore textum."

TEXTUARIES, TEXTUARI, a name given to the feot of the Caraites, among the Jews. Hillel shone among the traditionaries, and Schammai among the textuaries.

The civil and canon lawyers sometimes also call a book containing the bare text, without any gloss or commentary, a textuary, textuarium.

TEXTURE, TEXTURA, formed of texo, I weave, properly denotes the arrangement and cohesion of several slender bodies or threads interwoven or entangled among each other: as in the webs of spiders, or in cloths, stuffs, &c.

Texture is also used in speaking of any union or cohesion of the constituent particles of a concrete body; whether by weaving, hooking, knitting, tying, chaining, indenting, intruding, comprelling, attracting, or any other way.

In this sense, we lay a clofe, compact texture; a lax, porous texture; a regular or irregular texture, &c.

A great deal depends on the texture of the component parts of a body; hence most of its particular properties, its specific gravity, colour, &c.

TEXTUS Roffensis, is an ancient manuscript, containing the rights, customers, tenures, &c. of the church of Rochefort, granted by the laws of Ethelbert, Hothoer, Eadred, and Withred, kings of Kent, collected by Ernulf, the venerable bishop of Rochefort, about the year 1100.5.

TEYA, in Geography, a river of Austria, which rises about three miles N. from Germs, passes through a part of Moravia, and runs into the March, 11 miles N.E. of Zistersdorf.

TEYN, a town of Bohemia, in the circle of Boleflau; 12 miles W.N.W. of Jung Buntzel.

TE-YUEN, a town of Asia, in the kingdom of Corea; 93 miles N.E. of King-ki-tao.

TEZA, a town of Africa, in the kingdom of Fez, with a castle. It was once a populous city, but is now much decayed, yet is still the residence of a governor and a garrison; 20 leagues N.N.E. of Fez.

TEZCUCO, or Tetzucu, a lake of Spanish America, in the province of Mexico. The conjunct lakes of Tezcuco and Chalco are found to be about 30 English miles in length, and the former is about 15 miles in breadth; but as the latter is partly drained, so as to be at the distance of a league from the city, it is probably about twelve miles in breadth. This lake is celebrated in history, as originally containing the city of Mexico, and also as remarkable for the qualities of the water, partly fresh, and partly saline. The Chalco, or fresh-water lake in the south, appears to flow by a narrow channel into the salt lake of Tezcuco. See Mexico, substituting for Tezcuco, Tezaco.

TEZELA, a town of Africa, in the kingdom of Algiers; 5 leagues S.W. of Oran.

TEZERGBE, a town of Africa, in the kingdom of Fez; 100 miles E.S.E. of Teza.

TEZOUT, or TESSOT, a town of Africa, in the kingdom of Fez; 35 miles S. of Melilla.

TEFEN, a town of Egypt, on the Nile; 10 miles S.E. of Rosetta.

TFUOI, in the Chinese Manufactory of Persia, a word used to express a particular sort of varnish for that warp.
with violet-colour and gold. The usual method of doing this at first was by mixing gold with the common varnish, breaking the leaves very small, and then adding the common glue and the powder of calcined agate of a coarser kind, found in great plenty on the shores of their rivers. But they have since found that the brown varnish called tefkin succeeds much better, for when the blue is mixed with this, its brown colour is lost, and the gold lies on much better than it would any other way.

They had once a method of a varied varnish, which was very beautiful, but is much neglected now; this was the giving a vessel the brown varnish on the outside with a large portion of gold, and the common white varnish within. They also varied the degree of colour on the outside, by laying on more or less of the varnish; and gave this way a variety, even in the same colour. Obser, fur les Coutumes de l'Asie, p. 508.

TCID, in Geography, a town of Arabia, in the province of Oman; 48 miles N. of Tacht. THABBA, in Ancient Geography, a town of Arabia Felix, situated between Menambis and Seba, now Elba. Ptol.—Also, an ancient town of Africa, in the vicinity of Thila. THABET EBN KORRA, in Biography. See THEIRIT BEN CORAH.

THABILACA, in Ancient Geography, a town of Albania, between the rivers Gerrus and Soanes. Ptol. THABIR, in Geography, a mountain of Arabia; 20 miles S. of Medina. THABOR, in Ancient Geography. See TABOR.

THABORITES. See TABORITES.

THABRACA COLONIA, Tabarka, in Ancient Geography, a town and Roman colony of Africa, in Numidia, according to Ptolemy. It was situated on the western bank, and near the mouth of the river Taifa. Some wells remain of walls and cisterns.

THABUCUC, a town of Spain, in the interior of the Tarragonensis, belonging to the Vanduli. Ptol.

THACAS, Sasa, in Antiquity, a general name given to the place or seat where the augurs made their observations.

THACONA, in Ancient Geography, a town of Aisa, in Babylonia, upon an arm of the Euphrates. Ptol.

THACES, a people of Scythia, on the side of the Imaus, and near it. Ptol.

THACK TYLES. See TYLE.

THALEMA, in Ancient Geography, a town in the interior of Arabia Defera. Ptol.

THANA, or TIANE, a town placed by Strabo, Pliny, and Ptolemy, on the coast of Africa, towards the commencement of the Ifeer Syrtes.—Also, a town of Asia, in Syria, situated, according to Ptolemy, in Cyrrhetica. THAGIA, in Geography, a town of Africa; 100 miles S.S.W. of Fez.

THAGORA, TINGORAN, in Ancient Geography, a poit of India, at the bottom of a small gulf, in the easter part of the peninsula, beyond the Ganges.

THAGULIS, a town of Africa, situated between the Two Syrtes. Ptol.

THAHAR KIAEN, in Geography, a poit of Chinese Tartary; 15 miles N.E. of Ticutac. THAHATH, in Ancient Geography, the place of the 23rd station of the Israelites, where they encamped, after having left Mauloth; situated in the desert of Arabim, S. of Gauloth.

THAINNE, in Geography, a town of Africa, in the kingdom of Tunis, near the east coast, but without a harbour, at a small distance from the mouth of a river of the same name; 120 miles S. of Tunis.

THAIS, a town of France, in the department of Paris; 2 leagues S.S.E. of Paris. THAIS, a name given by Agineta to a cosmetic cream, intended to give a beautiful red to the face. Galen uses the same word to express a sort of handbag.

THALA, in Ancient Geography, a town of Africa, in Numidia, according to Sallust and Tacitus.—Also, a mountain of Africa, in Interior Libya, and the people inhabiting its vicinity were called Thale.

THALACH, in Geography, a river of Bavaria, which runs into the Schwarza; 5 miles W. of Greding.

THALAMENUS, among the Ancient, a ship of pleasure, or yatch used by princes. It was always provided with a good cabin, or bed-chamber. See SHIP.

THALAMI NERORUM OPTICORN, in Anatomy, two eminences in the brain. See BRAIN.

THALAMA, in Botany, one of the kinds of Apothecium, or receptacle, is so denominated by Acharius.

THALAMII, among the Ancient, theowers who fat in the lowest part of the ship. See the next article.

THALAMITE, in Ancient Geography, a term used to express those rowers in the polyere galley, or those who contained several series of rowers, who sat on the thalami of the vessel, and made the lowest row. These moved their oars and hands under the seats of the row that sat next above them. See POLYEREOTA.

THALAMIIUM, among the Ancient, a port-hole, through which the oars of the rowers in the bottom of the ship went.

THALAMUS, in Botany, a term used to express that part of the flower in the capitated or flosculous-flowered plants, where the embryo fruits of every separate flower are lodged, and where afterwards the seeds are contained. This is the bottom of the cup, in the central part of which it adheres to the calix.

THALASSAR, in Ancient Geography, a province of Asia, between Mesopotamia and Armenia.

THALASSOMELI, the name of a medicine used as a purge among the ancients. It was composed of equal parts of honey, sea-water, and rain-water, exposed to the sun in the dog-days, in a vessel pitched on the inlet. It purged in the same manner that sea-water alone would do, but only in a milder way.

THALASSUS, in Ancient Geography, a town or port in the southern part of the isle of Crete.

THALATHA, a town of Asia, in Babylonia, on the banks of the Tigris, and S. of Apamea.

THALATTA, a lake or marsh, at the foot of mount Caucasus, in the environs of the people called Corzesi. It discharged its waters into the Euxine sea, near a place called Bebaea-Ponti.

THALBIS, a river of Albania, between the Gerrus and the Soanes. Ptol.

THALEA, a town of Palatine, in the tribe of Simcon, according to the book of Jobuma.

THALER, in Commerce. See RIXDOLLAR.

THALES, in Biography, the founder of the Ionic school, and of the scientific method of philosophizing among the Greeks, was born of Phenician parents, at Mileus, in the fifth year of the 35th Olympiad, or about the year 580 B.C. He acquired wealth and distinction among his compatriots, and was employed at an early age in public affairs. He declined involving himself by marriage in the cares of a family, that he might devote his whole time and attention to the study of philosophy; alleging, as it is said, to his mother, who urged him to marry, at an early age...
"wisdom, and at a more advanced period "it is too late." In order more entirely to divagate himself from every avocation that would divert his mind from his favourite pursuits, he committed the care of his estate to his sister's son, whom he adopted. In search of wisdom, he travelled to Crete, and afterwards to Egypt. From the priests at Memphis in the latter country, he is said by several writers to have gained his knowledge of philosophy and mathematics. But it is more probable that he was more indebted to his own talents and affinities in the exercise of them, than to any communication from them; and accordingly it has been affirmed, that he taught them how to measure the height of their pyramids. Upon his return to Miletus, he was universally respected for his extraordinary wisdom and learning; and his acquaintance was eagerly courted by all who wished to improve in knowledge or to be ranked among philosophers. He was not prevented, however, by these engagements from prosecuting his mathematical, philosophical, and metaphysical studies. In this course of improvement and usefulness, and of imparting, as well as of acquiring knowledge, he professed his life to the great age of ninety years, and died, through mere infirmity, whilst he was attending the Olympic games. Thales was ranked among the seven wise men of Greece, and might justly be reckoned one of this number, whether we consider his ethical attainments, or the moral maxims and aphorisms which are ascribed to him. Of these maxims, we shall select the following: "Neither the crimes, nor the thoughts, of bad men are concealed from the gods. Health of body, competent fortune, and a cultivated mind, are the chief sources of happiness. What is the most difficult thing? To know one's self. What the easiest? To give advice to others. How shall we best attain to virtue? By abstaining from all that we blame in others. Parents may expect from their children that obedience which they paid to their own parents. Take more pains to correct the blemishes of the mind, than those of the face. Stop the mouth of slander by prudence. Be careful not to do that yourself, which you blame in another. Friends should be remembered when absent, as well as when present." —Laertius. Brucker by Enfield, vol. i. For an account of his philosophical doctrines and other particulars, we refer to the article Ionic Sect.

THALETAS of Crete, a famous lyric poet, celebrated by all antiquity as a musical musician, is said to have delivered the Lacedemonians from the pestilence by the sweetness of his lyre; but credulity in the powers of music must be very strong indeed, in those who could believe it possible for music to drive away the pestilence. Thaletas, however, was universally believed to have poissied this power; but it is impossible to render the fact credible, without qualifying it by several circumstances omitted in the relation. In the first place, it is certain that this poet was received among the Lacedemonians during the plague, by command of an oracle; that by virtue of this mission, all the poetry of the hymns which he sung, must have consisted of prayers and supplications, in order to avert the anger of the gods against the people, whom he exhorted to sacrifices, expiations, purifications, and many other acts of devotion; which, however superstitious, could not fail to agitate the minds of the multitude, and to produce nearly the same effects as public fasts, and, in Catholic countries, processions, at present, in times of danger, by exalting the courage, and by animating hope.

The disease having, probably, reached its highest pitch of malignity when the musician arrived, must afterwards have become less contagious by degrees; till, at length, ceasing of itself, by the air wafting away the seeds of infection, and recovering its former purity, the extirpation of the disease was attributed by the people to the music of Thaletas, who had been thought the sole mediator, to whom they owed their happy deliverance.

This is probably what Plutarch means, who tells the story; and what Homer meant, in attributing the effulgence of the plague among the Greeks, at the siege of Troy, to music.

"With hymns divine the joyous banquet ends,
The Paean lengthen'd till the sun descends:
The Greeks reftor'd, the grateful notes prolong:
Apollo listen, and approves the song."

Pope's Homer's Iliad, book i.

For the poet, in this passage, seems only to say, that Apollo was rendered favourable, and had delivered the Greeks from the scourge with which they were attacked, in consequence of Chryseis having been restored to her father, and of sacrifices and offerings.

This poet-musician has been confounded by some writers with Thales the celebrated Milesian philosopher; but according to Plutarch (in Lycurgus) he was cotemporary with Lycurgus the Spartan legislator, and lived about three hundred years after the Trojan war. Plutarch also informs us, that though Thaletas was only styled a lyric poet and musician, he was likewise a great philosopher and politician; inasmuch that Lycurgus brought him from Crete, when he returned from his travels, to Sparta, in order to have assistance from him, in establishing his new form of government. His odes, continues Plutarch, were so many exhortations to obedience and concord, which he enforced by the sweetness of his voice and melody. Plato, likewise, describes his captivating manner of singing; and Plutarch, in his Dialogue on Music, ascribes to Thaletas many musical compositions and inventions: such as Paean, and new measures in verse, as well as rhythms in music, which he had acquired from the flute-playing of Olympus, whom he first had imitated. Porphyry, in his Life of Pythagoras, says that this philosopher used to amuse himself with singing the old Paean of Thaletas; and Athenæus likewise tells us, that the Spartans long continued to sing his airs; and, according to the scholiast on Pindar, this poet-musician was the first who composed the Hyparchaeons for the armed, or military dance.

There was another poet and musician of the name of Thaletas, who was likewise a Cretan, but who flourished much later than the cotemporary and friend of Lycurgus.

THALFANG, in Geography, a town of France, in the department of the Sarre; 11 miles S.S.W. of Traarbach.

THALHEIM, a citadel of Bavaria, in the territory of Nuremberg; 6 miles S.E. of Herrbruck.

THALIA, in Botany, was so named by Linnaeus, in memory of John Thalius, a physician at Nordhausen, in Germany, who wrote Sygna Hercynia, a catalogue of the plants of the Hercynian forest towards Saxony, which accompanies the Hortus Medicus of Joachim Camerarius, both having been printed together at Frankfort on the Main in 1588; and they are both illustrated by excellent wooden cuts. Thalius died in 1587, of a fractured thigh, in consequence of a fall from his carriage. His work abounds with original descriptions and remarks; but as Haller observes, it is not easy to ascertain all the numerous species or varieties of which he treats. The genus before us was originally called CORTUSA by Plumier; but that name remains with a very different plant, as the reader will find its proper place.—Linn. Gen. 4. Schreb. 6. Wille Pl. v. 1. 15. Ait. Hort. Kew. v. 1. 3. Rolsoe T.
Between the 791, 1810, Curt. 791, 1810, Curt. ftyle Ic. Living T. next Peronia; (Cortufa the I. A Seed Redout. five the large South the the I. anther foliary, 108. 340. no arrived, for f. generic height, may figure, Cuba, in awl-fliaped tlian the Tube Juff. 307. Gen. it fares. albumen, 340. ovate. deep the Tube — 8. 340. ovate. oval, two-lipped Stam. Filament three-lobed, with one, attached to its its length, inferior, which has accumulated, do not belong to it; and that what Rottboll has described and figured, seems more akin to T. cannaformis, hereafter mentioned. We have indeed specimens, gathered by Mr. Frazer in 1810, in Cuba, near the Hannaban, which greatly reemember Plumer's figure, and may be his plant, though from the impossibility of examining their fructification, we dare not attempt them to be so. Nevertheless we shall describe them, that botanists may form their own opinion. The stem is several feet in height, erect, round, smooth, leathery, alternately branched. Leaves alternate, ovate, pointed, smooth, above a foot long, with one rib, and many fine transverse curved veins. Footstalks filiform, comprefsed, half as long as the leaf, with an oblong liniform knot at the summit. Panicle subdivided, at each subdivision. Flower-flask zigzag, knotty, round, two or three inches long. Partial bractes two at each knot, the outermost much the largest, embracing and concealing the other, an inch in length, elliptic-oblong, green, finely ribbed, clothed with scattered shining hairs. Between these bractes is situated a pair of flowers, whose dried corolla is partly purple, and whose pale, much convoluted and wrinkled lip bears some resemblance to Plumier's figure.

2. T. dealbata. Mealy Thalia. Roscoee Tr. of Linn. Soc. v. 8. 340. Dryand. in Art. n. 1. Pursh n. 1. Frazer's single plate. Curt. Mag. t. 1690. (Peronia firiéta; Redout. Liliac. t. 342.)—Leaves ovate. Flowers crowded. Bractes ovate, mealy.—Native of impenetrable swamps in South Carolina, flowering in August and September. Mr. Pursh says it was first discovered there by T. Millington, eqq. Living plants were brought to England by the late Mr. Frazer in 1791, by which this hand-fome and curious species first became known to botanists. Its root is of coarse perennia. Stem four or five feet high, erect, round, smooth; leafy at the bottom; pinnled at the top, covered with a filivry mealnkes, which clothes also the general as well as partial bractes, and is easily rubbed off by a touch. Leaves light green, smooth, above a foot long, on round sheathing stalls, with a knot at the top. General bractes lancelolate, concave, convolute, a fipan long. Flower-flanks aggregate or compound. Partial bractes crowded, in pairs, much more timid, ovate, and shorter than in the foregoing, each pair containing two purple flowers, whose structure is detailed in our generic character. Fruit purple, the fize of a hazel-nut, slightly pulpy.

3. T. cannaformis. Elliptical Thalia. Forl. Prodr. 1. Wildd. n. 3. Buchanan in Synn. Emphasly to Ava, ed. 2. v. 3. 305. t. 21.—Leaves elliptical. Partial bractes linear-lanceolate, shorter than the divided partial flower-flank.—Native of moif woods in the remote islands of the East Indies, and the New Hebrides, flowering in March and April. The stem is solid, branched, round, smooth, leafy, divericated at the joints. Leaves alternate, broadly elliptical, pointed, smooth, on round sheathing stalls. Panicle terminal, with long, flender, pendulous branches, upon which the flowers are arranged pretty closely. Every pair of long narrow partial bractes contains a divided flalk, bearing two large white flowers, each with the rudiment of another at its base. The corolla is somewhat tubular, and the lower lip of its inner limb has two large equal lobes, but in other respects the parts of fructification seem to answer well enough to the generic character. The fruit, however, which mufi settle that point, is unknown.

Our learned and highly valued friend Mr. Roscooe has sug- gested, that the Maranta Cachibeck, Jacq. Fragm. Bot. 52. t. 69 and 70, of which we have a specimen gathered by Mr. Maffon at St. Kitt's, may probably be a Thalia. Its feed certainly confirms this opinion, but the parts of the flower are not yet sufficiently described to authorize any conclusion, nor can we unravel their structure from the dried plant. Whatever becomes of this species, the Maranta Cachifeck, t. 63. f. 4. of the same work, and M. Ca- ]upita, t. 64. f. 2., mufi allured to be referred to the same genus.

Thalia, in Mythology, one of the nine Mufes, who pre- sided over comedy and pastoral. She is distinufhied from the other Mufes by her maff, and from the tragic Mufe by her shepheard's crook; her affect is likewise meaner than that of Melpomene, and her dress shorter and less noble than that of the other Mufes. Thalia was also the name of one of the Graces. THALICTRUM, in Botany, may possibly be, as gene- rally
THALICTRUM.

68. Wildl. n. 2. Ait. n. 2. "Waldfl. et Kutah-Hung. v. 2. 190. t. 174." (T. minimum maleficium; Buhl. Prodr. 147. Pluk. Phyt. t. 65. f. 4. Moris. sect. 9. t. 20. f. 13. T. n. 1140; Hall. Hist. v. 2. 58.)—Stem pinnate, round, leafy. Leaves triply compound, minutely downy on both sides. Flowers drooping. Petals lightly hairy. Stigmas variegated at the base.—Native of France, Switzerland, and Siberia, flowering in May. A species of a delicate aspect, and glaucous hue, about a foot high, with innumerable, small, round, lobed, tender leaflets. The petals are externally reddish, especially in the young plant, and finely downy or hairy. Stamens long and capillary. Seeds ovate, strongly furrowed, crowned with the permanent thrivalled stigmas, whose dilated or aliated base is distinguishable in our Swiss specimens. This last character is, in the Supplementum, p. 271, made the peculiar mark of T. flavidum, there described from a Siberian specimen, which Linnaeus did not recognize as his own T. faidiun. The flavidum, Wildl. n. 22, is therefore to be struck out. Several Swiss botanists have confounded the species before us with T. minus, hereafter described, which is Haller's n. 1139. That eminent writer had some doubts respecting the difference between the two, which we shall attempt to remove when we come to the other, Linnaeus having placed them far at under. The faidiun is said to exalt a very bad and powerful odour, like Geranium robertianum, or, as Haller says, the urine of cats.

3. T. tuberosum. Tuberous-rooted Meadow-rue. Linn. Sp. Pl. 270. Wildl. n. 3. Ait. n. 3. Mill. le. v. 177. t. 265 f. 2. (Oenanthe Myconi; Dalech. Hist. 785. Ranunculus thalictri folio minor, alsphodeli radice; Moris. sect. 4. t. 28. f. 13.)—Leaflets rounded, glaucous, smooth. Petals five. Root tuberous.—Native of Spain and the Pyrenees. A hardy perennial in our gardens, flowering in June, but confined to the more curious collections. The root conhilts of ovate knobs. Herb smooth, a foot or more in height, of a light glaucous green. Flowers pinnate, not numerous, distinguished by their five large, ovate, white petals, and small stigmas. Morison's figure is badly copied from that of Dalechamp.

5. T. dioecum. Dioecious Early Meadow-rue. Linn. Sp. Pl. 768. Wildl. n. 5. Ait. n. 5. Pursh n. 2. Mulhenb. Cat. 54.—Leaflets heart-shaped, many-lobed, very smooth. Panicles axillary. Flowers dioecious. Petals not longer than the filaments or germens. Stigmas almost capillary.—Native of shady woods and the hanks of rivers, from Canada to Virginia, flowering from May to July, according to Pursh, who says the flowers are white. He conceives his plant to be the same with T. lewisiiatum of Michaux, Fl. Borcali-Amer. v. 1. 322, who confesses his inability to determine the North American Thalictr, they being almost all dioecious. Specimens from the late Dr. Mulhenn, now before us, and agreeing exactly with those sent by Kalm to Linnaeus,

Gen. Ch. Calath leaves, none, the corolla be taken for such. Cor. Petals four or five, roundish, obtuse, concave, deciduous. Stam. Filaments numerous, dilated upwards, compressed, less than the corolla; anthers terminal, ob-long, erect. Pist. Germens superior, numerous, mostly flattened, roundish, igles none; stigmas thickish. There are also several very short imperfect pistils. Peric. none. Seeds several, ovate, furrowed, without any appendages. Eff. Ch. Calyx none. Petals four or five. Seeds naked, without appendages.

Obf. Linnaeus remarks, that his T. tuberosum and cor-nutum have five petals; dioecus has the flaments and pillifs on separate plants; aquilegelhium and contortum have flapped pendulous seeds, furnished with three dilated or winged angles; moreover, that the number of flaments and pillifs differs in the different species, being sometimes less than the characters of the clays and order require.

This is a very distinct well-marked genus of perennial herbaceous plants, all natives of the cold or temperate climates of Europe and North America. The leaves are compound, with roundish, rarely oblong, lobed or notched leaflets; paler, or glaucous, underneath; usually smooth. Inflorescence pinnate. Flowers white or yellowish, with some light ting of purple, generally of an elegant feathery appearance. Fourteen species are defcribed in Linn. Sp. Pl.; twenty-one in Syft. Veg. ed. 14. Willdow has twenty-three. Four are British. Nineteen are enumerated in Mr. Aiton's Hortus Kewensis. Their qualities in general are believed to be of an acrid nature, like those of Ranunculus and Clematis; but milder.

We have some additions and corrections to make, which require a compendious review of the whole genus.

1. T. alpinum. Alpine Meadow-rue. Linn. Sp. Pl. 767. Wildl. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 262. Lightft. 286. t. 13. f. 1, Fl. Dan. t. 11. (T. minimum montanum atro-rubens, folio splendentibus; Ralt. Syn. 204. Boerh. Ind. Alt. v. 1. 44. t. 1.)—Stem perfectly simple, and almost naked. Clusters simple, terminal.—Native of moist black bogs, or the turfy margins of alpine rides, on the loftiest mountains of Lapland, Scotland, and Wales, flowering in June. The root is perennal, creeping, with a few fimple fibres. Stem erect, about six inches high, round, glaucous or purpilish, in one leaf, more or less leaved, compound, about the middle. Radical leaves several, flattened, erect, half as tall as the stem; first ternate, then either again ternate, or pinnate; the leaflets roundish, or wedge-shaped, veiny; glaucous beneath. Clusters at first drooping, then erect, of eight or ten alternate flowers, whole petals, and eight or ten filaments, are either white or purple; their anthers orange. German two or four only, roundish, green, each with a whith, broadly-lanceolate, divaricated, downy stigma, about its own length. Linnaeus describes twelve flaments, and eight piliils.

**THALICTRUM.**

Linnaeus, as recorded in Sp. Pl., are certainly dioecious, about a foot high, very smooth, with three-ternate leaves, whose lobes are usually from five to seven, blunt, and rather shallow; both their surfaces reticulated with slightly prominent veins. *Panicles* solitary or in pairs from the axils of the leaves, somewhat umbellate, on long stalks, and often accompanied by a long-flaked solitary flower. *Panels* of the male flowers white or reddish, ovate, ribbed, the length of the very slender numerous *filaments*, whose anthers are yellow, very narrow, pointed: those of the female flowers much smaller and rounder, white or greenish, hardly so long as the little, oval, ribbed *germin*.

*The Pigeons* are very slender, and remain in a prominent, almost capillary, form, on the ovate-oblong, flattened seeds.

7. *T. majus.* Greater Meadow-rue. Jacq. Auctr. v. 5. 9. t. 420. Willd. n. 7. Fl. Brit. n. 3. Engl. Bot. t. 611. — *Leaves* roundish, somewhat heart-shaped, three-crested; glaucous beneath. Panicle leafy, with aggregate branches. *Flowers* drooping. — Native of woods and bushy places in Austria, Hungary, Mount Athos, and the north of England, perennial, flowering in June and July. The late Mr. Robson of Darlington found it at Baydals, near that town, as well as on the margin of Ullswater, Cumberland. This is about the size of the last, but the leaves are of a darker green on the upper side, very glaucous beneath. The branches of the panicle grow several together, from the axils of the upper leaves, and the flowers, at least their *flamens*, are pendulous, with longer *anthers* than the preceding. The petals moreover are green. In the *germin* and *Pigeons* we perceive no particular distinction.

11. *T. fistuliferum.* Siberian Meadow-rue. Linn. Sp. Pl. 769. Willd. n. 11. Ait. n. 11. (T. orientale minimum, fumarize folio ; Tourn. Cor. 20. Willd.) — "Leaves in three divisions; *leaves* somewhat reflexed, sharply cut. *Flowers* drooping." — Found by Gmelin in Siberia; and by Tournefort, if we are right in his synonym, in Armenia. Linnaeus doubtfully cites a synonym of Seguir, which, after Haller, we have referred to *T. minus*. His account of the present species, of which we know nothing, is, that its habit accords with *T. minus* or *purpurascens*, but the leaves are small, but one-sixth as large as those species, glaucous like Rue or Fumitory. *Stem* green, copiously panicked. *Panicle* brown at its dichasium. It flowers later, at the same time as *flamum* and *dioicum*.

12. *T. squarrosum.* Squarrose Meadow-rue. Willd. n. 12. — "*Leaves* three-crested or undivided. Footstalks membranous, winged, clasping the stem. *Flowers* drooping." — Native of Siberia. Differs from all the foregoing species which have drooping *flowers*, in the structure of its footstalk. The leaves are repeatedly compound, as in the reit; their lateral *leaves* mossily ovate, acute, and entire, but the terminal, and even the uppermost lateral ones, are divided or three-crested. *Footstalk* greatly dilated at the base, with orbicular membranous wings, toothed at the margin. There are also leifer orbicular toothed *auricles*, upon the partial footstalks, by which mark the species is easily known. *Wildieu.* We have met with nothing answering to this description.

THALICTRUM.

The leaves are nearly round, flowers drooping. Stamens coloured "— On dry sandy hills, in Pennsylvania and Virginia. Perennial. Stem and flowering in May and June. A small plant. Stipules and leaflets purple. Pursh. Linnaeus contrasts this with T. minus, a species concerning which his ideas were too vague for us to learn any thing from such a comparison, nor does his herbarium lead us any certain aid. There is, however, an unmarked specimen, which he associated with T. dioicum, but which may possibly be the purpureum. It has broad leafy-like leaflets, but is more particularly distinguished by short elliptical anthers, whose stamens are gradually dilated upwards, approaching to those of T. flavium hereafter described.

A tall species, with white flowers. Pursh. We have this from our late venerable correspondent, the Rev. Dr. Muhlenberg. The leaflets are rather large; dark green, and somewhat rugged, above; paler, reticulated with prominent veins, and minutely downy, at the back. Flowers nearest to those of T. dioicum, and like them distinguished by long tapering filaments. The anthers are linear-oblong; their stamens almost equally slender throughout.

15. T. angustifolium. Narrow-leaved Meadow-rue. Linn. Sp. Pl. 769. Willd. n. 14. Ait. n. 13. Jacq. Hort. Vind. v. 3. t. 25. t. 43. — Leaflets linear-lanceolate, or linear, mostly univerted, entire. Panicle much branched, dense. Flowers erect. Stigmas heart-shaped, half the length of the stamens. Native of Switzerland and Germany, but not frequent anywhere. Dr. Sibthorp, however, gathered it on the Bithynian Olympus. Miller feems to have cultivated it, in his time, at Chelsea, but we have scarcely ever seen a living specimen, and we are much inclined to concur in opinion with those who judge it a variety of the following, their habit, inflorescence, and flowers, being exactly the same, however different the breadth of their leaflets. Baulin's synonym, uniformly referred to this, certainly belongs to T. simplex, n. 17.

17. T. simplex. Simple-ruled Meadow-rue. Linn. Mant. 78, excluding the synonynm. Willd. n. 17. Ait. n. 15. Fl. Dan. t. 244. Ehrh. Phytoph. 15. (T. angustifolium; Villars Dauph. v. 3. 712. T. angustifolium folio; Bauh. Prodr. 146. Moris. fœct. 9. t. 20. f. 8.) — Leaflets linear. Stem angular, simple. Panicle branched, compound, lax, somewhat racemose. Flowers pendulous. Stigmas roundish-heart-shaped,— Native of Sweden, Denmark, Switzerland, and France. Introduced at Kew by the very eminent cultivator and botanist M. Thouin, in 1778. It is a hardy perennial, flowering in May and June. This is unquestionably akin to the last, but essentially different. The whole plant is but half as large, with a much more angular stem. The leaflets are extremely narrow, and revolute, unaccompanied by any of the partial stipulatory scales, seen on the leaves of T. flavum. The panicle is more oblong and lax, not comybofus. Flowers smaller, drooping, or rather quite pendulous, not erect. Petals green, not white or yellowish. Stigmas remarkably round and convex. We have specimens from Villars, which prove the correctness of Willdenow respecting his synonym. We have also from professor Lachenal a specimen gathered at Michel- feld, which shews this to be the plant of Baulin, cited by Linnaeus and others for T. angustifolium. Indeed Baulin's wooden cut, copied by Morison, sufficiently evinces this, though, being delineated perhaps from a dried specimen, it is not exact in the position of the flowers. T. gallowan, Willd. Enum. Hort. Berol. 585. we believe is a very narrow-leaved variety of simplex.

18. T. lucidum. Shining-leaved Meadow-rue. Linn. Sp. Pl. 770. Willd. n. 18. Ait. n. 16. (T. minus lucidum, libanoqidos coronaria folis; Pluk. Phyt. t. 65. f. 5.) — „Stem leafy, furrowed. Leaflets linear, fleshy." — Said to be a native of France and Spain. Miller had something in his garden which passed for this plant, and hence it is enumerated in Hort. Kew. We have never seen a specimen, nor did Linnaeus know any more of the matter than what Dalibard, whose specific character we more exactly copy, has given in his fl. Paris. 162. The late Mr. Davall sent us a Swis Thalictrum for lucidum, which answers to the character, but is indubitably the simplex in a luxuriant state. Linnaeus thought the lucidum was probably a variety of flavum. We preume various things have been taken for this plant, but in reality that it has no existence as a species.

19. T. aquilegifolium. Coburn-leaved Meadow-rue, or Feathery Coburn. Linn. Sp. Pl. 770. Willd. n. 19. Ait. n. 17. Jacq. Auct. v. 4. t. 40. t. 318. Curt. Mag. t. 1818. (T. sanguifolium; Jacq. Hort. Vind. v. 3. 34. t. 61. T. majus, folium flaminibus purpurascetibus; Bauh. Pin. 337. Moris. fœct. 9. t. 20. f. 16.) — Leaflets rounded, lobed, and cut. Stem round. Panicle comybofus. Flowers erect. Stamens dilated upwards. Germens flaked. Fruit pendulous, with three dilated wings.— Native of Sweden, Germany, Switzerland, Thrace, and Greece, common and hardy in our gardens, flowering from May to July. The stem is three or four feet high, round, somewhat furrowed, leafy, smooth, either glaucous or purple. Leaves large and spreading, much resembling those of Aquilegia vulgaris, though often more acute. Flowers large and elegant, white or pale violet; their petals reflexed; their very numerous stamens moderately dilated upwards, flattened, of the hue of the petals, with yellow anthers. Germens triangular, on long stalks, at length deflexed or pendulous, and becoming somewhat obovate, obtuse, straightish seeds, with three unequal, much dilated, smooth wings.
wings. Retzius, in his Olf. Bot. sive. 6. 30. sect. 52, justly indicates the identity of Jacquin's T. atrupurpureum and the Limnae aquilegifolium, confessing he could not decide concerning the aquilegifolium of Jacquin. We have a wild Swiss specimen of the latter, Hallier's n. 1141, precisely answering to the plate in Pfl. Austria, and certainly not differing in any essential character from the true plant of Limnae, so frequently cultivated for ornament, and preferred in his herbarium.

20. T. contortum. Twisted-fedeed Meadow-rue. Linn. Sp. Pl. 775. Am. Acad. v. 4. 47. Willd. n. 20. Ait. n. 18. Fruit pendulous, triangular, contorted. Stem rather two-edged.—Native of Siberia. Limnae thought it a hybrid offspring of aquilegifolium impregnated by the minus. His specimen is not to be distinguished from the former, and we cannot but agree with Willdenow's remark, that the contortion of the leaves is merely a sign of imperfection. Neither can any more fold dependance be laid on the comparative number of the parts of fructification, on the white colour of the flowers, or the humbler stature of the herbage. We conclude this fupposed species therefore to be hardly a separate species as a variety of the last.

21. T. petiolatum. Darvian Meadow-rue. Linn. Sp. Pl. 771. Willd. n. 21. Ait. n. 19. (T. flamineum; Linn. Suppl. 271.)—Leaflets rounded, obtuse; partly three lobed. Stem nearly leafless. Panicle somewhat umbellate. Stamens much dilated, linear-obovate. Gernerns fessile.—Native of Siberia. Mr. Lodigies is said to have introduced this curious and very distinct species to the knowledge of our cultivators, in 1796. It has a perennial root, with long, fimple, rather fleshy ftripes. Stem fimpie, about a foot high, ftriated, purple at the bottom, leafless, except an occafional leaf, accompanying a fmall lateral branch. Radial fefles two, spreading, thirfe compouneed, on purplie ftalks; leaflet very much like Common Rue, but smaller. Flowers white, large but not numerous, in a fort of corymb, or imperfet mmbellate, accompanied by a few small leaflets. Petals roundifh, deciduous. Stamens very numerous, white, flat, and sinularily dilated, with a mid-rib; their anthers yellow, narrow and fhort. Gernerns ovate, ribbed, with aw-conditioned recurved wing. Willdenow makes T. flamineum a variety, little supposing that the very identical specimens, fo minutely and accurately defcribed in the Species Plantarum, could be again defcribed, without a reference, in the Supplementum.

We have to exclude T. japonicum, Thunb. Tr. of Linn. Soc. v. 2. 337. Willd. n. 22, a fpecimen from Thumberg himfelf proving it to be no other than Coptis afflfensifolia of Mr. Sallybur, Tr. of Linn. Soc. v. 8. 303, a circumstance as wonderful as that its discovery fhould ever have thought this plant similar to a Solanum. See Pl. Aps. 564.

22. T. ranunculifum, Willd. Enum. Hort. Bor. 585. Pursh n. 6, having simpie leaves, and being not noticed as a Thal- lidium by Muhlenberg himfelf, who is quoted for it, is, we presume, hell oif ferved as well as T. continental, Willd. Enum. 584, which is probably comprehended under one of the foregoing species.

Thalictrum, in Gardening, contains plants of the hardy, herbaceous, fibrous-rooted, perennial kinds, among the number of which the species mostly cultivated are; the tuberous-rooted meadow-rue (T. tuberofum); the Canadian meadow-rue (T. cornuti); the fetid meadow-rue (T. fclidum); the narrow-leaved meadow-rue (T. anguillifolium); the shining-leaved meadow-rue (T. lucidum); and the columbine-leaved meadow-rue, or feathered columbine (T. aquilegifolium).

In the second fort there is a variety, which is smaller, with pale purple filaments, than the common kind.

Also in the fifth fort there are varieties with a green ftalk and white filaments, and with a purple ftalk and filaments. Besides, there are other forts that may be cultivated for variety.

Method of Culture.—All the forts are readily increafed by parting the roots, and planting them out in the autumn: when the ftems decay, or in the fpring before the new ones are set forth, the strongest where they are to remain, and the weaker ones in nurfery-rows for further growth: they may also be raised from seeds, which fhould be fown in a bed or border in the fpring: when the plants rife, they fhould be kept clean, and be planted out where they are to remain, in the following autumn. They are all hardy durable plants that fucced and grow well in any common foil and exposure in the open ground, but which flourifh most in mild fady situations. They afford variety in the borders, and other parts of ornamented grounds, when set out in a properly varied manner, requiring but little trouble or attention in such situations.

Thalina, in Ancient Geography, a town of Asia, in the Greater Armenia, upon the banks of the Euphrates.

Thallaba, Talaban, a town of Asia, in Mero- potamia, upon the banks of the river Chabors, situated E.S.E. of Retzius.

Thalland, in Geography. See Dalia.

Thallite, in Mineralogy; Epidote, Harly; Delphinius, Saufrure; Short vers du Dauphin, Rome de Bike; Aquaticus, dendrada; Pijluc, Werner. Few minerals have received so many names as this; it is at present better known by the name of epidote or thallite. It has frequently been confounded with aclinolite or strafheimen, and with green hornblende and green aiferus. Some account of this mineral is given under Piectite. We shall here add its diflinctive characters and confiuent parts. From aclinolite it may be distinguished by the colour, the latter being generally a lighter green. The flature of the maffive varieties of aclinolite is generally radiated, that of epidote compact or foliated. Both the joints of aclinolite are diftinately fen; but in epidote, frequently one joint only is fen. Epidote melts into a blackish fcoria before the blowpipe, and it is harder than aclinolite or hornblende; the latter has generally a different flade of green; the flature of hornblende is also less vitreous than that of epidote. Green aiferus is soft when fponded; the powder of epidote is harf and rough. Thallite or epidote occurs both maffive and cryftalized. The joints are in two directions, one of which is more obvious than the other. The alternate angles are about 114°3 and 65°3; the crofs flature is fimplicity. The primitive form of the cryftal is a prism with bhom- boidal bafe. The moff common forms are fix or eight- fided prisms, of which four are larger than the others. These prisms are terminated by feveral oblique planes, and are often flatly acumiated: the terminating planes of the cryftals are smooth, and have a high natural polish; they are fometimes convex. The lateral planes, or fides of the cryftals, are ftriated. This mineral is found in beds and veins, and fometimes as a confiuent part of rocks. It is associated with augite, garnet, hornblende, quartz, calcareous fpar, and magnetic iron-ftone. The varieties that occur in veins are of a lighter colour, and the cryftals are more aecinar than those which are found in beds. The veins contain felpar, azinite, rock-cryftal, chlorite, and other minerals: the epidote forming only a small part of the fubflance of the vein. It is found in several parts of the Scotch Hebrides, and in various Alpine districts, in sienite, porphyry, and granitic rocks. The feim cryftals have been procured at Arundel in Norway. The con-
fluent parts of this mineral, from different situations, agree more nearly than is frequently the case with other minerals.

It differs in chemical composition from hornblende and actinolite, by the absence of magnesia, and by the large proportion of alumina which it contains.

**THALLOPHORI**, χαλλόφοροι, in Antiquity, the old men and women, who, in the procession of the festival pana-chiron, carried olive-boughs in their hands.

**THALLUS**, in Botany and Vegetable Physiology, χαλλος, an olive bough, or a green bough; from χαλλος, to stand erect, to float, or to spread abroad; a term aptly enough chosen by the distinguished professor Archibald, for the frond, or foliage, of a *Lichen*, whether that part be of a leafy, fibrous, scaly, or crustaceous nature. But this term, however apt, is superficial, from, used by Linneus, being synonymous with it, and sufficient for every requisite purpose. See *Lichen* and *Lichenes*; also *Frond*.

**THALMANSFELD**, in Geography, a town of Germany, in the margravate of Anspach; 4 miles W. of Thalmassing.

**THALMESSING**, or Thalmensingen, a town of Germany, in the principality of Anspach; 31 miles S.E. of Anspach. N. lat. 49° 1'. E. long. 11° 10'.

**THALMIS**, or Talmis, in Ancient Geography, a town of Egypt, between Taphis and Tutzis. Anton. Itin.

**THALPUSA**, a town of the Peloponnesus, in Arcadia; which belonged to the Orcemenians.

**THALSEA**, or Thelsea, a town of Phœacia, marked on the route from Remmaris to Neapolis, between Geroda and Damaceus.

**THALUDA**, a river of Africa, in Mauritania Tingitana, the mouth of which is placed by Ptolemy on the coast of the Iberian sea, between Jagath and the promontory Oleslrum.

**THALYSIA**, χαλλος, in Antiquity, a sacrifice offered by the husbandmen after harvest. For the origin and ceremonies of which, see Potter, Aubach. Grec. tom. i. p. 400.

**THALAMAPATHRA**, See *Folium Indicum*.

**THAMAR**, a word used by the Arabian physicians to express a date. Hence a pectoral decoction, made with dates and other ingredients, was called *diathamyrin*; and the word was afterwards corruptly written *decameron*.

**THAMAR**, in Ancient Geography, a town of Judea, near Malis or Malath, which, according to Eusebius, had a Roman garrison.

**THAMARITA**, a town of Africa, in Mauritania Caærenis.

**THAMARO**, a town of Palestine, on the western side of Jordan. Ptolemy.

**THAMSALITIS**, a town of Africa Propria, on the route from the Greater Leptis to Tacupa, between Thamudifis and Thentei. Anton. Itin.

**THAMBES**, in Geography, a mountain of Algiers; 30 miles S. of Donz.

**THAME**, See Team.

**THAME, or Tame**, in Geography, a market-town in a hundred of the same name, and county of Oxford, England, is situated on the banks of the river Thames (whence it derives its name), at the north-eastern extremity of the county adjoining to Buckinghamshire, 13 miles E. from Oxford, and 46 miles N.W. by W. from London. Dr. Stukeley calls this place Tame, and it is unquestionable that a Roman military road went through the town, though it was by degrees neglected in the latter times of the empire. Thame was a place of some consequence in the tenth century; for we find that Wulfere, king of Mercia, granted a charter to the vill called Thame; and in the year 970, Okekeley, archbishop of York, is known to have died here. In 1010, when the Danes over-run these parts of the kingdom, this town, among others, suffered severely. The Domesday record describes the manor of Thame as a part of the bishop of Lincoln's extensive possessions in Oxfordshire. Leland says, "about Alexander, bishop of Lincoln's time, the town of Tame, being the king's, was given for rent, in fee-farm, to the bishop of Lincoln and his successors." To the patronage of the bishops the town was indebted for numerous advantages. By them the church was erected, the vicarage and a prebend endowed, and a neighbouring abbey reared. Through their intercessions the fairs and market were granted; and Henry Lexington, bishop in Henry the Third's reign, rendered an important service, by turning the high road through the middle of the town. Thame continued dependent on the bishops till the reign of Edward VI., when the fee was demifioned of many of its valuable possessions. Sir John Williams obtained a grant of the estate, which, descending by marriages to the family of Bertie, it became vested in the earls of Abingdon, the present possessors. During the civil wars of the seventeenth century, Thame was surrounded by garrisons of the contending parties, and consequently experienced its full share of the miseries of that period. The town consists principally of one long and spacious street, gently rising from the river. The church is a large, well-built structure, of the cruciform description, and comprising a nave, two aisles, a north and south transept, and a chancel; with an embattled tower supported by four massive pillars. The interior exhibits numerous tombs and memorials of families once important in this neighbourhood. Near the church are the remains of the prebendal houses, which evince considerable former grandeur, and consist of nearly three sides of a quadrangle. A school, once of great celebrity, was founded here by John, lord Williams: the house is a spacious building, and the school of noble dimensions. Through the whole of the seventeenth century, this establishment maintained a high character: but has now fallen into dilapse; though the building is in excellent preservation. There is likewise a charity-school of an humble description for the education of twenty-five boys. Thame has a good weekly market on Tuesdays, and two annual fairs: the market is of ancient date, for we find that the prior of Rufford was restrained from holding a market at Haddenham, to the prejudice of that of Thame. In the year 1811, the number of houses was returned as 460; the population as 2328, of which more than half were paupers receiving alms from the parih. By the return of the expenses attending the maintenance of the poor in 1811, those of this parish amounted to 3680l., a sum exceeding the expenditure of any other parish in the county. The parish contains about 4500 acres of land, and is divided into six hamlets or liberties, Old Thame, New Thame, Priest End, Thame Park, Moreton, and North Weston: the town comprises the three first. In Thame park, about a mile from the town, flour an abbey of some importance, established by bishop Alexander in 1138. At the dissolution, the society consisted of an abbot and fourteen monks; and the annual revenue was 250l. 14s. 7d. The abbey, with all its poffessions, was surrendered to the crown by Robert Kyng, the last abbot, who, for his ready compliance, was on the erection of the fee of Oxford appointed its first bishop. On the feite of a part
a part of the abbey the present manufaet was built by Philip, the father of the late lord Wemans. Considerable fragments of the abbey still remain, which are protected by the modern elevation. The park contains about 220 acres, and is skirted by woodland.

Sir John Holt, the celebrated chief justice of the court of king's bench, was born at Thame in 1642, and died in 1709. (See Holt, Sir John.) — Beauties of England and Wales, vol. xii. Oxfordshire; by J. N. Brewer. THAMES, the name of the most important river of Great Britain, is pre-eminently distinguished for its commercial confluence, the scenery, edifice; and towns on its banks; for the bridges which are ranged across its channel; for the vast docks, quays, and warehouses which are annexed to it; and for the variety and interest of the historic occurrences which are connected or associated with its name. Yet, though occasioned at the present time, it was neglected in former ages; and it is singular to remark, that its sources and early progress have occasioned much doubt and dispute. Some topographers have assigned its origin to a spot in Oxfordshire, near the town of Thame; while others, with more regard to probability and record, have traced its source to a spring near Cricklade, in Wiltshire. In that district three or four streams emerge from the earth, and each of these has been honoured with the appellation of Thames-head: but at present it is very generally admitted, that this name strictly belongs to a fine spring, which rises in the parish of Kemble, in Wiltshire, about five miles N.W. of Cricklade, and two and a half miles S.W. of the town of Cirencester. Some writers state that the spring-head is in the parish of Cotes, and county of Gloucester. As a proof that this stream was designated as the Thames, or Tems, at an early period, we may refer to a Saxon charter of Malmbury Abbey, wherein it is named "Temens," as the boundary of certain lands. Again, some of the old Monkish historians state that the Danes crossed the Thames at Cricklade in the early part of the tenth century.

It has been erroneously said, that the name of this river is the Ipsi till it arrives at Dorchester, and receives the waters of the Thame, where it attained the compound name of Thames: Some old Oxford poets have given currency and celebrity to this story. Pope, in his "Windsor Forest," speaking of the union of various streams with this river, thus sings:

"First the famed authors of its ancient name,
The winding Ipsi, and the fruitful Thame;
The Kenne swift, for silver cels renowned;
The Lodden flow, for verdant alders crowned;
Cole, whose dark streams his flowery islands love,
And chalky Wey, that rolls a milky wave."

Denham, the poetical encomiast of "Cooper's Hill," thus characterises the Thames.

"My eye-descending from the hill, surveys
Where Thames among the wanton valleys flares.
Thames the most loved of all the Ocean's sons
By his old fire to his embraces runs;
Hafting to pay his tribute to the sea,
Like mortal life to meet eternity."

The nature of the present work will not allow of a particular description of the course of this river, with brief accounts of all the prominent objects on its banks. It must suffice to specify the names of the towns, chief seats, and prominent features; and refer to the former, under their respective names in the Cyclopaedia, for further information, and to such books wherein the said accounts are to be obtained. One characteristic of this river is entitled to notice; and which

fews, that at the original formation of rivers, and subdivision of lands in England, the Thames was at that time a noted and considerable stream. From the town of Cricklade, to its junction with the Sea at Sheerness, this river is a boundary, or natural line of separation, to counties. Soon after its source, it divides the counties of Wilts and Gloucester; next thores of Oxford and Berks, and Buckingham and Berks; afterwards Middlesex and Surrey; and, lastly, Kent and Essex. The Thames is also a navigable river nearly the whole of its course, and thus affords an easy and cheap passage for heavy goods from the ocean, and the port of London, to the interior parts of the island. By means of a canal, extending from the town of Lechlade, in a north-westery direction, to the river Severn, the latter great western river and the Bridit Channel are joined by a navigable course to the English Channel. See CANAL, THAME, and SEVERN.

As nearly the whole course of the Thames is through a plain or level country, we find its current is consequently low and irregular. For fifteen or twenty miles it is only a narrow and small stream, but after receiving the waters of several rivulets, it assumes a river-like appearance at Lechlade, and is capable of sustaining barges of 100 tons burthen. From that town (about 138 miles by water from London) to Sheerness, it is strictly a navigable river. In its course to the sea, the following rivers, besides several smaller streams, pour their waters into the Thames: the Wainfrith, Evenlode, Cherwell at Oxford, Thame, Kennet, Loddon, Coln, Wey, Mole, Brent, Lea, Roding, Dart, and Medway.

The following cities, towns, and large villages are seated on the banks of this river: viz. the cities of Oxford, London, and Westminster; the towns of Cricklade, Lechlade, Abingdon, Wallingford, Henley, Great Marlow, Maidenhead, Windor, Staines, Kington, Richmond, Brentford, Greenwhich, Woolwich, and Gravesend; the villages of Pangbourn, Wargrave, Eton, Datchef, Old Windor, Shepperston, Walton, Sunbury, Moulfe, Hampton and Hampton-Court, Twickenham, Hieworth, Barnes, Chivick, Fullham, Putney, Hammerfmith, Chelsea, Blackwall, &c. The banks of this river are altogether ornamented with the palaces of Windor, Hampton-Court, Kew, Fullham, and Lambeth: likewise the following distinguished seats of English nobility and gentry, besides several smaller villas, &c.; Nuneham-Courtney, Bafflon House, Combe Lodge, Purley, Park Place, Pawley Court, Culham Court, Temple House, Marlborough House, Bingham Abbey, Taplow, Chiefden, Cookham, The Willows, Beaumont Lodge, Oatlands, Garrick's Villa and Pope's Villa at Twickenham, Strawberry Hill, Thames-Ditton, Marble-Hill Cottage, the duke of Bedflegh's, lord inceant Sidmouth's, and Mr. Keen's at Richmond, Keppell House, Sion House, Brandenburgh House, and Ingrams. Among the numerous bridges which cross this national river, the following are justly noted either for their beauty or extent. The first stone bridge on its course is at Elmham, and the next at Lechlade; Oxford, Abingdon, Shillingford, Wallingford, Ca- verham, Henley, Maidenhead, Eton, Staines, Walton, King- don, Richmond, Kew, Fullham, Batteries, Vauxhall, (famed 1816) Westminster, the Waterloo and Southwark (now erecting from designs by that scientific engineer, John Rennie, eqd.), Blackfriars, and London. The last fix are to be said to belong to the metropolis. The jurisdiction of the lord mayor of London over the river Thames, extends from Coln-Ditch, near Stains, to Yendal or Yenlech, near Sheer- nes, and also includes parts of the rivers Lea and Medway. A very interesting account of the scenery and various ob- jects on this river, with numerous beautiful etchings by W. B.
THAMES, a river of New Zealand. Capt. Cook, Mr. (now Sir Joseph) Banks, and Dr. Solander, failed up this river in a pinasse; at about fourteen miles from the entrance, it is as wide as the Thames at Greenwich, and the tide at flood is as strong; it is not quite so deep, but has water enough for vessels of more than a middle size, and a bottom of mud so soft, that nothing could take damage by running afire. The course is from north to south, and the entrance between Cape Colville and Point Rodney.—Alfo, a river of Upper Canada, which runs into St. Clair, N. lat. 45° 15'. W. long. 82° 10'.—Alfo, a river of Connecticut, which runs into the sea, 4 miles below New London.

THAMESIS, called Jamija by Ptolemy, in Ancient Geography, a river of the isle of Albion. See Thames.

THAMETHIS, a town of Egypt. See Dametta.

THAMMUZ, in Mythology, is a name under which the Phenicians worshipped Adonis or Osiris.

THAMMUZ, in Chronology, a name given by the Jews to the tenth month of the civil year, containing twenty-nine days, and answering to our June.

THAMNA, in Ancient Geography, a celebrated town of Palestine, on the road from Diapholis to Jerusalem. It was the capital of the Thamnitic toparchy.

THAMNATH-SAAR, a town of Palestine, in Samaria, in the tribe and upon the mount of Ephraim, N. of mount Caas. This town was built by Joshua, and his tomb was there in the time of Jerome.

THAMNERIA, a town of Asia, in Media, in the neighbourhood of the country belonging to the Cadusi. Xenophon.

THAMNIIUM, in Botany, a very small shrubbery, from Thamnium, a shrub, and Thamus, a name chosen by Ventenat, in his Table du Regne Vegetal, v. 2. 35, for the shrubby kinds of Lichen, of which he makes a genus. Its character is

Several kinds of入股. Tubercles fuggous, coloured.

Lichen rangiferinus, and L. Racemula, are mentioned as species of this genus, which is now, like the rest of the author's labours in this department, disfigured, the whole tribe having been so much better studied and arranged by Acharius. See Lichenes.

THAMNOCHORTUS, so called by Bergius, from Thamus, a shrub, and στεφανος, a crown; alluding to the hard shrubby habit, and natural affinity of the plant. Berg. Cap. 353. t. 5. f. 8. This genus is now sunk in Restio (see that article); and the particular species is R. scavina of Thunb. Prodr. 15, and Wild. Sp. Pl. v. 4. 723, though those authors have used Thamnochortus as the specific name of another plant, immediately preceding this in Willdenow, who enumerates thirty species of Restio.

THAMNSBRUCK, or Thomasbruck, in Geography, a town of Saxony, in Thuringia; 8 miles S.E. of Mullhausen. N. lat. 51° 53'. E. long. 16° 43'.

THAMYRIS, a town of Macedonia, near the Danube. It was built, according to Jornandes, by Thamyris, queen of the Geete.

Thamyris, in Mythology, called Homer Kithabit, one who plays on the cithara, was the son of Philammon. (See his article.) Plutarch, in his Dialogue on Music, tells us that Thamyris was born in Thrace, the country of Orpheus, and had the sweetest and most sonorous voice of any bard of his time. Homer, in his catalogue of ships, where he speaks of the cities under the dominion of Neleus, mentions Dorion as the place where Thamyris contended with the Muses, whom he had the arrogance to challenge to a trial of skill in poetry and music. The conditions and consequences of this contention are fully described by the poet.

"And Dorion, fam'd for Thamyris' disgrace, Superior once of all the tuneful race, Till, vain of mortals empty praise, he froze To match the feed of cloud-compelling Jove! Too daring bard! whose unsuccessful pride Th' immortal Muses in their art defy'd: Th' avenging Muses of the light of day Depriv'd his eyes, and frate'd his voice away; No more his heavy voice was heard to sing, His hand no more awak'd the silver string."—Iliad, book ii.

Homer availed himself of the popular story concerning the blindness of Thamyris, and embellished it by his verification. Probably the whole allegory of this blindness had its rise from his having injured the organ of sight by too intense an application to the study of music and poetry. And it is the opinion of Pausanias, that there was no other difference between his misfortune and that of Homer, than that Thamyris was wholly silenced by it, and Homer, without being discouraged, continued his poetical and musical occupation long after his blindness.

THAN, in Geography, a town of Hindoostan, in Guzerat; 55 miles N.E. of Junagur.

THANE, or Thain, Thamus, the name of an ancient dignity among the English, or Anglo-Saxons.

Skene makes thane to have been a dignity equal with that of the son of an earl; Camden will have it, that thanes were only dignified by the offices which they bore.

There were two kinds or orders of thanes; the king's thanes, and the ordinary thanes. The first were those who attended our English-Saxon kings in their courts, and who held lands immediately of the king; whence, in Domesday-book, they are promiscuously called thoni, and foreigns rege.

Soon after the Conquest this name was disused; and instead of it, they were called the king's barons, barones regis.

Their origin is referred to king Canatus, who, taking the chief of the Danish nobility, to the number of three thousand, for his guard, and arming them with battle-axes and sabres with gilt handles, called them thing lib, from the two Danish words thing or their, body of nobility, and lib, order of battle.

The ordinary thanes, or thani minoris, were the lords of manors, who had particular jurisdiction within their limits, and over their own tenants.

These changed their name for that of barons; and hence their courts are called courts baron to this day.

In old authors, charters, &c. we also meet with than as signifying
signifying a nobleman; though sometimes only a freeman, and sometimes a magistrate.

THANKLAND, were lands granted by charter of the Saxon kings to their thanes.

THANET, Isle of, in Geography, is a tract of land on the southern coast of the county of Kent, England, consisting of about 27,000 acres, and is separated from the remaining part of the county by the narrow channel of the river Stour, and the smaller stream called the Nethergong. The marshes which border these streams are extensive, and afford rich pasturage for cattle, but the higher grounds are principally appropriated to the growth of corn. The Isle is in shape a long oval, being about nine miles in length from east to west, and nearly five miles broad from north to south. Solinus, who is quoted by Camden, calls it Athianatos, and in some copies Thanatos, which probably gave origin to the Saxon appellation Tenet, or Tanelond; though Lewis derives this from Tene, a fire or beacon; and he supposes the Isle to have been so named on account of the beacons or fires which were kept here to give notice of Danish or other pirates, to whose ravages it was greatly exposed. Thanet is bounded on the north and east sides by the sea; a circumstance which, connected with the salubrity of its air, and its convenient distance from the metropolis, has led to the establishment of several watering-places; and these, in the summer and autumnal seascapes, occasion a continual influx of visitants, whose expenditure adds greatly to the wealth of the fixed inhabitants. The chalk cliffs which surround the coast abound in fossils; and among them, the cornua ammonis has been found, measuring upwards of three feet in diameter. The whole of Thanet is divided into the two capital manors of Minster and Monkton, by St. Mildred's Lynch, a narrow strip of land, left unploughed, and extending quite across the Isle, from Westgate by Woodchurch, to Sheriff's Hope near Monkton. The Isle anciently contained eleven parishes; but those of Sarre and All Saints have been united to St. Nicholas, and that of Woodchurch to Birchington. The parishes of Minster, Monkton, and Stonor, with parts of those of St. Nicholas and St. Lawrence, are under the jurisdiction of two courts; the other parishes, namely St. John's, including the town of Margate; Birchington, with Gore's End, St. Peter's, and Wood or Woodchurch, the ville of Ramsgate, and the ville of Sarre, with the remainder of St. Nicholas and St. Lawrence, are all members of, and subject to the control of the ports of Dover and Sandwich. The population return of the year 1811 stated the inhabitants of the Isle to be 16,156; the number of houses 3,299. (See Margin, Ramsgate, and Reculver.)—Beauties of England and Wales, vol. xiii. Kent; by E. W. Brayley.

THANN, or DANN, a town of France, in the department of the Upper Rhine; 15 miles N.E. of Belfort.

THANN, See Tanna.

THANNHAUSEN, or TANNHAUSEN, a town of Germany, in the circle of Swabia, and principal place of a lordship of the same name, on the river Mindel; 14 miles N. of Mindelheim.

THANNURIS, in Ancient Geography, a town of Asia, in Ophroene; and another in Mesopotamia.

THANTIA, a town of Palestine, in Batansea, eastward towards the mountains, S.E. of Adraa.

THANWALD, in Geography, a town of Sile sia, in the principality of Brandenburg; 13 miles N.W. of Breslau.

THAOUAOUIS. See TAVAVIS.

THAPAU, in Ancient Geography, a town situated in the interior of Arabia Felix. Ptol. Vol. XXXV.

THAPSA, a town of Palestine, in the tribe of Ephraim.

THAPSACUS, or AMPHIPOLIS, a large and flourishing town of Asia, in Syria, on the banks of the Euphrates. When Alexander, after leaving Egypt, came to Thapsacus, he found there two bridges over the Euphrates. Xenophon tells us that Cyrus is founnded here five days; and that it was here that he informed the Greeks of his intention to march to Babylon. The soldiers mutinied, but were afterwards appeased by his promises. Thapsacus is now a village, called "El-Der." The channel of the river is here about half a mile in breadth, and would appear to have been fordable from the earliest times to the present day. It was passed on foot by Cyrus and his whole army, and, as some say, by that of Alexander the Great.

THAPSA, in Botany, a name adopted from the ancient Greeks, which 6?k<, 6, if not precisely a species of our present genus, was certainly, like it, a large umbelliferous plant, yielding a gummy exudation, and bearing yellow flowers, succeeded by broad seeds. Such is the description given by Dioscorides, who moreover adds, that his 6k<, tio named from the island of Thapsos, where it grew, was in every respect like Pardela; but with a more slender stem, and leaves nearly akin to fennel. The root was large; white within, black on the outside, with a thick acid bark. It attributes various virtues to its gum or juice, either taken as a purge, or in preparations of the shell; or applied externally, along with honey, wax, or frankincense, for cutaneous complaints, tumours, &c.—Linn. Gen. 144. Schreib. 193. Wildl. Sp. Pl. v. 1. 1404. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 156. Sm. Prod. Fl. Græc. Sibth. v. 1. 201. Juss. 220. Tourn. t. 171. Lamiacec. Illurst. t. 206. Gartn. t. 21. —Clais and order, Pentandria Digyna. Nat. Ord. Umbellata, Linn. Umbelliferae, Juss. Gen. Ch. General Umbel large, with about twenty rays, of nearly equal length; partial of as many, nearly equal, rays. Involucrum none, neither general nor partial. Periamb scarcely discernible. Gen. Universal uniform; all the flowers fertile; partial of five lanceolate incurved petal. Stam. Filaments five, capillary, the length of the corolla; anthers simple. Pist. Germin inferior, oblong; &bys two, short; stigma obtuse. Peric. Fruit oblong, enwrapped longitudinally with a membranous border, separable into two parts. Seeds two, very large, oblong, convex, pointed at each end, enwrapped at each side with a large, flat, entire-edged border, which is emarginate at each extremity.

r. Th. villofa. Villous Deadly Carrot. Linn. Sp. Pl. 375. Wildl. n. 1. Ait. n. 1. (Th. prima; Clus. Hist. v. 2. 192. Th. latifolia Chufi; Ger. Lin. 1930.)—All leaves toothed, villous; confluent at the base.—Native of flouy ground, in Spain, Portugal, and the south of France. Dr. Sibthorp found it in the fields of Patmos and Cyprus, and Dr. Broussonet at Algiers. The root is perennial, tap-shaped, fald to be of an extremely foetid, acrid, and nauseous quality, which has given rife to the English name. Gerarde applies to this species what Dioscorides says of T. garranica, that exhalations from the root or plant exaluter the skin. The floem is three or four feet high, erect, round, smooth, leafy, branched at the top. Leaves large and spreading, two or three times pinnate; their leaflets sessile, obtuse, pinnatifid, notched, confluent at the base, in the manner of a fern; hairy on both sides; whitish and downy at the back. Umbels several, stalked, terminal, large, smooth, naked. Flowers yellow, rather small. Fruit about half an inch long, and a quarter broad, with four ribs at 3 L each.
each side, and a thin, brown, membranous double wing at each margin.

2. *Th. fsetida.* Stinking Deadly Carrot. Linn. Sp. Pl. 375. Willd. n. 2. Ait. n. 2. (Th. vulgaris; Ger. Em. 1031. Th. vulgaris, carota efficie; Lob. 1c. 780. Morif. sect. 9. t. 18. f. 7.)—Leaflets many-eleft, acute; contracted at the base.—Native of Spain, as well as of Zante and Cyprus. Gerarde had this plant in his garden, and it is still, like the foregoing, to be seen in curious botanical collections, though not very commonly. It differs from the *silofo* in having more finely, acutely, and deeply divided leaflets, which are wedge-shaped, not dilated at the base. The fize of the whole plant is smaller, and the stem more branched.

3. *Th. Afcelpium.* Fine-leaved Deadly Carrot. Linn. Sp. Pl. 375. Willd. n. 3. Sm. Fl. Gracc Sibth. t. 286, unpubl. (Th. apula, folis millefoli; Morif. sect. 9. t. 18. f. 9.)—Leaflets deeply pinnatifid, with long, green, glaucous, smootarters, to be seen in curious botanical collections, though not very commonly. The *silofo* in having more finely, acutely, and deeply divided leaflets, which are wedge-shaped, not dilated at the base. The whole plant is smaller, and the stem more branched.

4. *T. gar*ganica. Garganian, or rather Greek, Deadly-Carrot. Linn. Mant. 57. Willd. n. 4. Ait. n. 3. Gonan Illustr. 18. t. 10. Sm. Fl. Gracc Sibth. t. 287, unpubl. (Th. thalictii folio; Magn. Monsp. 287. t. 286. Th. fife Turbich gargasiecum, femine latifimo; Bauh. Hift. v. 3. p. 2. 50.)—Leaves radiato-pinnate; leaflets deeply pinnatifid, with linear decurrent segments. Native of Barbary, the south of Italy, and the Levant. Dr. Sibthorpe finding it very common throughout Greece, and the neighbouring islands, juftly concluded this species to be the true *silofo* of Dioscorides, with whose description it agrees better than any of the reft. It is a stately perennial plant, whose seeds were probably obtained from the garden of Montpellier, by our British cultivators, towards the year 1688. The firm round leafy stem, as well as the sheathing bases of the footstalks, and the ripening seeds, are tinged with a fine glaucous purple. Leaves long, green, smooth above; glaucous, and sometimes hairy, below; their segments near an inch long, linear, entire. Common footstalks long, round, sometimes very hairy. Umbels very large, yellow. Petals lanceolate, involute. Fruit an inch long, with broad, thinning, brown wings; its fides finely ruffled. For *Tb. trifolata,* Linn. Sp. Pl. 376, see *Smyrnium* t. 6, cardorum. *Th. polygamy,* Desfont. Atlant. v. 1. 261. t. 75. Mart. Mill. Dict. n. 6, found on the sea-coafl of Barbary, cannot belong to this genus, having a general, as well as partial, involucrum, and abortive central flowers. It should fcam to be a Laverperpusum. See that article.

**THAPSIS,** in *Ancient Geography,* a river of Scythia, in the environs of the Palus Mecotides, according to Dioscorus Siculus.

**THAPSOS,** in the *Materia Medica of the Ancients,* a name given to a kind of wood of a pale yellow colour, used of old in dyeing of linen and woollen cloths. The Greek *thapsos* signifies a pale dead yellow colour, and is applicable either to the substance, or the juice or tincture of all these.

The people of Crete at this time ufe the lygium-wood in dyeing a yellow colour, and it is probable that the *thapsos* was this very tree. Dioscorides tells us, that the wood of this tree was also ufed in his time to tinge the hair yellow, which was a favourite colour with the Greeks. The lygium is of a colour somewhat deeper than our box-wood, and parts with its fain so easily, that it fems very proper for such a purpofe.

**THAPSUM,** among the old Roman Writers, a common name for the verbascum, or mullein; but as there were many other plants, very different in their nature, yet whole names refemblcd this; fuch as the *thapsos,* or deadly carot, and the *thapsos* or geniftella tinctoria; it was foon found neceffary to add some other name, and it was then callcd *thapsos* barbatum, or barbafum.

The reafon of the geniftella being called *thapsos,* was, that its flowers were yellow, and were ufed to colour the ladies’ hair; that being the favourite colour of thofe days. The flowers of mullein are yellow, and seem more fit for the colouring of the hair than thofe of the geniftella; their colour being more easily feparated, and continuing on fo well, that the gloves of many parts of England ufe them in the feafon for colouring their yellow gloves.

It is probable, that the ladies of old ufed this, as well as the geniftella, for this purpofe: and it might hence obtain the common name *thapsos.* The other part of its dilinition, *barbatum,* seems owing to the leaves being fo coloured with a woofly down that they look bearded. And when this word is written *barbafum,* it may probably be given as the name of fome of thofe species of mullein which are not hairy, as our black or fage-leaved mullein, and be a corruption of the word *verbascum.* This black mullein has no lefs title than the white or bearded kind to the name *thapsos;* its flowers being of a yet finer yellow than thofe of that kind, and being as fit for the use of flaining. The gloves in fome places ufe this species for their leather-gloves.

**THAPSUM, DEMASS,** in *Ancient Geography,* a maritime town of Africa, upon a tongue of low land, S. of the Leffer Leptis. The place abounds with ruins.

**THAPSUM, or Tapsis,** in *Botany,* see *Verbascum.* This name feme to have originated with Gerarde, who gives no explanation, nor do we find any authority for the opinion of De Theis, that it alludes to the ifle of Thapsos, as the native country of the plant. Such indeed is the acknowledged derivation of *Thapsia,* fee that article; with which this *Verbascum,* a *verbos,* of the Greeks, has no relationfhip whatever.

**THAR,** in *Ancient Geography,* a town of Arabia Felix, belonging to the people called Themi.

**THARAND,** in *Geography,* a town of Germany, in the circle of Upper Saxony, and circle of Erzgebirg; 10 miles E.N.E. of Freyburg.

**THARE,** in *Ancient Geography,* a place of the encampment of the Iphracites, whence they went to Methea. (Numb. xxxii. 27.) Thare, situated in Arabia Deferta, was the 24th iflation of the Iphracites.

**THARELA,** a town of Palestine, in the tribe of Benjamin.

**THARGELIA,** in *Antiquity,* an Athenian festival in honour of the fun, and his attendants, the
TH A

Hours: or, as others think, of the Delian Apollo and Diana. For an account of the ceremonies of this solemnity, see Potter Archeol. Graec. lib. ii. cap. 26. tom. i. p. 420. seq.

THARGELION, in Chronology, the eleventh month of the Athenian year. It contained thirty days, and answered to the latter part of our April, and the beginning of May.

It took its name from the festival Thargelia, kept in it.

THARNAU, in Geography, a town of Silecia, in the principality of Neiff; 1 mile N. of Grotkau.

THARO, in Ancient Geography, an island, situated, according to Ptolemy, in the Perisan gulf.

THARPA, a town of India, beyond the Ganges, in the Golden Chersonesus. Ptolemy.

THARRANA, a town of India, beyond the Ganges, on the coast of the Great gulf. Ptol.

THARSIA, a town of Africa propria, or one of those which Ptolemy points out between Bagradas and the town of Thabraca.

THARSLIS, Tharsis, or Tarshis. See OPHIR.

THASO, in Geography, an island of the Grecian Archipelago, situated in the gulf of Consta, anciently called Ereia, or Æthria, being famous; even to a proverb, for its rich gold mines. It has a town or village of the same name. N. lat. 40° 34'. E. long. 42° 30'.

THASSUS, Thasos, or Thasus, in Ancient Geography, an island situated on the coast of Thrace, opposite to the mouth of the river Neftus. Thasus, son of Agenor, king of the Phoenicians, is said to have remained many years in this island; to have peopled it, and to have given it his name. It was afterwards increaced by a Greek colony. The Athenians made themselves masters of this island, and treated the inhabitants with great rigour; but they were expelled by the Macedonians, and these again by the Romans.

THATCH, in Rural Economy, prepared straw which is intended to be laid on the top of a building, rick, &c. to keep out the wet. There are many different sorts of materials that may be made use of as thatch, but those which are most commonly employed are the straw of different sorts of grain, as wheat, rye, &c. reed, fluttle, heather, &c. The straw of wheat and rye, when well prepared and laid, probably forms the neatest and most secure covering for general purposes. It has indeed been stated, that the most suitable material for the purpose is that of good wheat-straw that has been much bruised in threshing out the grain. But when this cannot be had in sufficient quantity, rye-straw may be substitutted in its place; however, from its rough and flabbish quality, it is neither so neat in its appearance, so durable, nor affords so secure a covering. And that barley and oat straw are sometimes made use of for the purpose, but they form very indifferent coverings, and such as are not by any means lasting. The former, when strong, is however preferable to the latter.

The reed is a highly valuable article for the purpose of thatch, where a leaking roof is required; but is much too expensive and flabbish for common purposes. It has been remarked by Mr. Marshall, in the Rural Economy of Norfolk, that there, the favourite material for roofs, and that which is the most eligible after good flax for farm purposes, is reed. And that a reed roof properly laid, will lie fifty years without touching; and thirty or forty more, with only adjufling (driving) it, and levelling the hollows with a little fresh reed. At an hundred years old it may be relaid; and will then, if laid upon the upper parts of the roof, last through a considerable part of another century. The reed is, he says, principally cut from the margins of the bords, (large pieces of water,) and is carried, perhaps forty or fifty miles into the central and northern parts of the county. And it is added, that though a covering of reed is, in the first instance, costly; when its durability, and the high degree of preservation in which it keeps the roof, are taken into the account, it is of all other the cheapest covering; besides its being, whether in the extreme of heat or cold, the most comfortable.

And it is stated, that the price of reed, in the place of its growth, is from three pounds to three guineas a hundred, containing six score fathoms; each fathom composed of five or six sheaves measuring six feet in circumference. A hundred of reed will cover five squares of roof: the laying is a halfpenny a yard, or four shillings and twopence a square; and the tar rope and rods for fastening it on cost eighteen pence a square; so that a covering of new reed costs about eighteen shillings a square, containing two square feet; besides carriage, and what is called roofings; namely, a cap of wheat-straw placed upon the ridge, in a somewhat similler manner, and for the same purpose, as ridge-tiles are put on. This capping, which is done in a most effectual, but in a tedious and expensive manner, coils, in materials and workmanship, about sixteen pence each foot in length: which, upon a roof of sixteen feet and a half spar, is an additional expense of four shillings each square of reeding.

With regard to the carriage, it is in proportion to the distance. Taking twenty miles as a medium distance, and one shilling a mile as a medium price; the expense is, he says, twenty shillings a 'load' of fifty fathoms, or forty shillings a hundred; which laying five squares is a further addition of eight shillings a square: therefore, the whole expense of a covering of reed fetched twenty miles, may, he supposes, be laid at thirty shillings a square. The writer has been thus minute, he says, in his account of this material, as it has been much overlooked in other districts, where it may be found useful.

This material is a great deal more expensive in every respect which has any relation to this object, at the present time, than it was then.

And with respect to the fluttle, it is said to be a material that may be made use of with propriety and advantage in some situations. This is the fluttle of fitch wheat or other crops as have been cut at a great height; which, after being mown close to the ground and raked up, serves this purpose, especially for the more common purposes of the farm, such as covering hay and straw flacks, &c. the thatching potatoes when hogged in the ground, and many other such cases.

The half material, heather, is also found a highly valuable article for the purpose of thatch in districts where it grows in abundance, as it is extremely durable. See Heather.

The thatch which is removed from the flacks or buildings may be used as a litter for various purposes.

The modes of preparing and applying these different matters to the roofs of flacks and buildings will be pointed out in speaking of the operation of securing fitch roofs by means of fitch fluttances. See Thatching.

Where straw of the rye or wheat kind is very strong, it is often termed reed or straw reed by the thatcher, and used for covering large hay-flacks very commonly in many districts.

THATCHAM, in Geography, a village and parish in the hundred of Reading and county of Berks, England, is situated 3 miles E. from Newbury, and 53 miles W. from London. It appears to have been formerly a town of some consequence, from the Domesday Survey, and other records.
cord, in which it is described as an ancient borough; but it does not appear ever to have sent representatives to parliament.

From a very early period it had a market on Sundays, which was confirmed to the abbey and convent of Reading by a charter of Henry II. The market-day was changed by Henry III. in 1218 to Thursday; but the market has long been discontinued. Two annual fairs are still held. The manor of Thatcham was given to the abbey and convent of Reading by Henry I. At the dissolution it was granted, in 1539, to John Winchcombe, son of the celebrated Jack of Newbury; it is now the property of William Mount, esq., of Waling. A charity-school was founded here, in 1707, by lady Frances Winchcombe, who endowed it with 53l. per annum. The school has been long discontinued, and its revenue lost to the parish; when Mr. Thompson, a late vicar, instituted a suit for their recovery, and after a long contest succeeded in the re-establishment of the school, with an income for the matter increased to 200l. per annum; forty boys are now clothed and educated, and six of them annually apprenticed with premiums of 10l. each. The parish of Thatcham is the most extensive of any in the county, excepting Lamborn, and includes six townships. The population, according to the parliamentary report of the year 1811, was estimated at 2104; the number of houses at 424. — Lysons's "Magna Britannia," vol. i. Berkshire.

THATCHER, a rock in the English Channel, on the north side of Torbay.

THATCHING, the operation of covering the roofs of buildings, stacks, and other things, with some fort of thatch. For this purpose, articles of the straw kind are prepared in the following manner: After being well moistened with water, they are drawn out in handfuls perfectly straight and even into regular lengths, and the short straw separated from them, leaving them placed in convenient ranges for forming bundles to be carried to the thatcher by the performer who has the sifting of them.

In regard to the application of the thatch to stacks of hay or corn, there are different methods pursued, according to the nature of the materials employed. Where long straw is made ufe of, the operator or workman usually begins at the eaves or bottom part of the roof, depositing it in handfuls in regular breadth till he reaches the top, the different handfuls being fo placed endways as to overlap each other, the upper ends being constantly pulled a little into the bottom parts of the sheaves or other matters. In this manner he gradually proceeds, breadth after breadth, till the whole of the roof is covered, which is ufually done to the thickness of about four or five inches. And in order to retain the thatch in its place, short sharpened sticks, termed prods in some places, are occasionally thrust in, in a flanting direction upwards; and sometimes small sticks, often called fields, sharpened at the ends, are bent and thrust in along the top parts and fides. But as the water is apt to follow the course of the ficks, it is perhaps a better practice to make ufe of ropes of twisted straw for this purpose. In some cafes, these are applied only round the bottom parts of the roof and the fides; while in others, which is a much better and more secure method, they are applied in such a manner over the whole stacks, as to form a fort of coarse net-work of nine or twelve inches in width in the niches, the ends being well fastened either to belt-wraps padded in fuitable directions for the purpose, or to different parts of the straw of the stack.

After being prepared, put on by flicking one of its ends into the roof of the stack in a regular and exact manner, so as that it may stand out very close and thick; when the other, with such loose straw as may occur, is to be cut over or pared off, with a very sharp tool for the purpose, so as to form a neat and impenetrable thatch, having the appearance of a newly thatched house roof; the whole being well secured in its place by short pegs made for the purpose, somewhat in the same way as in the thatch of other stacks.

In the thatching of the roofs of houses or other buildings with any of the different sorts of straw, the materials are to be laid on to a considerable thicknefs, and firmly secured. They are applied in regular narrow frips, or what in some districts are termed gauze, from the eaves of the building to the ridges, the ladder being moved forward as the work proceeds. The thatch is secured by short sharpened ficks, as above, or by сдела or where necessary. And bended ficks, sharpened at each end, are likewise sometimes made ufe of near the ridges, being thrust in at each end. In finifhing the work, the thatcher moftly employs an iron-toothed rake, with which the whole is raked and trimmed over from top to bottom, so as to render it completely smooth and even, and take away all the short straw, and other irregular matters.

The method of thatching with reed, according to Mr. Marshall, in his account of the Rural Economy of Norfolk, is this: no lafts being made ufe of, in laying it, a little of the longest and stoutest of the reed is scattered irregularly across the naked fpars, as a foundation to lay the main coat upon: this partial gauze-like covering is called the "flaking." On this flaking the main covering is laid, and fastened down to the fpars by means of long rods, proportionally "sways," laid across the middle of the reed, and tied to the fpars with rope-yarn, or with "bramble bonds," formerly much ufed, but now nearly laid aside. In laying on the reed, the workman begins at the lower corner of the roof, on his right hand, for instance, and keeps an irregular diagonal line, or face, until he reaches the upper corner to his left, a narrow eaves-board being nailed across the feet of the fpars, and some flaking flattered on; the thatcher begins to "set his eaves," by laying a coat of reed, eight or ten inches thick, with the heads refting upon the flaking, and the butts upon the eaves-board. He then lays on his swa (a rod about the fize of a small edder) about fix or eight inches from the lower point of the reed; whilst his affilant, on the infide, runs a needle, threaded with rope-yarn, close to the fpar; and, in this cafe, close to the upper edge of the eaves-board. The thatcher draws it through on one side of the fway, and enters it again on the contrary side, both of the fway and of the fpar: the affilant draws it through, unthreads it, and with the two ends of the yarn makes a knot round the fpar; whereby drawing the fway, and consequently the reed, tight down to the roof: whilst the thatcher above, beating the fway and pressing it down, affilts in making the work the firmer. The affilant having made good the knot below, he proceeds with another length of thread to the next fpar, and so on, till the fway be bound down the whole length; namely, eight or ten feet. This being done, another ferment of reed is laid on upon the firth, so as to make the entire coat eighteen or twenty inches thick at the butts, and another fway laid along, and bound down, about twelve inches above the firth.

The eaves being thus completely fet, they are adjusted and formed, not square with the fpars, but nearly horizontal: nor are they formed by cutting, but by "driving" them with a "logget," a tool made of a board eight or nine inches square, with a handle two feet long, fixed upon the back of it.
it, obliquely, in the manner of the tool used by gardeners in
beating turf. The face of the legget is set with large-headed
nails, to render it rough, and make it lay hold of the
butts of the reeds. Then another layer of reed is laid on,
and bound down by another sly, somewhat shorter than
the last, and placed eighteen or twenty inches above it; and
above this another, and another, continuing to shorten the
slys, until they be brought off to nothing, and a triangular
corner of thatching formed. After this the slys are used
their whole length, whatever it happens to be, until the
workman arrives at the finishing corner.

In order to give a finish to the ridge, a cap (provincially a
"roof") of straw is set on in a matterly, but in an expensive
manner. In this operation, the workman begins, it is ob-
served, by bringing the roof to an angle, with straw laid the
long way upon the ridge, in the manner in which a rick is
to be put up; and to render it firm, to keep it in its place, and
to prevent the wind from blowing it off, or ruffling it, he pegs
it down lightly with "double broaches," namely, cleft twigs,
two feet long, and as thick as the finger, sharpened at both
cents, bent double, and perhaps with the twirling of the
wood, and perhaps barbed, by partial chops on the sides, to
make them hold in the better. This done, the workman
lays a coat of straight straw, six or eight inches thick, across
the ridge; beginning, on either side, at the uppermost butts
of the reed, and muffling with straight handfuls evenly across
the top of the ridge. Having laid a length of about four
feet in this manner, he proceeds to fasten it firmly down, so
as to render it proof against wind and rain. This is done by
laying a "'trowen ligger" (a quarter-cleft rod as thick as the
finger, and four feet in length) along the middle of the
ridge, pegging it down at every four inches with a double
broach, which is first thrust down with the hands, and after-
wards driven with the legget, or with a mallet used for this
purpose. The middle ligger being firmly laid, the thatcher
smooths down the straw with a rake and his hands, about
eight or nine inches on one side, and at six inches from the
first lays another ligger, and pegs it down with a similar
number of double broaches, thus proceeding to smooth the
straw, and to fallen on liggers at every six inches, until he
reach the bottom of the cap. One side finished, the other
is treated in the same manner; and the first length being
completed, another and another length is laid, and finished
as the first, until the other end of the ridge be reached. He
then cuts off the tails of the straw square and neatly with a
pair of shears, level with the uppermost butts of the reed;
above which the cap (or most properly the roofed) flows an
eaves of about six inches thick. And lastly, he sweeps the
eaves of the main roof with a bow of holly, when the work
is completed. This, when well performed, must be a
durable and useful mode of thatching; and at the same time
one which has a neat appearance.

In thatching with heather, that material mostly under-
goes some sort of preparation, so as to render it as equal as
possible in size and strength, being laid and fastened upon the
roofs then in somewhat the same manner as that of straw.
It is afterwards swept, cleaned, and finished off in a neat and
exact manner, so as to look extremely well.

In some of the more exposed situations in the northern
parts of the island, they have other modes and practices of
thatching buildings with straw in use, such as performing it
with clay, or thin turf and that material.

If the roof be covered with thin turf or divots, the work-
man is to twist the upper part of the straw into a sort of
knot; then, with a flick prepared for the purpose, to force
the knot thus formed either under or through the turves or
divots, so that it may have a firm hold of the roof; after
which, to spread the lower part of the bundle of straw nicely
on the roof, continuing to do the same to the very top
of the roof; and then to clay it all over, and begin an-
other tier, gang, or row of the thatch. In this way, the
thatch should not be laid thinner than six inches, and when
it is laid eight inches thick, it is the more durable. Thin
turf, or divots, were originally thought the best foundation;
but it has been since found by experience, that they rot the
straw, and that straw alone, when wretched on with rope-yarn,
lasts much longer. If straw alone be used in this manner, it
will last twenty years, but the straw must be laid on two inches
thicker than when clay is added. A roof that is thatched
with divots, straw, and clay, in the common way, will last
from seventeen to twenty years; and is also capable of being
mended without raising any part of the roof that is entire.
The above kind of roof is much less liable to catch fire than
straw roofs without clay. The clay that answers the pur-
pose best is that which has a due proportion of sand in it.
If stiff clay should be used, it will be necessary to add one
cart-load of sand to every two of the clay.

This sort of claying may, of course, be useful and advan-
tageous in thatching the roofs of buildings in many situa-
tions and places.

THAU, in Geography, a lake of France, in the depart-
ment of the Herault, near the Mediterranean, between
Frontignan and Agde.

THAANA, in Ancient Geography, a town situated in
the interior of Arabia Felix.

THAUBA, a town in the interior of Arabia Felix.

THAUGHTS, or Thoughts, in a Beat, are the
berches on which the rowers set to row.

THAUMASISUS Mows, in Ancient Geography, a
mountain of Arcadia, N.W. of Mantinea, above the river
Molopus.

THAUMATURGUS, formed from θαυμάζω, wonderful
thing, and θαυμάζω, worker of miracles; an appellation
which the Romanists gave to several of their saints, eminent
for the number and greatness of their miracles.

St. Gregory, called Thaumaturgus, or Gregory of Neo-
caearea, was a disciple of Origen about the year 223, and
afterwards bishop of Caesarea, in Pontus; and in that cap-
acity he abiled at the first council of Antioch, and at that of
Ephesus, against Paulus Samosatenus. St. Leo of Ca-
tanea is also called Leo Thaumaturgus. He lived in the eighth
century; and his body is still honoured at Rome, in the
church of St. Martin de Tours. St. Francis Paul, and
St. Francis Xavier, are the great Thaumaturgi of these later
ages.

THAWING, the resolution of ice into its former fluid
state, by the warmth of the air.

THAXTED, in Geography, an ancient market-town in
the hundred of Dunmow, and county of Essex, England,
is situated 19 miles N.N.W. from Chelmsford, and 43 miles
N.N.E. from London. The town was known in the Saxon
times, as the church is recorded to have belonged, in the
reign of Edward the Confessor, to the college of St. John
Baptist, at Clare, in Suffolk. Thaxted was incorporated
by charter of Philip and Mary, which was confirmed by
queen Elizabeth; under this the civil government is vested
in a mayor, recorder, two bailiffs, and twenty principal
burgesses. In the reign of James II. the corporation ex-
perienced a temporary lufpension; for being served with a
writ of quo warranto, the corporate officers, either through
fear or poverty, thought fit to retire from their offices.
The market was granted by Edward II., but was discon-
tinued for a long period; it has been recently revived, and
is now held on Fridays. Here are also two annual fairs. In the population return of the year 1811, Thaxted was flated to contain 390 houses, occupied by 1733 persons. The church is a very large and beautiful structure, and appears, from the various arms and cognizances on several parts, to have been built at different times in the fourteenth and fifteenth centuries. The whole fabric is embattled, and supported by strong buttresses, terminated by canopied niches, and curiously purfled pinnacles. At the west end is an embattled tower, buttained by buttresses, and surmounted by a neat octagonal spire, rising to the height of 181 feet. The interior consists of a nave, transept, chancel, and side aisles: the arches of the nave are pointed, and supported by eight clustered columns on each side. The expense of the erection of this church was principally defrayed by the noble families of Clare and Mortimer, who then posfessed the manor, with some affiance from king Edward IV. A chantry, besides various chapels and altars, were ufed here before the reformation. The charitable benefactions for the use of the poor inhabitants of Thaxted are confiderable. An estate, called Yendeleys, deriving its name from Thomas Yendale (who refided on it temp. Henry VI.), was, on his death, veiled in trufi for his four sons and their ifuic; and in default of such issue, to be fold for the benefit of the church and poor. The sons dying childfeles, the eftate was fold 5 Henry VII. and the produce is applied to the support of a school, repairing the church, improving the highways, &c. In 1698, William, lord Maynard, bequeathed 4000l. in trufi, the produce to be applied for increafing the minister's falary, repairing the church, marrying poor young women, binding out apprentices, and relieving poor people overburthened with children. Among other benefactions are endowments for alms-houses in several parts of the town: one of the buildings appropriated for that purpose is the old chantry-houfe. The ancient guildhall is now the parish workhouse: the mote-hall is ufed for a public school.

THERE, in Ancient Geography, a town of the Pelopomneus, in Laconia.

THERE, in Botany, the Tea-tree, a name of barbarous derivation, originating in the Chinefe Tha, or Japaneffe Tja, of which the various nations of Europe have made, according to their fancy, Chaa, Tea, Thé, &c. and which Kempfer has formed in Latin into Thisa. This laft has been admitted by Linnaeus, for the fake of its Greek orthography, exactly that of θς, a goddess, a coincidence highly welcome to thofe who honour the cordial beverage of tea as it deferves.—

have been greatly at a loss for a specific name, and have adopted *viridis* to avoid any needles change, thinking it rather preferable to *Bohea*, which is a partial name, and of corrupt orthography. Dr. Sims, in *Curt. Mag.*, has used *chinensis*, but this is liable to objection, as the name of a country to which the plant is not quite peculiar; and Loureiro's *cautonensis* is therefore still more exceptional. This last author concurs in the opinion that all the common Chinese teas belong to one species. He describes indeed two others, *T. cochinchenensis*, which leaves a trifling variety of the above; and *T. oleifera*, growing wild near Canton, said to bear a yellow berry, whose seeds supply the Chinese with lamp-oil.

**Thea**, in *Gardening*, furnishes plants of the exotic shrubby kind, the species of which chiefly in use is the tea-tree (*Thea*).

This tree, as it is commonly described, differs in height, in its native climate, from five to six feet to thirty, and even one hundred and fifty, or more, when let grow to its full size and dimensions.

And in respect to the varieties of it, Martyn has considered them all as forming one species, in which he is, he affirms, supported by the best authorities. Kämpfer, he contends, attributes their difference to soil, culture, age of the leaves, and method of curing them. Mr. Ellis also directly affirms, that the green and bohea tea are one and the same species; and that it is the nature of the soil, the culture, and manner of gathering and drying the leaves, that make the difference. So also Sir George Staunton maintains, that every information received concerning the tea plant concurred in affirming, that its qualities depended upon the foil in which it grew, and the age at which the leaves were plucked off the tree, as well as upon the management of them afterwards. See *Tea* and *Thea*.

The bohea tea-trees now introduced into many botanic gardens near London, exhibit very obvious varieties: the leaves are of a deeper green colour, and not so deeply ferrated; and the stalk is usually of a darker colour: but the botanical characters are the same. Thunberg also distinguishes two varieties from the leaves, which in one are smaller, flat, darker green, with straight ferratures, and in the other larger, waved, brighter green, with obtuse ferratures: but they can scarcely be considered as distinct species. Loureiro observed little difference in the fou-chong which he examined; both these have a brown colour, but are more odoriferous and precious than the common bohea of the province Foo-kien, which he had not an opportunity of seeing in a living state, though it is the most common and cheapest of all. He examined the dry flowers of the green-tea from the province of Kiang-su, and observed the same inconstancy as to the number of parts in the calyx and corolla, as in the bohea. Upon the whole, he concludes that all the differences of Chinese tea form only one botanical species, owing their variation to soil, culture, and method of preparation; all retaining the same inconstancy in the parts of the flower, which gave occasion to Linnaeus to consider them as two species. Besides, it is evident that many varieties of tea are known in China, which arise from mixture and management.

The distinctions chiefly regarded in Europe are the following.

**Green Tea.**—1. *Bing*, imperial or bloom tea, with a large loose leaf, of a light green colour, and a faint delicate smell.

2. *Hy-tiann*, hikong, hayfwen or heechun, known to us by the name of hyson tea: the leaves are closely curled and small, of a green colour verging towards blue. Another hyson tea, with narrow short leaves, is called hyson-utchen. There is also a green tea named globe, with long narrow leaves.

3. Song-lo or singlo, which name it receives, like several others, from the place where it is cultivated.

**Bohea Tea.**—1. *Soo-chuen*, fut-chong, fon-chong, or fut-chong, called by the Chinese faa-tyang, and faet-chon or fy-tyann, is a superior kind of cong-fou tea. It imparts a yellowish-green colour by infusion, and has its name from a place or province in China. Padre futchong has a finer taste and smell: the leaves are large and yellowish, not rolled up, and packed in papers of half a pound each. It is generally conveyed by caravans into Russia: without much care it will be injured at sea. It is rarely to be met with in England.

2. *Cam-ho* or fourm-lo, called after the name of the place where it is gathered: a fragrant tea with a violet smell; its infusion is pale.

3. *Cong-fou, congfo*, or *pong-fou*: this has a larger leaf than the following, and the infusion is a little deeper coloured. It resembles the common bohea in the colour of the leaf.

There is also a sort called *lin-kifan*, with narrow rough leaves. It is seldom used alone, but mixed with other kinds. By adding it to congfo, the Chinese sometimes make a kind of pekoe tea.

4. *Pekao, pecko*, or pekoe, by the Chinese called back-lo or pack-lo: it is known by having the appearance of small white flowers intermixed with it.

5. *Common bohea or black tea*, called *moji* or mo-ee, by the Chinese, consists of leaves of one colour. The best is named *Taak-yoom*. An inferior kind is called *An-kei*, from a place of that name. In the district of Honam, near Canton, the tea is very coarse, the leaves yellow or brownish, and the taste the leaf agreeable of any. By the Chinese it is named *honam-te*, or *kuli-te*.

But besides these, tea, both bohea and green, is sometimes imported in balls, from two ounces to the fize of a nutmeg and of peas. The Chinese call it *pome-ul-tea*. The smallest in this form is well known under the name of gunpowder tea.

And sometimes the succulent leaves are twisted like packthread, an inch and a half, or two inches long; three of these are usually tied together at the ends by different coloured silk threads. Both green and bohea teas are prepared in this manner.

The manner of gathering and preparing the leaves, as practised in Japan, according to Kämpfer, as far as our information reaches, is in a great measure conformable to the method used by the Chinese. See *Tea*.

Whether the Chinese collect the tea precisely at the same seasons as in Japan, we are not well informed; but most probably the tea harvest is nearly at the same periods, the natives having frequent intercourse, and their commercial concerns with each other being very extensive.

For an account of the preparation of the tea-leaves, &c. see *Tea*.

The country people cure their tea-leaves in earthen kettles, which answer every necessary purpose, at least trouble and expense than by the processes described under the article *Tea*, and they are thus enabled to sell them cheaper. After the tea has been kept for some months, it is taken out of the vessels in which it was stored, and dried again over a very gentle fire, that it may be deprived of any humidity which remained, or it might have since contracted.
THE

The common tea is kept in earthen pots with narrow mouths; but the belt forts, used by the emperor and nobility, is put into porcelain or china vessels. The coarselain tea is kept by the country people in straw baskets, made in the shape of barrels, which they place under the roofs of their houses, near the hole that lets out the smoke.

Method of Culture.—Thee plants may be raised in this country by seeds, layers, and cuttings of the young branches. The editor of Miller's Dictionary advises that the seeds should be procured from China, and that care should be taken that they be fresh, sound, ripe, white, plump, and moist internally. After being well dried in the sun, they may be inclosed in bees-wax, or left in their capsules, they may be put into very close canisters of tin or tin tincture. Thouin, in his directions to Peronie, it is said, recommends thee and other seeds to be placed in alternate layers of earth or sand, in tin boxes, closed up exactly, and placed in solid cases, covered with waxed cloth; the boxes to be placed in a part of the ship the least accessible to moisture, and the most sheltered from extreme heat or cold. And Mr. Sneyd, it is added, was very successful in having seeds packed up in absorbent paper, and surrounded by raffia or moilt sugar, which kept them in a snate fit for vegetation. American seeds are frequently brought over, by putting them into a box, not made too close, upon alternate layers of mofs, in such a manner as to admit the seeds to vegetate. This might be tried with the seeds of the tea-tree; and to succeed more certainly, some of the seeds might be strown in pots or boxes, when the vellifer arrives at St. Helena, and after passing the tropic of Cancer, near the latitude of thirty degrees north. But the belt method seems to be, to sow ripe seeds in good light earth in boxes, at leaving Canton, covering them with wire, to prevent rats and other vermin from getting to them; and taking care that the boxes be not exposed to too much air, nor to the spray of the seas. A little fresh or rain-water should be sprinkled over them now and then; and when the seedling plants appear, they should be kept moist and out of the burning sun. If young plants can be procured in China, they may be strown in a growing state in boxes, forty inches long by twenty broad, and as much in depth, having a few holes bored through the bottom. When the trees arrive here, they must be kept in a greenhouse during the winter, and in the open air during the summer; and if they come in a bad condition, it may not be amiss to plunge the pots into which they are transplanted in a gentle hot-bed, or to let them in a tan-pit, to make them strike and shoot more freely. It is further remarked, that though the tea-tree will not at present bear the rigour of our winters in the open air, yet it is not impossible but it may gradually become naturalized to our climate, like the magnoliam, among several other trees and shrubs; especially if it were to be brought from the coldest provinces of China, where it grows, or from the parts of Europe a little to the northward of us, when it has been naturalized there. It is increased freely by cuttings, when managed in the same manner as gardenias; and it also sometimes grows from layers laid down in the autumn or spring.

Some of these plants should be always kept in pots, to be removed under the shelter either of a greenhouse, glass cafe, or deep garden frame, in winter; and others be planted in a dry, well-sheltered, warm, conspicuous part of the shrubbery, to be afforded occasional covering from rigorous frosts.

They afford variety in greenhouse collections, as well as in the shrubbery.

Although in this country, plants of this kind are only cultivated for the purpose of curiosity, variety, and diversity among greenhouse and other collections, in small quantities; in China, where they are natives, they are raised in vast abundance in plantations of very great extent for their leaves, which form a very great and valuable article of merchandise to that country for the supply of England and the other parts of Europe, they being employed, in their different prepared states, for the making of an infusion with boiling water, which is called tea, and which is very generally in use, especially in this and some other countries. For other particulars, see TEA.

THEAK, in Rural Economy, a word provincially used to signify thatch.

THEAKIKI, in Geography, a river of North America, which runs into lake Illinois, N. lat. 40° 52'. W. long. 89° 15'.

THEAME, in Ancient Geography, a town of Asia, in Babylonia, on the confines of Arabia Dextra. Ptol.

THEANDRIC, θεονικός, dei-virile; a term signifying divine and human, formed from θεος, God, and ανθρωπός, man.

St. Dionysius, bishop of Athens, first used the word theandric, to express a double operation, or two operations united in Jesus Christ; the one divine, the other human. The Monophysites afterwards abused it, to signify the one only operation which they admitted in Jesus Christ; in whom they believed there was a mixture of the divine and human nature, whence resulted a third nature, which was a compound of the one and the other, whose operations followed the essence and qualities of the mixture, and were neither divine nor human, both at once, or, in one word, theandric. θεονικός ομορρωπός, theandric, or dei-virile operation, in the sense of Dionysius and Damascenus, is thus exemplified by Athanasius. When Christ healed the person who was born blind, the spittle he voided was human, but the opening of the eyes was done by his divine power. And thus, in raising Lazarus, he called as man, but awakened him from the dead as God.

The term theandric, and the dogma of theandric operations, were examined with great care and attention, at the council of Lateran, held in 649, where Pope Martin solidly refuted the notion of theandric operations, and shewed, that the feme in which St. Dionysius first used the word was Catholic, and quite remote from that of the Monophysites and Monothelites.

THEANGELA, in Ancient Geography, a town of Asia Minor, in Caria.

THEANO, or Teano, in Geography, a town of Italy, in the kingdom of Naples, and province of Lavora; the site of a bishop, suffragan of Capua; 15 miles N. of Capua.

THEANTHROPPOS, θεονικός, formed from θεος, God, and ανθρωπός, man, denominated God-man; a term sometimes used in the schools to signify Jesus Christ, who was regarded as God-man; or represented by some scholastic theologians, as comprehending two natures in one person.

THEANUM, in Ancient Geography, a town of Italy, in Campania, upon the Latin way, S.E. of Caium. See THEANO.—Allo, a river of Italy.

THEATER, or THEATRE, Theatrum, formed from θεατρός, spetacle, of θεάω, I see, among the Ancients, a public edifice, for the exhibition of scenic spectacles or shows to the people.

Under the word theater was comprehended, not only the edifice of which the actors appeared, and the action passed,
THE BUT BEAUTIFUL FACE AND IS A FULL SPACE, WHICH ENCOMPASSED A SPACE CALLED THE ARCHETRA, IN THE FRONT OF WHICH WAS THE PROSCENIUM, OR PULPITUM, ON WHICH THE ACTORS PERFORMED, AND WHICH IS WHAT WE COMMONLY CALL THE THEATER, OR STAGE. THE PROSCENIUM WAS DIVIDED INTO TWO PARTS; THE ONE HIGHER, ON WHICH THE ACTORS DECLAIMED, AND THE OTHER LOWER, ON WHICH THE CHORUS WAS COMMONLY PLACED. THIS LATTER WAS RAISED TEN OR TWELVE FEET ABOVE THE PIT, FROM WHICH THERE WAS AN ASCENT TO IT; AND THUS SITUATED, THE CHORUS MIGHT EASILY TURN EITHER TOWARDS THE ACTORS OR TOWARDS THE SPECTATORS.

THE MOST CELEBRATED THEATERS REMAINING OF ANTIQUITY, ARE THE THEATER OF MARCELLUS, AND THAT OF POMPEY; WHICH ARE ALSO CALLED AMPHITHEATERS.

AT ATHENS ARE STILL SEEN THE REMAINS OF THE TEMPLE OF BACCHUS, WHICH WAS THE FIRST THEATER IN THE WORLD, AND WAS A MASTER-PIECE IN ARCHITECTURE. ALL THEATERS WERE CONFEERATED TO VENUS AND BACCHUS.

THEATER, AMONG THE MODERNS, MORE PECCULARLY NOTES THE STAGE, OR PLACE ON WHICH THE DRAMA, OR PLAY, IS EXHIBITED; ANswerING TO THE PROSCENIUM OF THE ANCIENTS.

IN ITS FULL LATITUDE, HOWEVER, THE THEATER INCLUDES THE WHOLE PLAY-HOUSE; IN WHICH SCENE IT IS A SPACIOUS ROOM, OR HALL, PART OF WHICH IS TAKEN UP BY THE SCENA, WHICH COMPRIZES THE STAGE, THE DECORATIONS, AND THE MACHINES; AND THE REST IS DISTRIBUTED INTO A SPACE, CALLED THE PIT, OR PARterre, WHICH IS COVERED WITH SEATS, BOXES, &C. AND TERMINATED WITH AN ELEVATION OF ONE OR TWO GALLERIES, DIPPOSED INTO BENCHES ASCENDING OVER ONE ANOTHER. SEE DRAMATIC SCENERY, PLASTIC ARTS, AND SCENOGRAPHY.

THEATER IS ALSO USED IN ARCHITECTURE, CHIEFLY AMONG THE ITALIANS, FOR AN AFFEMBLAGE OF SEVERAL BUILDINGS, WHICH, BY A HAPPY DISPOSITION AND ELEVATION, REPRESENTS AN AGREEABLE SCENE TO THE EYE.

SUCH ARE MOST OF THE VINEYARDS AT ROME; BUT PARTICULARLY THAT OF MONTE DRAGONE, AT PREFECATI; AND IN FRANCE, THE NEW CASTLE OF ST. GERMAIN EN LAYE.

THEATER, ANATOMICAL, IN A SCHOOL OF MEDICINE AND SURGERY, IS A HALL, WITH SEVERAL ROWS OF SEATS, DIPPOSED IN THE CIRCUMFERENCE OF AN AMPHITHEATER, HAVING A TABLE, BEARING ON A PIVOT, IN THE MIDDLE, FOR THE DISSECTION OF BODIES.

SUCH IS THE ANATOMICAL THEATER OF THE ROYAL GARDEN AT PARIS.

THE THEATER AT OXFORD IS A BEAUTIFUL BUILDING, ERECTED BY ARCHBISHOP SHELDON, FOR THE USE OF CHORALISTIC EXERCISES.

SEE OXFORD.

THEATINES, AN ORDER OF NUNS, UNDER THE DIRECTION OF THE THEATINES.

THERE ARE TWO KINDS OF THEATINES, UNDER THE TITLE OF VOL. XXXV.
faid to have been 43 stadia (1 league 1563 toises) in circumference. Its environs are embellished by two rivers, by meadows and gardens. Myron of Byzantium says, that Amphion was the first person who erected an altar to Mercury, and that the god recompensed his zeal by giving him a lyre. The Thebans carried on various wars with the Peloponnesians for ascertaining their respective limits; and against the Athenians at Platea for having fought the friendship of the king of Persia against the common interest of the Greeks. In process of time, the Thebans avenged themselves by defeating the Athenians at Delium, near the Tanagra. The Macedonians, after the battle of Cheronne, placed a garrison at Thebes, where it remained till after the death of Philip. Alexander having taken the city, and expelled its inhabitants, who retired to Athens, Callander, the son of Antipater, re-established them there, with the assistance of the Athenians, the Mefennians, and the Megalopolitans. Sylla at length reduced them to extreme misery, for having declared in favour of Mithridates.

In the time of Pausanias, the whole lower part of the town was in ruins, except the temples, and the citadel only was inhabited and denominated Thebes. The temple of Apollo was founded on an eminence near one of the gates, and the river Ison, which passed by it, gave to the god and the town its name of Istones. Mercury and Minerva had each a statue of marble at the entrance of the vestibule of this temple: that of Mercury was the work of Phidias, and that of Minerva was executed by Scopas. The statue of Apollo in the temple was wrought of cedar-wood. In this temple were also brazen tripods of excellent workmanship. Hercules Promachus had a temple near another of the gates of the city, in which was his statue of marble; a colossal figure by Alcamenes, and his labours by Praxiteles. The temple of Ammon had a statue executed by Calamis and dedicated by Pindar. Here was also the temple of Fortune, and the gods held Phoebus in her arms under the form of an infant. The temple of Ceres Theophanor, or the legislator, had been anciently the house of Cadmus, in which was exhibited a bust of the statue of the goddes. The theatre was near another gate, and near it a temple of Bacchus. The temple of Diana Euclea was in the same quarter; the statue of the goddess was the work of Scopas. Jupiter, surnamed the High, had a temple near the gate of this appellation. Here were a place of exercise and a stadium; and in the midst of the stadium was the tomb of Pindar. The river Ircé passed near Thebes, and beyond it were the ruins of the house of Pindar, and a kind of chapel which this poet had built in honour of Cybele. Her statue was formed of Pentelic marble. Entrance into the chapel was allowed only one day in the year. The temple of The mis was near one of the gates of Thebes, and her statue was of white marble. Jupiter Aegeus and the Parcae had also their temples. The statue of Hercules Rhinocolubus was in full view in this part of the city. The sacred wood of Ceres Cabiri and of Proserpine lay at about 25 stadia from Thebes. The temple of the Cabiri was at the distance of seven stadia. According to Pausanias, there was seen at Thebes a statue of Venus Urania, which was said to have been formed of parts of the ships that brought Cadmus into Greece. It was the most ancient statue in Greece. The population of this city was very considerable. When it was taken by Alexander, more than 6000 persons perished, and more than 30,000 were employed for slaves. Some priests were spared and many citizens fled. Hence we may presume, that the number of inhabitants in Thebes and its district might amount to 50,000 of all ages and sexes, without in-cluding slaves. The inhabitants, like those of Athens, were divided into three classes; the first composed of citizens, the second of naturalized foreigners, and the third of slaves. The Thebans were deemed to be courageous, inoffensive, and mild; and murders were frequently the consequence of the most frivolous quarrels. The women were both well made and generally of a fair complexion, of a noble carriage, and not inelegant dresses; their voice was remarkably sweet and tender; and that of the men harsh and disagreeable, and in some measure fitted to their character. The "sacred bat-talion" of Thebes is famous in history. It consisted of a body of young warriors, brought up together, and maintained at the public expense, in the citadel. Their exercises, and even their amusements, were regulated by the melodious sounds of the flute; and in order to prevent their courage from degenerating into blind fury, care was taken to inspire them with the noblest and most animated sentiments. Each warrior chose from the band a friend, to whom he remained inextricably united. These 300 warriors were anciently distributed in troops at the head of the different divisions of the army. Pelopidas, who had frequently the honour of commanding them, having made them fight in a body, the Thebans were indebted to them for almost all the advantages they gained over the Lacedemonians. Philip destroyed this hitherto invincible cohort at Cheronne; and the prince, seeing those young Thebans stretched on the field of battle, covered with honourable wounds, and lying side by side on the ground on which they had been Rationed, could not restrain his tears, but bore a noble testimony to their virtue as well as to their valour. Travels of Anci-naris, vol. iii. See THIBA.

Thiba, a town of Upper Egypt, on the right bank of the Nile. According to the ideas given us of this town by Homer, it was the most celebrated of antiquity. Ancient authors have given very different accounts of its extent. In the time of Strabo, this city had been destroyed. It had been ravaged by Cambyses; it was afterwards depopulated of its riches by Ptolemy Philometer; and under the reign of Augustus, it was severely treated by Gallus on account of its rebellion. From this time it fell into a state of decline, from which it has not recovered. Tacitus mentions it as a town in ruins; and Juvenal speaks of it as this city extended on both sides of the Nile, although it was more particularly situated on the right bank of this river: a considerable portion of it lay to the left, which, according to Strabo, bore the name of "Memnonium." For a further account of this city, see THIBES.

Thibes was a name given to many ancient towns. Thibe was a town of Asia, in Cilicia hypopagiania, situated on a plain, at the foot of mount Placion.—Alfo, a town of Judea, in the half-tribe of Manasseh, on this side of Jordan.—Alfo, a town of Macedonia, in the Phthiotide, 100 stadia from the town of Alos, according to Strabo.—Alfo, a town of Asia Minor, in Ionia, in the vicinity of Miletus.—Alfo, a town of Greece, in Attica.—Alfo, a town of Asia, in Catoonia.—Alfo, a town of Asia, in Syria.—Alfo, a town of Palestine, in the tribe of Ephraim.—Alfo, a town of Arabia Felix, upon the coast of the Red Sea, in the country of the Cinarcolities. Ptolemy.

Thebaid, Thebae, a famous heroic poem of Statius, the subject of which is the civil war of Thebes between the two brothers Eteocles and Polynices; or Thebes taken by Thebans.

Statius was twelve years in composing his Thebaid, which consists of twelve books; he wrote under Domitian. He is censured by the best critics, as BoiU, &c. for a vicious multiplicity of fables and actions, for too much heat and
THE

extravagance, and for going beyond the bounds of probability.

Several Greek poets had composed Thebais, or poems of this name, before him; the principal were Antagoras, Antiphanes of Coleophon, Menelaus the Argian; and an anonymous author mentioned by Paulanis, lib. ix.

Aristotle, prating Homer for the simplicity of his fable, opposes to him the ignorance of certain poets, who imagined that the unity of fable or action was abundantly provided for by the unity of the hero, and who composed Thefeids, Herculeids, &c. in each of which, they collected every thing that had ever happened to their principal person.

THEBAIS, or THEBAI, called also Said, in Ancient Geography, a name given to Upper Egypt, from its principal city Thebes. It is in Scripture called Pathros. This is the most southern part of Egypt next to Ethiopia, and is almost as extensive as all the other parts of Egypt, including the country on both sides of the Nile down to the Heptanomis or Middle Egypt; its best city, according to the ancients, being Lycopolis, (see Styur) on the western, and Antaeopolis on the eastern side of the river. These dimensions agree pretty exactly with the present extent of Al Said, the most northern city of which is Manelfet.

In this part of Egypt there were formerly several cities of great note; such as Lycopolis, on the site of which is supposed to be the present Manelfet; Hypfide, or Aboutig, about a mile W. of the Nile; Apedonepolis; Ptolemis; Abysus, once the second city of the Thebaid, famous for the magnificent palace of Memnon, but in the time of Strabo only a village; Little Diphopolis, probably the present Hou (which see); Tentyra, the inhabitants of which were famous for their eminence to the crocodile, the ruins of which are still to be seen at Dendera (which see); Latopolis, or Epyntis (which see); Great Apollinopolis, on the site of which Esfut is now supposed to stand (see Apollinis Ures, and Etpu); and Elephantine, on an island of that name, where are the ruins of a small temple. On the east side of the Nile are Antaeopolis, on the site of which Siout is supposed to have been built; Paffalus, conjectured to be the present Gava-Kibre, where is seen a very beautiful portico of a temple, with eighteen pillars, in three rows; Panopolis and Cheramis, supposed to be the same city, but distinguished by Herodotus; the site of Panopolis is said to be that of the present Akram, about a mile from the river; Chenobosco; Cane or Nespolis, perhaps the present Kene, a small town on an eminence, about a mile from the river Coptos or Kept, and called by Pliny the emporium of commodities brought from India and Arabia; Coptos, where Christians were formerly very numerous (see Coptos); Apollinopolis (see Apollinis Ures, or Apollinis Paron or Kous), and Thebes, which see. To the south of Thebes, and on the famous side of the river, were the following cities: see. Chnumis or Cnuphis; Elethya or city of Lucina; Onobos, now Comombo, or the hill of Ombo, on which are seen the ruins of an ancient temple (see Comombo); Syene; Philae, (see Ptolomos,) an island deemed facer from an opinion that Osiris was buried there. The Thebaid in the first ages of the church was rendered famous by the number of hermits who retorted thither.

THEBAIS, a river of Aia Minor, in Caria. Pliny says it traversed the town of Trallis.

THEBAN HARP. See HARP.

THEBANUS OPHITES, in Natural History, a name given by some of the ancients to that species of the ophites, or serpentine marble, more commonly called opites niger, the black serpentine.

THEBARMAI, in Ancient Geography, Ornmed, a town of Aia, S.W. of lake Spauta, and at some distance from it, lies between a mountain and a small river that falls into this lake. The worship of fire prevailed in this province, under a persuasion that the first pyreum was kindled by Zoroaster himself.

THEBES, the capital city of the Thebais, or Upper Egypt, which was deservedly reckoned one of the finest cities in the world. It was also called Dioptopolis, or the city of Jupiter, and was built, as some say, by Osiris, but according to others, by Buiris. Its length, in the time of Strabo, was eighty furlongs, or ten miles; but this was very inconsiderable, compared with its ancient extent, before it was ruined by Cambyses, which, we are told, was no less than 420 stadia, or 52 1/2 miles. Its wealth was so great, that, after it had been plundered by the Persians, what was found, on burning the remains of the pillage, amounted to above 300 talents of gold, and 2500 of silver. The 100 gates of Thebes are mentioned by Homer, and, after him, by many others; but some think that this was not the number of the gates, but of the temples; and that from them the city had the epithet Hecatompylos, expressing a definite for an indefinite number. Pomponius Mela, and others, by the 100 gates, undervind so many palaces of princes, each of whom could, if occasion, arm and send out 20,000 fighting men, and 200 chariots. A modern traveller could observe no signs or remains of walls round Thebes: and if it had none, we must conclude, that by 100 gates, were meant the gates of the temples, or rather the palaces of great men. In Strabo's time the city stood chiefly on the east side of the river. At Thebes there were anciently four remarkable temples; one of them is said, by Diodorus Siculus, to have been 1 1/2 mile in circumference, and 45 cubits in height, with walls 24 feet thick.

The venerable ruins of this city, probably the most ancient in the world, says Mr. Browne (Travels, &c.), extend for about three leagues in length along the Nile. East and west they reach to the mountains, a breadth of about 2 1/2 leagues. The river here is about 300 yards broad; the circumference of the ancient city must therefore have been about 27 miles. In falling up the Nile, the first village that occurs within the precincts is Kourna, on the W., with few houses, as the people chiefly live in the caverns. Next is Abuhedjoud, a village, and Karnac, a small district, both on the E. The largest portion of the city stood on the eastern side of the river. On the S.W. Medinet-Abou marks the extremity of the ruins; for Arment, which is about two leagues to the S., cannot be considered as a part. Modern authors have flayed the site of Thebes, "Lexos" (which see); and others have denominated it "Aktor," both of which terms are, in Mr. Browne's opinion, corruptions of "El Kaffir," the appellation still applied to the ruins by the Arabs. The most considerable ruins are thofe on the E. of the Nile. The chief of these is the "great temple," an oblong square building of vast extent, with a double colonnade, one at each extremity. The mafy columns and walls are covered with hieroglyphics. The "great temple" stands in the district called Karnac. Next to this in importance is the temple at Abu-Hedjdj, and here are numerous ruins, avenues marked with falsines, &c. On the W. side of the Nile appear two colossal figures, apparently of a man and woman, formed of a calcareous stone like the rest of the ruins;—remains of a large temple, with caverns excavated in the rock—the magnificent edifice flayed the "palace of Memnon," some of the columns being about 40 feet high, and about 9 1/2 in diameter; the columns and walls are covered with hieroglyphics; this stands at Kourna. Behind the palace is the pabbage denominated.
"Bibâni-Molûk," leading up the mountain; at the extremity of which pailage, in the sides of the rock, are the celebrated caverns known as the sepulchres of the ancient kings. These sepulchres, which have lately been discovered, are particularly described by Mr. Browne. In the cells or recesses of the pailage of the largest of these, appear the chief paintings, representing the mysteries, which, as well as the hieroglyphics covering all the walls, are very fresh. Our traveller particularly observed the two harpers described by Bruce, but his engraved figures, he found, seem to be from memory. Although Pococke and many others are of opinion that Thebes was never surrounded by a wall, Mr. Browne inclines to a contrary opinion, from some faint remains which are still visible.

We are principally indebted to Denon (Travels in Upper and Lower Egypt, in 3 vols. 8vo, translated by Aikin), for an interesting account of the magnificent ruins of Thebes, as well as of other places in Egypt, illustrated by beautiful engravings. Four large hamlets (says Denon) divide amongst them the remains of the ancient monuments of Thebes, whilst the river, by the immensity of its course, seems still proud of flowing among its ruins. In crossing the ground occupied by the ancient Thebes, Denon found nothing but temples; not a vestige of the 100 gates so celebrated in history; no walls, quays, bridges, baths, or theatres; not a single edifice of public utility or convenience. Temples indeed were numerous, and walls covered with obscure emblems and hieroglyphics, which attested the ascendency of the priesthood, who still seemed to reign over these mighty ruins. The space occupied by this incomprehensible town now enforces four villages and as many hamlets, thinly scattered over immense fields. Pafing through the territory of Thebes on another occasion, Denon saw at the distance of three-fourths of a league from the Nile, the ruins of a large temple not before noticed by any traveller, which may give an idea of the immensity of that city, since, if we suppose that it was the last edifice on the easterp side, it is more than 24 leagues distant from Medinet-Abu, where the most western temple is situated. The temple, on the site of which the village of Karnac has been built, is of such a circumference, that it would require half an hour to walk round it. Herodotus has given us a more correct idea of its grandeur and magnificence. Diodorus and Strabo, who examined it in its ruinous state, appear to have furnished a description of its present condition, but none of the travellers who have copied the accounts of these writers have presumed (says Denon) to prefer to this temple that of Apollonius at Eski, that of Tentyra, and the simple portico at Etekh. It is probable (says this writer) that the temples of Karnac and Luxor were built in the time of Sesostris, when the flourishing condition of the Egyptians gave birth to the arts among them, and when these arts were displayed to the world for the first time. Of the 100 columns of the portico of the temple of Karnac or Carnac (which fee), the smallest are 7/5 feet in diameter, and the largest 12. The space occupied by its circumvallation contains lakes and mountains. This edifice is now in a degraded state. The sphinxes have been wantonly mutilated; and the avenue that leads from Karnac to Luxor, nearly half a league in extent, contains a succession of chimerical figures to the right and left, with fragments of stonic walls, of small columns, and of statues.

Luxor (which fee), the finest village in these environs, is also built on the site of the ruins of a temple, not so large as that of Karnac, but in a better state of preservation, the maffles not having as yet fallen through time, and by the pressure of their own weight. The most colossal parts consist of fourteen columns of nearly eleven feet in diameter, and of two statues in granite, at the outer gate, buried up to the middle of the arms, and having in front of them the two largest and best preferred obelisks known.

A peculiarity belonging to the temple of Luxor, is, that a quay, provided with an eaupleum, secured the eastern part, which was near the river, from the damages the inundations might otherwise have occasioned. The eaupleum, which since its original structure has been repaired and augmented in brick-work, proves that the river has not changed its bed; and its preservation is an evidence that the Nile has never been banked by other quays, since no traces of similar constructions are elsewhere to be met with.

Nothing can be more grand, and at the same time more simple, than the small number of objects of which this entrance is composed. No city whatever makes so proud a display at its approach as this wretched village, the population of which consists of two or three thousand souls, who have taken up their abodes on the roofs and beneath the galleries of this temple, which has, nevertheless, the air of being in a manner uninhabited.

Denon has particularly described the tombs above-mentioned, in the village of Kurnu, the ancient Necropolis of Thebes; and he concludes with remarking, that the mystery and magnificence observable within these excavations, and the number of statues by which they are protected, indicate, that the religious worship which had scooped out and decorated these grottoes, was the same as that which had raised the pyramids; but our limits forbid a farther detail.

THEBET, in Chronology. See TESET.

THEBIT Ben CORAH, or THABIT BEN KORRA, in Biography, an Arabian teacher of philosophy and mathematics, was a native of Harran, and belonged to the sect of the Sabians, and on this account was surnamed "Al-Sabi-Al-Harrani." The time in which he flourished is uncertain. Some say that he was born in the 22nd year of the Hegira, or A.D. 835; others refer him to the 10th century; and others again have placed him in the 12th or 13th century. He was secretary to the caliph Mothaded; and was distinguished by his skill in the mathematics, and by his knowledge of astronomy. He is said to have observed the declination of the ecliptic, which he fixed at 23° 33' 30"; and from this circumstance it has been concluded, that he lived in the 12th or 13th century, or that he was contemporary with Almeon and Profalus, who about that period attested to the ecliptic the fame declination. To Thebit has been ascribed the origin of the astronomicel feet, which maintained the tredipation of the fixed stars. It was his opinion, founded on some erroneous observations, that the fixed stars moved for some time according to the order of the signs; that they afterwards proceeded in a retrograde direction and returned to their former places, after which they assumed a direct motion; and that then they had an irregular motion, which was rapid for a certain period, then became slower, and at last insensible. According to Thebit, the obliquity of the ecliptic was variable, and subject to similar periods of increase and decrease. His opinions prevailed for a considerable time, not only among the astronomers of his own nation, but among some Chritians. Montucla Hist. de Math. Pococke, p. 377. Fabr. Bib. Grac. v. ii. p. 354.

THECA, SHEATH, in Anatomy, hollow organs, serving to contain others. The threes of the fingers are strong sheaths binding down the flexor tendons. The theca vertebralis is the sheath of dura mater lining the vertebral canal, and containing the medulla spinalis.
THECA, in Botany, the Latin word for a cell, breath, or cage, is used occasionally by some botanists in their descriptions of feed-vessels; and especially by Acharium, for those minute vertical parallel cells, in the disk of the shields or tuberclos of a Lichen, in which its seeds are lodged. See Lichenes and Penzia.

THECHES, in Ancient Geography, a mountain of Asia, in Armenia, according to Xenophon, who says that the Greeks, after leaving Gymnias, arrived on the fifth day at the sacred mountain called Theches, and from thence they for the first time perceived the Euxine Sea, which occasioned loud exclamations of joy.

THECUA, a town of Palestine, in the tribe of Judah; situated 12 miles S. of Jerusalem, according to Eusebius and Jerome. Josephus says that it was in the vicinity of Herodium. See Tekoa.

THEDINGHAUSEN, in Geography, a town of Germany, in the county of Hoya; 12 miles N. W. of Hoya.

THEDO, in Ichthyology, a name given by Figulus and others to the trout.

THEFT, Punum, in Law, an unlawful, felonious taking away another man's moveable and personal goods, against the owner's will, with an intent to retain them. See Larceny.

Open theft from the person, or in the presence of the owner, is properly called robbery, which see.

THEFT-BOTE, the receiving of a man's goods again from a thief, or other amends, by way of composition; and to prevent prosecution, that the felon may escape unpunished; the punishment of which is now fine and imprisonment.

This is frequently called compounding of felony. By 25 Geo. II. c. 36, even to advertise a reward for the return of things stolen, with no questions asked, or words to the fame import, subjects the advertiser and the printer to a forfeit or of £5. each.

THEFENEKE, in Geography, a town of Carinthia; 3 miles N. E. of Wolfsberg.

THEIMSDORF, a town of Lusatia; 6 miles E. of Rothenburg.

THEIRRED, in Biography, precentor of the monastery of Dover, and author of a treatise on music, in Latin, preferred among the MSS. of the Bodleian Library, in three books, written about the year 1371.

The first book treats of musical proportion; "De Proportionibus Musiciorum Sonorum." This is a very early treatise upon harmonics, in which, when he speaks of the major and minor femitone, and of the different portions into which they are divisible, his doctrine is illustrated by many numerical tables, and nice splittings of tones into commas; "De Comatis; alia Proportio ejusdem Comatis, et c." which prove a temperament of the scale to have been then in use.

The second book treats of musical concords; "De Consonantia Musiciorum Sonorum." Here, after specifying the different kinds of concords, he informs his reader, that in organis and major and minor thirds, as well as sixths, are admissible in succession.

The third book contains diagrams and scales innumerable of different species of octave, in a literal notation. No musical characters, or examples of practical music in common notes, appear throughout the treatise.

The praises bestowed by Pits, Bale, Tanner, and others on Theinred, whose name is sometimes written Thaured, and thenred, make it necessary to acquaint such of our readers as may be inclined to take the trouble of examining this tract themselves, that, like many other musical writings of the middle and lower ages, it but ill rewards the drudgery of an entire and careful perusal; for after perusal it has vanquished the abbreviations, and the barbarism and obscurity of the Latin, the vain speculations and useless divisions of the scale, with which this work is so much abounds, and which could have been but of small utility to practical music, at the time when it was written, are such, that now, since the theory of sound is so much better understood, and explained by the writings of Galileo, Mercers, Holder, Smith, and many others; our old countryman, Theinred, may henceforth remain peaceably on his shelf, without much loss to the art or science of music. Bodl. 842. 1. De legitimis ordinibus Pentachordorum et Tetrachordorum, Pr. Quomun Musiciorum de his Cantibus frequents eft distincion, &c. 46 folios, small size. Wükker in his Lexicon calls this work a Phænix.

THEICRUS, in the Materia Medica of the Ancients, a name given by some to the melanteria.

The name theicrus signifies only sulphur-coloured, and was at first used with the name of vitriol, as expressive of the difference of this kind from others; but in time it became common to use it alone.

THEISM. See Deism.

THEISOA, or Thimoa, in Ancient Geography, a town of the Peloponnesus, in Arcadia.

THEIUM, a town of Greece, in Athamania.

THEIUS, a river of the Peloponnesus, in Arcadia, which discharges itself into the Alpheus.

THEKA, in Botany, the Malabar name of the Teak tree, returned as generic by Jussieu. See Tectona.

THEKUPHE. See Tekuha.

THELA, in Botany, so called by Lourié, Cochinch. 119, from όση, a nipple, in allusion to the little glandular prominences which cover the calyx, appears, by his description, to be the same genus with the Limnean Plumbago. See that article.

THELARY, in Geography, a town of Hindoostan, in Bahar; 18 miles S. W. of Bahar.

THELBALANA, in Ancient Geography, a town of Asia, in the Greater Armenia. Ptol.

THELENCANA, a town of Asia, in Babylonia, on an arm of the Euphrates.

THELDA, a town of Asia, in Mesopotamia, on the banks of the Euphrates. Ptol.

THELE, a word used by some to express the nipple, and by others for the whole breast.

THELEBOE, in Ancient Geography, a people of Epirus, in Aecnamis, who passed into Italy, and established themselves in the island of Caprea.

THELEBOLUS, in Botany, from θεληθη, a nipple, and θεληθη, a calf, or throw, because the little vessel, lodging the seeds, resembles a nipple, and is thrown off with a degree of elasticity. The name was originally written Thelebolus, but the above is justly preferred.—Tode Mecklentb. v. t. 41. perf. Syn. 116.—Class and order, Cryptogamia. Nat. Ord. Fungi angiospermi.

Eff. Ch. Receptacle cup-like, somewhat globoso, entire at the edge, discharging a papillary, nearly naked, feed-vessel.

1. Th. flavus. Small Nipple-fungus. Perf. n. 1. Tode n. 1. t. 7. f. 56.—Found by Tode on the dung of swine, after rainy weather in June and July. He compares it to the rose of fih in appearance, and to poppy-feed nearly in size. The colour is a tawny yellow. Each individual is globular, attached at the bottom by capillary roots, and crowned with a small papillary tubeckle, of a more
more orange or golden hue than the rest. This is at length thrown off, with a sudden and strong elastic force, leaving a minute, bordered, viscid pit, or cup, which gradually dilates into a level surface.

The minute fungus above described is closely related to Sphagnetopsis, and still more nearly perhaps to Pilobolus. (See those articles.) Whether it might be allowable to comprehend under one genus, may admit of much dispute. Even the many-eleft receptacles, or involucres of Sphagnetopsis can hardly be deemed a sufficient important difference to supersede this measure, and still left the elongated figure, or pellicul subsance, of Pilobolus. Botanists who follow their concentrated attention exclusively on particular tribes of plants, are prone to multiply distinctions; but they are not rashly to be corrected by those who have not looked so closely, nor, perhaps, so well.

THELEDA, in Ancient Geography, a town of Asia, in Syria, situated on a plain W. of Seriana, and E. of Capparex.

THELEPHORA, in Botany, from $\theta_{\lambda} \nu \mu \alpha$, a nipple, and $\gamma_{\nu} \mu \varepsilon$, to bear, because of the generally papillary covering of the under surface.—Wild. Berol. 296. Perf. Syn. 565. Schrad. Specil. 182. (Craterella; Perf. Obs. Mycol. v. 1. 39. Corticium; ib. 37.)—Clasf and order, Cryptogamia Fungi. Nat. Ord. Fungi gymnocarpi.

Eff. Ch. Head coriaceous, dilated; minutely papillary, finely, or smooth, beneath. An ample, and, in our opinion, rather vague genus of the fungus tribe, of which Peron reckon up forty-four species, ranged under three sections, once confidered by him as distinct genera. We shall, after our usual manner, feel a few examples of each.

Sec. 1. CRATERELLA. Head undivided, hollow or funnell-shaped above, with a fluffy edge. Two species.

Th. piluloid. Pale Thelephora. Perf. n. 1. "Ict. et Defer. Fung. 3. t. 1. f. 35. sub Craterella."—Aggregates, corky, pale. Head concave, fthaggly with fables.—Rarely found on the ground in moist woods. The fball is very fhort, villous at the fpace. Head rough with fides, with little bristles, visible under a magnifying glafs. Perfon.

Th. caryophyla. Carnation Thelephora. Perf. n. 2. Albert. and Schwein. Nifk. 272. (Craterebellum ambiguia; Perf. Obs. Mycol. v. 1. 39. f. 8—10. Helvella caryophyla; Scheff. Fung. v. 4. 115. t. 325. Dickf. Crypt. facie. t. 20. Auricularia caryophyllea; Buliardi. t. 278. 485. Sowerb. Fung. t. 215.)—Head funnell-shaped, thin, purplish-brown, fringed, varifiously jagged or clinifed. Found on the ground in fir woods. Mr. Woodward firft met with this fpecies in Britain, near Bangay, Suffolk. Continental botanists ufually fpeak of it as rare, but Mr. Sowerby fays it is "a very common parasite on the exfpoed fantastic roots of old firs, in autumn." The funbance is tough and somewhat woody; the colour a fweet-brown. The plants often grow in mafhes, atached by their upper fide to ficks, old bark, &c., and are from one to three inches in diameter. Sometimes the fluffy edge is white. Perfon in his Obs. Mycol. above quoted feems difposed to think the preffent fungus may vary fo much as to become Rhamaria palmata of Holmikiold, Fung. Dan. v. 1. 166. t. 335; but fully the multiplied divifions and ramifications of the latter, as well as its smoothness and colour, preclude fuch an idea.

Sec. 2. STEHUM. Head balved, finally horizontal. Thirteen fpecies.

Th. terrictrum. Ground Thelephora. Perf. n. 3. Ehrl. Crypt. n. 179. (Th. metenterterrarium; Wildil. Berol. 357. t. 7. f. 15.)—Somewhat imbricated, dull brown. Head flattened, fthaggly with fibres. On sandy ground. This seems to us a mere variety of the last, or rather its most usual form, as reprefented in Mr. Sowerby's t. 213. Yet Peron cites this plate, with doubt, under his fourth fpecies, Th. lactinata. He fays to lay too much frels on the abfence or presence of a fball, and perhaps makes too many difficultions.

Th. rubiginofa. Rusty Thelephora. Perf. n. 6. (Th. fragilis; Ehrl. Crypt. n. 278. Helvella rubiginofa; Dickf. Crypt. facie. t. 20. Auricularia ferruginea; Buliardi. t. 278. Sowerb. Fung. t. 26.)—Imbricated, rigid, rufly-brown, smooth on both fides, with cattered, rather large, knobs. Not uncommon on gate-potts or pales, generally placed so low as to be partly hid by the earth and neighbouring plants, as Mr. Sowerby remarks. It is very diftinct from the foregoing, soft like velvet to the touch; the under fide bearing scattered, roundifh prominences, which, however, do not appear concerned in the frutification. The edge is usually pale. No part is hairy or fthagggy. The diameter of each plant is about an inch.

Th. ferruginea. Stiff-coloured Thelephora. Perf. n. 9. Albert. and Schwein. Nifk. 273. (Auricularia tabacina; Sowerb. Fung. t. 25.)—Aggregates, rounded, coriaceous, convex, fomewhat zoned, yellow-brown; fthaggly above, smooth and tanvly beneath. Frequent on fumps and rotten branches, in various situations. The plants are fefile, attached by the back, projecting over each other, of an elegant undulated figure; the colour of both fides a bright reddifh-brown, especially the upper, elegantly contracted with the light-yellow border.

Th. hirsuta. Common Hairy Thelephora. Perf. n. 11. Wildil. Berol. 397. Albert. and Schwein. Nifk. 274. (Th. pallaide; Ehrl. Crypt. n. 169. Auricularia reflexa; Buliardi. t. 274. Sowerb. Fung. t. 27.)—Aggregate, rounded, coriaceous, convex, fomewhat zoned, yellow-brown; fthaggly above, smooth and tanvly beneath. Frequent on rotten fumps, potts, pales, tubes, &c.; either growing solitary, and roundifh, about an inch in diameter; or incontinued, confluent, fomewhat imbricated maffes. The under fide is yellow or tanvly; the upper of a pale yellow-brown, marked with different concentric shades, and rough with imbricated soft fthaggly hairs. The whole is often tinged with black, as if smoked. It varies in fize as well as colour, and often confifts of an expanded orange-coloured funace, closely prefied by its back to the wood, previous to its acquiring any projection by which the upper fide is exposèd. In this flate it might be referred to the next fection. Auricularia papyrina, Buliardi. t. 402, foems nearly akin to this.

Sec. 3. CORTICUM. Plant laid entirely on its back, imbricated in form, papillary, various in funace. Thirty-two fpecies, divided into subordinate fections, according to the colour, whether pale or dark red, yellow-brown, grey, or white.—It is very necfary to trace the progres of the fpecies of this divifion, in order to be certain they do not, at any period, acquire a distinct upper funace, fo as to range under the preceding.

Th. querina. Oak Thelephora. Perf. n. 16. Albert. and Schwein. Nifk. 276. (Th. carnea; Ehrl. Crypt. n. 269. (Auricularia corticalis; Buliardi. t. 436. f. 1.)—Oblong, coriaceous, ringed, pale flesh-coloured; the margin somewhat involute, of a blackifh-brown at the back.—Found running longitudinally along decayed branches of oak. Each plant is two or three inches in length, somewhat oval, of a light fhef-coloured hue, with a powdery or downy funace, which water will not moisten, and which is befprinkled with round defpeffed protuberances, obfcurly repce.
representing the shields of a *Lichen*. The margin soon becomes elevated and infixed, especially by drought or cold, and displays the blackish under side, which ought to be the upper.

Th. fanguiaca. Gory Thelephora. Perf. n. 27. (Tremla cruenta; Engl. Bot. t. 1800.)—“Widely spreading on the ground, somewhat gelatinous, blood-coloured, smooth.”—“This singular species,” says *Perfson*, “grows in the streets of towns, among the walls of houses, looking at a distance like blood poured on the ground. By drying it becomes paler. Is it not rather to be referred to the order of Algæ?” In this last suggestion we readily concur. The whole is truly an expanded mass of minute, uniform, gelatinous, pellucid granulations, with nothing of a coriaceous or fungous texture, nor any other character of the present genus.

Th. hydnoida. Aawl-bearing Thelephora. Perf. n. 28. Albert. and Schwein. Ninf. 279. (Corticum hydnoidenum; Perf. Ohn. Mycol. v. 1. 15.)—Spreading, concealed, orange-yellow, bearing aawl-shaped elongated prominences.—This spreads under the cephalic cuticle of decayed dry branches of beech, which it sometimes totally encircles, extending to the length of four or five inches. Its great peculiarity consists in the awl-shaped projections, thrown out from its surface, to the height of two or three lines, which either penetrate, or force off, the superjacent cuticle of the tree, and, except in their great irregularity of size and figure, resemble the prickles of a *Hydnrum*.

Th. umbrina. Umber-brown Thelephora. Perf. n. 36. Albert. and Schwein. Ninf. 281. —Spreading on the ground, soft, of an umber brown; the margin whitish and rather downy.—Found on the ground, in a sandy soil, spreading to the extent of two or three inches, and not of a very thin substance. *Perfson* speaks of it as very rare, but the observing authors of the Fungi *Nifienfis* find it not unfrequently, in August and the following months, in sandy sandy places.

Th. *cefa*. Grey Ground Thelephora. Perf. n. 40. (Corticum caesum; Ohn. Mycol. v. 1. 15. t. 3 f. 6.)—Orbicular, on the ground, nearly smooth, of a greyish ash-colour.—Not unfrequent in autumn, on the bare ground, from one and a half to three inches broad, with a white, fibrous, rounded, scalloped edge. The grey surface is besprinkled with minute powdery specks, regularly disposed in spots, four together. *Perfson*.

Th. *laeta*. Milk-white Fr Thelephora. Perf. n. 45.—“Nearly orbicular, of a livid white; somewhat flethy in the middle; fibrous at the margin.”—Rarely found on the bark of the Spruce Fir. The surface is smooth. The colour becomes paler by drying. *Perfson*.

Albertini and Schweinitz describe several more species of this genus, to which every thing of a membranous texture, and fungous aspect, seems to be referred by authors. Some such may possibly be imperfect vegetable productions, whose growth, when completed, might prove them of a different nature. When their smooth surface discharges powdery specks, they are to be considered as perfect species of *Thelephora*.

**THELIGONUM.** See *THELIGONUM*.

**THELMENISSUS**, in Ancient Geography, a town of Asia, in Syria, on an immense plain on the E. of the Orontes, N. of Apamea, and S.W. of Chalcis.

**THELONIUM, TELONIUM,** signifies toll.

Among the Romans, *telonium* denoted a custom-houle, or place where the toll was collected.

**THELONIO, Browe effendi qui te de,** a writ lying for the citizens of a city, or burgesses of a town, that have a charter or precept to free them from toll, against the officers of any town or market, who would contrain them to pay it, contrary to the said grant or precept.

**THELONIUM Racionali, habendo pro dominis bakelitsus dominica regis ad frinnam, a writ lying for him that hath of the king’s demesne in fee-farm to recover reasonable toll of the king’s tenants there, if his demesne hath been accustomd to be toll’d.

**THELOTREMA,** in Botany, from τὸς, a nipple, and ὁριστις, an orifice, in allusion to the pierced protuberances of the crust; a genus of the order of *Lichen*, instituted by Acharius, in his *Methodus*, 190. The original type of this genus is *Lichen pertusus* of Linnaeus, which is reduced, by the writer of the present article, to *Endocardium* (see that article,) in *Prod. Fl. Græc.* v. 2. 304. The rest of the supposed species may perhaps be in like manner disposed of, or referred to *Urecologia*.

**THELPUISA, in Ancient Geography.** See *THALPUSA*.

**THELSE.** See *THALSE*.

**THELYGONUM, in Botany,** a name of very whimsical derivation, concerning which Linnaeus has fallen into an error, like professor Martyn and M. de Theis, who have both of them been lefs penetrating than usual in their enquiries. They all deduce it from τὸς, a nipple, and γωνία, a joint, or knee; and the last of them supposes the original plant, which was our *Mercurialis*, (see that article,) to have been called τὸς κοινος, because its swelled joints resembled the knees of a woman. This we modestly presume to be a very unauthorized comparison; and Pliny, from whom the name is borrowed, leads us to a less injurious, if not a wiser, solution. His sapient pages assure us that *Arjenunon* (Ἀρφάνων, or Αρφάνιον) was taken to procure male children, its fruit resembling a part of the male organs; while *Thelygonum*, which, though otherwise the same, bore no such fruit, was supposed to cause the production of females. The word therefore is composed of τὸς, and γωνία, generation, or offspring, τὸς κοινος, a leaf, being understood, a confirmation of which may be found under the 6th species of our article *Mercurialis*, above-mentioned. If we may be allowed to play further upon this word, we should remark that its own generation is truly asile. Yet hence arose Buehins’s *Mercurialis tephroclata, tephrot spicata, tephrot femina*; apppellations perverely bestowed on the two sexes of our *Mercurialis annua*, as well as of *perennis*. How Linnaeus came to transfer *Thelogonum* to the genus which now bears it, can no otherwise be accounted for, than from the supposed affinity of the plants to each other, and both having borne the name of *Cynocrambe*, or Dog’s Cabbage; a name retained by Gartner, after Tournefort, and liable to no objection, except being composed of one already established, which doubtles caused Linnaeus to reject it. The imaginary affinity just alluded to has apparently stamped a poisonous character on the herb before us, which, considering its natural order, is probably undeserved.—Linn. Gen. 490. Schreb. 644. Willd. Sp. Pl. v. 4. 420. Mart. Mill. Diss. v. 4. Ait. Hort. Kew. v. 5. 285. Sm. Prod. Fl. Græc. Sibth. v. 2. 237. Juff. 405. Lamarcck Illutr. t. 777. (Cynocrambe; Tourn. t. 485. Garin. t. 75.)—Clas and order, *Monococc Polyandria*. Nat. Ord. Scabridse, Linn. Urtes. Juff.

Gen. Ch. Male, el. Perianth of one leaf, turbinate, coloured, cloven half way down into two revolute segments. Cor. none. Stam. Filaments numerous, from six to twelve.
or more, capillary, prominent, as long as the calyx, anthers versatile, linear, straight.

Female, on the same plant, Cal. Persianum minute, of two erect, lanceolate, acute, lateral leaves, permanent. Cor. none. Ptilt. German inferior, globose; style lateral, between the calyx-leaves, thread-shaped, much longer than the germen; stigma simple, curved. Peric. none. Seed solitary, globose, seated on a callose annular receptacle, which falls off with it.

Female, Calyx lateral, of two leaves. Corolla none. Style one. Seed naked, on a deciduous annular receptacle.

1. Th. Cyanoecrum. Dog's Mercury. Linn. Sp. Pl. 1441. Willd. n. t. Ait. n. 1. Sm. Fl. Grcec. Sibth. t. 941, unpublished. (Cyanoecrum Dieiroides; Bauh. Prodr. 59. C. alineolata; Barbel. t. 335. Albinse facie planta nova; Commun. Phyt. 28. t. 30. ed. alt. 120. t. 36.):-The only known species, found in waste ground and the shuffles of rocks, especially in shady or moist places, in the south of England, as well as in Alto, flowering at almost all seasons. About Rome and Naples it is very frequent. Its seeds may have been brought, from time to time, into our curious botanic gardens, but the plant has no charms, nor any known quality, to render it a popular favourite. The root is annual, simple, cylindrical, with many fibres below. Sems several, spreading or prostrate, a span long, leafy, feebly branched, round, very smooth and shining, mostly purplish. Leaves alternate, flaked, each with an axillary tuft of smaller ones, ovate, rather fusculent, an inch, or thereabouts, in length, of a bright shining green, very smooth on both sides; roughish at the edges. Flowers small, white, from the blosoms of the upper leaves. The calyx of the males is not unlike the corolla of a honey-luckle in miniature. Seed purplish-brown, furrowed, not much bigger than mullein-seed. The general aspect of the plant evinces its affinity to Paritaria, though the flowers in detail are extremely different. Dr. Sibbdoch's figure has but six flaments. We have usually found more, and authors describe from twelve to nineteen.

That this herb is the Call, or nography, of Dieciroides, there can scarcely be a doubt. He describes it sufficiently well, and informs us that it was sometimes called Wild Male Mercury; which renders the name of Thelymiton still more unsuitable; but Linnaeus did not always search deeply into such matters, though he will commonly be found quite as learned as most of his critics or correctors. Dieciroides speaks of the plant in question as a gentle purge. This probably caused the Mercury to be taken with the same intention, though at the peril of the patient's life, as we have already mentioned in its proper place; where also it may be seen that some of the earlier European botanists took that very plant for the thymiton.

Gen. Ch. Cal. Persianum of three equal, ovato-lanceolate, coloured leaves, exactly resembling the petals. Cor. Petals two, ovato-lanceolate, the size of the calyx, and exactly like it. Nectary a fiddle lip, of the shape, size, and appearance, of the petals and calyx, without a spur. Stam. Anther parallel to the stigma, permanent, of two cells close together, attached to the central lobe of a three-cleft hooded appendage to the column; "maffes of pollen powdery, pendulous by a thread from the gland of the stigma." Brown. Ptilt. German inferior, ovate; style short, united with the hood; stigma in front, obtuse. Peric. Capsule obovate, furrowed, with one cell and three valves. Seeds numerous, chaffy.

Eff. Ch. Calyx-leaves coloured, the size and figure of the petals and lip. Column encompassed by a three-lobed hood. Anther parallel to the style, permanent.

1. Th. Forstferi. Forster's Thelymitra. Swartz Act. Holm. 1800. 228. t. 3. f. L., c. Willd. n. t. (Th. longifolia; Forst. Gen. t. 49. Serapias regularis; Forst. Prodr. 59.)-Lateral segments of the hood plumous: intermediate one vaulted. Clutter many-flowered.—Gathered by Forster in New Zealand. The stem is above a foot high, round, fringed, somewhat spiralled, clothed with a few sheathing lanceolate leaves. Clutter terminal, erect, three inches long, of about a dozen upright flowers, fearfully half the size of the next species, each accompanied by an elliptic-lanceolate acute bract, longer than the partial flake. Of the colour of the flowers we have no information. Their hood appears, by the dried specimen, as well as Forster's figure, to have its middle segment vaulted, convex, and mid-divided.

2 Th. ixiolida. Large-flowered Thelymitra. Swartz Act. Holm. 1800. 228. t. 3. f. L, a, b, d—g. Willd. n. 2. Br. n. t. Ait. n. 1. Sm. Exot. Bot. v. t. 55. t. 29. Lateral segments of the hood plumous: intermediate one three-cleft; its lateral lobes jagged; central one short, cloven, crested at the back. Clutter many-flowered.—Found in the neighbourhood of Port Jackson, New South Wales, from whence we received specimens and drawings about the year 1790. Mr. G. Caley sent out plants to Kew in 1810, but they do not appear to have succeeded there. This is a larger taller species than the foregoing; its flowers above an inch in diameter, very handsome, of a fine blue, spotted, according to Mr. Brown, with a deeper colour. The hood is fringed with hairs, just below the summit, and overtopped by its two lateral, flaked, plumous tufts. The calyx, petals, and lip, spread almost equally in both thefe, and we believe, all the following species, except our n. 9, Mr. Brown's venosa.

3. Th. media. Intermediate Thelymitra. Br. n. 2.—"Outer segments of the hood plumous; intermediate one naked at the back, three-cleft; its central lobe emarginate, half the length of the others. Spike (or clutter?) many-flowered."—Gathered by Mr. Brown, near Port Jackson.

4. Th. canaliculata. Channeled Thelymitra. Br. n. 3.—"Outer segments of the hood plumous; intermediate one naked at the back, many-cleft; lobes corrugated; the outer one longed and mottled remote. Spike many-flowered."—Found by Mr. Brown, in the tropical part of New Holland.

5. Th. purpurata. Few-flowered Thelymitra. Br. n. 4.—"Hood half the length of the petals; its outer segments plumous; intermediate one naked at the back, emarginate, with rounded entire lobes. Spike of few flowers."—Gathered by Mr. Brown, near Port Jackson.

6. Th. nudata. Naked Thelymitra. Br. n. 5.—"Hood half the length of the petals; its outer segments plumous; intermediate one naked at the back, emarginate, with rounded entire lobes. Spike many-flowered."—Gathered in the island of Van Diemen, by Mr. Brown. By the above definition,
THELYPHONON, from δόξα, female, and σῶς, murder, or destruction, the name of an herb mentioned by Pliny, book 25, chap. 10, which he says is by some called Scorpiun, from the resemblance of its root to a scorpion, and the touch of which is fatal to that animal, as a remedy for whose sting it is given internally. He adds, that the same root kills any cat of quadrupeds, if applied to the parts of generation; and that its leaf, which resembles that of Cyclamen, produces the same effect within the course of a day. His description answers to the Dornicus foepsoides, Willd. Sp. Pl. v. 3. 2114; D. laetifolium, Clus. Hist. v. 2. 16; Great Leopard’s-bane, Ger. Em. 759; but there is apparently much superflition, mistake, or exaggeration, intermixed in his relation.

THELYPERIS, from δόξα, female, and σῶς, a fern, a name by which Pliny designates a species of the Fern tribe, whose habit appears to be more delicate than that of his Filis max, or Male Fern. The latter should seem, by his description, to be our Pteris aquilina. (See T. ERFIS.) The name of Filis max, however, has remained with a large species of Alsifodium, Sm. Pl. Brit. 1121. Engl. Bot. t. 1458; and that of Filis femina with a more slender and finely-divided one of the same genus, Engl. Bot. t. 1459; while a third, whose texture is more thin and tender than either, has received the appellation of Alsifodium Thelyperis. They were all referred by Linnaeus, under the same specific names, to Polypondium. (See that article.) Our present Thelyperis, therefore, must not be taken for that of Pliny, being rather a north-country plant, not hitherto noticed in Greece by any botanical traveller.

THEMA, in Ancient Geography, a town of Syria, in the Chalchonite territory; and also of Arabia Deserta.

THEMEN, a town of Arabia Petra, 5 miles from Petra, which had a Roman garrison. —Allo, a town of Judea, in the half-tribe of Manasséh, on the other side of Jordam; famed for the wildness of its inhabitants. Eliphaz, one of Job’s three friends, came from this place.

THEMAR, in Geography, a town of Germany, in the county of Hennberg, on the Werla; 12 miles s. e. of Meiungen.

THEME, THEMA, a subject or topic, upon which to write or compose.

Theme, among Astrologers, denotes the figure they construct when they draw the horoscope; representing the state of the heavens for a certain point, or moment, required; i.e. the places of the stars and planets for that moment.

The celestial theme consists of twelve triangles, included within two squares, and called the twelve houses.

Theme, in Grammar, denotes a verb, considered in its primary and absolute sense, and not limited to any particular mode or tense; or it is the verb in its primitive radical state, whence its different formations are derived.

Theme, in Music; Thema, Lat.; Thema, Ital.; Motivo, soggetto, is a series of notes selected as the text or subject of a new composition, or an old favourite and well-known air to grace and embellish with variations. About the middle of the last century, the musical world was overwhelmed with dull, unmeaning, and monotonous variations to old and new tunes, which consisted of nothing more than a regular multiplication of notes, without fancy, taste, or harmonical resources; till Haydn, in the flow and graceful middle movements of his quartets and symphonies, by a richness of imagination, by double counterpoint, and inexhaustible resources of melody and harmony, rendered variations the most ingenious, pleasing, and heart-felt of his admirable productions à grand orchestre; and Mozart, in a totally different style, and for a totally different purpose, has rendered little favourite French, Italian, German, and English airs the most beautiful, amusing, and useful compositions for the piano forte that have ever been produced since the invention of that instrument. More than twenty of these have been printed in England that were brought from Vienna by Mrs. Peploe, who played them, as she did all other music, with a firmness, accuracy, and spirit, which neither dilettante nor professor has ever exceeded.

These themes seem to have been a series of leffons, composed expressly to form the hand and taste of some disciple of the author, who promised to be a great performer. In every one of these themes, there are some peculiar difficulties of execution, refinement, and expression to vanquish, at which it is in vain for mediocrity to aspire.

THEMEDA, in Botany, a genus of grasses, so called from its Arabic name Themed.—Forke. Egypt.-Arab. 178. Juss. 447.—It is found in Yemen, near Haddie. Forskal names the only species T. triandra, and describes it as follows.

"... A polygamous grass. Spikes proceed from a sheath, capitate; the outer ones whorled, male. Calyx of one valve, single-flowered. Corolla of two valves. Styles and ams wanting. In the middle of the head of flowers arises a short flalk, bearing two ifalked male spikes, and a sessile hermanphrodite one; the calyx is of one valve, corolla of two; am proceeding from the receptacle, much longer than the flower."

3 N
THE TOWN

As recorded by Diodorus, and it is by an event never faid, this does not appear that Vahl, Willdenow, or any other author, has adverted to Themeda, except Jaffue, who has merely admitted it, on Forkall's authority, into his appendix, without examination or elucidation.

We premise here to observe, that every correct writer ought invariably to cite the page of his author; especially in referring to a confused posthumous work, without an index, like that of Forkall.

THEMIS, in Ancient Geography, a town of Africa Propria, situated between Tabraca and the river Bagradas. Themis, in Geography, a river of Transylvania, which runs into the Aluat, near Marienburg. Themis, in Astronomy, a name given by some to the third satellite of Jupiter.

Themis, according to Diodorus, established divination, sacrifices, the laws of religion, and every regulation that contributed to maintain order and peace among men. She also applied herself to astrology, inflicted predictions, and after her death temples were erected to her, in which oracles were delivered. She had a temple on mount Parnassus, and another in the citadel of Athens.

THEMISCYRA, in Ancient Geography, a town of Asia Minor, in the kingdom of Pontus, situated in the open country to which it gave name, upon the banks of the river Thermodon, towards its mouth in the Euxine sea. Diodorus Siculus says that it was a royal city of the Amazons, and that they founded it.

THEMISIUMON, a town and country of Asia, in Phrygia.

THEMISSUS, a town of Asia Minor, in Caria.

THEMISTEAS, a promontory of Asia, in Carmania.

THEMISTIUS, surnamed Euphrates, or the fine speaker, in Biography, an Eclectic philosopher, was born in an obscure village of Paphlagonia, about the year 317, and having fixed his residence at Constantinople, taught eloquence and philosophy with great reputation and success. His disciples, both Pagan and Christian, were numerous; to the former clas belonged Libanius, and to the latter, Gregory Nazianzen. By the emperors he was highly esteemed, and they conferred upon him distinguished honours. In the year 355, Constans admitted him into the senate; and in return for an eloquent eulogium, presented him with a brazen statue. Julian corresponded with him as a friend; and in 362, appointed him prefect of Constantinople. His character and eloquence induced other emperors to bestow upon him peculiar favours. When Jovian inflicted his edict of toleration, Themistius was deputed by the senate to express its loyalty; and on this occasion he expatiated with elegance and liberality on the rights of confidence, and the independence of the human mind. Of his candour and liberality, the following magnificent instance is recorded by Socrates, Sozomen, and other ecclesiastical historians. The emperor Valens, who favoured the Arian party, treated the Trinitarians with great severity. Themistius, disapproving the measures which the emperor pursued, addressed him in an eloquent speech, rating that the diversity of opinions among Christians was inconsiderable, compared with that of the Pagan philosophers; and urging upon his attention, that this diversity could not be displeasing to God, since it did not prevent men from worshipping him with true piety. By such arguments, Themistius, it is said, prevailed upon the emperor to treat the Trinitarians with greater lenity. What an example does this Pagan philosopher exhibit even to Christian divines! In the year 376 Themistius visited Rome, but though solicited to take up his abode there, he preferred returning to Constantinople. It redounds very much to the honour of this philosopher, and also to the liberal sentiments of Theodosius the Great, that during his visit to the Western empire, the emperor entrusted Themistius, notwithstanding the difference of religion, with the care and education of his own Arcadians. Themistius was no less distinguished by gentleness of temper and urbanity of manners, than by his eloquence and wisdom, and ability in the conduct of public affairs. After a long course of civil honours, he withdrew about the year 387, at an advanced age, from public business; and soon after died. Themistius, the subject of this article, who does not appear to have ever departed the Pagan schools, should be distinguished from a Christian deacon of the same name, who lived after the council of Chalcedon, held in the year 551, and who was the head of the sect called Acnemont; which see. As a philosopher, Themistius illustrated several of the works of Aristotle, particularly the Analytics, the Physics, and the book on the Soul, in commentaries, written with great perspicuity and elegance. His "Orationes," which were thirty-six, and of which thirty-three are still remaining, are strongly marked with the same characters. The best editions of his Orations are those of Petavius, Gr. and Lat. Paris, 1618; and of Hardouin, Gr. and Lat. Paris, fol. 1684. Fabr. Bib. Graec. Brucker by Enfield. Gibbon. Lardner's Works, vol. viii.

THEMISTOCLES, an Athenian statesman and commander, the son of Nectes, a person of middle rank at Athens. At a very early age he manifested, both in his amusements and in his literary pursuits, those views and inclinations, which marked the character and destiny of his mature years. To those who ridiculed him on account of his apparent contempt of ornamental accomplishments, he replied, "It is true, I never learned how to tune a harp, or play upon a lute; but I know how to raise a small state to a great one." Ambition seems to have been his ruling passion, and he lost no opportunity of acquiring military and political distinctions. He fought popularly with a view to his personal advancement; and he pure and disinterested in his principles than Arifides, his lothitude for the glory of his country was subservient to his own reputation and eminence. After the defeat of the Perian invasion by the battle of Marathon, an event which interested him, and which he thought into exercise his predominant love of glory, he foretold that the attempt might be renewed by sea as well as by land; and he therefore exerted his influence in rendering the Athenian state a naval power. With this view, he induced his countrymen to appropriate the revenue accruing from the silver mines to the equipment of a number of galleys; and as he posseffed the chief authority at Athens, in consequence of the banishment of Arifides, he found no obstacle to the execution of his design. In the course of three years after this event, the hostile preparations of Xerxes for an expedi-

"Stems racemose. Shreds compressed, broad, sword-shaped, concealing the branches, and the heads of flowers, before expansion. All the heads are originally concealed in the sheath of a leaf."
tion into Greece to enforce the demand of subjection, furnished him with a plea for urging the Grecian states to compromise their mutual differences, and to unite in defending themselves against the invader. In the choice of a general, with whom the command should be intrusted in this emergency, the Athenians favoured the claims of a democratic orator, named Epicydes, who had fascinated them by his eloquence; but Themistocles induced him to surrender his pretensions to an office for which he was totally unqualified by a bribe, and thus secured the appointment for himself without a competitor. When news arrived that the Persian army, conveyed by a fleet, was approaching the istraits of Thermopylae, Themistocles proposed that the Athenians should fit out their galleys and fail to meet them; but this counsel being rejected, he took the command of their troops, and having joined the Lacedaemonians, marched towards Tempé. In the mean while, intelligence was received that the passage of the istraits had been forced, and that Bœotia had submitted to the invaders; and upon this alarm the army returned without seeing the enemy. In these circumstances of apprehended danger, the Athenians, according to their customary practice, had recourse for counsel to the Delphic oracle. The answer, probably suggested by Themistocles himself, was, that they should rely solely on their fleet. It was now proposed, that the city should be wholly abandoned to the Persians, without any attempt for its defence; that the women, children, and aged should be removed to some place of security; and that all who were able to bear arms, should embark on board the galleys, and watch the event. A decree was obtained, after much fruitless opposition, to this purpose; and this was followed by another, which permitted all exiled citizens to return. Arilides was one of this number, who nobly sacrificing, in the moment of his country's danger, all private animosities, concurred in all the spirited measures of his former rival.

Eurybiades, a Spartan, to whom the command of the confederate fleet was assigned, and who was very unequal to the office, differed with Themistocles as to the measures proper to be pursued; and behaved with an incoherence, which, probably for the sake of the public service, the latter did not think proper to reprove. Eurybiades was pacified by the gentleness and self-command of Themistocles, and convinced by his reasoning. Finding it prudent, however, to change the measures which he originally contemplated, he employed a stratagem to induce the Persians to advance and make an attack. This was followed by the famous battle of Salamis, which took place in the year B.C. 480, and which terminated in the signal defeat of the Persian navy. The victory has been chiefly ascribed to the skill and valour of Themistocles; and having thus succeeded, he advised the confederates to fall immediately to the Hellespont, in order to destroy the bridge of boats by which the army of Xerxes had passed over, and thus to intercept his communication with Asia; but being overruled in this proposal, he dispatched a secret messenger to the Persian king, with information that the Greeks intended to break his bridge, and advising him to retreat immediately before the design was executed. The policy of Themistocles, as we may judge from this instance, was not always uniform and consistent; and in another cafe, which remains to be mentioned, on the authority of Plutarch, it was inexcusably flagitious. When the combined Grecian fleet was wintering at Pegasa in Magnesia, he informed the Athenians, that he had conceived a project which would be of infinite service to the republic, and at their desire, he would communicate it to Arilides. This virtuous man told them, that the scheme of Themistocles would be highly advantageous, but that nothing could be more unjust; upon which, very much to their honour, they determined not to adopt it. The plan was to burn all the ships of the fleet, except those of Athens, by which he would remain complete mistress of the seas.

The victory at Salamis advanced the name and character of Themistocles to the highest pitch of glory throughout Greece. On his visit to Sparta, he was received with every token of respect; and whilst the first prize of valour was decreed by the people to their countryman Eurybiades, the olive wreath of superior wisdom was placed on the head of the Athenian; and they also presented him with a magnificent chariot, and ordered three hundred of their youth to attend him back to the borders. At the next Olympic games, the eyes of the whole assembly were fixed upon Themistocles, and he was pointed out to strangers as the most interesting object at the spectacle. Themistocles himself acknowledged, that this was the noblest day of his life. When the constitution of Athens was about to be re-established, after the rebuilding of the city, Themistocles, in conformity to the political principles which he had adopted, proposed that every citizen should have an equal right to participate in the government, and that the members should be chosen from the body of the people, without distinction; and in his proposals the people unanimously acquiesced. He also proposed to fortify the city; but as the Lacedaemonians objected to the proposal, he was deputed upon an embassy to Sparta with a view of conciliating them. He contrived, however, by various artifices, to prolong the negotiation, so that the Athenians had constructed their walls before the Spartans were duly apprized of the fact. Themistocles vindicated this artifice by alleging, "that all things are lawful in serving our country;" and the Spartans, admiring his patriotism, silently acquiesced. In the following year, his scheme for rendering the Pyræum the principal port of Athens, and connecting it with the city by long walls, was adopted and accomplished.

Independently of the deceits which Themistocles had practiced with regard to the Lacedaemonians, another circumstance had occurred which increased their enmity against him. He had successfully opposed their sending deputies to the Amphictyonic council, and thus degraded their authority in Greece. Incensed against him, they joined his rivals at Athens, and used all their influence to destroy his reputation. His own conduct also had excited jealousy and reproof; for he had caused to be erected near his own house a temple to "Diana Arribobule," or "of the best counsel," thus intimating, that his counsels had been the best for the Grecian community. His enemies prevailed, and procured his banishment from Athens by the sentence of Otracism. During his exile at Argos, his enemies gained an additional advantage over him. Apprized of the treasonable designs of Pausanias, the Spartan, against the liberty of Greece, he declined the discomfiture of them; and after the detection and death of Pausanias, letters of Themistocles were found, which proved that they had conferred on this statesman. The Lacedaemonians preferred an accusation against him to the Athenians; and they called him to account in the presence of the states of Greece. Dreading a trial, he fled to Corcyra, and thinking himself secure there, he withdrew to Epirus; and at length was reduced to the necessity of seeking the protection of Admetus, king of the Molossi, whom he had formerly offended. The vengeance of the Spartans pursued him, and Admetus was threatened with a war, if he protected the criminal. The king dismissioned him with money across the continent to a port in the Ægean sea, whence he reached Asia in safety. In the year B.C. 462, he arrived at the Persian court; but here...
his name was so obnoxious, that a reward of 200 talents had been offered for apprehending him. Here he appeared in disguise, and pretending that he had important information which he wished to communicate to the king in person, he was admitted to the royal presence, and favourably received: the 200 talents, which were the price of his head, were paid to himself, and a more ample recompense was offered to him, if he would give useful information concerning Greece. He was granted time for acquiring the Periwan language, and after a year he appeared at court like a native. The king and royal family treated him with distinction; and it is said that the revenues of three cities, viz. Magnesia, Lampacus, and Myus, were assigned to him, under the name of bread, wine and meat; and as some fay, two more, for lodging and wardrobes. In this state of luxury and magnificence he was joined by the members of his family, who had been conveyed to him by his friends, and to them he expressed a kind of satisfaction with his condition, which proves that moral meaness may accompany exalted talents.

The close of his life is involved in obscurity. Plutarch relates, that upon the revolt of Egypt, supported by the Athenians, against the Periwan dominion, the Greek king, resolving to send an expedition into Greece, dispatched him to Themistocles and Magnesia, reminding him of his promises, and claiming the fulfilment of them: upon which it is said, that, in order to avoid the disgrace of bearing arms against his country, after sacrificing to the gods and taking solemn leave of his friends, he drank poison, and died in that city at the age of sixty-five years. Thucydides, his contemporary, says that he died of a distemper; and others again report, that he poisoned himself, because it was not in his power to accomplish what he had promised. The Magnesians honoured his memory with a tumulus tomb; but his remains, according to his own orders, were privately conveyed to Attica, where they were interred. It is further said, that the Athenians, repenting of their treatment of him, raised a tomb for him in the Pyreum, which was an interesting object to all who visited that port. His singular talents, and the services which he rendered to his country, must be acknowledged; and those who think favourably of him, ascribe his defection of them to unjust persecution. But in Themistocles we look in vain for the virtues of an Arilides; and he can only be allowed the honour of a distinguished general and statesman. Thucydides. Plut. in Them. Anc. Unit. Hist.

THEMNA, Timna, or Thannnata, in Ancient Geography, a town of Palestine, in the tribe of Dan. Jos. ix. 43. — Allo, a town of Arabia Deferta, on the confines of Melopotamia.

THEN, in Geography, a river of France, which runs into the Weze, near Frauncemont.

THENA, in Ancient Geography, an ancient town of Africa, situated N. E. of the Tanais and near it, and two miles in circuit. — Allo, a town of Samaria, in the vicinity of Sichem.

THENAC, or THANAC, a royal town of Judæa, in the half-tribe of Manassæch, on this side of Jordan. It was given to the Levites of this tribe, and its king was one of those who were vanquished and slain by Joshua.

THENE, a town of the isle of Crete, near Chiosius.

THENAR, in Anatomy. The eminence in the palm of the hand, formed by the muscles of the thumb, has been called thenar: and some of the muscles have been described under the same name.

The thean of Riolan and Winfulow includes the abductor pollicis brevis, and the opponens pollicis.

THENEATE or Gannin, the Sheep Cliffs, in Geography, mountains of Africa, in Sahara; 90 miles S. of Algiers.

THENEZAY, a town of France, in the department of the Two Sevres; 10 miles N. E. of Martain.

THENG, a town of Germany, which gives name to a principality, situated in the Hegau, bordering on Schaffhausen; 8 miles N. of Schaffhausen.

THENON, a town of France, in the department of the Dordogne; 6 miles N. W. of Montignac.

THENONGOUN, a town of the Birman empire; 4 miles S. W. of Ava.

THENOPSICHITES. See THENETOPSICHITES.

THENSA, among the Romans, a veil or canopy, used in the chariots of games; and likewise to cover a feast of flate. The sale could not be granted to any but by the express allowance of the senate. Hist. Acad. Inscript. vol. 1. p. 379.

THEOBALD, Lewis, in Biography, a professed writer, was the son of an eminent attorney at Sittingbourne, in the county of Kent, and is here noticed as one of the numerous editors of Shakspeare. Of his various works, critical, poetical, and dramatic, it is needless to give any account, as they have sunk into oblivion. He had the misfortune of becoming, to an undue degree, the object of Mr. Pope's contempt and satire, and of having the first place assigned him in the Dunciad, though he was afterwards superceded by Cliber. His edition of Shakspeare was preceded by a work entitled "Shakspeare restored," and published in 1726; and also by that of Mr. Pope. It is thus characterized by Dr. Johnson: *Pope was succeeded by Theobald, a man of narrow comprehension and small acquisitions, with no native and intrinsic splendour of genius, with little of the artificial light of learning, but zealous for minute accuracy, and not negligent in pursuing it. He collected the ancient copies, and rectified many errors. A man so anxiously furipulous might have been expected to do more; for what little he did was commonly right." Of the tragedy which he brought on the stage, and which is entitled "The Double Faithless," the greater part is ascribed by him to Shakspeare; but Dr. Farmer has proved that this is a mistake.

THEOBROMA, in Botany, the Chocolate-tree, received that name from Linæus, who probably, like the prudent Bacht, cited by De Theis, was fond of the delicious produce of this tree; for the word is formed of θεός, a god, and βρωμα, food. A French writer, M. Tuiliez, in his magnificent Flora des Antilles, has objected to the above generic name, for a reason which we confess has been one of the last we should have thought of; that it carries with it the signification of a quality, and seems therefore more fit for the name of a species. Surely nothing can be more desirable than a generic appellation which conveys information; on which account Amarantus, Artocarpus, Biferrated, are excellent; we need not run through the botanical alphabet in search of numerous others. Such probably was the origin of most names, in every language, and who can tell that the American word Cassia, substituted, or rather restored, by Tuiliez, may not express some quality of the plant? Neither is it an objection to any significative generic names, that they express merely some general property or peculiarity, not found in every one of the species, witness Urtica. The idea of stinging is associated with the name of a Nettle; like redsnefs with that of a Rose; though there are Dead Nettles, and White Roses. — Linna. Gen. 391, with an erroneous description, corrected in Linn. Suppl. 341. Schreb. 513. Willd. Sp. Pl. v. 3. 1422. Mart. Mill.

Gen. Ch. Cal. Perianth inferior, of five ovato-lanceolate, acute, spreading, coloured, deciduous leaves. Cor. Petals five, rather longer than the calyx; their claws dilated, concave, hollowed, marked internally with two ribs from the base, and one from the summit: their borders roundish-ovate, pointed, spreading, each contracted at the base into a narrow, erect and recurved stalk, connected with the claw. Nectary short, cup-shaped, crowned with five long, erect, awl-shaped, pointed, equal, converging segments. Stam. Filaments five, thread-shaped, erect, recurved at the upper part, concealed in the hollow claws of the petals, invested into the outside of the nectary between its segments, but not above half so long; anthers two to each filament, (one on each side, at the summit,) vertical, two-lobed, one lobe over the other. Pist. Gemen superior, nearly sessile, ovate, with five furrows; style cylindrical; stigma in five awl-shaped segments. Peric. Berry elliptic-obleng, beaked, coated, of one cell. Seeds large, ovate, smooth, numerous, in five rows: their cotyledons in many deep lobes.

Obf. Gertner observes that he could find no traces of the five cells attributed by authors to this fruit. It is probable, however, from analogy, that they may exisit in the germin, and Aublet’s account is sufficiently explicit of their presence in the fruit. The drawing in the Linnaean herbarium, which appears to have been lent by Allamand from the West Indies, has led us to suppose each filament bore four anthers; but it seems there are only two, each of two round, distinct, vertical lobes, as represented by Aublet, t. 275, and copied by Lamark. The order of Decandria must therefore be restored in the clas Polyadephia. See Sm. Intr. to Bot. ed. 3. 340. Linnaeus’s characters of Theobroma in Gen. Pl. were taken chiefly from Plumier’s Guasuma, the Bubroma of Schreb. Gen. 513; see that article. He has left a more correct description in manuscript, from which perhaps his son compiled what is given in the Supplementum. From these sources, with the help of Allamand’s drawing, and what is to be found in Aublet and Schreber, we have drawn up our account, having no opportunity of examining a flower.

1. Th. Cacao. Smooth-leaved Chocolate-tree. Linn. Sp. Pl. 1100. Suppl. 341. Wildt n. 1. Ait. n. 1. (Th. n. 2 and 3; Browne Jam. 326; Caco; Merian. Surin. t. 26 and 63. C. Theobroma; Tuffac Flore des Antilles, t. 13. Arbor cacaoe americana; Pluk. Almajag. 40. Phyto. t. 268, f. 3.)—Leaves entire, smooth on both sides. —Native of South America. Aublet appears to have had this plant alive at rhelea, but it has never long succeeded in our flowers; being extremely tender, even in some parts of the West Indies. Browne fays the Chocolate-trees, though naturallyized in the woods of Jamaica, are very delicate, and rarely survive when once they are loosened in the ground by hurricanes. (See Chocolate.) Thee trees are the size of a middling apple-tree, but seldom exceed fix or seven inches in diameter. They are very beautiful, especially when laden with fruit, which is dispersed, on short stalks, over the stem, and round principal branches; its yellow hue and warty surface somewhat resembling a citron. The leaves are alternate, flaked, drooping, a foot long, and three inches broad, elliptic-oblong, pointed, entire, slightly wavy, very smooth on both sides, with one mid-rib, and many transverse ones, connected by innumerable, minute, reticulated veins. Footstalks round, hairy, an inch long. Stipulas minute, deciduous. Flowers small, several together in tufts, at the sides of the branches, on simple stalks, only one in each tuft, commonly producing fruit. Calyx light rofe-coloured. Petals yellow.

2. Th. guianensis. Downy-leaved Chocolate-tree. Willd. n. 1. Ait. n. 1. (Caco guianensis; Aubl. Guian. v. 2. 683. t. 275.)—Leaves wavy, and somewhat toothed; downy beneath.—Native of marvhy woods in Guiana, bearing flowers and fruit in September. Of rather more humble growth than the foregoing. The leaves are, at most, but eight inches in length, and three in breadth; their margin wavy, or rather bordered with fhalow teeth, towards the extremity; their upper surface smooth and green; the under clothed with short, ash-coloured, or rufy pubescence, and reticulated with fine veins. Footstalks short, channelled, downy. Flowers situated like the former. Calyx green without, yellow within. Petals yellowish. Fruit elliptical, with five angles, and clothed with short rufly down. Aublet fays it has five cells, separated by membraneous partitions; the seeds enveloped in a gelatinous, white, melting substance; their kernel white, very good eating when fresh. He speaks of this species as the Chocolate of Guiana, though he mentions a Cacao sativa, with entire leaves, as a cultivated kind, under which he cites Theobroma Cacao of Linneaus, and its acknowledged synonymes.

Aublet has also a Cacoa sylvatica, v. 2. 687. t. 276, with entire leaves, downy beneath, and a downy fruit, without ribs. Willdenow afferts, we know not on what authority, that this last is Duroia Eriopila, Linn. Suppl. 209, of which we, unfortunately, have met with no specimne. A branch of Aublet’s plant, communicated from his own herbarium by sir Joseph Banks, appears a variety of the last, its leaves being obscurely toothed in a similur manner; but for want of flowers we cannot say how far it answers to Duroia, between which and Theobroma there is no affinity in that respect. Aublet clearly describes his as a Theobroma, and we cannot help suppecting some error in Willdenow, as well as, possibly, a disagreement between Aublet’s figure and our above-mentioned specimne, which latter may be, as above hinted, his Cacoa guianensis. At any rate, the two species of Theobroma which we have described, are certainly and permanently distinct.

Theobroma, in Gardening, contains a plant of the exotic tree kind, of which the species usually cultivated is the chocolate nut-tree (T. cacao).

In its natural state, this tree produces a nut or fruit which is smooth, of a yellow, red, or of both colours, about three inches in diameter; it has a sleeky rind, near half an inch in thickenes, which is flesh-coloured within: the pulp being whitish, of the consistence of butter, separating from the rind in a state of ripeness, and adhering to it only by the filaments, which penetrate it, and reach to the seeds. Hence it is known when the seeds are ripe by the rattling of the capsule when it is shaken: the pulp has a sweet and not unpleasant taste, with a slight acidity; it is sucked and eaten raw by the natives; it may be easily separated into as many parts as there are seeds, to which it adheres strongly, and they are wrapped up in it, so that each seed seems to have its own proper pulp: the seeds are about twenty-five in number: when fresh, they are of a flesh-colour: gathered before they are ripe, they preserve them in sugar, and thus they are very grateful to the palate: they quickly lose their power of vegetation, if taken out of the capsule, but kept in it, they preserve that power for a long time: the tree
bears leaves, flowers, and fruit all the year through; but
the usual feasons for gathering the fruit are June and De-
ember: in two years from the seed, the tree is above three
feet high, and sproads its branches, not more than five of
which are suffered to remain. Before its third year is com-
plete, it floews for fruit; a tree yields from two to three
pounds of feed annually. Such trees are of oue rod very
productive.

Method of Culture.—It is increafed by feed obtained from
abroad, fowing it as foon after its arrival as poffible, in pots
filled with light earth, and fpringing them in a hark-bed,
where they will foon come up; and when the plants are
about three inches high, putting them off Separately, and
replunging them in the hark-bed in the flove, managing
them as other woody exotics of the flove kind afterwards.
They afford an agreeable variety in feed collections.

This tree is cultivated to coniderable extent, and with
very great attention in its native situations in the hot parts of
America, for the fake of its fruit, the kernels of which are
much ufed in the making of chocolate there, as well as in
this country. In this intention, they are firit brought to a
pulverizable flate by drying or roafting in a proper appar-
ratus; they are then reduced into a fine powder by mills or
other contrivances; after which, this fine powder is wrought
up into a paste with orange-water, milk, and other liquids,
and has fugar, different sorts of aromatic spices, and some
aromatic perfumes, mixed and incorporated with it, when
it is formed into cakes, or made into pretty large rolls, for
exportation and fale in the European and other markets, if
prepared in the places of its native growth.

It is employed somewhat in the manner of coffee as a fine
rich breakfast article of diet, and ufed very extensively for
that purpofe in this and other countries.

THEOCITAGNOSTÆ, formed from Θεος, God, and καταγνωσθαι, I judge, or condenfa, a feat of hereticks, or
rather of baffambers, who prefumed to find fault with cer-
tain words and actions of God, and to blame many things in
the Scriptures.

Marshall, in his Tables, places these hereticks in the seven-
th century; for what reafon we know not. Damafeenus is
the only author that mentions them, but without taking any
notice of the time of their appearance.

THEOCRACY, formed from Θεος, God, and κράτος, power, empire, a feat governed by the immediate direc-
tion of God alone.

According to Josephus, the ancient government of the
Jews was theocratic; God himfelf ordering and directing
everything belonging to the fovereign authority.

By the oracle of Jehovah himfelf, all laws were enacted,
war was proclaimed, and magiftrates were appointed; in
which three particulars the fana praecipuæ, or fovereign
authority, of any flate, confift. And as Jehovah was the
king, as well as the God of Israel, the priests and Levites,
who were the flated attendants on his preence, and to whom
the execution of the law in many cafes was committed, were
properly minifters of flate and of civil government, as well
as of religion. The facrifices alfo, becide their religious
ufe, were intended for the support of the flate, and civil
government.

This theocracy failed till the time of Saul; when the
Israelites, weary of it, defired they might have a king
like other nations; and thence forward the flate became
monarchic.

There was also a kind of imaginary theocracy at Athens:
while the fons of Codrus were difputing the fucceffion, the
Athenians, wearied out with the trifleries of an interself war,
abolished the royalty, and declared Jupiter the only king of
the people at Athens.

THEOCRITUS, in Biography, a Greek poet, exalted
as the model of pastoral poetry, was a native of Syracuse,
and the fon of Praxagoras and Philina. The time in which
he flourifhed is aetcertained by two of his poems, one ad-
rected to Hiero, king of Syracuse, who began his reign
about the year B.C. 265, and the other to Ptolemy Phi-
ladelphia, whose reign comprehended the interval be-
tween 281 and 246 B.C. Although Hiero is reported to
have been a patron of literature, perfons of rank, as
we may infer from Theocritus's poem, did not fol-
low his example, at leaft in granting encouragement to
poets; and therefore Theocritus left Sicily, and vifited
the court of Ptolemy Philadelphia at Alexandria, on
whom he pronounces a splendid eulogy. The compositions
of this poet are denominated "Idyls;" they are written in
the Doric or rustic dialect, and few of them are pastoral
poems, though not of them relate to rural life and manners.

The purely pastoral are diftinguifhing by the truth and fimplicity
of the manners, defcribing sometimes even to cardinals, and
the pleafing defcription of natural objects, drawn from the
life. To thofe who have a taste for genuine fimplicity,
and the beauties of nature, fays one of his biographers,
the poetry of Theocritus is highly agreeable. The moft
exhufed editions of his works, are D. Heinifus's,480. Com-
mel. 1604; R. Wett's, Oxon. Svo. 1699; Th. Warton's,
Oxon. 2 vols. 4to. 1770; Valkenier's, cum Bione et Moff-

THEODOLITE, or THEODOLET, is an instrument
used for measuring horizontal and vertical angles in
land-surveying. This instrument was at first made on a small
portable fcale, supported by a tripod that would put up into
the form of a walking-flick, when the mechanism of brafs-
work is difmiffion; and the flate of dividing circles is
now brought to that perfection in England, that small port-
able theodolites are fit for use among land-surveyors, who
confine themselves to the planning of single fites, for
which these instruments are competent; but for surveys on
a large fcale, fuch as county surveys, or trigonometrical
measurement of diftant fhips, theodolites of an enlarged
conftitution have been ufed with confiderable advantage.
Out of the numerous modifications of this instrument, that
different artifls have contrived, we propofe to defcril two
for particuJar decription, which are generally confidered as
the felf for accurate surveys; one by Ramfden, and the
other by Troughton. We will begin with that large in-
strument already referred to in a former article, which was
made by Ramfden, in the year 1777, for the fufe of general
Roy, when he undertook his grand trigonometrical opera-
tions, and which is defcribed in the 8th vol. of the Phi-
losophical Transactions of London (1752), with all the
conftant parts given separate in four large plates.
A fimilar instrument, by the fame maker, has since been
ufed for the grand general survey of the different coun-
ties, by Meffrs. Mudge and Dalby. Plate VIII. fig. 1.
of Surveys, fhews the perfpective view of this master-
piece of workmanship, nearly as repreffed in gen-
eral Roy's third plate; but his account, having reference
to thefeveral plates, will not answer our purpofe.
The flat on which the instrument is placed for fufe, is a four-
legged mahogany fpool A B C, braced as seen in the figure,
with an octagonal top perforated at the centre by a hole
of nine inches diameter. This fpool or fland, when ufed,
hafs its feet screwed fast to the tops of four piles driven into
the ground, and nicely levelled, before the instrument is
placed
Upon the Hooke's may hung which fills it was quarter ufual, cone, and, which we may it is served by the plumb-line to the mark or hole under the instrument may require, for the exact place of the station, over which the centre of the instrument must be exactly fixed. The four horizontal screws of adjustment, of which three are seen at F, F, and F', carried by the board D E, are so contrived as to effect this adjustment by pressure against the edge of the stand, after which the two octagonal boards are made fast together by the said four vertical screws not shown. The upper octagonal D E has an open conical socket of brass, three inches in diameter, in its centre. Next above the board D E, thus adjusted and secured, comes the third board, which is circular, and which forms the base of the instrument. In the centre of this base another brass conical socket, three inches and a quarter in diameter, is made fast, and slips over the smaller conical socket of the board D E of adjustment for central position, so that the centre of the instrument being concentric with this board partakes of the adjustment, while the plumb-line defends through both sockets down towards the ground. The large mahogany circle G H, of more than three feet in diameter, is supported by several pillars connected with the circular board, which we have called the base of the instrument, and forms with them a bafufrade, that protects the instrument, as seen in the figure. A brass circle of three feet diameter, within the bafufrade, is attached by ten strong conical radii to the large vertical hollow axis, formed into the frustum of a cone, of twenty-four inches in height above the metallic wheel, which we shall in future denominate the graduated circle, when considered with its radii and hollow axis attached to it. This axis, by way of distinction, may be called the exterior axis; it has a collar of cast-steel driven fast into the cavity of its inferior or thicker end, and a plate of bell-metal, with a sloping edge, furnishes the superior end, which plate may be raised or lowered by means of five screws acting vertically. The instrument stands on three short feet near D and E, and at an equidistant point not seen behind, which feet are firmly united together, at the place where they branch off, by a circular strong plate of bell-metal, upon which is carried an attached vertical cone of metal smaller than the former one, and as it fills the cavity of the other, we will call it the interior conical axis; the exterior one being moveable round the interior one without the least perceptible liberty, beyond what is necessary for rotatory motion. On the vertex of this interior axis is inserted a cast-steel pivot with sloping cheeks, which, entering the central hole of the bell-metal plate, exactly fits its checks there, while the bell-metal base of the interior axis fits the cast-steel collar inserted into the lower extremity of the exterior conical axis. This mode of centering allows the wheel to be taken off and put on without injury, and is also free from the objection that applies to those large instruments that have the superior end of the vertical axis supported in a frame that is liable to alter in its dimensions by exposure to the sun; of which imperfection, as we have noticed in our article Circle, Piazzi had great reason to complain. Besides, this kind of centre-work allows of carriage from one place to another, without any danger of injury being done to the instrument when properly packed. There are two achromatic telescopes with double object-glasses of each thirty-six inches focus, with eye-pieces of different powers both for erect and inverted positions. One of these telescopes lies across the body of the instrument, with the ends seen between the opposite pillars of the bafufrade, the use of which is to watch the position of the instrument during the time of an observation being made; and, therefore, it requires but little elevation in altitude: the other is mounted, exactly like a transit-instrument, over the top of the exterior vertical axis, and has a semi-circle attached to the extreme end of its horizontal axis of motion, of six inches radius, and graduated for flowing angles of altitude or of depression. The Y's in which the pivots of the upper telescope move, are supported by the horizontal bar I K, which is braced by the ladder-pieces attached to the thick part of the exterior conical axis, and made fast to the top of this axis by its socket, as seen in the section in fig. 4; which section exhibits moreover the internal fittings of both the internal and external axes at their superior ends. This upper telescope has a spirit-level with the usual adjustments at the Y's, and at the bar of suspension for the horizontal position; and, as it will revolve in the Y's, and has moveable wires in the focus of the eye-piece, it may also be adjusted by a horizontal mark for collimation, and for taking exact altitudes, (as well as for taking minute angles of elevation without the semi-circle by the motion of the micrometrical wires,) when the level is applied to a rod on the side of the tube, as is the case in our drawing. When these adjustments are made, by dividing the errors between the proper screws, as usual, the level is hung to the cross-bar I K to watch its position while this telescope is used, and when both telescopes continue to effect the same distant point during an observation, with the bubble of the level in the middle, it is a proof that the instrument keeps its position. When a star or other object is viewed by night, the illuminating lamp K throws light into the axis of the telescope, which has a diagonal perforated reflector, as is usual in transit telescopes. A system of darkening prisms is also applied to the same end of the axis to regulate the quantity of light that shall come to the eye. All these adjustments and appendages have been minutely explained under our articles Circle and Transit-Instrument, and therefore need not be detailed in this article; but it may be proper to observe, that the semi-circle has a moveable clamping-piece, bearing the flec arbor of a vertical screw, the lower end of which falls on a polished piece of steel on the plane of the horizontal bar I K, the use of which clamp and screw is not only to give a slow motion in altitude, but to allow the preponderating eye-end of the telescope to rest steady thereon, while the observation has been read and repeated. The observation in altitude is read by the compound microscope at I, which is nine inches long, and which, by means of its micrometrical screw, reads the divisions of the semi-circle to the accuracy of 5", when an allowance of 12" is made for excentricity. When this theodolite was first brought into use, it was found that the screw L, with an ivory thumb-piece, moved the circle in azimuth by jerks, on which account the apparatus for flow motion, seen in fig. 2, was substituted, in which two crown-wheels and a Hooke's joint are introduced to give motion to the tangent-screw; which addition not only remedied the jerks, but allowed the observer to reach the handle while his eye remained at the upper telescope. The large brass horizontal circle is divided into quarters of a degree, and the subdivisions are made by the vertical micrometrical microscopes, the divided heads of which read exact seconds, when properly adjusted for zero, for
for distinct vision, and for power. The screw of the vertical micrometers has seventy-two threads in the inch, and the notches that indicate the fifteen minutes on the micrometrical scale of feet, are formed by this screw, which we mention particularly, because this mode of reading was probably an original mode, though now become common. These vertical micrometers, G and H, have each a flag, represented by Plate IX. fig. 4; and a dot made on a thin flip of gold, called a gold tongue, lies under the object-lens in such a situation, that the capstan screws can adjust it to a given place in the field of view of each microscope, so as to become a mark for making the adjustments by, and for bisecting the circle at reversed opposite readings. The position of the three glasses of each microscope is seen in fig. 3. of the same plate, together with the magnified appearance of the notched scale and divisions of the circle. In fig. 5, the general plan of the micrometer is exhibited, and in fig. 6, is the plan of the flag where the pillars enter, that support the microscope. Fig. 7, shows the lower or fixed slide, and fig. 8, the upper or bras slide, that separate the wires of the micrometer; while fig. 9, is a representation of the long horizontal microscope that reads the divisions of the semi-circle above noticed, at the letter I in the large figure of Plate VIII. As it was not easy to describe the construction of the three feet, two of which, we have said, only are visible, opposite to D and E, we have added figs. 3. and 5. in Plate VIII. to illustrate their position. In fig. 3. the piece F F, as before, is a portion of the and D E a portion of the octagonal board, to which the screw F is attached, that presses against the angular corner of the fland, into which a piece of brass is let for the screw to press against, an end section of which is shown in fig. 5., with the same letters of reference to the same parts: M N is a section of the base of the instrument, and O one of the three bras branches that bears the foot-screw P, and its two side screws or tightening screws Q, R, as seen in fig. 5. At S is a curved piece of box, fast to MN, which bears the principal part of the weight laid on this screw, and does not gall the parts on which it slides, when a circular motion is given; but, to take off a part of the weight, a cylindrical roller near S is put to a horizontal spring bearing the central pin of the roller, which pressing the roller even with the face of the curved block of box, and may be made to take more or less of the weight by a screw pressing upon it from above, and giving it more or less tension. Hence all the parts of this large instrument are strong, and yet the moving parts are made to go freely and smoothly; and the only alteration that can apparently be made for the better, is the addition of a third vertical microscope, for which the construction is peculiarly adapted; for each branch of the triple bar that carries the three feet, being braced firmly, is made as though each was intended to have a microscope over it, which is the case with only one; and an additional foundation for the second stage is made to receive the second microscope, as we think, unnecessarily; for if three equidistant microscopes have been used instead of two opposite ones, not only would the errors of division and of eccentricity have been lessened thereby, but in the reversed position new parts of the circle would have been pointed to, equidistant from the former three, so that six portions of the circle would thus have been employed in measuring a reversed observation, which the present astronomer royal first pointed out to be an advantage peculiar to three readings on a horizontal circle. We have been informed, that it is yet intended to have three microscopes attached to the horizontal circle of this large instrument, to be used as we have here suggested. For the advantage of a triple reading, see our table for three verniers in the article CIRCLE.

After having given a description of Ramden's great theodolite, we proceed, in the next place, to explain how its different adjustments are made, for putting it into a state proper for use, which we cannot do better, than by adopting the directions laid down by general Roy himself.

The Adjustment of the Axis Level.—The axis of the upper or transit telescope, being brought over any one of the feet, and the circle being clamped, hang the axis level on the pivots, or axe of the telescope, and bring the bubble to the two indices; then reverse the level, that is, turn it end for end, and note the difference. Bieft this difference, one half by the level's adjusting screw, and the other half by that foot-screw only which is in a line with the axis. This operation being repeated until the difference wholly vanishes, the level will be truly adjusted, that is to say, the bubble will rest between the same points in both positions.

Adjustment of the Elevation Level.—This level being suspended on the rod attached to the outside of the transit telescope, screw the erect eye-tube on, to make that end preponderate. Adjust the bubble to the indices by the fixed finger-screw at the tail of the semi-circle's clamp, reverse the level, and note the difference. Then bieft that difference, and correct one half by the finger-screw, and the other half by the proper adjusting screw under the level, and so on, repeatedly, until the difference wholly vanishes. The level may then be hung on the two pins that project from the horizontal bar which carries the telescope, where, being parallel to the axis level, it will lie, when that is removed (as is commonly the case when terrestrial objects only are observed) whether the plane of the instrument suffers any alteration. If this should have happened, the level on the horizontal bar is at all times sufficient to correct it.

To set the vertical Axis perpendicular.—This may be done by either level, but best with the axis level, which, being suspended on its pivots, must be brought parallel with two of the feet of the instrument; and by the screws of these two feet, the bubble is to be brought between its indices. The circle being then turned round 180°, if the bubble changes its place, half the difference is to be corrected by one of the feet-screws, and the other half by two capstan-headed screws, that adjoin each other, under and belonging to one of the Y's, or supports, in which the pivots rest. When the bubble is found to be just in these two positions, turn the circle 90°, which will necessarily bring the axis over the third foot of this instrument; then correct any error there may be by that foot-screw. In this manner the circle will be made to revolve again and again, without any alteration whatever of the bubble, which shows that the vertical axis is then truly perpendicular to the horizon.

To make the Line of Collimation in the Telescope at right angles with the transverse Axis. The pivots resting in their Y's, direct the telescope to some distant well-defined object, and let the circle be clamped. Then reverse the axis, that is, turn the telescope upside down. If the interference of the wires does not coincide with the object in both positions, half the difference must be corrected by the motion of the circle with the Hook's joint, and the other half by the motion of the brass slide in the eye-end of the telescope, by applying the milled-head key in the small socket-rod in the figure; and so repeatedly until the difference wholly disappears.

To set the Rod on which the Elevation Level hangs parallel to the Line of Collimation.—The vertical axis being supposed to be
THEODOLITE.

When nearly vertical, hang the level on its rod, and rectify the bubble by the finger-screw of the clamp. Set the horizontal wire on the heel slide, to intersect the centres of the oblique wires, and place the dart or index at zero on the micrometer head. Then observe some distant distant object by the horizontal wire. Invert the semi-circle, that is, turn the azimuth circle 180°, and the telescope upside down, so as to bring the wire upon, or nearly upon, the same object. Now, if the level be not right, rectify it by the finger-screw at the tail of the clamp. If the telescope does not now accurately cover the same object, as in the former position, differ the difference by the finger-screw of the clamp, and then rectify the bubble by the capstan-nuts under one end of the rod. Repeat this operation until the level is right, when the telescope sees the same object in both positions, and thereby the rod will be brought parallel in altitude to the line of collimation, or axis of vision.

We have described other and more recent constructions of large circular instruments, under the word Circle, that have all the properties of the theodolite which we have here described, and some of which have the advantage of a large vertical circle, that renders their use in astronomy co-extensive with their application to geodetical operations, and which therefore we recommend in preference to the bulky instrument with which the English trigonometrical surveys were performed.

A theodolite of a portable size, and of Troughton's best construction, is exhibited in Plate IX. fig. 1. of Surveying, such as is adapted for land-surveying, or for the surveying of harbours. A, B, C, are the three mahogany legs of a tripod, furnished with brasses joints which allow the legs to form one entire cylinder, about four feet long. The brasses-work above the three joints has a male screw, upon which a socket, under the brasses circular plate D E, fence, and bears the instrument, which is almost entirely of brass. This plate D E has four sockets made fast into it, projecting both above and below, as seen in the figure, in which are exhibited three out of the four, with as many screws with milled heads, that ascend and descend as they are turned round, forwards or backwards, by means of their connection with their respective sockets, that have each a female screw: the heads of those screws press against the inferior face of the upper circular brasses plate F G, to which a ball, ending with a vertical axis, is attached, and is embraced by the upper portion of the socket of plate D E, within the four screws. The intention of the ball and socket, and of the two plates with the four intervening screws, is to place the axis of the ball in a vertical position, and to keep it in that position while the parts above are employed in making an observation; which office this mechanism will perform on sloping as well as on level ground. The axis of the ball, however, is made hollow, to admit of a smaller solid axis within it, and has also two sockets or tubes surrounding it; all which have separate motions, when the ball is made fast by the prehure of the four screws. The inner tube is attached to the graduated circle L M, of eight inches diameter, the chamfered edge of which circle is solid silver, that receives the dividing looks read by the microscope K; and the clamping piece, keen separately m fig. 2, will fix the said tube and graduated plate in any given situation by means of the screw F, after which the screw G with the milled head, attached to the plate F G, will produce the flow motion when necessary. The lower telescope H I turns on two pivots not seen, one of which pivots has its hole in a cock, borne by a smaller circular plate under the graduated plate, into which the two screws H and I enter, and the other pivot enters the outermost tube; so that an elevation or depression of about 20° can be effected by this telescope, before its motion is limited by the superior and inferior plates. This telescope has a proper motion in azimuth, independently of the graduated plate, which motion is produced by the thumb-screw H, the head of which has a pinion acting with a concealed wheel made fast to the graduated plate; but when the clamping-screw I is made fast, then the telescope and graduated plate have but one common motion, which is commanded by the tangent-screw G of the clamping-piece F G.

The use of the separate motion of this telescope will be explained presently. Above the graduated plate L M, and in close contact with it, the vernier-plate revolves with the solid or innermost axis, that is fast to it, and its clamp and screw of flow motion are hid from the light by the superincumbent frame. This plate, which has four opposite verniers, each reading to the accuracy of 1°, will move separately, or may be clamped to the graduated plate, as occasion may require. Upon the plane of this vernier-plate, two spirit-levels are placed with their proper adjufting-screws, one of which is seen at N; but the other, which stands at right angles to this, is concealed in the drawing by the framework. A compass and magnetic needle are also concealed within the frame, but may be conceived to be concentric with the vernier-plate within the shaft frame. The tail-piece of the revolving microscope K fits into a circular groove under the graduated plate L M, and, without having a centre of motion, will slide along the groove into any of the four positions, where the verniers require to be read, without interfering with any of the other motions. The instrument now before us has been some years in use, and is drawn on an enlarged scale, that all the parts may be the better described; but the most recent theodolites of this construction have only three verniers, in preference to four, by reason of the property, which this number has, of measuring at five different and equidistant points on the graduated limb, when the measurement of an angle is repeated in a reflected position of the superior telescope; so that whatever errors of eccentricity or of graduation may exist in the horizontal circle, they will be made to vanish, in a great measure, by their counteraction in the reversed position of the verniers. Upon the plane of the vernier-plate is fastened, by three screws, forming an isosceles triangle, the frame which supports the pivots of the horizontal axis of the semi-circle F Q, on which the upper telescope T U is placed. The arm, which bears the microscope O for reading the altitude or depression measured by the semi-circle, has a tube that slides upon the projecting horizontal axis, that allows of some degrees of motion between the end-bars of the frame; and another arm, that clamps the opposite end of the said axis, has a tangent-screw of flow motion at R, which fixes the final contact of the intersecting point of the spider's lines, within the eye-end of the telescope, with the object viewed. The vernier for the semi-circle is fastened to the frame, after spanning over the compass-box; and its exact place may be adjusted by the screw of the frame above M, which stands at the apex of the isosceles triangle formed by the three screws. The level, that is seen under and parallel to the upper telescope, is attached to it by two pairs of screws, one pair of which adjoins for the elevation or depression of one end of the tube that holds the bubble, and the other pair adjoins laterally for true parallelism in this respect: when the pins T and U are removed, the upper semi-circle of each ring, V and W, will turn back each on a hinge, and allow the telescope to be taken out of its Y's, for the purpose of being revered in position;
position; and in both situations the telescope is capable of having a circular motion, that carries the attached level round with it an entire revolution. During this revolution, an eye observing the intercrossed point of the field of view, as projected on a distant point, will see whether or not any adjustment of the spider's lines is necessary, and in what respect. The aperture of each telescope is an inch and a half, and the ordinary magnifying powers are from ten to eleven, with nearly fourteen inches of tube; but the upper or measuring telescope has a second eye-piece of the positive kind, which produces a magnifying power of twenty times. There are three spider's lines in each eye-piece, one horizontal, and two crossing it so as to include a small angle between them; which method of fixing the lines, allows the observer an opportunity of bisecting the said small angle by a vertical staff erected at a distance, which is better than covering the staff with a vertical line, that would disappear upon the plane of such staff. Before we proceed to explain how this theodolite is used in the field, it will be requisite to shew how the previous adjustments are to be performed.

When the instrument is screwed to the head of the tripod, the legs must be opened wide enough to ensure a firm position, and the points must be pressed into the ground equally, exactly over the hole into which a staff or staff has been, or is intended to be, inserted; so that the plumb, suspended from a pin at the junction of the legs, will fall exactly upon the said hole; in which situation the staff, marked $\mathcal{C}$, is said to be taken.

When the theodolite has been properly fixed in its station, the first adjustment that will require to be made, is that which regards the line of collimation. When all the parts of the instrument are properly in their places, let the upper telescope be pointed in a horizontal line, that passes over two of the four screws of plate $D\,E$, and note what point in a distant object is covered by the horizontal spider's line, near the middle of the field of view; then turn the telescope half round in the Y's, till the level lies above it, and observe if the same point is again cut by the said line; if not, elevate or lower the horizontal line by the proper screws in the eye-piece, releveling one and screwing up the other, till the distance between the two points, corresponding to the two positions, is bisected by the horizontal spider's line: and if, when the telescope is turned back to its original position, with the level under it, the spider's line covers the point adjusted to, the line of collimation in altitude or depression will be correct; but if not, the operation must be repeated delicately, till the horizontal line covers the same distant point in both positions. The same operation will also put the vertical line correct, or rather the point of interjection, when there are two oblique lines instead of a vertical line, as in Troughton's theodolite; and the adjustments will be known to be complete, when the point of interjection continues on the same distant point, while the telescope is made to revolve round the line of collimation as an axis.

The second adjustment is that which puts the long level parallel to the rectified line of collimation. While the telescope remains parallel to the line that joins two opposite screws of plate $D\,E$, adjust those two screws by turning them in opposite directions, until the bubble is observed to be in the middle of its tube under the telescope: then, the semi-rings V and W being previously turned back, reverse the ends of the telescope, and also of the level attached to it; and if the bubble will reimburse its former situation in the middle of the tube, both the line of collimation and the level will be truly horizontal, and consequently parallel to each other; but if the bubble recedes to one end, bring it back one half by the screws that elevate or depress one end of the level, and the other half by the screws of plate $D\,E$. Let this operation be repeated till the bubble will remain in the middle of the tube, after the telescope has been reversed into both positions. The adjustment of the level, however, is not yet complete; for though the axes of the two tubes may be equidistant at both ends of the level, yet may they be inclined so as to form an horizontal angle with each other at some distance, and in this case the bubble will run to the higher end of its tube, when the telescope rotates; there are therefore two lateral screws, which adjust the parallelism of the two tubes, so that the bubble will remain in the middle, in every part of a rotation of the telescope round its line of collimation, which adjustment must now be made; and if this lateral adjustment should be found to derange the vertical one before made, it must be re-adjusted, and the level will then be in a proper plate for use, provided the Y's are alike, and also the cylinders that rest in them; but if not, the bubble will not rest in the middle in both of the reversed positions, till they are made so.

The third adjustment that we propose to explain, is that which puts the line of collimation exactly at right angles to the axis of the semi-circle's vertical motion, which has not yet been described, but which is essentially necessary to be attended to, more particularly by the maker. Let the upper telescope be directed to some horizontal well-defined mark, that is included within the angular space formed by the two oblique lines, just where the vertical line would have been, if such line had been used, while zero of the vernier coincides with zero (360°) of the horizontal limb of plate $L\,M$; then all the screws being fast, except the one which allows the vernier-plate to revolve, turn 180° in azimuth, and reverse the telescope by taking it out of its Y's, into its original position with respect to the mark; and if this is seen in precisely the same situation in the angular space, (though not perhaps with respect to altitude, if the axis of the vernier-plate was not previously adjusted,) the line of collimation will be at right angles to the axis of the vertical motion; but should this not prove to be the case, one of the Y's will require to be altered laterally, but the adjustment of the level will not be deranged thereby. This alteration of one of the Y's had, however, better be effected by a regular workman, and should never be neglected by the maker.

The fourth adjustment, which might have preceded the third without inconvenience, is that which makes the common axis of motion of the vernier-plate and horizontal graduated circle truly vertical. This is done partly by the screws that fix the ball and socket, inflected into plate $D\,E$, and partly by the adjusting-screw R of the vertical semi-circle. Hitherto the upper telescope has lain over two of the four screws only, and in a horizontal line, with the bubble in the middle. Let it now be turned along with the vernier-plate just 90°, till it lies over the other pair of opposite screws, and see if the bubble be now also in the middle, if not, make it so by those screws; and if, after this operation, the bubble will remain in the middle during a whole revolution of the vernier-plate, in both the reversed positions of the telescope, the vertical axis of motion will be truly adjusted.

The fifth adjustment relates to the levels fixed to the plane of the horizontal graduated circle, which are useful in watching the horizontal position of the instrument, while an observation is making; these, which are at right angles to each other horizontally, must also be separately at right angles to the vertical axis that carries them round. When this axis has been adjusted, as we have just explained, by the level of the upper telescope, the bubbles of both
the fixed levels must be brought to the middle of their respective tubes by their proper screws, so that the bubbles of all the three levels may remain stationary in every part of the revolution of the vernier-plate, which they will do if its axis is truly vertical.

The fifth adjustment is that which puts the axis of the semi-circle's motion truly horizontal, or at right angles to the vertical motion of the horizontal circles; this is known to be so, when the point of interection of the spider's lines will cover a long plumb-line, suspended at a distance, as the angle of elevation increases, from the inferior to the superior end of the suspended line; and will better by trying if the pole star, and its reflected image, seen in a biface or quick-fiver, will be successively covered by the said point of interection of the spider's lines. In some theodolites, the horizontal axis lies in adjustable Y's, like those of a transit-instrument; but in the instrument before us, the adjustment was made permanent by the maker.

Lastly, the adjustment of the vernier to zero of the semi-circle is made by the screw near M, which elevates or depresses the whole frame in which the telescope and semi-circle move more or less consequently, and the angle 15. of motion; but it is not essential that zero of the semi-circle should be at zero of the semi-circle when the level is known, because when an altitude or depression is repeated in the reversed positions of the telescope, the two readings will have equal and opposite errors; and one half of the difference of those readings will be the constant index error, which may be ascertained with great precision from an average of a number of reversed observations.

The lower telescope, being placed as a guard to watch any azimuthal alteration in the position of the instrument, requires no adjustments, except that for distinct vision, after it is brought to its object by its proper vertical and horizontal motions, in which situation its horizontal motion is clamped by the screw I under the horizontal plate.

After the adjustments are all made, or examined, the theodolite may be used for measuring either horizontal or vertical angles in the following manner. Let us suppose two lines erected vertically on level ground, one towards the north and the other towards the south of the station where the instrument stands in a flat of adjustment; and let it be required to ascertain the angle subtended at the centre of the instrument by a line joining these lines: in the first place, the lower vernier No. 1. must be clamped to 360° on the horizontal circle, and the clamping screw F must be released, so that the upper telescope, vernier-plate, and graduated horizontal circle, may all move in azimuth together, till the staff to the east is seen in the field of view; the lower vernier No. 1. may then also be made fast, and the screw of flow motion, G, will bring the staff to bisect the angle formed by the spider's lines, in which situation zero of the measuring circle is truly placed; in the next place, bring the lower telescope, by its proper screw H, into precisely the same situation, and fix it there by the fixing screw I. Then having examined that the upper telescope has not moved from the staff by any accident, release the clamping screw that held the vernier-plate, and turn the upper telescope, till the second staff in the south bisects the angle of the spider's hairs; which may first be done roughly before clamping, and afterwards more exactly, by the tangent-screw of the clamp; then, having examined the position of the lower telescope again, let all the four (or three) readings of the vernier-plate be put down, and take the fourth (or third) part of their amount as the true angle, and fee that both teleopes have their rays bisecting their respective angular spaces as at first, after the measuring are read, and then the average thus ascertained will be nearly the true angle: but to prove the exactness of the measure thus taken, and also the accurate construction of the instrument, the telescope being in the Y's may now have its position reversed, and then No. 3; of the four verniers must be clamped to the point 360° of the graduated circle, and the same operation must be repeated, when another average of four measures will be had, and an average of these two results with opposite index errors, may be considered as very near the truth; and more particularly if there are only three verniers; for then, as we have stated above, the readings will be at fixed equidistant points of the circle, and will correct for excentricity as well as inequality of divisions, if any exist. In ordinary measurements of angles, in small surveys of land, this attention to extreme accuracy may be superfluous, where the instrument is well centered and graduated; but where the lines to be measured are long, the angles cannot be taken with too much care; particularly when any side of a triangle is to be determined, or checked, by the opposite angle.

In taking an angle of altitude or depression with the semi-circle of the theodolite in question, very great accuracy is not to be expected, seeing there is but one vernier; but by proper attention to the previous adjustment of the level of the upper telescope, and by using the telescope in the reversed positions, two measures will be obtained with opposite errors, that counteract each other's effects, so as to render the measure true to 15°. It is hardly necessary to add, that the measure of a vertical angle is taken by the horizontal spider's line, and that the lower telescope is of no use in taking such measure.

We proceed, lastly, to exemplify the use of a common theodolite by an actual survey of a small estate, such as will come within the limits of one of our plates, and by an explanation of the manner in which a field-book is kept in practice, and its contents transferred to the formation of a map, agreeably to the most approved methods of measuring and plotting an estate of any assigned dimensions. For this part of our article we are indebted to Mr. James Wadmore, whose experience and acknowledged skill, in his profession of land-surveyor, eminently qualify him for communicating the requisite information which we have referred for this place, to render the subject of surveying complete.

Preparatory to making a survey with the assistance of a theodolite, I consider it indispensably necessary, (says Mr. Wadmore,) that the surveyor should feel well assured that his instrument is in a perfect state of adjustment, and also that his chain is correct, otherwise no dependance can be placed upon the most particular and minute field-book he could make; for if these primary things are not attended to, the result of his labours, on plotting his dimensions, will turn out to be only so much unhappiness, as he may have bestowed upon his survey.

In order to obviate these difficulties in some measure, I most earnestly recommend to the young practitioner, that, in choosing his theodolite, as well as his protractor, cafe of instruments, plotting scales, &c. on which every thing depends to enable him to complete his surveys with correctness, that he be not sparing of a little money in purchasing those that are good, and can be relied upon for accuracy; and as being furnished with such, in the first instance, will be the means of ensuring to him that ultimate dispatch in the progress of his profession, which will lead him to the most satisfactory results.

As nearly the whole of the profession of surveyors have some material or nice distinctions in keeping their field-books,
books, arising either from the peculiar methods they have been taught, the instruments they use, the methods the more experienced have been led to adopt; from the more enlarged and enlightened views they may have taken to ascertain the best possible manner of facilitating the desired object, of making a correct survey; or from the more improved state of mathematical science; I trust I may be permitted to offer the following method of taking dimensions, the form of keeping a field-book, and the method to be adopted in plotting the same. Having made use of the theodolite, and endeavoured, by practical experience, to avail myself of its most beneficial services. I have no doubt but the specimens I now submit will be most readily comprehended, and the most intricate and difficult surveys accomplished by the same means; viz. with the assistance of the theodolite, where other methods, by possibility, may be found partially (if not wholly) to fail.

On commencing a survey, I have always found it necessary to look out for an intelligent labourer, well acquainted with the locality of the neighbourhood, with whole affiance, and another to carry the theodolite; I usually commence; invariably taking the chain myself after the leader: and here it may not be amiss to remind the young practitioner, that, in following, he must be most particular in directing his chain-leader in a straight line, otherwise the relative bearings of the stations forward, taken by the theodolite, will be rendered incorrect, and the protractor in plotting will not fail to convince him of his error, to his great chagrin and disappointment. I must also remind him of the necessity of keeping his chain-hand, and also directing that of his chain-leader to be kept as near the surface as conveniently can be done, and the chain properly stretched, by which means he will obtain more correct lengths in measuring from station to station, inferring thereby the greater accuracy in his survey (particularly if it be large); as he will very early find, in the course of his practice, that errors, when once begun, will rapidly increase; to prevent which, it will be found very convenient to plot every day's work on his return home, before he commences another, when, if any error is found, it can be rectified on the following day.

Many other necessary precautions might be given to the young surveyor, which by some may be thought superfluous, but the following I cannot help recommending to his attention; viz. that of being exceedingly particular in marking and describing his exterior boundaries, having myself, more than once, found litigation prevented by the production of correct surveys, where the boundaries of estates in dispute were clearly defined. And let him not be fearful of taking too many offsets, or dimensions: for by truthfully observing necessary to his survey to memory, he cannot but fail to omit some; whereas by a copious field-book, not even the slightest bend in a fence, or object of any sort, can possibly be omitted. Above all, let him feel well satisfied of the correctness of his chain; to enable him to do which, he should always have a spare one, on a large survey, to correct by; as it is well known that accidents will happen by the breaking of the same, by lots of rings, &c.; and the offset staff, from being too short, cannot be depended upon for this purpose.

Having said thus much, I now proceed to shew the method I have practiced in surveying with the theodolite; in doing which, I shall first premise that I have always considered it advantageous to take a view of the estate to be surveyed, by doing which, I have been enabled to avail myself of studying the best stations, and to judge how the business may be accomplished with the greatest facility.

The theodolite which I have been accustomed to use is a very good one, made by Cary, about five inches diameter on the limb, which is finely graduated, with a vernier reading minutes, and with degrees numbered from 1 to 360; it has an achromatic telescope and vertical arc, for the purpose of ascertaining the angles of elevation and depression in hilly surveys, on one side, and the corresponding deductions to be made in the chain lines on the other, and moves by rack-work.

"The method adopted by me, after some years' practice, in keeping a field-book, perhaps may be thought singular, namely, that of commencing at the bottom of the half page of the same, and working upwards therefrom; but it will readily be seen, on reference to the accompanying field-book in Plate X. to be the best way, as in proceeding, you meet the objects you have to describe in succession as you advance, and it affords a much greater facility in laying off the offsets from the chain-lines, than in the other way.

"It is well known that the needle is frequently affected, in the first place, by the atmosphere, and liable to get out of order; in the second, the chain being made of iron as well as the arrows, and their not being moved a sufficient distance in general, when the theodolite is planted for taking an angle, it may thereby be very materially affected; in the third, articles of iron or steel may be about the persons attending the survey, which may have the same effect; in the fourth, it may not be found improbable, from the very nature of the ground on which a survey may be carried on, that veins of iron, or metallic ore, may exit under the surface, which will not fail to influence the polarity, to the utter detriment of ascertaining the true bearings; and, lastly, without a vernier, the angle cannot be read with sufficient accuracy.

"Trusting that the foregoing remarks will suffice to convince those, who may be as much as to surveys by the needle alone, of the danger of truing to this method, as well as to prevent the student in the profession from doing, I now proceed to shew, that by taking the included angles of the survey upon the limb of the theodolite, and by carefully noting them in the field sketch, (as seen in the plate,) no such danger can possibly exist. The following problem will give sufficient proof of the accuracy of this method of measuring the internal angles of any geometrical figure, whatever may be the number of its sides; viz. double the number of sides, and multiply them by 90°; and then, if 360° be subtracted from the product, the remainder will be the sum of all the internal angles; for if we suppose lines drawn from every angle to one common point in or near the middle of the figure, there will be as many triangles as there are sides, and the sum of all the angles at the apex, or point assumed, will be 360°, as will appear when circumscribed by a small circle: therefore, as every triangle contains 180°, the amount of all the triangles will be as many times 180° (or 90° x 2) as there are bases, when diminished by 360°. In our example, the survey is bounded by five chain lines, with as many included angles, and therefore the amount of the angles will be 5 x 90° x 2 = 360°; or 90° - 360° = 540°, agreeably to the subjoined measurements taken in the field; viz.

\[

\text{O} & 87° & 12° & \\
\end{array}
\]

Total sum \[540°\]

Having
THEODOLITE.

Having said so much relative to the means of applying the theodolite most beneficially, I shall now explain an example of each of the methods I have alluded to; in doing which, I beg it may be understood, that although the difficulties I have enumerated may in some cases exist, yet it is possible a survey of moderate extent may be carried on by the needle with caution sufficient to obviate them; though I am fully satisfied, from experience, that the latter method is the most to be relied upon: I shall, however, proceed to exemplify both in the order before-mentioned.

"The Method of using the Theodolite in ascertaining the Bearings by the Needle.—It will be seen by the field-book, that I commence at (station) 1, at the back of the mansion; here, having the theodolite firmly fixed in the ground, by means of the four adjusting-screws, I set it perfectly level, first in the direction of the magnetic north, and afterwards at right angles; being thus satisfied, I set the vernier on the upper limb correctly to 180° on the graduated circle, and loosen the screw that fixes the instrument. I then move the graduated circle round until I ascertain that the needle points to N. in the compass-box, and then tighten the same screw, which prevents it from moving. Being now ready to take the bearing from 1 to 2, I direct the telescope to some object in that direction, keeping as near to the boundary-fence as can well be admitted, in order to reduce the length of the offsets; and having brought the cross-wires in the telescope to bear upon the object, I then look to see what part of the limb is cut by the vernier, which I find to be 180° 1', and in a north-west direction. This I note down as in the field-book, and afterwards examine whether it is correct. I then direct the chain-man to move forward towards that object, leaving a mark behind, to return to, and proceed by first taking the following offset at 0°; that is, at the place of commencement, I find an offset to the right of 86 links to lady Buckinghamshire’s fence, and 40 from thence back to the building, which I note down. I then proceed, and at 212, I measure 5 links to the right, to a tree; and going forwards at 274, I measure 2 links to the left, to another tree, (which objects I always induce to mark in the survey, for the purpose of embellishing the final map); proceeding onwards at 310, the offset to the corner of lady Buckinghamshire’s hummer-house is 10; at 360, the chain touches the fence, consequently I mark the offset 0 (nothing); at 738, there is an offset to the left of 23 links, to a tree; and at 917, one to the fence of 13: continuing the line, I set up a mark at 950, and write the name down in the field-book, thus "950 (3) mark left," meaning it for a station, to join to hereafter: I call it station (3), being the next number following the station I am measuring towards; and I denote it in a circle, to make it more prominent to refer to; and mark the 950, the number of links on the chain-line, also in a circle, that I may not err in plotting off the situation of the same. I then go on, and at 960 come to the outer edge of a small clump of trees; at 975, an offset to the left affords the width of the clump that way to be 50 links, and one to the right of 13 links to the fence; 986 passes the outer edge of the clump; at 1031, an offset of 31 links on the left to the canal; at 1100, passing close to the edge of the canal, there being no offset on the left, I mark it 0 (nothing); at 1155, I cross the gravel-walk, the width of which was previously noted in the field-book to be 8 links; and at 1180, I halt, and mark the offset to the fence on the right 5 links. Here I again plant my theodolite, as before, exactly over the station-hole; and after setting it perfectly level, and having brought the vernier 360° on the circle, and ascertained that the needle was correctly pointing to N. in the compass-box, I tighten the fixing-screw, then move the telescope round gently to the left, until the cross-wires cut a conspicuous object in the direction in which I mean to proceed, and ascertaining that the vernier cuts 335° 7′ in a south-well direction in the box. This I note down immediately in the field-book, as there represented; and after examining that I had done so correctly, I proceed on to measure the line from 2 to 4, taking the offsets right and left, and making the necessary remarks, to enable me to give a correct map and description of the estate, and so on throughout the survey. I have been particular in the field-book, which I trust, by the above description, will be considered to be a plain and facile way.

"The Method of using the Theodolite in ascertaining the Angles upon the graduated Circle, without Reference to the Needle.—On commencing, I plant the theodolite firmly in the ground, and after adjusting the level perfectly, and setting the vernier to 360° on the limb, I move the circle round, until I ascertain that the needle in the compass-box points correctly to N.; then tightening the screw that fixes the instrument, as before, I move the telescope gently round in the direction of the line to 2, in doing which, I find that the vernier cuts upon 360° 2′ N.W. This is noted down, in order to have the bearing of the estate upon the map, and which, on being deducted from 360°, leaves an angle to the left of the meridian of 29° 58′, as shewn in the example: then leaving a mark at station (1), and having proceeded along the line to station (2), and taken the offsets, and made the necessary remarks in the field-book, as in the former method, on arriving at (2), I again plant the theodolite firmly in the ground, and adjusting it as before, move the telescope round until the cross-wires cut the lower part of the mark left at (2); then noting in my field sketch the number of degrees cut by the vernier upon the limb, without regarding zero, I afterwards move the telescope carefully round to the right, and direct it towards 4; and bringing the cross-wires in the telescope to cut the object proposed to be measured, I look and see the number of degrees cut by the vernier on the limb, as before: deducting one from the other, I get the 2 at (2), viz. 35° 14′; and after having measured the line, on my arriving at (4), I proceed exactly in a similar way, by first looking back to the last station, and then forward to the next, deducting the number of degrees and minutes in one direction from those read in the other, which gives the angle 88° 18′. Following this course, I proceed on the survey until all the angles and sides are completed.

"It is necessary, however, before quitting each station, to take particular care in reading off the angles by the vernier, and also in writing them down correctly; and in this way of proceeding, the trouble of adjusting for zero of the vernier to 360° at every station is avoided.

"By plotting, is understood the making of a draught of the estate from the field-book; and as the instruments necessary to be used by the surveyor, in taking the dimensions in the field, are such, that he may be enabled to ascertain distances and angles correctly; it naturally occurs that corresponding requisites are necessary to make a groundplot, or draught thereof, for laying down the quantities of the several angles, and of the distances measured by the chain upon paper, which are usually accomplished by means of the protractor for the former, and sakes of equal parts for the latter.

"With respect to the protractor, I have hitherto used, and recommended the young surveyor to use, one of eight inches
which, on deducting the quantity of one from that of the other, I find to be 85° 14': this I prick off, and drawing a line thereto, I mark off the length of the chain-line 1274 links, and so continue to proceed until the boundary is finished. I then proceed to mark off the offsets at their proper points in each chain-line, and connecting the points of such offsets, I have the boundary defined of its true shape and dimensions, as seen in the map. Lastly, I call up the dimensions of the several triangles and offsets, considered as small trapeziums, the method of doing which has been explained under the word CHAIN, and find the contents as expressed in the subjoined table.

**THEODORE I.** pope, in *Biography*, was the son of a bishop of the same name, and born at Jerusalem. He succeeded John IV. in the papal chair in the year 642. Of this pope no material circumstance occurs, except his controversy with the church at Constantinople, concerning the doctrine of the Monothelites; and this controversy is so little interesting to our readers, that we shall pass it over without any further notice. Theodore died in the year 649.

Besides some letters relating to the above-mentioned controversy, a memorial against Pyrrhus, the deposed patriarch of Constantinople, and his errors, addressed to the Eastern bishops, is preferred. **Bower.**

**THEODORE II.** pope, a native of Rome, succeeded Romanus about the close of the year 898. During his possession of the see, which he held only for twenty days, he castrated the body of his predecessor Stephen to be taken out of the Tyber, and interred in the Vatican, and declared all his acts to be legal and valid. **Bower.**

**THEODORE LASCARI.** a Greek emperor, was son-in-law of Alexius Angelus, who imprisoned his brother Isaac and usurped the throne. Having valiantly but unsuccessfully defended Constantinople against the French and Venetians in the year 1204, he withdrew from the scene of conflict across the Bosphorus, and put himself at the head of a body of troops; but when he found that the confederates were pursuading him, he sought refuge with the Turkish sultan of Iconium. Being joined by the inhabitants of Bithynia, he took possession of the country from the river Meander to the Euxine sea, and fixed his residence at Nice, where he was crowned by the patriarch of Constantinople. When his father-in-law heard of his success, he went over from Greece,
THEODORUS, a learned prelate of the Greek church, was born at Antioch about the year 386, and placed at the age of seven in the monastery of St. Euprepius. He was educated under Theodore of Mopsuestia and John Chrysostom, and from his youth addicted himself to all the authorities and exercises of a monastic life. Upon the death of his parents, he distributed his whole property among the poor. In the year 420, or 423, he was consecrated, against his own inclination, bishop of Cyprus in Syria, in the Eastern province, the inhabitants of which were ignorant and barbarous, and notorious for their superstitious practices and heretical errors. Theodoret laboured industriously and successfully in enlightening and reforming them. In his own conduct he was an exemplary pastor; and in every thing

Greece, where he had remained concealed, to Asia, and explored the affinities of the sultans of Iconium in recovering that part of his dominions of which Theodore had taken possession; and having induced him to march with 20,000 men, he laid siege to Antioch on the Meander. Theodore, at the head of 2000 men, marched to its relief, and routed the besiegers. The sultan renewed the contest, and trusting out Theodore, beat him off his horse; but the emperor recovering himself, unhorsed the sultan, cut off his head, and placing it on a pole, terrified his enemies, so that they all fled. Alexius was carried, as a prisoner, to Nice, where he was confined. Theodore, having made peace with the Turks, formed a treaty with the Latin emperor of Constantinople, and spent the remaining eighteen years of his reign, in securing his newly-founded empire, which he transmitted to his descendants; bequeathing it, at his death, to his son-in-law, John Ducas Valesiates. The Nicene empire terminated about fifty-seven years after its establishment by the elevation of its predecessor, Michael Palaeologus, to the throne of Constantinople. Anon. Dict. Gibbon. Gen. Biog.

THEODORE, bishop of Mopsuestia in Cilicia, was priest, and probably native, of Antioch, a disciple of Diodorus, and an intimate friend of John Chrysostom. He was ordained bishop in 392 or 394, and died in 428 or 429. Sozomen says, that he was well skilled in the sacred ceremonies, and in the liberal sciences of the rhetoricians and philosophers: and Theodoret calls him the doctor of the whole church, saying that he was bishop thirty-six years, and that he wrote against all heresies, particularly those of Arius, Eunomius, and Apollinaris. He wrote commentaries probably upon all the books of the Old and New Testament, though two or three of them are not particularly mentioned: and in these commentaries, as Photius says, he avoided all allegorical interpretations, and confined himself to the historical and literal sense. He defended this mode in a work concerning an allegory and history against Origen. Some have charged him with treating the book of Job, the Canticles, and the Psalms, with disrespect; but these are the accusations of his enemies, and perhaps founded in error, as he actually wrote comments on some of these books. The book of Job he is said to have represented as written in a fabulous manner, though founded on truth; the Canticles he is said to have considered as a nuptial poem, and the Psalms as chiefly referring to the history of the times. His other works were numerous, and related to the controversies of his times, and to various theological doctrines. Most of Theodore's works are now lost, but some fragments of them may be found, chiefly in Latin, and perhaps not fairly represented, in the Acts of the second general council of Constantinople, or the fifth general council, held in 553, and also in Facundus, and in the Greek Chains. Fabricius affirms us, that his commentary upon the Twelve Prophets is still extant in manuscript in the emperor's library at Vienna; and Montfaucon speaks of its being in the library of St. Mark at Venice, as well as in the library at Vienna, and in the Vatican.

Theodore was no less celebrated as a preacher, than as a commentator and general writer; under the former character he was admired at Antioch, at Constantinople, and all over the East. Distinguished by his learning and liberality, considering the time in which he lived, he has been charged with adopting the sentiments of Nestorianism and Pelagianism; and some moderns have called him the parent both of Pelagianism and Nestorianism; whilst others allow, that he held the Pelagian principle, but are of opinion that the charge of Nestorianism is not so clear. The above-mentioned council devoted a conference to the examination of Theodore's writings; and began with reading a creed attributed to him upon which the bishops clamoured for an anathema against his books and his person, and against all who did not join in that anathema. Several bishops, however, rofe in his defence, and refused to concur in the anathema. Some moderns have charged him with adopting sentiments concerning the person of Christ similar to those of the present Unitarians; but of this fact there is no satisfactory evidence. Motheim. Lardner.

THEODORE of Tarsus, a monk of that city, was ordained bishop by pope Vitalian, and being sent into England in the year 668, at the desire of king Egbert, was appointed to govern the church of Canterbury. In this high station he faithfully employed himself in digging the faith and ecclesiastical discipline of England; and after having spent twenty years in the performance of various important and useful services, he died in 690, at the age of eighty-eight years. With a view to the restoration of the neglected discipline of penance, he published a book of canons, under the title of "Penitential." In this book, sins were distributed into various classes, according to their respective nature and aggravation; and various kinds of penance were assigned to them; forms of confession, exhortation, and abjuration were preferred, and other such matters respecting discipline were regulated. This Penitential passed from Britain to other countries, and became the model of similar works. It is still extant, in an imperfect state; and an edition of it was published at Paris by Petit, in 1679, 4to, with notes and dissertations. Dupin. Motheim.

THEODORE STUDITA, an eminent ecclesiastic of the ninth century, was educated under Plato, head of the monastery upon mount Olympus, the government of which was committed to him in the year 795. By avowing his opposition to the marriage of Constantine Copronymus to one of the maids of honour of his wife, whom he had compelled for this purpose to take the religious vows, and by his separation from the communion of the patriarch of Constantinople, Theodore incurred banishment; but at the death of the emperor he returned, and was appointed abbot of the monastery of Studa, in the suburbs of Constantinople. On account of his disapprobation of the decision of a synod which declared the second marriage of Constantine lawful, he was banished a second time. After the death of the emperor Nicephorus, in 811, he returned from banishment, and was reconciled to the patriarch. For his zealous defence of image-worship in the reign of Leo, he was banished a third time, and treated by the emperor with great severity. In 821 the emperor Michael allowed him to return to Constantinople, where he indulged a freedom of speech which obliged him to withdraw. He died in the year 826, in his sixteenth year. He was a man of learning, and author of many works, which were published by Sirmond, in Greek and Latin, at the end of his own works. Dupin. Motheim.

thing that related to his own gratification, he was self-denying and frugal, that he might possess more ample means of relieving the poor and promoting works of public utility. No bishop of his time was more active in performing the duties that pertained to his profession and station, or had greater influence in every kind of public business, particularly of ecclesiastical nature.

He was prudent in counsel, and always disposed to compromise in his temper, and to command mutual forbearance and even among contending parties. Butlike other pacificators, he could not escape obloquy and harsh treatment. Between him and Cyril, however, an irreconcilable antipathy existed, as was generally the case between the Eastern and Egyptian bishops; and this antipathy was manifested, even after Cyril's death, by his successor Dionysius, who caused Theodoret to be anathematized, and to be deposed in a general synod at Ephesus. In the reign of the emperor Marcian, a general council was assembled at Chalcedon; and this council decreed, that Theodoret was worthy to hold his see, and he was accordingly restored to the church of Cyprus. He died, without any further molestation, in the beginning of the reign of the emperor Leo, A.D. 457 or 458.

Theodoret bears a high rank among the ancients as a commentator on the scriptures for the purity of his Attic style, and the clearness and good sense of his explanations. He wrote commentaries on most parts of the sacred Scriptures. His canon of the Old Testament was very little, if at all, different from that of the Jews. With regard to the New Testament, it appears that he received only four gospels, the book of Acts, which he ascribed to St. Luke, and fourteen epistles of the apostle Paul, upon which he wrote commentaries: digesting them according to the order of time in which they were written, and noticing the places from which they were sent. He has seldom quoted the Catholic epistles, though they are not wholly overlooked. He seems to have received the epistle of James, the first of Peter, and the first of John; but there is no certain proof that he received the book of the Revelation, or the other four Catholic epistles; so that we may conclude, that his canon of the New Testament was the same with that of the Syrian Christians. His "Ecclesiastical History," comprised in five books, may be considered as a supplement to those of Sozomen and Socrates; beginning where that of Eusebius ends, at the rite of Arianism in 322 or 323, and terminating in 428. Its style, according to Photius, is clear and sublime, but too much abounding in metaphors. It is deficient in chronological precision, but contains many valuable documents, and some remarkable circumstances, which other ecclesiastical historians have omitted. His "Philology," or treatise on the monastic life, the genuineness of which some have questioned without sufficient reason, relates the actions and extols the piety of the Eastern monks, and abounds with instances of the credulity and superstition of the times. In his work entitled "Of Heretical Fables," in five books, he distinguishes the different heresies into classes, and concludes with a statement of the faith of the Catholic church. "The Cure of the false Opinions of the Heathens," in twelve discourses, is a learned and valuable apology for Christianity. Lardner has given copious extracts from this performance, which, with high commendation. His other works consist of letters and tracts on different theological subjects. They are all comprised in the best edition of his writings, which is that of Father Sirmond, in four vols. fol. Gr. and Lat. printed at Paris in 1642. To these the defunct Garnier added a fifth in 1684. Beaufobre gives the following candid account of Theodoret. "Theodoret is, in my opinion, one of the most valuable of the Fathers. He is learned; he reasons well, especially in his dialogues against the Greek heretics of his time: he is a good literal interpreter of the Scriptures. I cannot but admire his prudence and moderation, when I consider that he ended his ecclesiastical history at the time when the Neflorian disputes, in which he was so deeply interested, began. But, I fear, his zeal against heretics imposed upon him all too much, as his admiration of the heroes of the world, with whom he was charmed. Monasteries have undoubtedly sent forth great men into the world; but the discipies of the monks contracted in their youth a supranatural disposition which is rarely ever shaken off; and the weak side of this able man seems to have been an excessive credulity." Dupin. Mofheim. Lardner. Beaufobre.

THEODORIC I., king of the Vigufoths, was the son of Alaric, and in 419 succeeded Wallia in the kingdom established in the south of France. After raising the siege of Arles, he made peace with the Romans, and was subsidized by them in the Spanish war; but being desirous of renewing his attempts in Gaul, he took an opportunity, in 435, of renewing his hostilities against them, and laid siege to Narbonne; but being compelled to raise the siege, he was under a necessity of directing his attention to the safety of Toulouse, his own capital, which was invested by a body of Huns, under the command of count Litorius. In a very fanguinary engagement with the assailants, he totally routed them, and took Litorius prisoner; who was first exposed to the insults of the populace at Toulouse, and then thrown into a dungeon, where he died. After this event, Theodoric made peace with the Romans. His rank among the sovereigns of that period was respectable; and both his sons and daughters were well educated. The latter formed matrimonial connections with the eldest sons of the kings of the Suevi and Vandals, who reigned in Spain and in Africa. But these connections proved unfortunate. The husband of the Suevian princess was assassinated by his brother; and the Vandal princes, being suspected of a design to poison her father-in-law, Gunderic, was doomed to lose his nose and ears, and in this mutilated condition was sent home to his father. Theodoric eagerly sought an opportunity for revenging this cruel insult. With this view, the Vigufoths and Romans formed an alliance to resist Attila the Hun, who, instigated by Genserich, invaded Gaul in 444; and Theodoric, at the head of his army, marched to the relief of Orleans, which was besieged by the Huns. In their way the hostile armies met on the plains of Chalons, and a dreadful battle ensued. Theodoric was wounded by a Goth in the service of Attila, and being disembowled, was trampled to death under the feet of his own cavalry. When his body was found, his funeral rites were performed in the face of the retiring enemy.

THEODORIC II., king of the Ostrogoths, surnamed the Great, was a descendant of the Gothic race of the Amali, and born near Vienna, A.D. 455. At the age of eight years, he was sent to Constantinople as a hostage for the fulfilment of the subsidiary treaty formed by the emperor Leo with the Goths. Here he had an opportunity of acquiring that character which he maintained among the princes of that age; but his means of instruction must have been very limited, when it is considered that, though he excelled in all military exercises, he was so badly taught, as not to be able to write his own name. After ten years' residence at the court of Leo, he returned to his father, Theodoric, who was then the sole ruler of the Ostrogoths, in whose service he distinguished himself by his martial spirit. Upon the death of his father, in 475, the crown devolved on Theodoric. The emperor
peror Zeno, wishing to secure the attachment of the young prince, invited him to his court, and conferred upon him the rank of patrician. After having rendered full and faithful service to the emperor, he was reduced to the necessity of defecting the Roman cause, and forming an alliance with Theodoric, the son of Triarius. Having been altogether neglected by Zeno, he marched in an hostile manner into the fertile provinces of Thrace, which he laid waste with wanton cruelty. In the war that ensued between the empire and the Goths, a variety of events occurred; but, upon the whole, Theodoric became more and more formidable, and by the death of the son of Triarius, he was placed at the head of his nation. Such was the power he acquired, that the emperor found it necessary to cede to him part of Lower Moesia and Lower Dacia, and to honour him with the consulship, which office he discharged at Constantinople. But conceiving that he was an object of jealousy, and that his life was in danger, he withdrew into Thrace, and afterwards avowed himself an undisguised enemy to the empire. Declining to lay siege to Constantinople, he determined, as it is said, at the suggestion of Zeno, to turn his forces against Odoacer, who having deposed Augustulus, the last Western emperor, had assumed the title of king of Italy.

In the year 488, Theodoric, having collected together all the swarms of Goths that had successively arrived on the frontiers of the empire, set out on his Italian expedition; and after encountering many difficulties in his progress, descended from the Italian Alps, and reached the banks of the Sontius near Aquileia. Here, in August 489, he attacked Odoacer's numerous host, and forced him to retreat as far as the plains of Verona. The result of a second engagement was a complete victory on the part of the Goths, which compelled Odoacer and his fugitives to take refuge within the walls of Ravenna, while the conqueror obtained possession of the cities of Pavia and Milan. But, as the fortune of war is uncertain, one of Odoacer's commanders, having defected to Theodoric, proved treacherous, and induced several of the officers of the Gothic king to join his former master. Odoacer, having also gained possession of other fugitives from the Gothic service, recovered Milan, and obliged Theodoric to immure himself in Pavia. Theodoric, however, in this crisis of danger, obtained a powerful reinforcement from Alaric II., king of the Visigoths, settled in Gaul, and attacking Odoacer on the Adona, totally defeated him. Upon this disfalter, Odoacer fled to Ravenna; where, in the autumn of 492, he was besieged by Theodoric, who had made himself master of all Italy, except this city. In the following spring, Odoacer was reduced to the necessity of proposing terms of accommodation, with which Theodoric complied; and the consequence was the surrender of Ravenna to the Gothic army. It was stipulated between these two sovereigns, that they should govern Italy with equal authority. Such a stipulation was not likely to produce any permanent effect; and it was very soon violated on the part of Theodoric, by an act which entails on his memory eternal dishonour. Having invited Odoacer to a banquet, he stabbed him, as it is said, with his own hand, under a pretext that his dead rival had formed a similar design with regard to himself. After this event, Theodoric assumed the enigms of royalty, and caused himself to be proclaimed by his army "king of Italy." This assumption was reluctantly confirmed by Anastasius, the successor of Zeno. The manner in which he exercised the royal authority, however unwarrantable the means by which he acquired it, placed him far above all the sovereigns of that age. Steady having been united to Italy by a voluntary cession, Theodoric sheathed the sword of war, and cultivated alliances with neighbour-
count of the circumstances to which we here refer, see the article Boethius. Theodoric, at the close of life, reflected without doubt with remorse and self-reproach on his conduct towards Boethius and Symmachus. It is said that, whilst he was sitting at table, he perceived the gaping head of a large fish, which was served up before him, and at the sight exclaimed, that he beheld the angry and menacing countenance of Symmachus. Then probably did that fever commence, which being attended with a dysentery, terminated his life within three days, August, A.D. 526, in the 73rd year of his age, and the 14th of his reign, dating its commencement with the death of Odooerus. His dominions were divided by his testament between his two grandsons, Amalric and Atha-

Athenian monies.

THEODORIC, of Thieny of Nien, an ecclesiastical writer, was born at Paderborn, and served Gregory XI. Urban VII. and several succeeding popes, as under-secretary. The time in which he lived may be inferred from his "History of the Schism of the Popes," written between the years 1400 and 1410; in which he says that he had lived near thirty years at the court of Rome, and that being then worn down with age, it was his intention to withdraw from public business. This work, compiled in Latin, comprised, in three books, the interval from the death of Gregory XI. to the election of Alexander V. Another work relating to the same subject was entitled "Nemus Unions." In 1412 he published a "Treatise on the Rights and Privileges of the Emperors in the Inveifiture of Bishops and Abbots." He also wrote a journal of the proceedings of the council of Conftance, ending in June 1416, in which year he died. From his own observation, he exhibits a shocking picture of the court of Rome, and the clergy of that period. Dupin. Moreiri.

THEODORIDPOLIS, in Ancient Geography, a town of Myconda, founded by the emperor Justinian, who called it after the name of his wife.

THEODORUS, in Biography, a Cyrenean philosopher, was a disciple of Ancierris, and for speaking freely concerning the gods, he was stigmatized with the appellation of Atheist, and banished from Cyrene. At Athens, where he sought refuge, he was protected by Demetrius Phalerus, and gained access to the court of Ptolemy Lagis. Afterwards, upon his return to Athens, he is said to have suffered death by hemlock; but it has been disputed whether atheist, or contempt of the Grecian superstitions, was the cause of his death. He is joined by Sextus Empiricus with Eume-

us, and others, who maintained, that those who were esteemed gods, were men who had possessed great power on earth; and Clemens Alexandrinus expresses his surprize, that Eumenus, Nicander, Diogoras, Theodorus, and others, who had lived virtuously, should be pronounced atheists from their opposition to gentle polytheism. Brucker by Enfield, vol. i.

Theodorus, an Athenian flute-maker, the father of Hocrates the orator. How great the demand was at this time for flutes at Athens, may be conceived from a circumstance mentioned by Plutarch in his life of the orator. His father, says he, acquired wealth sufficient by his busi-

ness, not only to educate his children in a liberal manner, but also to bear one of the heaviest public burdens to which an Athenian citizen was liable; that of furnishing a choir or chorus for his tribe, or ward, at festivals and religious cere-

monies. See Isemnias.
and as their own country was occupied by the Huns, he permitted them to settle in Thrace and Media, with exemptions from tribute and taxes. With Maximus, who had revolted against the emperor Gratian, Theodosius entered into a treaty, by which it was stipulated that the usurper should retain the countries beyond the Alps, and that Valentinian, the brother of Gratian, should be secured in the possession of the remaining part of the Western empire. Maximus was acknowledged by Theodosius as his colleague in the Roman empire, and Arcadius, the son of Theodosius, though only eight years of age, was admitted to a share in the purple.

At this time Theodosius issued some severe edicts against heathen idolatry; and he passed a law against the marriage of cousins-german, which condemned both parties to be burnt alive, and which declared their children illegitimate. In 386, the Gruthungi, or Ostrogoths, in their attempt to pass the Danube, were defeated with great slaughter. In 387, Maximus invaded Italy; and Valentinian, defeated by hissubjects, took refuge in the dominions of Theodosius, who married Galla, the sister of that emperor. In this year the people of Antioch, having without effect remonstrated against the proceedings of Theodosius, both as to religious matters and the imposition of an extraordinary tax, broke out into an insurrection; threatened the life of the governor; and, disappinted in this effort of their rage, demolished the statues of the emperor and his family. Theodosius, in the first transports of remonant, upon receiving intelligence of their conduct, ordered the city to be laid in ashes, and all the inhabitants, without discrimination of age or sex, to be put to the sword. Upon cooler reflection he revoked this fangui-

nary order, and contented himself with deposing Antioch from the rank of a city, and depriving the inhabitants of their customary largesses of bread. Those who upon inquiry were found guilty, were condemned to death. But by the intercession of the bishop of Antioch, and other holy men, the culprits were pardoned, and the city restored to all its privileges.

Theodosius, on a visit to Valentinian at Thessalonica, prevailed on him to renounce Arianism, and to adopt the Nicene faith; and determined to take up arms in his cause against Maximus. After several successful encounters with the usurper, he was deposed of all his imperial ornaments, and dragged like a malefactor into the presence of Theodosius, who caused him to be beheaded. His son Victor was also put to death; and the civil war terminated A.D. 388. In consequence of these events, Theodosius became the sole head of the Roman world; and he invested the son of Valentinian, now a minor, with the sovereignty of the provinces wrested from him by Maximus, and also with the possession of Gaul, Spain, and Britain, of which Gratian had been deprived by this usurper. Theodosius remained three years in Italy, giving vigour to the law, correcting abuses, and adopting a variety of measures for totally eradicating paganism.

In 390, a sedition took place at Thessalonica, which was followed by many disastrous consequences, and by the exercise of a degree of cruelty, which the emperor was obliged to expiate by a public penance. About this time he took advantage of a religious tumult at Alexandria for demolishing the famous temple of Serapis, and of all the heathen temples throughout Egypt. He also issued a final edict against the ancient worship.

In 392, the emperor Valentinian was murdered by his general Arbogastes, and Eugenius was placed on the throne. When this measure was announced to Theodosius, he prepared for war; and having obtained a favourable anefer from a holy hermit in Thesba, whom he consulted, issued new edicts against hereby, and abrogated the ancient penalties of treason against those who uttered seditious words against the prince; he openly took up arms, A.D. 394, and forcing the passage of the Alps, descended into Italy. He met Eugenius and Arbogastes with a great force, and, after several conflicts, Eugenius was totally defeated, and put to death by the foolders. His children, however, and thefe of Arbogastes, who put an end to his own life after the battle, were treated humanly, and removed to their paternal possessions.

After this success, Theodosius lent for his son Honorius to Milan, and declared him emperor of the West; Arcadius having been already put in possession of the Eastern empire. In January 395, Theodosius terminated his life by a dropehe disorder at Milan, at the age of fifty years, and at the close of the sixteenth year of his reign.

The name of Theodosius has been celebrated, but his character has been very differently appreciated. Politically considered, whilst it exhibits many virtues and excellencies, it is chargeable with many errors and obliquities. Connected with the ecclesiastical interests of the period in which he lived, his conduct on various occasions was altogether indefensible; and we may add, that how much fower he has been extolled by partial historians, his bigotry and intolerance were very reprehensible. Anc. Un. Hist. Gibbon's Rom. Hist. Gen. Biol.

Theodosius II., son of the emperor Arcadius, and grand-

son of the preceding Theodosius, was born in the year 401; and being of feeble faculties, was educated merely to sustain the pageantry of a throne; or, as Mr. Gibbon expresses it, "to represent with grace and dignity the external figure of a Roman emperor." His only active pursuit was hunting; and his more private exercises were painting and carving, making elegant transcripts of religious books, and singing psalms. He also failed, gave credit to miracles and doctrines professed to his faith, and paid due homage to all the dead and living saints of the Catholic church. His disposition was gentle and kind; in his conduct he was free from vices, and yet, as his biographer says, "he did not yield to virtues." Upon his father's death, A.D. 408, he succeeded him in the Eastern empire. To the influence of his sister Pulcheria, superior in talents to himself, he implicitly submitted; and in 414, he raised her to the rank of Augusta, and entrusted with all the reins of government. By her selection and recommendation he married, A.D. 421, the celebrated Athanasia, afterwards named Eudoxia. The war which broke out in 422, in consequence of a persecution excited by the Magi against the Christians, terminated in a truce of a hundred years, and a division of the kingdom of Armenia between the contending powers. On the death of the emperor Honorius, in 423, the throne of the West was usurped by John; but Theodosius restored it to its proper heir, Valentinian III., who afterwards married his daughter. When Attila made an irruption into the Roman empire, he was opposed by Theodosius, whose armies were repeatedly defeated; and Theodosius himself was compelled in 446 to make a humiliating treaty with the king of the Huns. By one of his favourites, the eunuch Chryphius, he was induced to free himself from Attila by affiliation, but the treachery was defeated, and he received a jurt and severe reprimand from the barbarian. Soon after this mortification, he died in consequence of a fall from his horse, A.D. 450, in the fiftieth year of his age. What his grandfather had done towards the subversion of the pagan religion in the East, Theodosius completed. He always approved himself a dutiful son of the church, but he is said to have favoured the Eutychian heresy. His principal merit was the publication, A.D. 438, of the
THEODOSIUS, an eminent mathematician, was born at Tripoli, and flourished about the second or third century. On the doctrine of the Sphere he wrote three books, containing a considerable number of propositions, demonstrated in the pure geometrical manner of the ancients, and establishing the geometrical principles of astronomy. Ptolemy and succeeding writers availed themselves of these books, which were translated by the Arabs from the original Greek into their own language. They were afterwards translated from the Arabic into Latin, and printed at Venice; but the defects of the Arabic version were supplied in a more complete edition, published in Greek and Latin at Paris in 1556, 4to, by John Pena, regius professor of astronomy. On this work there have been many comments; but the edition of Theodorus's Spheres now generally used is that of Dr. Barrow, published in 1675, illustrated and demonstrated in a new and concise method.

Theodorus was also the author of two other treatises, one "De Habitationibus," and the other "De Diebus et Noctibus." Greek copies of these were preserved in the king's library at Paris, and a Latin edition was published by Peter Dalypodius in 1572. Montucla Hill. des Mathiens.

THEODULF, a learned prelate of a Gothic family, was a native of Cisalpine Gaul; and being invited to France by Charlemagne, he was promoted to the bishopric of Orleans, A.D. 794, and the abbacy of the monastery of Fleury. He continued in favour at court till the death of Charlemagne, and for some time under the emperor Lewis. But being implicated in the conspiracy of Bernard, king of Italy, against Lewis, he was committed to prison at Angers, where he remained in confinement for three years. After his liberation, and before his return to his diocese, he died at Angers, about the year 821. Theodulf was the friend of Alcuin, and deserves honourable mention as one of theTonyaries and promoters of literature in a dark age. He was the author of several works, published by Father Sirmont, in 1646, 8vo. One of his hymns, beginning

"Gloria, laus et honor tibi sit, Rex Christe Redemptor,"

has been adopted by the Catholic church for the service on Palm-Sunday. Dupin. Gen. Biog.

THEOGAMIA, Θεογαμία, in Antiquity, a Sicilian festival, in honour of Proserpine, which seems to have been instituted in memory of her marriage with Pluto.

THEOGNIS, in Biography, a Greek poet, was a native of Megara, in Attica, and flourished about the year B.C. 546. He has been denominated "Gnomologus," or the writer of sentences; and we have extant a work written by him, without order, consisting of moral maxims or precepts, simply expressed and dedicated to poetical ornaments, verified probably for affilling the memory. Athenaeus reckons him among the advocates for licentious pleasures; and Suidas refers to a work of his composition, entitled "Exhortations" or "Admonitions," which contained various impurities. In the verses that now remain, nothing of this kind appears; so that if the charge be true, they must have undergone callillation. "The Sentences of Theognis" have been often printed by themselves, and with the works of other minor Greek poets. Among the best editions are those of Camerarius and Sylburgius. Volsh Poet. Græc. Gen. Biog.

THEOGONY, formed from Θεός, God, and γόν, genus, birth, offspring, that branch of the heathen theology which taught the genealogy of their gods.

Aeschylus gives us the ancient theogony, in a poem under that title. This poem treats of the origin and descent of the gods; or rather, under the allegorical dress of theogony, represents the formation of the world, and the history of eminent men. The plan of this work is intricate and confused. (See Hesiod.) The writer seems to have made use of several different theogonies, and to have blended them together with little regard to consistency. He also frequently adds, for the sake of poetical ornament, fictions of his own, which have no relation to the history and origin of the world. Arilophanes, in his comedy of "The Birds," has introduced a description of the formation of the world, which was borrowed, without doubt, from the ancient theogonies; but it deferves little attention. All the theogonies make an eternal chaos the origin of all things. Thus Ovid. Met. l. 1. v. 5.

"Ante mare, et terras, et quod tegit omnia caelum.
Unus erat totus natura vultus in orbe,
Quem dixere Chaos, rudis indigilque moles,
Nec quicquum nisi pondus iners, convagilque eodem
Non bene juncturam discordia feminam rerum."

"Ere sea and earth, and heaven's high canopy
Were form'd, great Nature's face was one;
A lifeless, rude, and undigested mass
Of jarring feeds in one wild chaos lay." See Chaos.

Whether, besides this chaotic mass, the ancient theogonies supposed an infinite, active, intelligent principle, who from the first matter formed the universe, is a question that has occasioned much debate. It is evident, upon the most cursory review of the ancient theogonies, that God, the great Creator of all things, is not expresally introduced; but it is doubted, whether the writers meant to exclude him, from their system, or indirectly to suppose his existence, and the exertion of his power in giving motion to matter. In the solution of this question, it ought to be considered, whether the theogonists supposed God to have existed before chaos, and to have created it from nothing; or thought him to have sprung from a pre-existing chaos; or conceived God and matter to have been two co-existing and independent principles; whether they imagined God to have been the soul of nature, informing the eternal mass of matter; or were of opinion, that God forth matter as an emanation from himself; if the latter, whether this emanation was the effect of necessity, or of a free act of volition; whether it was from all eternity, or began at some limited period of duration. It must also be inquired, whether, according to the doctrine of the theogonies, a divine mind interposed in the formation of the world, or the effect was produced by the necessary laws of motion acting upon homogeneous and heterogeneous portions of matter. If the latter of these was their doctrine, it is to be further considered, whether it necessarily follows, that they denied the existence of God, or whether it may not be supposed, that, neglecting all consideration of deity, they only endeavoured to explain the physical formation of the world, by laws originally impressed upon matter by the author of nature.

The theogonies certainly do not suppute God to have been prior in the order of time to matter; they speak of chaos as eternal, and seem to have been wholly unacquainted with the doctrine of creation from nothing. But, on the other hand, they never suppute the Deity to be derived from chaos: for Jupiter is not to be confounded with the Supreme Being, but merely to be considered as the chief of those inferior divinities, who, according to the Grecian theology, were either portions of the divinity, inhabiting and animating parts of nature, or departed spirits of heroes and illustrious beings.
illustrious men, exalted to divine honours. There is no sufficient proof, that Orpheus, Hesiod, or any other Grecian cosmogonist, supposed two independent principles in nature: tor, though they ascribe the origin of evil to Chaos, they might, nevertheless, be of opinion, as we shall find to have been the case with many later philosophers, that matter is derived from God.

There were, perhaps, different opinions among the ancient cosmogonists, concerning the first cause of nature. Some might, possibly, ascribe the origin of all things to a generating force, definite of thought, which they conceived to be inherent in matter, without looking to any higher principle. But it is probable, that the general opinion among them was that which had prevailed among the Egyptians and in the East, and was communicated by tradition to the Greeks, that matter, or chaos, existed eternally with God, and that by the divine energy of emanation, material forms were sent forth from him, and the visible world arose into existence. This principle being admitted, the whole system of the ancient theogonies appears consistent, and a satisfactory explanation may be given of most of the Grecian fables. Upon this supposition, the sum of the doctrine of the theogonies, divested of allegory and poetry, will be as follows:

The first matter, containing the seeds of all future being, existed from eternity with God. At length, the divine energy upon matter produced a motion among its parts, by which those of the same kind were brought together, and those of a different kind were separated, and by which, according to certain wise laws, the various forms of the material world were produced. The same energy of emanation gave existence to animals and men, and to gods who inhabit the heavenly bodies, and various other parts of nature. Among men, those who possessed a larger portion of the divine nature than others, are hereby impelled to great and beneficent actions, and afford illustrous proofs of their divine original, on account of which, they are after death raised to a place among the gods, and become objects of religious worship.

Upon the basis of these notions, it is easy to conceive, that the whole mythological system, and all the religious rites and mysteries of the Greeks, might be founded. Brucker's Hist. Phil. by Enf. vol. I.

Among the most ancient writers, Dr. Burnet observes, that theogony and cosmogony signified the same thing. (See Cosmogony.) In effect, the generation of the gods of the ancient Persians, fire, water, and earth, is apparently no other than that of the primary elements.

THEOLOGICAL CRITICISM. See Criticism.

THEOLOGICAL Prebend. See Prebend.

THEOLOGIUM, formed from θεός, and λόγος speech, or discourse, in the ancient theatre, was a place, or little stage, above that on which the ordinary actors appeared. See Theater.

The theogonium was the place where their gods appeared. It also included the machines on which they depended, and from which they spoke.

There was a theogonium required for the representation of the Ajax of Sophocles, the Hippolitus of Euripides, &c. Scal. Poet. lib. i. cap. 1.

THEOLOGY, compounded of θεός, God, and λόγος discourse, divinity; a science, which instructs us in the knowledge of God, and divine things; or which has God, and the things he has revealed, for its object.

Theology is a science which shews us what we are to believe of God, and the manner in which he would be served.

It is divided into two branches, the natural, and the revealed or supernatural.

THEOLOGY, Natural, is the knowledge we have of God from his works, by the light of nature, and reason.

THEOLOGY, Supernatural, is that which we learn from revelation. See Religion.

THEOLOGY, Poëtic, is the knowledge of the holy Scriptures, and of the signification of them, conformably to the opinions of the fathers and councils; without the assistance of any argumentation. But some will have it, that this ought to be called expository, rather than poëtic.

THEOLOGY, Moral, is that which teaches us the divine laws relating to our manners and actions; in contradistinction to

THEOLOGY, Speculative, which explains and establishes the doctrines of religion, as objects of Faith.

THEOLOGY, Scholastic, or School, is that which proceeds by reasoning; or that derives the knowledge of several divine things from certain established principles of faith. See Scholastic Divinity.

The ancients, according to Varro, Scaevola, and Plutarch, had a three-fold theology; the first poëtic, poëtic, fabulous, which flourished among the poets; and was chiefly employed in the theogony, or genealogy, and history of the gods: to whom all things were attributed, which men, and even the vilest of men, could be guilty of. Nevertheless, the popular religion and worship were in a great measure founded upon that mythology, which run through the whole of their religion, and was of great authority with the people. Many unexceptionable proofs of this are produced by Dr. Leland, in his "Advantage and Necellicity of the Christian Revelation," vol. i. part i. chap. 6.

The second, theological, political, or civil, was that established by the Roman laws, and chiefly embraced by the politicians, priests, and people, as most suitable and expedient to the safety, quiet, and prosperity of the state. This, though not the true, was the vulgar theology, and constituted the public and authorized religion. It was that which the philosophers themselves, whatever private opinions or speculations they might entertain, or dispute of in their schools, universally conformed to in their own practice, and also exhorited others to do so. Varro informs us, that this theology particularly determined what gods they were publicly to worship, what sacred rites they were to observe, and what sacrifices to offer.

Although even the vulgar among the Pagans seem, in general, to have had some notion of one supreme God, yet their theology was properly polytheism; and the providence they acknowledged, was the providence, not of one God, but of many gods. The learned Dr. Cudworth, who seems inclined to put the most favourable construction upon the Pagan theology, acknowledges, that the civil theology, as well as the poëtical, had not only many fantastic gods in it, but an appearance of a plurality of independent deities; several being made supreme in their respective territories or functions. Arifiole (Oper. tom. i. p. 1246. edit. Paris, 1629) intimates, that according to the laws of cities and countries, that is, in the civil or political theology, there seems to be no one absolutely powerful or all-perfect being, but a plurality of gods, one of whom is supposed to be more powerful in one respect, and another in another respect. Besides, the public religion was made up partly of the physical, and partly of the poëtical theology. Those poëtical fables, which Varro cenures as unworthy of the gods, and as ascribing to them actions which none but the vilest of men
THE

men would be guilty of, were not only permitted to be acted on the public theatres, and heard with pleasure by the people, but they were regarded as things pleasing to the gods themselves, by which they were propitiated and rendered favourable; and accordingly they were taken into the public religion. Games were celebrated, and plays were founded upon them; and the public games and plays were on certain occasions considered as acts of religion, encouraged by their deities, and celebrated in honour of them. It is also justly observed, that the images, forms, habits, and ornaments of their gods, their different faces and ages, and the sacred festivals instituted to their honour, had all of them a reference to the fables of the poets and mythologists, and were founded upon them; so that the civil and the fabulous theology might each of them be called civil, and each fabulous. Hence proceeded many absurd and ridiculous, and many immoral and inhuman rites, which were made use of in the worship of their gods, and which were either preferred by the laws, or were established customs, countenanced by the magistrates, and which had obtained the force of laws, and may, therefore, be regarded as belonging to the public religion of the Pagans. See Leland's Christian Revelation, ubi supra, cap. 7.

The third, \textit{natural}, was chiefly cultivated by the philosophers, as most agreeable to nature and reason. The physical or natural theology acknowledged one only supreme God; to which it added \textit{demons} or \textit{spirits}, as mediators between him and man.

Dr. Leland has urged a variety of considerations to prove that, notwithstanding the high encomiums which have been heaped upon the philosophical theology of the Pagans, it was of little use in leading the people into a right knowledge of God and religion, and for reclaiming them from their idolatry and polytheism. To this purpose he observes, that, if the philosophers had been right in their own notions of religion, they could have but little influence on the people, for want of a proper authority to enforce their instructions. The affected obscurity of the Pagan philosophers was another cause which rendered them unfit to instruct the people in religion; to which it may be added, that some of them used their utmost efforts to destroy all certainty and evidence, and to unsettle men's minds as to the belief of the fundamental principles of all religion; and even the best and greatest of them acknowledged the darkens and uncertainty they were under, especially in divine matters. The philosophers themselves were also, for the most part, very wrong in their own notions of the Divinity; they very much corrupted the ancient tradition relating to the one true God and the creation of the world, and endeavoured to account for the formation of all things without the interposition of a Deity. And the opinions of those philosophers who were of a nobler kind, were chargeable with great defects: they generally expressed themselves in the polytheistic strain, and instead of leading the people to the one true God, they spoke of a plurality of gods, even in their most serious discourses; ascribing those works to the gods, and directing those duties to be rendered to them, which properly belong to the supreme. The philosophers likewise referred the people for instruction in divine matters to the oracles, which were managed by the priests; this was particularly the case with Socrates, Plato, and the Stoics.

It was an universal maxim among them, that it was the duty of every wife and good man to conform to the religion of his country; and they not only worshipped the gods of their respective countries according to the established rites, and exhorted others to do so; but when they took upon themselves the character of legislators, and drew up plans of laws, and of the best forms of government, polytheism, and not the worship of the one true God, was the religion they professed to establish. Moreover, they employed their learning and abilities to defend and justify the popular idolatry and polytheism. The worship of inferior deities was recommended by them, under pretence of it tending to the honour of the supreme. Some of the most eminent of them endeavoured to colour over the most absurd part of the Pagan poetical theology, by allegorizing the most indecent fables. They apologized for the Egyptian animal worship, which the generality of the vulgar Pagans in other nations ridiculed. They vindicated idolatry and image-worship, as necessary to keep the people from falling into irreligion and atheism; and besides, some of the more refined philosophers were against any external worship of the supreme God.

Many of the philosophers, and of the learned and polite Pagans, denied a providence. Of those who professed to acknowledge it, some confined it to heaven and heavenly things; others supposed it to extend to the earth and to mankind, yet so as only to exercise a general care and superintendence, but not to extend to individuals; others, again, supposed all things, the least as well as the greatest, to be under the care of providence; but they ascribed this not to the supreme God, who, they thought, was above concerning himself with such things as these, and committed the care of them wholly to inferior deities. See the illustration and proof of these several allegations by Dr. Leland, ubi supra, cap. 10—17.

\textit{Theon}, in \textit{Biography}, a mathematician of the Platonic school, was a native of Smyrna, and flourished under the emperors Trajan and Adrian. His mathematical treatises are said to have been written for the purpose of elucidating the philosophy of Plato; and his discourses, treating of geometry, arithmetic, music, astronomy, and the harmony of the universe, may serve to throw some light upon the Pythagorean system. Part only of his work, "De is quæ in Mathematicis ad Platonis sectionem utilia sunt," or that which relates to arithmetic and music, has been published. The remainder, which pertained to astronomy and geometry, is said to have been preferred in the Ambrobian library at Milan. Ptolemy refers to his astronomical observations. Brucker in \textit{Enfield, Montucla Hist. des Math.}

Another mathematician of the same name belonged to the Alexandrian school, and flourished about A.D. 356. He was the father of the learned but unfortunate Hypatia; his works are various among these we may mention his "Recensio Elementorum Euclidis," published by Commandini; his "Oeconomiae Naturae," and Fragmenti Commentarii in Ptolomei Canonem expeditum, five Recensiones fucitans Chronologica regem a Nabinahflarid Antinomum Pius; "Scholia in Aritm," said to be interpolated; and "Commentarius in Magnum Ptolemai Syntaxum," which is incomplete. Montucla.

\textit{Theopaschites, Theopaschite, in Ecclesiastical History}, a sect of heretics in the fifth century, the followers of Petrus Fullenis, or Peter the Fuller, who ulurped the see of Antioch; and after having been several times
times deposed, and condemned, on account of his opposition to the council of Chalcedon, was at last fixed in it, A.D. 482, by the authority of the emperor Zenon, and the favour of Acacius, bishop of Constantinople; whence they are also sometimes denominated *Pullonian*.

Their distinguishing doctrine was, that the whole Trinity suffered in the passion of Jesus Christ. This hereby was embraced by the Eutychian monks of Scythia, or, according to La Croze, of Egypt; who using their utmost efforts to make it obtain, raised great disorders towards the beginning of the following century. It was condemned, at its first rite, in the councils of Rome and Constantinople, held in 483. It was again revived in the ninth century, and again condemned in a council at Rome, held in 862, under pope Nicholas I.

F. le Quien, in his notes on Damascenus, says, that the fame error had been taught before Pullenius, by Apollinarius, whose disciples were the first that were called Theophanes, or Theopaschites.

**THEOPHANES**, in *Biography*, a Greek historian and poet, was of noble extraction, and born at Mitylene, in the island of Lesbos. About the commencement of the Mithridatic war, he is supposed to have come to Rome in his youth; and when Pompey was appointed to the chief command against Mithridates, he took Theophanes with him to record his exploits, procuring for him the citizenship of Rome, and adding to his name those of "Cornelius Balbus." It is also supposed that it was principally on his account, that on his return he visited Lesbos, and restored to the Mitylenians the privileges of which they had been deprived by the Roman senate. At Rome he connected himself with the most distinguished citizens, and he was deputed to Alexandria for the confirmation of treaties of alliance with Ptolemy Auletes. After the defeat of Pompey at Pharsalia, he accompanied him in his flight; and by his advice this commander declined to take refuge with Juba, king of Mauritania, and failed to Egypt, where he met his fate. Theophanes afterwards joined the party of Caesar. The most important of his writings was a "History of the Wars of the Romans, in different Countries under the Command of Pompey." Of this work there remain only five fragments, quoted by Strabo, Plutarch, and Stobaeus; but Plutarch is supposed to have made great use of his authority in his life of Pompey, though he does not speak favourably of his character. He says, "Theophanes affirms, that in the private papers of Mithridates taken at Cannae, there was found a memorial, composed by Rutilius (Rufus), exhorting Mithridates to massacre all the Romans in Asia. But it is generally believed, that this was a malicious fiction of Theophanes to blacken Rutilius, whom probably he hated, because he was a perfect contrast to himself; or it might be invented by Pompey, whose father was represented by Rutilius in his history, as one of the world of men." Rutilius was a man of such excellent character, as to be incapable of the crime with which he is charged; and without doubt such a falsification of history, for base and private purposes, is sufficient to destroy all esteem for the writer.

Of the poetry of Theophanes, which was celebrated in his time, there remain only two epigrams, inserted in the *Anthologia* Vossii. Morei. Gen. Biog.

**THEOPHANES**, George, a Constantinopolitan Greek, of a rich and noble family, married young, but from superlative motives lived in a state of celibacy. He afterwards became a monk. At the general council held in 787, he was present, and was treated with respect. When Nichphorus, patriarch of Constantinople, was exiled by the emperor Leo the Armenian, Theophanes paid him extraordinary honours, and was himself banished to the isle of Samothrace, where he died in 818. His chronicle, commencing where that of Syncellus terminated, was extended to the commencement of the reign of Michael Caphalata. This was printed at Paris, with the Latin version and notes of F. Goar, under the care of Combefis, in 1665, fol. It is valuable for its facts, but displays the credulity and weak judgment of a superstitious mind. *Vollius*. *Gen. Biog.*

**THEOPHANES PROKOPOVITCH**, the son of Procopius, archbishop of Novgorod, a learned Russian historian, and miscellaneous writer, was born at Kiev in the year 1681, and having studied under his uncle Theophanes at the Bratki convent in Kiev, travelled into Italy in his eighteenth year. In three years he completed his course of preparatory study, and then returned to his native town, where he read lectures on the Latin and Slavonian art of poetry, at the seminary where he had received his education. Having assumed the monastic habit, with the name of Theophanes, he was appointed, at the age of twenty-five, prefect of the seminary, and professor of philosophy. By a Latin oration and a sermon, delivered before czar Peter the Great, he attracted his notice, and was chosen his companion in his war against the Turks. In 1711 he was made abbot of the monastery of Bratskoi, rector of its seminary, and professor of divinity. By enfuring the ignorance of the clergy, and endeavouring to excite a taste for literature, he recommended himself to the czar as a proper coadjutor in his plans for re-forming the church. He was accordingly placed at the head of the yod, in the new ecclesiastical establishment, the plan of which he had prepared, and in 1718 he was promoted to the bishopric of Pleskof. In 1720 he was created archbishop of the same diocese, and soon after the accession of Catharine I., he was advanced to the rank of archbishop of Novgorod, and metropolitan of all Russia; and in this station he died in 1730. This prelate was in a high degree the patron of literature, and engaged in a variety of ways, by his personal munificence and labour, in promoting it. His works were sermons and theological tracts, a treatise on rhetoric, and rules for composing Latin and Slavonian poetry, Latin verses, and more especially the Life of Peter the Great, terminating with his battle of Pultawa. Le Clerc affirms that he endeavoured to persuade Peter to introduce the Protestant religion into Russia, and that this event would have taken place, if it had not been prevented by Peter's death. The prelate's education at Rome, and the high rank he sustained in his own church, render this anecdote improbable. *Coxe's Travels in Russia*.

**THEOPHANIA, Θεοφάνεια,** formed of Θεός, God, and Φανερός, visible, in Antiquity, a festival observed by the Delphians upon the day on which Apollo first manifested himself to them.

**THEOPHANY, in Church History,** is sometimes used in the same sense with *Epiphany*.

**THEOPHILA, in Ancient Geography,** a town of India, on this side of the Ganges.

**THEOPHILE, named Vivald, in Biography,** a French poet, was born at Clerae, in the Agenois, about the year 1590. By education he was a Calvinist, but in his conduct and writings he was licentious. In 1619 he withdrew to England, and unsuccessfullly attempted to introduce himself to king James. After his return he abjured Calvinism, but his manners remained the same. On account of a work entitled "Le Paralle Satirique," published in 1622, and attributed to him, in which were several pieces offensive to decency...
decrecy and religion, he was prosecuted. Being arrested in Picardy, he was brought to Paris, and thrown into the dungeon that had been occupied by Ravalliac, where he remained for two years. He was at length released by the parliament, and sentenced to banishment. The duke of Montmorency took him under his protection, and at his hotel he died in 1626. His writings are partly prose and partly verse. His verses are negligent and irregular, but they display genius and imagination. His works consist of odes, elegies, sonnets, &c.; tragedies; a dramatic dialogue on the immortality of the soul, entitled "Socrate Mourant;" apologies for himself, and letters. A collection of his poems and apologies was printed at Rouen in 1627, 8vo.; and his friend Mairet printed his French and Latin letters at Paris, in 1642, with his portrait prefixed. Nouv. Dict. Hist. Gen. Biog.

THEOPHILUS, emperor of Constantinople, was the son of Michael the Stammerer, and succeeded his father in 829. He began his reign with the exercise of justice in its utmost rigour, heedless not only of the claims of gratitude, but of the feelings of humanity. His father had been indebted for his life and crown to the murderers of his predecessor Leo IV. Theophilus, under a preterence of paying the debts of his father to those who had contributed to his elevation, fummoned them, among other considerable persons in the empire, to his presence; and deiring the former to withdraw into an adjoining apartment, that their claims might be examined, he ordered them, on their own confession, to be capitaliy punished. In another cafe, a poor woman threw herself at his feet, complaining of the injury which she had sustained from a powerful neighbour (the empress's brother), who had raised the wall of his palace so high, that his humble dwelling was deprived of light and air. Theophilus gave her the palace, with the ground upon which it stood, and caused the offender to be striped and scourged in the public square of the city. The effect of his singular rigour, though altogether indefensible, was, that a scrutiny of seventeen days could not discover a single crime or abuse in the court or city.

During this emperor's whole reign he was engaged in wars with the Saracens, the detail of which we shall omit. Theophilus died in 842, after a reign of more than twelve years. His zeal against the worship of images has caused his character to be treated with great severity, and his faults to be exaggerated. Although he was inexcusably rigorous in his administration, he was a reformer of manners. Of his superiority to avarice, and high Ideas of the dignity of the regal character, the following anecdote furnishes an instance. Seeing one day a merchant-ship, which was deeply laden, entering the harbour of Constantinople, he ordered the mariners to whom it belonged: they replied, "to the empress." "God has made me (he exclaimed) a prince, and am I your a merchant? If princes trade, their subject must starve!" he then ordered the vessel to be set on fire with all her cargo. Anc. Un. Hist. Gibbon's Rom. Hist.

THEOPHILUS, bishop of Antioch, was ordained to this see in 168 or 170, and governed it for twelve or thirteen years. In his zeal against herey, he wrote against Marcion and against Hermogenes, and he composed other tracts, of which are preferred. We have also extant three books against Autolycus, a learned heathen, in which he displays great learning, and from which it appears that he had once been a heathen. These works afford, as it is said, the earliest example of the use of the term "Trinity," applied by the author to the three persons of the Godhead. Some have supposed that he approaches to Ariana, when he afferts that the Word may exist in place, and that he was gotten in time. Theophilus's books to Autolycus were published in Latin by Conrad Gfner at Zurich, in 1546, and were inserted in the "Orthodoxographia," Balf, 1555. They were annexed in gr. and Lat. to the Supplement of the "Bibliotheca Patrum," 1624; and were printed at the end of St. Justin's Works by Morelle. Lardner.

THEOPHILUS, bishop or patriarch of Alexandria, of violent and turbulent disposition, was ordained to that see in 385. He gained reputation and influence by his zeal in destroying the temple of Serapis, and other pagan temples of Egypt in 389. (See THEODOSIUS.) He was, under the guile of a friend, a secret enemy to John Chrysofom, after he had been ordained to the see of Constantinople in 397. Without much regard for religion, he was the zealous champion of orthodoxy; and having called a council at Alexandria in 399, he prevailed with the assembly to condemn all the followers of Origen, and with the affiance of a band of soldiers, compelled them to abandon their residence on mount Nitria. The poor monks, falling to find a secure refuge, repaired to Constantinople, to lay their complaints before the emperor. The humanity of John Chrysofom irritated Theophilus, who was employed by the empress Eudoxia, for prosecuting her revenge against Chrysofom. Accordingly, he arrived at Constantinople at the head of a body of Egyptian sailors and dependent bishops, avowing that he was going to depose John. His purpose was executed at the synod of Chaledon in 403. (See CHRYSOSTOM.) His malignity pursued this venerable prelate in his exile, by a libel filled with abusive expressions, which was translated at his request by Jerom, from Greek into Latin. Theophilus died at Alexandria in 412. The most confiderable of his works was a large treatise against Origen. Some of his epistles are found among those of Jerom, and some of his canonical epistles are contained in the collections of Zonaras and Balfam. Of this prelate Dupin has given the following character: "There is nothing in the writings of Theophilus that can turn to his commendation; they are obscure, unintelligible, and full of falte and impatient reasonings and reflections. He was a good politician, but a bad author. He knew better how to manage a court intrigue, than to resove a question in divinity. The only rule for his opinions was his interest or his ambition. He was ready to embrace any opinion or party that suited his purpose, without examining whether it was just or reaonable." Dupin. Lardner. Gibbon.

Gen. Ch. Cal. Perianthus inferior, small, of one leaf, in five deep, obtuse, permanent segments. Cor. of one petal, bell-shaped, spreading, cut more than half way down into five rounded equal segments. "Nectary five small, ovate, obtuse glands, thickest at the point, lying upon the segments of the corolla." — Jacq. Stam. Filaments five, thread-shaped, united below to an internal membrane, fo as to form a short, thick, furrowed column, crowned with a five-rayed horizontal disk; anthers five, of two separate oblong lobes,
loves, attached to the sides of each segment of the disk, underneath. *P. fill.* German superior, ovate; style cylindrical, the length of the filaments, erect; stigma in five obtuse lobes. **Peric.** Berry globose, coated, of one cell. Seeds several, roundish, somewhat compressed.

Eff. Ch. Corolla bell-shaped, in five obtuse spreading segments, with a nectary of five incumbent glands. Berry coated, of one cell, with several seeds.

1. *Th. americana.* Large-fruited Theophrastus. Linn. Sp. Pl. 212. Willd. n. 1. Swartz Obsl. 59. (Eresia foliolis aquifolii longijulmis; Plum. Ic. 119. t. 126.)—Leaves obtuse. Clusters terminal, erect.—Native of barren dry bushy stony places in Hispaniola. Swartz. Stem tubby, one or two feet high, erect, simple, leafy in its upper half, round, thorny, clothed with rusty down. Leaves opposite or whorled, on very short stalks, erect, oblong-lanceolate, obtuse, tapers at the base, very rigid, serrated; their ferratures alternately inflexed and reflexed, each tipped with a small, prominent, rigid, black-pointed spine. *Flower-flake* thick, rufous, closely pressed to the stem. Clusters short, terminal, from the midst of the terminal leaves, many-flowered, partial *flower-flake* numerous, short, curved, single-flowered. *Flower* two inches in diameter, yellow, brittle, often for the most part hollow or empty, its receptacle juicy at the bottom. Seeds black, hard, attached by their base. Swartz. We presume the clusters, from Plummer's figure, to be erect, and the seeds numerous.

2. *Th. floribunda.* Small-fruited Theophrastus. Jacq. Coll. v. 4. 136. Hort. Schoenbr. v. 1. 62. t. 116. Willd. n. 2.—Leaves acute. Clusters lateral, drooping.—Native of the Caracas. It flowered in the vase at Schoenbrunn from August till November. The stem is said to be twenty feet high, but always unbranched. Leaves imperfectly whorled, near two feet long, reaching, with spiny ferratures, smooth, of a dark shining green, with numerous transverse veins from the mid-rib. Clusters numerous, scattered between the whorls of leaves, lank, drooping, a span long, of numerous little orange-coloured or scarlet flowers. Fruit in its native country about an inch in diameter, with about four seeds; but in the garden it did not attain more than half that size, and perished only one. If there be no mistake in Dr. Swartz's description of the first species, there is a prodigious difference between the stature of the two. Yet we have a suspicion, that they may possibly not be more than varieties of each other. As to the generic character, Plummer's representation of the parts of the flower is too imperfect for us to suppose him more right than the faithful Jacquin. Swartz's description may easily be reconciled with the *Hortus Schoenbrunnensia.*

THEOPHRASTICS, a name given to the followers of Parmeicus, from his name Theophrastus.

THEOPHRASTUS, in *Biography,* a distinguished Greek philosopher, the favourite pupil of Aristotle, and nominated by him as his successor in the school of the Lyceum, was born at Eresin, a maritime town of Lesbos, in the second year of the 102d Olympiad, B.C. 371. His first rudiments of education were received under Alcippus in his own country, and being sent by his father to Athens, he became first a disciple of Plato and afterwards of Aristotle. Such were his natural talents, that, under such tuition, he made great progress both in philosophy and eloquence: so that his original name, Tyrtamus, was changed, either by his master or his followers, into Theophrastus. After he undertook the Peripatetic school in the year B.C. 323, his reputation was so distinguished, that the number of his scholars was about 2000. His erudition and engaging manners recommended him to the notice of Caffander and Ptolemy; by the former he was invited to Macedon, and by the latter to Egypt; and among the Athenians he was so great a favorite, that, when he was accused by one of his enemies of teaching impious doctrines, the accuser could not without difficulty escape the punishment which he endeavoured to bring upon Theophrastus. Theophrastus is no less highly esteemed for his generosity and public spirit, than for his industry, learning, and eloquence. He is said to have twice saved his country from the oppression of tyrants; and he contributed liberally towards defraying the expense of public meetings held by philosophers for learned and ingenuous conversation. In the public schools he appeared, after the manner of Aristotle, in an elegant dress, and was very attentive to the graces of eloquence: and hence it is said he obtained the appellation of Theophrastus, the divine speaker. Towards the close of life, which was prolonged to the age of 85 years, he became very infirm, and was conveyed to the school in a carriage. In contemplating the shortness of life, he expressed great regret; complaining that long life was granted to flags and crows, to whom it was of little value, but was denied to man, who, if it were of longer duration, might attain the summit of science: whereas now, as soon as he arrives within sight of it, he is taken away. His last advice to his disciples was, that since it is the lot of man to die as soon as he begins to live, they should take greater pains to enjoy life as it passes, than to acquire posthumous fame. A large body of Athenians attended his funeral.

The works of Theophrastus comprehended a variety of subjects, and were numerous. His doctrine differed in some respects from that of his master Aristotle. He taught that the predicaments, or categories, were as numerous as the motions and changes to which beings are liable; and that among motions, or changes, are to be reckoned defiles, appetites, judgments and thoughts. He maintained, that all things are not produced from contraries; but some from contraries, some from similar causes, and some from simple energy; that motion is not to be distinguished from action; and that there is one divine principle of all things, by which all things subsist. By this divine principle, it is thought that Theophrastus meant the First Mover, without whom other things could not be moved, and therefore could not subsist. Of his moral maxims, the following are the most worthy of notice. "Respect yourself, and you will never have reason to be ashamed before others. Love is the passion of an indolent mind. Blustering is the complexion of virtue. Time is the most precious expenditure."

Few of his works, of which Diogenes Laertius enumerates more than 200, have reached our time: of these, the most famous is entitled "Characters," describing different moral classes of men, such as the flatterer, the impudent, the disincontented, the garrulous, the superfluous, &c.; so distinguished and described, as to shew great knowledge of mankind. Of his other works on natural history, the principal are his "History of Plants," in nine books, which Haller has particularly recommended to the notice of botanical students; "On the Causes of Plants," relating chiefly to the natural and artificial means of bringing them to maturity; to agriculture and horticulture; to the tastes and odours of vegetables; "On Stones;" "On Winds;" "On Fire;" "On Honey;" "On the Signs of Fair Weather, and of Tempests and Rain;" "On Animals which change their Colour;" "On Animals which are born suddenly;" "On Fish which live out of Water." Theophrastus ranks amongst the most distinguished of the ancients for comprehensive genius and diligent inquiry into nature. The last edition of the whole extant works of Theophrastus is that

Vol. XXXV.
of Dan. Heimius, Greek and Latin, fol. Lugd. Bat. 1613. Of his history of plants, the most complete is that of Budaeus, Greek and Latin, fol. Amst. 1644. Among the most esteemed editions of his "Characters," which are numerous, we may reckon those of I. Cusabon, of Neder- 

THEOPHYLACT, named Simocatta, a Greek historian, a native of Greece, but of Egyptian origin, flourished about A.D. 612. His history of the reign of the emperor Maurice is comprised in eight books, and terminates with the massacre of this prince and his children by Phocas. Cusabon reckons Simocatta one of the belt of the later Greek historians. The work just mentioned was printed at the Louvre, in 1647, fol. and forms a part of the Byzantine historians. An edition of his "Epitomes, Moral, Rural, and Amatory," was given by Aldus. His "Physical Problems" were published first by Vulcanius at Leyden, and afterwards by Andrew Schottus. His "History of the Habitable World" is cited by Euthamius, in his Commentaries on the Periplus of Dionysius. Gen. Biog.

THEOPHYLACT, archbishop of Acris, the capital of Bulgaria, was a native of Constantinople, and flourished under the emperors Michael Ducas, Nicephorus Botoniates, and Alexis Comnenus. After his elevation to the archbishopric of Acris, by the persuasion of the wife of Ducas, he diligently laboured in propagating the Christian faith, and composed several works, which give him rank among the principal ecclesiastical writers of his age. The time of his death is not known; but he was living in 1071. His "Commentaries on the Four Gospels, the Acts of the Apostles, and the Epistles of St. Paul," which are his chief work, are for the most part abridged from Chryso- 
tom and others. He also wrote "Commentaries on the Minor Prophets." Several editions of his Commentaries have been published in Greek and Latin, and also in Latin only. "Seventy-five Epitomes" of this author were published by Meurinus, in Greek, in 1617, and a Latin translation in 1632. Some other tracts have been attributed to this author. Dupin says, that the Commentaries of Theophylact are very useful for the literal explanation of the Scriptures; and Lardner observes, that he quotes no forged writings or apocryphal books of the New Testament, many of which he excludes by his observation on John, i. 31—34. that Christ wrought no miracle in his infancy, or before the time of his public ministry. Dupin. Lardner.

THEOPNEUSTÆ, Θεόπνευστη, formed of Θεός, God, and πνεῦμα, I breathe, an epithet given to enthusiastic diviners.

THEOPOLIS, in Ancient Geography, a town of Gallia Narbonenensis, belonging to the Aventici, N.E. of Forum Novum.

THEOPROPIA, Θεοπρουπία, formed of Θεός, God, and πρᾶξις, I excel, a designation given to oracles. See Oracle.

THEOPSIS, Θεόπνευσις, formed of Θεός, God, and πνεῦμα, I live, in Mythology, denoted the appearance of gods. Cicero, Plutarch, Arnobius, and Chrysoform, mention appearances of this kind.

THEORÆ, THEORIA, or THEORIA, a musical instrument, made in form of a large lute; except that it has two necks, or juga, the second and longer of which fitts the four leaf rows of chords, which are to give the deepest sounds. See LUTE.

The word is formed from the French teorbe; or theorbe, and that from the Italian teorbe, which signifies the fame, and which some will have to be the name of the inventor.

The theorbo is an instrument which for many years succeeded to the lute, in the playing of thorough basses; it is said to have been invented in France, by the fieur Hottemann, and thence introduced into Italy, &c.

The only difference between the theorbo and the lute is, that the former has eight bass or thick strings twice as long as those of the lute; which excess of length renders their sound so exceedingly soft, and keeps it up so long a time, that it is no wonder many prefer it to the harpsichord itself. At least it has this advantage over it, that it is easily removed from place to place, &c.

All its strings are usually single; though there are those who double the bass-strings with a little octave, or the small strings with an unison; in which case, bearing more resemblance to the lute than the common theorbo, the Italians call it the arcithuto, or arch-lute.

THEOREM, in the Mathematical Method, a proposition which terminates in theory, and which considers the properties of things already made or done.

Or, a theorem is a speculative proposition, deduced from several definitions compared together. Thus, if a triangle be compared with a parallelogram standing on the same base, and of the same altitude, and partly from their immediate definitions, and partly from other of their properties already determined, it is inferred, that the parallelogram is double the triangle; that proposition is the theorem.

Theorem stands contradistinguished from problem.

There are two things to be chiefly regarded in every theorem, viz. the proposition and the demonstration: in the first is expressed what agrees to some certain thing under certain conditions, and what does not.

In the latter, the reasons are laid down, by which the understanding comes to conceive, that it does or does not agree to them.

Theorems are of various kinds: as,

Theorem, Universal, is that which extends to any quantity without restriction, universally. As this, that the rectangle of the sum and difference of any two quantities is equal to the difference of their squares.

Theorem, Particular, is that which extends only to a particular quantity. As this: in an equilateral right-lined triangle, each of the angles is sixty degrees.

Theorem, Negative, is that which expresses the impossibility of any affection. As, that the sum of two biquadrate numbers cannot make a square number.

Theorem, Local, is that which relates to a surface. As, that triangles of the same base and altitude are equal.

Theorem, Plane, is that which either relates to a rectilinear near surface, or to one terminated by the circumference of a circle. As, that all angles in the same segment of a circle are equal.

Theorem, Solid, is that which considers a space terminated by a solid; that is, by any of the three conic sections. E. gr. this: that if a right line cut two asymptotic parabolas, its two parts terminated by them shall be equal. See Solid.

Theorem, Reciprocal, is one whose converse is true. As, that if a triangle have two equal sides, it must have two equal angles: the converse of which is likewise true, that if it have two equal angles, it must have two equal sides.

Theorem, in Algebra and Analysis, is sometimes used to denote a rule, particularly when that rule is expressed in symbols or formulae, of which there is of course a great number; but of these, some few, either from their impor-
Theorem.

Binomial Theorem, or Newtonian theorem, is a general formula for the development of any binomial of the form \((a + x)^n\); viz.

\[
(a + x)^n = \sum_{k=0}^{n} \binom{n}{k} a^{n-k} x^k
\]

and

\[
\binom{n}{k} = \frac{n!}{k!(n-k)!}
\]

See Binomial Theorem.

Briggs's Theorem.—There are more than one formula that have received this designation, but we believe that the following is generally understood to be implied; viz.

"The nth differences of any consecutive nth powers, or of any nth powers whose roots are in arithmetical progression, are expressed by the formula

\[
n(n-1)(n-2)(n-3)(n-4) \ldots 1 \cdot d^n
\]

d being the common difference of the roots."
Theorem.

But since \( n - n = 0 \), the \((n + 1)\)th differences \(= 0 \); and since \( w^2 - w = 0 \), the \(n\)th differences become

\[ n (n - 1) (n - 2) (n - 3) \ldots \cdot 3 \cdot 2 \cdot 1 \text{ d.} \]

It may not be amiss to observe, that we have only employed the first term of the several orders of differences, which however is sufficient for our purpose, since it is obvious that the \(n\)th difference can have but one term; for the development of \((p + d)^n\) gives \(n + 1\) terms; and since one term vanishes with every difference, the \(n\)th difference will have \(n\) terms, the second \(n - 1\), the third \(n - 2\), &c.; and consequently the \(n\)th difference will have \(n - (n - 1) = 1\) term only. See Irish Transactions, vol. xi. or Monthly Review, vol. lxxiv.

Cotes’ Theorem, or Cotesian Theorem.—The geometrical properties of this very interesting theorem are explained under the article COTESIAN Theorem; it will only be necessary therefore in this place to state the theorem analytically. In this case, the general enunciation is:

"All the imaginary roots of the binomial equation \(x^n - 1 = 0\), are contained in the general formula \(x^n = 2\cos \left(\frac{2k\pi}{n}\right)\) and \(\sin \left(\frac{2k\pi}{n}\right)\), and those of \(x^n + 1 = 0\), in the formula \(x^n - 2\cos \left(\frac{(2k + 1)\pi}{n}\right)\) and \(\sin \left(\frac{(2k + 1)\pi}{n}\right)\), \(k\) being any integer not divisible by \(n\), and \(\pi\) representing the semi-circumference."

See Reciprocal Equations.

Euler’s Theorem was used to denote the theorem or formula first given by this author, for ascertaining the direct integrability of differential equations, which is as follows. The equation being reduced to the form

\[ M\, d\, x + N\, d\, y = 0, \]

where \(M\) and \(N\) are functions of \(x\) and \(y\); if \(M\, d\, y = N\, d\, x\), then the integration may be obtained by a direct process; but if this equality has not place, the integration can then only be effected by indirect means, which frequently involve considerable difficulty.

Fermat’s Theorem.—There are several theorems in the theory of numbers which are due to this ingenious analyst; but that which is more particularly designed by Fermat’s theorem is this; viz. "Neither the sum nor difference of any two integral powers, above the square, can be equal to a rational power of the same dimension." Or, which is the same, the equation

\[ x^n \pm y^n = z^n \]

is always impossible in rational numbers, if \(n\) be greater than 2.

The cases of \(n = 3\) and \(n = 4\) have been demonstrated; but notwithstanding the numerous attempts of the most celebrated analysts of the last and of the present age, the case of \(n = 5\), and all the succeeding values of \(n\), remain without demonstration; and as this is now the only theorem of this author which has not submitted to the power of the modern analysts, the National Institute of France has made it the subject of the prize of 3000 francs, to be decided by 1818.

Under the article Numbers, amongst the miscellaneous propositions, we have mentioned another theorem of Fermat’s, which had not then been demonstrated, but which has since been effected by M. Cauchy, corresponding member of the Institute. The reader will also find some farther remarks relative to the equation \(x^n \pm y^n = z^n\), under our article Power.

Gauß’s Theorem is used to denote a theorem invented by this distinguished mathematician, for the solution of certain binomial equations. We have seen, in the article Reciprocal Equations, in what manner the roots of binomial equations may be obtained by means of a table of sines and cosines; but Gauß’s theorem is the converse of this, and shews in what manner the sines and cosines of certain angles may be obtained, by the numerical solution of such equations. See Polygon.

Guldin’s Theorem is the same as the Centrobaric Method; which fee.

Lagrange’s Theorem is commonly used to denote the general formula assumed by Lagrange as the foundation of his theory of functions; which may be thus enunciated.

"If \(z\) be any function whatever of a variable quantity \(x\), and if \(x\) changes its value, and becomes \(x + \delta\), then the \(z(x + \delta)\) may be reprented or resolved into a series of the form

\[ \phi(x + \delta) = \phi(x) + \frac{d\phi}{dx} \delta + \frac{1}{2!} \frac{d^2\phi}{dx^2} \delta^2 + \ldots + \frac{1}{n!} \frac{d^n\phi}{dx^n} \delta^n + \&c. \]

in which the co-efficients of the powers of \(\delta\) are new functions of \(x\), derived from the primitive function \(\phi\), independent of \(\delta\); and, moreover, that every co-efficient is derived from the preceding one, in the same manner as the first \(\delta\) derived from the original function." See Functions.

Leibnitz’s Theorem is a theorem proposed by this author for differentiating under the sign \(\int\), and it may be exhibited under the form

\[ \frac{d}{dx} \int M \, dx = \int \frac{dM}{dy} \, dx, \]

where \(M = \frac{d}{dy} u\) being any function of \(x\) and \(y\).

Since \(u = \frac{d}{dx} x\), by the known principles of the differential calculus; if we make \(u = \int M \, dx\), we shall have

\[ \frac{d}{dx} u = M, \frac{d^2}{dx^2} u = \frac{dM}{dy}, \text{ and integrating with regard to } x, \]

we shall find

\[ \int \frac{d^2}{dx^2} u \, dx = \int \frac{dM}{dy} \, dx = \frac{d}{dy} u + \int \frac{dM}{dy} \, dx. \]

This is called by Leibnitz, differentia et curva in curvam, because in the question which he proposed to resolve, he passed from one curve to another of the same species, by making one of the constant quantities variable. See La Croix "Calculus Integral."

Maclaurin’s Theorem is a formula which we owe to this author for expressing any function \(y\) of a variable quantity \(x\); viz. adopting the differential notation,

\[ y = (y) + \left(\frac{dy}{dx}\right) x + \frac{1}{2!} \left(\frac{d^2y}{dx^2}\right) x^2 + \frac{1}{3!} \left(\frac{d^3y}{dx^3}\right) x^3 + \&c. \]

where \((y), \left(\frac{dy}{dx}\right), \left(\frac{d^2y}{dx^2}\right), \&c.\) represent what these several quantities become when \(x = 0\).

Let \(y = A + Bx + Cx^2 + Dx^3 + \&c.\), differentiating, and dividing by \(dx\), we have

\[ \frac{dy}{dx} = B + 2Cx + 3Dx^2 + \&c. \]

\[ \frac{d^2y}{dx^2} = 2C + 2 \cdot 3Dx + \&c. \]

\[ \frac{d^3y}{dx^3} = 2 \cdot 3 \cdot 4D + \&c. \]
consequently, when $x$ in each of these $= 0$, we have
\[
(y) = A, \left(\frac{d^3y}{dx^3}\right) = B; \left(\frac{d^2y}{dx^2}\right) = C; \left(\frac{dy}{dx}\right) = D;
\]
therefore,
\[
y = (y) + \frac{d}{dx} + \frac{1}{2!} \left(\frac{d^2y}{dx^2}\right) x^2 + \frac{1}{3!} \left(\frac{d^3y}{dx^3}\right) x^3 + \&c.
\]
See Maclaurin’s “Fluxions,” and Boucharlat’s “Calcul Differéncial, &c.”

**Moivre’s Theorem.** See the next article.

\[
(A + A x + A x^2 + A x^3 + \ldots + A x^n)^m = A^m + 3 m A B \left(\begin{array}{l}m \cr 2\end{array}\right) + \frac{4 m A B}{3 A} \left(\begin{array}{l}m \cr 3\end{array}\right) + \&c.
\]

Where $B = A^n$, and $B, B, B, &c.$ are the co-efficients of the terms immediately preceding those in which they first appear; and the manner of applying this theorem to any particular case, is by substituting the numbers or letters in the given example for $A, A, A, &c.$ and the numerical value of $m$ for $m$. It would lead us too far to attempt the demonstration of this theorem in this place, we must, therefore, refer the reader for such information to the works above-mentioned.

**Newtonian Theorem.** See Binomial Theorem.

**Taylor’s Theorem,** an elegant and valuable formula, which was first published by Dr. Brook Taylor in his “Methodus Incrementorum,” which is as follows; viz.

"If $Y$ represent any function whatever of the variable quantity $x$, and if $x$ be increased by any difference $\Delta x$, the value of $Y$, viz. $Y + \Delta Y$, becomes, (employing the differential notation)

\[
Y + \Delta Y = Y + \Delta x \frac{dY}{dx} + \frac{\Delta^2 x^2}{2!} \frac{d^2Y}{dx^2} + \frac{\Delta^3 x^3}{3!} \frac{d^3Y}{dx^3} + \&c.
\]

or $\Delta Y = \frac{\Delta x dY}{dx} + \frac{\Delta^2 x^2 d^2Y}{2! dx^2} + \frac{\Delta^3 x^3 d^3Y}{3! dx^3} + \&c.$

The demonstration of this celebrated theorem is given very concisely by La Croix, on the following principles.

Let $Y$ be any function of $x$, and let $Y'$ denote what this function becomes, when $x$ becomes $x + h$, we may write

\[
Y' = A + B h + C h^2 + D h^3 + \&c.
\]

in which development, it is obvious that $A, B, C, &c.$ are functions of $x$.

If now we difference this equation with $h$ variable and $x$ constant, we obtain, dividing by $d h$,

\[
\frac{Y'}{d h} = B + 2 C h + 3 D h^2 + \&c.
\]

Again, differentiating with $x$ variable and $b$ constant, we have

\[
\frac{Y''}{d x} = \frac{d A}{d x} + \frac{d B}{d x} b + \frac{d C}{d x} b^2 + \frac{d D}{d x} b^3 + \&c.
\]

But as $x$ and $b$ enter exactly in the same manner, it follows that $\frac{d}{d x} = \frac{Y'}{d x} \frac{d}{d h}$ whence the first of these series is equal to the second; equating, therefore, the co-efficients of the like powers of $h$, we have

\[
B = \frac{d A}{d x}, C = \frac{d B}{d x} b, D = \frac{d C}{d x} b^2 + \&c.
\]

Now

\[
A = Y, B = \frac{d Y}{d x}, C = \frac{d^2 Y}{d x^2}, D = \frac{d^3 Y}{d x^3};
\]

whence

\[
Y' = Y + \frac{d Y}{d x} x + \frac{d^2 Y}{d x^2} b + \frac{d^3 Y}{d x^3} b^3 + \&c.
\]

Or writing

\[
Y'' = Y + \Delta Y, x + b = x + \Delta x,
\]

we have

\[
\Delta Y = \Delta x \frac{d Y}{d x} + \Delta x^2 \frac{d^2 Y}{d x^2} + \Delta x^3 \frac{d^3 Y}{d x^3} + \&c.
\]

See La Croix “Calcul Differéncial,” p. 21.

**Trinomial Theorem** is only a particular case of the Multinomial Theorem, which see.

**Wilson’s Theorem** is a curious formula relative to prime numbers, published first by Waring in his “Meditations Algebraicae,” which is as follows.

"If $n$ be any prime number, then will

\[
1 \cdot 2 \cdot 3 \cdot 4, &c. (n - 1) + 1
\]

be divisible by $n$.”

This curious theorem was not demonstrated by Sir John Wilson, who first discovered it, nor by Waring, by whom it was first made public; it has, however, since received different demonstrations from Lagrange, Gauss, &c. the latter of which is very simple, and has been adopted by Darlow in his “Theory of Numbers,” to which work we beg to refer our readers, as it would require more room than we can allow ourselves to give it at full length in this place.

The above include, we believe, all those theorems which are known by any particular designation; there are, doubtless, many others equally important, and which are equally entitled to bear the names of their respective authors, but custom has not functioned the adoption; and we have, therefore, not introduced them.
THEORETIC, Theoretical, or Theoric, formed from theos, $\phi$, or a perception, something relating to theory, or that terminates in speculation. In which sense it stands opposed to practical.

The sciences are ordinarily divided into theoretical, as theology, philosophy, &c.; and practical, as medicine, law, &c. See Science.

Theorétique, Théorétique, is an appellation peculiarly given to an ancient sect of physicians, contradistinguished by it from the empirics. See Empiric.

Theoretic physicians were such as applied themselves to a careful study and consideration of what relates to health and diseases; the principles of the human body, and its structure and parts, with their actions and uses; whatever befals it, either naturally or preternaturally; the differences of diseases, their nature, causes, signs, indications, &c.; the textures, properties, &c. of plants, and other medicines, &c.

In a word, the theoretic physicians were such as proceeded in their judgment and practice on the foot of reason, in opposition to the empirical physicians, who proceeded wholly on experience. See Medicine.

Theoretical Arithmetic and Philosophy. See the sub-

Theor. $\phi$, in Antiquity, an appellation given to the Athenians who performed the solemnity called theoria.

Thoria. $\phi$, a solemn annual voyage to Apollo's temple, in the island of Delos, performed by the Athenians always in the same ship in which Theseus went. For the particularities of this naval procession, see Potter Archzol. Græc. lib. ii. cap. 9. tom. i. p. 284, &c.

Theorick Money, in Ancient Authors, was what was raised, by way of tax on the people, to defray the expenses of theatrical representations, and other spectacles.

There were particular quitters and treasurers of the theoretic money. By a law of Eubulus, it was made a capital crime to pervert the theoretic money to any other use; even to employ it in the occasions of war.

Theorical Astronomy, is that part of astronomy which considers the true structure and disposition of the heavens, and heavenly bodies; and accounts for their various phenomena therefrom. See Astronomy.

It is thus called, in opposition to that part which considers their apparent structure, or their disposition as viewed by the eye, which is called spherical astronomy.

The several parts of theoretical astronomy, fee under Systems, Sun, Star, Planet, Earth, Moon, Satellite, and Comet.

Theory, a doctrine which terminates in the sole speculation, or consideration, of its object, without any view to the practice or application of it.

To be learned in an art, &c. the theory suffices; to be a matter of it, both the theory and practice are required. Machines, many times, promise very well in the theory, yet fail in the practice.

We say, theory of the moon, theory of the rainbow, of the microscope, the camera obscura, the motion of the heart, the operation of purgatives, &c.

Theories of the Planets, &c. are systems or hypotheses, according to which the astronomers explain the reasons of the phenomena or appearances of them. See System.

Theory, in Music, in the hands of a mere mathematician is confined only to ratios and the philosophy of sound. (See Harmonics.) But among practical musicians, the theory of harmony or composition is connected with the combination of agreeable sounds, and the practice and performance of real music.

Theory, Atomic, in Chemistry, the means of explaining the composition and decomposition of chemical bodies, by considering their ultimate atoms or particles as peculiar and distinct elementary solids, never changing in their figure, weight, or volume, under any circumstances.

It would be difficult to conceive the existence of any compound, without supposing it to have originated by union, in some way or other, of particles of its elementary constituents: but the prevalence of a doctrine, which has been generally advanced by mathematicians, viz. the infinite divisibility of matter, has never allowed philosophers to conclude that the circumstance of compounds being made up of particles, must necessarily limit the proportions in which the elements combine. If the elementary bodies be conceived infinitely divisible, the molecules, or compound particles, may be conceived infinitely small, and the number of mean compounds existing between any two given extremes may be also considered infinite.

If such were the nature of elementary matter, and no other causes interfered, there could be no limitation to the proportions in which simple matter would combine. This, however, is contrary to fact; as it is a fact known from the earliest dawns of chemical knowledge, that bodies are limited in the proportions of their elements; the most striking of these facts being the mutual saturation which takes place between an acid and an alkali, and the uniform proportions afforded in the analysis of many native compounds.

Philosophers were always satisfied to consider this fact of the limitation of the proportions of bodies as one of the hidden secrets of nature, as difficult to conceive as the nature of the attraction by which their elements were held together. Berthollet appears to have been the first to attempt this arduous task, in his ingenious work, entitled "Chemical Statics." He supposes that the particles of bodies, when brought within the sphere of attraction, combine without contact till the compound assumes some definite form, by which it is withdrawn from the situation in which it was formed. He supposes the chemical affinity of bodies to be distinct from that power on which their cohesion depends, and also that power by which they tend to an elastic state.

Hence he concludes, that every solid compound is determined by the cohesion which takes place at some limit in the proportion of its elements; such he supposes to be the case with fats and other crytallizable compounds. On the other hand, he supposes the limitations of the proportions of the elements of gaseous compounds to arise from the elastic form which they assume in certain stages of combination. This hypothesis was supported by so many striking facts, that it was thought by some to explain in general the cause of limited proportions. All agreed, that whatever might be the true theory, the causes pointed out by Berthollet had considerable influence in the composition and decomposition of bodies, but they faw at the same time numerous cases in which this hypothesis failed to explain the facts.

Chemists have, from the earliest times, been acquainted with those points of limitation which we call mutual saturation, and have been long familiar with those limited augmentations of their proportions, called by some dozes and by others particles. Among the oxys of metals, which had been little examined before the time of Lavoisier, it was found, that instead of having an infinite number of means between the lowest and highest stages of oxydation, only a certain number of oxys of each metal could be formed, in which the ratio of the metal to the oxygen is uniform. Many of the fats in the same way are formed by limited dotes of acid. Some of the facts in the latter have been explained on Berthollet's hypothesis, while its application
THEORY.

to the former facts is totally insufficient. Long previous to the true cause of these limited doses, the facts were so conspicuous, that a decided nomenclature was adopted for the purpose of expressing these different stages of combination. The oxides have been distinguished by the Greek numerals prot, deut, trit, &c. The fats containing two doses of acid have been called super-falts; and those containing an extra dose of base, have been called sub-falts.

Although chemists have frequently used a language which appeared to furnish their acquaintance with the real cause of the definite proportions, such as one compound being formed by one proportion, dose, or particle of one of its elements, and another with two proportions, doses, or particles: on the other hand, we find expressions which would favour the idea of indefinite proportions; such as bodies losing a small portion of their oxygen, or absorbing a little oxygen from the atmosphere. Salts are sometimes said to contain a slight excess of acid, or a small excess of base.

The most decided language used in any chemical work before the discoveries of Mr. John Dalton, giving any idea that the doses are limited by distinct atoms, will be found in a work by Mr. Higgins, entitled "A Comparative View of the Phlogistic and Antiphlogistic Theories." We beg leave to correct a mistake in a former article, in which we have entitiled this work a Treatise on Phlogiston.

This work was written for the express purpose of combatting the phlogistic theory, and principally in answer to Mr. Kirwan's treatise of phlogiston. In order to show the contradictions and absurdities of the phlogistic doctrine, which, under the name of phlogiston, confounded a number of bodies which were very different, he exhibited by diagrams a number of chemical operations, in which he supposed the elementary bodies concerned to be ultimate particles, and their immediate compounds molecules. He in the same diagrams also used numbers, which he supposed to be elements of the strength of affinity of the combining particles. By this means he very successfully showed many of the inconsistencies which must be admitted to explain the phenomena on the phlogistic theory. In this mode of proceeding, however, the numbers expressing the relative attractions, served his purpose much more than the consideration of the proportions being caused by distinct atoms; and the language which would induce the belief that he had such a conception of the nature of elementary matter, occurs only in a very few parts of his work.

After concluding that it is unnecessary to admit the existence of the imaginary substance phlogiston in sulphur, he concludes, in page 36, that sulphurous acid is composed of one ultimate particle of sulphur with one of oxygen, and that sulphuric acid consists of one of sulphur and two of oxygen.

In the same page he also observes, that water is formed by one ultimate particle of water united to one of oxygen.

In page 81, he supposes sulphuretted hydrogen to consist of nine ultimate particles of sulphur with five of hydrogen. Previous, however, to this conclusion, he believes that the sulphur and hydrogen are not chemically combined, but that the sulphur is dissolved in hydrogen, as a salt dissolves in water.

After using arguments to shew, in answer to Mr. Kirwan, that the nitric acid does not contain what was thought to be phlogiston, he concludes, in page 132, with giving what he conceives to be its constituents, viz. that the nitrous oxide consists of one ultimate particle of azote and one of oxygen; nitrous gas, of one of azote and two of oxygen; red nitrous vapour, one of azote and three of oxygen; straw-coloured nitrous acid, one of azote to four of oxygen; and lially, that the nitric acid is constituted by one of azote and five of oxygen. These facts are certainly very remarkable, as they agree with the conclusions in the present time, and give a strong proof of Mr. Higgins's genius at the time he wrote.

He does not, however, lay any stress upon these remarks, and was not probably aware that they would be confirmed by future research. We are induced to think no, from the manner in which he expresses himself in other parts of his work, in which he frequently speaks of the absorption of small portions of oxygen, and of bodies having a small portion of oxygen more than they can retain. This vague manner of speaking, and others which we do not immediately recollect, is sufficient to shew that Mr. Higgins had no fixed notions of the cause of definite proportions, and that the language in which he has used the words ultimate particles and molecules, was employed rather with a view to illustrate his examples, than to broach any new theory to explain indefinite proportions. Indeed it would have been inconsistent to have treated two subjects, so very different in their objects, in the same pages.

As a proof that there was nothing striking in the remarks in which the words ultimate atoms and molecules are mentioned, we only need refer to the article which Mr. Higgins himself quotes from the Analytical Review, written some time after the appearance of the work in question. The reviewer gives him the highest praise for the able manner in which he has refuted the doctrine of phlogiston, but does not even hint at his diagrams or the ultimate particles. Indeed we can venture to assert, that if no more had been said on the subject of definite proportions than is to be found in this work, we might yet have been as much in the dark as we were twenty years after the publication of Mr. Higgins's "Comparative View."

It was not enough to know that compound bodies were formed of particles, to enable us to explain the cause of definite proportions; and we want no greater proof of this, than the fact of the true cause not being known till twenty-eight years after Mr. Higgins had told us that one particle of sulphur and one of oxygen formed sulphurous acid, and that one to two formed sulphuric acid. These loose expressions were but a small step indeed towards the discovery of the atomic theory in its present form, which has placed chemistry on the same ground with that on which the discovery of the laws of gravity placed the science of astronomy.

We are inclined to believe that the first step towards this important discovery was given by Richter. He found, in the double decomposition of salts, that the acid of one salt was always just sufficient to saturate the base of the other, and nitre of another. He also ascertained, that when one metal was precipitated by another, the oxygen of the precipitated metal was just what was required by the precipitating metal.

The inference to be drawn from these facts was, that if A combine with x to saturation, and B with y to the same; then, if A should be found to saturate y, B would also saturate x. This inference may be still further extended; for if A be a body capable of combining with B, they will mutually saturate each other.

It is the means of drawing these inferences arising from the mutual fitness of those parts of bodies which combine, that constitutes the importance of the atomic theory, and it is for the establishment of this new principle that we are indebted to Mr. John Dalton. When Mr. Higgins can shew, from the data given in his work, that similar inferences
Theories could be drawn, he then will be entitled to share in the merit of the discovery of the atomic theory. We say share with him, for we are firmly convinced that Mr. Dalton had never read Mr. Higgins’s book previous to the publication of his own work.

We perfectly recollect the time, not more than four or five years ago, even when Mr. Dalton’s book was before the public, very few chemists understood the true spirit of the atomic theory; and those who conceived they did understand it, in general discarded it. All know that he considered compounds to be formed of atoms united 1 to 1, 1 to 2, 1 to 3, etc.; but it was not till the reciprocal fitness of these atoms with each other was found to agree with analysis, that it was generally received. When they saw that the numbers, which Dalton called the weights of the atoms, expressed the simple proportions in which bodies combine, they knew it could not be the effect of chance, and have willingly joined in the research. It is for this part of the discovery that Mr. Dalton justly merits the fame he has acquired.

We have given all the facts on which Mr. Higgins could possibly found his claim to the discovery; and we must leave it to our readers to judge, whether they contain the smallest data on which to establish what in the present time we call the atomic theory.

In all the chemical articles since the article Iron, we have had the greatest confidence in the atomic theory; and we have never failed to compare the analyses of different authorities with the results given by theory. We have in general found, that these results have been nearer to the belief of these authorities, than they have been to each other.

We have already given an outline of the atomic theory, with a table of the weights of the simple atoms, and another of some of the most conspicuous compounds, in our articles Definite Proportions, and Simple Bodies.

The French chemists have adopted the atomic theory under another form, which will be found to agree with the language given by Berzelius, who uses the word volume for atom, as we have already explained in the article above alluded to.

Gay Lussac several years ago published a new law respecting the combination of gaseous bodies. He held that gases which combine chemically, either unite in equal volumes, or 1 to 2, or some multiple of 1, by a whole number. Although a number of facts seemed to agree with this law, the truth of it was doubted by some chemists, and principally because no apparent reason appeared for such a law.

In flating (under the article Proportions) the notion of Berzelius respecting volumes, we have pointed out a curious coincidence between the specific gravity and the weight of atoms of the gases, which has since been confirmed by Dr. Prout in Dr. Thomson’s Annals. In order that the weights of the atoms may be equal to their specific gravities, we have there stated, that the number of particles in equal volumes of all gases must be equal, and the distance between the centres of the particles of all gases the same, so that the weights of equal volumes of different gases, would be as the weights of the atoms.

This would also require, that the attraction between the particles should either be the same in all, or that it should be nothing; and the distance of the particles be at points where the repulsion of the caloric atmosphere is balanced by the incumbent pressure.

The flate here supposed, however, is not the case, since we find that the weights of the atoms of the gases generally are not equal to the specific gravity, when reduced to the same standard, although it is strictly the case with a great proportion of them. And in those cases where they are not equal, the one is said to be some multiple of the other, by a whole number.

This circumstance favours the hope that some general law exists, by which the weights of the atoms of bodies are intimately connected with their specific gravities in the elastic form. When the specific gravity is double the weight of the atom, as is the case with oxygen, we have to suppose, that the particles are nearer each other in the proportion of 2 to 1, or that two particles come together, and are surrounded by the caloric, which belongs to one of them in their single state.

It would appear that the oxygen puts on this single state of existence in the formation of carbonic acid, because that gaseous body contains only one atom of oxygen; hence its specific gravity is the same as if it were formed from a gaseous oxygen of half the real specific gravity united to an atom of carbon without any change of volume, the same as takes place when sulphur or carbon is burned in oxygen gas. Hence we may explain the great tendency that oxygen has to combine in double doses with bodies, as is the case with carbon, sulphur, phosphorus, iron, and many other bodies.

We have also an infallence of a compound gaseous body becoming of double the specific gravity which would be expected in oleaceous gas, which is composed of an atom of carbon and an atom of hydrogen. The specific gravity (hydrogen being 1) ought to be $1 + 5.4 = 6.4$; but in fact it is about the double of this. Hence we should conclude, that the repulsion between the particles is halved, or that the compound atoms have united in pairs, by which the densit is doubled.

Theory of the Manufacture and Production of Bread, in Rural Economy, the explanation of the principles and practices on which it depends in different cases. The means which are employed in such cases are mostly well understood; but the principles upon which they depend are far from being so well known. The writer of a late work on the Elements of Agricultural Chemistry, has, however, thrown some light on this hitherto intricate subject. He has noticed, that a number of the changes taking place in the vegetable principles, depend upon the separation of oxygen and hydrogen as water from the compound; but that there is one of very great importance, in which a new combination of the elements of water is the principal operation: this is in the manufacture of bread. When any kind of flour, which consists principally of starch, is made into a paste with water, and immediately and gradually heated to about 440°, it increases, it is said, in weight, and is found entirely altered in its properties; it has lost its solubility in water, and its power of being converted into sugar. In this state it is unleavened bread.

And when the flour of corn, or the flour of potatoes, mixed with boiled roots of the same kind, is made into a paste with water, kept warm, and suffered to remain thirty or forty hours, it ferments, and carbonic acid gas is diffused from it, and it becomes filled with globules of elastic fluid. In this state it is raised dough, and affords by baking leavened bread; but this bread, it is said, is sour and disagreeable to the taste; and that leavened bread for use is made by mixing a little dough that has fermented, with new dough, and kneading them together, or by kneading the materials for the bread with a small quantity of yeast.

It is flated, that in the formation of wheaten bread, more than one-fourth of the elements of water combine with the flour;
flour: that more water in proportion is consolidated in the formation of bread from barley, and still a larger quantity in that from oats; but that the gluten in wheat, being in much larger quantity than in other grain, seems to form a combination with the flour and water, which renders wheat bread more digestible than other species or kinds of bread.

On this principle too it is probable, that this sort of bread may be more suitable and proper for the less laborious classes of society, though the other kinds may be equally or more nourishing and saluting for those who are engaged in hard work.

THEOSOPHISTS, the denomination of a class of philosophers, who profess to derive their knowledge of nature from divine revelation. Not contented with the natural light of human reason, nor with the simple doctrines of scripture understood in their literal sense, these persons have recourse to an internal supernatural light, superior to all other illuminations, from which they pretend to derive a mystic and divine philosophy, manifested only to the chosen favorites of heaven. They boast, that, by means of this celestial light, they are not only admitted to the intimate knowledge of God, and of all divine truth, but have access to the most sublime secrets of nature. They ascribe it to the singular manifestation of divine benevolence, that they are able to make such an use of the element of fire, in the chemical art, as enables them to discover the essential principle of bodies, and to dissolve insipid mysteries in the phyzical world. (See Fire Philosophers.)

They pretend to an acquaintance with those celestial beings, which form the medium of intercourse between God and man, and to a power of obtaining from them, by the aid of magic, alchemy, and other similar arts, various kinds of information and assistance. This they affirm to have been the ancient secret wisdom, first revealed to the Jews under the name of Cabbala, and transmitted by tradition to posterity. Philosophers of this class have no common system; but every one follows the impulse of his own imagination, and constructs an edifice of fanaticism for himself. They only agree in abandoning human reason, and pretending to divine illumination. Many traces of the spirit of Theophosthism are to be found in the whole history of philosophy, in which fanatic and hypocritical pretensions to divine illumination frequently occur. Among moderns, the first name that is mentioned with any distinction in this class of philosophers is Paracelsus. (See his biographical article.) He was succeeded by Robert Fludd, who compounded into a new mass of absurdity all the mysterious and incomprehensible dreams of the Cabbalists and Paracelsians. He ascribed two universal principles, the northern or condensing power, and the southern or rarefying power; and over these he placed innumerable intelligences and geniuses, and called together whole troops of spirits from the four winds, to which he committed the charge of diseases. (See his article.) Another dazzling luminous in the constellation of Theosophists was Jacob Behmen. See Behmen.

A more scientific Theosophist than Behmen was Van Helmont. (See Helmont.) The most elegant and philosophical of all the Theosophists was Peter Poiret, who was born at Metz in the year 1646, and educated in the academy of Bafil. In 1668 he became a student in the university of Heidelberg, with a view of qualifying himself for the clerical profession, and in 1672 he assumed the character of an ecclesiastic in the principality of Deux-Ponts. After a severe fit of ill health, he wrote his "Cogitationes Rationales de Deo, Anima, et Malo," in which he mostly followed the principles of Des Cartes, having in his youth studied the Cartesian philosophy; a work which he defended against the censures of Bayle. Being obliged by the public tumults to withdraw from his clerical cure, he removed to Holland, and afterwards to Hamburg, where he became acquainted with the celebrated mystic Mad. Bouignon, and cultivated himself in the number of her disciples. Abandoning Cartesianism, and fascinated with Bouignonian mysticism, he rejected the light of reason as useless and dangerous, and inveighed against every kind of philosophy that was not the effect of divine illumination. Towards the close of his life he settled at Rheinsburg, in Holland, and employed himself in writing mystical books, such as his treatises "De Economia Divina," "De Eruditione Tripli," and the last edition of his "Cogitationes Rationales." He died in the year 1719. Some of his mystical notions may be collected from the preliminary dissertation prefixed to his works: they are such as these: "It hath pleased God, in order that he may enable a vivid and delightful contemplation of himself, by yond that solitude which belongs to the divine efficacy, to create external beings in whom he may produce an image of himself. The essence of the human mind is 'thought'; capable and dirious of light, and joyful complacency; the properties in which it bears a resemblance of the divine essence. Nothing is more intimate or essential to the mind than this divinity; by which it is borne always towards the true and infinite good. In order to satisfy this divinity, the illumination of faith is necessary; by means of which the mind, conscious of its weakness and impotence, deifies all the fictions of human reason, and directs itself towards God with an intense and ineffable ardor, till, by the intense contemplation of him, it is filled with tranquilizing light and joyful complacency; although, whilst oppressed with the weight of mortality, it cannot behold his unveiled face. From this divine illumination proceeds the most pacific felicity of mind, the most ardent love of God, and the most intimate union with him."

To the class of Theosophists it has been usual to refer the entire society of Rosicrucians; which see.

It will be sufficient to observe, at the close of this article, that the whole system of Theosophism is founded in delusion, and that it is injurious both to philosophy and religion. These supposed illuminations are to be ascribed either to fanaticism or to imposture. The fanatical conceptions, with which these pretenders to divine wisdom have treated those who are contented to follow the plain dictates of common sense, and the simple doctrine of scriptures, has unquestionably imposed upon the credulous vulgar, and produced an indifference to rational inquiry, which has obstructed the progress of knowledge. And their example has encouraged others to traduce philosophy and theology in general, by representing them as resting upon no better foundation than enthusiasm and absurdity. It is to be charitably presumed, that these deluded visionaries have not been themselves aware of the injury which they have been doing to the interests of science and religion. Nevertheless, it must be regretted, both on their own account, and on account of the multitudes they have misled, that whilst they have thought themselves following a bright and steady luminous, they have been led astray by wandering meteors. Brucker by Endfield.

THEOTOCUS, Deipara. See Mother of God.

THEOXENIA, Θεοξενία, in Antiquity, a festival in honour of all the gods, and celebrated in many cities of Greece, but especially Athens.

THEOXIN Malagma, the name of a sort of cataplasm, good against pains of the feet.

THÉRA, in Ancient Geography, one of the islands called Sporades.
Sparades, in the Ægean seas, between the island of Crete and the Cyclades. It is said to have taken its name from Theras, a prince of the race of Cadmus, who removed from Lacedæmon into this island, which was occupied by the descend-ants of the Membrarini, who had possession of it 1550 years before our era; whereas Pliny says that it first appeared in the fourth year of the 135th Olympiad. This island is now called Southampton; for it was also, a town of the island of the same name.—Also, a town of Asia Minor, in Caria, between Idyamus and Pythius.—Also, a town of Asia, in Sog-diana.

THERAMBUS, a town of Macedonia, in the peninsula of Pallene.

THERAMNE, a town of Asia Minor, in Lycia; con-fecrated to Apollo.

Therapeutæ, σημανοῦσα, a Greek term signifying servants, more especially those employed in the service of God. The Greeks gave the appellation therapeutæ to such as applied themselves to a contemplative life, whether it were from the great concern they had for their souls, or from the particular mode and manner of their religion; the word σημανοῦσα, whence therapeutæ, signifying the care a physician takes of his patient, or the service any one renders another.

Philo, in his first book of the Contemplative Life, relates, that there were a people spread throughout most of the known world, but particularly throughout Egypt, and about Alexandria, who renounced their friends, their goods, &c. and who, after discharging themselves of all temporal concerns, retired into solitary places, where they had each their separate mansion, called semnium, or monastery, and placed their whole felicity in the contemplation of the divine nature.

The principal society of this kind was formed near Alexandria, where they lived, not far from each other, in separate cottages, each of which had its own sacred apartment, to which the inhabitant retired for the purposes of devotion. After their morning prayers, they spent the day in studying the law and the prophets, endeavouring, by the commentators of their ancestors, to discover some allegorical meaning in every part. They also amused themselves with composing sacred hymns in various kinds of metre. Six days of the week were thus passed in solitude. On the seventh day they met, decently clothed, in a public assembly, where, feated according to their age, they held the right hand betwixt the breasts and the chin, and the left at the side. Then one of the elders, stepping to the middle of the assembly, discoursed, gravely and calmly, on the doctrines of the sect; the audience remaining silent and occasionally expressing their approbation by a nod. The chapel in which they assembled was separated into two apartments, one for the men, the other for the women. At the close, the speaker sung a hymn of praise to God, in the last verse of which the whole assembly joined. On great festivals, sacred music was performed, accompanied with solemn dancing; and these vigils were continued till morning, when the assembly, after a morning prayer, in which their faces were directed towards the rising sun, was broken up. Such was their abstemiousness, that they commonly ate nothing before the setting sun, and often fasted two or three days. They wholly abstained from wine, and their ordinary food was bread and herbs.

There are two points relating to these therapeutæ exceedingly controverted among critics, viz. 1. Whether they were Jews or Chriftians; and 2. If they were the latter, whether they were monks or seculars? Mosheim affirms, that the therapeutæ were neither Chriftians nor Egyptians, as some have erroneously imagined; they were undoubtedly Jews; nay, they gloried in that title, and styled themselves, with particular affectation, the true disciples of Mofes, though their manner of life was equally repugnant to the institutions of that great lawgiver, and to the dictates of right reason, and shewed them to be a tribe of melancholy and wrong-headed enthusiasts.

Calmet also, in his Dictionarv of the Bible, alleges a variety of reasons to prove, that the therapeutæ were Jews and not Chriftians; and that they were not monks in the fene which ecclefsiatical writers affix to this term. Some have imagined that they were judaizing Gentiles; but Philo, by claffing them with the Essenes, evidently supposes them to be Jews. Others have maintained, that they were an Alexandrian fect of Jewish converts to the Chriftian faith, who devoted themselves to a monafic life. But this is impossi-ble; for Philo, who wrote before Chriftianity appeared in Egypt, speaks of this as an established fect. From a com-paration of Philo's account of this fect with the flate of philo-sophy in the country where it flourished, we may reason-ably conclude, that the therapeutæ were a body of Chriftian fanatics, who suffered themselves to be drawn aside from the simplicity of their ancient religion by the example of the Egyptians and Pythagoreans. It is uncertain how long this fect continued; but it is thought not improbable, that, after the appearance of Chriftianity in Egypt, it soon be-came extinct. See ESSENES.

Therapeutæ, Therapeutä, σημανούσα, formed from σημανοῦσα, to attend, to nurse, cure, &c. that part of medicine which is employed in seeking out remedies against diseases, and in prescribing and applying them to effect a cure.

Therapeutæ teaches the use of diet, pharmacy, surgery, and the methodus medendi.

Therapeutæ is also used figuratively, in speaking of the mind, and of discourses made to correct the errors and defects of it.

Such is the Therapeutæ or Therapeutics of Theodoret; being a treatiie against the errors of unwholofome opinions of the Greeks, i. e. the heathens.

Theraphim, or Teraphim, an Hebrew term, which has given great exercise to the critics. We meet with it thirteen or fourteen times in Scripture, where it is com-monly interpreted idoles; but the rabbins are not contented to have them simply signify idols, but will have it denote a peculiar sort of idols or images intended for the knowledge of futurity, i. e. oracles.

R. David de Pomis observes, that they were called theraphim, from σημανοῦσα, to have, because people quitted every thing to consult them.

Others hold, that the theraphim were brazen instruments which pointed out the hours and minutes of future events, as directed by the stars.

R. Eliezer tells us the reason why the rabbins will have the theraphim to speake, and render oracles: it is, says he, because it is written in the prophet Zechariah, x. 2. "The theraphim have spoken vain things."

The same rabbins adds, that to make the theraphim, they killed a first-born child, clove his head, and seasoned it with salt and oil; that they wrote on a plate of gold the name of some impure spirit, laid it under the tongue of the dead, placed the head against the wall, lighted lamps before it, and prayed to it, and that it then talked with them.

Vorlifius also observes, that, beside the passage of Zechariah, juft quoted, it appears likewise from Ezekiel, xxi. 27. that the theraphim were consulted as oracles.

F. Kircher directs us to seek the origin of the theraphim in
in Egypt; adding, that the word is Egyptian. Spencer, in his dissertation on the urim and thummim, maintains the word to be Chaldee, and to signify the name with ephraim: the Chaldeans being frequently known to change the y into j, that is into i. He adds, that those images were borrowed from the Amorites, Chaldeans, or Syrians; and that the Seraph of the Egyptians is the same thing with the theraiph of the Chaldeans. See Seklen de Dios Syris, fyst. i. cap. 2.

Calmet observes, that the figure of a winged serpent, called šeraph, whence the name seraphim, has given rise to the appellation theraiph, because in the abraxas and other talismans of the ancients, which are real theraiphims, we find the figures of serpents both with and without wings; whence he infers, that the theraiphims of Laban, which were stolen by Rachael, were real talismans. Jurieu conjectures, that these theraiphims were the penates, or household gods of Laban, which, he says, were the souls of the heroes of families, deified and worshipped; and he adds, that the theraiphims of Laban were the images of Noah, the refoter of the human race, and of Shem, the chief of the family of Laban. But Calmet, in reply to this conjecture, observes, that it is by no means credible, that the worship of the penates and lares was known in the time of Laban; and that it is not likely, that Laban should have ranked among the gods Noah and Shem, who had died so near his own time; for Noah died A.M. 2106, and Shem A.M. 2158, about eighty-seven years before Jacob came to Mesopotamia after Laban.

THERAPIGON, in Botany, a name given by some authors to the common oyster-green, or sea-laver, a substance of the tremella kind.

THERASIA, in Geography, a small rocky island in the Grecian Archipelago, separated from the N.W. coast of Sclater (the ancient Thera) by a narrow channel, which forms a secure harbour for boats: 3 miles N. of St. Nicola. Thera is said by Tournefort and Sommier to be the present Alpronif (which fee); but Oliver mentions them as distinct islands. Thera is, in the same, supposed to be the principal town, and which Pliny conjectures, with reason, to have been detached from Thera, cannot be taken for Alpronif, nor the latter for the former, as Tournefort imagines. Alpronif is not large enough to have upon it the smallest village, or the smallest habitation; whereas Thera has sufficient extent, and its territory is sufficiently good, to have been always the fide of a town, as one is still to be seen there at the present day.

THERESA, a river of Africa, which runs into the Atlantic, S. lat. 13°.

Theresa, Order of Maria, a military order instituted by the empress-queen in Germany, on the 18th of June, 1757, and composed of two classes, viz. grand crosses and knights. To thesee the emperor Joseph III., in the year 1765, added an intermediate class, under the appellation of commanders. The number of knights is not fixed, and the emperor is grand-master. The badge of the order is, "a crof of gold, enamelled white, edged with gold;" on the centre of the arms of Austria, viz. "gules, a fette argent, encircled with the word Fortitudinis;" on the reverse is "a cipher of the letters M.E.F. in gold, on an enamelled green ground." The badge is worn pendant to a stiffened crimson and white ribbon.

THERGUSIS, in Ancient Geography, a town of Asia, in the interior of Mesopotamia, situated on the bank and towards the source of the river Chaborras.

THERIACA, Seriaca, Treads, in Medicine, a name given by the ancients to various compositions esteemed good against poifons; but afterwards chiefly restrained to what, by way of distinction, has been called theeriaca Andromachi, or Venice treacle: but now altogether out of ufe.

This is a compound of no lefs than fifty-four drugs, prepared, pulverized, and reduced, by means of honey, into an electuary. The basis or foundation of the composition is viper's flesh. M. Charas has written a particular history of the animals, plants, and minerals, which enter the composition of this famed remedy.

It is said to be sovereign against the bites of venomous beasts, and in the wind-colic; and was also used in intermitting fevers, and in cases requiring periphrastics and diaphoretics: also in continual fevers, especially such as are malignant, and where the pulse is low and ticking: and in the small-pox and meafeus: and, as most of the ingredients of it are very hot, in all diseases where the natural heat is weak and languid.

Andromachus, Nero's physician, praises for the inventor of the theriaca; at leafl, it was he who gave the first description of it in elegiac verses; his fon did the fame in prose, and Damaecrates in labytes.

Anciently, the treacle made at Venice had all the ufe: and many still retain the ancient prejudice; but it has been since prepared at Montpellier, at Paris, and at London, with as much advantage as at Venice.

There is another vulgar kind of theriaca, called diaterrism, because it only consists of four ingredients.

Treacle-water and treacle-vinegar are found good preservatives against putrid air, whether by only being finct at, or by rubbing the winds, temples, and nofe with them.

THERIACA Rufficum, a name given to garlic, from its ufe as an antidote against the contagion of putrid and other putrid disorders.

THERIOMA, from Íeìgës, to rage, in Surgery, a ma- llignant ulcer.

THERMA, in Ancient Geography, a town of Cappadocia, on the route from Tavia to Cefarea, between Tavia and So- arus. Anton. Itin.—Als, a town situated on the confines of Macedonia, or rather of Thessaly, towards Thermopylae. This town was situated on the gulf called Thermaes, whence its name.

THERMA Pythis, baths of Asia Minor, in Bithynia. Pro- corpus mentions this place; and says that Juffianus constructed here a bath for public ufe, and a canal to conduct into it fresh water, and that he also provided others, which indicated a magnificence truly royal.

THERME, Íyám, in Architecture, ancient buildings, furnished with baths, especially of the hot kind.

Among the noblest of monuments of ancient Rome, are reckoned the therme, or baths of Diocletian. See Baths. Therme, or hot springs, it is commonly argued, owe their to a ccluciation, or effervescence, of the minerals in them. Though Dr. Woodward ascribes it to the subterraneous heat, or fire, which communicates with them by some spireacle, or canal, whereby a greater quantity of heat is derived thither, than to ordinary springs. See Bath.

THERMIÉ, Íyám, in Ancient Geography, a place on the southern coast of Sicily. Pliny denominates this place a Roman colony; and Antonine calls the sources of the hot water which gave the name of Thermæ to this place "Aqua Laroda." There were also baths at Selinunt in Sicily, called Thermæ Selinuntiz. The name thermæ was also given to those highly saline warm waters that were found in the neighbourhood of Corinth. THERMÆUS SINUS, a gulf of the Ígean sea, on the coast of Macedonia.

THERMASMA, a word used by some of the ancients, to
to express any thing that warms the body, and by others particularly for a warm fermentation, preferred by Hippocrates for removing pains in the side, and giving ease in pleurisy.

THERMES, in Ancient Geography, a town of Hispania Citerior, S. of Numantia.

THERMI, in Geography, a town of Atilic Turkey, in the province of Natolia; 24 miles N. of Burfa.

THERMIA, an island in the Grecian Archipelago, so called from its abounding with hot springs. It is not so mountainous as some of the other islands, and the soil, when well cultivated, produces very large quantities of barley, wine, and figs. The island also affords plenty of honey, wax, partridges, a great quantity of fine silk, and as much cotton as the inhabitants require for their own use. The Greek Christians in this island are computed at 16,000. Thermia is the see of a bishop, and contains fifteen or sixteen churches, and several convents. On the island are still visible the ruins of two cities; one of which, on the south coast, must have been of extraordinary splendour. N. lat. 37° 20'. E. long. 24° 32'.

THERMIA, a town and capital of the island of Thermia. N. lat. 37° 24'. E. long. 24° 26'.

THERMOMETER, Thermometric, derived from θερμα, heat, and μετρέω, to measure, an instrument shewing, or rather measuring, the increase and decrease of the heat and cold of the air.

The degree of heat, as ascertained by a thermometer, is only to be considered in relation to the surrounding bodies, by virtue of which a body supports the equilibrium of temperature, when it is in the neighbourhood of bodies equally heated: thus, if a thermometer stands at 60°, both in a vessel of water and in another of mercury, we may infer that the water and the mercury may be mixed without any change of their temperature; but the absolute quantity of heat contained in equal weights, or in equal bulbs, of any two bodies at the same temperature, is by no means the same. See Heat.

The general principles upon which the construction and use of thermometers, or measurers of heat depend, are stated and explained under the articles Caloric, Cold, Congelation, Freezing, Heat, &c.

It will be sufficient to observe in this place, that the well-known and most general effect of heat, whether it be obtained by compounding a certain substance into a narrower space, so that a quantity of heat may come out of it and be communicated to certain bodies, or by expanding a certain substance into a larger space, so that it may absorb a quantity of heat from surrounding bodies, and thus cool these bodies, or in whatever other way it be procured, is a dilatation of bodies, or an augmentation of their bulbs. The contrary effect is produced by cold, i.e. by a diminution of the free caloric. It must, however, be observed, that bodies of equal bulbs, but of different kinds, are not expanded alike by being heated to the same degree; nor are the increments of bulk in the same body always proportional to the quantities of heat which are communicated to it. E.g. if a given quantity of water, by being heated to a certain degree, be increased in bulk one cubic inch, the addition of double or treble that quantity of heat will not increase its bulk two or three cubic inches respectively; therefore the expansions of water are not proportional to the increments of heat.

The only practicable method of measuring the expansions of fluids, is by involving them in certain vessels, and by measuring that part of the cavity of each vessel which is occupied by the particular fluid which fills it in different temperatures.

It is evident, that the substance of the vessel is also expanded by the heat, and of course its cavity is enlarged. Therefore, when we find that the bulk of the fluid is increased, that apparent increment is only the difference between the enlarged capacity of the vessel and the increased bulk of the fluid. For this reason those vessels must be made of such substances as are least expansible by heat. Indeed glasses is the substance which is universally used for such purposes, both on account of its little expansibility, and of its transparency, besides its having other remarkably useful properties.

A glass vessel filled to a certain degree with a liquid, for the purpose of shewing the expansion of that liquid in different temperatures, or for the purpose of shewing the temperature by the corresponding expansion of that liquid, is called a thermometer.

The thermometer and thermoscope are ordinarily accounted the same thing: Wolfius, however, makes a difference; but shews, at the same time, that what we call thermometers are, in reality, no more than thermostopes.

The invention of the thermometer is attributed to several persons by different authors, viz. to Sanctorio, Galileo, Father Paul, and Drebbel. The invention is ascribed to Cornelius Drebbelius of Almeaer, about the beginning of the seventeenth century, by his countrymen Boerhaave (Chem. i. p. 152. 156.) and Mufchenbroeck, Introduct. ad Philat. Nat. vol. ii. p. 625.

Fulgenzio, in his life of Father Paul, gives him the honour of the first discovery. Vincenzio Viviani (Vit. de l'Galil. p. 67. See too Oper. di Galil. pref. p. 47.) speaks of Galileo as the inventor of thermometers. But Sanctorio himself (Com. in Galen. Art. Med. p. 736 — 842. Com. in Avicen. Can. Fen. i. p. 22. 78. 219.) expressly affirms this invention; and Borelli (De Mot. Animal. ii. prop. 175.) and Malpighi (Oper. Polth. p. 30.) ascribe it to him without referre. Upon which Dr. Martine remarks, that these Florentine academicians are not to be suspected of partiality in favour of one of the Patavinesian school. But whoever was the first inventor of this instrument, it was very rude and imperfect; and as the various degrees of heat were indicated by the different contraction or expansion of air, it was afterwards found to be an uncertain and sometimes a deceiving measure of heat, because the bulk of air was affected, not only by the difference of heat, but likewise by the variable weight of the atmosphere.

There are various kinds of thermometers; the contraction, defects, theory, &c. of which, are as follow:

Construction of the Thermometer, depending on the Rarefaction of the Air.—This aerial thermometer, which was that first invented by Drebbel, consists of a glass tube B E (Plate XVI. Pneumaticks, fig. 1.), connected at one end with a large glass ball A, and at the other end immerged in an open vessel, or terminating in a ball D E, with a narrow orifice at D; which vessel, or ball, contains any coloured liquor that will not easily freeze. Aqua fortis tinged of a fine blue colour with solutio of vitriol or copper, or spirit of wine tinged with cochineal, or Brazil wood, will answer this purpose. But the ball A, must be first moderately warmed, so that a part of the air contained in it may be expelled through the orifice D; and then the liquor pressed by the weight of the atmosphere will enter the ball D E, and rise, e. g. to the middle of the tube at C, at a mean temperature of the weather; and in this state the liquor by its weight, and the air included in the ball A, &c. by its elascitt, will counter-balance the weight of the atmosphere. As the surrounding air becomes warmer, the air in the ball and upper part of the tube, expanding by heat, will drive the liquor into the lower
lower ball, and consequently its surface will descend; on
the contrary, as the ambient air becomes colder, that in the
ball is condensed, and the liquor pressed by the weight of
the atmosphere will ascend; so that the liquor in the tube
will ascend or descend more or less, according to the rate
of the air contiguous to the instrument. To the tube is
attached a vane of the same length, divided upwards and
downwards from the middle, C, into one hundred equal parts,
by means of which the ascendent and descendent of the liquor
in the tube, and consequently the variations in the cold or heat
of the atmosphere, may be observed.

It must be acknowledged, that the expansion of elastic
fluids affords, in some cases, a test of heat, which is very
convenient from its great delicacy, and because a very small
quantity of heat is sufficient to raise their temperature very
considerably.

A similar thermometer may be constructed by putting a
small quantity of mercury, not exceeding the bulk of a pea,
into the tube B C (fig. 2.) then bent in wretches, that taking
up the less height, it may be the more manageable and less
liable to harm; divide this tube into any number of equal parts
to serve for a scale.

Here appear the approaches of the mercury towards the ball, A,
will show the inerat of the degree of heat. The reason is
the same as in the former.

The defect of both these instruments consists in this,
that they are liable to be acted on by a double cause: for, not
only a decrease of heat, but also an increase of weight of the
atmosphere, will make the liquor rise in the one, and the
mercury in the other; and, on the contrary, either an in-
crease of heat, or decrease of weight of the atmosphere, will
make it descend.

In winter, for example, the liquor would rise and sink too
much; for a frost condensing the internal air, the liquor
would ascend, but as the air is heavier in frosty weather, its
pressur on the liquor in the vessel D E (fig. 1.) being in-
creased, would raise the liquor still higher in the tube, and
thus indicate a degree of cold greater than it really is. On
the other hand, if the weather grows warm, as it does in
rainy weather in winter, the air in the ball will expand, and
the liquor descend in the tube; but as the weight of the at-
mosphere is less in foul weather, the liquor in D E, will be less
pressed than it was, and suffer the liquor to descend more than
it should do, and show a greater degree of warmth than that
of the ambient air. The reverse of this will happen in sum-
mmer: for warm weather being fair weather, and the atmo-
sphere being then heavier than usual, the liquor will be made
to stand higher in the tube than it should do, and shew the
degree of heat to be less than it really is. And as in
summer, the weather becomes cold with rain; but the
weight of the atmosphere being diminished, the liquor will
not ascend so far as it ought to ascend by the condensation
of the internal air, and therefore indicate the cold to be less
than it really is: and when the two causes, thus contributing
to the rise and fall of the liquor, act equally in opposite di-
rections, the liquor would appear neither to ascend nor de-
scent, whatever might be the changes in the temperature of
the atmosphere, on account of equal corresponding varia-
tions in its gravity. Besides, the air in the ball, &c. is liable
to be affected more or less in its elastic quality by the vapours
that detach themselves from the included liquor according to
the degree in which it is heated or cooled. For these and
other purposes, thermometers of this kind have been long
diffused.

Instruments of this kind, when they are subject to the
variations of the pressure of the atmosphere, as well as to
those of its temperature, are properly called manometers,
and require, for enabling us to employ them as thermo-
meters, a comparison with the barometer; while, on the other
hand, they may be used as barometers if the temperature be
otherwise ascertained. They are, however, very useful
without this comparison, in delicate experiments of short
duration; besides, the changes of the barometer are seldom
very rapid, and they may also be wholly freed from the
effects of the pressure of the atmosphere in various ways.

Bernoulli's method consists in closing the tube of a com-
mon barometer so as to leave the column of mercury in equi-
lbrum with the air contained in the bulb at its actual tem-
perature, and capable of indicating, by the changes of its
height and of its pressure, any subsequent changes in the
temperature of the air, which must affect both its bulk and
its elasticity. (See fig. 3.) Mr. Lefle's photometer, or
Differential Thermometer (which he), has some advantages
which render it better than this instrument; but it can only
be employed when the changes of the temperature can be
confined only to a part of the instrument. The elasticity of
the air contained in the bulb is here counteracted, not by the
pressure of a column of mercury, but by the elasticity of
another portion of air in a second bulb, which is not to be
exposed to the heat or cold that is to be examined; and the
difference of the temperatures of the two bulbs is indicated
by the place of a drop of a liquid, moving freely in the
tube which joins them.

M. Amontons, in 1703, with a view of perfecting the
aerial thermometer, contrived his universal thermometer.
Finding that the changes produced by heat and cold in the
bulk of the air were subject to invincible irregularities, he
substituted for these the variations produced by heat in the
elastic force of this fluid. This thermometer consisted of a
long tube of glass (see fig. 4.) open at one end, and recurved
at the other end, which terminated in a ball. A certain
quantity of air was compressed into this ball by the weight
of a column of mercury, and also by the weight of the at-
mosphere. The effect of heat on this included air was to
make it sustain a greater or less weight; and this effect
was measured by the variation of the column of mercury in
the tube, corrected by that of the barometer, with respect
to the changes of the weight of the external air. This instru-
ment, though much more perfect than those in the room of
which it was substituted by its inventor, is nevertheless sub-
ject to very considerable defects and inconveniences. Its
length of four feet renders it unfit for a variety of experi-
ments, and its construction is difficult and complex; it is
extremely inconvenient for carriage, as a very small inclina-
tion of the tube would suffer the included air to escape;
and the friction of the mercury in the tube, and the compre-
sibility of the air, contribute to render the indications of
this instrument extremely uncertain. Besides, the dilatation
of the air is not so regularly proportional to its heat, nor is its
dilatation by a given heat nearly so uniform as it supposed.
This depends, as the abbé Nollet has suggested, much on its
moisture; for dry air does not expand near so much by a
given heat, as air stored with watery particles; which by
being converted into steam, very much increase the feeing
volume of the air. For these and other reasons enumerated
by M. de Luc, (Rêcherches fur les Mod. de l'Atm. tom. i.
p. 278, &c.) this instrument was imitated by very few, and
never came to be of general use.

Construction of the Florentine Thermometer.—The acade-
miasts del Cimento, about the middle of the seventeenth cen-
tury, considering the inconveniences of the air-thermo-
meters above described, attempted another, that should mea-
ure heat and cold by the rarefaction and condensation of
spirit of wine; though much less than those of air, and con-
sequently
to express anything that warms the body, and by others particularly for a warm fermentation, preferred by Hippocrates for removing pains in the side, and giving ease in plentifuls.

THERMES, in Ancient Geography, a town of Hispania Citerior, S. of Numantia.

THERMI, in Geography, a town of Asiatic Turkey, in the province of Natalia; 24 miles N. of Burfa.

THERMIA, an island in the Grecian Archipelago, so called from its abounding with hot springs. It is not so mountainous as some of the other islands, and the soil, when well cultivated, produces very large quantities of barley, wine, and figs. The island also affords plenty of honey, wax, partridges, a great quantity of fine silk, and as much cotton as the inhabitants require for their own use. The Greek Christians in this island are computed at 16,000. Thermia is the see of a bishop, and contains fifteen or sixteen churches, and several convents. On the island are still visible the ruins of two cities; one of which, on the south coast, must have been of extraordinary splendour. N. lat. 37° 20', E. long. 24° 32'.

THERMA, a town and capital of the island of Thermia. N. lat. 37° 24'. E. long. 24° 26'.

THERMOMETER, Thermometrum, derived from
hebes, heat, and μετρειν, to measure, an instrument shewing, or rather measuring, the increase and decrease of the heat and cold of the air.

The degree of heat, as ascertained by a thermometer, is only to be considered in relation to the surrounding bodies, by virtue of which a body supports the equilibrium of temperature, when it is in the neighbourhood of bodies equally heated: thus, if a thermometer stands at 60°, both in a vessel of water and in another of mercury, we may infer that the water and the mercury may be mixed without any change of their temperature: but the absolute quantity of heat contained in equal weights, or in equal bulks, of any two bodies at the same temperature, is by no means the same. See HEAT.

The general principles upon which the construction and use of thermometers, or measurers of heat depend, are stated and explained under the articles CALORIC, COLD, CONGELATION, FREEZING, HEAT, &c.

It will be sufficient to observe in this place, that the well-known and most general effect of heat, whether it be obtained by compressing a certain substance into a narrower space, so that a quantity of heat may come out of it and be communicated to certain bodies, or by expanding a certain substance into a larger space, so that it may absorb a quantity of heat from surrounding bodies, and thus cool these bodies, or in whatever other way it be procured, is a dilatation of bodies, or an augmentation of their bulks. The contrary effect is produced by cold, i.e. by a diminution of the free caloric. It must, however, be observed, that bodies of equal bulks, but of different kinds, are not expanded alike by being heated to the same degree; nor are the increments of bulk in the same body always proportional to the quantities of heat which are communicated to it. E.g. if a given quantity of water, by being heated to a certain degree, be increased in bulk one cubic inch, the addition of double or treble that quantity of heat will not increase its bulk two or three cubic inches respectively; therefore the expansions of water are not proportional to the increments of heat.

The only practicable method of measuring the expansions of fluids, is by inclining them in certain vessels, and by measuring that part of the cavity of each vessel which is occupied by the particular fluid which fills it in different temperatures.

It is evident, that the substance of the vessel is also expanded by the heat, and of course its cavity is enlarged. Therefore, when we find that the bulk of the fluid is increased, that apparent increment is only the difference between the enlarged capacity of the vessel and the increased bulk of the fluid. For this reason those vessels must be made of such substances as are least expansible by heat. Indeed glafs is the substance which is universally used for such purposes, both on account of its little expansibility, and of its transparency, besides its having other remarkably useful properties.

A glass vessel filled to a certain degree with a liquid, for the purpose of shewing the expansion of that liquid in different temperatures, or for the purpose of shewing the temperature by the corresponding expansion of that liquid, is called a thermometer.

The thermometer and thescope are ordinarily accounted the same thing; Wolhus, however, makes a difference; but shews, at the same time, that what we call thermometers are, in reality, no more than thescope.

The invention of the thermometer is attributed to several persons by different authors, viz. to Sanctorius, Galileo, Father Paul, and Drebble. The invention is ascribed to Cornelius Drebbelius of Almeaer, about the beginning of the fourteenth century, by his countryman Boerhaave (Chem. i. p. 152. 156.) and Mufchenbrock, Intro. ad Phil. Nat. vol. ii. p. 625.

Fulgenzio, in his life of Father Paul, gives him the honour of the first discovery. Vincenzo Viviani (Vit. de' Galil. p. 67. See too Oper. di Galil. pref. p. 47.) speaks of Galileo as the inventor of thermometers. But Sanctorius himself (Com. in Galen. Art. Med. p. 736—842. Com. in Avicen. Can. Fen. i. p. 22. 78. 219.) expressly assumes this invention; and Borelli (De Mot. Animal. ii. prop. 175.) and Malpighi (Oper. Polth. p. 30.) ascribe it to him without reserve. Upon which Dr. Martine remarks, that these Florentine academicians are not to be suspected of partiality in favour of one of the Patavini school. But whoever was the first inventor of this instrument, it was very rude and imperfect; and as the various degrees of heat were indicated by the different contraction or expansion of air, it was afterwards found to be an uncertain and sometimes a deceiving measure of heat, because the bulk of air was affected, not only by the difference of heat, but likewise by the variable weight of the atmosphere.

There are various kinds of thermometers; the construction, defects, theory, &c. of which, are as follow:

Construction of the Thermometer, depending on the Rarefaction of the Air.—This aerial thermometer, which was that first invented by Drebble, consists of a glass tube B E (Plate XVI. Pneumatics, fig. 1.), connected at one end with a large glass ball A, and at the other end immered in an open vessel, or terminating in a ball D E, with a narrow orifice at D; which vessel, or ball, contains any coloured liquor that will not easily freeze. Aqua fortis tinged of a fine blue colour with solution of vitriol or copper, or spirit of wine tinged with cochineal, or Brazil wood, will answer this purpose. But the ball, A, must be first moderately warmed, so that a part of the air contained in it may be expelled through the orifice D; and then the liquor pressed by the weight of the atmosphere will enter the ball D E, and rise, e.g. to the middle of the tube at C, at a mean temperature of the weather; and in this state the liquor by its weight, and air included in the ball A, &c. by its elasticity, will counterbalance the weight of the atmosphere. As the surrounding air becomes warmer, the air in the ball and upper part of the tube, expanding by heat, will drive the liquor into the lower
lower ball, and consequently its surface will descend; on
the contrary, as the ambient air becomes colder, that in
the ball is condensed, and the liquor preffed by the weight
of the atmosphere will ascend: so that the liquor in the tube
will ascend or descend more or lefs, according to the rate
of the air contiguous to the instrument. To the tube is
affixed a scale of the fame length, divided upwards and
downwards from the middle, C, into one hundred equal parts,
by means of which the acent and defcent of the liquor in
the tube, and consequently the variations in the cold or heat
of the atmosphere, may be obferved.

It must be acknowledged, that the expansion of efiastic
fluids affords, in fome cafes, a teft of heat, which is very
convenient from its great delicacy, and because a very small
quantity of heat is fufficient to raise their temperature very
considerably.

A similar thermometer may be constructed by putting a
small quantity of mercurv, not exceffing the bulk of a pea,
into the tube B C (fig. 2.) Thus bent in wretches, that taking
up the lefs height, it may be the more managable and lefs
liable to harm; divide this tube into any number of equal parts
to serve for a fcale.

Here the approaches of the mercury towards the ball, A,
will fhew the increase of the degree of heat. The reafon is
the fame as in the former.

The defect of both these instruments consists in this,
that they are liable to be acted on by a double caufe; for, not
only a defcent of heat, but alfo an increafe of weight of the
atmosphere, will make the liquor rife in the one, and the
mercury in the other; and, on the contrary, either an in-
crease of heat, or defcence of weight of the atmosphere, will
make it defend.

In winter, for example, the liquor would rife and sink too
much; for a frot condensing the internal air, the liquor
would ascend, but as the air is heavier in frotty weather, its
preffure on the liquor in the vefsel D E (fig. 1.) being in-
creased, would rife the liquor still higher in the tube, and
thus indicate a degree of cold greater than it really is. On
the other hand, if the weather grows warm, as it does in
rainy weather in winter, the air in the ball will expand, and
the liquor defcend in the tube; but as the weight of the at-
mosphere is lefs in foil weather, the liquor in D E will be lefs
preffed than it was, and fuffer the liquor to defcend more than
it fhould do, and fhew a greater degree of warmth than that
of the ambient air. The reverse of this will happen in fum-
mer: for warm weather being fair weather, and the atmo-
sphere being then heavier than usual, the liquor will be made
to stand higher in the tube than it fhould do, and fhew
the degree of heat to be lefs than it really is. And as in
summer, the weather becomes cold with rain; but the
weight of the atmosphere being diminished, the liquor
will not defcend fo far as it ought to defcend by the condenfation
of the internal air, and therefore indicate the cold to be lefs
than it really is: and when the two cafes, thus contributing
to the rife and fall of the liquor, act equally in opposite di-
rctions, the liquor would appear neither to defcend nor
defcend, whatever might be the changes in the temperature
of the atmosphere, on account of equal correponding varia-
tions in its gravity. Besides, the air in the ball, &c. is liable
to be affected more or lefs in its efiastic quality by the vapours
that detach themselves from the included liquor according to
the degree in which it is heated or cooled. For thefe and
other reasons, thermometers of this kind have been long
diffufed.

Instruments of this kind, when they are fubject to the
variations of the preffure of the atmosphere, as well as to
thofe of its temperature, are properly called manometers,
and require, tor enabling us to employ them as thermo-
meters, a comparifon with the barometer; while, on the other
hand, they may be used as barometers if the temperature be
otherwise ascertained. They are, however, very useful
without this comparison, in delicate experiments of fhort
duration; besides, the changes of the barometer are feldom
very rapid, and they may also be wholly freed from the
effects of the preffure of the atmosphere in various ways.

Bernouilli’s method confifts in closing the tube of a com-
mum barometer fo as to leave the column of mercury in equi-
librium with the air contained in the bulb at its actual tem-
perature, and capable of indicating, by the changes of its
height and of its preffure, any subsequent changes in the
temperature of the air, which mufi affect both its bulk and
its efiaticity. (See fig. 3.) Mr. Leflie’s photometer, or
Differential Thermometer (which fee), has fome advantages
which render it better than this instrument; but it can only
be employed when the changes of the temperature can be
confined only to a part of the instrument. The efiaticity of
the air contained in the bulb is here counteracted, not by the
preffure of a column of mercury, but by the efiaticity of
another portion of air in a fecond bulb, which is not to be
exposed to the heat or cold that is to be examined; and the
difference of the temperatures of the two bulbs is indicated
by the place of a drop of a liquid, moving freely in the
tube which joins them.

M. Amontons, in 1702, with a view of perfefiting the
aerial thermometer, contrived his univerfal thermometer.
Finding that the changes produced by heat and cold in the
bulk of the air were fubject to invincible irregularities, he
fubliftuted for thefe the variations produced by heat in the
efiastic force of this fluid. This thermometer confifted of a
long tube of glafs (see fig. 4.) open at one end, and recurved
at the other end, which terminated in a ball. A certain
quantity of air was comprefTed into this ball by the weight
of a column of mercurv, and also by the weight of the at-
mosphere. The effect of heat on this included air was to
make it retain a greater or lefs weight; and this effect was
measured by the variation of the column of mercury in the
tube, corrected by that of the barometer, with refeft to
the changes of the weight of the external air. This instru-
ment, though much more perfect than thefe in the room of
which it was fubfifted by its inventor, is nefertheless fub-
ject to very considerable defects and inconveniences. Its
length of four feet renders it unfit for a variety of expe-
mements, and its construftion is difficult and complex; it is
extremely inconvenient for carriage, as a very small inclina-
tion of the tube would fuffer the included air to efcape: and
the friction of the mercury in the tube, and the comprefti-
bility of the air, contribute to render the indications of this
inftument extremely uncertain. Besides, the dilatation of
the air is not fo regularly proportional to its heat, nor is its
dilatation by a given heat nearly fo uniform as he fuppoTed.
This depends, as the abbe Nollet has fuggedted, much on its
moifure; for dry air does not expand near fo much by a
given heat, as air flored with watery particles; which by
being converted into steam, very much inereafe the foming
volume of the air. For thefe and other reafons enumerated
by M. de Luc, (Rercherches fur les Mod. de l’Atm. tom. i.
p. 278, &c.) this instrument was imitated by very few, and
never came to be of general ufe.

Conftitution of the Florentine Thermometer.—The acade-
mifts del Cimento, about the middle of thefeventeenth cen-
tury, confidering the inconveniences of the air-thermo-
meters above defcribed, attempted another, that should mea-
sure heat and cold by the rarefaction and condensation
of spirit of wine; though much lefs than those of air, and con-
sequently
frequently the alterations in the degree of heat likely to be much less sensible.

The spirit of wine was enclosed in glass tubes, hermetically sealed; so that these thermometers could be subject to no inconvenience by the evaporation of the liquor, or the variable gravity of the incumbrant atmosphere. Instruments of this kind were first introduced into England by Mr. Boyle, and they were soon universally used among philosophers in other countries. The Florentine thermometer consists of a small narrow tube B C D (fig. 5) connected with a glass ball A. The tube should be procured as cylindrical as possible; and it may be tried, by putting into one end of it as much mercury as will fill the length of one inch, and letting this quantity of mercury pass from one part of the tube to another, through its whole length; measure with compasses the length it occupies in every part of the tube; and if it everywhere takes up an inch, the tube is cylindrical, and the scale of equal divisions will agree with it: otherwise it will be longer where the tube is smaller, and shorter than an inch where the tube is larger; and in this case, the divisions must be suited to the contents of the bole. The glass ball may then be joined to the tube, and a small cavity be made at the other end. Fill the ball and tube with rectified spirit of wine to a convenient height, as to C, when the weather is of a mean temperature, which may be done by inverting the tube into a vessel of marked coloured spirit, under a receiver of the air-pump, or by many other ways. The spirit may be coloured by pouring a quantity of it on small pieces of turmeric, which will hereby receive a red tincture; and the spirit may be repeatedly filtrated through brown paper, in order to separate from it the coarser particles of the root. Some persons, in filling the ball and tube, for preventing the spirit from wholly descending into the ball in winter, recommend putting the ball into a lump of snow, mixed with salt; or if the instrument be made in summer, into spring-water impregnated with salt-petre, that the condensed spirit may flow slow. It will retire in extreme cold. If it rises to too great a height from the ball, part of it is to be taken out; and that the tube may not be made longer than necessary, it is convenient to immerge the ball, filled with its spirit in boiling water, and to mark the farthest point to which it then rises. When the thermometer is properly filled, with a lamp heat the little bubble left at the end of D red-hot, and seal it hermetically, leaving, as Dr. Defaguliers recommends, in the thermometer only the third part of the air that was in it, which will give room to the dilatation of the spirit; and this rarefied air will prevent the air left in the spirit, even after the air-pump has been applied, from dividing the spirit by its expansion. To the tube apply a scale, divided into one hundred equal parts, from C towards D, and also from C towards B.

Now, spirit of wine rarefying and condensing very considerably; as the heat of the ambient air increases, the spirit will dilate, and consequently will ascend in the tube; and as the heat decreases, the spirit will descend; and the degree or quantity of ascent and descent will be seen in the scale. Yet as the ratio of yesterday's heat to to-day's is not hereby discovered, this instrument is not strictly a thermometer, any more than the former.

It is to be here observed, 1. That as the natural gravity of the liquor makes it tend downwards, so it refits its ascent out of the ball into the tube; and that the more, as it rises higher; for which reason, some have advised to have the tube horizontal.

2. Since there must of necessity be some air left in the void part of the tube, over the liquor, that air, by its elasticity, will tend downwards, and of consequence will refit the rise of the liquor, and be compressed by it as it does rise: its elasticity therefore is thus increased.

3. Since it is found from experience, that a lees degree of heat is communicated more easily to the spirit of wine in the ball than a greater, the rarefactions of the spirit of wine are not proportionable to their producing caufes; especially since a greater degree of heat finds more liquor in the tube than a less does, to which, notwithstanding, the heat may be more easily communicated than to that stagnating in the ball.

4. Spirit of wine is incapable of bearing very great heat or very great cold. It boils sooner than any other liquor, and, therefore, the degrees of heat of boiling fluids cannot be determined by this thermometer. And though it retains its fluidity in pretty severe cold, yet it seems not to condence very regularly in them; and at Torneo, near the polar circle, the winter cold was so severe, as Maupertius informs us, that the spirits were frozen in all their thermometers. So that the latitude of heat and cold, which spirit of wine is capable of indicating, is much too limited to be of very great or universal use. On these accounts, the Florentine thermometer, though it has been much ufed, is far from being an accurate measure of heat, &c. to which may be added what Dr. Halley observes in the Philosophical Transactions, that he has learned from those who have kept spirit of wine long, that it always loses part of its expansive force in course of time.

This objection, fuggled by Dr. Halley, and often infilled on by others, has, according to Dr. Martine, no great weight. Well rectified spirit of wine, if sealed up in a glafs, is in a considerable degree unalterable. It cannot evaporate; and by many years experience its force of expansion has continued the same; as, beside other observations, we know especially from the Annual Register of M. de la Hire's spirit thermometer, that have been kept in the Observatory for many years.

Another great defect of these, and other thermometers, is, that their degrees are not comparable with each other. They mark, indeed, the different degrees of heat and cold; but each marks only for itself, and after its own manner; because they do not proceed from any point of heat, or cold, that is common to them all. It is with them as with two clocks, which for want of having been first set to the same hour by the sun, will, indeed, mark that one, two, or more hours are passed, but not what hour it is by the day. Nor can we be assured, that when the liquid is rifen a degree in two different thermometers, they have both suffered the same impression of an equal additional heat: since the spirit of wine may not be the same in both; and, in proportion as the spirit is more or less rectified, it will rise more or less high by the same heat. Nor is this all; for in graduating thermometers, they often take equal lengths of the tube for equal facets of the spirit: whereas, supposing the diameters of the tube equal throughout, which very rarely happens, there are so many irregularities withinide, that a certain length of tube sometimes requires double the quantity of liquor to fill it, that the fame length in another tube of the same diameter requires. All which arises from the unequal thicknesses of the parietes of tubes in different places; and from accidental prominences and cavities, always found in the inner surfaces of tubes; and especially from their being always bigger at one end than the other.

Besides, the divisions of the scale cannot accurately indicate the quantity of rarefaction, unless the proportion of the cavity of the tube D B to that of the ball A were known. Hence it is, that the comparifon of thermometers becomes so precarious and defective. Yet the most curious and interesting use of thermometers is, what ought to arise from such
such comparison. It is by this we should know the heat or
cold of another season, of another year, another climate,
&c. and what is the greatest degree of heat or cold in
which men and other animals can subsist.

M. de Réaumur contrived a new thermometer for the pur-
pose; wherein the inconveniences above recited are pro-
poed to be remedied. He took a large ball and tube,
and knowing the content of the ball as well as that of the
tube in every part, he graduated the tube, so that the space
from one division to another might contain a thousandth
part of the liquor, which liquor would contain one thousand
parts when it froze at the freezing point: then putting
the ball of his thermometer, and part of the tube, into boiling
water, he observed whether it rose eighty divisions; and if
it exceeded those, he changed his liquor, and by adding
water lowered it, so that on the next trial from the freezing
point to the point of boiling water, it should only rise
eighty divisions: but if the liquor, being too low, fell short
of eighty divisions, he raised it by adding rectified spirit to
it. The liquor thus prepared suited his purpose, and served
for making a thermometer of any size, whose scale would
agree with his standard. Such liquor, or spirits, being
about the strength of common brandy, may easily be had
any where, or made of a proper degree of density by raising
or lowering it.

The abbé Nollet made many excellent thermometers upon
M. de Réaumur's principle. Dr. Martine, however, ex-
presses his apprehensions that thermometers of this kind are
constructed on principles, that will by no means be found so
accurate as were to be wished and expected. The balls,
or bulbs, being large, as three or four inches in diameter,
are neither heated nor cooled soon enough to shew the
variations in the heat of bodies, and in the weather. Small
bulbs and small tubes, be they, are much more convenient,
and may be constructed with sufficient accuracy. Though
it must be allowed, that Réaumur, by his excellent scale,
and by depriving the spirit of wine of its air, and expelling
the air by means of heat from the ball and tube of his
thermometer, has brought it to as great a degree of perfor-
cation as it may possibly admit; yet it is liable to some of the
inconveniences of spirit thermometers, and much inferior to the
mercurial thermometers. Thermometers of this kind,
and those of mercury, do not agree in indicating the same
degrees of extreme cold; for when the mercury has frozen
at 25° below 0, the spirit indicated only 18°; and when
the mercury froze at 26° or 27° below 0, the spirit rested at 25°
or 26°. See the description of Réaumur's thermometer at
In 1740, M. Michieli di Creth contrived a spirit ther-
meter, to which he annexes four scales besides its own, viz.
that of the old thermometer in the Observatory at Paris,
Réaumur's, de l'Inde's, and Fahrenheit's. See Fixed Points
of Thermometers.

Thermometer, Mercurial. It is a circumstance of prin-
cipal importance in the construction of thermometers, to
procure a fluid that measures equal variations of heat by
corresponding equal variations in its own bulk or volume:
and the fluid which possesses this essential requisite in the
most perfect degree is mercury: the variations in its bulk
approaching nearer to a proportion with the correspond-
ing variations of its heat than any other fluid. This general
proposition M. de Luc has very elaborately evinced, by
shewing that the condensations of fluids, which increase in
bulk when they freeze, are not proportional to the dimin-
utions of heat; and that the dilatations of fluids, which are
easily converted into vapour by heat, are not proportional
to the augmentations of heat: whereas the bulk of mercury
is not enlarged when it freezes, and it refills evaporation
more than every other liquid that has been used in the con-
struction of thermometers. Besides, it is of all liquids the
most easily purged of its air. It is also the most proper for
measuring very considerable variations of heat; for, if a scale
be graduated with 0 at the point of melting ice, and 80 at
that of boiling water, mercury well purged of its air will
indicate seven times this difference of heat, or 561 degrees
in such a scale; as it will condense without freezing to 261
of this scale, and expand without boiling to 300 of the
same scale. Mercury is also more flexible than any other
fluid, air excepted, and conforms more readily to the several
variations of heat. Moreover, as mercury is an homogeneous
fluid, it will in every thermometer exhibit the same dilata-
tion or condensation by the same variations of heat. The
expansion of mercury is scarcely less regular than that of
solids, which probably approaches the nearest to the steps
of the natural scale, though not without some inequality;
and therefore a portion of mercury included in a bulb of gla-
ss, having a fine tube connected with it, forms a thermometer
the most convenient and probably the most accurate of any,
for common use; the degrees corresponding very nearly
with those of the natural scale, although, according to the
most accurate experiments, they appear to indicate, towards
the middle of the common scale of Fahrenheit, a temperature
two or three degrees too low. There is an inequality of
the same kind, but still greater, in the degrees of the spirit
thermometer; and this instrument has also the disadvantage
of being liable to burst in a heat below that of boiling water;
nevertheless, it is well calculated for the measurement of
very low temperatures, since pure alcohol has never yet been
frozen, while mercury has been reduced to a solid by the
cold of Siberia and of Hudson's Bay; but both mercury
and linseed oil support a heat of between 500° and 600°,
without ebullition.

In order to render thermometers uniform and comparable,
it is desirable that mercury, so excellently adapted for this
purpose, should be the only fluid used in the construction of
them, more especially as a thermometer with mercury may
be more easily constructed than any others. De Luc's
Récherches, &c. vol. i. part ii. cap. 2. passim.

Dr. Halley, though approved only of some of the remark-
able properties of mercury above recited, seems to have
been the first who suggested the application of this fluid
to the construction of thermometers. Phil. Trans. Abr.
vol. ii. p. 34.

Boerhaave (Chem. i. p. 720.) says, these mercurial ther-

mometers were first contrived by Olaus Roemer; but the
claims of Fahrenheit of Amsterdam, who gave an account
of his invention to the Royal Society in 1724 (Phil. Trans.
N° 381, or Abr. vol. vii. p. 49.) have been generally
allowed. And though Prins and others, in England,
Holland, France, and other countries, have made this in-
strument as well as Fahrenheit, most of the mercurial ther-

mometers are graduated according to his scale, and are called
Fahrenheit's thermometers. There are made of different
lengths, and with some variation in the form of the bulb,
according to the purposes for which they are designed.
Instead of the ball, used in the spirit thermometer, a cone
or cylinder is annexed to the tube, which may be easily enlarged
or diminished, and made of such a magnitude, that its
capacity may have a certain and known proportion to that
of the tube; and by this means several thermometers may
be constructed to the same scale: besides, the heat more
easily
THERMOMETER.

easily penetrates and reaches the innom parts of the cylindrical bulb, and causes the whole content to expand uniformly, and the mercury to rise almost immediately; whereas in thermometers with a spherical bulb it is seen first to fall, and then to rise. This phenomenon has been long since noticed both in Florentine and mercurial thermometers, when they are suddenly plunged into a heated liquid, the spirit of wine or mercury first descends, and then ascends; and when they are plunged into a cold fluid, the included liquid first ascends and then descends: this is the more remarkable in thermometers whose bulb is made of thick glass; and the reason of the phenomenon is obvious. The bulb of glass is sooner affected by the heat or cold applied to it than the included fluid; and as the glass expands by heat, the capacity of the bulb is enlarged, and the liquid descends in the tube, but being condensed by cold, and its capacity diminished, the liquid is pressed upwards in the tube: and both these effects continue till the heat and cold equally affect the included fluid. Hence it follows, that all the variations of acet and deficient, to which the spirit or mercury is subject in the thermometer, are only the differences of the rarefacts and condensations of glass, and of the contained fluid. Hilt. Ac. Royal, 1705.

The cone, or cylinder, of the thermometer is made of glass of a moderate thickness, left, when the exhausted tube is hermetically sealed, its internal capacity should be diminished by the weight of the ambient atmosphere. When the mercury is thoroughly purged of its air and moisture by boiling, the thermometer is filled with a sufficient quantity of it; and before the tube is hermetically sealed, the air is wholly expelled by heating the mercury, so that it may be rarefied and ascended to the top of the tube. To the side of the tube is annexed a scale (see fig. 4.) which Fahrenheit divided into six hundred parts, beginning with that of the sever cold which he had observed in Iceland in 1709, or that produced by surrounding the bulb of the thermometer with a mixture of snow or beaten ice and salt-ammoniac or sea-salt. He apprehended to be the greatest degree of cold, and accordingly he marked this, as the beginning of his scale, with °; the point at which mercury begins to boil, he conceived to have the greatest degree of heat, and this he made the limit of his scale. The distance between these two points, he divided into six hundred equal parts or degrees; of which 32 reckoned from °, indicates the degree of cold when snow or ice thaws naturally, or when water begins to freeze, and this is called the freezing point: and he marked the heat of boiling water with 212, &c. In order more particularly to explain the divisions of this scale, and to show how the dilatation and condensation of the mercury are estimated by it, we may observe that the bulb is supposed to contain, according to Boerhaave and Mulchenbroek, 11124 parts of quicksilver, which stands at the lowest mark, or gr. °, in an intense cold, &c. as above determined: if the bulb be immersed in snow or ice thawing naturally, or in water beginning to freeze, the quicksilver is diluted, and rises in the tube 32 of these 11124 parts; and therefore the space of the tube from gr. ° to the freezing point gr. 32, is divided into thirty-two equal parts. When the thermometer is placed in water brought to a strong boiling at a middle state of the atmosphere in places near the level of the sea, when the mercury in the barometer stands at about 30 inches or a very little under it, the quicksilver is diluted 212 of these parts beyond its original bulk of 11124, fo as now to poife the bulb and tube together a space equal to 11356 such parts; and the space from gr. 32 to gr. 212, is divided into 180 equal parts or degrees of the thermometer; which, if the tube be long enough, may be protracted as far as is convenient. It may extend well enough to gr. 600, and not much farther, for with a heat but little greater than that the mercury begins to boil.

Dr. Boerhaave, in one place, makes the number of parts into which the mercury in the bulb is supposed to be divided to be 10782 instead of 11124, and in another place states it at 11520, which Dr. Martine apprehends to be nearer the truth, or about 17990 parts, and he thinks the cáius and uret method is to fill the bulb and tube, without being solicitous about the bulk of the quicksilver, so that in freezing water, or melting ice, the mercury shall stand at a convenient height, which must be very nicely marked gr. 32; and then as accurately to observe where it stands when distilled by the heat of boiling water to gr. 212. The intermediate space is then divided into 180 degrees, which scale may be protracted upwards or downwards as far as we shall judge convenient. See Fixed Points of Thermometers.

In the above method of graduating the scale, the bore of the tube is supposed to be perfectly cylindric, which cannot always be obtained. But though it be tapering or somewhat unequal, it is easy to manage that matter, in the manner proposed by the abbé Nollet (Leçons de Phyt. Exp. tom. iv. p. 376.) by making a small portion of the quicksilver, e. g. as much as fills up an inch or half an inch, slide backward and forward in the tube; and thus to find the proportions of all its inequalities, and from thence to adjust the divisions to a scale of the most perfect equality. See Observations on the Construction of Thermometers.

Other thermometers of a similar construction have been accustomed to common use, the scale of which is only a part of that above described. They have been made of a small fixed and portable form, and the tube with its annexed scale has been enclosed in another thicker glass hermetically sealed, in order to preserve it from injury. Mr. Ramden, at the desire and for the use of Mr. Hunter in his experiments on the heat of animals and vegetables, constructed very small thermometers, 10 or seven inches long, and not above two twelfths of an inch thick in the stem; having the external diameter very little larger than that of the stem, on which was marked the freezing point. The stem was embraced by a small ivory scale, so as to slide upon it easily, and retain any position. Upon the hollow surface of this scale were marked the degrees which were seen through the stem. Phil. Trans. vol. lviii. part. 1. p. 8.

Several varieties of thermometers are constructed for philosophical purposes. For comprehending the whole range of thermometrical temperature from the most intense artificial cold to the boiling point of mercury, it is necessary to be provided with a very long tube; but for most chemical purposes, it need only be graduated to about ten degrees above the boiling point, which will reach the temperature of most saline solutions when boiling. For experiments in intense cold, a spirit thermometer should be graduated about 100 degrees below °, and the lower extremity of the scale should be at some distance from the bulb, that the temperature may be observed without lifting the bulb out of any deep vessel that may contain the freezing mixture. The most delicate and sensitive thermometers are made with a very small bulb, scarcely larger than the stem, and a tube of an extremely narrow bore, not larger than a horse-hair. For chemical purposes also, the scale should either be scratched on the glass itself, or, as this is difficult to be seen in a common light, an ivory scale should be attached without reaching so low as the bulb, that the latter may be safely immersed in acid or corrosive liquors.
In 1733, M. de l'Ille of Peterburg constructed a mercury spirit thermometer (see fig. 4.) on the principles of Reaumur's spirit thermometer. In his thermometer, the whole bulk of quicksilver, when immersed in boiling water, is conceived to be divided into 10,000, or rather 100,000 parts ; and from this one fixed point, the various degrees of heat, either above or below it, are marked in these parts on the tube or scale, by the various expansion or contraction of the quicksilver in all the imaginable variety of heat. Dr. Martine apprehended it would have been better if M. de l'Ille had made the integer of 100,000 parts, or fixed point of freezing water, and from thence computed the dilatations or condensations of the quicksilver in those parts. All the common observations of the weather, &c. would have been expressed by numbers increasing as the heat increased, which is the more natural way; nor would there have been any great incongruity, or inconvenience, in expressing, after the manner of Reaumur, the few observations that occur below simple freezing by numbers of contraction below gr. 0, or 100,000. However, in practice, it will not be very easy to determine exactly all the divisions from the alteration of the bulk of the contained fluid. And besides, as glass itself is dilated by heat, though in a less proportion than quicksilver, so that it is only the excess of the dilatation of the contained fluid above that of the glass that is observable; if different kinds of glass be differently affected by a given degree of heat, this will make a seeming difference in the dilatation of the quicksilver in the thermometers, constructed in the Newtonian method, either by M. de Reaumur's or M. de l'Ille's rules. Accordingly, it has been found, that the quicksilver in thermometers, constructed in M. de l'Ille's way, has found at different degrees of the scale when immersed in thawing snow. In some it was at gr. 154, in others at 156, and in another at 158: and it appears by M. de l'Ille's own account, that his thermometers disagree considerably from one another. Celsius's thermometer has been chiefly used in Sweden, and hence it has been called the Swedish thermometer. The French chemists have lately adopted it, under the name of centigrade thermometer. See Fixed Points of Thermometers, and the table at the close of this article.

Thermometer, Metaline, is a name given to a machine composed of two metals, which, whilst it indicates the variations of cold and heat, serves to correct the errors that result from hence in the construction of pendulum clocks. Instruments of this kind have been contrived by Graham, Le Roy, in 1738, Ellicot, Harris, &c. See Compound Pendulum.

We have also an account of instruments of this kind invented by Morton, Frothingham, and Fitzgerald, in the Phil. Trans. vol. xiv. p. 689, vol. xlv. p. 129, and vol. li. p. 823; to which we must refer for a particular description of each, illustrated by figures.

M. de Luc has likewise described two thermometers of metal, which he uses for correcting the effects of heat upon a barometer, and an hygrometer of his construction connected with them. In one of these, a strong rod of well-hardened brass, supports upon an edge, at a convenient distance from the centre of motion, a lever, which holds the scale of the barometer suspended, and makes it rise or fall by the dilatation or condensation of the brass rod, as the quicksilver rises or falls in the barometer, by the corresponding variations of heat. This scale of the barometer, when it moves, draws or loosens a thread of slip-grafs, which goes over a small pulley placed upon the same axis with a much larger one, to which the scale of the hygrometer is hung likewise by a similar thread, which thus varies, by the proportion of the diameters of the pulleys, as the heat makes the quicksilver in the byrometer vary. This instrument is convenient for meteorological observations; because it faves one observation and two corrections for the heat; but it is necessary from time to time to correct an irregularity in it, which is easily perceived by means of an index, carried by the moveable scales of the two instruments, which, going over inmoveable scales of the same fort, shews their difference of height. When this difference is no longer con- formable to the indication of the thermometer, it is easily rectified by turning small pegs, on which is twisted the thread of slip-grafs, which serves for the suspension of the scales. The irregularity just mentioned confines in this, that when the heat, after having varied, returns to the same point of the quicksilver thermometer, the metallic thermometer does not return to it exactly, but varies nearly in the following manner: during the summer, the latter gains constantly on the former, i. e. amidst its variations, it always preservs a small part of the lengthening, which is at that time its ordinary state. In winter, on the contrary, it becomes insensibly a little too short. The other metallic thermometer, which is more curious than useful, on account of its greater irregularity, consists of a rod of lead, which, communicating by a thread of slip-grafs with a small pulley fixed to the same axis with a greater one, conducts, by means of another pulley; a needle through whole axis, which is bored, paffes another axis that carries the needles of a pulley barometer. Thus this instrument marks the heat and weight of the air upon two concentric circles, by means of two needles turning upon the same centre, as in clocks; by which, the needle of the thermometer points out upon a third circle the correction for the heat, to be made on the barometer. See Phil. Trans. vol. xxviii. part i. p. 437, &c.

Thermometers, Oil. To this class belongs sir Isaac Newton's thermometer, constructed in 1701, with linseed oil instead of spirit of wine. This liquor has the advantage of being sufficiently homogeneous, and capable of a considerable rarefaction, not less than fifteen times greater than that of spirit of wine. It has not been observed to freeze even in very great colds, and it is able to bear a great heat, about four times that of water, without boiling. With these advantages it was made use of by sir Isaac Newton, who discovered by it the comparative degree of heat for boiling water, melting wax, boiling spirit of wine, and melting tin; beyond which it does not appear that this thermometer was applied. The method he used for adjusting the scale of this oil-thermometer was as follows: supposing the bulb, when immersed in thawing snow, to contain 10,000 parts, he found the oil expanded by the heat of the human body so as to take up one thirty-ninth more space, or 10256 such parts; and by the heat of water boiling strongly, 10725; and by the heat of melting tin, 11516. So that, reckoning the freezing point as a common limit between heat and cold, he began his scale there, marking it gr. 0, and the heat of the human body he made gr. 12; and, consequently, the degrees of heat being proportional to the degrees of rarefaction, or 10256: 10725: 11516, that the heat of boiling water was expressed by gr. 34 = $\frac{725 \times 12}{256}$; and that of the melting tin by gr. 72. Phil. Tran. No. 270, or Abr. vol. iv. part ii. p. 3.

Although in this graduation for sir Isaac Newton does not specify any degree of cold below that of freezing water, yet it would be easy to prolong his scale downward below gr. 0, or the freezing point, and thus to adapt it for estimating greater degrees of cold, like other thermometers. But there is another insuperable inconvenience that attends all the-
thermometers made with oil, or any other viscid liquor, viz. that such a liquor adheres too much to the sides of the tube. In a sudden cold or fall of the oil, much of it flicks by the way, and only licks gradually afterwards, so that at first the surface appears really lower than the present temperature requires. And besides, as at all times some of the oil must continue to flick and moisten the inside of the tube, in different degrees of heat and cold, the oil, becoming alternately more or less viscid, will adhere sometimes more and sometimes less; and will, therefore, inevitably disturb the regularity and uniformity of the thermometer. Martine's Essays, Eff. iii.

**THERMOMETERS, Fixed Points of.** Various methods have been proposed by various authors, for finding a fixed point, or degree, of heat and cold, from which to reckon the other degrees, and adjust the scale; so that observations made at the same or different times, in different places, might be compared together. For want of this, notwithstanding all the numerous registries of the weather, &c., that have been kept and published by different authors, we are much at a loss to determine the comparative differences of heat and cold in different countries and climates, and the result of many other observations. If all the weather-records in the world had been made according to one determined scale, these inconveniences and uncertainties would have been prevented; which, indeed, are now unavoidable, and must still continue for all alike to grade their thermometers in the same manner, or at least define some fixed or unalterable points of heat, to which all the different scales of those instruments may be reduced. The honourable Mr. Boyle was very sensible of this inconvenience, and many lamented it; and he proposed the freezing of the essential oil of aniseed, as a term of heat and cold that might be of use in making and judging of thermometers, and so to graduate them from this point according to the proportional dilations or contractions of the included spirits. He mentioned also the coldness requisite to begin the congelation of distilled water as another fixed term that might be adopted; for he was persuaded, that among the ordinary waters, some were apt to freeze more easily than others. But he was deterred from prosecuting this scheme of fixing a standard for making and graduating all thermometers in the same way, experiments, &c. on cold, in his works abridged by Shaw, vol. i. p. 579.

Dr. Halley (Phil. Trans. Abr. vol. ii. p. 36.) seems to have been fully apprized of the bad effects of the indefinite method of constructing thermometers, and wished to have them adjusted to some determined points. What he seems to prefer for this purpose is the degree of temperature which is found in subterranean places, where the heat in summer and cold in winter appears to have no influence. But this degree of temperature is shewn by Dr. Martine to be a term for the universal construction of thermometers, both inconvenient, as it cannot be easily ascertained: and a precarious one, as the difference of soils and depths may occasion a considerable variation. Another term of heat which he thought might be of use in a general graduation of thermometers, is that of boiling spirit of wine that has been highly rectified: but a much more convenient term of heat, though less inflected on by Dr. Halley, is that of boiling water. The first trace that occurs of the method of actually applying fixed points or terms to the thermometer, and of graduating it, so that the unequal divisions of it might correspond to equal degrees of heat, is the project of Renaldinus, professor of Padua, in 1694: it is thus described in the Acta Erud. Lips. "Take a flender tube, about four palms long, with a ball fastened to the fame; pour into it spirit of wine, enough just to fill the ball, when surrounded with ice, and not a drop over: in this flat, seal the orifice of the tube hermetically, and provide twelve vessels, each capable of containing a pound of water, and somewhat more; and into the first pour eleven ounces of cold water, into the second ten ounces, into the third nine, &c.: this done, immerse the thermometer in the first vessel, and pour into it one ounce of hot water, observing how high the spirit rises in the tube, and noting the point with unity: then remove the thermometer into the second vessel, into which are to be poured two ounces of hot water, and note the place the spirit rises to with 2. By thus proceeding till the whole pound of water is spent, the instrument will be found divided into twelve parts denoting so many terms or degrees of heat; so that at 2 the heat is double to that at 1, at 3, triple, &c."

But this method, though plausible, Wallis shews, is deceitful, and is built on false suppositions; for it takes for granted, that we have one degree of heat, by adding one ounce of hot to eleven of cold water; two degrees, by adding two ounces to ten, &c.: it supposes, also, that a single degree of heat acts on the spirit of wine in the ball with a single force; a double with a double force, &c. lastly, it supposes, that if the effect be produced in the thermometer by the heat of the ambient air, which is here produced by the hot water, the air has the fame degree of heat with the water.

Soon after this project of Renaldinus, viz. in 1701, Mr. Isaac Newton constructed his oil thermometer, and fixed the base or lowest fixed point of his scale at the temperature of thawing snow, and twelve at that of the human body, &c. in the manner explained under the article Oil Thermometer.

M. de Luc observes, that the second term of his scale should have been at a greater distance from the first, and that the heat of boiling water would have answered this purpose better than that of the human body.

In 1702, M. Amontons contrived his universal thermometer, the scale of which was graduated in the following manner. He chose for the first term the weight that counterbalanced the air included in his thermometer, when it was heated by boiling water: and in this flat he so adjusted the quantity of mercury contained in it, till the sum of its height in the tube, and of its height in the barometer at the moment of observation, was equal to seventy-three inches. Fixing this number at the point to which the mercury in the tube rose by plunging it into boiling water, it is evident, that, if the barometer at this time was twenty-eight inches, the height of the column of mercury in the thermometer above the level of that in the ball was forty-five inches; but if the height of the barometer was less by a certain quantity, the column of the thermometer ought to be greater by the same quantity, and reciprocally. He formed his scale on the supposition that the weight of the atmosphere was always equal to that of a column of mercury of twenty-eight inches, and divided it into inches from the point 73 downwards, marking the divisions with 72, 71, 70, &c. and he subdivided the inches into lines.

But as the weight of the atmosphere is variable, the barometer must be observed at the same time with the thermometer, that the number indicated by this last instrument may be properly corrected, by adding or subtracting the quantity of which the mercury is below or above twenty-eight inches in the barometer. In this scale, then, the freezing point is at 51.5 inches, corresponding to 32 of Fahrenheit, and the heat of boiling water at 73 inches,
The fixed points of Fahrenheit's thermometer, which is generally used in Great Britain, as we have already observed under Mercurial Thermometer, are the congelation produced by salt ammoniac and the heat of boiling water. The interval between these points is divided into 212 equal parts; the first of these points is marked 0, 32 degrees below the freezing point, and the other 212; the distance of course between the freezing and boiling points being 180. The reason why Fahrenheit fixed his scale so far below the water-freezing point was founded on an erroneous hypothesis relative to the real zero or point of absolute privation of heat; nevertheless it has this advantage, that the distinction between the positive and negative terms, or those which express degrees above or below the zero, much less frequently occurs in any experiments, and scarcely ever in the register of natural cold in temperate climates, by which many accidental errors are avoided.

Reaumur, in his thermometer, the construction of which he published in 1730, and which is generally used in France and other parts of the continent, begins his scale at an artificial congelation of water in warm weather, which, as he uses large bulbs for his glasses, gives the freezing point much higher than it should be, and at boiling water he marks 80; (the distance between both points being 80,) which point Dr. Martine apprehends to be more vague and uncertain than his freezing point. The spirit in the thermometer, he observes, is absolutely incapable of such a great heat as Reaumur ascribed to it, and that not by a small or trifling difference. He finds, that highly rectified spirit of wine cannot be heated beyond gr. 175 in Fahrenheit's thermometer, while boiling water raises the quicksilver 37 degrees higher; and common brandy was able to conceive a heat no greater than about gr. 190. So far, he concludes, was Reaumur in the wrong, when he thought that all spirits, weak and strong, immerged in boiling water, received a given degree of heat, and that equal to the heat of the surrounding water. He supposes his standard heat could take a heat only of about gr. 180; less by 32 degrees than what he reckoned. In order to determine the correspondence of his scale with that of Fahrenheit, it is to be considered that his boiling-water heat is really only the boiling heat of weakened spirit of wine, coinciding nearly, as Dr. Martine apprehends, with Fahrenheit's gr. 180. And as his gr. 105 is the constant heat of the cave of the observatory at Paris, or Fahrenheit's gr. 53, he thence finds his freezing point, instead of answering just to gr. 32, to be something above gr. 34.

The thermometer of M. de l'Ile, of which he presented an account to the Academy of Sciences at Petersburg in 1733, has only one fixed point, which is the heat of boiling water, and, contrary to the common order, the several degrees are marked downwards from this point or zero, according to the condenfations of the contained quicksilver, and consequently by numbers increasing as the heat decreases to 150, the freezing point. In order to determine the extent of the degrees of this scale, M. de l'Ile first weighed the empty tube, and then weighed it full of mercury; and the difference of these two weights gave him that of the mercury. He then exposed the thermometer to the heat of boiling water, and took care to preserve the mercury, which this increase of heat forced out of it; this he accurately weighed, and deducting its weight from the total weight of the mercury, he made the remainder, or that which was left in the thermometer, equal to 10000; he then found by calculation how many 10000 parts of this residue that forced out of the tube contained, and these parts formed the divisions of the scale from the point, determined by the condenfation of the mercury to the same point at which it stood before it was plunged in boiling water, to the upper end of the tube; and these divisions formed the extent of the degrees of M. de l'Ile's scale. According to his standards, the freezing point, says Dr. Martine, is near to his gr. 150, corresponding to Fahrenheit's gr. 32, by which means they may be compared; but M. Ducreff says, that this point ought to be marked at least at gr. 154.

M. Ducreff, in his spirit thermometer, constructed in 1740, made use of two fixed points; the first, or 0, indicated the temperature of the earth, and was marked on his scale in the cave of the Royal Observatory at Paris; and the other was the heat of boiling water, which the spirit in his thermometer was made to endure, by leaving the upper part of the tube full of air. He divided the interval between these points into 100 equal parts; calling the divisions upwards degrees of heat, and those below 0 degrees of cold.

He afterwards regulated his thermometer by the degree of cold indicated by melting ice, which he found to be 105. In Celsius's, or the centigrade thermometer, the freezing point, like that of Reaumur's, was 0, the boiling point at 100, and the distance between both 100. See the table at the close of the article.

The Firenze thermometers made and used by the members of the famous academy del Cimento, being some of the first instruments of the fort, were vaguely graduated, some of them having many more degrees than others; but those of their most common graduation were of two forts; in one fort the freezing point, determined by the degree at which the spirit stood in the ordinary cold of ice or snow (probably in a thawing state), and coinciding with gr. 32 of Fahrenheit, fell at gr. 20; and in the other fort at gr. 13; and the natural heat of the viscera of cows and deer, &c, raised the spirit in the latter, or less, to about gr. 40, coinciding with their summer heat, and nearly with gr. 102 in Fahrenheit's, and in their other long thermometer, the spirit, when exposed to the great midsummer heat in their country, rose to the point at which they marked gr. 80. The freezing point of one was 20, the boiling point 174, and the distance between both was 154; in the other the freezing point was 13, the boiling point 81, and the distance 684.

In the Parisian thermometer, or the ancient thermometer of the Academy of Sciences, the freezing point was at 25, the boiling point at 239, and the distance between both 214.

In the thermometer of the observatory at Paris, made of spirit of wine by M. de la Hire, the spirit always stands at gr. 48, in the cave of the observatory, corresponding to gr. 53 in Fahrenheit's; and his gr. 28 corresponded with 51 inches fixed lines in Amonton's thermometer, and consequently with the freezing point, or gr. 32 of Fahrenheit's. This thermometer of De la Hire, which stood in the observatory of Paris above 60 years, seems to have been graduated thus; the freezing point 28, the boiling point 199, and the distance between both 171. In Amonton's thermometer the freezing point was 51, the boiling point 73, and the distance between them 218.

In the thermometer of Poleni, made after the manner of Amonton's, but with less mercury, 47 inches corresponding, according to Dr. Martine, with 51 in that of Amonton's, and 53 with 59. It was graduated thus; the freezing point at 47, the boiling point at 62, and the
the distance between them 15. In Crucquius's, the freezing point was 1070, the boiling point 1510, and the distance 440.

In the ancient standard thermometer of the Royal Society, after which thermometers were for a long time constructed in England, Dr. Martine found that gr. 34, answered to gr. 54 in Fahrenheit's, and gr. 0 to 89 or 88. From that point the number ascended and descended thus; the freezing point was 735, the boiling point 1415, and the distance between them 2155. In Sir Isaac Newton's, the freezing point was 0, the boiling point 34, and the distance 35.

In the thermometers graduated for adjusting the degrees of heat proper for exotic plants, &c. in flowerbeds and green houses, the middle temperature of the air is marked at gr. 0, and the degrees of heat and cold are numbered both above and below. Many of these are made on no regular and fixed principles. But in that formerly much used, called Fowler's regulator, the spirit fell, in melting snow, to about gr. 34 under 0; and Dr. Martine found, that his gr. 16 above 0, coincided with nearly gr. 64 of Fahrenheit. His 0 seems to have coincided with about the 53d or 54th degree of Fahrenheit's, and from that point the number ascended and descended thus; the freezing point 34, the boiling point 2501, and the distance between them 2844.

Dr. Hales (Statical Essays, vol. i. p. 53.) in his thermometer made with spirit of wine, and used in experiments on vegetation, began his scale with the lowest degree of freezing, or gr. 32 of Fahrenheit, and carried it up to gr. 100, which he marked where the spirit, when the bulb was heated in hot water, on which wax swimming first began to coagulate, and this point Dr. Martine found to correspond with gr. 142 of Fahrenheit. But by experience Hales's gr. 100 falls considerably above our gr. 142. According to others, his freezing point was 0, his boiling point 163, and the distance of course 163.

In the Edinburgh thermometer, made with spirit of wine, and used in the meteorological observations published in the Medical Essays, the scale is divided into inches and tenths. In melting snow the spirit stood at 83, and the heat of the human skin raised to 23 °. Dr. Martine found, that the heat of the person who graduated it was gr. 97 of Fahrenheit. It seems to have been graduated thus; the freezing point 81, the boiling point 47, and the distance between them 38.

As it is often of use to compare different thermometers, in order to judge of the result of former observations, we have annexed from Dr. Martine's Essays, the table by which he compared fifteen different thermometers. See Plate XVII. Pneumatics, fig. 4. See also the table at the close of this article.

There is a thermometer which was formerly much used in London, called the thermometer of Lyons, because M. Griffis brought it there into use, which is made of mercury; the freezing point is marked gr. 0, and the interval from that point to the heat of boiling water is divided into 100 equal degrees.

From the above abstract of the history of the construction of thermometers, it appears that freezing and boiling water have furnished the distinguishing points that have been marked upon almost all thermometers. The inferior fixed point is that of freezing, which some have determined by the freezing of water, and others by the melting of ice; and though the difference between these two temperatures is not commonly very considerable, yet it is not invariable.

It is now well known, that all, or almost all bodies, by changing from a fluid to a solid state, or from the state of an elastic to that of an unstable fluid, generate heat; and that cold is produced by the contrary process.

In order to obtain this fixed point or limit, melting ice, or ice powdered and mixed with water, will produce the same temperature. And though there may be some trifling difference between the temperature of ice disposed to melt, and that of melted ice or the water produced by it; this difference, however, has no sensible effect on the thermometer; consequently, the temperature of water successively produced by ice, and accumulated in its interstices, or from powdered ice mixed with the water which is produced by it in melting, affords, as De Luc observes, a fixed point, which is easily obtained, and which should be adopted in the construction of all thermometers.

The superior fixed point of almost all thermometers, is the heat of boiling water; but this point cannot be considered as fixed, unless the heat be produced by the same degree of boiling, and under the same weight of the atmosphere. With regard to the first circumstance, it is observed, that water, when it begins to boil, has not attained to its greatest degree of heat, which is known by its bubbling or foaming from the bottom of the vessel, and over the whole surface of the water, with the greatest violence which it is capable of acquiring; and in this state the water discovers an augmentation of heat more than one degree above the heat it had when it began to boil. The temperature of water which boils with vehemence should, therefore, be the standard of the fixed point of thermometers; nevertheless it is to be considered farther, that this degree of heat with which water violently boils, is invariably the same, only under a given pressure of the atmosphere; but if the pressure be diminished or increased, the boiling heat is diminished or increased. It is well known that water, placed under the exhausted receiver of an air-pump, will be converted into steam with a degree of heat far inferior to that which is necessary to its boiling in the open air; and under the pressure of its own vapour, confined in Papin's digester, it is said to sustain a degree of heat, without boiling, far exceeding that which, in the open air, would convert it into steam. Hence it follows that, in climates where the pressure of the atmosphere is liable to considerable change, the heat of boiling water, in open air, will be different at different times. Consequently thermometers, made in different states of the barometer, will disagree; unless allowance has been made for the effect of the variation of the barometer upon accurate principles. That the heat of boiling was variable, according to the pressure of the atmosphere, seems to have been known to Fahrenheit as early as the year 1724. See Phil. Tran. vol. III. p. 148.

Some time after this period, Meffrs. Monnier and Cafrini (Mem. de l'Acad. des Sc. for 1740) made some decisive observations, in order to shew that this quantity was very considerable.

M. de Luc, in 1762, made a much more complete series of experiments, which he has described and reduced into a system in his Recherches fur les Mod. de l'Atmosphère, vol. i. p. 382, &c. vol. ii. p. 383, &c. and these have been since verified by Sir George Shuckburgh, in 1775 and 1778. See Phil. Tran. vol. LXIX. part ii. p. 362, &c.

M. de Luc fixes the boiling point of his thermometer when the barometer is at 27 Paris, or 28.75 English inches, that being its mean height at Geneva. He divides the fundamental interval, i.e. the whole extent of the scale, between melting ice and boiling water, after the French manner, into eighty equal parts; and by a great number of experiments
periments on the heat of boiling water, at different heights above the level of the sea, he hath found, that the height of his thermometer, plunged in boiling water, may be expre
s
sed, in all states of the barometer, by the following formula, viz.

\[
\log y - a = T
\]

in which \(y\) denotes the height of the thermometer in sixteenths of a Parifian line, \(T\) the height of a thermometer, plunged in boiling water, above melting ice, in hundredths of a degree of his scale; and \(a\) the con
stant number 10387.

By logarithms he always makes the tabular or Briggian logarithms, and considers the seven figures given by the tables, besides the index, as integral figures, \(i.e.\) he considers the eighth figure of the logarithm as standing in the place of units. But as it is more usual with mathematicians, and, in general, more convenient, to consider all the figures after the index as decimals, the number which M. de Luc expresses by \(99 \frac{x}{100} \log y\), would in that case be

\[
99 \times \frac{x}{100} \log y \quad \text{or} \quad 99 \times \frac{3}{50} \log y
\]

However, in the sequel, M. de Luc's notation is retained.

Now if care were taken by the above formula, or in any other way, to adjust the boiling point to the main height of the barometer in every country, the instruments of the same country would always be consistent; but those of different countries would still disagree; that is, they would express the same temperature differently, though their similar intervals should be similarly divided; for in every scale, the number of degrees above or below melting ice, by which any given temperature is expressed, will be as the value of each degree inverely; that is, if each be a given part of the fundamental interval, as the value of the fundamental interval inverely; but if the degrees of different scales be different parts of the fundamental intervals, as the value of the fundamental interval inverely, and the number of degrees contained in it directly.

In order, therefore, to compare the thermometers of different countries, the proportions of their fundamental intervals to each other must be ascertained, or we must have some means of finding, upon one scale, the place of the boiling point of another. For this purpose, a general solution is requisite of the following problem, viz. the fundamental interval being given for a given height of the barometer, to find the fundamental interval for any other given height of the barometer. The solution is furnished by M. de Luc's rechanges; and his formula, above given, is reduced to English measures, and adapted to English instruments, by Dr. Horsley. As the subject is curious and important, we shall subjoin the process he has pur
sued for this purpose. It is but seldom that the barometer in this country stands so low as 27 Paris inches. Its main height upon the plain country about London is near 30 English inches. It may, therefore, be proper for the London workmen to fix their boiling point when the barometer is at 30 inches. Fahrenheit's division of the scale, which makes 180 degrees between melting ice and boiling water, and places the point \(\theta\) at the 32d degree below melting ice, may be retained; and the thermometer thus constructed is called by Dr. Horsley, Bird's Fahrenheit, because Mr. Bird, he apprehends, is the first workman who took the pains to attend to the state of the barometer in making thermometers, and has always fixed the boiling point when his barometer has stood at 30 inches. \(T\), then, being put for the height of a thermometer plunged in boiling water, above melting ice, in 100ths of a degree of De Luc's scale, in any given state of the barometer; let \(\theta\) denote the same height in 100ths of a degree of Bird's Fahrenheit; put \(y\) for the height of the barometer, in 16ths of a Paris line; \(z\), for its height in Paris lines; \(x\), in 10ths of a Paris inch; \(x\), in 10ths of an Eng
lish inch; and for \(10387\) put \(a\); for 16, \(b\); for 10, \(c\); for \(12, d\); and let \(E\) and \(F\) represent numbers expressing the proportion of the English foot to the French foot. M. de Luc hath found that, whatever be the value of \(y\),

\[
99 \log y - a = T
\]

But \(\log y = \log v + \log b\); and \(\log v = \log x + \log d - \log c\); and \(\log x = \log z + \log E - \log F\); therefore \(\log y = \log z + \log E + \log d + \log b - \log F - \log c\); and

\[
99 \log y - a = T
\]

or \(99 \log y = 10387 - a\). But \(99 \log E + \log d + \log b - \log F - \log c - 4171.55\); the French foot being to the English as 2.1345 to \(T\). Therefore \(\frac{99}{100} \log z = - 4171.55 + \frac{99}{200000} \log z = - 4171.55 = T\); and \(\frac{99}{100} \log z = \frac{T}{200000}\)

is the height of the thermometer, plunged in boiling water, above melting ice, in degrees of De Luc's scale, when the height of the barometer in tenths of an English inch, is \(z\). For \(z\) write 300; then \(\frac{T}{200000} = 80.902\); which is therefore the height of the thermometer, in boiling water, above melting ice, in degrees of De Luc's scale, when the barometer is at 30 inches English. And in the same state of the barometer, the height of the thermometer plunged in boiling water, above melting ice, in degrees of Bird's Fa
renheit, or \(\frac{1}{180}\), is 180. Hence the numbers \(T\) and \(\theta\)

are in the constant proportion of 809 and 1800, whatever be the value of \(z\). For the change produced in the heat of boiling water, by any change of \(z\), being always the same for both thermometers, the temperature expressed by \(T\) in parts of one scale is always the same, as \(\theta\) ex
presses in parts of the other; and therefore putting \(\frac{1}{L}\) and \(\frac{1}{B}\) for the values of the 100th part of a degree of the scales of De Luc and Bird respectively, the fractions \(\frac{T}{100} \theta\)

are always equal, and \(T\), \(\theta\) are in the constant propor
tion of the invariable numbers \(L\), \(B\): consequently, when the proportion of \(T\) and \(\theta\) is determined for any particular value of \(z\), it is found generally for all: consequently \(T\), \(\theta\)

:: 809 : 1800. And \(T = \frac{809}{1800} \theta = \frac{899}{2000} \theta \) very nearly in all values of \(z\); and substituting this value for \(T\) in the equation
THERMOMETER.

Equation exhibiting the relation between \( z \) and \( T \), we have,

\[
T = \frac{899}{2000 \times 100} \log z - \frac{92.804}{100} = \text{the height of the thermometer in boiling water, above melting ice, in degrees of Bird's Fahrenheit, when the height of the barometer in tenths of an English inch, is } z. \quad \text{And thus M. de Luc's formula, for the variation of the boiling point, is adapted to English instruments, and reduced to English measures of length.}
\]

For \( z \) write 287.7525, the length of 27 French inches in tenths of an English inch, and \( \theta \), the height of De Luc's boiling point above melting ice, in degrees of Bird's Fahrenheit, comes out 177.989. Hence M. de Luc's boiling point falls upon 209.989 of Bird's scale, i.e. upon 210 very nearly, or infensibly more than two degrees below Bird's point of boiling. But as 899 is a troublesome divisor, the computation will be more easy and expeditious, by writing

\[
\frac{11}{1000000} \text{ log. } z = s. \quad \text{Then } s + \frac{1}{900} = 92.804 = \theta \text{ very nearly.}
\]

Upon these principles Dr. Horfley has computed the table following, for finding the heights to which a good Bird's Fahrenheit will rise, when plunged in boiling water, in all states of the barometer, from 27 to 31 English inches; which will serve, among other uses, to direct instrument-makers in making a true allowance for the effect of the variation of the barometer, if they are obliged to finish a thermometer, when the barometer is above or below 30 inches; though it is best to fix the boiling point when the barometer is at the height prescribed.

Equation of the Boiling Point.

The Royal Society, fully apprized of the importance of adjusting the fixed points of thermometers, appointed a committee of seven gentlemen to confider the best method for this purpose; and their report is published in the Phil. Trans. vol. lxvi. part ii. art. 37. From a variety of experiments and observations, relating to this subject, the committee have deduced the following practical rules, which they recommend in adjusting the fixed points of thermometers. The most accurate way of adjusting the boiling point is, not to dip the thermometer into the water, but to expose it only to the steam, in a vessel closed up in the manner represented in Plate XVI. Pneumatics, fig. 5, where A B c is the vessel containing the boiling water, D d the cover, E a chimney made in the cover intended to carry off the steam, and M M the thermometer paffed through a hole in the cover. In the pursuit of this method the following particulars must be regarded: the boiling point must be adjusted when the barometer is at 29.8 inches; and the thermometer must be kept in the manner.

Sir George Shuckburgh has also subjoined the following general table for the use of artists in constructing the thermometer, both according to his own observations, and those of M. de Luc.

</table>

The numbers in the first column of this table express heights of the quicksilver in the barometer in English inches and decimal parts: the second column shews the equation to be applied, according to the sign prefixed, to 212° of Bird's Fahrenheit to find the true boiling point for every such state of the barometer. The boiling point for all intermediate states of the barometer may be had with sufficient accuracy by taking proportional parts, by means of the third column of differences of the equations.

(See Phil. Trans. vol. lxx. part i. art. 30. See also an excellent paper on this subject by Dr. Magleyne, in the Phil. Trans. vol. lxxiv. part i. art. 20.) In the following table we have the result of fifteen different observations made by Sir George Shuckburgh (ubi supra) compared with the result of M. de Luc's rules.
The ball of the thermometer must be placed at such a depth within the pot, that the boiling point may rise very little above the cover; and the surface of the water in the pot should be at least one or two inches below the bottom of the ball. Care must be taken to fill up the hole in the cover through which the tube is inserted, and to make the cover fit pretty close, so that no air shall enter into the pot that way, and that not much steam may escape. A piece of thin flat tin-plate must also be laid on the mouth of the chimney, so as to leave no more passage than what is sufficient to carry off the steam.

If the artist pleases, he may tie each corner of this plate by a string to prongs fixed to the chimney, and standing on a level with the plate, as it will be thus always kept in its place.

Fig. 7, is a perspective view of the chimney and tin-plate; A, B, C, D is the plate, E the chimney, F, G, H, M, and N, the prongs fastened to the chimney, to which the four corners of the plate are to be tied by the strings A, B, C, D, and M, N; the ends F, G, M, and N, of the prongs must be on a level with the plate, and the prongs should not be stretched tight. The chimney ought not to be less than half a square inch in area, and not less than two or three inches in length. The cover should be made to take on and off easily, and a ring of woollen cloth may be placed under it, so as to lie between it and the top of the pot. The hole in the cover may be filled up by a cork, with a hole bored through it, big enough to receive the tube, and then cut into two, parallel to the length of the tube. Another method. more convenient in use, but not so easily made, is represented in Fig. 8, which exhibits a perspective view of the apparatus: A, H is the cover, H the hole through which the thermometer is passed, B a flat piece of brass fixed upon the cover, and D, E, F a sliding piece of brass, made so as either to cover the hole H or to leave it uncovered, as in the figure, and to be tightened in either position by the screw s sliding in the slit M; also in the edge D, E, to enclose the tube of the thermometer: pieces of woollen cloth should also be fastened to the edges B, and D, E, and also to the bottom of the sliding piece D, E, unless that piece and the cover are made sufficiently flat to prevent the escape of the steam. In order to keep the thermometer suspended at the proper height, a clip may be used like that represented in Fig. 9, which, by the screw s, must be made to embrace the tube tightly, and may rest on the cover.

Another method, which is rather more convenient, when the top of the tube of the thermometer is bent into a right angle, in the manner often practised at present for the sake of more conveniently fixing it to the scale, is represented in Fig. 10: G, F, G, F is a plate of brass standing perpendicularly on the cover, and L, N a piece of brass bent at the bottom into the form of a loop, with a notch in it, so as to receive the tube of the thermometer, and to suffer the bent part to rest on the bottom of the loop; this piece must slide in a slit K, K, in the plate L, N, and be tightened at any height by the screw T.

Moreover, it is best to make the water boil pretty briskly, as otherwise the thermometer is apt to be a great while before it acquires its full heat, especially if the vessel is very deep; and the observer should wait at least one or two minutes after the thermometer appears to be stationary, before he concludes that it has acquired its full height.

Another way of adjusting the boiling point is to try it in a vessel of the same kind as the former, only with the water rising a little way, viz. from one to three or four inches above the vessel, taking care that the boiling point shall rise very little above the cover. In this method there is no need to cover the chimney with the tin-plate, and there is less need to make the cover fit close, unless to prevent the operator from being incommoded with the steam. The height of the barometer in this method is 29.1 inches.

It will be convenient to have two or three pots of different depths for adjusting thermometers of different lengths. A third way of adjusting the boiling point is to wrap several folds of linen rags or flannel round the tube of the thermometer, and to try it in an open vessel, taking care to pour boiling water on the rags, in order to keep the quicksilver in the tube as nearly of the heat of boiling water as possible. In this method the barometer should be at 29.8 inches; the water should boil fast, and the thermometer should be held upright, with its ball two or three inches under water, and in that part of the vessel where the current of water ascends.

Whichever of these methods of adjusting the boiling point is used, it is not necessary to wait till the barometer is at the proper height, provided the operator will take care to correct the observed height according to the following table.

In using this table, seek the height of the barometer in the column answering to the method of adjusting the boiling point, the corresponding number in the third column shows how much the point of 212° must be placed above or below the observed point: e.g. supposing the boiling point to be adjusted in them when the barometer is at 29 inches, and that the interval between the boiling and freezing points is 11 inches; the nearest number to 29 in the left-hand column is 29.03, and the corresponding number in the table is 7 higher, and therefore the mark of 212° must be placed higher than the observed point by 1000ths of the interval between boiling and freezing, i.e. by \( \frac{11 \times 7}{1000} = 0.77 \) of an inch. This method of correcting the boiling point is not strictly just, unless the tube is of an equal bore in all its parts; but the tube is seldom so unequal as to cause any sensible error, where the whole correction is so small. The trouble of making the correction will be abridged by a diagonal scale, such as is represented in Fig. 10.

Although it is of no great consequence what kind of water is used in adjusting the boiling point, so that it is not hot,
It is observed, that though the boiling point be placed so much higher on some of the thermometers now made than on others, this does not produce any considerable error in the observations of the weather, at least in this climate; for an error of 1° in the position of the boiling point, will make an error only of half a degree in the position of 92°, and of not more than a quarter of a degree in the point of 62°.

It is only in nice experiments, or in trying the heat of hot liquors, that this error in the boiling point can be of much significance.

In adjusting the freezing, as well as the boiling point, the quicksilver in the tube ought to be kept of the same heat as that in the ball. When the freezing point is placed at a considerable distance from the ball, the pounded ice should be piled to such a height above the ball, that the error which can arise from the quicksilver in the remaining part of the tube, not being heated equally with that in the ball, shall be very small, or the observed point must be corrected on that account, according to the following table:

<table>
<thead>
<tr>
<th>Heat of the Air</th>
<th>Correction</th>
</tr>
</thead>
<tbody>
<tr>
<td>42°</td>
<td>-00087</td>
</tr>
<tr>
<td>52°</td>
<td>-00174</td>
</tr>
<tr>
<td>62°</td>
<td>-00261</td>
</tr>
<tr>
<td>72°</td>
<td>-00348</td>
</tr>
<tr>
<td>82°</td>
<td>-00435</td>
</tr>
</tbody>
</table>

The correction in this table is expressed in 1000th parts of the distance between the freezing point and the surface of the ice: e.g. if the freezing point stands seven inches above the surface of the ice, and the heat of the room is 62°, the point of 32° should be placed at 7 x 0.00261, or 0.018 of an inch lower than the observed point. A diagonal scale will facilitate this correction.

The committee observe, that in trying the heat of liquors, care should be taken that the quicksilver in the tube of the thermometer be heated to the same degree as that in the ball; or if this cannot be done conveniently, the observed heat should be corrected on that account; for the manner of doing which, and a table calculated for this purpose, we must refer to their excellent report in the Phil. Trans. vol. lxxii. part ii. art. 37.

Several experiments made by governor Hutchins, at Albany Fort, in Hudson's Bay, in 1782, in pursuance of a method suggested by Dr. Black and Mr. Cavendish, and for which he obtained Sir Godfrey Copley's medal from the Royal Society in 1783, have not only confirmed the observations before made, relative to the solid state into which quicksilver can be brought by cold, its metallic splendour and polish when smooth, its roughnesses and crystallization where the surface was unconfined, its malleability, softness, and droll found when fric Peace. but have also clearly demonstrated, that its point of congelation is no lower than 40°, or rather 39°, of Fahrenheit's scale; that it will bear, however, to be cooled a few degrees below that point, to which it jumps up again on beginning to congeal; and that its rapid deposit in a thermometer, through many hundred degrees, when it has once passed the above-mentioned limit, proceeds merely from its great contraction in the act of freezing. See Phil. Trans. vol. lxii. part ii. art. 20, 20, 21.

Thermometers, Observations on the Construction of. It is absolutely necessary that those who would derive any advantage from these instruments, should agree in using the same liquor, and in determining, according to the same method, the two fundamental points. If they agree in these fixed points, it is of no great importance whether they divide the interval between them into a greater or less number of equal parts. The scale of Fahrenheit, in which the fundamental interval between 212°, the point of boiling water, and 32°, that of melting ice, is divided into 180 parts, should be retained in the northern countries, where Fahrenheit's thermometer is used: and the scale, in which the fundamental interval is divided into 80 parts, will serve for those countries where the thermometer of M. de Réaumur is adopted. But no inconvenience is to be apprehended from varying the scale for particular uses, provided care be taken to signify into what number of parts the fundamental interval is divided, and the point where 0 is placed.

With regard to the choice of tubes, it is most desirable to have them exactly cylindrical through their whole length. See Mercurial Thermometer.

The kapillary tubes are preferable to others, because they require less bulbs, and they are also less brittle, and more sensible. Those of the most convenient size for common experiments are such as have their internal diameter about the fourth of a line: and those made of thin glass are better than others, as the rise and fall of the mercury may be more distinctly perceived. The length of nine inches will serve for all common occasions; but for particular purposes, the length both of the tubes and of the divisions should be adapted to the uses for which they are designed.

In determining the best size of the balls or bulbs, it has been usual to compare new tubes with such thermometers as are well proportioned. But M. Durand has proposed a formula for finding the proportion which the balls ought to bear to their respective tubes. With this view he expresses the length of the tube, measured in diameters of itself, by a; the whole capacity of the ball and tube by c; the capacity of the fundamental interval, expressed in the same parts with the whole capacity, by d; the number of degrees of the fundamental interval by m; the number of other degrees which the scale is to contain, besides those of the fundamental interval both above and below it, by n; and the diameter of the ball measured in diameters of the tube by b: and b = \sqrt{\frac{\pi}{6} \frac{a \times \frac{c}{m}}{d \times m + n}} - 1. For two cylinders having equal bases being as their heights, m : n :: d : m, which is the capacity of that part of the tube which exceeds the fundamental interval, to which adding d, that interval, we have the total capacity of the tube = \frac{d_n + d_m}{m}. Subtracting this from c, we shall have the capacity of the ball = c - \frac{d_n + d_m}{m} = \frac{c \times m - d_m - d_n}{m}. If this quantity be divided by the capacity of the tube, the quotient will shew how often the capacity of the ball contains that of the tube; and this quotient is = \frac{1}{m}.
cylinder having \( a \) diameters of the tube, for their respective heights, and \( d \) diameter for the base, as are contained in this last quotient; and, therefore, its cylindric solidity expressed in the cylindric solidities of the tube will be \( a \times \frac{c m - d m - d n}{d m + d n} \). But the diameter of this ball is equal to the base of the cylinder in which it may be inscribed, and the solidity of this cylinder is equal to \( \frac{a}{2} \times \frac{c m - d m - d n}{d m + d n} \); and the diameter of its base equal to the diameter of the ball, will be

\[
\sqrt{\frac{a}{2} \times \frac{c m - d m - d n}{d m + d n}} \text{ or } \sqrt{\frac{a}{2} \times \frac{c m}{d \times m + n} - 1}.
\]

It is evident that, ceteris paribus, the larger the bulb is, in proportion to the diameter of the cavity of the tube, or the narrower the latter is in proportion to the former, the greater will the motion of the surface of the fluid be in the tube. But it must be observed, that when the bulb is very large, the thermometer will not easily arrive at the precise temperature of any place, wherein it may be situated. Some persons, in order to give the bulb a greater surface, and of course to render it more capable of readily attaining a given temperature, have made it not globular, but cylindric (which shape was adopted by Fahrenheit), or flat, or bell-like, &c.; but those shapes are improper, because they are liable to be altered by the varying gravity of the atmosphere, consequently those thermometers cannot be accurate. The bulb should be clean and colourless; since coloured surfaces are apt to be partially heated by a strong light. If you take two equal thermometers, and paint the bulb of one of them black, or of any dark colour, and expose them both to the fun; the mercury in that whole bulb is painted will rise several degrees higher than in the other; even a strong day-light, independently of the direct rays of the sun, will affect them differently. The ball of the thermometer should not be in contact with the substance of the scale, lest it should be influenced by the temperature of that substance.

When a proper tube and ball are procured, and their proportion ascertained, the next object which requires peculiar attention is that of filling the thermometer. For this purpose the tubes should be clean and dry, and the mercury very pure. (See Mercury and Barometer.) The mercury may be introduced into the tube by means of a kind of reflow fixed at the top of it, and proportioned in size to the bulk of the ball, or by rolling upon the tube a strip of fine paper, about two or three inches broad. In order to clear the tube of its air and moisture, it should be held over a gentle fire, so disposed, as that it may heat at once the whole extent of the tube, till its heat becomes too great for the operator's hand to bear, who therefore uses a glove or nippers for this purpose; care being taken that the ball is not heated at the same time. After the inclosed air is thus rarefied, and the particles that might obstruct the free motion of the mercury are made to float in vapours within the bore of the tube, the tube is to be held upright, and the ball suddenly heated, by which means the air contained in it will be dilated, and carry off the impurities of the tube, so that it will be rendered clean and free from air. When the ball is heated to a considerable degree, the mercury may be poured into the reflow fixed at the top of the tube, through a small corner of the paper. When the reflow is almost full, the ball should be withdrawn from the fire, and the air will then be condensed, and the space left by it will be soon occupied by the mercury. By alternately heating and cooling the ball, it may thus be filled with mercury; but when it is nearly full, the mercury contained in it must be made to boil, by placing it over burning coals, in order to purge it of its air. However, as a small quantity of air will be left in the ball after this operation, it will be expedient to remove the mercury, which remains in the reflow, immediately after the thermometer is withdrawn from the fire; and thus the whole column, unsupplyed with mercury from the reflow, will descend into the ball by the condensation of that which is contained in it, and the tube being empty, the small bubble of air will escape. Let the tube be again heated successively through its whole length, commencing from the bottom, and preferring the heat of the ball, that the mercury may occupy it entirely, and no air be allowed to enter. During this operation, when the mercury of the thermometer begins to appear in the reflow, let the mercury contained in a paper funnel be poured into it in such a quantity as will more than fill the thermometer, which is then to be removed from the fire. The mercury of the tube, and that discharged from the funnel, will unite, and pass together into the thermometer, and thus it will be wholly filled. In this state it may be left for any time at pleasure, without any apprehension of its imbiving either air or moisture. Nothing now remains but to get rid of the superfluous quicksilver, and to seal the tube. For this purpose the thermometer is held in the hand and heated, till a drop of mercury falls out of it, and is then left to recover the temperature of the air; by which means there will remain at the top of the tube a small empty space. Then with a blow-pipe and the flame of a candle, let the end of the tube be formed into a fine point, of such a length as will admit of its being properly sealed. When this preparatory process is completed, let the thermometer be gradually plunged into boiling water, so that the superfluous mercury may issue from it slowly; and when it ceases to be discharged, withdraw the thermometer from the boiling water; wipe it dry, and as soon as possible, put the ball of it over a small fire, covered with ashes, and previously prepared for the purpose. In this part of the operation, it is necessary to be quick, that the mercury may not have time to condense, and the air enter into the tube. In this state the thermometer may be left to heat, till it parts with more or fewer drops of the mercury, according to the proportion which the length of the tube bears to that of the scale applied to it. The thermometer is then sealed, by melting only the end of the point above mentioned, and at the flame instant withdrawing it from the fire.

The method of filling the thermometer with a paper tube, or funnel, is as follows. Let the ball be heated, so that the mercury may rise to the top of the tube; whilst it approaches it, apply the tube of paper to the end of the tube, so that it may serve for a reflow. The thermometer being placed near the fire, so that it may always preserve the same degree of dilatation, take some well purified mercury in a paper cornet, and communicate a little more heat to the ball. When the mercury rises, and forms a small drop at the end, pour the mercury of the cornet into the reflow of paper, and withdraw the ball from the fire. Having removed the paper reflow, place the ball again over the fire, and seal the point of the tube at the moment when the mercury rises to it, and withdraw the thermometer from the fire. This operation will be acquired by use.

Vol. XXXV.
Thermometers that are designed for measuring great degrees of heat, require to be filled with particular precautions, which M. de Luc has minutely described.

When the thermometer is filled and sealed, nothing more is necessary than to mark the two fixed points, graduate the scale, and attach it to a proper frame. See de Luc’s Récherches, &c. vol. i. p. 393, &c.

The frame may be made of any substance, or kind of wood, at pleasure: and the degrees may be marked on metal or wood, or paper, or ivory, &c.; but such substances should be preferred for the scales of thermometers as are not apt to be bent or shortened, or otherwise altered by the weather, especially if the instruments are not defended by a glass case, or by a box with a glass face. Thermometers for indicating the temperature of the atmosphere need not have scales that are much extended; if they go as high as 150° it is sufficient. The lower degrees may be carried down as low as may be necessary for the cold of any particular climate. The mercurial thermometer need not be graduated lower than 40° below 0, because at about that degree mercury ceases to be fluid. The spirit thermometer may be graduated lower, if necessary.

Thermometers used for observation, must be situated in the open air out of the house, and at the distance of a foot (at least) from the wall, and where the light of the sun may not fall directly upon them. For chemical purposes, the bulbs and part of the tubes of the thermometers should project some way below the scales, that they may be dipped in liquids, mixtures, &c. For other purposes, as for botanical observations, hot-houses, brewing manufactories, baths, &c. the thermometers must be made longer or shorter, or narrower; and particular directions may be given with regard to the scales and other appendages.

Great inconvenience has attended the use of various kinds of thermometers with different graduations. Kirwan proposed to lay all these aside, and to construct a general one, beginning at the congelation of mercury, and terminating at the boiling of water, and divided into 250°. Mr. Murray of Edinburgh has since suggested, that it would be convenient to form a scale whose extreme points should be the temperatures of freezing and boiling mercury, both of which are now capable of being accurately ascertained, and to divide this scale into 1000°.

Martine’s Essays, p. 284, &c.

We must here observe, that the heat of a hen hatching chickens is placed, by this table, at 108° of Fahrenheit’s thermometer; but it appears from M. Reaumur’s experiments, that eggs will hatch in a heat no greater than that of the human skin. See Hatching.

THERMOMETERS for particular Uses. In 1757, the right hon. the earl of Cavendish presented to the Royal Society an account of a curious construction of thermometers, of two different forms; one contrived to shew the greatest de-

gree of heat, and the other the greatest cold; that may happen at any time in a person's abstinence. The first consists of a cylinder of glass joined to a tube, and differs from the common form only in having the top of the tube drawn out into a capillary tube, which enters into a glass ball C (Plate XVI. Physic, fig. 11.) joined on to the tube at the place where it begins to be contracted. The cylinder, and part of the tube, are filled with mercury, the top of which shews the common degrees of heat as usual. The upper part of the tube above the mercury is filled with spirit of wine, and some of the same liquor is left in the ball C, so as to fill it almost to the top of the capillary tube.

When the thermometer rises, the spirit of wine will be driven out of the tube, and will fall into the ball C. When the thermometer sinks again, as the spirit cannot be returned back from the ball, the top of the tube will remain empty, and the length of the empty part will be proportional to the fall of the thermometer. Consequently, by means of a proper scale, the top of the spirit of wine will shew how many degrees it has been higher than when observed, which being added to the present height, will give the greatest degree of heat it has been at. To fit this thermometer for a new observation, it is necessary to fill the upper part of the tube with spirits, by inclining the instrument till the spirits in the ball C cover the end of the capillary tube; for if the cylinder is then heated, by applying the hand to it, or by the flame of a lamp held at some distance, the spirits rise to the top of the tube, and run over into the ball C, and is then suffered to cool in the same position, the tube will remain full of spirits, and the thermometer will be fitted for a new experiment.

The scale of degrees at top, which shews the descent of the thermometer from the highest point it has arrived at, ought not, in strictness, to be the same at all times of the year; for these degrees exceed the common degrees of heat pointed out by the top of the mercury, as much as the column of spirit of wine expands, and therefore are greatest when that column is fo; i.e. when the greatest heat to which the instrument has been exposed is leaf. A difference of 30 degrees of Fahrenheit's scale, in the greatest rise of the thermometer, would require the scale to be altered one sixtieth part; and the error arising from making use of the same scale, will be about one-sixth of a degree, if the thermometer is observed when it has fallen ten degrees.

In the thermometer here described, the bore of the tube is about 0.027 inches; and one inch of it contains two grains of mercury, and answers to about ten degrees, the cylinder containing about 2280 grains. When the scale of degrees is large, the cylinder must be of considerable size. The quicksilver in the ball C serves to supply the tube, in case any of it should be driven into the ball by the thermometer's being exposed to too great a heat.

If the weight of the mercury be thought inconvenient, it may be avoided by the construction in fig. 12. where the bottom of the tube is bent fo as to point upwards, and is joined to a ball A, which communicates with a cylinder placed above it. It is in all other respects the same as the former instrument. It is filled with spirits of wine and mercury; the quantity of the latter being sufficient to fill the whole tube and the ball A.

The thermometer for shewing the greatest degree of cold that happens in any place during the time the instrument is left in it, is represented in fig. 13. The tube is bent into the shape of a tiphon, of unequal legs, standing parallel to one another; the top of the shorter leg is bent to a right angle, and opens into a ball A, which, by means of a short bent tube on the opposite side, communicates with a cylin-

3 T 2
THERMOMETER.

uder standing parallel to the legs of the fiphon, and point- ing downwards. This cylinder contains the greatest part of the fluid, and is added only to make the thermometer more fin- enible than it would be, if the ball A were made of a suf- cient size to contain the proper quantity of fluid. This instrum- ent is filled with spirit of wine, with the addition of as much mercury as is sufficient to fill both legs of the fiphon, and about a fourth or fifth part of the ball A. The common degrees of heat are shown by the top of the mer- cury in the longest leg, or by the top of the spirit, in cafes any of it is left above the mercury. When the mercury in the longest leg sinks by cold, that in the shorter leg will rise, and will run over into the ball A; from whence it cannot return back when the thermometer rises again, as the surface of the mercury in the ball is below the orifice of the tube n. Therefore the upper part of the shorter leg will be filled with a column of spirits of a length proportional to the increase of heat; the bottom of which, by means of a proper scale, will shew how much the thermometer has been lower than it is; which being subtracted from the present height, will give the lowest point that it has been at. In order to prevent the mercury from falling into the ball A in large drops, which would affect the accuracy of the instru- ment, the top of the shorter leg, close to the ball, is con- tracted, by being held in the flame of a lamp, and the pad- fage farther slighltened by a solid thread of glass placed within the tube, and extending from the bottom of the shorter leg to the part near the ball A, where it is most con- tracted. By this means, as soon as any small portion of mercury is got beyond the thread of glass, it breaks off, and falls into the ball in very small drops.

In order to fill the shorter leg with mercury, for a new experiment, it must be inclined till the mercury in the ball covers the orifice of the tube n. The cylinder being then heated, the mercury will be forced into the shorter leg, and will run down the thread of glass in drops, which will soon unite. To such a quantity of mercury must be got into the shorter leg, as, upon the cooling of the instrument, will be sufficient to drive all the spirit of wine into the ball, with a legs degree of cold than what the thermometer is likely to be exposed to. The ball A must always have some mercury in it, but never enough to fill it up to the orifice of the tube n. It will be best to have a little of the spirit above the mercury in the longest leg; in which case the top of the spirit will shew the common degrees of heat. The scale of degrees on the shorter leg will, in different seasons, be liable to an error similar to that which was explained in the first mentioned thermometer; but it will be less considerable, as the space between the two scales is filled with mercury, whose expansion is about six times less than that of the spirit of wine. In the thermometer now described, the bore of the tube is about .054 inches; and one inch of it contains eight grains of mercury, and answers to seven degrees of Fahrenheit's scale. The drops of mercury which fall into the ball A, answer to about one-eighth of a degree.

Instruments of this kind, with some alteration in their con- struction, would serve for finding the temperature of the sea at great depths, and also for finding that of the air at consider- able heights. Lord Charles Cavendish has shewn how to adapt them for such purposes. See Phil. Trans. vol. l. art. 38. p. 500, &c.

Since the publication of Mr. Canton's discovery of the comprcnsibility (see COMPRESSION) of spirits of wine and other fluids, there are two corrections necessary to be made in the refract given by lord Charles Cavendish's thermometer. For in estimating, e. g. the temperature of the sea at any depth, the thermometer will appear to have been colder than it really was; and besides, the expansion of spirits of wine by any given number of degrees of Fahrenheit's thermometer is greater in the higher degrees than in the lower. For the method of making these two corrections by Mr. Caven- dish, see Phipps's Voyage to the North Pole, p. 145.

Instruments of this kind, for determining the degree of heat or cold in the absence of the observer, have been in- vented and described by others. Van Swinden (Diff. fur la Comparifun du Therm. p. 255—255.) describes one, which, he says, was the first of the kind made on a plan communica- ted by M. Bernoulli to M. Leibnitz. M. Kraft, he also tells us, made one nearly like it. Mr. Six, in 1782, pro- posed another construction of a thermometer of the fame kind, which has been well received.

This is properly a spirit thermometer, though mercury is employed in it for the purpose of supporting a certain in- dext: a b (fig. 14.) is a tube of thin glafs, about sixteen inches long, and 4/ths of an inch in diameter; cdefgh is a smaller tube, with the inner diameter about 2/ths, joined to a larger at the upper end b, and bent down fift on the left side, and then, after defending two inches below a b, upwards again on the right, in the several directions e a, f g h, parallel to, and one inch diant from it. At the end of the fame tube at b, the inner diameter is enlarged to half an inch from b to f, which is two inches in length. This glafs is filled with highly rectifed spirit of wine to within half an inch of the end f, excepting that part of the small tube from d to g, which is filled with mercury. From a view of the instrument it will be readily conceived, that when the spirit in the large tube is expanded by heat, the mercury in the small tube on the left side will be prefled down, and caufe that on the right side to rife: on the contrary, when the spirit is condenfed by cold, the reverse will happen. Fahrenheit's scale, which begins with c at the top of the left side, has the degrees numbered downwards, while that at the right side, beginning with c at the bottom, ascend. The divisions are acertained by placing the thermometer with a good standard mercurial one in water, gradually heat- ing or cooling, and marking the divisions of the new scale at every five degrees. The divisions below the freezing point are taken by means of a mixture of sea-falt and ice, as de- scribed by Nollet, De Luc, and others. In order to shew how high the mercury has rifen in the obferver's absence, there is placed within the small tube of the thermometer, above the surface of the mercury on either side, immerfed in the spirit of wine, a small index, fo fitted as to pafs up and down as occasion may require. One of these indices is re- presented in fig. 15; a is a small glafs tube, three-quarters of an inch long, hermetically sealed at each end, inclufing a piece of fleg wine nearly of the fame length; at each end e, d, is fited a fhort piece of a tube of black glafs, of fuch a diameter as to pafs freely up and down within the small tube of the thermometer. The lower end, floating on the surface of the mercury, is carried up with it when it rifes, while the piece at the upper end, being of the fame diame- ter, keeps the body of the index parallel to the fides of the thermometrical tube. From the upper end of the body of the index at c is drawn a spring of glafs to the fides of a hair, about five-fourths of an inch in length, which being let a little oblique, palls lightly against the surface of the tube, and prevents the index from following the mercury when it defends, or being moved by the fpirit palling up and down, or by any fudden motion given to the instru- ment ; but at the fame time the prefure is fo adjusted as to permit this index to be readily carried up by the surface of the rifing mercury, and downwards, whenever the instru- ment is retificed for observation. This index, by not re-
turning with the mercury when it descends, flows distinctly
and accurately how high the mercury has risen, and con-
sequently what degree of cold or heat has happened. To
prevent the spirit from evaporating, the tube at the end is
closely sealed. The daily rectification of this instrument is
performed, by applying a small magnet to that part of the
tube against which the index rests; by the action of which
the included piece of steel wire, and consequently the index,
is easily brought down to the surface of the mercury. When
this has been done, the instrument is rectified for the next
day’s observation, without heating, cooling, separating, or
at all disturbing the mercury, or moving the instrument.
With a thermometer of this sort, Mr. Six observed the
greatest heat and cold that happened every day and night
throughout the year 1781. But for the more particular de-
scription of this instrument, the illustration of it by figures,
and an account of its advantages, the limits of this work
require our referring to Phil. Trans. vol. lxxii. part i.

A similar effect to that produced by Six’s thermometer is
obtained in Rutherford’s arrangement of a pair of ther-

mometers, one with mercury, the other with spirit of wine,
placed in a horizontal position; one index being without
the surface of the mercury, the other within that of the
spirit, the thermometers being in contrary directions, both indices
may be brought back to their places, by merely raising the
end of the instrument. (See fig. 16.) Self-registering ther-
mometers have also sometimes been constructed for keeping a
still more accurate account of all the variations of tempera-
ture that have occurred, by describing a line on a revolving
barrel, which flew the height for every instant during the
whole time of their operation.

M. de Luc has described the best method of construct-
ing a thermometer, fit for determining the temperature of the
air, in the menuration of heights by the barometer. He
has also shewn how to divide the scale of a thermometer,
so as to adapt it for astronomical purposes in the observa-
tion of refraction. See Récherches, &c. tom. ii. p. 35, &c.
p. 265, &c.

Mr. Cavallo, in 1781, proposed the construction of a
thermometrical barometer, which, by means of boiling water,
might indicate the various gravity of the atmosphere, or the
height of the barometer. This thermometer, he says, with
its apparatus, might be packed up into a small portable box,
and serve for determining the heights of mountains, &c. with
greater facility than with the common portable barometer.
The instrument, in its present state, consists of a cylindrical
vessel, about two inches in diameter, and five inches high,
in which vessel the water is contained, which may be made
to boil by the flame of a large wax-candle. The ther-
mometer is fastened to the vessel in such a manner, as that
its bulb may be about one inch above the bottom. The
scale of this thermometer, which is of brass, exhibits on one
side of the glass tube a few degrees of Fahrenheit’s scale,
vis. from 200° to 216°. On the other side of the tube are
marked the various barometrical heights, at which the boil-
ing water flew those particular degrees of heat which are
set down in Sir G. Shuckburgh’s table. With this instru-
ment the barometrical height is shewn within one-tenth of an
inch. The degrees of this thermometer are somewhat
longer than one-tenth of an inch, and therefore may be
divided into many parts, especially by a Nonius. But the
greatest imperfection of the instrument arises from the small-
nesses of the vessel, which does not admit a sufficient
quantity of water; but when the quantity of water is
sufficiently large, e.g. 10 or 12 ounces, and is kept boiling
in a proper vessel, its degree of heat under the same pressure
of the atmosphere is very settled; whereas when a ther-

mometer is kept in a small quantity of boiling water, the
quicksilver in its stem does not stand very steady, sometimes
rising or falling even half a degree. Mr. Cavallo proposes
a farther improvement of this instrument in the Phil. Trans.
vol. lxxi. part ii. p. 524.

The ingenious Mr. Wedgwood, so well known for his
various improvements in the different sorts of pottery-ware,
has contrived to make a thermometer for measuring the
higher degrees of heat, by means of a distinguishing property
of argillaceous bodies, viz. the diminution of their bulk by
fire. This diminution commences in a low red heat, and
proceeds regularly, as the heat increases, till the clay be-
comes vitrified. The total contraction of some good clays
which he has examined in the forge of his own fires, is
considerably more than one-fourth in every dimension.
If, therefore, we can procure at all times a clay sufficiently
apprising and unvitrefcible, and always of the same quality in
regard to contraction by heat; and if we can find means of
measuring this contraction with ease and accuracy, we shall
be furnished with a measure of fire sufficient for every pur-
purpose of experiment or business. Some of the purest Cornish
porcelain clays (which, by the analysis of Mr. Wedgwood,
appear to contain no calcareous earth nor gypseous matter,
but to consist of pure argillaceous or alum earth, and
another indissoluble earth, which he apprehends to be of the
siliceous kind, in the proportion of three parts of the former
to two parts of the latter) seem the best adapted, both for
supporting the intensity, and measuring the degrees of fire.
This material is prepared for use by washing it over, and
whiff in a dilated plate passing it through a fine lawn: it is
then dried and put up in boxes. The dry clay is to be
softened for use with about two-fifths its weight of water;
and formed into small pieces, in little moulds of metal, \\
\textit{\textfrac{1}{6}ths} of an inch broad, with the sides exactly parallel; about
\textit{\textfrac{1}{6}ths} of an inch deep, and an inch long. The moulds are
to be oiled and warmed. These pieces, when perfectly dry,
are put into another iron mould or gage, confining only of
a bottom, with two sides, \textit{\textfrac{1}{6}ths} of an inch deep, to the
dimensions of which sides the breadth of the pieces is to be
poured down. For measuring the diminution which they are
to suffer from the action of fire, another gage is made of two
pieces of brass, twenty-four inches long, with the sides
exactly straight, divided into inches and tenths, fixed five-
tenths of an inch aunder at one end, and three-tenths at the
other, upon a brass plate; so that one of the thermometric
pieces, when poured down in the iron gage, will just fit to
the wider end. If this piece be supposed to have diminished in
the fire one-fifth of its bulk, it will then pass on to half the
length of the gage: if diminished two-fifths, it will go on to
the narrowest end; and in any intermediate degree of con-
traction, if the piece be slid along till it rests against the
converging sides, the degree at which it stops will be the
measure of its contraction, and consequently of the degree of
heat it has undergone. The thermometric pieces may be
formed much more expeditiously than in the single mould
by means of an instrument, consisting of a cylindrical iron
vessel, with holes in the bottom, of the form and dimensions
required.—The soft clay, put in the vessel, is forced by a
press down through these apertures, in long rods, which
may be cut while moist, or broken when dry, into pieces of
convenient lengths. After which, recourse should be had
to the proper gage for ascertaining and adjusting their breadth
when perfectly dry.

Each division of the scale, though so large as a tenth of
When Sulphuric acid stands 14° to 33° differential fill the tank, and the little piece of clay. When one gage is accurately adjusted to the proportional measures above stated, two pieces of brass should be made, one fitting exactly into one end, and the other into the other, which will serve as standards for the ready adjustment of other gauges to the dimensions of the original, and thus we may be assured, that thermometers on this principle, though made by different persons, and in different countries, will all be equally affected by equal degrees of heat, and all speak the same language. The scale commences at a red heat fully visible in day light; and the greatest heat which Mr. Wedgwood has hitherto obtained in his experiments, is 160°. Swedish copper has been found to melt at 27°, silver at 28°, and gold at 32°, of this thermometer. Brass is in fusion at 21°; the welding heat of iron is from 90° to 95°, and the greatest heat that could be produced in a common smith's forge, 135°. Call iron melted at 150°; and the heat by which iron is run down among the fuel for casting is 150°. A Hessian crucible melted into a flag-like subsance at about 150°. The founding heat of glafs furnaces, or that by which the perfect vitrifications of the materials is produced, was at one of them 114° for flint-glafls, and 124° for plate-glafls. Delft-ware is fired by a heat of 40° or 41°; Queen's-wafl by 56°; and flone-wafl by 102°, which degree of heat changes it to a true porcelain texture. The thermometer pieces begin to acquire a porcelain texture at about 110°. A piece of an Etruscan vase melted completely at 35°; pieces of other vase and Roman ware about 36°; Worceftcr china vitrified at 94°; Mr. Srimont's Chelfea china at 105°; the Derby at 112°; the Bow at 121°; but Brifol china fhewed no appearance of vitrification at 125°. The common fort of Chinefe porceflain does not perfectly vitrify by any fire which Mr. Wedgwood could produce; but began to fofen about 120°, and at 156° became fo soft as to fink down and apply itfelf clofe upon an irregular furface underneath. The true flone Nankeen does not fofen in the lead, by this strong heat; nor even acquire a porcelain texture. The Drefden porceflain is more common in the Chinefe, but not equally so with the flone Nankeen. The cream-coloured or Queen's-wafl bears the fame heat as the Drefden. Mr. Pott fays, that to melt a mixture of chalk and clay in certain proportions, which appear from his tables to be equal parts, is "among the matter-pieces of art." This mixture melts into a perfect glafs at 235° of this thermometer. For other curious particulars, fee Phil. Trans. vol. lxxii. part ii. p. 305, &c.

This thermometer, fays Dr. Young, (Lecl. on Nat. Philof. vol. i. 648.) may be extremely ufeful for identifying the degree of heat which is required for a particular purpofe; but for the comparison of temperatures by an ex- tension of the numerical fcale, we have not fufficient evidence of its accuracy to allow us to depend on its indications; and it is scarcely credible, that the operation of furnaces of any kind, can produce a heat of fo many thousand degrees of a natural fcale, as Mr. Wedgwood's experiments have led him to fuppofe; nor is the fuppofofion confident with the obfervations of other philofophers.

THERMOMETER. Differential, a curious fort of thermometer invented by profeffor Leffie, which exprifes not the abfolute degree of heat, but the difference, when any exifts, between the temperatures of the two flots where its two bulbs are placed. The method of constructing it is as follows. (See Plate XVI. Pneumatics, fig. 17.) Select two thermometer tubes with bores rather wider than usual, and one a little wider than the other. Let the balls be blown as equal as the eye can judge, and from .4 to .7 of an inch in diameter, and let the open end of the tube also be widened in a right angle. The tubes must be of unequal length, the longest being nearly twice the length of the other. Then introduce into the longer tube a little sulphuric acid tinged with carmine, sufficient to fill about an inch of its cavity; then join the two tubes together by the blow-pipe, and when joined, bend them in the form of the letter U, with the bulbs about three or four inches asunder, making one flexure just below the juncture of the two tubes, where the small cavity (which is represented in the plate) facilitates the adjustment of the instrument, which by a little dexterity is performed by forcing a few globules of air by the heat of the hand from one bulb to the other. Attach a graduated scale to the shorter tube, making the zero about the middle of it, and adjust to it the quantity of air in each bulb, so that when the bulbs are at the fame temperature, the upper surface of the coloured liquor may just correspond with the zero. Sulphuric acid is chosen as the liquor interpofed between the bulb, on account of its bearing any heat or cold that would be used without being evaporated or congealed.

In this instrument the air inclofed in the bulbs is the sub- stance, which, by its expansion or contraction, caufes the motion of the coloured liquor up or down the scale, and as gases are much more expanfible than liquids, the instrument is sooner affected by minute changes of heat. But as the two bulbs are of equal size, and both filled with air, and separated from each other by the intervening liquor, it is obvious that when the temperature is the fame in each bulb, be it high or low, the preflure on each fide of the liquor is also equal, and it muft remain flationary; fo that it can only move when one bulb is warmer than the other. Hence the particular and sole ufe of this instrument as a differential thermometer. The lower part of the instrument (or the space included between the two bends) is cemented to an upright stem, by which it is supported.

This instrument has been employed by the inventor in a variety of curious experiments on caloric, or the matter of heat. The peculiar advantage which this instrument poffefeis is, that, besides its extreme fensibility, in using it the common temperature of the surrounding air may, in general, be disregarded; this being always the zero of the fcale, whatever be the actual variation of heat in the surrounding atmosphere; and hence a much greater degree of fimplicity is introduced into the delicate researches on this subjedt. For the reflection of heat mirrors were employed, generally of block-tiln, highly polished, and hammered to fit a wooden gage, the segment of a parabolic curve, by which much of the defipofion produced by a simple concave form was avoided; fo that when expofed to the direft rays of the sun, they collected them into a pretty difinft focus, of about half an inch in diameter. The subfance employed to generate the radiant heat was a hollow cubic tin cafleril, placed directly in front of the mirror of its focal point, and when used, filled with boiling water, and fitted with a common thermometer, paffing through a hole in the cover, and immerfed in the water. The cubical form of the cafleril allowed of four fides, of perfectly equal dimensions, each of which, when turned to the mirror, afforded a heated surface for the transmission of radiant caloric, and they were occasionally coated with various subftances to acertein the efleet of colour, polifh, and the like, in re- garding or promoting the radiation of the heat within. With this apparatus, and his differential thermometer, Mr. Leffie performed a variety of interefling experiments, for
for the general results of which we refer to the article on
Heat; and for a more minute detail to Lefèvres “In-
quiry into the Nature of Heat,” and for an extensive
abstract, to an elaborate article on Caloric in Aikins’s
Dictionary. See also our articles Caloric, Radiant Heat,
&c. &c.

**Thermometer, Balance.** An instrument invented by Mr.
James Kewley, of the Isle of Man, and for which he ob-
tained a patent for Scotland, dated Nov. 6, 1816; for Eng-
land, dated Nov. 21, 1816; and for Ireland, dated Jan. 4,
1817. This instrument (besides answering the purpose of
measuring the quantity of heat,) was used as a first moving
power for putting machinery into motion, for the purpose of
regulating the temperature, by opening or closing the flues,
windows, or doors of the apartment in which it is placed.
This instrument must therefore be of great importance to the
horticulturist; as by it the artificial climate of hot-houses,
conservatories, hot-beds, &c. can be accurately regulated,
without the least attention from the gardener, farther
than occasionally to wind up the machine to which it is
attached.

In Plate XVI. Pneumatics, fig. 18, is a perspective represen-
tation of Kewley’s balance thermometer. A is a glass tube,
with its bulbs ε and δ hermetically sealed at ε, and having
a very fine aperture at η, for the admission of the pressure
of the atmosphere upon the surface of the quicksilver con-
tained in the bulb δ; ε is a milled nut, let into a mortise
in the frame θ, having a female screw in its centre, throu-
gh which the screw i is made to pass. This nut serves to

**THERMOPOLIUM**, formed of *Stipa fruticosa*, and *Arundo*, a name for a fort of public houses among the ancients, in which hot liqueurs were sold, in the manner of our coffee-houses.

**THERMOPSIS**, in Botany, from *thermos*, a hot, and *opsis*, a view, *appearance* or *aspect*; indicating a general resemblance to that genus of plants.—Brown in Ait. Hort. Kew. v. 3. 3.

Linn. *Leguminosae*, Juss.

Ch. Calyx oblong, five-cleft half way down, two-lipped; convex behind; tapering at the base. Corolla papilionaceous; petals nearly of equal length; standard reflexed at the fides, keel obtuse. Stamens permanent. Legume compressed, linear, with many seeds. *Br.*

1. Th. lanceolata. Sharp-leaved Thermopsis. Ait. n. 1. (Podaaria lupinoides; Willd. Sp. Pl. v. 2. 504. Sophora lupinoides; Linn. Sp. Pl. 534. “Pallas Alfr. I. 119. t. 89.”) Leaflets oblong-lanceolate. Stipulas lanceolate, twice as long as the footstalks. Flowers whorled. Native of Siberia; from whence the late duke of Northumberland is said to have received it in 1776. This is a hardy perennial herbaceous plant, flowering in June and July. The stems are spreading or decumbent, about a foot long, branched in an alternate manner, round, hairy, leafy. Leaves ternate, light green, hairy, on short stalks; their leaflets about an inch long. Stipulas half as large, or more. Flowers stalked, about three in each whorl, yellow, much resembling those of a Lupine. Calyx hairy.

By Mr. Brown's specific character, we presume there are more species of this genus, though not in our gardens, of which he will one day give an account. For the foundness of the generic distinctions, we rely on them. The compressed legume teems the important difference between *Thermopsis* and the *Baptisia* of Ventenat and Brown; see Ait. Hort. Kew. v. 3. 5; also our articles *Sophora* and *Podaarya*.

**THERMOPYLAE**, in Ancient Geography, a strait or pass, rendered famous by the valor of Leonidas and his companions, who defended it against the army of Xerxes in the year 480 B.C.; and which, long after that celebrated event, was defended against the Gaels. This pass is the only road by which an army can penetrate from Thessaly into Locris, Phociis, Bœotis, Attica, and the adjacent countries. The following succinct description is given of this strait by the abbé Barthelemy, in his "Anacharsis". On quitting Phocis to go into Thessaly, having passed the little country of the Locrians, we arrive, says the abbé, at the town of Alpenus, situated by the sea. As it flanks at the entrance of the strait, it has been fortified. The road at first is only wide enough for the passage of a waggon; but
it afterwards enlarges itself between moraines formed by the waters of the sea and almost inaccessible rocks, which terminate the chain of mountains known by the name of Oeta. After leaving Alpenus, a floe is discovered on the left, congealed to Hercules Melanippos, and a path presents itself that leads to the summit of the mountain. Farther on, the traveller crosses a current of hot water, which gives this place its name of Thermopylae. Next to this stream is the town of Anthela; and in the plain which surrounds it are a small eminium and a temple of Ceres, in which the Amphydrons annually held one of their assemblies. On coming out of the plain there is a road, or rather causeway, only about seven or eight feet wide. Here the Phocians had formerly built a wall, to protect their country from the inroads of the Thessalians. After passing the Phenix, which at first falls into the Alpes, a river that rises in an adjacent valley, we come to the last defile, half a plethrum (15 or 16 yards) in breadth. The road then widens as far as Trachina, which takes its name from the city of Trachis, that was inhabited by the Malians. This country presents to the view of the traveller extensive waters supplied by the Sperchius and other rivers. To the E. of Trachina stands the city of Heraclea, which did not exist in the time of Xerxes.

The whole strait, from the defile before we arrive at Alpenus to that which is beyond the Phenix, may be about 48 fadia (about 2 leagues) in length. Its breadth varies almost at every step; but through its whole extent it is flinted on one side by steep mountains, and on the other by the sea, or impenetrable moraines. The road is often destroyed by the torrents, or by stagnant waters. Leonidas posted his little army near Anthela, rebuilt the wall of the Phocians, and dispatched a few advanced troops to defend the approaches. But it was not sufficient to guard the passageway of the foot of the mountain; on the mountain itself there was a path, which, beginning at the plain of Trachis, terminated, after various windings, near the town of Alpenus. Leonidas entrenched the defile of this path to the thousand Phocians he had with him, and who took post on the heights of mount Oeta. As soon as these arrangements were completed, the army of Xerxes was discovered, spreading itself over Trachina, and covering the plain with its innumerable tents. The Greeks deliberated on the measures proper to be adopted; most of the generals were for retiring to the Ithmenus; but Leonidas rejected this counsel. A Persian horsemanship was deputed to reconnoitre the advanced post of the Greeks, which was composed of Spartans; and as the rest of the army was concealed from him by the wall, he only gave an account to Xerxes of the 300 men he had seen at the entrance of the defile. After various messages from Xerxes to Leonidas, and the firm and calm replies of the latter, the Persian king was enraged, and gave orders for an attack. The Medes rushed on with fury, and one rank fell after another, while the Greeks, prelled close against each other, and covered with large bucklers, presented an impenetrable front of long pikes, and a phalanx which freth troops succressively in vain attempted to break. At length the Medes were forced away from their panic, and fled; but they were speedily relieved by the chief body of the 10,000 immortals, commanded by Hydarnes. The action now became more bloody; but the Greeks had the advantage of situation, and superiority of arms. The Persians lost many men; and Xerxes, witnessing their flight, leaped, as it is said, more than once from his chariot, and trembled for his fate. Next day the attack was renewed, but with so little success, that Xerxes depended on forcing the passageway. At length Epilates, an inhabitant of those districts, discovered to him the fatal path by which he might turn the Greeks; and served as a guide to Hydarnes and his corps of immortals, under whose conduct they arrived near the spot where Leonidas had posted a detachment of his army; and prepared to attack it. When this dreadful news reached the Greeks, their leaders answered.

Some were for retiring, and others for remaining; but Leonidas declared for himself and his companions, that they were not permitted to quit a post which Sparta had confided to their care. In the middle of the night, the Greeks, with Leonidas at their head, inflamed out of the defile, advanced through the plain, overthrew the advanced posts, and penetrated to the tent of Xerxes, who had already taken flight. They spread over the camp, and glutted themselves with carnage. The Persians were terrified and confounded, and many of them perished by the hands of one another. At length, with the dawn of day they discovered the inconsiderable number of their victors, and rallying, attacked the Greeks on all sides. Leonidas fell beneath a shower of darts; and a contest for the honour of carrying off his body, occasioned a terrible conflict between his companions and the most expert and hardy warriors of the Persian army. The Greeks, however, prevailed, and carried off their general; and having regained the defile, posted themselves on an eminence, and for some time continued to defend themselves. When Xerxes offered to Leonidas the empire of Greece, if he submitted to his power, he replied, "I rather choose to die free than to enslave my country." When the king commanded him to surrender his arms, he wrote the laconic answer, "come and take them." "The Persians are near us," said one of his soldiers to Leonidas: "rather far," he coolly replied, "that we are near the Persians." See LEONIDAS.

It has been a subject of dispute what was the number of Grecian troops under the command of Leonidas at Thermopylae. Herodotus states them at 1000, Pausanias at 11,200, and Diodorus at 7400. The abbé Barthélemy attempts to reconcile these different statements, and concludes, upon the whole, that Leonidas had with him about 7000 men. If we may credit Diodorus, he had no more than 500 foldiers when he determined to attack the Persian camp.

On the eminence to which the companions of Leonidas retired after the death of their commander, there were several monuments erected by order of the Amphydron council, in honour of the 300 Spartans, and the other Grecian troops engaged in the combat. On one of these tripodsa is inscribed, "Here four thousand Greeks of Peloponnesus fought against three millions of Persians."

THERMOSCOPE, an instrument shewing the changes happening in the air with respect to heat and cold.

The word thermoscope is generally used indifferently with that of thermometer. There is some difference, however, in the literal import of the two; the first signifying an instrument that shews or exhibits the changes of heat, &c. to the eye; formed from θερμός, heat, and οσκός, to measure, &c. and the latter an instrument that measures those changes, from θερμός, heat, and μέτρον, to measure, &c. on which foundation the thermometer should be a more accurate thermoscope, &c. This difference the excellent Wallius taking hold of, defends all the thermometers in use as thermopes; shewing that none of them properly measure the changes of heat, &c. none of them do more than indicate the same. Though their different heights yesterday and to-day shew a difference of heat; yet, since they do not discover the ratio of yesterday's heat to to-day's, they are not strictly thermometers.

THERONDEL'S, in Geography, a town of France, in the department of the Aveyron; 3 miles N.E. of Mir.

THEROUANNE, a town of France, in the department of the Straits of Calais, on the Lys. It was anciently the
the capital of the Morini, and afterwards an episcopal see, with several churches and convents; but being taken in the year 1553 by the emperor Charles V., he demolished it. The district belonging to it, however, was ceded by Spain to France, at the treaties of the years 1559 and 1659; 6 miles S. of St. Omer.

THERSA, or THANSA, in Ancient Geography, a royal town of Judea, in the half-tribe of Manasseh, on this side of Jordan. Terfa was the seat, capital, and burying-place of the first kings of Israel.

THERSA, or Thirza, a town of Palestine, in the tribe of Ephraim.

THERSARA, a town of Asia, in the interior of Asia. Ptolemy.

THERSITÆ, a people of Spain, in Iberia; they were of the number of those whom Annibal caused to pass into Africa.

THERUINGI, a people who inhabited a part of Dacia, on the other side of the Danube.

THESEON, a town of Palestine, on the other side of Jordan, in the tribe of Gad.

THESEA, or thesea, crete, in Antiquity, feated celebrated by the Athenians in honour of Theseus.

In spite of the important services that hero had done his country, in delivering it from a shamefule tribut of so many youths, of either sex, fent yearly to be devoured by the Minotaur in Crete (as the fable has it), or fent as flates to Minos, king of Crete, as the histories have it, from which he f Freed them, by overturning Taurus, Minos' general; he was banifhed for fome time, and retired to Scyros, under the protection of Lycomedes, king of that ifland, where he finally left his life either by accident, or in confequence of the jealousy of the king.

The gods, it is faid, revenged this treatment Theseus received from the Athenians, by afflicting them with a famine, which the oracle affured them they could not ceafe till they had avenged his death. Upon this they flew Lycomedes, brought Theseus' bones to Athens, placed them in a temple erected to him, and appointed Thesea to be held every eighth day of each month, in which large feries were distributed to the people, and the day was fpent, by the rich, in feafing and rejoicing, and with peculiar feomerity on the eighth day of the month Pyanepfion.

Plutarch, however, gives a different account of the origin of this feast; he fays that the Athenians, imagining they faw Theseus at the battle of Marathon under the form of a tuefary deity, confulted the oracle on this prodigy: and being ordered to collect his bones in the ifland of Scyros, removed them with great pomp to Athens; and deponed them under a magnificent monument erected in the middle of the city, which became afterwards an afylum for flasses, in commemoration of the fuccour afforded by this prince to the unfortunate during his life. They also erected a temple where they offered facrifices, &c. At Rome, Theseus was held in very different estimation, for Virgil (Aen. lib. vi.) places him in Tartarus, among thofe who were tormented for their crimes.

THESEUS, in Biography, a hero celebrated in the fabulous ages of Greece, and referred by chronologists to the thirteenth century B.C. was the illegitimate fon of Ægeus, king of Athens, by Æthra, daughter of Pittheus, king of Teucria; and as he advanced towards maturity discovered a vigorous spirit in an athletic frame. In his journey to Athens by land he met with many adventures and conflicts, and on his arrival found the city agitated by diffenfions. The fons of Pallus, the brother of Ægeus, suspecting that the aged and childfles sovereign would adopt this newly arrived stranger for his heir, fomented his jealousies, fo that Ægeus prepared poison for dispatching him; but before his plan could be accomplished, he discovered by certain tokens that he was his fon. The confequence of this discovery was a revolt of the Pallantides, which Theseus fuppreffed.

For an account of the further exploits of Theseus for the relief of the Athenians, we refer to our article History of Athens. Theseus having, in the manner there related, eftablihed a confederation for the Athenians, yielded to the impulfe of ambition; and quitting his throne, and fometimes in the company of Hercules and fometimes of Pirithous, fon of Ixion, king of Thellaly, whose friendship he had secured, undertook a variety of enterprizes, the account of which is fo intermixed with the fabulous, that it is impossible satisfactorily to develope it. He is faid, however, to have conquered certain Amazons on the banks of the Thermopy, in Asia, taking a queen from among them for his wife; to have affifted Pirithous in overcoming the Centaurs in Thellaly; and to have stolen away from Sparta the celebrated Helen; and afterwards to have joined the fame friend in a fimilar attempt upon Proserpina, the daughter of Alcmena, king of the Moloiânes, in which Pirithous lost his life, and Theseus underwent an imprisonment, from which Hercules procured his escape. Upon his return from this romantic expedition, he found his kingdom and family in confusion. Calfort and Pollux, the brothers of Helen, ravaged Attica by way of revenge for the inftult offered to their sister. His queen Thedra, falling in love with Hippolytus, his fon by the Amazon, and being rejected, calumniated him to his father, and occafioned his death, as his tragedy has recorded. From a variety of circumftances that occurred, Theseus finding that he had loft the attachment of the Athenians, abandoned the city, and intended to repair to Demetrius, fon of Minos, now reigning in Crete. In his paffage thither he was driven by a frcorn to the ifle of Scyros, where he was kindly received by the king, Lycomedes; but foon afterwards he loft his life by a fall from a rock. (See THESEA.) The reparation of the Athenians afterwards fubfided, and they regarded him only as a hero and benefactor; and Cimon, fon of Miltiades, having conveyed his bones, as they were fuppos'd to be, to Athens, in confequence of the injuncfions of an oracle, a magnificent temple was erected over them, which was made an afylum for the unfortunate. Its remains ftill subsist as one of the nobleft relics of ancient art in that famous capital. Plut. in Vit. Thefci. Aice. Univ. Hist. Travels of Anacharsis, vol. i.

THESIN.—Per Aris and Thefis. See Per Aris.

THESIS, signification, formed from τῆς θεῖας, I put or lay down, in the Schools, a general proposition, which a perfon advances, and offers to maintain.

In the college it is frequent to have placards, containing a number of theses in theology, in medicine, in philosophy, in law, &c. The maintaining a thesis, is a great part of the exercife a student is to undergo for a degree.

The thesis, in Logic, &c.—Every proposition may be divided into thefis and hypothetical; thefis contains the thing affirmed or denied, and hypothetfis the conditions of the affirmation or negation.

Thus, in Euclid, if a triangle and parallelogram have equal bases and altitudes (is the hypothetical), the firth is half of the second (the thefis).

Aris and Thefis. See Aris.

Thesis, bona, deposito or remiffo, the beating down the hand or foot at the beginning of a bar in music. See Aris, tally, which is the fifting up the hand or foot in the middle or latter part of a bar.

THESISUM, in Botany, an ancient name, adopted from the Greeks, enumerated by Linnaeus, Phil. Bot. 174, among those...
chiefly derived, is extremely difficult, and, after all, doubtful. Pliny has the Thesium in two places: book 21, chap. 17, and book 22, chap. 23. In the former, it is mentioned amongst bulbous plants, as having a harsh taste: in the latter, it stands next to Picris, as very bitter, and purgative. This last account is copied from Theophrastus, who, in his book 7, chap. 11, speaks of θέσιων in the same terms, along with a number of plants of the Sow-thistle and Dandelion tribe, or Cicuraceae. To these indeed some of the Arum family are subjoined, and Thesium is placed at the end. All we can hence gather is, that the plant in question may possibly be some plant of the Syngenia Polygamia-equales, of the section Spermopodia, whose root is tuberous. Of this description there are several natives of Greece; see Scorzonera, n. 12 and 13. Ambrofins derives the word from στειφειν, or rather a peer tradescant, because, as he thinks, of its being serviceable in many respects, both for food and medicine. Possibly Linnaeus, who frequently confounded this author, may hence have been led to apply the name of Thesium to the present genus, totally different indeed from all that is recorded of the Greek θέσιον, but remarkable for its sweet habit and hard texture.—Linn. Gen. 114. Schreb. 160. Willd. Sp. Pl. v. 1, 12. 1211. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 269. Profr. Fl. Græc. Sibth. v. 1, 162. Ait. Hort. Kew. v. 2, 64. Pursh 177. Brown Profr. Nov. Holl. v. 2, 152. Juss. 72. 75. Lamarck Histo. t. 142. Gurt. t. 86. Clafs and order, Pentandria Monogynia. Nat. Ord. V. p. 307. Linn. Elsinog. Juss. Sankt. Linæ. Brown.

Gen. Ch. Col. Perianth superior, of one leaf, tubular, in four or five cleft fragments, internally coloured and hairy, permanent. Cor. none. Stam. Fragments equal in number to the fragments of the calyx, but not so long, inserted into their base, awl-shaped; anthers roundish, of two lobes. Pist. German inferior, roundish, confluent with the base of the calyx; style thread-shaped, the length of the fragments; stigma tumid, cloven. Peric. none. Sred. Nut oval, angular, coated, crowned with the permanent involute calyx, of one cell, with a foliaceous kernel.

Eff. Ch. Calyx superior, of one leaf, bearing the fragments. Corolla none. Nut solitary, coated, crowned with the calyx.

Obf. Our learned friend Mr. Brown proposes to separate the Cape species of this genus from the rest, perhaps even into two distinct genera; but as we cannot find sufficient grounds for this measure, we shall admit the whole here, at least till we can obtain fuller information. Th. Colpoon, Linn. Suppl. 161. Willd. n. 18, is of course excluded, having a Drupa, and a very different habit. This is described, by some one of our correspondents, under the article Fusanus. See also Leptoneria. We are enabled to add a few in its stead to Willdenow's list, but cannot adopt such as are merely named by Mr. Brown, unless where we happen to have specimens.

The whole genus is of a rigid broom-like habit; sometimes roughish, though scarcely pubescent; with simple, usually very narrow, scented leaves; and inconspicuous green, whitish, or yellowish flowers, either clustered, spiking, or somewhat capitulate.

1. Th. lingulophyllum. Baffard Toad-flax Thesium. Linn. Sp. Pl. 301. Willd. n. 1. Brit. Fl. Brit. n. 1. Profr. Fl. Græc. n. 1. Engl. Bot. t. 257. Pollich Patat. v. 1, 238. Roth. in Sims and Konig's Ann. of Bot. v. 2, 18. (Th. pratense; Ehrh. Herb. n. 12. Th. montanum; ibid. n. 2. Th. intermedium; Schrad. Spicil. 27. Acanthos lini folio; Clus. Hift. v. 1, 323. Linaria adulterina; Ger. Em. 555.)—Stem erect, somewhat branched. Cluster mostly compound. Bracteas ternate. Leaves linear-lanceolate. Tube of the calyx cup-shaped, very short.—Native of dry chalky hills throughout most parts of Europe, though reckoned among our rarer English plants, flowering in July. The roos is woody, perennial, branched, crooked, whitish, fending up several erect or reclining, smooth, leafy, more or less angular, rigid, branched stems, from four to twelve inches high. Leaves numerous, alternate, linear, entire, in some degree succulent and glaucous, minutely rough at the edges, as are sometimes the angles of the stem. Clusters, rather than spikes, more or less branched, or even panicled, each branch bearing one or more flowers, either solitary at the extremity, accompanied by three lanceolate, leafy, unequal bracteas, or without bracteas, in the fork of the stalk, whose divisions bear other flowers, with one or more bracteas. The latter is the more luxuriant state of this plant, in which it has been called intermedium by Schrader, and montanum by Ehrhart; we cannot see, by original speciments, that these two suppos'd species differ at all, not even so as to merit Wildenow's distinction of them as varieties. Our English plant is less luxuriant, answering to Pollich's excellent description. The calyx is turbinate, having hardly any tube: its limb five-cleft, whitish, spreading, acutely five-cleft, sometimes with intermediate teeth; closely involute after flowering. Anthers yellow. Stigma white, of two knobs. Fruit hard, frated, with five angles. The herb is scarcely bitter, a little fœthous. It usually grows among grass, which it so much resembles at a little distance, as not to be readily discernible. The pure air of the open hills about Bury, and similar situations, seems to fuit this plant, though the soil does not much promote its luxuriance of growth.

2. Th. ramatum. Brachy German Thesium. "Hayne in Schrad. Journ. v. 1, 30, 4, 5." Roth in Sims and Konig's Ann. of Bot. v. 2, 18. Marfich. von Biebcrst. Cac. v. 1, 175. (T. alpinum; Pollich Patat. v. 1, 239.)—Stem erect, branched. Clusters elongated. Bracteas ternate. Leaves linear-lanceolate. Flowers three or four-cleft, with a very short, cup-shaped tube.—Native of heaths, and sandy pastures or woods, in the Palatinate, flowering at the same time as the preceding. Not having been able to ascertain this species amongst our speciments, we shall copy Pollich's description, having endeavoured to improve our specific character by the alliteration of that faithful and instructive writer. "The root," says he, "is white, fibrous. Stem erect, from three inches to a foot high, round, frated, smooth, branched from the very base; the branches alternate, very short. Leaves alternate or scattered, linear-lanceolate, sharpish, entire, rather fœthous; convex on one side, flat on the other; fœthous, above an inch long, three-quarters of a line wide. Flowers solitary and fœthous at the ends of the very short branches, between three leaves, of which the two lateral ones are smaller than the third. There is a white roundish basis, or receptacle, on which each flower stands. The calyx is two lines in diameter, green without, white within, having but three or four segments, which spread croswise. Anthers pale yellow. Stigma white, capitulate. Evidently different from the foregoing," Pollich. He mistakes however in his reference to Linnaeus, Gerard, and Haller. As to Jacques's Enumeration, 90 and 213, we have no positive means of determining, the tube of the calyx not being there described. Marcelli von Biebcrst. considers our English plant, above described, as belonging to this species, and not to lingulophyllum.

THESIUM.

12. Th. capitatum. Capitate Thefium. Linn. Sp. Pl. 202. Wild. n. 9. Thumb. Prodr. 46. — Flowers capitate, sessile, terminal. Leaves three-edged, pointed, smooth. Bracteas ovate. Segments of the calyx strongly pointed; densely woolly within.—Native of the same country. The fém is hard and shrubby, with alternate distant bracteas; the upper ones gradually longer. Leaves alternate, small, awl-shaped, pointed. Heads of flowers terminal, a fresh branch shooting out from beneath each. Segments of the calyx very much pointed, and internally villous throughout their whole length. Linnaeus. In his herbarium it is specimens which answer to this description, though left by him without

7. Th. lineatum. Lincated Thefium. Linn. Suppl. 162. Thumb. Prodr. 45. Wild. n. 4. — Leaves linear—awl-shaped, recurved. Stem round. Flowers axillary, sessile.—From the same country. Thunberg says the flowers are flaked. The younger Linnaeus remarks that the recurved, or reflexed, foliage gives this plant a very fquarrose aspect. It does not appear that he pollied any specimen.

9. Th. Friesia. Little Trailing Thefium. Linn. Mant. 213. Wild. n. 6. Thumb. Prodr. 46. — Stem decumbent. Leaves awl-shaped. Flowers spikèd; densely woolly within. Fruit globose, wrinkled.—Found at the Cape of Good Hope by Koenig, who sent specimens to his preceptor Linnaeus, under the new generic name of Friesia, by which, we presume, he meant to commemorate his own countryman Christian Friis Rotblid; but Linnaeus reduced the plant to Thesium. It is one of those species whose calyx is densely lined with reflexed pubescence, and of which Mr. Brown has, justifiably perhaps, made a distinct genus, on that account. Yet it has all the habit of an European Thesium. The little woody knobbled root sends forth numerous decumbent, simple, leafy, roundish, smooth fém, two or three inches in length. Leaves not an inch long, linear, acutely pointed; channelled above. Flowers sessile, each accompanied by two small acute bracteas. Calyx in five deep, lanceolate, acute segments, with scarcely any tube; their dense internal white woollines did not escape Linnaeus. Fruit nearly globose, much wrinkled, not so large as Coriander-feed.

10. Th. funeæ. Stringy Thefium. Linn. Sp. Pl. 322. Wild. n. 7. Thumb. Prodr. 45. — Stem with numerous long, nearly naked, branches. Leaves, and lateral bracteas, awl-shaped, very short. Flowers spikèd; their segments lanceolate, densely woolly within.—Native of the Cape. The spikèd round smooth fém, with its numerous crowded upright branches, has a very fquarrose aspect. The little leaves are f quarry scattered. The spikes are terminal, solitary, feafly an inch long, composed of several small, crowded, not quite felli, flowers, in ftricture like the laf; each accompanied by one ovate, pointed, keeled bratetia, and a pair of minute, lateral, awl-shaped ones.

11. Th. fpicatum. Large-spiked Thefium. Linn. Mant. 214. Wild. n. 8. — Stem erect, repeatedly branched. Leaves awl-shaped, minute, scattered. Flowers spikèd; their segments linear, densely woolly within. Lateral bracteas lanceolate.—From the fame country, growing on hills. Allied to the laf, but thrice as large in almost every part, with a f stout, round, ftai:lar, determinately branched fém. The leaves however are even more minute than in that fpecies. The spikes are thick, of numerous, very densely crowded, flowers, which Linnaeus defines leaves, smooth, apparently in contradifferentiation to those of Th. funeæ; but however smooth, or even, like that, externally, their segments, which are linear, narrow, and parallel, are full as hairy or woolly within. The outer bracteas are much dilated and rounded in their lower half; the lateral ones also are broadly lanceolate, very different from those of funeæ.

8. Th. fquareum. Recurve-leaved Thefium. Linn. Suppl. 162. Thumb. Prodr. 46. Wild. n. 5. — Leaves linear—awl-shaped, recurved. Stem round. Flowers axillary, sessile.—From the same country. Thunberg says the flowers are flaked. The younger Linnaeus remarks that the recurved, or reflexed, foliage gives this plant a very squarrose aspect. It does not appear that he pollied any specimen.

4. Th. erraticum. Naked-flowered Thesium. “Hayne in Schrad. Journ. v. 1. 32. t. 7. Termin. Bot. n. 6. t. 26. f. 4.” Roth in Sims and Kon. Ann. of Bot. v. 2. 18.—Stem erect, unbranched. Cluster simple. Flowers without lateral bracteas; their tube cup-shaped, very short. —Found near Berlin, by Mr. Hayne, author of an elegant German and Latin work on botanical terminology. We have an authentic specimen from professor Schrader, though we accidentally are deficient in that Faciculus of his Journal, which contains the description of the present species. No dispute can arise as to its difference from all the foregoing. The wide shallow form of the calyx is like the two first, but the narrow fowages, and the long narrow terminal bracteas, agree with Th. alpinum. The total absence of the pair of smaller lateral bracteas, essentially distinguishes it from all three.

5. Th. humile. Dwarf Thefium. Vahl Symb. v. 3. 43. Wild. n. 3. (Achimilla linaria folio, floribus et valvis in febrium alis felliibus; Shaw Afric. n. 14.) — Stem erect, branched. Flowers axillary, sessile, five-eleft; their tube very short. Gathered in cultivated ground near Tunis, by Vahl, who refers the synonym of Shaw, applied by Linnaeus, not without error, to his alpinum; from which therefore it must of course be erased. The present is said to be annual, with an herbaraceous fém hardly three inches high, branched from the base; branches smooth, angular, somewhat divided, as tall as the main fém. Leaves linear, thick, numerous, acute, an inch and half long. Tube of the calyx feaxly any; not elongated as in Th. alpinum. Fruit globose, rugosé, the size of Coriander-feed. Vahl.

6. Th. asperula. Australian Thefium. Dr. n. 1. — Cluster simple, elongated, somewhat spikèd. Partial-flats shorter than the flower. Calyx four or five-eleft; its segments bordered longitudinally, rather longer than the tube.—Gathered by Mr. Brown, at Port Jackson, as well as in Van Diemen’s land, and on the south coast of New Holland. We have seen no specimens.
out any specific name, he having originally described the
present species in Van Royen’s Prodrumus. The younger
Linnaeus took these specimens for *fearum*, with which they
agree only so far as to confirm their being the *capitaturn*,
contrasted therewith in Sp. Pl. Their leaves however can
hardly be termed small, measuring near an inch in length.
The *bracteae* have dilated membranous edges; fringed, as
Thunberg describes them. *Calyx* with an oblong, five-
angled tube. We cannot so blindly follow Willdenow, as to
infer any species between this and *fearum*.

Leaves three-edged, pointed; their edges very rough with
cartilaginous teeth. — Native likewise of the Cape. Nearly
 allied to the last, though undoubtedly a very distinct species.
The leaves are but half as large, and remarkable for the
cartilaginous teeth of their three edges.

Linn. Mant. 214. Willd. n. 10. Thunb. Prodr. 45.—
Leaves lanceolate, with a deciduous keel. Cymes terminal.
*Calyx* obtuse, smooth, except at the back of each flamen.
— Found at the Cape, and first described by Bergius.
Linnaeus originally referred the description of this author
to his own *Th. capitaturn*, from which scarcely any species
can be more distinct. In general dimensions, and shrubby
habit, indeed they are not unlike; but the leaves of the
present plant are much fewer, and more distant, and the in-
*florifcence* totally different, being a sort of compound irregular
umbel, or cyme. The *calyx* being smooth both within and
without, except a slender tuft of hairs at the back of each
flamen, as observed by Mr. Brown, reduces this species to a
different section, according to that author, along with
*saquariform*, n. 8, *fragile*, n. 16, and some others.
A note at the back of one of the Linnaean specimens of *Th. sirium*,
gathered by Sprengmann, says “the fruit is a *drupa*, like
that of *Praunus Padus*.” If so, this species should seem referrible to some other genus, as *Fusanus*; yet their habits are
too dissimilar.

Pl. 302. Willd. n. 1. Ait. n. 2. Pursh n. 1. (Cen-
taureum luticum acrocyrides virginianum; Pluk. Mant. 43.
Phyt. 1. 342. f. 1.)—Flowers umbellate. Leaves elliptic-
oblong.—On dry hills and fields, from New York to Caro-
lina. Pernal, flowering in June and July.—*Flowers* white.
Pursh. Mr. Aiton records its having first been introduced
into the British gardens in 1782, by the late Dr. Hope, profeffor of botany at Edinburgh. This is an
herbaceous species, about a foot high, erect, scarcely branched,
except at the top, and having more of the apect of some annual *Euphorbias*, than of the genus of which we are
 treating. The *leaves* are scattered, on short stalks, erect,
smooth, nearly oval, about an inch long. *Flowers* three or four together in small umbels, on slender, solitary
*flalks*, either axillary or terminal. *Bracteae* three or four
under each umbel, pale, lanceolate, deflexed. Mr. Brown
says the character of the *flower* of this, the only American
species, is between *Fusanus* and *Sanatium*. Of the fruit
nothing is known.

Willd. n. 12. Thunb. Prodr. 45.—Leaves three-edged,
somewhat ovate, keeled, deciduous. Stem angular. *Flowers
axillary, effuse.—Discovered by Thunberg at the Cape of
Good Hope. We have seen no specimen of this species.
It is said to have the habit of a *Salsola*, and to be extremely
brittle. The *leaves* are so very short, that at first sight
they seem to be altogether wanting.

branches diffuse, panicled, angular, many-flowered.
*Flowers* foliar, falked. *Leaves* awl-shaped.—From
the Cape of Good Hope,—The *flam* is round, fburbby, with
several round primary branches, subdivided throughout into
many lateral and terminal, slender, angular ones, repeatedly
and irregularly cloven and forked, bearing innumerable,
small, terminal, falked, solitary *flowers*, each of which is
inferted by five or five sharp awl shaped *bracteae*, which
Linnaeus describes as an inferior, but not a proper, *calyx*.
The real *calyx* is obtuse and fivel-efte.—*Fruit* like Coriander-
seed. Many of the flowers are abortive. The *leaves* are
scattered, and for the most part very minute. Mr. Brown
does not mention this species, perhaps from not having been
able to examine the inside of the *flowers*.

Brown Prodr. Nov. Holl. v. 1. 353.—Stem much branch-
ed, panicled; branches erect, many-flowered. *Flowers
capitate. Leaves lanceolate, channeled, deciduous, acute.
—Native of the Cape of Good Hope. This has a round
shrubby *flam*, with the panicled habit, and innumerable
small *flowers*, of many *Species*. The younger Linnaeus con-
6ounded it very negligently with the last, and it seems to
have passed undescribed, being only mentioned in Mr.
Brown’s work, by the apt name it bears in the Bankfian
herbarium. The *leaves* are pretty numerous, minute, spreading,
concave, broad at the base; deciduous at the margins and
keel. *Flowers* fellite, two, three, or four, in each little
terminal head, accompanied by several imbricated, ovate, keeled, sheathing *bracteae*, partly jagged or fringed
at the edges. These *bracteae* evince the true nature of what
Linnaeus terms, in the foregoing, an inferior *calyx*.

Mant. 213. Willd. n. 15. Ait. n. 3.—“Clusters terminal.
Leaves heart-shaped, fellite.”—Native of lofty hills at
the Cape of Good Hope.—Stem rather woody, erect, some-
what angular, four feet high, smooth. *Leaves* alternate,
fellite, clasping the *flam*, heart-shaped, entire, rather acute,
smooth, thickish, an inch long. *Clusters* terminal, conflit-
ing of minute *flowers*, intermixed with large ovate *bracteae*.
Linnaeus. Neither Mr. Brown nor profeffor Thunberg men-
tion this species. There is no authentic specimen of it in
the Linnaean collection, and we are almost convinced of its
being the same plant as the following. Willdenow has made
a singular miftake in copying the fpecific character of *Th.
Frisia*, see n. 9, over again, for the *plexicaule*, which
stands above it in the *Manifia*.

Prodr. 46. (Planta africana frutecens, portulaca folis,
Morgiani Syrorum, ex brevi pediculo binis, firmulis; Pluk.
Amalth. 173.)—Stalks three-flowered, terminal. Leaves
roundish-ovate, acute, fletthy. Stem shrubby, with alter-
ate corymbofe branches.—Native of the Cape of Good
Hope. This was adopted from Bergius by Linnaeus, with-
out seeing a specimen, at least from that author. One is
preferred in his own herbarium, on which he had written
*Thesium capense*, which his fon altered to *euphorbiioides*,
considering it as the fame with the plant of Bergius. A similar
specimen lies in the Bankfian collection for *Th. amplexicaule*.
Both names are excellent, but perhaps *euphorbiioides*, as the
original
original one, ought to be preferred. The plant is of a
brittle shrubby habit, turning black in drying. Leaves about
the size of the finger-nail, alternate, sessile, ovate or rather
heart-shaped, clasping the stem, acute, entire, glandular, smooth,
without rib or veins. Flowers about the tops of the alternate
corymbose upper branches, enveloped in bracteas, like
the leaves, but smaller. Tube of the calyx very short,
and strongly angular; limb smooth within, except perhaps a
few minute hairs behind the flowers, indicated by Mr.
Brown. Fruit globose, usually angular at the top.

Suppl. 162. Willd. n. 16. Thunb. Prodr. 46.-"Leaves
 lanceolate. Stem angular. Flowers axillary, trifoliate,
compound."—Gathered by Thunberg at the Cape.
The flower-flasks are three-flowered, sometimes divided, or
three-cleft, greatly divaricated. Linn. We have met with no
specimen answering to this species, nor does Mr. Brown
adept to it.

awn-shaped, spinous-pointed, spreading, felthy, deciduous.
Flowers axillary, stalked, solitary. — Gathered by
Thunberg at the Cape. A very singular species, whose woody
decumbent perennials are beset with numerous, ascending, funce
branches, two or three inches long, clothed with alternate,
horizontally projecting, glandular leaves, one-third of an
inch in length, giving the plant the aspect of an Ulex.
Flower-flasks about as long as the leaves.—Mr. Brown
places this in his section of such Cape species as have the
calyx internally naked, except a slender tuft of hairs behind
each flower. With it ranges squamulatum, fragilis, filicium,
spinifolium, ericoides, euphorbiaceae, and one unknown to us,
called fruticetum. The scent whose calyx is lined with a
dense deflexed beard, consists of Prunus, bullata, ficatam,
capitatum, and seuabrum, besides five species unknown to us,
called caffiffolium, terebrifolium, dible, ciliatum, and divari-
catam.

THESMOPHORIA, Θέσμοφορία, in Antiquity, a festival
in honour of Ceres, which was celebrated by many
cities of Greece; but especially the Athenians observed it
with great devotion and pomp. For the ceremonies of this
festival, see Potter, Archzool. Gez. tom. i. p. 403, eqn.
See CEREA and ELEUSINIA.

THESMOTHERME, Θέσμοθρημα, an appellation given
to fix of the nine Athenian archons; the first and chief
of the nine was called, by way of eminence, archon; the
second in dignity was called boleus; the third, polemarchus;
and the other fix, thespia: for an account of whose
power and jurisdiction, see Potter, Archzool. Gez. tom. i.
P. 77.

THESPANIS, in Ancient Geography, a river of Aetis,
Sarmatia; the mouth of which, according to Ptolemy, lay
between that of Rhenumus and the town of Azara.

THESPHAIA, Θήσφαία, in Antiquity, an appellation
given to oracle. See ORACLE.

THESPIS, or THESP., in Ancient Geography, a town
of Arcadia, situated at the foot of Mount Helicon, about
50 stadia from the city of Thebes. The Thebans, who
destroyed this city, spared nothing but the sacred monu-
ments, among which were the temple of Hercules, which
was served by a prieutes confined to celibacy during her
whole life, and the statue of that Cudus (or Cupid),
sometimes confused with the god of love, which was
only a shapeless stone as it was dug in the quarry, for thus
the objects of public worship were reprehended in ancient
times. Praxiteles is said to have formed a statue of Cupid
of Pentelic marble; and Lyseus made one of bronze.

The Thespians reported, that the statue of Praxiteles
was taken away by Caius, the Roman emperor; but others
say, that it was returned by Claudius, and that Nero
removed it to Rome, where it was consumed by fire.
This statue was so beautiful, that, according to Cicero,
Theophis was visited merely for the sake of seeing it. The Cupidion
that existed in the time of Paunias was an imitation of
that of Praxiteles by Meonorus, the Athenian; but here
were a Venus and Flora in marble, executed by Praxiteles
himself. In one quarter of the city there was a temple
consecrated to Venus Melanis. The temple was a beautifull
structure, ornamented with a statue of Hecid in bronze.
Near it was a Victory in bronze, and a chapel consecrated
to the Muses, each of which had a small statue in marble.
At Theopia there was a statue of Venus in marble, made
by Praxiteles.

THESPIADES, in Mythology, an appellation given
to the Muses from the city of Theophis, where they were
honoured.

THESPIS, in Ancient Geography, a town of Thessaly,
in Magnesia.

THESPISANA, the name of an antidote intended for
internal scabres.

THESPIS, in Biography, an ancient poet, and the
founded inventor of tragedy, was born in a small borough
of Attica, named Icara, and he, as well as Sphorion, a native of
the same place, appeared each at the head of a company of
actors, one on a kind of stage and the other in a cart. Sphorion
attacked the vices and abominations of his time, and represented
his first pieces towards the year 520 B.C. Thefis treated
nobler subjects, which he drew from history: he appeared
some years after Sphorion, made his first attempts in tragedy,
and acted his Alcestis in the year 536 B.C. He was
followed in this species of drama by Aeschylus, Sopho-
icles, and Euripides. Thefis having observed at the festi-
ivals, in which before his time hymns only were sung, one
of the fingers, mounted on a table, forming a kind of dia-
logue with the chorus, took the hint of introducing into his
tragedies an actor, who by simple recitals, introduced at
intervals, should relieve the chorus, divide the action, and
render it more intelligible. This innovation, together with
some other liberties in which he indulged himself, alarmed
Soline, the legislator of Athens, who condemned a species
of composition, in which the ancient traditions were dis-
guised by fiction. "If we applaud falsehood in our public
exhibitions," said he to Thefis, "we shall soon find that
it will infalute itself into our most sacred engagements."

The excessive approbation and delight with which both
the city and country received the pieces of Thefis and
Sphorion, at once justified and rendered useful the fulcru-
ful forefist of Solon; the poets, who till that time had only
exercised their genius in dithyrambs and licentious satire,
fruck with the elegant forms which these species of com-
position began to assume, dedicated their talents to tragedy
and comedy. See TRAGEDY.

Thefis, according to the description of Horace, ex-
tended his plan farther than the introduction of a single
actor in the intervals between the songs of the chorus, to
the representation of some fable by actors on a kind of
moveable stage, which alternately sung and played, with their
faces turned by the bees of wine.

"Ignorant tragediae genus invenisse Camenae
Dicitur, et pleuratis vexisse poenitit Thefis,
Ut canerent agonumque concivit facibus ora."

Art. Poet.

Some writers have mentioned three pieces of Thefis,
THE

THE SPONTI, a people of Epirus, who inhabited Thessaly, in the vicinity of the Ambraeciates; and formed one nation with the Chaoioni. They derived their name from Thisproton, the son of Paflegus, who was the son of Lycoiog, and who was the first that conducted the Paflegus into Epirus.

THESPONTI, a small country of Epirus, S. of Chonia, having to the E. the lake Ambraecus and Ambraeci, and to the S. the sea. This country was watered by three rivers, which ran from W. to E., viz. Thias, Coeytas, and Acheron.

THESSALIA, THESALY, a celebrated country of Greece. This country, comprising Magnesia and other small districts which have particular denominations, is bounded to the E. by the sea, to the N. by mount Olympus, to the W. by mount Pindus, and to the S. by mount Oeta. From these permanent boundaries branch out other chains of mountains and hills, that wind through the country, occasionally embracing fertile plains, which, from their form, and the manner in which they are inclosed, resemble vast amphitheatres. Opulent cities are seated on the heights that encircle these plains; and the whole country is watered by rivers falling in general into the Peneus, which, before it looses itself in the sea, flows through the famous valley of Tempel. The Apeiron, or Apidanus, proceeded from the S. where was Dolopla, ascended northward (see Peneus), traversed the plains of Phalnoria in the Thessalian coast, and discharged itself into the Alpheus, W. of Larissa. (See APIDANO.) The Onchelius, or Onchones, took its rise S. of Larissa, passed by the Palus Borbeis, and after having received the Naurus, discharged itself into the Pelasgic gulf, between Demetrias on the left and Pagan in the right. The Sperchius commenced S.W. in an angle which was formed by the chains of Pindus with those of mount Oeta, ascended N.E., watered Sperchium, turned to the E., and having passed Hyppata, received the Athelous of Thessaly, which proceeded from mount Othrys, and being joined by the Lamina, discharged itself into the Malac or Lamiac gulf. The country was marshy, and abounded with a variety of plants, fome of which were medicinal and fanotive, and others venomous and pernicious. The knowledge of their different properties caused the Thessaliens to be regarded as a clafs of forcers, who possessed the art of producing supernatural effects. The principal people of Thessaly were the Athenae, situated towards the N.W., whose chief town was OXinia, near a lake that lay between small chains of mountains;—the Pelagoni Tripolitis, in a kind of hollow territory, separated from Macedonia by a chain of mountains, called Cambrunni montes; denominatod Tripolitans on account of their three towns, Dolicha, Pythum, and Azorus; in the eastern part of this territory was the Aecuris palus, or marsh Aecuri:—the Perrhab, lying S. of the mountains which formed this territory, and extending from W. to E., the N. of the Peneus:—S. of the Peneus, towards the W., was the Elisotis, watered by the rivers Ion and Theues, and bounded W. and S. by mount Pindus: its most considerable towns being Comphi, Trica, Peliasum, and Phaciodon:—the Paflegiots, towards the E., having the Peneus to the N. and commencing W. from the Apidanus, which received the Elipeneus, that pafted to Pharsalia: the principal towns of this part of Thessaly were Larissa, reckoned the capital of Thessaly; Pharsalia, one of the largest and most opulent towns, now Pharsalia, Scytopha, Cranna, &c.:—the Thessaliots being to the S. and watered by the Elipeneus in the lower part of its course, and having to the S. mount Othrys, and to the S.W. Dolopia; its principal town was Metha upon the Elipeneus:—the Phthiotic, towards the S.E., terminating in a peninsula, and watered by the Sperchius and Acheron; its principal towns were Phraes, to the N.; Thauacas, to the W., commanding one of the finest prospects in Greece; Alos and Lamia, towards the middle; Phalar, at the bottom of the Amalac gulf; in the peninsula, Thebes, Lariss, Cremona and Echium: at the extremity the port of Apheta, and S.E. Heralde Trachion, the road from which led to the fraits of Thermopylae: which fee. Magnesia was separated from the sea by mount Pelion: here were the towns of Demetrias and Ioloeos, and S.E., on the eastern coast, the town of Magnesia, and at the extremity of the peninsula to the S.W. the town of Antium. At the bottom of the Pelasgic gulf were the two small islands of Deucalion and Pyrrha. Dolopia lay towards Atolia, and contained no considerable towns. The extremity of the S.E. of Magnesia was terminated by the promontory Sepias, where the fleet of Xerxes was battered by a tempest. The town of Gunas, at the entrance of the valley of Tempel, was the key of Thessaly on the fide of Macedonia, as the port of Thermopylae was on the fide of Phocis. See Thessaly.

The several nations which we have recounted, as properly Thessalian, were formerly governed by kings, but after various revolutions became for the most part subject to an oligarchy. The fates and the towns were independent of each other. The confederacy of the Thessaliens, properly so called, was the most powerful of all, both from the number of towns pertaining to it, and from the accession of the Magnesians and Perrheians which were brought almost under complete subjection. There were some free cities, unconnected with any of the fates. The Thessaliens could bring into the field an army of 6000 horse and 10,000 infantry, exclusively of their archers, who were excellent, and who from their infancy were accustomed to draw the bow. The Thessaliens are said to have been the first who managed horses with the bit, and used them in battle; and hence, it is said, originated the tradition that a race of creatures, called centaurs, half horse and half man, formerly existed in Thessaly. This country produced wine, oil, and fruit of different kinds. The land has been represented to be so rich, that the corn grew too fast, if it were not cut, or sheep turned to graze upon it. They carried on a considerable commerce in corn. The Thessaliens, though they boasted of their liberty, were the first to reduce Greeks to slavery. Amongst them they had a prodigious number of slaves, known by the name of Penelée. These people are very hospitable to strangers, and treat them magnificently. In their dress and houses luxury is conspicuous; and at their entertainments they hire dancing girls to amuse them. They are reckoned passionate and turbulent, and very difficult to be governed; and they are reproached with insincerity and falsehood. They have cultivated poetry from their most early ages, and pretend that Thessaly gave birth to Thamyris, Orpheus, Linus, and many others who lived in the heroic age; but since that period, they have produced no writer nor any celebrated artist. They were much addicted to dancing; and in some places generals or magistrates were called chiefs of the dance. Their music observes a medium between the Dorian and Ionic, and accordingly harmonizes with the character and manners of the country.
country. They have never on any occasion killed flocks, and the same punishment was inflicted on a peafon who killed one of these birds as if he had taken away the life of a man. This fact it is said, was founded on the circumstance, that flocks had freed Thelfaly from the enormous serpents which formerly infested it.

THESALICUM SEPTIME, the Thelfalian chair, fo called from Thelfaly, where chairs of this figure were moft in use: it is recommended by Hippocrates, Lib. de Art. in place of a machine for reducing a recent luxation of the shoulder-bone. The back of this chair is perpendicular to the seat, as Galen tells us, by which construction it is distinguished, and accommodated to the operation.

THESSALIOTIS. See Thessalia.

THESSALON, in Geography, a river of Canada, which runs into lake Huron, N. lat. 49° 6'. W. long. 82° 8'.

THESALONIANS, Epiflates to, in Scripture History. See Epiftle.

THESALONICA, in Ancient Geography, a town of Macedonia, in the Thracian gulf; and built on the declivity of a mountain in the form of an amphitheatre, the summit of which was defended by a caufe of great extent. Strabo says that it was named "Tharmon," and that it was only a village; that Caffander augmented it considerably, and transported the inhabitants of some neighbouring cities, and gave it the name of Thefalonica, that of his wife, the fifter of Alexander the Great. In the year 168 B.C., Macedonia was divided into four parts, and Thesalonica was the capital of the second part. Its government was regulated by magiftrates, called "Political." Under the Greek empire it continued to be governed by a fenate. Cicero, during his exile, paffed fome time at Thesalonica. This city had feveral divinities, and alfo emperors, who were objects of public worship. Jupiter was the principal; Apollo was alfo repreffed on its monuments; and the Cabiri had a temple in Thesalonica. The Cabirian and Pyrrhic games were exhibited in this city in honour of the Cabiri, and the Olympic games were celebrated in honour of Jupiter. That rich and powerful city had, for its fpectacles and the amufement of the citizens, an amphitheatre for the combats of gladiators, and a circus for the public games. The emperors Valerian and Gallienus gave it the title of a colony. It had alfo the title of Neocorus, The modern name of Thesalonica is Salonica or Saloniki. (which fee.) Although there are different routes by which goods are transported from Macedonia into the Austrian dominions, the beft, fays Dr. Holland in his Travels into Albania, &c. is through Bulgaria, by Widin and Offovo, where it enters the Austrian territory, and is then continued through the Bannat by Tomsvar, Pelt, Raab to Vienna. The goods landed at Salonica are made up in packages of 14 hundred weight, and two of these are the load of a horfe. The cavalcades for this inland journey confift ofen from 200 or 300, and sometimes of 1000 horses. The property fo transported, at a moderate estimate, might be worth 30,000l. on its arrival in Germany. The time occupied between Salonica and Vienna was in general thirty-five days, exclusive of the quarantine at Offovo, which sometimes took place. The cavalcades usually travel eight hours in the twenty-four.

THESSALY, or JANNA, in Geography, a province of European Turkey, bounded on the N. by Macedonia, on the E. by the Archipelago, on the S. by Livadia, and on the W. by Livadia and Epire, anciently called Thesalia, Pelagia, and Pyrrhs, (see Thessalia,) and now by the Turks Janna. It was sometimes annexed to Macedonia, and sometimes separated from it. The celebrated mount

Pindus, now Meifova, or Meffo Novo, separated it from Epirus, or a part of the prefent Albania. Amongf its once celebrated twenty-four mountains, the moft remarkable are Olympus, Pelion, and Oifa. Here are alfo situated the plains of Pharsalia, and the delightful valley of Tempé. The country is extremely fertile, and retains its ancient character in this respect. It produces oranges, citrons, lemons, pomegranates, very fweet grapes, excellent figs and melons, almonds, olives, cotton, and chinamus, which take their name from Callanca in Magnesia. The modern Thesalian are a well-made spiritifed people. The moft remarkable places in the country are Larissa and Janna. See Thessalia.

THESTIA, in Ancient Geography, a town of Epirus, in Acmarnia.—Alfo, a river of the Peloponnesus, in Laconia.

THESTIDION, a town of Greece, in Theffaly.

THESTIS, a town which belonged to the Arabs.—Alfo, a town of Africa, in Libya.—Alfo, a fountain of Africa, in the Cyrenaica, near Yrifa.

THETA, 6, among the Ancients, one of the Greek letters. It was ufed as a mark on the ballots of judges, by which they condemned the perfon to death, it being the firft letter of the word 60o0, death. Whence it had the epithet of niger and inflinx, thus:

"O multum ante alias inflinx iterata theta."

THETES, 6o0, in Antiquity, the lowest clafs of people at Athens. Aristides repealed Solon's law by which the thetes were made incapable of bearing an office in the government.

THETFORD, in Geography, an ancient borough and market-town, partly in the hundred of Shropham, and county of Norfolk, and partly in the hundred of Lackford, in the county of Suffolk, England, is situated at the distance of 28 miles S.W. from Norwich, and 80 miles N.N.E. from London. It was a place of considerable confluence at an early period.

Thetford, called in the Saxon Chronicle Thedford, has an acknowledged claim of having been once the seat of the East Anglian kings. Being the metropolis of that portion of the heptarchy, it became subject to the ravages of the Danes, by whom it was repeatedly laid in ashes. From numerous coins, it is evident that there was a mint at Thetford from the time of Athelstan to the reign of king John. At the eastern extremity of the town are some extensive remains of fortifications, consisting of a large artificial mount, or keep, with lofty banks and deep ditches. These fortifications were probably first formed by the early kings of East Anglia, and the keep an addition, made subsequent to the Norman conquest. East of the mount is a large area, or place of arms, three hundred feet square. The mount is about one hundred feet in height, and one hundred and eighty-four feet in circumference, at the base. The slope is extremely steep; and yet no traces remain of any path or steps for the purpose of carrying up machines or weighty ammunition.

In the Conqueror's time, Herfaft having removed the episcopal fee from North Elmham to Thetford, the latter became the head of the East Anglian diocfe; but in the succeeding reign, the fee was transferred to Norwich. The ruins of ecclesiastical and other buildings strongly point out the ancient splendour of this town. At one period it is said to have had twenty churches, answerable to the number of parishes, and eight monasteries, besides other religious and charitable foundations. But of these, the names only of some remain; and of others, a few dilapidated walls serve
to mark their fenes. Of the twenty churches, three only are preferred; St. Peter's, and St. Cuthbert's, on the Norfolk side of the river; and St. Mary the Lea on the Suffolk side. St. Peter's, commonly called the Black church, from its being constructed chiefly of flint, consists of a chancel, nave, two aisles, and a tower. The latter was rebuilt in 1789, when a great part of the church was also re-edited. The battlements on the south side, and the buttresses, are decorated with allusive ornaments and large letters inlaid in the flint work.

The Nunney was founded by Uvius, the first abbot of St. Edmund's Bury, in the reign of king Canute; in commemoration of the number of persons who fell at Snareshill, near this town, in the fangunary conflict between king Edmund's army and the forces under the Danish leaders Ingwar and Ubba. A few monks were placed in this monastery, which was then considered as a cell to Bury Abbey. In the year 1176, the monks, being reduced to two, renounced, by the request of the abbot of Bury, who placed in their hand a convent of nuns, who had previously reided at Lynn. At the dissolution, the revenues and feite were granted to sir Richard Fulmerston, who made this house his residence. It was afterwards let to a farmer, and some years since the greater part was taken down: a new farm-house was built of the materials, and the conventual church converted into a barn. Some of the walls, with buttresses, windows, &c. still remain.

The Priory or Abbey was founded by Roger Bigod, in the year 1104, for monks of the Cluniac order. This was a peculiarly privileged house; for other Cluniac monasteries were subject to have their revenues feized, on a war breaking out between England and France, because being dependent on the abbey of Cluny, in Burgundy, the monks were considered as foreigners; but the religious persons of this monastery were naturalized, and treated as other subjects of the realm. At the suppression the revenues were granted to the duke of Norfolk, and are now the property of Lord Petre. The ancient gateway, constructed with freestone and black flint, with parts of the church, &c. still remain. This monastery had been the burial-place of the several noble families who had successively borne the title of earls of Norfolk.

St. Albin's Priory was founded by John of Gaunt, duke of Lancaster, in the year 1387, for friars mendicant of the Augustinian order. The feite, granted to sir Richard Fulmerston, is still called the Friar's Close.

The Monastery of St. Sepulchre was founded in 1169, by William, earl of Warren and Surrey, for canons of the Augustinian order, and additionally endowed by king Henry II. The feite is still called Canons: part of the conventual buildings, yet standing, has long since been used as a barn. The gate of the porter's lodge, and some other parts of the buildings, remain. Of the other four religious houses, no vestiges are now left. In the Suffolk part of the town, near St. Mary's church, is a free grammar-school. In the year 1566, sir Richard Fulmerston bequeathed property for the erection of a free school, with dwelling-houses and salaries for a master and usher; and also habitations and weekly penions for two poor men and two poor women. The benevolent design of the donor, however, was not carried into effect till the time of James I., when it was enacted by authority of parliament, that there should be for ever a free grammar-school and hospital; and that the master, usher, and the four poor people, should be a body politic, under the title of "The master and fellows of the school and hospital at Thetford, founded by king James the First, according to the will of sir Richard Fulmerston, kat."

Thetford, though a very ancient burgh, is comparatively a modern corporation. In the time of the Conqueror, the town was governed by a confid and other inferior officers. Not being a free burgh, it suffered greatly at times by the oppression of the officers nominated by the crown. But in the year 1573, queen Elizabeth granted a charter, by which a mayor, ten aldermen, twenty common-councilmen, a recorder, town-clerk, sword-bearer, and two ffejants at mace, constituted the corporation. The mayor for the time being is clerk of the market, and in the year after his mayoralty officiates as coroner. The corporation had also permission to lend two burgesse to parliament, "provided they were discreet and honest men, and were elected at the expense of the borough." This charter was surrendered to the crown in the thirty-fourth year of Charles II., and a very imperfect one obtained in its stead. But in 1602 an order was procured from the court of chancery for cancelling the surrender, and procuring a transcript of the charter granted by Elizabeth, under which the town is at present governed. Thetford has been honoured with the presence of many of our sovereigns, particularly Henry I. and II. Several charters, granted by the former, bear date from this town. When the manor fell with the duchy of Lancaster, of which it formed a parcel, to the crown, the ancient seat of the earls Warren became the royal palace. This was rebuilt in the time of queen Elizabeth, who occasionally resided here. King James I. made it one of his hunting seats; but being disgraced with the abrupt remonstrance of a farmer, over whose lands he had been hunting, he gave the palace to Sir Philip Wodehouse. It has been rebuilt, and is now the property of a private gentleman; but still bears the appellation of the "King's House." The old guildhall or council-house being in a dilapidated condition, Sir Joseph Williamson, secretary of state to king Charles II., erected at his own expense the present council-chamber, and the apartment for the juries. Thetford has been much improved within the last twenty years. A new bridge has been built, the principal street paved, and several handsome houses have been erected. The navigation of the river has been attended to, and by this communication some mercantile burthens are transferred in the corn and coal trade. Five fairs are held annually, and a market weekly on Saturdays; but, compared with its former greatness, it is now a very inconsiderable place. The population in the return of the year 1811, was rated to be 2450, occupying 530 houses.

Near to Thetford is a mineral spring, the waters of which possesses considerable virtues, though their celebrity has by no means been commensurate with their acknowledged efficacy. Thomas Paine, well known for his political and theological tracts, was a native of this town, and received his education in the grammar-school. — Blomfield's "Topographical History of Norfolk, vol. ii. Beauties of England and Wales, vol. xi. by John Britton, F.S.A. History, &c. of Thetford, by Thomas Martin, 410.

Thetford, a town of the United States, in the county of Orange, Vermont; 10 miles N. of Hanover; containing 1735 inhabitants.

THETIS, in Mythology, the name of the most beautiful of the Nereids.

THEVACOURCHY, in Geography, a town of Hindoojan, in the Carnatic; 20 miles W.S.W. of Tiragar.

THEUDORIA, in Ancient Geography, a town of Achaia, from which the Macedonians were driven by the Romans.

THEUDURUM, a town of Lower Germany, on the route
route from Colonia Trajana to Colonia Agrippina, between Mederiacum and Coriovaum. Anton. Itin. THEVEN, in Geography, a town of Peria, in the province of Laridam; 40 miles E. of Lar.

THEVENARD, Gabriel Vincent, of Paris, in Biography, born in 1669, became in the operas of Lulli the first singer and actor of his time. He had a tenor voice, which made the public forget that of Beaumarchais; it was famous, mellifluous, and extensive in compass. He sung a little through the throat, but by dint of art, he found the means of rendering this little defect even agreeable. His appearance on the stage was dignified, and his performance wonderful! It was to him that the present manner (1780) of speaking recitative is due. He excelled above all in singing at table; nor has he ever been surpassed in that talent, except by De Château and Jehote, who in many years delighted their friends.

He sung more than forty years at the Opera, and only retired in the year 1730. He was more than sixty years old, when, seeing a beautiful female slippers in a shoemaker's shop, he fell violently in love, unhappily, unseen, with the perfon for whom it was made; and having discovered the lady, married her, after obtaining the consent of an uncle on whom she was dependent, with the assistance of many bottles of wine which they cracked together with the utmost cordiality, and which Thevenard mollified with the charms of his voice.

He died at Paris in 1741, at the age of 72. Thevenard was the cause of the duke d'Antin quitting the management of the opera. This singer having a penfion offered him for his services, found it too considerable, that he refused to accept of it, saying it was only fit for his footman. The duke, piqued at this insolence, would have sent him to prison; but it having been represented to him that the public would suffer by his absence, he sacrificed to this consideration his resentment; but determining to have nothing more to do with such people, he quitted the superintendence of the opera. Laborde.

THEVENOT, John, a traveller in the Levant, was born in Lorraine, and after repeated journeys, died in Peria in 1667. He is said to have introduced the use of coffee into France. His "Voyage in Asia" was published in 1664, which is a work considerably enlarged, and has been often re-edited. The Amsterdam edition in 12mo., 1727, is comprised in 5 vols. Nouv. Dict. Hilar.

THEVENOT, Nicholas Melchisedec, a writer of travels, was born in 1621, probably at Paris, and having finished his studies, indulged his propensities for visiting foreign countries, confining himself chiefly to various parts of Europe. Some perfons have given him the credit of being a great linguist, but this is disputed by Huet, who was personally acquainted with him. The result of his observations and inquiries was published in a "Collection of Voyages and Travels," comprised in 4 vols. fol. from 1663 to 1672. Thevenot was a great collector of books, consisting of more than 2000 volumes, in which the royal library, of which he was keeper, was deficient. Nothiel, on returning from his embassy to Constantinople, enriched this collection by a present of his marbles, inscriptions, and bas-reliefs. He died in 1692. From various MSS. in the royal library, he had compiled "The Works of Ancient Mathematicians," an edition of which was published after his death. Moreri.

Huet.

THEVET, Andrew, a traveller and writer, was born at Angouleme in 1502; and being devious of visiting foreign countries, he obtained, by the interest of the cardinal of Lorraine, an opportunity of going to Jerusalem. His travels in the Levant occupied him from 1549 to 1554; and after his return to France, he accompanied the fieur de Villegaignon, in 1555, to found a colony in Brazil. In 1556 he took the habit of an ecclesiastic, and was appointed almoner to queen Catharine de Medici. He also obtained the titles of historiographer and cosmographer royal, and died at Paris in 1570, at the advanced age of 88 years. Besides other works, he published "Cosmographie du Levant," 1554, 4to.; "Les Singularitez de la France Antartique," 1588, 4to.; and "Cosmographie Universelle," 2 vols. fol. 1575; but unfortunately his veracity is questionable. Moreri.

THEVESTE, Tiffeine, in Ancient Geography, a town of Africa, situated on a delightful plain in the interior of the country, on the banks of a river, E. of Sigus, and E.S.E. of Cirta. In Anton. Itin. this town has the title of a Roman colony, and is placed on the route from Carthage to Cariaca, between Annemata Colonia and Attaba. Thevet. See Tisse.

THEVETIA, in Botany, a name given by Linnaeus, in his Hortus Cliffortianus 55, to a genus distinguished by Plu- tier, and other authors, under the American appellation of Abouai. The person commemorated by the above name was Andre Thevet, a French monk, who travelled to Brail, of which he published an account in 1554, under the title of Les Singularitez de la France Antartique, autrement nommes Americi, &e. Of this book there are several editions, with rude wooden cuts, and some accounts of plants, amongst which the Abouai is, for the first time, described. The author, according to De Theis, died in 1592, about the age of eighty-eight. Haller says he has injudiciously applied passages in the writings of the ancients to the productions of the new world; and that he has described many countries which he never visited. Linnaeus himself appears not to have been satisfied with the honour he was conferring on him, as he should not be displeased with any person who might change this name for another. He subsequently retained it as a specific name only, when the genus in question was funk in his own Ceberea. See that article.

THEU-PROSOPON, in Ancient Geography, a promontory of Phœnicia, between Tripolis and Botrys. Metc. calls it Euprostonan.

THEURGY, theurgy, a name which the ancients gave to that facer part of magic which we sometimes call white magic, or the white art.

The word is formed from θεος, god, and τερας, work; q. d. the art of doing divine things, or things which God alone can do: or the power of working extraordinary and supernatural things, by invoking the names of God, saints, angels, &c.

Accordingly, those who have written of magic in the general, divide it into three parts: the first of which is called theurgy, as operating by divine or celestial means; the second, natural magic, performed by the powers of nature; and the third, necromancy, which proceeds by invoking demons.

This theurgy, or pretended art of fo purging and refining that faculty of the mind, which receives the images of things, as to render it capable of perceiving the demons, and of performing many marvellous things by their aid, was adopted by the disciples of Ammonius towards the close of the second century. Ammonius, the founder of the sect of modern Platonists (see Platonism), with a view of reconciling the popular religions of different countries, and particularly the Christian, with his own system, turned into mere allegory the whole history of the gods, and maintained that those beings, whom the priests and people dignified with this title,
The songs of this prince are placed by some at the head of those that have been preferred in the French language, as those by Guillaume IX., duke of Aquitaine, are in that of Provence. There were indeed songs written in both languages before these princes had done poetry the honour to make it their favourite amusement; but the chief part of those of higher antiquity than the time of these patriarchs of Provencal and French verification are either lost, or thought of little value.

This prince was contemporary with Philip Augustus, and Lewis VIII. and IX., who left him as prince he accompanied to the Holy War. It has been said by several historians that he was much captivated by the charms of queen Blanche of Castile, mother of St. Lewis, to whom many of his songs were addressed; but this point of history has been disputed with great zeal by M. P. Eveque de la Ravalliere, editor of Thibault’s poems, which he published in 1742, with notes, in 2 vols. 12mo. and a history of the revolutions, in the French language, from the time of Charlemagne to that of St. Lewis, together with an Effay on the Antiquity of French Songs. This learned prelate has defended the honour of queen Blanche with his pen, five hundred years after her decease, as much proof and true chivalry, as the most valiant champion of injured innocence could have done with his sword and lance, he has been animated by the presence of that prince, and the heroism of the times in which he lived.

"Les Grandes Chroniques de France" tell us that Thibault, at the age of thirty-five, having conceived a violent and hopeless passion for queen Blanche, was advised by wise and prudent counsellors to apply himself to music and poetry, which he did with such success, that he produced "the most beautiful songs and melodies that have ever been heard."

Fauchet Des Anciens Poetes Francois.

Two airs by Thibault may be seen in Burney’s General History of Music, from the Vatican collection of Provencal floggs in Gregorian notes, without bars or bafe; and given afterwards in modern notation, with a base, and an English version of the words.

Thiberville, in Geography, a town of France, in the department of the Eure; 9 miles E. of Lieux.

Thibet, or Tibet, pronounced Tibeet and Thti in Bengal, and called by its own inhabitants Pu, or P'k, kachin, p'k signifying northern, and kachin, faxow, that is, the snowy region of the North, is a country of Asia, of which our knowledge, principally obtained at a very recent period, is still very imperfect. We have no evidence that the ancients ever penetrated the snowy mountains of Tibet. It seems to have been in some measure discofled to the Portuguese, in their commercial intercourse with the East Indies; and the name of it was known to Marco Polo and other travellers of the 12th and 13th centuries. Accordingly, Tibet seems to have been the southern part of their Tangut. Paolo indeed describes the province of “Tebeth,” as containing eight kingdoms, with many cities and villages, and as being a mountainous country, which produced some gold and spices, a large breed of dogs, and excellent falcons. But we have no geographical nor statistical account of this country upon which we can depend previously to the last century; and even now our knowledge of it is very partial and defective. About the year 1715, the emperor of China, as we learn from Du Halde, being desirous of obtaining a map of Tibet, sent two lamas, who had studied geometry, for this purpose. These lamas drew a map, from Sining, in the province of Shen-fu, to the sources of the Ganges, which was afterwards examined by the Jesuits, and improved. This map is published in the Atlas of Du Halde, and has been followed, with few variations, by our modern geographers.
THIBET.

Its authority is doubtful, its accuracy very dubious, and the information it affords concerning kingdoms, states, and provinces, as well as particular places, very limited and unsatisfactory. According to our most recent maps, Tibet extends from about the 77th to the 101st degree of longitude, which, in the latitude of 35°, may be about 1350 geographical miles. The breadth may be regarded as extending from the 25th to the 35th degree of latitude, or about 480 geographical miles. It appears, however, from the testimonies of two intelligent travellers, Mr. Forster and Tiefenthaler, that the northern boundary of Tibet may be safely extended two degrees farther than it appears in our best maps, in which there is no portion of Great Tibet to the N.E. of Cashmir. Major Rennell moved it one degree farther to the north than D’Anville’s boundary in lat. 34°, and Pinkerton thinks that he might safely have extended it at least 3°. The northern boundary of Tibet, according to the French, is Mus Tag, and they place that range in 38°. By adding 2° to 3°, we ascertain an addition of 120 geographical miles to the number of 480 above stated.

Tibet, according to Mr. Bogle’s account (Phil. Transt.), begins properly from the top of the great ridge of the Caucasus, and extends from thence in breadth to the confines of Great Tartary, and perhaps to the dominions of the Russian empire. He says, that having once attained the summit of the Bootan mountains, you do not descend in an equal proportion on the side of Tibet; but continuing still on a very elevated base, you traverse valleys which are wider and not so deep as the former, and mountains that are neither so steep, nor apparently so high. On the other hand, it represents itself as the most horticultural and delightful country he ever saw; and the climate as extremely severe. According to Mr. Turner, the boundaries of Tibet and Bootan are separated by the lofty range of mountains called Soomoonang, and are marked by a long row of white inconstant flags, fixed in rude heaps of stones, and fluttering in the wind. There, at the same time, are supposed to operate as a charm over the Dewtas, or “genii loci,” who are paramount here. No mountain is thought to be wholly exempt from their influence; and they range chiefly in the most elevated regions, where, drenched with dews, and covered with snow and snow, they are supposed to dwell among them, in ill humour, their most benevolent spells, to harass and annoy the traveller.

Tibet is sometimes divided into three parts, viz. Upper, Middle, and Lower. Upper Tibet comprehends chiefly the province of Nagari, abounding with tremendous rocks and mountains, always covered with snow. The countries of Lata or Ladak (Latac) and Bregnout or Bramasion (perhaps Sinagour) probably constitute a portion of Upper Tibet, as well as Nagari. Middle Tibet contains the provinces of Shang, Ou, and Kang; and those of Lower Tibet are Takto, Congbo, and Kagang. Many of these provinces are again subdivided: e.g. Nagari, which is considered as a kingdom consisting of three departments, Sanghar, Touroang, and Tamo (Dam or Daum). Shang is on the W. bounded by Nepal. The province of Ou contains Laharfa or Laffa, the capital of Tibet. Kang lies to the N. (or N.E.) of Ou, and is inhabited by a mixture of Tibetans and Mongols in tents. Kangang is on the S.E. bordering on the Birmanis, and is divided into twelve departments. To these we must add the wide region of Amdo, if it be not the same with Kangang, the natives of which speak the Chinese language. The country of Hor lies between Tartary and the provinces of Nagari and Kang, and seems to be the Hohonor of our maps. Our Bootan (which fee) is called by the natives Dope or Takto; and the countries W. of it, viz. Moringa or Morung, Mocampour, Nepul, Gora, and Kamaon, are not considered as parts of Tibet. On the western side, high mountains, covered with perpetual snow, and terrible avalanches, have prevented the access and invasions of the Persians and the conquerors of Bucharia; while the deferts on the N.E. have proved ineffectual barriers against the Monguls and Eluta. Travellers have also been prevented from exploring this quarter by the western mountains, so that it is even now little known.

According to the topography, compiled from the papers of Pinnebull, a Capuchin friar, who died in 1747, and was buried at Patan, by father Giorgi, in a work published at Rome in 1762, Tibet is bounded on the E. by China and Tartary, a province abounding with tea, and, since the year 1720, incorporated with the Chinee empire; on the S. by Bengal, Lofice, Altibuxy, Mou, Bruckps, Lhoba, Lhoka, Krapa, Sciapado, and Bha; on the N. by Casmir, Nekpul, and Moronga; and on the N. by Great Tartary, the Ulheba, Cash, and Janzkar, as far as Zerkend and Cokonor or Kokonor. The kingdoms and provinces in this topography are enumerated by Pinkerton, ubi infra.

The government of Tibet has been considered as ecclesiastical or spiritual; though the lamas were accustomed to appoint a “tip,” or secular regent, a right which has been probably transferred to the Chinee emperor. This officer resides at Laffa, the capital, and is invested with the government and supreme control over the whole country. Mr. Turner, however, is of opinion, that the temporal authority of the lamas may again recover its former dignity and splendour. Bootan, which is generally considered as a feudatory province of Tibet, has a raja or prince called Daib, of no very permanent or extensive authority. The laws must, like the religion, bear some affinity to those of the Hindoos.

The lama of Tibet was the Prester John of the middle ages, if we were not some Nefferian khan; and the appellation was unaccountably transferred by Portuguese ignorance to the emperor of Abyssinia. (See Prester John.) In the time of Marco Polo, Tibet, having been ravaged by the Monguls, was almost depopulated. For some time this country had been subject to secular kings, called Tien Pa; and the lama resided at Laffa, with a power resembling that of the spiritual prince of Japan. According to Giorgi, the consecration of kings and lamas commences about 1340 years B.C. but about 1100 years after Chrift the Chinee emperor gave to a celebrated lama the regal power. These Monguls, called Elet, conquered the secular prince, and transferred the whole power to the lama. (See Du Halde, iv. 50.) In 1792, the Napoleons, having committed great ravages in Tibet, the Chinee emperor sent an army to protect the lama; in consequence of which the Chinee established military posts on the frontiers, so that the intercourse between their country and Bengal is now precluded. The revenues of the lama and of the secular princes are trifling; nor is it likely that Tibet can ever aspire to any political importance.

Some have said, that the religion of Tibet is a corrupted Chritianity; and even father Dienderli, a Jesuit, who visited the country about the beginning of the last century, thinks he can resolve all their mysteries into ours; and he afferts that they have a good notion of the Trinity, since, in their address to the Deity, they say as often kowick-oik in the plural, as kowiek in the singular, and with their explanations pronounce these words, Om, Ha, Hum. Of these whimsical conjectures we shall say no more, but pass on to observe, that the religion of the Tibetans seems to have derived its origin, says Turner, (ubi infra,) from a disciple of Budh, who first broached the doctrine which now prevails over the wide extent of Tartary. It is reported to have received its earliest admission
admission in that part of Tibet bordering upon India, (which
from hence became the seat of the sovereign lamas,) to have
traversed over Manchow Tartary, and to have been ulti-
mately diffeminated over China and Japan. Though it dif-
fers from the Hindu in many of its outward forms, yet it
still bears a very close affinity with the religion of Brahma in
many important particulars. The principal idol in the temples
of Tibet is Mahamoonie, the Budha of Bengal, who is
worshipped under the and various other epithets through-
out the great extent of Tartary, and among all the nations to
the eastward of the Berampooter. In the wide extended
space over which this faith prevails, the fame object of
veneration is acknowledged under numerous titles; among others,
he is styled Godam or Gowtama, in Affam and Ava; Sa-
manu, in Siam; Anida Buth, in Japan; Fobi, in China;
Budha and Shakamuna, in Bengal and Hindoostan; Dharma
Raja and Mahamoonie, in Bootan and Tibet. Durga and
Kali; Ganeif, the emblem of wildom; and Cartikcâh, with
his numerous heads and arms, as well as many other deities of
the Hindu mythology, have also a place in their affemblage
of gods.
The fame places of popular esteem or religious refor,
are equally respected in Tibet and in Bengal; Prâaç, Calhi,
Durgeedon, Sâugar, and Jagarnaut, are objects of devout pil-
grimage; and loads of the sacred water taken from the Ganges,
have been seen travelling over these mountains, (which, by the
bye, contribute largely to its increafe,) upon the shoulders of
men, whom enthuilats have deemed it worth their while to
hire at a considerable expense for fo pious a purpoze.
As far as can be judged respecting their ritual or ce-
monial worship, it differs materially from the Hindu.
The Tibetians affemble in chapels, and unite together in
prodigious numbers, to perform their religious service, which
they chant in alternate recitative and chorus, accompanied by
an extensive band of loud and powerful instruments. So that,
whenever these congregations were heard, they forcibly re-
called to remembrance, both the solemnity and found of the
Roman Catholic mafs.
The instruments made use of were all of an enormous size.
Trumpets above fix feet long; drums stretched over a cop-
per cauldron, such as are termed novabut in Hindoostan; the
gong, a circular Chinese instrumt of thin hammered bell-
metal, capable of producing a surprifing sound; cymbals,
lautboys; and a double drum, shallow, but of great circum-
ference, mounted upon a tall, slender pedetall, which the
performer turns with great facility, striking either fide with
a long curved iron, as the piece requires a higher or a lower
note: these, together with the human tibia, and fcea-conch, a
large species of the buccinum, compofe, for the most part,
their religious band. Harfii as these instrumts, individually
taken, might found to a musical ear, yet when joined toget-
er in union with the voices of two or three hundred boys
and men, managed with varying modulation, from the loweft
and fowteft cadence to the loudeft swell, they produce to the
ear an effect extremely grand.
Other musical instrumts are in the hands of the people
of Tibet.
Among the Tibetians, says Mr. Turner, all is fyllem and
order. The mind readily obeys the superiority it has been
acquainted to acknowledge. A sovereign lama, immaculate,
immortail, omniprefent, and omnifcient, is placed at the fun-
mitt of their fabric. He is esteemed the vicegerent of the
only God, the mediator between mortals and the supreme.
They view him only in the most amiable light, as per-
petually absorbed in religious duty; and, when called to be-
low attention on mortal beings, as employed only in the be-
ign office of diatributing comfort and consolation by his
blessing, and in exercising the firit of all attributes, forgiver-
nels and mercy. He is also the centre of all civil govern-
ment, which derives from his authority all its influence and
power. At the fame time that he is the soul which animates
their whole fyllem, a regular gradation, from the moft ven-
nerated lama, through the whole order of Gylongs to the
young novicate, is observed with rigid ferverity.
The inferior gradations from the prefident of a monaftery,
who is always ifyled lama, in addition to the name of the
fitation to which he belongs, are Gylong, Tobba, and
Tuppa. See GYLONG, TEOHO-LOOMBOO, TOHBA, and
TUPPA.
The nation is divided into two distinct and separate claffes,
thofe who carry on the businefs of the world, and thofe who
hold intercourfe with heaven. No influence of the lafter
ever interrupts the regulated duties of the clergy. The
latter, by mutual compaét, take charge of all their spiritual
concerns; and the former, by their labours enrich and pop-
ulate the flat.
In Tibet there are two fects, distinguished by the appella-
tions of Gylloopka and Shammar, but the external appear-
ance, or drefs of both, is fimilar, except the diftinction
in the colour of the cap; the Gylloopka having adopted
yellow, the Shammar red; a circumstance which is
ftrictly attended to, on all occafions of ceremony. Three
lamas are placed at the head of each fect; Dalai lama,
Tefhoo lama, and Taranatu lama, prefide over the Gyl-
loopka, who have their refidence at Pootahal, Tefho-
loomboo, and Kharka. This fect prevails over the greatest
part of Tibet, and a division of the fame is faid to be esta-
blifhed in a province of the Decan, called Seurra or Serrora.
In like manner, three lamas also, lam' Rimbochay, lam'
Sobroo Nawangnamghi, and lam' Ghaffartoo, prefide over the
Shammar; these have their refidence in Bootan, in separate
monaftries, but, from the limited extent of that country,
at no great distance from each other. The principal of the
Shammar fect in Tibet is ifyled Gongfo Rimbochay, and
has his refidence at Sakia.
The Tibetians are actuated by an ardent spirit of devo-
tion; and they attribute the merit of every thing great,
or singularly beneficial, to the agency of some supernatural
being. It is the cuftom in Tibet to preferve entire the
mortal remains of their sovereign Lama only; every other
corps is either confumed by fire, or given to the promif-
cious food of beasts and birds of prey. As soon as life has
left the body of the Lama, it is placed upright, fittin
in an attitude of devotion, the legs being folded before him,
with the infep reaching upon each thigh, and the foles of
the feet turned upwards. It is the practice here to cover
the bodies of men, found dead in the fields, with cloths of
earth, which the rains gradually diffolve and incorporate,
forming the loofe mafs into a compact hillock. This
always attracts the fame refpect, and passengers continue to
add to the heap, long after all traces of the body are,lolft,
and its exiftence forgotten. Thus also the piety of the
Tibetians offers a fimilar rite to the bodies of thofe
whom chance may have led to the fpot, where the fragmen-
lay at the infant of its fall, though the fatal effects of it
may not have been certainly known.
A tribute of refpect is paid, in this region, to the manes
of the dead in various ways. The sovereign lamas are devo-
fited entire, in shrines prepared for their remains, which
ever after are looked upon as sacred, and visited with reli-
gious awe. The bodies of inferior lamas are usufally burnt,
and their ashes preferred with great care in little metallic
idols, which have places affigned them in their facred
ofbines. Common fubjects are treated with left cere-
mony;
fome have been incorruptible; but conformable to the usual declaration. This last, but less frequent, mode of disposing of the dead, is committing them to the waters of the river. Burial, that is, inhuming the corpse entire in the earth, is altogether unpractised.

On one side of this monastery of Tshul-po Loomboo is the place to which they convey their dead. It is a spacious area, enclosed on one part by a perpendicular rock, and on the others by lofty walls, raised probably with a view to exclude, from public observation, the disgustful objects contained within. At the top it was totally uncovered, so as to be perfectly open to the birds; and at the bottom a narrow passage was left through the walls, near their foundation, for the sole purpose of admitting dogs, or other beasts of prey. On the rock above, a platform overhung the inclosure, which had been contrived for the convenience of precipitating the dead bodies with greater ease, over the walls, into the area. And here, the only rites performed, in honour of the dead, were merely such as tended to facilitate the destruction of the body by dogs or birds of prey. But though this was the general receptacle, yet there were fome who declined the use of it, and conveyed their friends to the summit of some neighbouring hill, where they disjoined and mangled the dead body, that it might become a more easy prey to carnivorous birds. Hence it was concluded that there was a strong prejudice in their minds of some idea of pollution attached to "being given to the dogs," which was sufficient to create a preference of the contrary practice.

In Tibet, as well as in Bengal, an annual festival is kept in honour of the dead.

The Tibetans are much addicted to superstition; and accordingly they lay great stress on lucky and unlucky days. They also pay great respect to the professors of astrology. Hence we find no prudent traveller ever attempting to undertake a journey, without previously appealing to this authority, and endeavouring to obtain an auspicious preface. The fame signal of favour is deemed indispensably requisite in every important enterprise, and the fame wary circumlocution enters equally into all the more minute concerns of domestic life. The union of the sexes, and the giving names to infants, are neither of them events to be accomplished without a regular appeal to the fame decisive oracle. This science is also regarded in the contruction of their almanacs. Their year, which is lunar, consists of 12 months, each month having 29 days; and the days are reckoned from the appearance of the new moon, in regular succession, till it shews itself again. The parts of the days are, evening, night, morning, and noon; and their computation of time is conformable to the general practice of the East, by a cycle of 12 years. The art of printing is said to have been very anciently practised in Tibet; but it has hitherto been principally appropriated to sacred works, and to the service of learning and religion. Their books are printed with blocks of wood, on narrow slips of thin paper, fabricated from the fibrous root of a small shrub. The printed and written letters appropriated to works of learning and religion, are called "uchen"; and those of bufinses and correspondence are called "umin." The Gyangs, or priests, pass through a regular education. As for the language of Tibet, its origin is not satisfactorily ascertained. Du Halde reports, that it is the same with that spoken by the people of Sifan, on the frontiers of China; but as this province is sometimes included in Tibet, this information is vague and indeterminate. Their characters, says Sir William Jones, are apparently Indian, but their language has now the disadvantage of being written with more letters than are ever pronounced; for, although it was anciently Sanscrit and polysyllabic, it seems at present, from the influence of Chinese manners, to consist of monosyllables, to form which, with some regard to grammatical derivation, it has become necessary to suppress, in common discourse, many letters which we see in their books; and thus we are enabled to trace in their writings a number of Sanscrit words and phrases, which, in their spoken dialect, are quite undistinguishable.

A singular custom prevails in this country, which may be called polyandry. One female associates her fate and fortune with all the brethren of a family, without any restriction of age or of numbers. The choice of a wife is the privilege of the elder brother; and it is said, that a Tibetan wife is as jealous of her consanguineous, though thus joined to a numerous party of husbands, as the defpot of an Indian zemina is of the favours of his imprisoned fair. The bufinses of propagating the species is abandoned to mere plebeians; and marriage seems to be considered rather as an odium and a burden. The influence of this custom on the manners of the people is not found to be unfavourable. Humanity and gentleness of disposition are the concomitant inheritance of a Tibetan. Mr. Turner says that he never saw the quality polliated by any people in a more eminent degree. Without being very officious, they are always obliging; the higher ranks are unassuming; the inferior, respectul in their behaviour; nor are they at all deficient in attention to the female sex; but, as we find them moderate in all their passions in this respect, also their conduct is equally remote from rudenes and adulation. Comparatively with their southern neighbours, the women of Tibet enjoy an elevated station in society. To the privileges of unbounded liberty, the wife here adds the character of mistress of the family, and companion of her husbands. The company of all, indeed, he is not at all entertaining to expect. Different pursuits, either agricultural employment or mercantile speculation, may occasionally caufe the temporary absence of each; yet whatever be the result, the profit of the labourer flows into the common trea; and when he returns, whatever may have been his fortune, he is feer of a grateful welcome to a sociaal home. The men are generally stout, having in a degree the Tartar features, and the women are of a ruddy brown complexion, heightened like the fruits by the proximity of the sun, while the mountain breezes bestow health and vigour.

The ceremonies of marriage are neither tedious nor intri- cate in Tibet. Their courthips are carried on with little art, and quickly brought to a conclusion. The elder brother of a family, to whom the choice belongs, when en- couraged of a damsel, makes his proposal to the parents. If his suit is approved, and the offer accepted, the parents, with their daughter, repair to the tutor's house, where the male and female acquaintance of both parties meet and carouse for the space of three days, with music, dancing, and every kind of festivity. At the expiration of this time the marriage is complete.

Tibet is thinly peopled with inhabitants, on account of its mountainous surface and the severity of its climate; nor can any accurate estimate be made of its population. From some circumstances it has been conjectured, that upon the whole it cannot be less than half a million. Giorgi, indeed, or rather Pinzabilla, from whom he deduces his statement, computes the number of inhabitants in 1730 at 33 millions, and the soldiers at 690,000; but both these numbers are most extravagantly exaggerated; for Tibet has been
been often conquered by the Chinese with armies not exceeding 40,000 men. The singular custom of polyandry, already mentioned, seems adapted to check the progress of population, the superabundance of which, in an infertile country like Tibet, would be one of the greatest calamities, as it must produce internal warfare or internal want.

Bootan and Tibet exhibit a very remarkable contrast in their external appearance. Bootan presents to the view nothing but the most mis-shapen irregularities; mountains covered with eternal verdure, and rich with abundant forests of large and lofty trees. Almost every favourable aspect of them, coated with the smallest quantity of soil, is cleared and adapted to cultivation, by being shovelled into horizontal beds; not a slope or narrow slip of land between the ridges lies unimproved. There is scarcely a mountain, whose base is not washed by some rapid torrent, and many of the loftiest bear populous villages, amidst orchards and other plantations, on their summits and on their sides. It combines in its extent the most extravagant traits of rude nature and laborious art.

Tibet, on the other hand, strikes a traveller, at first sight, as one of the least favoured countries under heaven, and appears to be in a great measure incapable of culture. It exhibits only low rocky hills, without any visible vegetation, or extensive arid plains, both of the most stern and stubborn aspect, promising as little as they produce. Its climate is cold and bleak in the extreme, from the severe effects of which the inhabitants are obliged to seek refuge in sheltered valleys and hollows, or amidst the warmest aspects of the rocks. Yet perhaps Providence, in its impartial distribution of blessings, has bestowed on each country a tolerably equal share. The advantages that one poises in fertility, and in the richness of its forests and its fruits, are amply counterbalanced in the other by its multitudinous flocks and invaluable mines. As one seems to poise the pabulum of vegetable, in the other we find a superabundance of animal, life. The variety and quantity of wild fowl, game, and beasts of prey, flocks, droves, and herds in Tibet, are astonishing. In Bootan, except domestic creatures, nothing of the fort is seen. It has been asserted that Tibet was, in remote times, almost totally inundated; and the removal of the waters that covered its surface is ascribed to the miraculous interposition of some object of their worship, whose chief temple is reported to be at Dungceedin, Gya. In this traditionary belief we may possibly discover some traces of the universal deluge; though the tradition be obscured by fable and disfigured by a mixture of absurdity. In the temperature of the fowons in Tibet, a remarkable uniformity prevails, as well as in their periodical duration and return. The same division of them takes place here, as in the more southern region of Bengal. The spring is marked from March to May, by a variable atmosphere; heat, thunder-showers, and occasionally with refreshing showers. From June to September is the season of humidity, when heavy and continued rains fill the rivers to their brim, which run off from hence with rapidity, to aflift in inundating Bengal. From October to March, a clear and uniform sky succeeds, seldom obscured either by fogs or clouds. For three months of this seafon, a degree of cold is felt, far greater perhaps than is known to prevail in Europe. Its extreme severity is more particularly confined to the southern boundary of Tibet, near that elevated range of mountains which divides it from Affam, Bootan, and Nipal.15 The summits of these are covered all the year with snow, and their vicinity is remarkable, at all seafons, for the dryness of the winds. The range is confined between the twenty-sixth and twenty-seventh degrees of northern latitude. During the winter, a practice is adopted in the neighbourhood of these mountains, similar to that in use in the coldest parts of North America, but in some respects more complete. It is that of preparing meat and fish for carriage, by the action of extreme cold. This practice, however, seems to be confined to the preparation of mutton alone, which is a very simple process, and requiring no ufe of salt. The Tibetians generally use that which is recently killed in a raw state, without any previous cookery.

Among the valuable and useful animals of Tibet, which are musk-deer, hares of a small size, goats yielding the hair that is manufactured into shawls, and cattle that are diminutive, to which we may refer the yak of the Tartars, their breed of sheep claims a distinguished rank. Of thee the flocks are numerous, and upon them they chiefly depend for their winter food. A peculiar species, thought to be indigenous to this climate, is marked almost invariably by black heads and legs. Their fize is small, their wool is soft, and their flesh, says Mr. Turner, is the finest mutton in the world. The wool affords material for one of their principal manufactures. (See Lhansa-jeung.) Their skins and those of the lambs are cured with the wool on, and constitute a valuable article for winter garments, and for foreign traffic.

The soil and climate of Tibet are very unfavourable to any kind of exertion and activity that have for their object the cultivation of the land; but from time immemorial it has been the resort of merchants. Commerce, however, has been very languidly encouraged. The form of government, which is arbitrary, is inimical to industry and enterprise. In Tibet, and also in Bootan, the first member of the flate is the chief merchant; and his flation and power of controul give him great advantages over the common adventurer; and of course by this monopoly of the sovereign, emulation is restrained and suppreffed.

Although, as we have said, the nature of the foil prohibits agriculture; yet the vales on the approach of winter being laid under water, they are ploughed and sown in spring, and the crops are matured by frequent showers and a powerful sun. The autumn being clear and tranquil, the harvest is long left to dry on the ground; and when sufficiently hardened is trod out by cattle. The course of cultivation is wheat, peas, and barley; rice being confined to a more southern foil. Nevertheless, the country abounds with commodities, which in different circumstances would give spirit and extent to commercial transactions, whilst they are languishing in floth, or exhibiting every indication of poverty. The trade with Bengal was formerly not inconsiderable; but this has been interrupted and diminished by the communications which have long distracted the kingdom of Nipal, which was the only known channel of communication. Bengal transmitted to Tibet, broad cloth, chiefly of inferior quality and of yellow and scarlet colours; some few trinkets, such as snuff-boxes, smelling-bottles, knives, scissors, and optic-glares; and spices, particularly cloves and nutmegs; fandal wood, pearls, emeralds, sapphires, lapis lazuli, coral, jet, amber, shells, cloth, leather, tobacco, indigo, and otter-skins; and it received from Tibet, gold-dust, musk, and tincal. The articles of trade in next importance, amongst the natural productions of Tibet, are goats’ hair and rock-salt. Bootan, Nipal, Bengal, and Hindooftan, are supplied with tincal from Tibet. The hair of the goats is carried to Cashmire, where it is manufactured into shawls. The demand for full is in the consumption of Nipal and Bootan.

The trade from Tibet to Bootan consists of gold-dust, tea,
tea, woollen cloths, and felt; from Bootan to Tibet, the articles are English broad cloth, Rungpo leather, tobacco, coarse cotton cloths, &c. paper, rice, landal wood, indigo. Tibet sends to Ludclark, the mart between Cashmir and Teshoo-Loomboo, the fine hair of goats, and receives in return gamboge, shawls, dried fruits, as apricots, raisins, currants, dates, almonds, and saffron. Khambatik sends to Tibet, horses, dromedaries, and Balgar hides. In Tibet there are several mines of lead; and as lead-ore contains silver, it might be separated from it to great advantage, if the method of doing it were known. There are also mines of cinabar, which contains a great proportion of mercury, if the Tibetans knew how to extract it. The copper-mines furnish materials for the manufacture of idols, and all the ornaments dispofed about monasteries, on which gilding is bestowed, for which there is a great demand in Tibet.

A very small quantity of specie is current in Tibet, and that is of a base standard. It is the silver coin of Nepal, here denominated indermiller, and worth about one-third of a fice rupee; and it is cut into halves, third parts, and quarters. In all mercantile transactions, however, the equivalent is made in bullion, i.e. talents of gold and silver, valued in proportion to the purity and specific gravity of the metal.

The commerce between Tibet and China is carried on principally at a garrifon town, on the western frontier of China, named Sinning, or Silling: thither merchants resort from Tibet with their manufacture; viz. a thin cloth resembling friece, but rather of a more open texture, gold-dust, and some other commodities procured from Bengal; which they exchange for tea, silver bullion, brocades, and fruit. In these articles an extensive trade is carried on; and Mr. Turner has been assured that, on the territory of Teshoo-Loomboo alone, tea, to the amount of five or six lacs of rupees, is annually consumed. From hence, too, Bootan is supplied with tea, which is in the same general use there.

Tibet exports to China, gold-dust, diamonds, pearls, coral, mufk, woollen cloths of its own manufacture, lamb-skins and otter-skins, called eel, brought from Bengal; and China returns to Tibet, gold and silver brocades, plain silk, fatins, black tees of four or five different forts, tobacco, silver bullion, quicksilver, cinabar, china ware, trumpets, cymbals, and other musical instruments; furs, viz. fable, ermine, black fox; and dried fruits of various sorts.

The regulations for carrying on the commerce of the English East India Company through the dominions of Bootan, by means of the agency of native merchants, were settled by the treaty entered into by Mr. Bogle, in the year 1775.

The cities and towns of Tibet are little known; the capital is Laffa; which fee. Among the edifices, the monasteries occupy the first elats. (See Teshoo-Loomboo.) The chief river of Tibet is Barhampoar; which fee. The Hoon-ho and Kiu-ku of the Chinese also derive their origin from the eastern boundaries of Tibet. The great Japaneke river of Cambodia, or Maykaung of Laos, that of Nou Kia, suffused to pafs near Marytan, into the gulf of Pegu, and the Irawaddy of the east country, are suffused to have their sources from the mountains of Tibet, which may be ityled the Alps of Asia. Another large river, called the Sardjo or Gagra, which, after a course of about 600 miles, nearly parallel on the E. with that of the Ganges, joins it near Chupra, and derives its fpring from the lofty western mountains of Tibet. In these Alpine regions are many lakes, as such as Tarkiri, and Jamdro or Pelte; which fee.

The ranges of Tibetan mountains in the W. and S. seem to bend in the form of a crescent, from the sources of the Ganges to the frontiers of Assam, in a N.W. and S.E. direction. To the N. of Sampo a parallel and higher ridges seems to extend, the northern extremities abounding with large frozen lakes. The chief elevation of mountains appears to be central, S. of the lake Tarkiri, and is called Koirin, the western part being denominated Kantiel. The southern range presents many names of distinct mountains, comprehended under the Hindoo name of Himmela. From these ranges many branches extend N. and S. This country posseses many mineral waters, the salutar nature of which is not unknown to the natives. Among its natural curiosities we may reckon a singular rock, N. of Taffudon, described by Mr. Saunders in the Appendix to Turner's Travels, and forming in front of seven angular semi-pillars of large circumference, and some one hundred feet in height. This natural curiosity is partly detached from the mountains, and projects over a considerable fall of water, which heightens the picturesque appearance of the whole. The rock is laminated, and might be formed into slaty; and iron-frames are found in the vicinity, these pilasters probably, like those of bafals, arise from the influence of that metal.

TIBET or THIBET, Little, a district N.W. of Cashmir, which is supposed to contain the chief fource of the Indus. The itution of this country is doubtful; it probably lies on the N. and N.W. of Cashmir, and is divided from Great Tibet by a high mountainous ridge, and by a higher chain, that of Belur, from Great Bucharia. It is described as a very mountainous and poor country, pervaded by the Indus, and towards the N. full of forests. The capital is Afeardu, and further to the N. is Schekar, Temir-kand, or the fortrefs of iron, seems to command the paths between Great and Little Tibet; and the two Ganges of the Chinefe maps (supposed fources of the Ganges) are probably rivers which join the Indus from the Laff. Pinkerton.

The delineation of the country of the Sæcs, by Ptoley and Strabo, (see SÆCE.) will be found to correfpond, says Hugh Murray, eqq. in his Ancient Geography of Central and Eastern Asia, in every refpect, with that given by Mr. Elphimstone of the Plain of Pamera and Little Thibet. It was bounded on the S. by Hindoootan, from which it was separated by the ridge of Imaus. On the N. it was bounded by the next parallel chain, Monns Afeateenas, which cannot possibly be any other than the Mooz-Tangu, to whose name, indeed, it bears a rude refemblance. It extended E. from the Montes Comedorun, (the Boloo or Belur,) to some what beyond the head of the Ganges; precisely the dimensions of Little Tibet. Great and Little Thibet form a table land of extraordinary elevation, bordering on Hindooottan to the S.; and two parallel chains, running from E. to W., prop this mighty bulwark of Asia. The northern barrier is formed by an immense chain, known under the name of Hindoo Coofii, and Himmela or Himalaya, which forms the northern limit of India. The whole extent of it is covered, to a great depth, with perpetual snow; and every measurement yet made, from Pehaur to Nepal, has made it exceed 20,000 feet above the level of the plain, being higher than the highest peaks of the Andes. The whole is recognized by Ptoley under the name of Imaus. The northern range, known by the uncouth appellation of Mooz-Tangu, taugh being merely the generic name of mountain, or Karrakorum, Mr. H. Murray apprehends to be defcribed by him under the name of Monns Afeateenas. Its absolute elevation seems to exceed that of Himalaya, and yet from the high level of its base, it does not present formidable an aspect. At right angles

Vol. XXXV.
THICKEN, in Gardening, a sort of close plantations of trees and shrubs, in pleasure-grounds, parks, &c. They are designed for different purposes, as sometimes to repel the force of tempestuous and cold cutting winds, either from the habituation, or from particular part of the garden; or to form places of shade and retirement in summer, having spaces for walks, recollections, &c. under the shade of the trees, and occasionally to conceal from view any unattractive or disagreeable object, and also sometimes to form a screen or blind arranged towards some outward boundary.

They are sometimes planted wholly of the large tree kinds, five or six to eight or ten feet asunder, some in regular lines, like a close grove, or more generally in a sort of promiscuous planting, but with some degree of order in the distances: they are also often composed of various trees and shrubs together, to effect a more full, close growth below and above, and to display a greater diversity in the plantation, by disposing the various shrubs properly between the larger trees, in some order of gradation, the lowest towards the front, and the taller growths backward, so as to form a sort of underwood thickets below, while the trees run up and form a thicketty growth above; and sometimes they are formed wholly of shrubs of different sorts and degrees of growth, from the lowest placed forward, to the tallest behind.

They are sometimes, too, formed wholly of particular sorts of trees disposed separately in distinct plantations, as of elm, ash, beech, poplar, alder, willow, &c.

The planting of thicket plantations should be effected with young trees of four, five, or six, to eight or ten feet growth, and the shrubs kinds proportionally; in which of the planting may be performed in the common seasons of autumn, winter, and spring.

In the culture of thicket plantations, little is required but that of keeping them clear from large overbearing weeds, while the trees and shrubs are in young small growth.

Thickets are now much less in use than was formerly the case in ornamental gardening, and pleasure-ground planting; they may, however, on some occasions, be introduced with good effect.

THICKON, in Geography, a river of Pennsylvania, which runs into the Delaware, N. lat. 40° 25'. W. long. 75° 5'.

THICKSTUFF, a name for fided timber exceeding four inches in thicknefs, but not being more than twelve inches in thicknefs.

THIEBLEMONT, in Geography, a town of France, in the department of the Marne; 8 miles E.S.E. of Vitry le Franciz.

THIEL, or Tilt, a city or town of Holland, in the department of Guelderland, situated on the north side of the Wahal, in a small island called Tilt-Wser. In one of its faubous, called Santwyck; which is well fortified, is a strong citadel: the fortifications were destroyed in the year 1674, by the French, who had made themselves masters of the place about two years before, and have been since repaired. In the year 1528, it was besieged by the Spaniards, when Charles V. was at war with the duke of Gueldres; but they were compelled to raise the siege, through the brave resistance of the citizens. The country about it is marvishly, and the air reckoned unwhofome. The fortifications are destroyed; 18 miles N.N.E. of Bois-le-Duc.

THIELLE, a town of the county of Neufchâtel, between the lake of Bienne and the lake of Neufchâtel; 5 miles N.E. of Neufchâtel.—Alto, a river of Switzerland, which rises in the Vaudois, passes through the lakes of Neufchâtel and Bienne, and runs into the Aar, 3 miles below Buren.

THIELLEN, a town of Switzerland, in the canton of Uri; 2 miles N.W. of Altorf.

THIET, a town of France, in the department of the Lys; 10 miles N. of Courtray.

THIÈNE, a town of Italy, in the Vicentin; 9 miles N.W. of Vicenza.

THIERS, John Baptist, in Biography, a divine, was born at Chartres about the year 1636, and became a baihelor of the Sorbonne, professor in the college of Du Plessis at Paris, and cure of Chaupre, in the diocese of Chartres. Being arrested in consequence of a dispute with the clergy of Chartres, and a dispute against one of them, he escaped by a stratagem, and found refuge with the bishop of Mans, who gave him the cure of Vibraye, where he died in February, 1703. His works are numerous, freely written, and on singular subjects; but we refer for an account of them to Moreri, the Nouv. Dift. Hiftor. and Gen. Biog.

THIERS, in Geography, a town of France, and principal place of a district, in the department of the Puy-de-Dôme; here are manufacturies of cutlery, playing-cards, paper, thread, &c.; 21 miles S.E. of Gannat. N. lat. 45° 52'. E. long. 3° 38'.

THIERSHEIM, a town of Germany, in the principality of Culmbach; 6 miles N.E. of Wonfiedel.

THIERSTEN, a town of Germany, in the principality of Culmbach, on the Egger; 5 miles N.E. of Wonfiedel.

THIE-WEY-ARA-YETH LAKE, a lake of North America. N. lat. 61° 20'. W. long. 106° 30'.

THIGH, Femur, a part of the body of men, quadrupeds, and birds, between the leg and the trunk. See Extremities.

We have an account in the Philosophical Transactions of a large piece of a young man's thigh-bone being taken out, and the place so well supplied by a callus, that he walked straight. See No. 461. feh. 2.

THIGH-Bone, Fractured. See Fracture.

THIGH, Laxation of. See Laxation.

THIGH, in the Manage. The effect of the horfeman's thigh is one of the aids that serves to make a horfe work vigorously. See Aid.

Fore-thigh, or arm of a horfe, is that part of the fore-leg that runs between the shoulder and the knee: though the fore-thigh does not bend or bow, yet we commonly say, a horfe goes fine, that bends well the fore-thigh, importing by it, that he bends well his leg.

Horses should always be full and well made in the thick parts of the thigh, especially in horses of the working kinds.

THIGHT, in Agriculture, a term provincially applied to turnip, or other crops which are thick or closely set. It also signifies impervious, when applied to roots or veillons in some districts.

THILACHIUM, in Botany, so named by Loureiro, from
from above, a little bag, alluding to the form of the calyx. It ought rather therefore to have been *Thylachium*—Loureiro. Cochinch. 342.—Claws and order, *Polyandria Monogynia*. Nat. Ord. *Caparides*, Juff.

Eff. Ch. Calyx of one leaf, oblong, burbling all round. Corolla none. Berry flaked, with ten angles, one cell, and many seeds.

1. *Th. africanum*. African Pouch-flower.—Observed by Loureiro on the eastern coast of Africa, near Mozambique, where it is called by the Portuguese *Mangueiro*. The tree is small, with spreading branches. Leaves alternate, flaked, ovate, entire, smooth. Stalks terminal, bearing several flowers, whose long filaments are of a fawn colour. The author observes that this genus approaches *Capparis*, in its flaments and the flake of its berry, but differs widely in the unusual form of the calyx, as well as the want of a corolla, and the figure of the seed-coat. De Theis thinks it allied to *Marcgravia*, see that article. As far as it is related to *Capparis*, he is right; but between the corolla of *Marcgravia*, and the calyx of *Thylachium*, which he seems to have had in view, there can be no affinity; any more than between the latter and the pouch in the outer calyx of *Rhus*, which article the reader may likewise consult. We must be content to leave the matter as we find it, there being great probability, considering how little we know of the botany of its native country, that the plant, and even its genus, are entirely new to Europeans.

**THILAY**, in Geography, a town of France, in the department of the Ardennes; 7 miles N.E. of Charleville.

**THILCHATEL**, a town of France, in the department of the Cote d'Or; 14 miles N. of Dijon.

**THILCO**, or rather *Thilco*, in Botany. See *Fuschia*, n. 9.

**THILL**, in Rural Economy, the name of the framed shafts of carts and wagons, between which the horse draws and moves. The thills of these kinds of carriages should always, as much as possible, be made of tough ash-wood, and light in proportion to the nature and uses of them.

**THILL-HORSE**, the half-horse in a team, or the horse that goes between the thills or shafts; which often sustains much undue weight and pressure on the back, in consequence of the load which is drawn. This is capable of being relieved in various ways and by different contrivances, but the two which are noticed below would seem to be the most simple and easy. It is well known to be almost universally the practice to hook or attach the second horses, in cart or wagon teams, on at the end of the shafts. The consequence of which is obviously this: whenever the cart or carriage ascends a hill, and the fore part of the team comes to level ground, which not unfrequently happens, while the thill-horse or horses are still on the declivity, from their force being exerted in a right line to the ends of the shafts, all the powers of the whole of the leading horses must, in such cases, inevitably load and oppress the thill-horse or horses, when so directed, as they tend to depress the shafts, in their exertion to draw at the proper point of draught; that is, in the line with the axle. The thill-horse or horses are often seen, in such instances, nearly borne down, where the accents are steep, and the levels rather suddenly regained. The back, or backs, of such horses become a fort of fulcrum, on which the strength of all the preceding horses acts as a kind of lever; which, if sufficiently forcible, and the thill-horse or horses' backs were strong enough to bear the pressure, must lift the carriage off the ground, until it is come to a level with the line of their pull.

In order to remedy this great prejudice and inconvenience, it is advised that a looped iron, of about a foot in depth, in the whole, be fastened to the end of the shaft; nailing and riveting it firmly, by means of expanded flats. The looped part will then reach about eight or nine inches under or below the shafts. Each trace is to be carried through these loops instead of looking on there, and be fastened at the bottom of the shaft, near to where it hitches on to the frame of the carriage. This will give play to the traces, and wholly relieve the thill-horse or horses from the undue prejudice to which they are exposed.

The principle here laid down is necessary, whatever other method may be had recourse to in removing the inconvenience.

**THILYPTERIS**, in Botany, a term used by Dickianus to express the common female fern or brakes.

**THIMA**, in Geography. See *TIMA*.

**THIMBLE**, a cover for the finger, made of brass, steel, or silver, and used by all people who few, as taylors, milliners, &c.

**THIMBLE**, in Sea Language, an iron ring with a groove round the outside, to receive the rope it is spliced into. Thimbles are spliced into the rigging and falls for blocks to be hooked to, or ropes to receive through where blocks would appear too heavy.

**THIMBLE ISLANDS**, in Geography, small islands near the coast of Connecticut. N. lat. 41° 9'. W. long. 71° 42'.

**THIMBRIC-KENY**, a village of Atian Turkey, in the province of Natolia, on the site of an ancient town called "Thymbra," built by Dardonus, king of Phrygia. Here are some considerable ruins, superseded of a temple of Apollo.

**THIMDA**, a town of Tunis; 8 miles S.W. of Bizerta.

**THIMIO**, in the *Materia Medica*, a name used by some authors for a peculiar fort of lignum aloes, which is blackish and very heavy, and extremely sweet.

**THIN**, a name given by the Arabian writers to earth of any kind.

Thus the bole armenic of Galen is called by Avicenna *thin Armeni*; and hence the word *muthin*, an adjective signifying earthy, or approaching to the nature of earth; a term applied to many medicines of this kind.

**THINA**, in Botany, a name by some authors have called the larix, or larch-tree.
THINGVALLA, a place of Iceland, about 26 miles distant from Reikjavik, and 24 miles from Skalholt; in which is a small, mean, and dirty church. The scenery about it is romantic; but the want of wood, and the effects of subterraneous heat, combine to give it a dreary appearance. The adjoining lake of the same name is a fine sheet of water, reckoned to be about ten miles long and from three to seven in breadth. In the lakes are two pretty large islands, called Svaradal and Nefty, composed entirely of volcanic matter. The depth of the lake is said to be very great; a line of rocks having been sunk without reaching the bottom. It receives the waters of the surrounding bogs, and near it is a place of springs, where the courts of justice were formerly held; but as Reikjavik is now the seat of government, the courts are held there. It does not appear why this place was originally selected for the seat of justice; but a town being once established, and trade carried on freely, and to a greater extent than in former times, ready recourse to the law became necessary. Although not more than fifteen years have elapsed (1817) since the judicial courts were transferred to Reikjavik, few remains are left to mark a spot so famous in the history of Iceland. The only building is a small wooden house, in which the consultations were held and sentence pronounced by the ridditman or governor. The magistrates and people assembled on the occasion lived in tents. The culprits who were condemned to die were beheaded on a small island in the lake Oxeran, which here flows into the lake. The females were drowned in a deep pool below the lake, a little farther up the valley. An ecclesiastical court used to be held at Thingvalla by the bishop of Skalholt, attended by the provosts and two ministers from each Syffel. It is suggested, that Thingvalla in Shetland, and Dingwall in Ross-shire, are evidently the same names as Thingvalla; and were probably, in ancient times, places where justice was administered. Towards the N. are several ranges of mountains, which, from the account received, and the appearances observed, are volcanic. Among these, the principal seems to be Skalbraided, a lofty Jokul, of which description of mountains others were seen at a distance. Although the preference of the superior court from Thingvalla to Reikjavik has, probably, been attended with advantage, the Icelanders, as a people, have some reasons for regarding this change with regret. The annual meeting at Thingvalla was not merely that of a tribunal of justice, but an assembly of the nation; and though the importance of this assembly was diminished, and its dignity degraded, by the subjection of the island to a foreign power, yet on the spot where the greatest among his ancestors often flew, the mind of the Icelanders and all ever have been awake to enthusiasm and patriotic pride. Heic fero, hic genus, hic majorum multa vestigia!"—Mackenzie's Iceland.

THINKING, cogitation, a general name for any act or operation of the mind.

Chauvin, with the Carthians, will have thinking to consist in a certain native, inherent motion or agitation of the human mind, of which itself is conceptions.—Native and inherent, since he conceives it no other than the very essence of the mind itself, or, at least, its principal and fundamental property: an agitation, since there is a new modification or change made in the mind, which we fearely know how to conceive without motion; add, that the origin and etymology of the word cogitation, according to Varro and Feildus, implies as much: cogito being used for cogitis.

When the mind turns its view inwards, upon itself, the first idea that offers, says Mr. Locke, is thinking; in which it observes a great variety of modifications, and of them from itself distinct ideas; thus the perception annexed to any impression on the body, made by an external object, is called sensation.

When an idea recurs without the presence of the object, it is called remembrance.

When brought after by the mind, and brought again into view, it is called recollection.

When held long under attentive consideration, it is called contemplation.

When ideas float in the mind without regard or reflection, it is called a reverie; when they are taken express notice of, and, as it were, registered in the memory, it is attention; and when the mind fixes its view on any one idea, and considers it on all sides, it is fully and attention.

These are the most obvious modes of thinking; but there are several others which we know of; and, doubtless, the mind is capable of infinite others, of which we have no notion at all.

The school-philosophers usually divide thinking, with regard to the object it is employed about, into understanding, intellectus; and willing, voluntas.

And hence, those are said to be the two powers or faculties of the human mind.

Intellectual thinking is further subdivided into divers kinds; the first, when the mind merely apprehends or takes notice of a thing, called perception; the second, when it affirms or denies a thing, called judgment; the third, when it gathers or infers a thing from others given, called reasoning; the fourth, when the mind disperses its own thoughts or ideas in order, called method.

Volitive thinking, or volition, admits of infinite different modifications, or new determinations.

Some authors extend the idea of thinking farther; and consider it in God, angels, brutes, &c. whence results a new division of thinking, into divine, angelical, human, and animal or sensitifive.

But the two first we know little or nothing of: the third is that of which we have already been treating. As to the last, viz. animal or sensitivfe thought, it is defined to be, an action of the soul attending to an external object, affected by means of the animal spirits duly agitated in the brain, to excite an idea.

The Cartesians maintain, that thinking is essential to the human soul; and, consequently, that there is no time when the soul does not think: but this doctrine has been very vigorously attacked by Mr. Locke; who labours to shew, that in sleep, without dreaming, there is an entire cesseation of the modes of thinking.

I think, cogito, according to Des Cartes, is the first, and most certain, of all truths; from which, alone, we draw this consequence, therefore I am, or exist, sum.—One might also say, cognosco, ergo Draus el. I think, therefore there is a God. —Logic is defined, the art of thinking methodically.

THINNING of Plantations and Woods, in Agriculture. The practice of thinning plantations of trees and woods, so as to let the plants of them have more room as they advance in growth, is mostly an operation of considerable importance; as upon it, perhaps, more than upon any other point of the after-management in such cafes, depends the nature, quantity,
ty, and modification of the timber which is raised and produced.

Woods of the natural kinds, the seeds of which are sown by birds or the winds on soils and surfaces of very different descriptions and forms, rise and spring up at different times, and of very different degrees of thickness, strength, and vigour in themselves and their different parts; consequently it is easy to suppose, that those which are placed in favourable situations and circumstances, will quickly overtop the others; and if they do not wholly destroy, will at least weaken them in such a way as not to be affected or inconvenienced by them, until the strongest trees ultimately find ample and sufficient room for their growth. In this way, although nature may be slow in her operations, she effects her purpose in a very complete manner. Besides these observances, Mr. Loudon has noticed that artificial thinning is only alluring nature; and that hence even leaving natural woods to be thinned by time, would not be economical.

It is suggested with regard to artificial plantations, that in these the soil is equally cultivated, and the plants are put into the ground much about the same size, and at the same time, and that hence they of course rush up together all nearly of the same height, producing neither ornament nor timber; and none being produced so strong as to take the lead and destroy the rest, they grow in this manner until they are so crowded as to exclude air and moisture. At which period, unless affluence has been previously given by thinning, the whole of the plantation dies together, and is destroyed.

Where thinning is necessary in old natural woods, or such as have been planted, it should constantly be performed by degrees in a regular manner, well considering the state, qualities, and habits of the trees, as well as the nature of the soil on which they grow, the situation and exposure in which they are placed, and other familiar matters. The outside of them should commonly be left thinner than the other parts, and the trees on the richer parts of the land be more thinned than those on the other descriptions of it. The thinning of the fide shoots and branches of the trees should likewise, in some measure, accompany the other thinnings, and be performed in a suitable manner to their natures, states, and purposes for which they are intended.

It is, however, wholly the custom to thin them out at about seven years from the time of planting them, or that of their first growing up, and to repeat it every seven years afterwards. When the planting has been performed in the proportion of from six to eight hundred trees to the acre, they may be made to stand, in the first thinning, at about one tree to each rod of ground, or nine trees to eight rods. But in the second thinning, a rather larger proportion of trees should be taken out, as rather more than one to each rod; and in the third thinning, the proportion may be made still in a larger ratio, so as to leave the trees about a rod square each. Much must, however, always depend upon the nature, situation, and circumstances of the particular plantations and woods.

In all these thinnings the worst trees should be removed, so as to leave the strongest and best plants to stand for timber or other purposes.

It is suggested, that as in most plantations the fir tribe of trees has been introduced either for the purpose of ornament or shelter; where thinning is practised, in such cafes, too large a proportion of these firs are molotly left. Hence, from their comparatively quick growth, it is concluded that such plantations have a disagreeable sameness through-
The town, they should always be thinned out to the distance of a foot and a half, two feet or more, as the soil may be of a light or more rich quality. And lettuces, when put in by trowel, should be thinned to the distance of from eight to twelve inches, according to the nature of the soil.

The thinning out of any other sorts of field-crops of these kinds must also be performed according to their natures and particular habits of growth.

Some of these sorts of crops are best thinned out in a gradual manner, as the turnip, carrot, beet, &c.; while in others it may be done all at once, as for the cabbage, and some other kinds.

There are several different methods practised in accomplishing this business, as by means of the hand simply, the use of the hand-hoe of different suitable sizes, according to the stature and circumstances of the crops, and lately in the raw kinds, by an implement invented for the purpose. This last is by much the cheapest and most expeditious manner of performing the work; if it should be found, on further trial, to be equally accurate and effectual in the execution of the business. This fort of tool or machinery was invented and constructed on the farm of Charles Gibbon, esq. at Quarner Park, near Lancaster, and a representation of it is given in the Corrected Agricultural Survey of that county, lately published. See Thinning and Hoeing Machine for Turnips, &c.

The other modes of effecting and completing this kind of work, are a great deal more troublesome, laborious, and expensive than the above, especially the first of them, as many hands and much time are required for doing it in the most proper and effectual manner by such means. Where the hand-hoe is employed, two or three different sized hoes are mostly made use of for the purpose in the different successive thinning hoeings, which, when in the hands of experienced workmen, do the business in a pretty quick, easy, and complete manner, as the supernumerary plants are struck and cut out with such exactness and regularity. It is consequently necessary in such cases to keep the hoes in a pretty sharp state, in order to perform the work well, and with neatness. The principal objections to doing this sort of labour by the hand, are its tediousness, and the treading which takes place during the operation.

Thinning out Plants, in Gardening, the pulling or drawing out such as are too close and thick in some crops of the general and other kinds, as well as in some other crops, so as that the remaining ones may stand at proper and suitable distances for producing the most favourable crops, plants, or other productions. This is mostly practised in the cases of the main crops of onions, carrots, parsnips, beets, spinach, and several other similar kinds, which are grown in the broad-cast manner; in different small feed crops, for raising plants to be afterwards set out, such, for instance, as the cauliflower, broccoli, cabbage, bokchoy, lettuce, endive, and many others; and in the producing and bringing forward young tree plants of mott forts in nursery grounds and other places.

Onion crops are, for the most part, thinned out at different times, as the demands of the markets, or in other ways may be, so as to leave the remaining plants at the distances of six or six inches or more from each other, according to their natures, kinds, and other circumstances; always, however, allowing sufficient room for their full and complete growths. Much advantage is often made in this way by the young onions which are thinned out, which would otherwise be lost and thrown away.

The carrot, parsnip, and beet crops are commonly thinned out at one or two thinnings, the standing plants being left at the distances of about six or eight inches apart, as the nature of the soil and crops may be. The young plants of the carrot kind, thus drawn, are in some cases bunched and made use of, especially when the crops are late in being thinned out, which should always be avoided as much as possible.

Lettuce and spinach crops may be thinned out at once to the distances of six, eight, or more inches between the plants, in the different kinds, as the nature of them may be, when put in upon the broad-cast plan. The thinnings are of little use or value, except for wattle purposes, such as being thrown to the hogs, &c. in these instances. Most other similar sorts of crops may be thinned out in the same manner.

The small feed crops of the different kinds should constantly be kept so thinned out as to prevent the plants of them from being drawn up in a weak manner, and unfit for being set out; as where the contrary is the case, there is always great wattle, and the plants seldom succeed so well. They should be gradually thinned out by planting, as well as in other ways.

Young tree plants, in mott crops, require frequently thinning out in their early growths, in order to raise and bring them forward in the best and most perfect manner. They should therefore, in general, be so kept thinned out as never to want sufficient room for rising in the manner which is the most natural and proper for them, and for preventing the injury they may suffer by standing too close in the rows or other ways.

Due, early, and proper thinning out of crops and plants, is of course a matter of considerable importance and utility in the garden culture of different sorts of vegetables, trees, and other productions of the same kinds.

Thinning and Hoeing Machine for Turnips, that sort of implement or machine which is contrived for the purpose of thinning or setting out this as well as other similar kinds of crops that stand in rows. It is made light, and constructed somewhat in the form of the plough, having a suitable apparatus attached to it behind as to be put in motion, and strike out the supernumerary plants as the horse proceeds regularly along the intervals of the ridges. The horse is driven by the person who holds and directs the tool while at work. It is capable of going over a very considerable space of ground in a short time, and if found, on the result of further trials, to perform the work with due accuracy and correctness, will be a very great acquisition to the drill turnip husbandry, and for different other purposes of the same nature.

THIONVILLE, in Geography, a town of France, and principal place of a district, in the department of the Moselle. The place contains 5014, and the canton 13,988 inhabitants, on a territory of 175 kilometres, in 27 communes; formerly belonging to the duchy of Luxembourg, and ceded to France by the treaty of the Pyrenees in 1659. N. lat. 49° 21'. E. long. 6° 15'.

THIORSAA, a large turbid river of Iceland, on the road from Skalholt to mount Helta, the course of which is nearly from N.E. to S.W. In its passage over rugged masses of lava rising abruptly from its bed, this river dalls among the rocks, and forms impetuous rapids and falls.

THIR, in Chronology, the name of the fifth month of the Ethiopians, which corresponds, according to Ludolf, to the month of January.

THIRD, TERTIUS. See Number and Numeration.

Third, in Music. The 3d is the most agreeable and necessary
necessary concord in counterpoint, throughout the whole system of practical harmony.

There are two kinds of thirds; the major or sharp 3d, which is four semitones or half notes above the base; and the minor or flat 3d, which is three.

Very agreeable music in two parts may be composed, and often is composed, of thirds only. The 3d is wanted with every other concord, and even discord, except the 4th, when it is used as such with the 2d instead of the 9th.

Dr. Pepusch, in his "Treatise on Harmony," has given curious and ample instructions for the use of thirds in composition.

It would be a curious inquiry, why a 3d was regarded by the ancients as a discord; and why it is called by the moderns an imperfection. We cannot afford space for long disquisitions on every subject of vain and frivolous curiosity, among which this would probably be numbered. But it seems as if the ancients estimated the perfection of consonances by the simplicity of ratios in the division of the monochord; regarding the octave as the most perfect concord next to the unison, as it was produced by a simple division of a string into halves, expressed by

\[ \frac{2}{2} \]

The next in perfection was the 5th, produced by a third part of a string.

After this, the 4th, which was reckoned by the ancients not only a concord, but a perfect concord, expressed by the ratio of

\[ \frac{3}{2} \]

A fourth part of a string gives the 15th, or double octave.

The fifth part of a string produces the major 3d to the 15th, which, though in the organ the flop called the tierce, it is a major 17th to the diapason; its ratio is expressed by

\[ \frac{5}{4} \]

The minor 3d is expressed by

\[ \frac{5}{3} \]

The major 6th, composed of four tones and a semitone major, as \( G \): its ratio is

\[ \frac{5}{2} \]

The minor 6th, composed of three tones and two major semitones, as \( C \): its ratio is

\[ \frac{5}{3} \]

The extreme sharp, or, as the French call it, the superficial 6th, composed of four tones, a semitone major, and a semitone minor, as \( G \# \): the ratio of this 6th is

\[ \frac{72}{2} \]

We believe that the triple progression of a series of perfect 5ths made the major 3ds so extremely harsh, that no natural good ear could admit them among the concords. And in the first attempts at counterpoint, it was a long time before a 3d was admitted in discant, in which diatessaronar and quintonar, or a diatonic series of 4ths and 5ths, now prohibited, was preferred to 3ds and 6ths in succession.

Third Borough, in our Ancient Law-Books, denotes a confable.

Third Earings, in Haddingly, the tilling or ploughing of the ground a third time.

Third Fiddle. See Estate, Commons, &c.

Third Night-and-hyd. By the laws of Edward the Confessor, a guest, who had lain three nights in an inn, was reputed a domestic, and his host was answerable for what offence he should commit.

For one night he was accounted uncouth; for two nights, guest; and the third, night-and-hyd, or hogen-hyde. "Prima nocte incognitus, secunda hostes, tertia domesticus centuror."

Third Order, a sort of religious order, that observes the

fame rule, and the fame manner of life, in proportion as some other two orders instituted before.

The third orders are not originally religious orders, but associations of secular, and even married persons, who conform, as far as their condition will allow them, to the design, intention, and rules of a religious order, which associates and directs them.

The Premonstrates, Carmelites, Augustinians, and Francisians, dispute among themselves the honour of having first introduced third orders; but the pretensions of the last appear to be the boldest.

The first contend, that the third order of Premonstrates began in the life-time of their founder St. Norbert, who died in 1134.

F. Diego de Coria Maldonado, a Spanish Carmelite, who has a particular treatise on the third order of Carmelites, derives them immediately, as well as the Carmelites themselves, from the prophet Elijah.

The third order of Augustinians, if we credit F. Bruno, was instituted by St. Augustin himself; but the arguments he produces are so frivolous, that F. Helyot observes, they are not worth refuting.

The third order of Francisians was instituted by St. Francis in 1221, in favour of people of both sexes; who being convened with the preaching of that saint, demanded of him an easy manner of living a Christian life; upon which he gave them a rule, the constitutions of which are not now extant, as written by himself, but only as reduced and confirmed by pope Nicholas IV. sixty-eight years afterwards.

The first order of this faint are the monks called Minor Friars, comprehending the Cordeliers, Capuchins, and Recollets; the second comprehends the nuns of St. Clare; and the third, several orders of both sexes, who live at liberty: and these are what we call the third order. See Francisians, &c.

Of this order, which was only established for secular persons, several of both sexes, to attain the greater perfection, have afterwards commenced religious, and formed various congregations, under various names; as Religious Penitents of the Third Order, &c.

Third Point, or Tierce-point, in Architecture, the point of section in the vertex of an equilateral triangle.

Arches or vaults of the third point, called by the Italians tierzo acuto, are those confiting of two arcs of a circle meeting in an angle at top. See Arch.

Third Point, in Perspective. See Point.

Third Rate. See Rate.

Third Subsidy Duty. See Duty.

Third Year, Tithe of the. See Tithe.

THIRDENDALE, a liquid measure used at Salisbury, containing three pints.

THIRDINGS, the third year of the corn or grain growing on the ground at the tenant's death, due to the lord for an heriot, within the manor of Turfat, in Herefordshire.

THIRLAGE, or Thirlage to Mills, in Rural Economy, a contract or power authorized by law, to prevent the tenants of certain districts from carrying their corn to be ground any where else than at a particular mill. It was a practice which formerly prevailed much; and it was too often used as an engine of oppression, that proved extremely galling to those who were obliged to submit to it, but which at present is nearly, if not wholly done away, except in certain places.

The account of the origin and nature of this oppressive practice,
THIRLAGE.

It is stated that this species of thirlage existed in most of the boroughs of the above country; and that the mill generally belongs to the incorporation, where the borough holds directly of the crown, or what are called royal boroughs. But where a borough holds of a subject superior (the lord of the manor), the mill generally belongs to the superior, and the accustomed duties are paid to him, or to his tenant in the mill.

It is to be observed, the writer says, that in all these thirlages, it was the land of the fervient tenement that was bound; and that although it should pass by purchase through twenty different hands, every purchaser, and all his people upon these lands, were equally bound to frequent the dominant mill.

It is further noticed, that there were also three different species of duties paid at the dominant mill; as, first, the muture (mutura, grinding); secondly, the bannock (loaf); and, thirdly, the knaveship.

It is remarked, that the first of these duties belonged to the heritor and proprietor of the mill; and seems evidently to have been the fine or prenium, originally settled, as the inducement for his being at the expense of erecting the mill, and for supporting the machinery of it in future. The bannock was the duty paid to the miller; and the knaveship the duty paid to the under servants in the mill.

It is stated, that the quantity of meal paid under the name of muture, varied considerably in different counties, and even at different mills. It has been known as high as the eleventh boll, and sometimes as low as the twenty-second boll; and in one particular instance so small as the thirty-second: but it may be taken, on the average, at nearly the seventeenth boll.

The other duties were also various; but they may, it is supposed, be taken jointly as equal to the half, or from that to three-fourths of the muture.

But wholly independent of these several duties, the poffessors of the fervient tenement were, it is said, bound to perform certain personal services to the mill and its appendages: for instance, when the dam-dyke, or the rampart that directs the stream of water from the river to the mill wanted repair, or when the aqueducts to and from the mill required to be secured, the people of the servient tenement must turn out and perform these works. When the roof of the house in which the mill flood decayed, they must find thatch for making that repair, and they must put it on.

When grind-flones were wanted, or an axle, or any other part of the machinery that required a heavy carriage, they must go with their horses and carriage to the nearest place (whatever might be the distance) to bring these articles to the mill.

But this species of thirlage, it is believed, never was known in the above county; or that at least, if it was, it has long since been forgot. Besides, it is noticed, that there was another circumstance peculiarly fortunate, which put it in the power of most of the landed proprietors of that county, without difficulty, to emancipate their tenants from the thirlage even of grindable grain, namely, that the landlord almost universally was proprietor both of the dominant and servient tenement; and that as he afflicted his tenants to his own mill by a covenant in the lease, progressively as the leases of the mills expired, the landlords in general emancipated their tenants from every species of thirlage, at a conversion of twenty shillings per plough, which was paid by the tenant; and he and his servants were left at perfect freedom to retort to any mill, where they could get their work best done, and at the lowest rate.

The cafe, however, it is remarked, was widely different in practice, which has been given by the author of the original Agricultural Survey of East Lothian, in the latter district of country, may not be uninteresting to the curious inquirer. It is remarked, that in former times, corn was reduced into meal, at ancient Rome, by a hand mill, which was called a quern; and which was used in the more remote parts of the Highlands of Scotland long after the year 1445.

It is certain, however, that the water machine called the mill, for the grinding of corn into meal, is of high antiquity in the same country; and as it was introduced before the period of record, it may be fairly said "caput inter nubila condit." But from the ancient name of one of the duties, knaveship, which will be afterwards explained, the mill would seem to be of Saxon origin.

It seems also natural, that a person who pollished a stream of water upon his estate, should be invited by his neighbours to be at the expense of erecting a mill upon this stream; and that they, on the other hand, should thirds, that is, affrict and bind their lands, in all time coming, to use and frequent this mill with their corn, and to pay a certain proportion of the meal according to the universal mode then practiced of paying in kind for the grinding of it.

Anciently, it is contended, there is reason to believe, the mills were at first erected upon ecclesiastical lands, and belonged to the clergy.

It is stated, that there are three different species of this sort of servitude known and acknowledged in the law of the above country; but of these, two only belong properly to rural economy; however, in order more thoroughly to understand the subject, the whole may be shortly explained.

It is noticed, that the first and the lightest species of thirlage, is called the thirlage of grindable corn. By this covenant of thirlage, it is stated, that every ounce of corn produced upon the servient lands, let the quantity be ever so great, must be brought to the dominant mill, and there manufactured into meal, and the covenantor or accustomed duties paid.

It is suggested, that the only limitation that this severe thirlage admitted of, was in favour of feed and of horse corn.

Sometimes a special covenant was made, by which the poffessors of the servient lands paid what was called dry muture; that is, they paid a quantity of corn to purchase the freedom of going to market with the remainder in the future state; and where confluent immemorial use has functioned, this custom, the courts of law generally, it is said, have for a long time mitigated the severity of this species of thirlage, as to find, that the proprietor of the dominant mill can demand no more than that quantity of dry muture, which the immemorial use has established. Such decisions are affected to be grounded upon the principle of a preformed contract, of which the record or memory has been lost betwixt these parties, whereby the one was bound to pay, and the other to receive, the commutation fixed by the usage.

The third and last species of thirlage's, it is observed, called the thirlage of in erva et ilato, and belongs properly to urban tenements; the meaning of it is, that corn, whenever produced, if brought for consumption within the boundaries of the dominant mill, must be carried to the mill and manufactured there, and pay the accustomed duties.
THI

in many parts of the north of the above country: and it is known, from what has already been mentioned, that there were many estates, or servient tenements, belonging to one proprietor, which were affixed to mills, or the dominant tenements, belonging to another proprietor, and that not a few of these thirlages were the severe one of growing corns.

The writer does not think it here necessary to inquire whether these mills were originally erected by the clergy, and since the reformation in religion, have passed into the hands of laymen; or whether, perhaps, if mills are truly of Saxon origin, they were generally, and at once introduced into the above country, when under the Saxons, who certainly were, it is thought, a more enlightened people than the Scottish and Pictish inhabitants of the North, whole ignorance, of course, may have led them more generally to subject themselves in the servitude of thirlage, to invite their clergy, or a few of the more wealthy among them, to undertake the arduous task of erecting mills.

From the near analogy betwixt tithes and thirlage, it has appeared to the writer a matter of just suprize, that the parliament of the above country, which, in the course of a preceding century, first authorized the valuing of tithes for the purpose of fixing a modulus of payment, and afterwards compelled the lay titulaires (proprietors) to sell their tithes at nine, and in some cases at six years' purchase, to the proprietors of the lands, did not introduce a fixed modulus for thirlage, which certainly operated like tithes, as a tax upon industry, to bar, or at least to retard agricultural improvement in its progress. See Tithes.

THIRLBY, SYAN, LL.D. in Biography, a learned critic, was born about the year 1692 at Leicetser, and finished his education at Jesus college, Cambridge, blending promising talents with self-conceit, litigiousness of temper, and a habit of intemperance. He appeared at an early age as a writer of controversial pamphlets, and thus acquiring some degree of reputation, obtained the fellowship of his college at the age of about 21 years. In mature life he probably applied to study with greater diligence, for his edition of Justin Martyr, to which he was indebted for literary reputation, was published in 1722. Verstife in his disposition, he diverted his attention at this time from divinity to physic, and accepted the post of librarian to the duke of Chandos. In this station he continued for a short time, and being under a necessity of quitting it, he became a subscriber in civil law, and afterwards in common law. Weary of these pursuits, he resided in the house of his former pupil, Sir Edward Walpole, by whose interest he obtained a free place in the port of London, of the value of about 100l. a-year. Upon leaving this asylum, he took private lodgings; but continued to indulge his habit of gaming and intoxication. He is said to have contributed some notes to Theobald's edition of Shakspeare; but his self-indulgence and indolence rendered him unfit for mental exertion, and he closed his career in December 1753. His edition of Justin Martyr, cenured by some, but regarded upon the whole as a valuable performance, contains Justin's two apologies, and his dialogue with Tryphon the Jew, Greek and Latin, with notes and emendations by the editor, and select notes by former editors. Nichols's Lit. Ancrd. Gen. Biog.

THIRLWAL CASTLE, in Geography, a boundary fortress between England and Scotland, on the Piets' Wall; 3 miles N.W. of Haltmefel.

THIRONE de Gardais, a town of France, in the department of the Eure and Loire, 21 miles S.W. of Chartres.

Vol. XXXV.

THIRSK, or Thrusk, a borough and market-town in the wapentake of Bridorth, North Riding of the county of York, England; is 23 miles N.W. by N. from the city of York, and 223 miles N.N.W. from London. It is situated in a plain, nearly surrounded by hills, on the banks of a rivulet called Cod-heck, which divides the town into two parts, respectively named the Old Town and the New, which are connected by two small stone bridges. The two towns are distinct, as far as relates to the election of members; but in all other respects are considered as one. The civil government is vested in a bailiff, annually chosen by the burgage holders. The New Town stands within the precincts of the ancient castle of the Mowbrays. In the centre of the town is the market-place; which would be one of the finest in the county, were it not for the tolbooth and shambles, now in a ruinous condition. The market is held on Mondays, and is well supplied with all kinds of provisions. Five fairs are held annually for horned cattle, sheep, leather, and woollen cloth. These fairs attract a considerable number of dealers, and, with the advantage of the great North road from York, are very beneficial to the town, and in some degree supply the want of manufactures, of which there are only a small quantity of coarse linens and facking, and a few bridles and saddles. The population, as returned to parliament in the year 1811, consisted of 2155 persons, occupying 549 houses. The parish church stands on a rising ground at the northern extremity of the town. The roof, which is elliptical, and of oak, ornamented with carving, is supported by a double row of pillars and pointed arches. In the south wall of the chancel, near the altar, are three ornamented stone seats. The church is generally supposed to have been built out of the ruins of the ancient castle, which was demolished in the reign of Henry II. A moat and rampart are still to be seen, but no vestige of the building remains; and in Camden's time, it was nearly in the same state. It had once, however, been a place of great strength, when held by the potent Mowbray family. It was here that Roger de Mowbray began his rebellion against Henry II. and joined the king of Scotland against his own sovereign. The revolt was suppressed, and the castle of Thirsk, as well as several others belonging to the rebellious lords, were by the king's order destroyed. Besides the parish church, the Calvinists, the Quakers, and the Methodists, have their respective meeting-houses. Here is also a School of Industry for poor girls, who are clothed and taught reading, writing, and arithmetic, plain work, knitting, &c.

That division of the town called Old Thirsk, is a borough by prescription, and returns two members to parliament. The right of election is in the occupiers of burgage tenements, now only fifty in number, of which forty-nine are the property of Sir Thomas Frankland, bart. Old Thirsk consists of a range of cottages on each side of the turnpike road leading from York to Stockton, and of two squares surrounded by the same kind of buildings. In one of these squares, called St. James's Green, the cattle fairs are held; the other is the steeple of an ancient church, of which, time has long since swept away every vestige. In the latter of these squares is an elm-tree of venerable antiquity, from which the place takes its name, Hawm (that is Elm) Green; and under the shade of whose branches the members of parliament are elected. One of the chief inconveniences of Thirsk and the adjacent country, is the scarcity and high price of coal, which is brought from the county of Durham in small carts, containing from eighteen to twenty-two bushels, varying in price according to the season.

In the vicinity of the town is Byland abbey, which was founded
banded in the year 1177, by Roger de Mowbray, when a
stately monastery and church were erected, and dedicated
to the Virgin Mary. This abbey continued to flourish till
the general dissolution in 1540, when the site and most of
the demesnes were granted to Sir William Pickering. At
present, the ruins and feite belong to the honourable family
of Stapylton.

Near the base of the Hambleton hills, within four
miles of Thirsk, is Thirskly-Hall, the seat of Sir Thomas
Frankland, Bart. The walks and pleasure-grounds are ex-
tensive and well laid out; and the house is an elegant mo-
dern structure.— Beauties of England and Wales, vol. xvi.
Yorkshire; by J. Bigland.

THIRST, a painful sensation, occasioned by a vellic-
tion of the nerves of the throat or fauces, and producing a
desire of drinking. See Digestion.

Thirst may be sometimes elicited by rolling a clean bullet
or a pebble in the mouth, which occasions an extraordinary
issue of saliva to moisten the throat, &c.

Mr. Boyle mentions a man who could easily abstain from
drinking for nine days, and yet have his diet nothing more
liquid than usual; the secretions of urine, sweat, &c., being
performed all the while regularly, and in the same quantity
as usual.

In tropical cafes, where there is not a right secretion of
the urine by the renal glands, and the vessels and parts of
the body are loaded with too great a quantity of serous
humours, a great moderation in drink might be attended
with good success, provided some liqueur could be found
out to allay that uneasy sensuation. Probably this would be
best performed by mucilages acidulated with spirit of vitriol
or sulphur, or jellies with juice of lemon, &c. and that a
small quantity of such a composition, now and then used,
might be of as much real service, in quenching thirst, as
draughts of liquors, which increase the symptoms.

In feverish disorders, the patient is frequently tormentcd
with a violent thirst, which is moderated by acidulating the
barley-water, or sage-tea, with spirit of vitriol, or with lemon-juice; but by nothing so much, as allowing the
patient some slices of an orange. Pringle, Observ. on Dif-
calcs of the Army, p. 135.

THIRSTY Sound, in Geography, an inlet or bay on the
N.E. coast of New Holland, so called by Cook in 1770,
because it afforded no fresh water. It lies in S. lat. 23° 10',
and W. long. 21° 18'; and may be known by a group of
small islands lying under the shore, from two to five
leagues distant, in the direction of N.W., and by another
group of islands that lie right before it, between three and
four leagues out at sea. In this inlet is good anchorage in
6, 8, and 4 fathom; and here are places very convenient
for laying a ship down, where, at spring-tides, the water
does not rise less than 16 or 18 feet. The N.W. point of
Thirskly Sound was called "Pier-Head."

THIRTEEN ISLANDS, a cluster of islands in the
Pacific ocean, among the New Carolinas, so named by
Capt. Wilson. Lat. of the most southerly 7° 10'.
L. long. 14° 30'.

THISATON, a river of Canada, which runs into lake
Huron, N. lat. 46°. W. long. 84°.

THISMA, a name used by some for any subterranean
wine, or bed of a mineral.

THISTLE, in Agriculture, a well-known prickly trou-
ble-some weed, common in corn and other fields. It has
been observed, that wherever thistles grow naturally, it is a
fire fly that the land is strong, and of a tolerable good
quality; but that they are at the same time a great annoy-
ance to every plant intended to be cultivated. And it has
also been well remarked, that there are no weed-plants over
which the economical farmer ought to keep a more watchful
eye than the thistle tribe, as they are not only wholly use-
less, but occupy much ground, and being furnished with
downy feets, are capable of being multiplied and car-
ried almost to any distance. Besides, they do much mis-
cchief by impeding the work both in handling hay and corn
crops. It is of course a matter of much consequence to be
well acquainted with the qualities of each kind, in order
to enable the farmer to judge with certainty how far and by
what means their destruction may be effected in the most
certain and ready manner.

There are a great many sorts of thistles; and those which
chiefly deserve the attention of the farmer, are the annual,
biennials, and perennial kinds.

There are four of these plants belonging to the first divi-
sion or fort, namely, the milk-thistle, which grows to the
height of two or three feet; the heads hang down, and the
flowers smell somewhat like milk. It is frequently found
occupying whole fields, particularly where the lands are of
a chalky or barren quality; and sending forth flowers in
July and the following month in great abundance. The
milk-thistle, which is found plentiful in most waste places,
and upon old banks, being well known by its beautiful
large leaves, which are variegated with white spots and
veins, as if they had been sprinkled with milk. The flow-
ering season of this plant is in August, or thereabouts.
The 

...
the corn saw-thistle, which is a very troublesome weed in arable land, flowering in July and the succeeding month. See Sonchus.

And the common or field-thistle, which has many provincial names in different places, as the horse-thistle, the cursed thistle, &c. This is a thistle which is more general in its growth than any of the others, being found not only by the sides of roads, but also in arable and pasture lands, and it is remarkably prickly, growing from two to three feet in height, but the heads of the flowers are small, and of a purplish colour, though sometimes white; it flowers in July, or about that period. See Carduus and Serratula.

It is obvious, from what has been said, that the annual and biennial sorts of thistles may be readily removed, by preventing their running to seed and disintegrating themselves over the land; which is best effected probably by carefully eradicating them, or frequently moving them over closely by the surface, and rolling. But in the perennial sorts, from their roots continuing in the earth, increas- ing and throwing out new shoots or items every year, there is much more difficulty in extirpating them, and they, perhaps, can be no other way completely destroyed than by rooting them out on arable land by trench or deep ploughing and frequent harrowing, or by fallowing or laying the land down to pasture; for the first of these sorts seldom appears in pasture lands. But for destroying the common thistles, the best method is perhaps by cutting them over in the bleeding season frequently by proper implements. The writer of the Berkshire Agricultural Report, who thinks them particularly noxious, troublesome, and inconvenient among the corn and grass crops, proposes drawing them up by an implement of the forceps kind, somewhat similar to that described under the head noticed below, especially the for the which is termed Ferrariata aevus; or if they be cut over about an inch above the surface of the ground, it is believed they will be liable to rot, on account of the item being filled with water. They also frequently bleed to death when cut over in this way about the month of Au-
gust, as hinted at above. See Thistle-Drawer.

Others suggest that thistles might probably be destroyed in arable land by continued fallowing for one or two summers; with such repeated ploughing and hoeing as wholly to prevent their vegetating; but as such a progress would be tedious and expensive, an easy, expeditious, and effectual mode of eradicating them in this cafe, seems equally want- ing and desirable, as in that of grass lands. Thistles are likewise very troublesome in hedges, especially those of the forow and the large rough kinds, and should constantly be rooted out and removed as soon as possible, as no hedge can go on well that is much infested with them. See Thistle-Cutter, Weed, and Weeding.

It may be noticed, that by an excellent regulation in France, a farmer may use his neighbour who neglects to thistle his land at the proper saisons, or may employ people to do it at the other's expense. And it were to be wished that a similar law was enacted here, to prevent the wide-spreading mischief occasioned by the seeding of this pernic- ious weed; among which may be reckoned, besides its choking the young corn, that if wheat in particular be not well thilled, the reapers take up the griss fo tenderly, left they should prick themselves, that by their loose handling of them, they sometimes leave upon the ground corn enough to sowe the whole field. There is much in- convenience often experienced too in working hay from them.

Something in the same way as above has also lately been done here, especially in regard to the removal of them from the sides of highways and roads.

Though the sow-thistle has commonly been considered as a troublesome and injurious weed in tillage lands, it has lately been conceived by some to possess no small degree of nutrient power; and on this ground it has been suggested by the writer of the "Experienced Farmer," that it may be a plant of considerable fattening properties when properly raised and cultivated. When taken young, and cut or broken, it produces something, it is said, like cream; and he has noticed that many animals eat it in preference to every other plant now in vogue. Sheep, when in clover, &c. will feed upon it so greedily as to eat the very roots. Pigs likewise prefer it to almost any other green food. Rabbits will breed more speedily when fed with saw-thistles, than with any other food he knows of, except dandelion; which is of the same nature: and is now sold in Covent Garden market to the breeders of tame rabbits, to make the does take buck more readily. A man of his acquaintance, who was allowed better skill with stallions than the generality of people, used to search for saw-thistles, and give them to his horses to make them serve mares more readily and effectually. When he could not get saw-thistles, he fed them, it is said, with new laid eggs and milk, or cream, if he could get it; but he preferred saw-thistles or dandel- ion to any thing.

And there is, he contends, a well-known and remarkable proof of the nourishing and feeding quality of the saw-thistle, in the fat weather sheep fed to such an amazing size by Mr. Trimnell, of Bicker-fen, near Boflon, upon fen-land. This sheep, it is said, was bred by Mr. Hutchinson, in Hail- fen, from a ram bred by Mr. Robinson of Kirby, near Sleaford. He never ate any corn, oil-cake, or other similar dry food, but fed wholly on grass and herbage. Being turned with many other sheep into a field of clover, he was observed first to search for the saw-thistles, and would eat no other food while any of these could be found in the parts of the field that were hurdles off successively, a little at a time. None of the other sheep that fed with him, how- ever, thowed any extraordinary liking for the saw-thistle. A small hut was built for him in the field to repose under in hot weather: and when the part that was hurdles off became bare of food, his attendants, on account of his liking for saw-thistles, gathered a quantity of them for him, which they gave him at particular hours, three times a day, from two to five pounds at a meal.

It is added, that when standing on his feet, he measured only two feet six inches high: he was weighed once a month, and weighed alive twenty-six stones, at fourteen pounds to the stone. He gained only one pound the last month; and as it was judged, therefore, that he was quite ripe, and would not increase any more, but might possibly lose weight the next month, he was killed on the 15th of October 1791, by Mr. Isaac Lumby, of Bicker, being then a four-year-old, or four-year-old sheep.

The writer further states, that the skin, hung up by the nape part, measured ten feet two inches from the point of the nape to the tip of the tail; and was fold for 7s. 6d. in the common course of butchery. And that the carcass measured five feet from the nape to the tail; the rump or cufion eight inches and a half in depth; plate or fore-flank the same thicknees; breast and seven inches; and was one yard five inches and a half round the collar. That the legs were reckoned at 40lbs. each; but if cut haunch of venison fashion, they would, it is said, have weighed 60lbs. each. Mr. Lumby was offered 2s. a pound for them; so that he could have sold the two legs along for 10d. when fo cut.

3 Z 2 This
This is certainly a remarkable instance of fatness, but it
might probably depend more on the disposition of the
animal to take on fat, than on the fattening quality of the thistle
or food on which the sheep was fed. Many further trials
are necessary to fully ascertain the point.

Thistle, Biseled, Carduus benedictus, vul. enicus. See Centaurea.

As an article of the Materia Medica, the biseled thistle,
which is the hairy wild enicus of Miller, and the centaurea
benedicta of Linnaeus, was formerly much used in infusion,
as a gentle emetic, in fevers and certain mists.

Dr. Lewis has often observed excellent effects from a
light infusion of carduus, in weaknesses of appetite and in-
digestion, where the stomach was injured by irregularities,
or opprised by viscid phlegm; nor has he found any one
medicine of the bitter kind to fit so easily on weak stomachs,
or to heat so little. These infusions, taken freely, promote
the natural secretions. Drink warm in bed, they com-
monly increase perpiration or excite sweat; and as they
act with great mildness, not heating or irritating consider-
ably, they have been used, in this intention, in acute as well
as chronic cases. The seeds, which, as well as the leaves,
have a considerably bitter taste, have sometimes been used
as sudorifics or diaphoretics, in the form of an emulsion.
Cold water poured on the leaves, extracts, in an hour or
two, a light grateful bitterness; by standing long upon the
plant, the liquor becomes disagreeable; a strong decoction
is very nauseous and offensive to the stomach. The ex-
tracts, obtained by infusing both the cold infusion and decoction,
have the same differences as the liquors them-
selves. Rectified spirit extracts, in a short time, the light
bitter part of this plant, but does not take up the nauseous
near so easily as water. On keeping the watery extracts
for some months, a considerable quantity of salinic matter
was formed on the surface, in small crystals, resembling
in shape those of nitre, in the taste bitterish, with an impression
of coolness. Lewis's Med. See Centaurea Bene-
dicta.

Some diil a water from it, which they use in cordial and
sudorific potions.

Thistle, Cardine. See Carline.
The root of the cardina acutus of Linnaeus, is suppos-
ed to be diaphoretic, antityphic, and antemtic. It has
been greatly esteemed by some foreign physicians, in acute
malignant as well as in chronic diseases, and given in sub-
stance from a scruple to a drachm, and in infusion from one
to two drachms and more. It is rarely to be met with in our
shops. See Carline Gipsfeens.

Thistle, Dijaff. See Atractylis.
The roots of the atractyla gymmifera of Linnaeus, or pine-
thistle, which is a native of Italy and the island of Candy,
yield, if wounded when fresh, a viscid milky juice, which
concretes into tenacious mlasses, at first whitish and refhbling
wax, but when much handled growing black; supposied to
be the ivion, and acanthina majufhe of the ancients. The
juice is said to have been formerly chewed for the fame pur-
pofes as maltich, and the root itself of the fame virtue with
that of the carline thistle. Lewle.

Thistle, Fife, a species of Carduus; which fee.
Thistle, Fuller's. See Dipsacus and Teasel.
Thistle, Gentle, a species of Carduus; which fee.
Thistle, Globe. See Echinops.
Thistle, Golden. See Scobilus.
Thistle, Hedge-bog, a species of Cactus; which fee.
Thistle, Ladies, or Milk, a species of Carduus; which fee.
Thistle, Melon. See Cactus.

Thistle, Saw. See Sonchus.
Thistle, Downy Saw. See Andryala.
Thistle, Star. See Centaurea.
Thistle, Torch. See Cactus.
Thistle, Woolly. See Onopordum.

Thistle-Cutter, in Agriculture, a tool of the sward-
dressing kind, for cutting up thistles and other coarse weeds
and plants.

An effective implement of this fort has lately been in-
vented, delineated, and described by Mr. Amos, in his work
on "Agriculture and Planting."

The plan of the whole machine, when complete, is that of
a fort of square, in which the leading share is made of caft-
steel, in the form of an isosceles triangle, whose equal sides
are fourteen inches long, and its base twelve inches, being
about one-eighth of an inch thick in the middle, tapering
to a very fine edge on the outside. There are four pieces
of ash-wood, three inches square, and two feet four inches
long, to which the fetyhes are fixed, and which are called the
fetyhe-handles. There are also four fetyhes, three feet long
from point to point, four inches broad at the widest part,
made of caft-steel, and which, the inventor fays, are manu-
factured by Meffrs. Hunt and Company, at their caft-steel
manufactory, Brades, Birmingham. There are likewise four
other pieces of ash-wood, three inches square and two feet
five inches long, for throwing the two hindmost fetyhes to
their proper distance, and which are braced two and two
gether by four bars, which are one by two inches square,
and eighteen inches and one-fourth long. And there is a
main piece of ash-wood, three by four inches square, and
five and a half feet long, to which all the other pieces are
fixed by hooks, and eye-bolts, by means of which the fetyhe-
handles act as it were upon hinges, and the fetyhes are
thereby made to form the fame parallel line with the surface
of the land, whether it be concave, convex, or level. For
this purpofe, it is fuppofed that it might be useful to make
a joint in the middle of this piece, where the land is uneven.
And in the fore part of this piece a fawgate is to be made,
three-fourths of an inch from the under fide, at the hind
part of the share, and one inch from the under fide at the
front of the wood, which gives an elevation to the point of
the share, to receive the share where it is fixed.

There are four iron braces, one of the ends of which are
fixed in the fetyhe-handles, and the other ends to the under
fides of the fetyhes by a fcrew. There is a flape, to which
the chain and fwinging-tree is fixed, and by which the ma-
chine is drawn. There are two mortifc-holes on the fides,
which receive the tenons of two upright fids, to which
pullies are fixed for lifting the fetyhes off the ground, where
there is any thing to obftruct them or retard their progres.
Each of these fids is one and a half by four inches square,
and three feet long. Two small pullies are fixed on each
side of these upright fids. Through the pullies of the
foremost fid, a small rope fasses (one end of which is fixed
to the outside of the iron braces), and likewise through
the pullies of the hindmofl fid, and then the two ropes
unite at about two or three feet behind the whole machine;
and through the pullies of the hindmofl fid pass two other
small ropes (one end of each being fixed to the outside
of the hindmofl iron braces), and then the four ropes unite to-
gether, where the manager holds them as a coachman does
the reins of four horses. By means of these ropes the
fetyhes may be lifted to any degree of elevation, by which
contrivance any unevenness of the ground, or other obftruc-
tions on its surface, such as ftones, roots, ant-hills, &c. &c.
may be easily avoided and paffed by.

The fwinging-tree is thirty-three inches long, and the
chain
chain which looks into the flap for drawing the machine by, is thirty inches long.

The whole of the scythes, when properly fixed, projects beyond the wood, and cut the thistles three-quarters of an inch above the surface of the ground. In cafes where the scythes want sharpening, it is observed that they may be fixed perpendicularly up, or taken off entirely; and that, at the same time, the horses should be unearthened and taken away.

In using the machine, it is advised by the ingenious inventor, that as soon as the thistles are in full flower it should be set to work, the length way of the ridges; and that if the scythes are kept very sharp, it will make excellent work. And when the thistles have been cut, they should lie a day or two, it is said, to perish by the loss of their sap-juice: the ground must then be cleared, and the close or field rolled, the cross ways of the ridges, with a very heavy roller, which so crushes the hollow rumps, and renders them so porous to water, that their roots soon rot and are destroyed. But to expedite the operation of the implement, and the destruction of the weeds and plants, the land should be cleaned of all kinds of rubbish, the latter end of March or beginning of April, being dressed with the sward-dresser, and then rolled the cross ways of the land, or ridges, with a weighty roller, as just mentioned. See Sward-Dresser.

Thistle-Drawer, an useful implement of the forceps kind, which is extremely beneficial in drawing up the common field-thistle and some other strong sorts of weeds. It may be constructed either of wood or iron, in the latter case having sockets for receiving wooden handles. When made of wood, it should be of the hard and lefs brittle kind, as good tough ash. It is usually formed from two to three feet in length, having six notches or blunt teeth cut in each blade, at the bottom part, where it bites or seizes the plants, and each arm well fitted to the other, turning upon a strong pivot or pin. In its operation the thistle is seized close to the ground and firmly held, so as to be drawn out with considerable length of root. It has been long in use in the northern parts of Lancashire; and is said to be lately introduced from Wilts into the county of Gloucestershire, in the agriculture report of that district. It is an useful and effective tool for the above purpose, and only calls about two shillings when made of wood, and three or four when of iron. It has long been known in the first of the above counties by the provincial name of Gripe.

Thistle-Fly, in Natural History, a small fly produced from a fly-worm hatching in the protuberances of the carduus hemorrhoeadalis. In the protuberances of this thistle, while they are closed in all parts, the worm of this fly, from whose injuring it, at the time of depositing the eggs from which it was hatched, the protuberances arose, undergoes its last transformation. It here makes of its own skin a shell in form of an egg, within which it puts on the nymph plate. When this nymph becomes a living fly, the least part of its difficulty is the finding its way out of this shell; it has a stronger prision than that, and before it can obtain its liberty, must force its way through the much more closely compacted fibres of the protuberance of the vegetable. It has, however, no other means of doing this difficult work, but that of infesting its head, and throwing out the bladder or muzzle with which all these creatures are provided in this flate. See Thistle-Galls.

This is a difficult operation, and many of the creatures perish in the attempt; but what much forwards the success of it, in many cases is, that the flake of the thistle often becomes naturally half rotten before the time of the fly’s egres. Reaumur, Hist. Inf. vol. iv. p. 338.

Thistle-Galls, a name given by the more accurate authors to the protuberances on the flake of a species of thistle, called by authors cardus hemorrhoeadalis, from those tubercles, which are supposed to resemble those of the hamorrhoidal veins in persons subject to the pikes. These have been supposed a natural production of the plant; but they are far otherwise. The whole history of them is, that a certain species of fly always deposits its eggs on the flakes; and the young ones, when hatched, gnaw their way into the substance of the flakes, and the copious derivation of the juice, occasioned by their sucking, produces the tubercles which are found on it.

These tubercles are of a roundish or oblong figure, and are of various sizes, from that of a pea to the biggest of a nutmeg; they are much harder than the rest of the flake, approaching to a woody structure; when cut open, they are found to contain several oblong and narrow cells; there have no communication with one another, and are each inhabited by a small white worm, which has two hooks at the head; with these it breaks the fibres of the plant, in order to get at its juices. When it has arrived at the time of its change into the nymph flate, it ceases to eat, and drawing up its body much shorter than usual, its skin hardens, and forms a shell, under which it changes into a very beautiful two-winged fly; the wings are whitish and transparent in the middle; and at the edges surrounded with black in the form of a chain of figures like the letter Z; the body and breathing of this fly are of a beautiful black, with some flight variations of yellow, with which the shoulders are streaked; the anterior part of the head is white, and its back-part edged with a yellow down; the antennae are reddish, and the legs are partly black, and partly of a fine clear brown.

In observing the changes of the worms of these galls, there are often observed some which go through them in a different manner from the rest, and finally produce a very different species of fly. These are the progeny of the eggs of some other species of fly, whose worm being carnivorous, is lodged by the art of its parent, while it is yet in the egg flate, in the substance of this gall, there to prey upon the defenceless inhabitants.

There are many species of galls the inhabitants of which are exposed to enemies. In those it is common to find the proper inhabitant and the devourer in the same cell; the one feeding on the juices of the plant, the other on its juices; but this is not the case here, these worms immediately destroying the proper inhabitants, and being found always alone in their cells. Reaumur, Hist. Inf. vol. vi. p. 221.

Thistle, Order of. See Andrew.

Thistle, our Lady of the, was also a military order, instituted in 1370, by Louis II, duke of Bourbon. It consisted of twenty-six knights, of which that prince and his successors were the kings. Their badge was a sky-blue girdle; and, on solemn occasions, a mantle of the same colour, with a gold collar, interwoven with flower-de-luce; among which was the word of service, hope, in capitals.

Thistle-Take, a custom in the hundred of Holton, in the county of Chester, whereby, if in driving heales over the common, the driver permits them to graze, or take but a thistle, he shall pay a halfpenny a beaft to the lord of the fide.

At Fiskerton, in Nottinghamshire, by ancient custom, if a native, or cottager, killed a swine above a year old, he paid the lord one penny, which was also called thistle-take.

Thiva, or Stibes, in Geography, a town of European Turkey,
Turkey, in the province of Livadia, anciently called "Thbes," and the capital of Bæotia, situated on a rising ground between two small rivers, supposed to be the Ilmenus and Dirce of the ancients. (See Thb.) The town is of an oval form, about three miles in circumference, and the houses are higher and better built than is usual in most parts of Greece. It contains four or five thousand inhabitants, about half Turks and half Christians, which latter have several churches, not remarkable for any thing except some few inscriptions to be seen upon the pavement of the cathedral. The air of the country about Thbes is thick and foggy, whence the ancient inhabitants of Bæotia were accounted dull and phlegmatic, and were neither famous for their wit nor valor. (See Bæotia.) Epaminondas raised Thbes to its highest pitch of grandeur; after whose death it was not remarkable for its virtues, but misfortunes, till it sunk into its original obscurity; so that its glory took birth with this great man, and with him expired; 28 miles W.N.W. of Athens. N. lat. 38° 25'. E. long. 23° 34'.

THIVIERS, a town of France, in the department of the Dordogne; 7 miles N.W. of Exideuil.

THIULETIS-TSKALLI, a river of Georgia, which runs into the Kur.

THIZY, a town of France, in the department of the Rhone and Loire; 27 miles N.W. of Lyons.

THLALIAS, a term used by the ancients to express a cuunch made by a compreッション or contussion of the tcellles, not by the cutting them out.

THLALIS, a word used by the ancients to express either a contusion without a wound, or a wound made by some blunt instrument, which contused the parts.

THLALMA, a word sometimes used like thlasis, to express a contusion either with or without a wound; sometimes applied particularly to a recce of the cranium inward without a fracture, an accident principally afflicting children.

THLASEPOS SEmEN, in the Materia Medica, the name of a seed produced by the common thlaphi arvensi jiluquis latis, or common treacle-mustard. It used to be an ingredient in several of our shop compositions, and was esteemed attenuating, detereive, and aperient, and is said to promote urine and the menses, and to expel the after-birth.

THLASPIS, in Botany, θασπις, an ancient name, which Dioscorides tells us, in his book 2. chap. 186, originated in the broken, or panned, appearance of the seed, alluding, we suppose, to its smallness. The word therefore is derived from θασπι, a bruiser, or boat. He compares this seed to that of the κρατουσία, or Lepidium flavum, or Garden Cress, adding that the seed-velvett is moderately dilated upwars, the flower white, and the plant found about paths, walls, and banks. Every other part of his description, respecting the leaves and stems, is so apposite, that no doubt can remain of his θασπις being our Shepherd's Purse, which Dr. Sibthorp found common in Greece and the Archipelago, in the early spring. Linnaeus might freely have spared his mark of uncertainty concerning the etymology of the above name, in Philos. Bot. 183. But as he translates θασπι by the Latin word compresse, to compresse, he, most likely, had in view the Th. arvensi, which several old writers have taken for the plant of Dioscorides, and whose seed-velvett is very remarkably compresse.—Linn. Gen. 334. Schreb. 437. Willd. Sp. Pl. v. 3. 442. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 683. Compend. ed. 2. 98. Prodr. Fl. Græc. Sibth. v. 2. 7. Brown in Ait. Hort. Kew. v. 4. 80. Jull. 241. Lamarck Illusr. t. 557. Gerten. t. 141.—Clafs and order, Tetradynamia Silicula. Nat. Ord. Siliquose. Linn. Crucifere, Jull.

Gen. Ch. Cal. Perianth inferior, of four ovate, concave, somewhat spreading, deciduous leaves. Cor. cruciform, equal, of four obovate petals, twice the length of the calyx, with narrow claws. Stam. Filaments six, but half the length of the corolla, the two opposite ones flll shorter; anthers pointed. Pffl. Germen superior, roundish, compresse, emarginate; fyle fimple, the length of the rramens; fligins obtuse. Peric. Pouch compresse, inverely heart-shaped, emarginate, the flye being mostly the length of the notch in which it stands, of two cells, the partition lanceolate, and the valves boat-like, with more or less of a dilated keel. Seeds several in each cell, pendulous, inserted into the futures, roundish, compresse.

Obf. Mr. Brown has very happily separated from this genus the Linnaean Th. conpresse. That species, on account of its solitary feeds, properly belongs to Lepidium, to which genus it, as well as Th. birtuin, is removed in the new edition of our Compendium Fl. Brit. The fame ingenious botanist, of whose elucidation and reformation of the crucifom genera we have spoken under the article Tetradynamia, has founded a new genus, called Aethionema, upon Th. faska- tube, with another fpecies, whose pouch has no valves, and only a single feed. With this latter, a Spanish plant, we are unacquainted; but as the faska-tube has two cells, and many feeds, we can hardly either disjoin it from Thalpi, or unite it with this, though, it feems, they agree in having an unequal infection of their calyx-leaves, which in Thalpi is equal; and their longer filaments are either combined, or ellic toothed near the top. As there are but two fpecies, we presume one of these laft charactes belongs to each. The queftion feems at leaff doubtful, and therefore, without prefuming to form an opinion refpeccing Mr. Brown's Aethionema monopervatum, we prefer keeping his faska-tube where it is.

The plants of this genus are herbaceous, and most of them annual, with simple leaves, and numerous corymbose flowers; their surface more frequently smooth, and somewhat glaucous, than pubescent; fleem leafy and branched.

1. Th. peregrinum. Red Penny-Cress. Linn. Sp. Pl. 901. Willd. n. 1. Scop. Carn. v. 2. 17. (Th. capula cordata, peregrinum; Bauh. Hift. v. 2. 927, badly copied in Morif. feats. 3. t. 18. f. 30.)—Pouches roundish-heartshaped. Leaves lanceolate, entire.—Native of dry hills, above Heidenfchaf in Carniola. Scopoli. Of this very rare plant we have never seen a certain specimen. Scopoli says the ftemes are a fpan high, hard, branched, turning reddish, as well as the leaves, as they advance in age. The leafes grow on fhort ftalks. Flowers small, red, with entire ovate petals, and reddish filaments. Anthers yellow, as well as the fhort flyle, and the fligmat, which falt is flat at the top. Seed two in each cell, ovate, yellowith, slightly rugged, fitting, attached to the faleate partition.

2. Th. arabicum. Purple Arabian Penny-Cress. Vahl Symb. v. 2. 76. Willd. n. 2. (Th. humile, fipica purpu- recea; Buxb. Cent. 1. 2. f. 1. Iberis arabica; Linn. Sp. Pl. 905. Am. Acad. v. 4. Subularia purpurea; Forik. Ægypt.-Arab. 117.)—Pouch nearly orbicular, compresse, with a notch at each extremity. Lower leaves wedge-shaped; upper oblong-heartshaped, entire, clafping the stem.—Native of Arabia and Cappadocia.—The root is tapering, fibrous, annual. Stem more or less branched, round, smooth, from three to fix inches high, leafy, corymbo- fe. Leaves an inch long, acute, entire, smooth, rather succulent, slightly falked. Flowers small, purple or red-dish. Pouch light green, with a very broad fritated border, much exceeding the flyle, and notched at the bafe as well as fume.
**THLASPE.**

_somn. Seeds_ two in each cell. This species appears nearly related to the foregoing, nor should we be greatly surprised if they proved one and the same. If Baghania’s delineation of the pouch of the former be correct, they must be different.

4. _Th. alliaceum._ Garlick Ballard-Cress. _Linn. Sp._ Pl. 901. Willd. n. 4. Ait. n. 2. _Jacq._ Cc. Rar. t. 121. (Th. allium redolens; Morif. fect. 3. t. 28).—Pouch nearly obovate, tufted, with a narrow border. Leaves oblanceolate, obtuse, smooth, somewhat toothed. Native of the south of Europe. An annual herb, much resembling the laft, but the leaves are blunter, and less toothed. The pouches are very different, having but a flight border at their upper part only, their base being wedge-shaped.

5. _Th. Pscrinum._ Long-ryled Ballard-Cress. _Willd._ n. 5. (Physeinum lyllofa; Desfont. Atlant. v. 2. 60. t. 148. Burf. paflos hirufuta, erucce flore, filo proumiente; Shaw Afric. n. 91. f. 91.).—Pouch abrupt. Style prominent. Leaves heart-shaped-oblong, toothed, downy, clasping the stem. Native of the borders of fields in Barbary. Root annual. Herb larger than the foregoing, and clothed with hoary hairs. Leaves rounded, not acute at the base. Flowers pale yellow, as large as the Common Mustard. Pouch wedge-shaped, or triangular, being quite abrupt at the end; the style, which is as long as the whole pouch, fading prominent at the summit. Willdenow is certainly correct as to the genus.

6. _Th. fuscatic._ Rock Ballard-Cress. _Linn. Sp._ Pl. 901. Willd. n. 6. _Jacq._ Cc. Rar. t. 236. (Lithothalius quaternium, carnofo rotundo folio; _Col._ Ecpr. 279. t. 277. f. 2._Aethionema fasciatum; Br. in Ait. Hort. Kew. v. 4. 82.)—Pouch nearly orbicular; concave above; convex below. Stems mostly simple. Leaves linear-lanceolate, fleshy, obtuse. Native of dry hills, and the crests of rocks, in Italy, Austria, Switzerland, Greece, and the south of France, flowering in April and May. The root is perennial, and in some degree woody, though generally marked as annual. _Stems annual_, ascending, fix or eight inches high, round, leafy, rarely subdivided. _Leaves_ numerous, scattered, on short flanks, glaucous, smooth, entire, three quarters of an inch long; the lower ones rather elliptic. _Flowers_ small, pink, numerous, in dense terminal corymba, soon elongated into a lax _clefiers_ of glaucous pouches, tinged with pink, each on a slender, spreading, partial stalk; their border broad, atrivated, somewhat crenate, emarginate at the top only, where the minute _style_ is situated. The shrubby habit, glaucous hue, and very pretty little red flowers with a pale-green _calyx_, render this one of the most elegant plants of its natural order. _Hcris fuscaticus_; _Linn. Sp._ Pl. 905, distinguished from this by the accurate Fabius Columna, and figured in the fame place of his work, is fo like it, that they are hardly to be known at firder, except by the unequal _petals_, proper to _Hcris_, and the downiness of this latter plant. On a close comparison, the shapes and surfaces of their _seeds_, will be found effentially different.

7. _Th. montanum._ Mountain Ballard-Cress. _Linn. Sp._ Pl. 902. Willd. n. 9. Ait. n. 7. _Jacq._ Cc. Rar. t. 237. (Th. montanus, burf. paflos fructu; _Col._ Ecpr. 275. t. 276. f. 1. _Th._ precox; Wulf. in Jacq. Coll. v. 2. t. 124. t. 9. _Lepidium n. 518; Hal._ Halft. v. 1. t. 223. _f._ Th. alpinum; Jacq. Cc. Rar. t. 238. Willd. n. 10. _Crantz._ Cc. Rar. t. 25. t. 3. f. 1. (Th. minimum; _Arduin._ Spec. 2. 33. t. 15. f. 2.)—Pouch inerely heart-shaped. Leaves smooth, nearly entire; radical ones obovate, flaked; the _seeds_ clasping the stem. Petals three as long as the _calyx_. Stems simple.—Native of Rocky places, on the lofty mountains of Switzerland, Austria, Dauphiny, and Italy, flowering in April or May. The roots are perennial, long, subdivided at the summit, each trailing shoot crowned with a tuft of obovate _leaves_, rarely a little ferrated, their size, and the length of their _footstalks_, varying according to luxuriance of soil, or a more or less elevated place of growth. From the centre of each tuft arises a solitary, simple, ascending, or upright _stem_, from three inches to a span long, round, smooth, clothed with numerous, alternate, sessile, cordate, or arrow-shaped, very rarely toothed, _leaves_, whose base is more or less elongated and acute; their length three quarters of an inch. _Flowers_ in solitary terminal _corymba_, numerous, large, white and handfome; their broad, obovate, spreading _petals_ at least three as long as the smooth, often purplish, _calyx_. _Pouch_ tapering at the base; more or less deeply lobed at the end, with a _style_ almost as long as itself, projecting far beyond the lobes. _Seeds_ naturally two in each cell, as Jacquin describes them. Haller found one only. This may be accounted for from their being often abortive, as indeed are generally most of the _pouches_ themselves, the plant increasing much by root. Having had occasion to fludy this and the neighbouring species very minutely, in our investigation of Swiss and British plants, we can with confidence maintain the correctness of our synonyms, on the authority of original specimens. Our _b_ alone is entitled to be distinguished as a variety, and that an insignificant one, being merely rendered small in size by its very elevated or exposed situation. The faithful Jacquin himself evidently mistrusted this supposed species, though he says it retained the fame habit when cultivated.

8. _Th. oldebree._ Alpine Shepherd’s Purée. _Linn. Sp._ Pl. 903. Willd. n. 12. _Fl._ Brit. n. 5. _Engl._ Bot. t. 81. Ait. n. 6. (Th. folis globulares; _Rau._ Syn. ed. 2. 175. ed. 3. 309._Bau._ Halft. v. 2. 926. Th. montanum; _f._ ecundam badæfe; _Coll._ Halft. v. 2. 131. Th. albi supini varietas; Ger. _Em._ 268. f. 2. _Lepidium n. 519; Hal._ Halft. v. 1. t. 223, on the authority of specimens from Davall and Du Cros.)—Pouch obovate, abrupt, somewhat heart-shaped, with many seeds. Stem-leaves arrow-shaped. Stems simple. Style prominent.—Native of mountainous pastures in Switzerland and England, flowering in June and July. It abounds on limestone rocks, and about lead-mines, in Yorkshire and Derbyshire. Many authors have confounded this
THL

1. with the leaf, from which it differs in having a tufted root, not throwing out scions, or runners; usually taller and more numerous stems; more glaucous herbage; much smaller flowers, whose petals are erect, and though variable in dimension, never a quarter so large as in montanum; but above all, in having at least three or four seeds in each cell. The petals merely are always numerous, and all perfect. Their terminal lobes are variable in length or dilatation, but constantly much shorter than the style. (See the following.) We have often been inclined to remove from this species to the foregoing the synonyms of Baulin, Clatius, and Gerard, cited in Fl. Brit. on account of the large spreading petals of their figures. But this appears to be an inaccuracy on their part. The habit of their plant; several stems from the simple crown of the root; and the copious petals in long continued clusters, all properly belong to our alpestris, by no means to montanum. We have some suspicion that the alpestris is rather biennial than perennial. It never remains long in gardens, but that is no proof, nor have we had an opportunity of watching the plant through a season, on its own native hills. Hudson mitook the perforatum, next described, for alpestris.

9. Th. perforatum. Perfoliate Shepherd's Purse. Linn. Sp. Pl. 622. Willd. n. 11. Fl. Brit. n. 4. Eng. Bot. t. 2354. Jacq. Audl. t. 375; not. 237, as in Wildenow. (Th. alteran mimus rotundifolium, burfæ pastoris fructu.) Column. Ecphr. t. 278. f. 2. Th. rotundifolium; Ger. Em. 268. Th. cardo minus, flore albo, infulid.; Barrel. l. c. f. 815. Th. tertium pianulum; Cluf. Hift. v. 2. n. 131. Th. minus Clufi; Ger. Em. 268. Nafturium n. 510; Hall. Hift. v. 1. n. 220. Pilofera filiciflora; Thal. Harcyn. t. 7. f. C, at the end of Camer. H. (Pouch exactly inwards heart-shaped. Stem-leaves heart-shaped, sharpish at the base, clasping the branched stem. Style very short—Native of calcareous pastures or rocks, walls, and dry places, in Switzerland, Germany, France, Italy, Greece, and England, flowering in the spring. In the last-mentioned country it is hardly known any where but in the limestone part of Oxfordshire, about Witney and Burford. We have gathered it at Caferata, near Naples. The root is fibrous and annual. Stem branched from the bottom, except on poor ground, usually from four to fix inches high, round, smooth, leafy. Leaves glaucous, smooth, various in size, entire, or now and then slightly toothed; the radical ones flaked, ovate, obtuse; the reft fefile, alternate. Flowers white, small, with narrow, erect petals. Style fo short as to be scarcely discribable between the rounded lobes of the pouch. Sands three or four, at leaf, in each cell. The small annual root, usually branched stem, and minute style, are quite sufficient to distinguish this species from the leaf, with which it has been confounded; nor is it difficult, with a moderate degree of observation, to avoid the error of those old botanists, who defcribed its flared and luxuriant fronds for distinct species. Ray suspected this, and has adverted to it in his own frequent edition of the Synopsis, by far the moft exact, p. 176.

10. Th. teneum. Yellow Sicilian Shepherd's Purse. Bivon. Cent. i. 78. (Th. montanum, glafi folio, parvum, perfoliatus, noninhil ferratum, pilösula cordata; Cusan. Panphty. v. 2. t. 256. Th. montanum luteum, glafii folio, parvum, perfoliatus, noninhil ferratum, pilösula cordiformi; Cusan. Hort. Cathol. 212.)—Pouch inwards heart-shaped, nearly orbicular. Leaves toothed, the lowermost flaked; the reft clasping the stem. Style almost equal to the lobes of the seed-vessel.—Native of dry mountainous places near Palermo, flowering in April and May, and sent us by the baron Bivona. This is a fmall, smooth, glaucous, annual plant, from one to three inches high. Stem erect, either simple, or branched from the bafe. Leaves half an inch, more or less, in length; the lower ones fpatulate; the others ovate-oblong, bluntish, with a heart-shaped bafe; all having one or two large teeth at each fide. Flowers remarkable for being yellow. They are small, not many together, in short terminal corymbus, becoming elongated clusters of rather large, rounded, reticulated pouches, with a few seeds in each cell. The petals are emarginate, erect, longer than the calyx. S stigma large, on a level with the lobes of the pouch.

11. Th. Burfa Pafforis. Common Shepherd's Purse. Linn. Sp. Pl. 503. Wildl. n. 13. Fl. Brit. n. 6. Prodr. Fl. Grecq. n. 1409. Eng. Bot. t. 1435. Curt. Lond. f. c. 1. t. 50. (Burfa Pafforis; Ger. Em. 276. Matth. Valgr. v. 1. f. 521.)—Hairy. Pouch inwards heart-shaped, somewhat triangular, scarcely bordered. Radical leaves pinnatifid.—A very common weed in cultivated and waste ground, throughout Europe, as well as in North America, and in most countries where European merchandise or cultivation has reached. We have already mentioned that this species is indubitably the burfa of Dioscorides. It flowers at all times, from the beginning of spring to the end of autumn. The white tapering annual root is distinguished by a very peculiar nauseous smoke-like scent, when pulled out of the ground. Whole herb rough with flairy as well as prominent hairs. Stem various in height, erect, round, with alternate spreading branches, though sometimes fo flared as to be quite flimp and flender, with all the leaves of the plant undivided; in which state the species is difficult to be recognized. The radical leaves are numerous, close to the ground, variously pinnatifid, moftly toothed, somewhat lyrate, about two or three inches long; the reft linear-oblong, acute, fefile, entire or toothed, embracing the stem with their elongated heart-shaped bafe. Flowers small, white, in dense corymbus, often tinged with purplish-brown. Pouches smooth, fatchel-shaped, whence the modern name, difpoled in very long, lax, upright clusters. Style rather prominent. Seeds numerous, small, oval, a favourite food of small birds, as well as the flower-buds. The flavour of both is warm and pungent.

12. Th. ceraeocarpum. Horned Shepherd's Purse. Murray in Comm. Goett. v. 5. 21. t. 1. Linn. Suppl. 295. Wildl. n. 14. Ait. n. 3. Scop. Infub. v. 10. t. 4.)—Very smooth. Pouch obovate, tumid, with a terminal, double horn-like, comprised boder. Leaves lanceolate, somewhat toothed; arrow-shaped at the base.—Native of Siberia, from whence Pallas brought the seeds. The root is annual, tapering. Stem solitary, erect, twelve or eighteen inches high, leafy, moftly quite fimpie. Leaves all smooth, slightly toothed, or wavy; the radical ones obovate, on long falks; the reft fefile. Flowers numerous, white, very small. Pouches composing a long cluster, very confpicuous for their two sharp prominent horns, between which flonds the very short style. Seeds large, about two in each cell.

THLASPIDIUM, Gephisa of Crates, according to Tragus; a name whose etymology has been mistaken, like Thlapst, (fee that article,) from whence it is manifefly derived. Tournefort, who in his Inflitutiones 214, adopts this name, for what Linnæus more aptly termed Bisflculella, explains it as meaning that the plants which bore it were allied to Thlaspis; and this, no doubt, is correct. But Ambrofini, who confiders Thlaspis itself as applying to the beaten or flattened form of the seed-vessel, deduces the pre- sent word from thlasp, to bruife or beat, and ois, a little field, which is evidently applicable to the flat shield-like fruit of Thlaspis arvensis, and is fo plausible an explanation, that
THO

that it seems to have chiefly led the modern expounders of ancient writers to take this species for \textit{Saccitt} of Dioscorides. We have already, in its proper place, shown our Shepherd's Purse to be what he describes; and we can understand the name, as derived from \textit{Saw}i, \textit{Sawz}, in no other light, than alluding to the minute seeds, which seem as if beaten to powder. This is by no means the first instance, in which the most apparently just etymology, proves not to be the real one.

\textbf{THERIBIA}, in \textit{Antiquity}, a kind of cumachs. See \textit{Thalassas and Castratio}.

\textbf{THLIPIS}, \textit{Saccitt}, is used, by anatomists, for the comprehension of any vescel or aperture, by which its cavity is lined.

\textbf{THNETOPSYCHITIS}, composed of \textit{S RBI} the \textit{mortal}, and \textit{JX}, \textit{foul}, in \textit{Ecclesiastical History} ; a fell in the ancient church, who believed the foul of man perfectly like that of brutes; and taught that it died with the body. See \textit{Soul}.

We meet with no account of these heretics any where but in J. Domianus Hare. 10, unless they be the same with those Eufebius speaks of, Hist. Ecclef. lib. ix. c. 38, who relates, that in Origen's time, there were heretics in Arabia, who taught, that the foul of man died with the body; but that it should rise again with it at the end of the world. He adds, that Origen refuted them in a numerous council, and exclaimed them from their errors. St. Augustine and Isidore call them the Arabian heretics.

Marshall, in his table, uses the word \textit{Thromyphlactis} instead of \textit{Thonetopethritis}.

\textbf{THOA}, in \textit{Botany}, a Guiana name adopted by Aublet, and retained by Jussieu, and even Schreber; see our article \textit{Gnetum}, to which genus this plant is there, for the first time, referred, as a second species.

\textbf{THOALABIAN}, in \textit{Geography}, a town of Arabia, in the province of Nedsjed; 260 miles E.N.E. of Hajar.

\textbf{THOANOHA}, a town of Cochinchina, at the bottom of a large bay. N. lat. 16° 45'. E. long. 106° 27'.

\textbf{THOARD}, a town of France, in the department of the Lower Alps; 9 miles E.S.E. of Sitten.

\textbf{THOCO}, an island in the Grecian Archipelago, near the coast of Greece, about eight miles in circumference. N. lat. 37° 20'. E. long. 23° 21'.

\textbf{THOCOS}, \textit{Saccitt}, in \textit{Antiquity}, the name with \textit{Thacas}.

\textbf{THOGRAI}, in \textit{Biography}, a Persian of Ipahan, who was grand vizier to the sultan Malch Mahud, is celebrated for his poetical talents, a specimen of which is given by Pococke; and for a commentary upon the republic of Plato, to whom the Saracenps paid little attention. After a strange reverse of fortune, Thograil was put to death by order of the sultan in the year 1212.

\textbf{THOIRY}, in \textit{Geography}, a town of France, in the department of the Ain; 6 miles S.S.W. of Gex.

\textbf{THOSES}, in our \textit{Old Writers}, fifth with broken bellies, forbid by statute to be mixed or packed with tale-fish. 22 Ed. IV. cap. 2.

\textbf{THOLEN}, in \textit{Geography}. See \textit{Tolen}.

\textbf{THOLES}, in \textit{Sea Language}, denote small pins driven perpendicularly into the upper edge of a boat. In rowing, the oar passes between the two tholes, in the space called the \textit{row-lock}. Sometimes there is only one pin to each oar, as in the boats navigated on the Mediterranean sea: in that case the ear is hung upon the pin by means of a flap.

\textbf{THOMAENS, THOMAEANS, THOMITAE, or CHRISTIANS of St. Thomas}, a people of the East Indies, in Cochinn, and upon the coast of Malabar and Coromandel, who, according to tradition, received the \textit{Gospel} from the apostle St. Thomas.

It appears by the testimony of Cofmas, who wrote about A.D. 547, and whose work is translated by F. MONTFAUCON, that Christianity was established in India in the sixth century. We also find in the subscriptions of the council of Nice, that of a prelate, who calls himself bishop of Peria. Moreover, an ancient author, cited by Suidas, says, that the inhabitants of interior India, (a name which Cofmas gives to the coast of Malabar,) the Iberians and Armenians, were baptized under the reign of Constantine.

The princes of the country, and particularly Serant Peroumal, emperor of Malabar, the founder of the city of Calicut, A.D. 825, granted extraordinary privileges to these Christians.

When Valdo de Gama, the Portuguese admiral, arrived at Cochin with a fleet, in the year 1502, these Christians sent deputies to him, imploring his protection, and that of the king his master. The admiral treated them kindly, but was in no condition to afford them any effectual assistance, in relieving them from the yoke of the Pagan kings, to which they were then subject. The language they use is \textit{facris}, is the Syriac, or, as some say, the Chaldean; but their ordinary language is the same with that of their neighbours. The first missionaries, who attempted to profelyte them to the church of Rome, were Cordeliers, but their endeavours proved ineffectual. The distinguishing opinions and religious rites of these Christians are as follow.

They are charged with an invincible attachment to the doctrine of Neoforisus, and with an obdurate refusal to acknowledge, that the Virgin is the mother of God: they have no images in their churches: they believe that the souls of the blest are not admitted into the presence of God till after the day of universal judgment: they allow only of three sacraments, viz. baptism, orders, and the eucharist: they deler the baptim of infants for some time, as for a month, or even for seven, eight, or ten years, after they are born: they make no use of holy oil, neither in baptism, nor in the administration of the other sacraments; but after baptizing their infants, they sprinkle the oil of a species of Indian saffron all over their bodies: they allow of no auricular confession, treat purgatory as a fable, and their priests are permitted to marry: they entertain an extraordinary affection for the Nestorian patriarch of Babylon, but will not suffer any mention of the pope, or of the Roman churches in their assemblies. Their days of abstinence are Wednesday and Friday, and the rest is very severe in Lent, during which time they go to church three times a day. They also fast in the same manner during the time of Advent. Besides these two greater fasts, which are enjoined on pain of excommunication, they have several others of a religious nature. Their women do not enter a church for forty days after their deliver of a male child, nor for eighty days after the birth of a daughter.

These Christians are in general poorly instructed, knowing only the Lord's prayer and the angelical salutation. Their churches are mean and undecored buildings, and constructed after the manner of the pagodas. They appear to maintain many of the religious opinions and practices received among Protestants, and reject either wholly, or in a very great measure, those of the church of Rome. They deny the supremacy of the pope, and transubstantiation, and exclude from the number of sacraments, confirmation, extreme unction, and marriage. Such are the errors proferbed by the synod of Diamper, held in 1599, by Alexo de Menees, archbishop of Goa, in order to unite the Thomaeans to the Roman church. However, notwithstanding the temporary success that attended the vigorous exertions of the archbishop, for which he was recompened after his return to Europe, with the archbishopric of Braga, the viceroyhip of

4 A of
of Portugal, and the presidency of the council of state at Madrid, these Christians, oppressed and abused by the Jesuits, escaped from the church of Rome soon after the death of the archbishop; and notwithstanding the endeavours of Alexander VII. to conciliate them by the munificence of four bare-footed Carmelites, they could no more be reduced to submission. At length, when the Dutch took Cochin, in 1663, the Christians of St. Thomas recovered the liberty which they had formerly enjoyed; but they derived little advantage besides from their new masters.

Encyclopædia, and Gokkes's History of the Church of Malabar and Sum of Damper, in his Tracts, vol. v. For a further account of this fact, see Christianus of St. Thomas.

THOMAS, in Geography, a town of Portugal, in Erremadura, containing two churches, an hospital, four convenants, and about 2600 inhabitants; 63 miles N.E. of Lisbon. N. lat. 39° 34'. W. long. 8° 8'.

THOMAS, surname'd Dihymus, or the Tassian, in Scripture Biography, one of our Lord's twelve apostles, of whom the evangelist John has given a short account in the 20th chapter of his Gospel. John Chyfotom informs us, that Thomas preached the gospel to the Ethiopians, Parthians, Persians, and Medes, and even, according to tradition, to the Indians, and in the isles of Taprobana; and the Christians called after his name in the East, regard him as the founder of their church. See Christianus of St. Thomas, and Thomasians.

For an account of the pious gospel attributed to St. Thomas, we refer to the article Gospel.

Thomas, Antony Leonard, in Biography, a distinguished French writer, was born in the diocese of Clermont, in Auvergne, in the year 1732, and designed for the profession of the law; but his attachment to literature induced him to prefer a professorship in the college of Beauneus. His reputation as a man of letters recommended him to the office of confidential secretary to the duke De Pralifin, in which he conducted himself with integrity and honour. When he was advised by the duke to become a candidate for a seat in the French Academy, after having five times gained the prize for his compositions, and discovered that he was put forward as a competitor to Marmontel, who was out of favour with persons in power, he refused to be the instrument of such a design. In consequence of this circumstance, the duke defi-

miffed him his office, but procured for him the place of secretary-interpreter for the Swiss Cantons, to which a very considerable salary was annexed; and yet this was the whole benefit which he obtained from court-favour. His career as a writer commenced in 1756, by "Reflections historical and literary on Voltaire's Poème on Natural Religion;" and on all subsequent occasions he proved himself the friend of virtue, and a lover of mankind. His eulogies, particularly those on Des Cartes and Marcus Aurelius, were highly commended. His "Essai sur les Charactères, les Mœurs, et l'Esprit des Femmes," 1772, is a sprightly performance, in which fine writing and philosophical observation are combined. His "Essai sur les Eloges," in 2 vols. 1775, exhibits striking portraits with just ideas. As a poet, he appears to advantage in his "Épitre au Peuple," his "Ode sur les Temps," and his "Poeme de Junonville." His epic poem, entitled "Le Petreide," the hero of which was Cesar Petre, was left unfinished. He was distinguished by his singularities, and also by his sympathy with persons in distress, for whose relief he submitted to personal inconvenience and privation. His death took place at the seat of the archbishop of Lyons, in September 1785, at the age of 53. His works, in prose and verse, were published at Paris, in 7 vols. 8vo. Gen. Biog.

Thomas, Christian, an Eclectic philosopher of the German schools, who deserves notice on account of the boldness with which he threw off the yoke of human authority, and the perseverance with which, against much opposition, and in many vicissitudes of fortune, he maintained and exercised the right of free inquiry. He was born at Leipsic in the year 1655, and finished his course of education in the university of his native city. Upon a perusal of Puffendorf's Apology for rejecting the scholastic principles of morals and law, he renounced implicit deference to all ancient dogmas; and engaged in reading lectures on the subject of natural law, first from the text of Grotius, and afterwards from that of Puffendorf, in the full exercise of his own judgment, with prudent caution while his father lived, but after his death, with a boldness which incurred the violent resentment of theologians and professors. In 1687 he published an "Introduction to Puffendorf," in which he deduced the obligation of morality from natural principles, and thus gave great offence. In the following year he became still more unpopular, by commencing a monthly literary journal, entitled "Free Thoughts; or, Monthly Dialogues on various Books, chiefly new," containing a severe attack upon many of his contemporaries. Complaints of the raillery of this satirical work were lodged before the ecclesiastical court of Dresden; and Thomas with difficulty escaped punishment. Some other satirical pieces inflamed the resentment of his enemies, and he was charged before the same court by the clergy of Leipsic with a contempt of religion. Soon after he published another satirical work "On the Divine Right of Kings," "A Defence of the Sect of the Pilgrims," and some other eccentric works of the same general character, for which he was threatened with imprisonment; but obtaining permission from the elector of Brandenburg to retire, he became a voluntary exile from Leipsic; and soon after was appointed public professor of jurisprudence, first in Berlin, and afterwards at Halle. In these situations he indulged his satirical humour, and his inclination for controversy, as long as he lived; persevering in his endeavours to correct and subdue the prejudices of mankind, and to improve the state of philosophy. He died at Halle, in the year 1728. Thomas was the author of several treatises on logic, morals, and jurisprudence, in which he deviates from opinions generally received; and his latter publications are, in many respects, inconsistent with the former. His principal philosophical works are, "An Introduction to Aulic Philosophy; or Outhines of the Art of Thinking and Reaoning," Leipf. 1688; "Introduction to Rational Philosophy," 1692; "A Logical Praxis," Hal. 1691; "Introduction to Moral Philosophy," 1692; "A Cure for irregular Passions, and the Doctrine of Self-knowledge," 1696; "The New Art of discovering the secret Thoughts of Men," "Divine Jurisprudence," "Foundations of the Law of Nature and Nations," "Dissertation on the Crime of Magic;" "Essay on the Nature and Essence of Spirit, or Principles of Natural and Moral Science," 1699; and "History of Wisdom and Folly." As a specimen of the peculiar tenets and maxims of this eccentric philosopher, we shall subjoin the following.

"Thought arises from images impressed upon the brain; and the action of thinking is performed in the whole brain. Brutes are destitute of facnation. Man is a corporeal substance, capable of thinking and moving, or endowed with intellect and will. Man does not always think. Truth is the agreement of thought with the nature of things. The senses are not deceitful, but all fallacy is the effect of precipitation and prejudice. From perceptions arise ideas, and their relations; and from these, reasonings. It is impossible
to discover truth by the syllogistic art. No other rule is necessary in reasoning, than that of following the natural order of investigation; beginning from those things which are best known, and proceeding, by easy steps, to those which are more difficult.

"Perception is a passive affection, produced by some external object, either in the intellectual sense, or in the inclination of the will. Intclence is that without which a thing cannot be perceived. God is not perceived by the intellectual sense, but by the inclination of the will: for creatures affect the brain; but God, the heart. All creatures are in God; nothing is exterior to him. Creation is extension produced from nothing by the divine power. Creatures are of two kinds, passive and active; the former is matter; the latter, spirit. Matter is dark and cold, and capable of being acted upon by spirit, which is light, warm, and active. Spirit may subsist without matter, but defines a union with it. All bodies consist of matter and spirit, and have therefore some kind of life. Spirit attracts spirit, and thus sensibly operates upon matter united to spirit. This attraction in man is called love; in other bodies, sympathy. A finite spirit may be considered as a limited sphere in which rays, luminous, warm, and active, flow from a centre. Spirit is the region of the body to which it is united. The region of finite spirits is God. The human soul is a ray from the divine nature; whence it derives union with God, who is love. Since the essence of spirit consists in action, and of body in passion, spirit may exist without thought: of this kind are light, ether, and other active principles in nature.

"Good consists in the harmony of other things with man and his several powers. The highest felicity of man consists in tranquil delight. The fountain of this delight is the rational love of man and of God. Internal love and reverence are all the homage which nature teaches us to pay to God. With respect to God, the two capital errors are atheism and superstition. Superstition is worse than atheism. The love of God is a supernatural affection, which prepares the soul for future felicity. The rational love of man comprehends all social virtues. Rational self-love includes self-preservation, temperance, purity, industrious, fortitude. To wise men, virtue is its own reward. Laws are appointed for the sake of fools, to conduct them to internal tranquillity, and external peace. Of fools, there are three classes; those who disturb external peace; those who do nothing to promote it; and those who do not enjoy internal peace. The first have need of authority; the second of authority and counsel; the third of counsel alone. The obligation of authority and law extends only to external actions, which are just when they are conformable to law: justice is therefore to be distinguished from virtue, which respects the internal man, and requires a conformity to the law of nature."

Brucker by Ensfild, vol. ii.

THOMAS'S Hospital. See Hospital.

THOMAS, S., in Geography, an island of the Atlantic, near the coast of Guinea, situated on the equinoxial line, of a circular form, about ten leagues in circumference, discovered by the Portuguez in the year 1640. The climate is salubrious, and at some seasons of the year the sky is even darkened by thick fogs, which are diffused by the winds that blow in the months of July and August. In this island the inhabitants have two winters, like those of other places that are under the same parallel, but without the cold that distinguishes that season in Europe. The rains continue from December to February; and spring begins with our summer, in the month of May. During the first three months of this period, the heat is insupportable, and the first settlers gradually inured themselves to the climate. The soil on this island is fertile and clayey, and mixed with chalk; but it is rendered fertile by the heavy night dews. The plants and shrubs, which it rapidly produces, are buried to ashes, and applied as the most beneficial manure to sugar-cane; which were first planted here by the Portuguez: in their endeavours to cultivate which they have been disappointed. Rice and millet succeed, and vines of the richest kind, as well as melons, cucumbers, figs, giner, and all sorts of roots, pulses, and pot-herbs, are cheaply reared, and they arrive at the utmost perfection. Yams are in this island a very wholesome and delicious diet. The land of this island is well watered, and much fertilized by its rivers and streams. In the centre is a high mountain, covered with wood and fruit-trees, whose summit is nevertheles always covered with snow. Its quadrupeds, birds, and fishes, are very various, and abundant; and St. Thomas would be equal to any spot in the globe, if its temperature corresponded to its other qualities. The inhabitants are the descendants of the Portuguez first settlers and the negroes, who are retained in the service of Europeans, and such as prefer a residence here to Angola. They are for the most part Roman Catholics, and extremely ignorant, superstitious, and bigotted. The ecclesiastical government is under the direction of the bishop, who is a suffragan of the archbishop of Lisbon. E. long. 8° 6'.—Alfo, a town of Hindoostan, on the coast of Coromandel. Here was formerly a powerful city, called "Meliapour," or "Melibour," the capital of the kingdom of Coromandel; but on the ruins of this city the Portuguez erected the lately city of St. Thomas. This is inhabited chiefly by weavers and dyers, who manufacture the best coloured ruffs in India. The Portuguez, who rebuilt this place in 1545, have raised it from a flat of defolation to a flourishing state, both with regard to its buildings and inhabitants. Whilft the Portuguez retained it, it was a bispopric under the archbishop of Goa; and they had several churches, besides monasteries, and a college for the instruction of the Portuguez and Malabar children. Here is also the famous church of St. Thomas the Apostle, where it is pretended that he was buried. (See Thomæns, and Christians of St. Thomas.) The city had seven gates, and was, on account of its situation, guarded by the sea on one side, and a chain of mountains on the other, very strong: nevertheless it was taken by the Moors after a long siege, and retained in their possession.—Alfo, a town of Germany, in the archduchy of Austria; 6 miles N.W. of Grein.—Alfo, a town of Savoy, in the county of Maurienne; 3 miles N. of Monfier.—Alfo, the principal of the Virgin Islands, in the West Indies, about six leagues in circumference, belonging to the Danes. It abounds with potatoes, millet, manioc, and mofl sorts of fruits and herbage, and especially sugar and tobacco, but is much exposed to the attacks of mosquitoes and other vermin. The English had formerly a spacious settlement in this island; and here is a safe and commodious harbour, with two natural mounds upon it, fitted for the reception of two batteries to guard its entrance. Nearly in the centre of the harbour is a small fort; and about 50 or 60 paces W. of it is the town, consisting chiefly of one long street, at the end of which is the Danish factory, with convenient warehouses. On the right side of this factory is the Brandenburgh quarter, containing two small streets, full of French refugees from Europe and the islands. Most of the houses are built of brick, and one story high. The trade of this small island is considerable, particularly in time of peace; as it is the staple for such articles of traffic as the French, English, Dutch, and Spaniards are not allowed to deal in publicly in their own islands; and
in war, their privaters bring their prizes hither for sale. N. lat. 12º 22'. W. long. 61º 30'.—Allo, the capital of Spanish Guiana, called "San Tomé," which is situated at the foot of a small mountain on the right bank of the Oro-noko. For its defence, a fort is placed opposite to the city and on the left bank of the river; it is surrounded by a number of houses, dependent, like the fort, on the province of Guiana. They call this place Port Raphael; and it is here the communication between Guiana and the provinces of Venezuela and Comana is found. Between Port Raphael and the city is seen the island called "Del Medio," or the Middle, because it is in the middle of the river. It is a rock, which, in its southern part, discovers itself in summer, and is under water in floods. The principal channel is between the city and this island: when the water is low it has 200 feet, and on the increase of the river 50 or 60 more.—Allo, a town of the United States of America, in South Carolina; 21 miles N. of Charleston.—Allo, a town of the island of Cuba; 130 miles W.S.W. of Havana.

Thomas de Caffite, St., a town of North America, in the government of Mexico, and province of Guatemala.

Thomas's Bay, a bay on the W. coast of Antigua.

Thomas's Creek, a river of South Carolina, which runs into the Great Pedee.

Thomas's Gulf, St., a bay on the Atlantic, on the W. coast of Africa. S. lat. 24º 50'.

Thomas's Head, St., a cape of England, on the N.W. coast of the county of Somerlet, at the mouth of the Severn. N. lat. 51º 20'. W. long. 73º 35'.

Thomas's Hospital. See Hospital. THOMASBRUCK, in Geography. See Thoms Bruck.

Thomasius, Jacobus, in Biography, a writer in history and philosophy, professor of eloquence in the university of Leipsic, and chiefly distinguished as the preceptor of the illustrious Leibnitz, was born at Leipsic in the year 1622. Having obtained distinction by his lectures and public theses in his native city, he was advanced to the office of co-rector, first of the college of St. Nicholas, and afterwards of that of St. Thomas. His erudition was extensive, nor was he less distinguished by his modesty and by his disinclination to controversy. Among his numerous works, the principal are "Antiquities of Philosophical and Ecclesiastical History;" "Dissertations on the Stoical Philosophy, and on other Subjects relating to the History of Philosophy;" and "A Dissertation on Literary Piagarium, with a List of 100 Plagiaries," all in Latin. He died in the year 1684. Brucker.

Moreri.

Thomasius, Christian, son of the preceding, an eminent jurist, was born at Leipsic in 1655. Having studied the law at Francfort on the Oder, he was made a doctor in that faculty in 1679; and returning to his native city, he attended the bar, and wrote some treatises on the law. He was the friend of Puffendorf. By opposing the scholastic philosophy in a German journal, commenced in 1688, he excited opposition, and raised against himself many enemies. Many circumstances occurred which increased the number of his adversaries, and at length he was denounced to the court of Dreden as a heretic and Calvinist. The dread of persecution induced him to withdraw to Berlin, and the King of Prussia offered him an asylum at Halle, where he intended to found an university. In this intitution he occupied the second chair of law, and on the death of Struycks, in 1710, he was advanced to the first chair. In 1713 he defended concubinage, and being denounced for this opinion by the theological faculty of Halle, orders were issued for proceeding against him criminally. But upon the examination of his theses, by commissioners, the proceedings against him were stopped. The dispute, however, continued; nevertheless he re-© to the post of privy-councilor to the king, and director of the university of Halle, and died in 1728. Moreri has given this character of Thomasius. "His views were vast; he aimed at the reformation of philosophy in general, and of the Peripatetic system in particular; and he unilaterally employed both the power of exhortation and the influence of example, in order to persuade the Saxons to reject the Arif- totelian system, which he had never read, and which most certainly he did not understand. The scheme of philosophy which he substituted in its place was received with little applause, and soon sunk into oblivion; but his attempt to overturn the system of the Peripatetics, and to restore the freedom of philosophical inquiry, was attended with remarkable success, made in a little time the most rapid progress, and produced such admirable effects, that Thomasius is looked upon, to this day, as the chief of those bold spirits who pulled down philosophical tyranny from its throne in Germany, and gave a mortal blow to what was called the sectarian philosophy in that country." Moreri's Eccl. Hist. Moreri.

THOMASSIN, Louis, an ecclesiastical writer, was born at Aix, in Provence, in 1619, and was admitted into the congregation of the Oratory in the fourteenth year of his age. He afterwards became professor of theology at Saintmur, and laying aside scholastic subtleties, adopted the method of teaching by the scriptures, fathers, and councils; and in 1654 he was called to the seminary of St. Magloire at Paris. His "Latin Dissertations on the Councils," were published by the desire of the archbishop of Paris, of which the first and only volume appeared in 1667, 4to. In the following year he published "Memoires fur la Grace," 3 vols., 8vo., in which work he attempts to conciliate the Greek fathers with St. Augustine. This was reprinted in 1682, with the addition of two memoirs. In 1678 he published the first volume of a work, entitled "De la Discipline Ecclesiastique," which was followed by a second volume in 1679, and a third in 1681. This work was translated into Latin, in 3 vols. fol., from respect to pope Innocent XI., and for the advantage of more unlimited circulation. His other works, which we can merely enumerate, were "Dogmata Theologic," 3 vols., 1680-89; "The Discipline of the Church and Christian Morality;" "On the Divine Service;" "On Feasts;" "On Fasts;" "On Truth and Falsehood;" "On the Unity of the Church;" "On Alms, Trade, and Usury;" "Methode d'enfeignir chrétienment la Grammaire, ou les Langues par rapport a l'Ecriture Sainte," 2 vols., 8vo.; and "Glosaire universelle Hebräique," which latter appeared after his death in 1697, folio.

Thomassin died in the year 1695, having for some time enjoyed a pension of 1000 livres granted to him by the French clergy, and of which he gave one half to the poor. One of his biographers characterizes him as "humble, modest, and mild, fond of study and retirement, and fuming disputes."—Although his reading was extensive, his erudition was not of the highest class, and it is said that his work on Discipline contains many mistakes where Greek authors are cited. Moreri. Gen. Biog.

THOMASTOWN, in Geography, a post-town of the county of Kilkenny, Ireland, situated on the river Nore, over which it has a fine bridge. The castle was built about 1180, by Thomas Fitzsaltanthy, from whom the town takes its Irish name of Ballymac-Andan; i.e. town of Anthony. It was a borough, and sent two members to parliament, but lost that privilege by the Union. The Nore is navigable to this town for
THOMISM, or THOMISM, the doctrine of St. Thomas Aquinas, and his followers the Thomists, chiefly with regard to predestination and grace. See his biographical article.

There is some doubt what the true, genuine Thomism is: the Dominicans pretend to hold pure Thomism; but there are others who distinguish the Thomism of St. Thomas from that of the Dominicans.

Others, again, make Thomism no other than a kind of Jansenism dilugued; but Jansenism, we know, has been condemned by the popes, which pure Thomism never was.

In effect, the writings of Alvarez and Lemos, were appointed, by their order, to lay down and defend before the holy see, the dogmata of their school, have since been reputed the rule of pure Thomism.

Those two authors distinguish four classes of Thomists: the first, which they reject, destroys or takes away liberty; the second and third do not differ from Molina. The lat, which Alvarez embraces, admits a physical premonition, or predetermination, which is a complement of the active power, by which it palies from the first act to the second; that is, from complete and next power to action.

This promotion, they hold, is offered in sufficient grace: sufficient grace is given to all men; and that they have a complete, independent, next power not to act, and even to reject the most efficacious grace.

THOMISTS, a sect of school divines, who maintain Thomism.

The avowed antagonists of the Thomists are the Scotists.

THOMITES. See THOMISTS.

THOMMDAMM, in Geography, a town of the duchy of Saxe Lauenburg, on the Elbe; 25 miles S.E. of Lauenburg.

THOMPSON, Sir Benjamin, Count of Rumford, in Biography, distinguished by his industry and zeal in the promotion of science, and in devising and executing schemes of public utility, was born at the village of Rumford, in New England, in the year 1752; and with the assistance afforded him by a professor of natural philosophy in the American University of Cambridge, acquired in early life such a degree of knowledge as enabled him to give instruction to others. By an advantageous marriage, while he was young, his advancement was accelerated, so that he obtained the rank of a major in the militia of his native district. When the war broke out between the mother-country and her colonies, he took part with the former, and by means of his local knowledge, he rendered himself useful to the British generals in America. In course of time he repaired to England, and recommending himself to Lord George Germain, the chief minister in the American department, he obtained a place in his office. Towards the close of the war, the same nobleman, with a view of securing for him a permanent provision, sent him to New York, where he raised a regiment of dragoons, and by being appointed lieutenant-colonel, became entitled to half-pay. Upon his return to England, his majesty, in 1784, conferred upon him the honour of knighthood; and for some time he occupied the post of one of the under-secretaries of state. Soon after he made a tour to the continent, and being warmly recommended by the prince of Deux-Ponts, afterward king of Bavaria, to his relation the reigning elector-palatine, and duke of Bavaria, he was admitted into his service, and occupied an eminent station. He had thus an opportunity of effecting many important and useful reforms in the departments of the state, both civil and military. His attention was at this time particularly directed to the suppression of mendicancy, which prevailed not only at Munich, the capital, but through the whole country, to an extent that rendered the restraint and abolition of it a very difficult and hazardous undertaking. With this view he formed a plan for employing all mendicants; and having provided a building for their reception, and materials for their labour, he fell into the streets of the city on the 1st of January 1790 (New-year's day being set apart for giving alms in Bavaria), accompanied by the field-officers of the garrison and the magistrates of the city; and arresting with his own hand the first beggar that came in his way, his attendants followed his example, so that before night not a single beggar was to be seen in the whole metropolis. Those that were arrested were conducted to the town-hall, where their names were inscribed, and then ordered to repair to the work-house, where they would find employment, and a sufficiency of wholesome food. In consequence of these prompt and vigorous measures, the evil was redressed, and the mendicants were led by habit to prefer industry to idleness, and decency to the fifth, rags, and squalid wretchedness attendant on beggary. He also introduced into Bavaria the culture and use of potatoes. For all these services Sir Benjamin was decorated by the Bavarian sovereign with several orders, promoted to the rank of lieutenant-general, and created a count by the title of his native place, Rumford. During his abode at Munich, he commenced his experiments upon the improvement of fire-places, with respect to the economy of fuel, and the convenience of cooking; and also his plans for a cheaper and more nutritious mode of feeding the poor, which gave him peculiar celebrity. Having quitted Bavaria in 1799, he resided for some time in this country, pursuing a variety of experiments on the nature and application of heat, and the construction of chimneys, grate, and fire-places. He also promoted science both by his own researches and experiments, and by liberally exciting emulation in others, upon a more enlarged plan. For the latter purpose, he transferred, on an occasional visit to this country in 1796, to the Royal Society of London, of which he was a member, 1000l. 3 per cent. Rock, the interest of which was to be applied every second year as a premium to the author of the most important discovery on the subjects of heat and light in any part of Europe during the two preceding years; the preference to be always given to such discoveries as, in the opinion of the president and council, tend most to the benefit of mankind; which indeed was the leading object of all his researches. He also suggested the plan, and assisted in the formation of the Royal Institution, which has produced several other establishments of a similar nature.

In the year 1802 he left England for Paris, which became his fixed residence, and where he married the widow of the celebrated chemist, Lavoisier; but this connection proving unhappy, it was soon terminated by a separation. The count afterwards retired to a country-house at Auteuil, about four miles from Paris, which he rendered a delightful habitation. Besides the improvement of his grounds, in which he took great pleasure, he pursued a variety of philosophical and mechanical researches. With his superior talents he combined certain peculiarities, and a tenaciousness, not to call it obstinacy, of temper, which prevented his enjoying the pleasures of social intercourse. Although he disapproved both the character and politics of the French, he preferred their climate to every other; and he obtained permission from the king of Bavaria to continue in France, and to enjoy his pension of 1200l. a year. He lived in a state of retirement, and also in a course of abstruse researches, which
which debilitated his constitution, and rendered it incapable of resisting an attack of small fever, by which he was carried off in August 1814, in his 63d year. By his first wife he had one daughter, now resident at Boston.

Although Count Rumford was not a learned man, he acquired by his knowledge of the French and German languages, and by his extensive acquaintance, and frequent conversation with literary men, a large stock of literature and science. His peculiar talent was that of contriving instruments, and devising experiments for facilitating his researches in those branches of economics and scientific philosophy to which his attention was directed. He was also distinguished by a readiness and perseverance of pursuit, which were favourable to the attainment of the objects which he had in view. As to his person, his stature was above the middle size, his countenance was dignified and pleasing, and his manner and tone of voice mild and gentle. He was, nevertheless, ambitious of distinction, and too prone to dictate in transactions with regard to which other persons were jointly concerned with himself. The papers which he communicated both to the Royal Society and French Institute, and which are published in their Transactions and Memoirs, are numerous. The only separate publication of count Rumford was a series of "Essays, Experimental, Political, Economical, and Philosophical," commencing with the year 1796, and continued to 1799 in number, and occupying 4 vols.

THOMPSON, in Geography, a town of America, in the state of New York, the capital of Sullivan county; bounded N. by Wawarsing and Neverlink, E. by Mamakating, S. by Deerpark in Orange county, and W. by the Montauk, which separates it from Long Island, Bethel, and Liberty. Its length N. and S. is about 34 miles, and breadth 12. The principal settlements are Thompson, Monticello, Bridgeville, and Concord. The whole area of Thompson is 135,500 acres; and the population by the census of 1816, consisted of 1290 persons. The principal streams are the Neverlink, Montauk, and Sheldrake. Also, a township of Connecticut, in the county of Windham; 20 miles N. W. E. of Windham: the place contains 2457 inhabitants.

THOMPSON'S Creek, a river of South Carolina, which runs into the Atlantic, N. lat. 34° 44'. W. long. 79° 46'. Also, a river of West Florida, which runs into the Mississippi, N. lat. 30° 50'. W. long. 91° 30'.

THOMPSON'S Harbour, a harbour in Hudson's Bay. N. lat. 60° 20'. W. long. 78°.

THOMPSON'S Island, a small island of Upper Canada, at the entrance of the river St. Claire.

THOMPSON'S Borough, a town of America, in the district of Maine; 30 miles N. E. of Portland.

THOMS, a town of Hungary; 11 miles S. W. of Camnica.

THOMSON, James, in Biography, a popular English poet, was born at Ednam, near Kelso, in Scotland, in the year 1720, being one of the nine children of the minister of that place. Whilst he was at school at Jedburgh, he manifested no powers superior to those of other boys, except in a taste for poetry, which he betimes indulged, and which introduced him, during his vacations, to the society of some neighbourly gentlemen. Of his productions, however, he thought so humbly, that on New-year's day he committed to the flames those of each preceding year. From Jedburgh he was removed to the university of Edinburgh, where he persevered in the cultivation and exercise of his poetical talents; but upon the death of his father, he complied with the wishes of his friends by entering on a course of divinity. His probationary exercise was the explanation of a psalm, which was written in a style so splendid, as to incur reproof from the theological professor, as being altogether unfuitable to the audience which might probably attend his future ministry. Having no great inclination for the office, this admonition induced him to devote himself entirely to poetry: and after spending some time as private tutor in the family of Lord Binning, he determined, at the suggestion of a lady, who was his mother's friend, to try his fortune in London. In 1725 he came to London, and meeting with his college acquaintance Mallet, he shewed him his poem of "Winter," in an imperfect state; who advised him to finish and publish it. Mr. Millar, a well-known London bookseller, bought it for a small sum, and published it in 1726. At first it attracted little attention; but Mr. Whateley, a gentleman of acknowledged talents, giving a favourable account of it, brought the poem and its author into notice. The author was introduced to Pope, and recommended by bishop Rundle to lord chancellor Talbot. In 1727 he published his "Summer," and in the same year "A Poem faced to the Memory of Sir Isaac Newton," just deceased, and also his "Britannia." His "Spring" was published in 1728; and in 1730 the Seafons were completed by "Autumn," and published collectively. In 1738 Thomson, aspiring to the popularity and emolument of dramatic composition, succeeded in introducing upon the stage of Drury-lane his tragedy of "Sophonibla." Its reception, however, was not very flattering. Soon after he was appointed, by the recommendation of Dr. Rundle, travelling companion to the Hon. Mr. Talbot, the eldest son of the chancellor, and had an opportunity of visiting most of the courts and countries of the European continent. During this tour, the idea of his poem on "Liberty" was suggested to him, and he employed two years in completing it. In consequence of this excursion, he obtained, by the intered of Mr. Talbot, the place of secretary of the briefs, which, being almost a sinecure, afforded him leisure for his private literary pursuits. His poem on "Liberty" was more quietly received than the nature of the subject led him to expect. When lord Hardwick succeeded the lord chancellor Talbot, Thomson lost his place; but upon being questioned by the prince of Wales, to whom he was introduced, by Mr. (afterwards lord) Lyttelton, as to his circumstances, a pension of 100l. a year was granted to him.

Upon the introduction of his second tragedy, "Agamemnon," to Drury-lane, in 1738, he was so anxious concerning its success, that he is said to have been thrown into a cupulous periphrasis. His "Edward and Eleonora" was prevented from appearing by the interference of the lord chamberlain. The "Marlow of Alfred," performed before the prince at Cliefden-bouge, in 1746, was the joint production of himself and Mallet; and in this piece was introduced the famous song of "Rule Britannia," the composition of one or other of these two persons. The most successful of Thomson's dramatic pieces was his "Tancred and Sigismunda," which appeared at Drury-lane in 1745; but his "crowning performance," as one of his biographers calls it, was "The Castle of Indolence," published in 1746. Our poet was now rendered independent by the interest of Mr. Lyttelton, who obtained for him the office of surveyor-general of the Leeward islands, which, after payment of a deputy, yielded him about 300l. a year. Death, however, in consequence of a fever occasioned by a cold, deprived him, in August 1748, of the comparative affluence derived from this appointment. His remains were interred in Richmond church, without any memorial; but in 1762 a monument was erected in Westminster Abbey, the expense of which was defrayed out of the profits of an edition of his works, published by Mr.
Mr. Millar. His "Coriolanus" was brought on the stage by his executors, in 1749, for the benefit of the surviving branches of his family. The prologue, composed by Lyttelton, was very feebly delivered by Quin, the intimate friend of Thomson.

Thomson's person was large and awkward, and his countenance unanimated; nor did his appearance or manner indicate genius or refinement. With select friends, however, he was gay and cheerful, and universally beloved for the kindness of his heart, and freedom from those passions that sometimes disgrace men of literary character. He was indolent and self-indulgent in his habits; although "no poet," as his biographer says, "has deferred more praise for the moral tenor of his writings. Unbounded philanthropy, enlarged ideas of the dignity of man, and of his rights, love of virtue, public and private, and a devotional spirit, narrow by no views of sect or party, give soul to his verse when not merely descriptive; but no one can rise from the perusal of his pages without melioration of his principles or feelings." His poetical merit is most confinuous in his "Seasons," and though Dr. Johnson charges it with a defect of method, yet as a history of the year through its changes, depending upon the vicissitude of the seasons, it adheres sufficiently to its general plan for preserving a continuity of subject, with due allowances for the moral and philosophical digressions by which it is varied. Its dictum, though somewhat laboured, is energetic and expressive. Its verification, though it does not indicate a nice ear, is seldom unpleasantly harsh. Upon the whole, continues the biographer now cited, "feerely any poem has been more, and more deservedly, popular; and it has exerted a powerful influence upon public taste, not only in this country, but throughout Europe. Thomson's other pieces in blank verse display a vivid imagination, a comprehensive underlaying, and exalted sentiments, but are not marked with any peculiar character. The addition to his fame as a poet has principally arisen from his "Cattle of Indolence," an allegorical composition in the manner of Spenser." Of his tragedies, the best that can be said is that they maintain a respectable rank among the productions of the modern school of the drama, which, when they disapper from the stage, are seldom taken up in the closet. Murdoch's Life of Thomson. Johnson's Lives of the Poets. Gen. Biog.

THONE, in Geography. See TONE.

THON, in Agriculture, a term signifying somewhat damp and cold, not thoroughly dry. Also fluid or limber, as undried hay, corn, or straw in a moist flafe.

THONGTONG, in Geography, a town of the Birman empire; 10 miles N.W. of Raynangong.

THONNA, a town of Saxony, in the principality of Gotha; 12 miles from Gotha.

THONNAUSTAFF, a town of Bavaria, near the Danube; 3 miles from Ratibon.

THONNES, or THONNEX, a town of France, in the department of the Leman; 9 miles S.E. of Annecy.

THONON, or TOXON, a town of France, in the department of the Leman, late capital of the duchy of Chablais, on the lake of Geneva, situated on a plain a little elevated. It is not envioned with walls, but was formerly defended by a strong castle, surrounded with lofty towers, where Amadeus VIII. and IX. and Louis, dukes of Savoy, resided for some time. The castle was burned and demolished, in the 16th century, by the Bernois. It has one parish church and several convents; 18 miles N.E. of Geneva. N. lat. 46° 18'. E. long. 6° 32'.

THOPH. See MACHUL and SISTRUM.

THOPHAILE, ABU CIAPAR, in Biography, a celebrated Peripatetic philosopher and physician, was a native of Seville in Spain, and preceptor to Maimonides and Avemroes. This philosopher employed the Ariflotian doctrine to the purposes of enthusiasm, in the elegant tale ill extant of "Hai Ebr Yockdan?" a youth who, having been exposed when an infant on the sea-coast, was nourished by a hind, and grew up in the woods, without any intercourse with human beings; and who, by the unaided exertions of his own powers, attained to the knowledge of things natural and supernatural, and arrived at the felicity of an intuitive intercourse with the divine mind. This piece is written with such elegance of language and vigour of imagination, that, notwithstanding the improbability of the story, it has been universally admired. It exhibits a favourable specimen of Peripatetic philosophy, as it was taught among the Saracens; and, at the same time, affords a memorable example of the unnatural alliance, which was now so generally established between philosophy and fanaticism. This work was translated by Edward Pocock, jun. from the Arabic into Latin, under the title of "Philosophus Autodidactus," and printed in 1601 at Oxford, in 1700. It was also translated into English by S. Hoadley, professor of Arabic in Cambridge, ed. Lond. 1711, 5vo., and also into Dutch. Thophaile is said to have written several other works, and died at Seville in 1175. Brucker by Enfield. Gen. Biog.

THOR, in Mythology, a deity worshipped by the ancient inhabitants of the northern nations; particularly by the ancient Scandinavians and Celts. Julius Caesar (Com. lib. vi. c. 17.) speaks of a god of the Gaals, who was charged with the conduct of the atmosphere, and presided over the winds and tempests, under the name of Jupiter; but Lucan gives him a name, which bears a greater resemblance to that of Thor, viz. Tarantus, a word which, to this day, in the Welsh language, signifies thunder. The authority of this deity extended over the winds and seafons, and particularly over thunder and lightning. In the sytem of the primitive religion, the god Thor was probably one of those genii, or sibyls, sprung from the union of Odin, or the supreme Deity, and the Earth. The Edda calls him the most valiant of the sons of Odin; and in the Icelandic mythology, he is considered as the defender and avenger of the gods. He always carried a mace, or club, which, as often as he discharged it returned to his hand of itself; he grasped it with gauntlets of iron, and was poffessed of a girdle which had the virtue to renew his strength as often as was needful. With these formidable arms he overthrew the mounlers and giants, when the gods sent them to oppose their enemies. Thor, Friga, or Freyja, and Odin, composed the court or supreme council of the gods, and were the principal objects of the worship and veneration of all the Scandinavians. The Danes seem to have paid the highest honour to Odin. The inhabitants of Norway and Iceland appear to have been under the immediate protection of Thor; and the Swedes chose for their tutelar deity Freyja, or Frey, an inferior divinity, who, according to the Edda, presided over the seafons of the year, and bellowed peace, fertility, and riches.

There was a day consecrated to Thor, which still retains his name in the Danish, Swedifh, English, and Low Dutch languages, viz. Thursday. This word has been rendered into Latin by dies Jovis, or Jupiter's day; for this deity, according to the ideas of the Romans, was the god of thunder. Mallet's North. Ant. vol. i. p. 95.

THOR, Le, in Geography, a town of France, in the department of the Mouths of the Rhone; 9 miles E. of Avignon.

THORA, a town of Hindostan, in the circuit of Rantamour; 45 miles S. of Rantamour.

THORA,
THORA, in Botany. See Aconitus.

THORACIC, in Anatomy, an epithet applied to various parts in and about the chest, as to the aorta above the dia-
phragm, and to some branches of the axillary artery (see Artery); to some branches of the axillary plexus of nerves (see Nerve); to the trunk of the absorbing system of vessels. See Anomeraents.

THORACICI, in the Linnæan System of Ichthyology, the name of the third order of bony fishes, respiring by means of gills only; the character of which is, that the bronchia are oblique, and the ventral fins are placed underneath the thorax. This order in Gmelin's edition of the Linnæan system, includes nineteen genera, and a good number of species. The genera are, the cepala, cebene, coryphaena, gobius, cottus, scophena, zeus, pleurometes, chabdo, sparus, scarus, labrus, seiana, perca, saltuscolus, flomer, centrogofer, mullet, and tripla.

THORÆ RADIX, in the Materia Medica, the name of a root which keeps its place in the catalogues of official simples, but is seldom used. See Aconitus and An-
thora.

The plant which produces it is the thoræ Waldensteii of Gerard. It is kept in the gardens of the curious, but grows wild in the mountainous parts of Germany. The root is composed of a number of granules or small lumps, like that of the common ranunculus; the leaves are roundish, and stand on small pedicles, and the flaks are about six inches high, and the flowers yellow, and like those of our common wild ranunculuses.

The root is acrid and corrosive, and the juice of the leaves is said to poison animals, and to have been used by the ancients for that purpose.

THORAME, in Geography, a town of France, in the department of the Lower Alps; 13 miles E. of Digne.

THORAX, in Anatomy, that division of the skeleton which contains the bones forming the cavity of the chest; or it is used to denote the cavity of the chest. See Lung, where the bones and their articulations are described, as well as the cavity they form, and its contents.

THORAX. For an account of the operation of tapping, refer to Empyema, Paracenthes, and Wounds of the Thorax.

The subject of wounds of the chest will be found in the article Wounds.

THORDO, DIACONUS OR LEGIFER, in Biography, de-
scended from an ancient family, was provincial judge in North Jutland, and flourished in the time of Waldemar III., or about the year 1340. He was the author of the following work; "Constitutio Voldemari Regis, per Thordem Regiferum, &c." Ripis, 1564; et Hav. 1568, 4to; translated into Latin together with Waldemar's Jutland Laws, and afterwards pub-
lished in Ludwigs' "Reliquiae MSS." tom. xii. and also in German by Eric Krabbe, in "Weltphal's Monuments." Gen. Bio.

THORDSEN, or THEODORI STURIA, called also Frode or Polyhjoter, was born in Iceland, about the beginning of the 13th century. His father was Thordur Sturison, brother to the celebrated Snorro. (See Sturluson.) He is represen-
ted to be one of the greatest Icelandic poets of his time, as well as an eminent lawyer and historian. His talents excited enemies, so that he was forcibly carried away from the island in 1263, and conveyed to Norway, where he was favourably received by the king Magnus Lagebeater, ad-
mitted into his council, and appointed his historian and da-
pifer, one of the highest offices at the Norwegian court. Afterwards, however, he returned to Iceland, and having been chief justice of the country for many years, died in

1284. His works are "Landnana Saga," or "Libor Ori-
ginum Islandie," published entire by bishop Thordur Thor-
fakar, Skalholt, 1688, 4to., and by J. Finnezus, Hav.

1774, 4to.—A continuation of "Sturlunga Saga," or the history of the Sturia family, and almost the whole of Ice-
land, during his time, which was begun by the learned bishop Brand:—" The History of King Haager Haagen-
fen," published at the expense of the crown-prince Frede-
ric:—" The History of King Magnus Lagebeater," com-
piled from the public records of the kingdom, the greater part of which has been lost. Gen. Bio.

THORESBY, RALPH, an eminent antiquary, the son of a considerable merchant of an ancient family at Leeds, where he was born in the year 1658. His father belonged to the body of Presbyterians, and being addicted to anti-
quarian studies, founded the collection entitled "Museum Thorubresianum." The subject of this article was intended for a mercantile profession; and in order to complete his edu-
cation, begun at Leeds, and prosecuted in London, he was sent, in his twentieth year, to Rotterdam, to acquire the Dutch and French languages. But his father dying in 1679, he succeeded him in business, married, and settled in his na-
tive town. To antiquarian researches, for which his father's example had given him an early taste, he devoted much time and attention. In the earlier period of his life he had been an occasional confidant, in common with many of those who were called Dilleniers, and disgrusted by the indiscriminate zeal of his patron in mature life, as well as probably influenced by his diocesan, archbishop Sharp, he joined in full commu-
nion with the established church. His connection and cor-
respondence with persons engaged in similar pursuits with his own were gradually enlarged; and upon communicat-
ing, by Dr. Martin Lijfer, an account of some Roman anti-
quities discovered in Yorkshire, to the Royal Society, he was admitted a member of that learned body in 1697. In 1714 he published a work in which he had been long engaged, containing a history of his native town, and entitled "Du-
tus Leodenis; or the Topography of Leeds, and Parts adja-
cent," together with a catalogue of the antiquities, &c. contained in the Museuim Thorubresianum. An historical part, to which he often refers, and comprehending a view of the state of the northern districts of this kingdom in remote ages, was left in MS. continued to the sixh century; which MS. being communicated to the editors of the Biographia Britannica, was by them printed entire in the article "Tho-
rebey." He published also "Vicaria Leodenis, or the His-
story of the Church of Leeds," Lond. 1724, compr-
prehending observations on the origin of parochial churches, and the ancient manner of building them, together with biographical memoirs of several clergymen. In the fol-
lowing year he was feized with a paralytic affection, which ter-
minated his life at the age of sixty-eight years. Possessing an extensive acquaintance with the history of his country, genealogy and heraldry, and ancient coins and medals, he was always manifestly disposed to assist those who were en-
gaged in works of the antiquarian and biographical descrip-
tion. The sentiments of Mr. Thorubey were liberal and Catho-
lic; his manners regular, and his discharge of social and religious duties exemplary. Gen. Bio.

THORIGNY, in Geography, a town of France, in the department of the Channel; 6 miles S.E. of St. Lo.—
Also, a town of France, in the department of the Yonne; 18 miles S.S.E. of Provins.

THORLASKEN GUDBRAND, in Biography, an Ice-
landic writer and prelate, was born at Stadarakke, in the diocese of Holm, in 1542. In 1561 he was sent to the university of Copenhagen; in 1564 he became rector of the school.
school of Holm; and in 1570 he was appointed bishop of that diocese. With a view of diffusing knowledge, he established a printing-press, first at Rupenfel, and afterwards at Holm, which he personally superintended. He was one of the most learned of the Icelandic Bishops, but too arbitrary in the exercise of his episcopal functions. He died in 1629, in the 87th year of his age. Many considerable works, partly his own, and partly those of others, issued from his press. He also constructed a map of Iceland, which was engraved by Ortollus. Gen. Biog.

THORN, in Geography, a city of Prussia, situated on the Vistula, formerly the chief city of Polich Prussia. It was founded by Herman Bolek, first grand-master of the Teutonic order, who built the castle of Thorn in 1235. In the following year, the foundation of the town was laid; but the building was discontinued in 1235, on account of the inconvenient situation, and Thorn was built about a German mile farther up the river, on the spot where it now stands. It is supposed to have been called Thorn, because the knights of the Teutonic order, by building this city, opened themselves a thor or door into Prussia. When the knights of the Teutonic order enormously abused their power throughout all Prussia, Thorn was the first city which formed the noble scheme of shaking off their oppressive yoke. The inhabitants then put themselves under the protection of Casimir the Great, King of Poland, upon advantageous conditions, as a free city. Thorn has ten gates, and is divided into the Old and the New Town, each of which had formerly its respective council, magistracy, and police. But, in 1454, they were incorporated into one city. They are, however, separated from each other by a wall and moat within the town; and without, they are defended in common by a fine double wall and moats. Thorn was formerly strongly fortified; and it gradually improved its advantageous situation, so as to become a place of very considerable trade, and one of the principal of the Hanse towns. It likewise carried on an extensive commerce in the Baltic, independently of the other cities of that confederacy, for before the river widened so much, and consequently became shallower, ships of burden could come up to the very city. From various causes, in little more than half a century, Thorn greatly declined from its flourishing condition; for it surrendered by capitulation, in 1655, to Charles Gustavus, king of Sweden; and, in 1658, after a vigorous siege, it was taken by the Poles and Brandenburger. In 1793, it was bombarded and taken by Charles XII. king of Sweden, who not only extinguished it by the heaviest contribution, but also demolished all the fortifications, contrary to the articles of capitulation. Between the years 1708 and 1710, great numbers of its inhabitants were swept away by the plague. In the following years, the revenues of the city suffered considerably by the confederations in Poland, and no less by the commotions occasioned by the competitors for the crown of that kingdom. In 1793, some Prussian troops entered this town, and from that time it has formed part of the dominions of that king; the king of Prussia taking possession of Thorn and Danzig, together with the palatinate of Posenia, Kalisz, &c. agreeably to a proclamation, published on the 25th of March. The loaf, ginger-bread, &c. of Thorn, are every where in great request; and, accordingly, great quantities of them are exported. The apple-juice that grows wild on some of the city lands, is not inferior to that which is cultivated with so much care in other countries; 70 miles S. of Danzig. N. lat. 52° 55'. E. long. 18° 30'.

THORN, or Thoren, a town of France, in the department of the Lower Meuse. It had a noble abbey, whose superior was a princess. This abbey was affeles in the matricula at one horse or twelve florins; 7 miles S.W. of Ruremond.

THORN, in Botany, a name generally given to all trees, or the larger kinds of shrubs, which are armed with spines or prickles, but more particularly applied to the Linnaean genus CRTAGUS, now sunk in MESPILUS. (See these articles.) Otherwise this name is almost as vaguely applied as its Greek and Latin synonyms, θρίηνος and πένθος, neither of which is strictly appropriated to any one plant, or family of plants. Accords in Dioclesides, is the name of that well-known herb, whose leaves compose the ornamental part of a Corinthian capital, and which is the Brant-urine, or Acantbus of modern botanists, and as well as of the generality of writers. But he applied the same likewise to a kind of thistle. The Acantbus of Virgil can scarcely be anything else than the Common Holly, Ilex Aquifolium, though we do not find that this idea has occurred to his critics or illustrators. This shrub, so abundant in Italy, cannot be traced, under any other name or allusion, in the poet; while the bright aspect, the farron or scarlet colour, the plant twigs of his Acantbus; but, above all, its being evergreen and bearing berries, Georg. 2. 119, and subjected in winter to the fhears of the gardener, i. e. the Acantbus of Virgil, as circumstances strikingly appropriate to the Holly, not to the Brant-urine, though the name may allude to the prickly foliage of either.

THORN-Apple. See Datura, and Datura Stramonium.

THORN, Black, or Sloe-tree, a species of the prunus, called prunus fayaefris. See PRUNUS and SLOE.

THORN, Box. See Lycium.

THORN, Buck. See Rhamnus, and Rhamnus Catharticus.

THORN, Christ's. See PALIURUS and RHAMNUS.

THORN, Cockspur. See CRTAGUS, MESPILUS, and PYRUS.

THORN, Egyptian, a name sometimes applied to a plant which is armed with strong thorns or prickles, which is said to have been lately found to make a good hedge-plant when kept low by being well cut in. It is also a very ornamental shrubby tree-plant for pleasure-gardens. See ACACIA.

THORN, Evergreen. See MESPILUS and PYRUS.

THORN, Glassabbury, a variety of the Hawthorn. See CRTAGUS and MESPILUS.

THORN, Goat's, a species of Astragalus; which see. See also TRAGACANTHA.

THORN, Haw. The fruit of this thorn has been found useful by farmers in feeding team and other horses. See CRTAGUS and MESPILUS.

THORN, Lily. See CATESBEA.

THORN, Purging. See RHAMNUS.

THORN, Scorpion's, a species of Ules; which see.

THORN, Spanish Hedge-hog, a species of Anthis; which see.

THORN, White, a species of CRTAGUS; which see. See also MESPILUS.

THORN, in Vegetable Physiology. See SPINA and FULCRA.

THORN-Hedges, in Agriculture, a term often applied to such as are made of that plant, whether of the white or black kind. They in most cases form the best fences. See FENCE, QUICKSET, QUICKSET-HEDGE, &c.

THORNBACK, in Ichthyology, the English name of a species of ray-fish, the raiia clavula of Linnaeus, priskly on the back, and with tubercle teeth, and a transverse caristle in the belly: the young fish have very few spines on them, and their backs are often spotted with white, and each spot encircled with black. (See RAIa.) This species frequents
frequents our sandy shores, is very voracious, and feeds on all sorts of flat fish, and is particularly fond of herrings and saus-cells, and sometimes eats crustaceous animals, such as crabs. The thornbacks begin to generate in June, and bring forth their young in July and August, which (as well as those of the skate) before they are old enough to breed, are called maidens. They begin to be in season in November, and continue to later than skate; but the young of both are good at all times of the year. Pennant.

THORNBURGH, in Geography, a town of Virginia; 74 miles S. of Washington.

THORBURY, an ancient market-town in the lower division of the hundred of the same name, in the county of Gloucester, England; is situated 24 miles S.W. from the city of Gloucester, and 182 miles W. by N. from London. The town consists particularly of three streets, in the form of the Roman Y, "having first," says Leland, "one long stretre, and two horns goynce owt of it." The corporation is composed of a mayor, twelve aldermen, and a town-Clark; but the power of these offices is become much limited by difufe. A weekly market is held on Saturdays, but is not much frequented: here are three annual fairs. The church is spacious and handsome: the tower is lofty, and ornamented with rich open-worked battlements, and eight pinnacles. The population, as returned under the act of the year 1811, amounted to 1083; the number of houses to 216. At the north end of the town are the remains of an unfinished castle, which was commenced by Edward Stafford, duke of Buckingham, but stopped when he was beheaded in 1522. This castle may be considered as particularly deserving notice, from its aforning some interesting specimens of the last gradation of castellated architecture. The former splendour of Richmond and Nonfuch, which were contemporary with it, are known only by description and engravings; and Hampton Court, though it rofe under the hands of Wolley at the fame period, is certainly less rich in the minute and capricious ornaments peculiar to the buildings of Henry VII. and his successor. A small part most reembling Thornbury, is seen at Windsor Castle, in an addition made by the first-mentioned sovereign. It is evident, from a survey made in the year 1582, that the whole southern side was habitable, and that it confifted of several chambers, of magnificent dimensions. The tower, the walls of which are perfect, was divided into four rooms, the duke's own apartments; this stands at the south-west angle of the castle. The duke was meditating the completion of the quadrangle which would have included an area of two acres and a half, when his fatal attainer closed his views for ever. Within the circuit walls twelve acres were inclosed: annexed to them are small rooms, intended as barracks for soldiers. In the reign of Elizabeth, the principal timbers were taken away; and time has forwarded the dilapidation. A singular coincidence has been remarked between the front of Thornbury castle and that of Christchurch, Oxford; and it appears as if the rivalry of the duke and cardinal Wolley was exerted even in their architecture. — Beauties of England and Wales, vol. v. Gloucestershire; by J. Britton and E. W. Brayley. Lyfons's "Gloucestershire Antiquities," folio.

THORNE, a market-town in the lower division of the wapentake of Strafford and Tickhill, in the West Riding of the county of York, England; is situated near the south bank of the river Don, at the distance of 10 miles N.E. from Doncaster, 29 miles S. by E. from York, and 167 N. by W. from London. The town appears to be in a progressive state of improvement: it carries on a considerable commerce by the Don; and vefiels trade regularly to London. Ships of a size sufficiently large for the coaling trade, are built at the suburb called Hangman Hill, on the banks of the river, which is also the landing-place for all the merchandise. A canal cut from the Don to the Trent passes within a furlong on the west side of the town. A weekly market is held on Wednesdays; and two fairs annually, each of three days continuance, for horned cattle, woolen cloth, &c. According to the population returns of the year 1811, Thorne contained 637 houses, the number of inhabitants being 2715. The country about Thorne is for the most part fertile; but low, flat, and totally unpicturesque. On the east side of the town is a field of rich sandy loam, and more elevated than the other lands in the vicinity. Beyond this are vast moors, which however are mostly drained and inclosed.

At the distance of about three miles westward from Thorne, and on the Doncaster road, is Hathfield, a large village, famous in the annals of history for the battle fought there A.D. 633, by Edwin, the first Christian king of Northumbria, against Cadwalla, king of Wales, and Penda, the Pagan king of Mercia. This conflict, which was extremely fantastic, terminated fatally for the Northumbrians; their monarch, and his eldest son Offred, were slain, their kingdom subdued, and their country laid waste. This village was the birth-place of William de Hathfield, the second son of king Edward III. The extensive level of Hathfield Chase is laid to contain within its limits 180,000 acres, of which nearly one-half was formerly a great part of the year under water. It was sold by Charles I. to Cornelius Vermuyden, a naturalized Dutchman, without the consent of the commissioners and tenants, to drain and cultivate; which he effected at the expense of about 300,000l., but the affair involved him in ruinous law-suits. In the year 1811, an act was obtained for inclosing between eight and nine thousand acres of rich common in this neighbourhood, which must be ultimately productive of great public and private advantage. — Beauties of England and Wales, vol. vi. Yorkshire; by J. Bigland.

THORNE, a small island of Denmark, in the Little Belt, near the island of Funen. N. lat. 59° 15'. E. long. 9° 53'.

THORNESS BAY, a bay on the N.W. coast of the Isle of Wight, between Newtown and Cowes.

THORNEY, a market-town in the north part of the hundred of Withford, and county of Cambridge, England; is situated in the north-west side of the county bordering on Northamptonshire, 10 miles W. from March, 5 miles S.E. from Crowland, and 84 miles N. from London. It is surrounded by low and fertile grounds, which are now in a very complete state of drainage, the expense of which is defrayed by an annual tax of about a shilling per acre. Its ancient appellation was Ankeridge, which it obtained from the ancients who dwelt in a monastery, or rather an assemblage of hermitages, founded here about the year 662, by Saxulph, the first abbot of Peterborough. The Danes destroyed these hermitages in 870, and the place lay waste till 972, when Etheledwold, bishop ofWinchefter, founded on the site an abbey for Benedictine monks, which became an opulent estabishment, and ranked among the mitred abbeys. In the year 1085, the ancient church was taken down, and a new one commenced by the abbot Guter, but it was not completed till 1128. This structure poffessed considerable magnificence, and was, according to Brown Willis, "at least five times as large as at present." When the abbey was dissolved by Henry VIII. great part of the church was destroyed; but the remainder escaped by being made parochial. The west front, which is the entrance to the church,
church, is the most perfect part of the ancient building. The revenues of the abbey were eliminated, at the dissolution, at 411l. 12s. 11d. clear yearly value. Great part of its poffeifions, with the feite, was granted in 1549 to John, lord Ruffell, ancestor to the duke of Bedford, who is lord of the manor, and owner, not only of the town, but also of 19,000 acres of the surrounding lands. This extensive property is divided into farms from 25l. to 400l. per annum, generally in a very improved state of cultivation. A market is held on Thursdays, and two annual fairs were granted for Thorny to Francis, earl of Bedford, in the 13th year of Charles I. by the charter of incorporation for the government of the Bedford Level. The inhabitants of the parish, who are chiefly the defendants of French Protestants, are rated in the population return of the year 1811, to amount to 1675; the number of houses being 251.—Lyfons's Magna Britannia, vol. ii. part 1. Cambridgeshire. Beauties of England and Wales, vol. ii. Cambridgeshire; by J. Britton and E. W. Brayley.

Thorney Island, a small island, in a bay of the English Channel, near the coast of Suffolk, about four miles in circumference, with a village of the same name, at the mouth of the Lavant; 7 miles S.W. of Chichester.

THORNHILL, Sir James, in Biography, may be called the father of historic painting in England. He was the son of a gentleman of an ancient family in Dorsetshire, and was born at Weymouth in 1676. His family having fallen in fortune, he was obliged to refert to some profefion for support, and guided by an early taste for painting, fixed upon that art as a bafe on which to raife a fortune and a name. He came to London, and was affifted by the celebrated phyfician Sydenham, who placed him under the tuition of an artist of little note, whose name is not known, and to whom, from the flate of the art at the time, he must have been far less indebted for the progrefs he made, than to his owne ingenuity and industry. After having practiced for a while with some celebrity, he travelled to Holland and to Flanders; and thence visited France, but did not proceed to Italy. Most probably his object in this journey was only to acquire a knowledge of colouring; and he might have satisfied his mind on composition and form, by having spent three years in copying the cartoons of Raphael, which he was permitted to do by the favour of the earl of Halifax. These copies are in oil, and were bought after his death by the then duke of Bedford; and by his grace's successor, the late duke, were presented to the Royal Academy. They are wrought with care, but lack the delicacy of character and feeling obfervable in the originals. On his return to England, his reputation was increafed, and honour and employment accompanied it. Queen Anne commifioned him to paint the interior of the cupola of St. Paul's, which he did in eight compartments. The subjeft alligned him was the history of St. Paul; and he treated it with confiderable grandeur of style, both as to composition and execution; but his defign wanted chaffity and fimplicity, and the heads of his figures have not sufficient refinement of expression. It was, however, the firft attempt by an Englishman of the kind, and fully justified the preference given to him by La Guerre and La Foffe, who were then painting the halls and staircases of our nobility. He was afterwards employed to decorat an apartment at Hampton Court, with emblematical allusions to the history of the queen, and her union with her confort, George, prince of Denmark. But his grand work is the great hall at Greenwich Hospital, where he has painted naval trophies and allegorical figures in great profuion; and if much praise cannot be given to the purity of the design, it ought not to be withheld from the brilliancy and vigour of the execution. Altogether, it is a work unrivalled in its kind here, and well entitled him to the honour of knighthood, which George I. soon after conferred upon him. This was some compensation to him for the mortification of having his demand for these paintings contested, and being in the end paid only at the labourer's rate of so much per square yard, (40s.) He had the honour of so far re-establishing his family influence as could be effected by being chosen to represent his native town in parliament; but he did not enjoy his honours long, as he died at the early age of 57, leaving a fon, named Alls James, for whom he had procured the appointment of fermant-painter to the king, and a daughter married to Hogarth.

THORNY TREEFOIL, in Botany. See FAGONIA.

THORNY Reft-Harow, in Agriculture, a frequent weed in poor barren pasture land, which is not removed without difficulty, in consequence of its perennial nature.

THOROE, in Geography, a small island of Denmark, in the Little Belt, near the island of Funen. N. lat. 55° 15'. E. long. 9° 53'.

THOROLD, a township of Upper Canada.

THOROUGH, the common name of an inter-furrow between two ridges. They should always be clean and well-drawn.

THOROUGH-BASE, or accommodation to a continued base by figures.

Thorough-base is but an awkward translation of the Italian terms bafco continuo, by which accommodation by figures, without any other guide for the right-hand on keyed-instruments, was at first called. The French term accompagne was the shortefl and most comprehensive title for the harmony expressed by figures over the base; if, as Rameau has done in his "Code de Musique," we add "for the harpsichord or organ," as there are several other kinds of accommodation besides that on keyed-instruments. Rameau defines accompaniment or thorough-base in the following manner. "Accompaniment on the harpsichord or organ, consists in the execution of a complete and regular harmony, by seeing only the notes of one part of that harmony; and this part is called the base, being in reality the basis or foundation of the whole composition. This base is played with the left-hand, and its harmony with the right."

We shall endeavour to affift our musical reader, who has every thing to learn in the art of accompaniment, more by example than precept, and shall give him a series of progressive lessons in the musical plates, which will explain the whole mystery of musical combinations from the common chord, to the most extraneous harmony.

We take it for granted that he is perfectly acquainted with the musical scale or gamut, in the base and treble clefs at least, as well as with the time-table; and that the accidents of flat, sharp, and natural, are familiar to him. The first thing, therefore, that we shall recommend to his study, is a table of intervals, both in notes and figures. See Plate 11.

1. Presents a scale in half notes, in which all the flats occur, from the unison to the 6th; another scale expressed by sharps.
2. Number of semitones above the base in each interval.
3. Common chords, major and minor, to all the twelve semitones, modulating by 5ths.
4. Modulation in common chords, major and minor alternately, the base falling a 3rd at each change. And in order
order to familiarize the student to these chords in every part of the instrument, he is advised to make three voyages round the harmonic world: beginning with the 8th uppermost, then the 5th, and lastly the 3d, and if no mistake is made, the last chord in each of these circumnavigations will be an octave above the first. But all difficulty in these exercises will be removed, if it be remembered that, in going from chord to chord, only one note is to be changed by the right-hand, which note is always the octave of the new base.

5. Exercise of common chords in accompanying the hexachords in all the keys, major and minor, to their fundamental bases: in the practice of which, dots are placed on the notes in the treble, which are to be played with the little finger. And though only the first hexachord, or fix notes, is written backwards, each of them is intended to be played backwards as well as forwards.

Many years ago, we tried to reduce all the rules of thorough-bass to the compass of a measure-card, and almost all the combinations expressed by figures to common chords. And now, if the preceding exercises of the hand in common chords have done their duty, the student will perceive, from an engraving of the two sides of this thorough-bass card, that what has been explained in words and figures on one side, is illustrated with notes on the other.

The second card goes somewhat deeper into harmonical mysteries, by what the French call la regle de l'obtuse, or rule for accompanying with a specific chord every note of the key, ascending and descending; which, if practiced well in all the 24 keys, and impressed on the memory, will enable the student to figure a base himself, or to play without figures; and by a feeming divination, without a treble part, to know the harmony that belongs to each base of a regular composition, in a diatonic accent and defect.

After these chords are literally at the fingers' ends of the student, the following eight rules and exceptions in playing without figures must be observed.

1. An accidental sharp note in the base is generally accompanied with a 7, and changes the key to the half note above such sharp.

2. An accidental flat note in the base is generally accompanied with a 9, and changes the key to the 4th below such flat.

3. To the 5th of a key, if repeated at a close, two chords are generally played in modern music: the 7 and 9; in old music, the 9, and sometimes the 7th with the common chord.

4. When the base moves per saltum, a 3d, 4th, 5th, or 6th, common chords will do.

5. When the base rises a 4th, and falls a 5th alternately, and the contrary, each note may be accompanied by a 7th.

6. In syncopated or binding notes the 7 are played to the last part of the ligature, by anticipation.

7. Slow notes in the base, in old music, are generally accompanied, as on the plate, by a 9, and 7 alternately.

8. Sustenions of a whole chord, or part of a chord, are expressed by a dash (—) preceding the resolution.

The reverse of the second card contains explanations of these eight rules in notation.

It must be remembered, that whoever is ambitious of playing thorough-bass without figures, must previously perfect the art of accompanying readily with figures. See Composition and Counterpoint, to which thorough-bass is the best introduction: as what is good in playing, would be good, as far as harmony is concerned, in writing. Invention, fancy, and good taste, are necessary to break these chords into melody.

THOROUGH-Wax, in Botany. See Bupleurum.

THORPE ARCH, in Geography. A village of England, in the county of York, where is a medicinal spring, impregnated with sulphur and steel; 3 miles S.E. of Wetherby.

THORPE, Bishop's, a village of England, in the county of York, where the archbishop has a palace, built by archbishop Grey in 1241; 3 miles S. of York.

THORPNESS, a cape on the east coast of England, in the county of Suffolk, forming the southern part of Solebay.

THORSAKER, a town of Sweden, in Geftricia; 21 miles S.W. of Gefle.

THORSBERG, a mountain of Norway, in the province of Aggerhus; 18 miles W. of Tomberg.

THORSHAVEN, a sea-port town of the island of Stromoe, and capital of the Faroer islands, as well as the common market, and residence of the landvogt, and king's counsellor.

THORSTORP, a town of Sweden, in Vefl Gotland; 28 miles S.E. of Gotheborg.

THOS, Thous, &c., in Zoology, a name given to an animal of the wolf-kind, but larger than the common wolf, common in Surinam. It is a species of the canis, with a light bent tail, and white belly. It never touches men or cattle, and rather provides its food by cunning than open force; preying chiefly on poultry and water-fowl.

THOTCHI, or Thatchi Hotun, in Geography, a town of Chinefe Tartary; 368 miles W. Tourfan. N.lat. 42° 32'.

E. long. 83° 8'.

THOTPHA, a town of Hindooflan, in the circuit of Rantapour; 46 miles S.S.W. of Rantapour.

THOU, James Augustus de, (Thuanus, in Biography, an eminent magistrate and historian, was the son of Christophe de Thou, president of the parliament of Paris, distinguished for integrity and patriotism, and born at Paris in the year 1553. In the college of Burgundy, where, he was placed at the age of ten years, his education was interrupted by a fever, which seemed for some time to have proved fatal to him; but upon his recovery he studied the civil law, first at Orleans, and afterwards at Valence, under the celebrated Cujiacus, in which latter place he commenced an intimate acquaintance with Joseph Scaliger, which was continued through life. Upon his return to Paris in 1572, he witnessed the horrors of the massacre of St. Bartholomew, and this scene impressed him with an eternal detestation of bigotry and intolerance. He was originally defined for the church, with the prospect of valuable preferments, which his uncle, the bishop of Chartres, intended to resign to him. In the mean while he travelled to Italy, the Low Countries, and Germany; but upon the death of his brother, his views were changed, and the law became his destined profession. After the death of his father, whose memory he held in high veneration, he was made master of requests in 1584; and in 1587, he married Marie Barbanfon, a lady of a noble family. Upon the revolt of Paris, on occasion of the league, in 1586, he repaired to Henry III. at Chartres, and was deputed by him to confirm the province of Normandy in its allegiance. On the affiliation of the duke of Guise, his family at Paris received public insults, which made it necessary for his wife to make her escape in disguise, and he went to the king at Blois, who was almost delirious, and induced him to form a coalition with Henry, king of Navarre. Being at Venice, he was informed of the affiliation of Henry III., after which he immediately joined the legitimate successor to the crown.
THOU, in Geography, a town of France, in
the department of the Mayne and Loire; 12
miles S. of Angers.

THOUARE, a town of France, in the
department of the Lower Loire; 5 miles N.E.
of Nantes.

THOUARS, a town of France, and principal
place of a district, in the department of
the Two Sevres, near the river Thoue.
The place contains 2035, and the
canton 13,950 inhabitants, on a territory of
5176 square kilometres, in
24 communes; 31 miles W. of Poitiers.
N. lat. 46° 58'.
E. long. 0° 8'.

THOUIE, a river of France, which runs into the
Loire, a little below St. Florent.

THOUGHT, SENTIMENT, a general name for all
the ideas consequent on the operations of the mind, and even
for the operations themselves.

As, in the idea of thought, there is nothing included of
what we include in the idea of an extended fubstancce; and
that whatever belongs to body, may be denied to belong
to thought; we may conclude, that thought is not a mode
of extended fubstancce, it being the nature of a mode not to
be conceived, if the thing, of which it is the mode, be
denied. Hence we infer, that thought, not being a mode
of extended fubstancce, must be the attribute of some other
fubstancce very different.

F. Malebranche, with the spirit of a Cartesien, denies
that a man who thinks seriously on the matter, can doubt
but that the essence of the mind consists altogether in
thought, as that of matter does in extenfion; and that,
according to the various modifications of thought, the mind
sometimes wills, sometimes imagines, &c.; as, according to
the various modifications of extension, matter is sometimes
water, sometimes wood, fire, &c. By the way, by thought
he does not mean the particular modifications of the soul,
but such or such a thought, but thought, or thinking in the
general, considered as capable of all kinds of modifications,
or ideas; as by extension he does not mean such or such an
extension, as a square, oval, or the like, but extension in the
abstract, considered as susceptible of all kinds of modifi-
cations or figures.

He adds, that he takes it to be impossible to conceive a
mind which does not think, though it be easy to conceive
one which does not feel, or imagine, or will; in like manner
as it is impossible to conceive a matter which is not extended, though it be easy to conceive one that is neither earth nor metal, nor square, nor round, but that is even in motion.

Hence it may be concluded, that as it is possible there may be matter which is neither earth nor metal, nor square, nor round, nor even in motion; it is also possible, that a mind may neither perceive heat nor cold, nor joy nor grief, nor imagine any thing, nor will any thing; so that these modifications are not essential to it. Thinking alone, therefore, according to this author, is the essence of the mind, as extension alone is the essence of matter.

But this doctrine is not now generally received. The followers of Mr. Locke deny thought to be the essence of the mind; and the followers of Mr. Onck deny thought to be the essence of the mind.

THOUGHTS, or Thoughts, in a Boat, a name given by seamen to the benches on which the men sit down to row.

THOUINIA, in Botany, a noble genus, though consisting of only one known species, so named by the writer of this, in grateful remembrance of his distinguished friend M. André Thouin, member of the Institute, and at present Professor of Agriculture at Paris. This gentleman is one of the original foreign members of the Linnean Society, and ranks among the best and most philosophical cultivators, as well as botanists, of this or any age. The present plant was collected out of the large and fine collection of new and rare specimens, given by himself to the younger Linnaeus, chiefly from the herbarium of Comeron. We were not aware of its having been named Humbertia by its discoverer, or Endrachium by Lamarck (see the latter article); where we have remarked that the name is barbarous; we should therefore not have adopted it, if known. Humbertia is not accounted for, there being no botanist on record of the name of Humbert, nor has any body explained or defended this appellation. The younger Linnaeus had in fact established a Thouinia, Suppl. 9, after Thunberg; neither of them suspecting their plant to be a real Chionanthus, the exalatana of Limn. Sp. Pl. 11. Swartz, moreover, in his Prod. 14, added a second species to this supposititious genus, which he afterwards disfigured from it, by the name of Linociera, under which head our doubts respecting even that matter are recorded. Considering therefore our original name no more justly superseded than our genus, we cannot allow it to give place to M. Poiteau's Thouinia, Ann. du Musée des. 13, though De Theis has decided otherwise.—Sm. Pl. 7. Schrep. 793. Willd. Sp. Pl. v. 1. 935. Mart. Mill. Dict. v. 4. (Endrachium; Juss. 133. Humbertia; Lamarck Dict. v. 1. 356. Ilustr. 1. 103.)—Clad and order, Pentandria Monogynia. Nat. Ord. Convolvul., Juss.

Gen. Ch. Cal. Perianth inferior, permanent, of five roundish, coriaceous, concave leaves, the three outer ones most thick and rugged, naked; two inner membranous at the margin, filky at the back. Cor. of one petal, twice the length of the calyx, bell-shaped, plaited, externally brilly. Style simple. Berry coriaceous, of two cells. Seeds two in each cell.

Ohf. We see no reason to adopt Jullieu's or Lamarck's idea of this fruit. They call it a coriaceous, or woody, capsula, which does not burst. Commerson, who alone has examined it fresh, denominates it a drupa, which term we would prefer to pulpy fruits with a single nut, and therefore we judge the present to be a bacca, however tough or dry its substructure may appear when dry.

1. T. speciabilis, Beautiful Thouinia. Sm. Pl. Ic. t. 7. Willd. n. 1. (Humbertia madagascariensis; Lamarck n. 1. "H. axifera; Commerr. MSS. et Ic. Endrach-Endrach; Flac. Hift. Madagac. 137. f. 100. Arbre immortel.")—Native of Madagascar; unknown in the gardens of Europe. A tall and large tree, whose wood is yellowish, compact, heavy, as hard as iron, and almost incorruptible even under ground. Lamarck. The branches are round, scarred, filky towards the ends, where they bear tufts of leaves, intermixed with axillary flowers. The leaves are scattered, two or three inches long, obovato-lanceolate, obtuse, entire, smooth and shining, with a strong mid-rib, on channelled filky footstalks, without stipulas. Flowers on solitary, axillary, simple stalks, rather shorter than the leaves, each with a pair of small bractes about the middle. Of the colour of the corolla we have no account; its length is about an inch; and the filky hairs on the outside, in a dry state, are of a shining brown. Fruit the size of a small plum.

THOUN, in Geography, a town of Persia, in the province of Khorasan; 75 miles W. of Herat.

THOURY, a town of France, in the department of the Eure and Loire; 3 miles E. of Janville.

THOUSAND. See Numeration.

THOUSAND Tears' Reign. See Millennium.

THOUSAND Islands, in Geography, a cluster of small islands in the Straits of Sunda. S. lat. 5° 33'. E. long. 106° 33'.—Allo, a number of small islands in the river St. Laurence, a little below lake Ontario; the part of the river being called Thouand Island Lake.

THOUSAND Lakes, a name given to a number of small lakes in America, near the river Mississipi; 60 miles above St. Anthony's Falls.

THOUSAND Rocks, rocks in the river St. Laurence; 72 miles S.W. of Montreal.

THOWLES, in a Boat. See THOLES.

THOYARD, Nicholas, in Biography, a native of Orleans, was born in 1629, and at an early age a proficient in the learned languages, and in medallie science. His own original works were few, but he was liberal in the afflance he afforded to other writers. He published two short Latin dissertations on particular medals, and notes upon "Laecantius de Mortibus Persecutorum," and also a Critique on R. Simon's translation of the New Testament; but his principal performance was "A Concord of the Four Evangelists," in Greek and Latin, which was printing at the time of his death at Paris in 1706, and appeared in 1707, with learned notes, chronological and historical. In this work he maintains that St. Matthew, of all the evangelists, paid the least regard in his narrative to the order of time. This work was printed at considerable expense, and is now rare.

Moreri.

THOY. See THAHT.

THRACE, in Ancient Geography, an extensive country of Europe, situated in the S.E. Its natural boundaries are, on the S. the Aegean sea, the Propontis, and the Bosphorus of Thrace; on the E. the Euxine sea. Its limits to the N. and W. are not so determinately ascertained.

A penin-
A peninsula to the S., between the Melanic gulf and the Hellepont, made part of the continent of Thrace, but it assumed the name of the Chersonesus of Thrace.

The continent may be considered as divided into six parts: viz. 1. The part bounded to the W. by the river Melas, which discharged itself into a gulf of the same name. To the S. it had the Chersonesus and the Propontide, and to the E. the Bosphorus of Thrace and the Euxine sea. The chief towns of this part were, on the borders of the Propontide, Galas, Bithynia or Joseph, Perinthus called also Heraclea, Selymbria, Byantium; and on the Euxine sea, Dercon, Salmydus.

2. The second part of Thrace extended from Melas to the Hebrus. It had several towns on the banks of the Hebrus, of which the principal were Philippopolis and Adrianopolis, called also Orestes, and Trajanopolis. The Hebrus took its rise in mount Haemus, and discharged itself into the Melanic gulf, near the town of Enos.

3. The third part lay between the Hebrus and the lake Bilbionis to the W., colliding, according to some authors, of two subdivisions, viz. from the Hebrus to Littus, and from Littus to the lake Bilbionis. On the sea-coast was situated Maronea, and in the interior of the country Scapathyla, enriched by its mines.

4. The fourth part was narrow, and lay between the lake Bilbionis and the Nileus to the W. The Nileus had its source to the N.W. of mount Rhodope, and near it were the towns of Jamphorinum and of Nicopolis ad Nileum.

5. The fifth part was situated N. of the Tyras, a river which had its source in the mountains S. of Delnetum, and not far from the Euxine sea, and which ran into the Hebrus on the left side of it.

6. The sixth part lay N. of that part of the Hebrus which ran from Beffa towards the S.E. to Oreflis. In this part were the towns of Berea and that of Cabylia, S. of the Haemus.

The Chersonesus of Thrace had for its boundaries to the S.E. the Hellepont and a small portion of the Propontide; to the N. the continent of Thrace; to the N.W. the Cardia or Melanic gulf; this is the peninsula of Romania; and a wall separated it from the continent.

Those who seek the origin of the Thracians in the Old Testament, trace them to Tiras, one of the first descendants of Japhet. But whatever was the origin of these ancient people, it is certain that they were warlike and ferocious, and lived very much like savages. They were divided into different hordes, like the ancient Scythians or modern Tartars. This country, on account of the coldness of its climate, attributed to its mountains, was regarded by the Greeks with a kind of horror.

Thrace, in the Notitia Imperii, is divided into six provinces, viz. Europe, Rhodope, Thrace, Hemonont, the second Macedonia, and Scythia. According to the Notitia of Hierocles, these six provinces contain 53 cities, of which the Thrace of Europe contained 14.

Thrace was anciently governed by kings; of these, the first who gave them laws for regulating and civilizing their manners was Zamolxis, a disciple of Pythagoras. Our limits will not allow us to trace its subfsequent history, as far as it is known. The whole, or various parts of this country were possessed by Philip of Macedon, by the Athenians, by the Lacedemonians, and by Alexander, who made a conquest of the whole country, nor did they recover their liberty till after his death. Lycaenthus, one of the successors of Alexander, was vanquished by a descendant of one of the ancient sovereigns of Thrace. But the tranquillity of the country was of short duration; for a party of Gauls, under Brennus, ravaged Greece, and took possession of Thrace. The Thracians afterwards exterminated the Gauls, and restored the race of their ancient kings. This prince, whose name was Scuthes, and his descendants, reigned without interruption till the time of Vespuian, who reduced Thrace into a Roman province. It afterwards became subject to the Turks, who now possess it. See Rumania.

THRACES, or Thracians, in Antiquity, were an order of gladiators, reputed to be the most fierce and cruel of all. They were so called, either because they were natives of Thrace, or wore armour after the manner of that country. The particular weapon they used was the fist or pugilism, and their defence consisted in a parma, or a little round shield, proper to their country.

THRACIA GEMMA, a stone mentioned by Pliny, and described by him to be of three kinds: the one of a plain green, but a considerably deep and strong colour; the other of a paler green, without variegation; and the third spotted with blood-coloured spots. This is a short description, but the stone seems to have been a Jasper, of the nature of our green Oriental Jasper and heliotrope.

THRACIUS LAPIs, in the Natural History of the Ancients, a stone often mentioned, and first called Bena lapis, from the place where it was first found, which was in the neighbourhood of Bina, or Bena, a town in Thrace. It has been by some authors placed a place in the catalogues of the materia medica; but it is impossible for us to say, with any certainty, which, of several substances now known (which all answer in some degree to the accounts left of it) is the real body they meant by that name.

It was an inflammable body, found in mines, and in the beds of rivers; and, in burning, afforded a very offensive smell.

Some of the late authors have supposed it was our common pit-coal the ancients expressed by this name; others, that it was jet; and others, the common cannel coal. Hill's Theophrastus, p. 34.

THRANITE, in the Roman Trireme-gallic, or those which had three rows of oars; those of the upper row were called by this name, the second the zigita, and the lowest thalamite.

The zigita, or middle row of men, in these vessels, took up but very little room, having a conveniency of moving their hands and oars under the feet of those who sat next before them. See Enneris and Polycrata.

THRASPSTON, in Geography, a small market-town in the hundred of Navisford, and county of Northampton, England; is situated on the southern banks of the river Nen, 22 miles N.E. by E. from the town of Northampton, and 75 miles N.N.W. from London. The town, in general, is well-built; and at the west end is a handsome stone bridge crossing the Nen. By this river a considerable trade is carried on with Lynn, Northampton, and various other towns in its course. The country round Thrapston is open, and affords extensive prospects: from an eminence, half a mile to the south-east, may be seen at one view thirty-six church towers and spires. An annual court-leet and court-baron is held here; at which are appointed the governing officers, a constable, and a third borough; and also broad-weighers, whose office is to see that the bread, butter, and every other marketable commodity, is good and of just weight. A well-supplied market is held on Thursdays; it is the largest mart for logs in the country, that branch alone returns every market-day, on an average, about 500l. Here are also two annual fairs, besides a large market, equal to either of the fairs, which is held yearly at Michaelmas. The population return.
return of the year 1811, states the number of houses in this town to be 13,3, occupied by 762 persons. It appears from Leland, that there was formerly a monastic establishment here. He says, "At the very end of Thracefton bridge stands the ruins of a very large hermitage, and principally well preserved, but a late discovered and repaired."—Beauties of England and Wales, vol. xi. Northamptonshire; by J. Evans and J. Britton.

**THRASEA PETSUS**, in *Biography*, a Roman senator, who deferred to be recorded for his integrity and patriotism, was a native of Padua; educated in Stogai tenets, and a great admirer of Cato of Utica, whose life he composed. As a senator, he was a strenuous adherent of the liberty that remained under imperial despotism, and on this account he exposed himself to the obloquy of all the Jacobins of power. His integrity commanded the acknowledgment of Nero, the execrable tyrant who put him to death, and many instances occur of his undaunted fortitude in maintaining it. We can only felect the following: After Nero had committed the detestable crime of matricide, when the fervile war was decaying, a solemn thanksgiving and annual festivals to commemorate the event, Thrasea, who, we are told, had been accustomed to suffer other adulations to pass in silence, or with a light heart, marked the profusion of these motions by walking out of the senate-house; thus openly exposing his life to a danger which he contemned; for, conformably to the Stoical principles, he was used to say, 'Nero may kill me, but he cannot hurt me.' But though Thrasea often escaped the brutal vengeance of this imperial tyrant, his fate was at length decreed. In the year 66, the 15th of Nero, this monster having imbrued his hands in the blood of many of the most illustrious Romans, now resolved, says Tacitus, to extirpate virtue itself, by the destruction of Thrasea Petus and Barcas Soranus. The amount of the charges against Thrasea alone evinced his contempt of the base adulation of the senate, and his displeasure with the vices and enormities of the reign. No defence could be of any avail, and therefore Thrasea prepared in silence to submit to his fate. When the determination of the senate was announced to him, he was in his garden surrounded by a number of illustrious persons of both sexes, and attentively listening to Demetrius, a Cynic philosopher, who was discoursing on the nature of the soul, and its separation from the body. Having received the decree of the senate, he retired into his bed-chamber, and laid bare the veins of both arms, and then bled to death. Tacit. Annot. Suetonius. Dion Caff. Plin. Epist.

**THRASHING**, &c. in *Agriculture.* See **Threshing**.

**THRASOS**, a term used by Hippocrates, to express a wildness and fiercefns in the eyes of persons who approach to a delirium.

**THRASYBULUS**, in *Biography*, an eminent Athenian, was the son of Lycus, and the restorer of liberty to his country. When the government of 410 succeeded the overthrow of the democracy in the year B.C. 441, he was commander of a galley; and in connection with Thrasybulus, he destroyed the aristocracy in the camp at Samos, and re-established democracy there, and then proposed the recall of Alcibiades, in exile at Magnesia, and restored him to his country. Thrasybulus and Thrasybulus, having purposed the Peloponnesian fleet, brought it to an action in the straits between Selinos and Abyds, in which the Athenians captured 20 ships of the enemy, with the loss of 15 of their own. Another engagement soon after occurred, and the result of the arrival of Alcibiades's squadron was a complete victory on the part of the Athenians. When Alcibiades was made general of the Athenian forces both by sea and land, he nominated Thrasybulus for one of his colleagues; but a misunderstanding afterwards taking place between them, Thrasybulus impeached Alcibiades before an assembly of the Athenians, and procured his disgrace. On the occasion of the establishment of the thirty tyrants at Athens by the influence of the Lacedaemonians, Thrasybulus was one of several other citizens who took refuge in the Thessalian territory; and zealous for the immediate protection of his country, from ferocity, he engaged a small body of fugitives to join him in an expedition to Attica, and took possession of the important fortresses of Phylea, a town on the frontier of Bocotia. Beguiled by the Greeks, Thrasybulus by his activity repelled them, and even followed them to the borders of Athens. Having also hurried a fleet which they occupied near Phylea, the thirty tyrants removed from Athens to Eleusis, and Thrasybulus seized this opportunity of attacking the Piraeus, and his enterprise succeeded. He then issued a proclamation, announcing the Athenians to refit their tyrants, and to restore a free government. Having done this, he established himself in the Piraeus. The constitution of Athens was then changed, by substituting instead of the thirty tyrants, ten magistrates, one from each tribe. The Lacedaemonians still retained their influence over these magistrates, who sent to Sparta soliciting assistance against Thrasybulus. At length, however, this restless commander prevailed so as to open a negotiation between the Athenians and the Spartan government, which terminated in the withdrawing of the Spartan garrison, and the re-establishment of a popular constitution at Athens. This happy close of the contest was followed by the union of citizens of both parties, in a solemn thanksgiving to Minerva at her temple in the citadel, when Thrasybulus exhorted them to future concord. The remaining tyrants at Eleusis endeavoured to foment dissensions in Athens; but the business terminated in an act of amity or oblivion, which was passed by the influence of Thrasybulus in the assembly of the people, and ratified by an oath. This revolution happened in the year B.C. 401. In accomplishing this event, Thrasybulus acted with the most disinterested patriotism; for the thirty tyrants, when he feized the castle of Phylea, had offered to make him one of their number, and to pardon any twelve of the exiles whom he might name; to which offer he replied, that exile was much more honorable than any civil authority purchased on such conditions. Thrasybulus remained for some time in un molested retirement, enjoying the honour accompanying the olive wreath, which, according to the simple manners of the age, was bestowed upon him for his services. But in the year B.C. 390, after the death of Conon, the foreign polleflions and influence of the Athenians were in danger of being lost, and therefore a fleet of forty ships was placed under the command of Thrasybulus, with which he failed to the Hellas. On this occasion he induced two Thracian princes to become allies to Athens, and compelled the Byzantines and the inhabitants of some other cities to abolish their aristocratical governments, and accept of the Athenian model and alliance. He next proceeded against the state of Lebos, in the Lacedaemonian interdict, and reduced the whole island to obedience. Thence he failed for Rhodes having previously raised supplies from the maritime towns of Asia, and the capital of Pamphyia. He also indulged his men in private pillage; and thus so much provoked the inhabitants, that they made an attack in the night on the tents, and put a number of the Athenians to the sword, among whom was Thrasybulus himself. Such was the inglorious termination of a life that had been devoted to the benefit of his native country. Corn. Nepos. Un. Hist. Gen. Biogr.

**THRAVE, or THRAVE, of CORN.**, in most parts of England, is twenty-four shaves, or four sheaves of six sheaves...
to the shock: though, in some counties, they only reckon twelve shocks to the thrave.

King Athlifan, anno 923, gave by charter, to St. John of Beverley, four thraves of corn for every plough-land in the East Riding of Yorkshire.

"Ya fou thre be heaven king,
Of ilka plough of ilf riding."

THRAUPIS, in Ornithology, a name given by many authors to the bird more commonly called Citrinella.

THRAUSMA, a name given by the ancients to a kind of gum ammoniacum, which was drier than the common, and more easily crumbled to pieces.

THRAUSTOMICTHES, in Natural History, the name of a genus of compound earths. The word is derived from the Greek ἄρσμα, brittle, and μίξη, mixt.

The bodies of this genus are loams composed of sand and a lefs vifeid clay, and are therefore of a friable or crumbly texture.

The earths of this genus are generally used to make bricks; and there are several species of them. Hill.

THREAD, in the Linen Manufacture, a small line or twist of flax, the weaving of which composes cloth. There is a stronger kind made ufe of to few the seams of linen garments, or to mend them. The fame term is applicable to cotton or wool. See Spinning.

Thread, says an eminent French writer (Pajot des Charmes), bleached by the oxygenated muriatic acid, may be ufed by the sempitrefhs with much greater speed and brillenfs than thread of the fame quality bleached in the field: it is lefs brittle, and may be fruck much more effectually home to its place in weaving, and does not move afterwards. This information, he says, was received by him from impartial and unprejudiced manufacturers.

The thread of the Laplanders is very fine, white, and strong, but it is of a very different nature from our's; they know nothing of flax or hemp, nor of any other plant whose flalks might supply the place of these in making thread, but their's is made of the finews of the rein-deer.

They kill of these animals a very great number continually, partly for food, partly for the finews, which they ufe in clothing themselves, covering their huts, and on many other occasions; the finews of all they kill are very carefully preferved, and delivered to the women, whose province it is to prepare this neceffary matter. They beat the finews very well, after having fteeped them a long time in water, and then they spin them out.

The thread they thus make is of any degree of finenefs they pleafe; but it is neuer any longer than the finew from which it is made. They ufe this in feving their clothes, shoes, gloves, &c. and the trappings of their rein-deer. The threads of the fame finew are laid up together, and are all of a length; and as the different finews afford them very different lengths, they accordingly pick out such as the present ufe requires, both in regard to length and finenefs. This fort of thread is made with much more labour than our's; but it is greatly superior to it on many occasions, where strength is rather required than beauty.

These people have, besides this, a way of making a fort of yarn of sheep's wool, which they weave into garments and a fort of ribbands, ufed by way of ornament; but they place no value on it, because of its want of strength. Scheffer's Hill, Lapland.

Thread, in Botany, is underfoot of those capillaments usually found in the middle of flowers, as in the lily, tulip, Vol. XXXV.

rofe, &c. There are two kinds: thefe which support apices, are particularly called fiamina; and thofe which have none, pistilla.

Thread, Gold. See Gold.

Thread, Virgin's. See Virgin.

Threads, Air, a term ufed by fome to express thofe fine long white filaments, or thready fubstances, which we meet with in vaft numbers floating about in the air in August and September.

The world has been much perplexed about the generation of thofe, till it was known that they were the work of spiders, and that they served thofe creatures to move from place to place by. They are long, downy, and very soft, and though they hold together when untouched, they flick to the fingers in handling, and easily break with a light touch.

The general method of thofe creatures spinning and weaving the webs, is by letting down the thread, then drawing it after them, and fo disposing it as they think proper; but in the midst of their work of this fort, if they are closely observed, they will be sometimes found to deftill, and turning the tail to the contrary way of the wind, they will emit a thread with great violence, no lefs than that with which a jet of water is difcharged from a cock. In this manner they continue darting forth the thread, which the wind takes, and carrying it forwards, it soon becomes many yards long. Soon after this the creature will throw her felf off from the web, and truffling her felf to the air with this long tail, will afcend with a great height with it. The fragments of thofe lines, or the whole lines, and the spiders attached to them, though not observed, make thofe air-threads, and the ufe nature defines them for, is evidently the waiting of the creature along the air, and giving it an opportunity of preyng on gnats, and many other insects that inhabit the air, out of the reach of thofe creatures by any other means.

When the threads are newly spun, they are always single, and are generally seen ascending higher and higher in the air; but when they are seen coming down, they are found sometimes composed of three or four others, and either without any spider at the ends, or with two or three, or more. It is plain that this happens from the meeting of thofe threads one with another in the air, and their tangling together; and this incumbrates the creatures, and brings them down.

Thofe are what fill the air with the loofe threads we fee in autumn; and as thofe soon entangle together, and bring one another down, it is no wonder that they are more frequent in the lower regions of the air, than thofe with the spiders adhering to them, which uffually rise to great heights, and fillain themfelves there. And hence the origin of the threads was much perplexed among the enquirers, because they were found without any mark of the animal to which they owed their exifence. The bufinefs of feeding is not all the ufe of thofe threads, but the creatures evidently fport and amufe themfelves by means of them, floating about in the air, and changing height and place at pleasur.

When a spider has once raised itfelf from the earth in this manner, it does not defcent always on the fame thread it arose by, but draws that up at times, and winds it up into a bank with its fore-feet, and darts out another by way of support; and the new thread is made more or lefs long, as it is intended for a higher or lower flight. Philof. Tranf. No. 50.

Thread of Glafs may be obtained of indefinite minuteces by means of the blow-pipe. When no thicker than
fine hair, it is extremely flexible and elastic; and if still finer, it may be wound almost like common thread without breaking. The way of doing it is very simple. A piece of glass tube is heated in the lamp, and the end drawn out into a thread by means of another piece of glass cemented to it. When a fine thread is once drawn, the end is carried round a reel or wheel two or three feet in diameter, and by turning the wheel and continuing to heat the tube, an endless thread is drawn out, winding round it as long as the artist pleases or the glass lasts. The quicker the wheel revolves, and the hotter the glass is kept, the firmer the thread, which may thus be made as delicate as a single silk-worm's thread, with extreme flexibility. Different coloured threads are made in this way by using very deeply coloured glasses instead of common glass.

**Threads, in Glass.** See Glass.

**THREAD, in Agriculture,** a term signifying a handful, a bundle, or a pottle, in different districts of the country.

**THREATENING LETTERS,** in Law. By statute 9 Geo. I. c. 22., amended by stat. 27 Geo. II. c. 15. knowingly to send any letter without a name, or with a fictitious name, demanding money, venison, or any other valuable thing, or threatening (without any demand) to kill any of the king's subjects, or to fire their houses, out-houses, barns orricks, is made felony without benefit of clergy. This offence was formerly high treason, by 8 Hen. V. c. 6.

The offence of sending letters, threatening to accuse any person of a crime punishable with death, transportation, pillory, or other infamous punishment, with a view to extort from him any money or other valuable chattels, is punishable by stat. 30 Geo. II. c. 24. at the discretion of the court, with fine, imprisonment, pillory, whipping or transportation for seven years. Blacklt. Com. book iv.

**THREATS,** a species of personal injury. Threats and menaces of bodily hurt, through fear of which a man's business is interrupted, are comprehended under this description. A menace alone, without a consequent inconvenience, does not constitute the injury; but, to complete the wrong, there must be both of them together. The remedy for this is in pecuniary damages, to be recovered by action of trespass, *et armis;* this being an inchoate, though not an absolute violence. Blacklt. Com. book iii.

**THRAVE.** See Thrave.

**Three Chapters.** See Chapter.

**Three Legs, Compasses of.** See Compasses.

**Three, Ombre by.** See Ombre.

**Three, Rute of.** See Rule.

Three-legged Staff, an instrument consisting of three wooden legs, made with joints, so as to flint all together, and to take off in the middle, for the better carriage; and usually having on the top a ball or socket: its use is to support and adjust instruments for surveying, &c.

**Three-pointed Pick, in Agriculture and Rural Economy,** a tool of the pick-kind, having the broad end formed in a three-toothed manner, about six inches in length, of great strength, and having the width, from the out-sides of the teeth or prongs, of about six inches. The other end is formed in the gently curving ordinary one-pointed manner. When complete, it is provided with a handle of the strong wooden kind, inserted into the eye or socket of the head part.

**Three-pronged Fork,** a name sometimes applied to the common fork which is employed for various purposes on farms. See Prong and Spud.

**Three-share Horst-bee,** a light three-shared tool of the horse-hoe kind, for one horse, which is often found very convenient and useful in working the intervals of ridged turnip crops, and those of similar kinds, as well as for different other purposes of tillage husbandry.

It is constructed and wrought somewhat in the form and manner of the common plough, the hoe parts being so contrived and let as to pare and clean the sides and bottom of each of the ridges in the same operation. See Horse-Hoe.

**Three Brethren Hill,** in Geography, a town of Scotland, in the county of Selkirk; 5 miles N.W. of Selkirk.

**Three Brothers,** three islands in the Indian ocean. S. lat. 3° 44'. E. long. 62° 25'.—Alfo, three islands in the East Indian sea. N. lat. 10° 42'. E. long. 108°.—Alfo, three small islands on the coast of Guiana, in the mouth of the Essequibo.—Alfo, three small islands in the Indian sea, near the E. coast of Madagascar. S. lat. 13° 20'. E. long. 51° 10'.—Alfo, three small islands in the East Indian sea. S. lat. 5° 30'. E. long. 132° 15'.—Alfo, three small islands in the Atlantic, near Prince's island. N. lat. 1° 32'. E. long. 9°.—Alfo, three small islands in the East Indian sea, near the W. coast of Amboyna. S. lat. 3° 39'. E. long. 128° 18'.—Alfo, small islands in the East Indian sea, near the S.W. coast of Celebes. S. lat. 5° 25'. E. long. 119° 39'.—Alfo, small islands in the bay of Gunong Tellu, on the coast of Celebes. S. lat. 1° 1'. E. long. 120° 17'.—Alfo, small islands in the Indian sea. S. lat. 6°. E. long. 71° 36'.—Alfo, three hills on the N.E. coast of Terra del Fuego; 9 miles W. of Cape St. Diego.—Alfo, three hills on the E. coast of New Holland, so called by captain Cook. S. lat. 31° 40'.—Alfo, three islands on the Spanish Main, near the Moliquito shore. S. lat. 11°. W. long. 82° 52'.

**Three Greek Run,** a river of Virginia, which runs into the Nottoway, N. lat. 36° 36'. W. long. 77° 12'.

**Three Hill Island,** a small island in the Mergui Archipelago. N. lat. 10° 13'.

**Three Hills Island,** one of the New Hebrides, in the South Pacific ocean, about 12 miles in circumference. S. lat. 17° 7'. E. long. 168° 35'. See Hebrides.

**Three Island Harbour,** a bay on the coast of Patagonia, in the Straits of Magellan; 8 miles N.N.W. of Bachelor's river.

**Three Islands, small islands in the East Indian sea, near the E. coast of Bintang. S. lat. 1° 10'. E. long. 158° 21'.—Alfo, small islands in the Indian sea, near the coast of Africa. S. lat. 4° 50'.

**Three Islands Bay, or Harbour,** a bay on the E. coast of the island of St. Lucia.

**Three Kings,** an island in the South Pacific ocean, near the N. coast of New Zealand, discovered by Tasman. S. lat. 34° 12'. E. long. 172° 12'.

**Three Rivers.** See Tris Rivieres.

**Three Rivers Harbour,** a bay on the E. coast of the island of St. John, in the gulf of St. Lawrence. N. lat. 46° 8'. W. long. 62° 10'.

**Three Sisiers,** three small islands on the W. side of Cheapeake bay.—Alfo, small islands in the East Indian sea. S. lat. 5° 42'. E. long. 105° 41'.

**Three Stone Oak,** a rock near the W. coast of Cornwall. N. lat. 56° 11'. W. long. 5° 32'.

**Three Sugar Leaves,** small islands in the Mergui Archipelago. N. lat. 9° 13'.

**THRELKELDIA,** in Botany, has been so named by Mr. R. Brown, in memory of Dr. Caleb Threlkeld, a Dublin physician, who published a *Synopsi Stirpium Hibercica*.
rum in 1727. This is an alphabetical catalogue, principally founded on the papers of Dr. Thomas Molyneux, on the communications of other people; nor does it, according to our judgment, entitle its editor to any scientific rank.—Brown Prodr. Nov. Holl. v. 1. 409. —Cliff and order, *Viannia Digynia*. Nat. Ord. Holbage, Linn. Arricplic, Juff. Charnodore, De Candolle, Brown.

**ELL. CH. Calyx pitcher-shaped, with an abrupt inner margin.** Petals three, membranous. Stamens opposite to the petals, inserted into the receptacle. Capsule membranous, imbedded in the pulpy permanent calyx. Seed solitary, ovate.

1. *T. diffusa*. Spreading Threlkeldia.—Gathered by Mr. Brown on the south coast of New Holland, and in Van Diemen's island, growing on the beach. This is a small, diffuse, smooth *frub*. Leaves alternate, semicylindrical. *Flowers* axillary, solitary, sessile, without bracteas. Seed furnished with albumen, which is embraced by the circularly inverted embryo. *Brown*. We have presumed to take for petals, though by no means pertinaciously, what Mr. Brown, led by the analogy of the natural order of the plant, considers as mere scales belonging to the calyx.

**THRENGI, or THRENGES, in our Ancient Customs, a denomination given to vassals, but not those of the lowell degree, but such as held lands of the chief lord; other-wile called *drensi, or drenches*.**

"Quia vero non erant adhuc temporis regis Wilhelmi miles in Anglia, fed threnes; praecipt rex, ut de eis miles furent ad defendendam terram: fecit autem Lanfrancus thrensus fuorum miles, &c." Somm. Gavelk.

The name was imposed by the Conqueror: for when one Edward Sharnbourn, of Norfolk, and others, were ejected out of their lands, they complained to the Conqueror, insisting that they were always on his side, and never opposed him; which, upon inquiry, he found to be true; and therefore he commanded that every one should be restored to their lands, and be for ever after called *drenches, or threnes*. Spelm. Du-Cange.

**THRENOYD, THRENODIA, formed of *spiris*, mournful, and *canto, fong*, a mournful or funeral song.**

**THRESHER, in Ichthyology, a name sometimes given to the sea-fox.**

**THRESHER, in Agriculture, a person employed in threshing out grain and other seed crops by means of the flail.** See Threshing, and Threshing-Machine.

**THRESHING, the act of beating out the corn or other produce from grain or other crops.** The flail was the implement formerly used for threshing of corn, and which separated the grain from the straw and husks effectually and expeditiously; but which is now become much too tedious and expensive, as well as liable to many other objections, and always bruises a great many feeds, besides leaving many in the ears. It has been attempted to avoid these inconveniences by proper machines provided with a number of flails, or other parts anfwering the fame purpoze, made to move by the power of water, wind, steam, or horsefr. Of these, various forts have been lately invented, and brought to very great perfection. See Threshing-Machine.

Although there are many different methods made use of in separating the grain from the ear of the corn, that by the flail is the most general and common.

Sometimes two persons thresh together: and where more than two are employed together, which is sometimes the case, there must be frequent interruptions, and a consequent loss of time. It is suggested also, that the tool by which this fort of busines is performed, should be well adapted to the size and strength of the person who uses it, for preventing prejudicial fatigue. The best method of attaching the different parts of the implement together, is probably, it is thought, by means of caps and thongs of good tough leather. Iron is, however, sometimes employed. In the execution of the work, when the corn is bound into sheaves, it is usual for the threshers to begin at the ear-ends, and proceed regularly to the others; then turning the sheaves in a quick manner by means of the flail, to proceed in the same way with the other side, thus finishing the work in a quick easy manner by their becoming loose and open.

It is, however, observed by the author of the "Experienced Farmer," that threshing with the flail is uncertain when most carefully performed, for the thrresher may beat a long time and not meet with every head, which with the machine it is hardly possible to miss; and that the grain wafted by the use of the flail is certainly great. In short, he is of opinion that the corn lost by threshing with the flail, is more than would pay for threshing it by the machine all over the kingdom.

In some places it is the practice to thresh by the measure of grain, as the bushel, quarter, &c. while in others it is done by the threalve of twenty-four sheaves, and in some by the day.

In whatever way the farmer has this fort of busines performe, there is always much necessity for his constant inspection, in order to prevent the frauds and impositions that are too frequently practised upon him by the persons engaged in the execution of it.

The flail practice, however, from its being so extremely slow, tedious, and expensive, and at the same time requiring a great number of labourers, is perhaps only capable of being had recourse to with advantage on the smaller kinds of grain-farms, that are cheaply situated in regard to the command of workmen, and where the expense of having large machines would be much too great for the quantity of grain which they produce. But even in these cafes, if the small horse or hand threshing engines that are constructed on cheap simple principles, and which occupy but little room, should be brought to perform the busines in an easy, expeditious, and effectual manner, which seems not improbable from the improvements that have been recently made in this fort of machinery, it will most probably be to the advantage of such farmers to abandon it, as the saving in various ways must soon repay them the expense of the machine, and at the same time afford them a considerable profit.

It is moreover stated, that where threshing is performed by the flail, expensive barn-floors, either of the fixed or moveable kind, will constantly be necessary; but that the latter fort may sometimes be capable of being converted to other purposes, which may render it useful in other views and intentions, and thereby lessen the heavy charge of providing them. See Threshing-Floor.

It is flated by the author of "Practical Agriculture," that the superiority of the method by machinery over that of the flail is very considerable in many other respects, besides those of its executing the work in a much more clean and perfect manner, more cheaply, and with much greater dispatch, so as to admit of the farmer being present during the process in most cases.

It has been further stated, that the flail is a tool which is only fit for the rude or savage state of a people; while the threshing by the machine can be performed at any season, as when the weather is wet, and when no other fort of work can be done, especially of the out-door kinds; and it will employ women and children, or boys, as well as other
The Threshing.

For labourers. By the use of it, the farmer is enabled to get the advantage of markets, as he has thereby the power of selling and delivering almost any quantity within a little time; and by threshing out and placing the corn in a secure store room or granary, the great loss often occasioned by vermin may be wholly prevented and removed. Numerous other beneficial consequences may likewise result from the practice of threshing by means of machinery, but particularly that of saving the heavy expense of raising and upholding many different large buildings of the barn kind, on extensive farms of the arable description.

It may be stated, that the writer of the Account of the State of Agriculture in the County of Kent, found, on having different parcels of wheat-straw, of thirty-six pounds each, threshed out clean by the flail, by different farmers, and the same weight of straw threshed after it came from the machine, the average produce of corn left in the straw by the common mode of threshing was half a pint in every thirty-six pounds of straw, more than that left in by the machine method. And that, besides, sufficient supplies of both corn and straw may at any time be almost immediately provided, either for the purposes of feed, the market, or the feeding of animals, without the other operations of the farm being in any degree interrupted. It is likewise obtained with much less waste of the grain, and with less danger of its being injured by being bruised. Likewise, that from the then increasing scarcity of labourers, the great advance in the price of labour in all the well-cultivated districts, and the impossibility of having this sort of work performed in a clean and exact manner by the flail, the necessity as well as utility of the machine are established. And it is further contended, that the principal obstacles to machines of this nature being more generally made use of, are those of expense in their construction and erection, and the littering slovenly practice which prevails in some of the more southern districts of harvesting or securing the grain crops in a loose, uneven manner. But the first of these objections may probably, it is supposed, be obviated by the construction and introduction of hand, or one-horse, or ox-threshing machines; and the latter by the daily discoveries that are making in the improvement of this sort of machinery.

It is conceived, that the opposition that has been raised against this practice, on the ground of its being calculated to deprive and prevent the labourers of employment during the winter season, is scarcely deserving of notice, as experience has fully shewn that no injurious consequences can result from it, as there must always be work enough of other kinds at such periods, where farms are under a judicious mode of cultivation.

It is on the whole supposed, however, that the saving of expense in this mode of threshing over that of the flail, must differ much according to the nature and manner of constructing the machinery, the power by which it is wrought, and also on the flate and condition of the grain at the time of performing the operation, as well as the full manner and regularity with which it is supplied and managed. By some farmers it is considered as nearly, if not quite, one half, while others make it much less than that proportion. But with the best constructed machinery, there can be little doubt but that it will be performed on an average of different sorts of grain, and different flates of them, at leas than one-third the expense of the flail method, without taking into the account any thing that the vaff faving in grain, in which some reckon a profit of at least 5 per cent.; others, as equal to the seed and prices of threshing, which is somewhat more than half the price in the flail method; or either of the other operations that may be performed at the same time with the same machinery, such as those of winnowing or cleaning the corn, cutting straw into chaff, bruising and grinding the grain for cattle food, breaking bones for manure, and various other purposes and works.

In addition to the advantages that have been chiefly considered in respect to these machines, there is another which, in the then scarcity of procuring labourers, and indeed at all seasons and times, must be of great importance to the farmer, which is that of their enabling him to perform his work with greater certainty and convenience, and at much less expense of labour. It has indeed been stated by a writer, in a late periodical work on farming, that with a machine, two labourers on a farm will be equal to four without it, as they are left at liberty, during the winter months, for performing various other sorts of farm labour.

It has already been noticed, that the charge of this sort of work with these machines will vary considerably, according to the manner in which they are constructed. In the Agricultural Survey of the County of Kent, the expenses and produce of threshing per day, in different sorts of corn, with an engine of the common construction, without the late improvements, are stated in the manner following:

**Estimate of Threshing Expenses, &c. by the Machine.**

<table>
<thead>
<tr>
<th>For Wheat</th>
<th>£ s. d.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Eight men, at 1s. 4d. each</td>
<td>- - - 0 13 4</td>
</tr>
<tr>
<td>Four boys, at 1s. each</td>
<td>- - - 0 4 0</td>
</tr>
<tr>
<td>Four horses, at 2s. 6d. each</td>
<td>- - - 0 10 0</td>
</tr>
<tr>
<td>Cleaning and measuring 24 qrs. at 3d. each</td>
<td>- - - 0 6 0</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>1 13 4</strong></td>
</tr>
</tbody>
</table>

This is about 1s. 4d. per quarter, or nearly half the price of the flail method.

<table>
<thead>
<tr>
<th>For Barley</th>
<th>£ s. d.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cleaning and measuring 32 qrs. at 3d. each</td>
<td>- - - 0 8 0</td>
</tr>
<tr>
<td>Other expenses, as above</td>
<td>- - - 1 7 4</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>1 15 4</strong></td>
</tr>
</tbody>
</table>

This is somewhat more than half the price of the flail method, this sort of grain having of late been usually threshed at about 1s. 6d. the quarter.

<table>
<thead>
<tr>
<th>For Oats</th>
<th>£ s. d.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cleaning and measuring 40 qrs. at 1d. each</td>
<td>- - - 0 3 4</td>
</tr>
<tr>
<td>Other expenses, as before</td>
<td>- - - 1 7 4</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>1 10 8</strong></td>
</tr>
</tbody>
</table>

This is a little more than half the price of that by the flail; this sort of grain being commonly threshed at about 1s. 3d. per quarter.

The expenses are here, however, calculated considerably too low for the succeeding times, as the men would since require 2s. or 2s. 6d. and the horses 5s. or 6s. each at least for the day.

But in the improved machinery of this kind fewer hands are required, and a number of other operations are performed
THRESHING.

formed at the same time, which greatly lessens the expenses of executing the work.

In threshing with a powerful improved machine belonging to Mr. Harbottle, on the Rimmersham farm in Berkshire, according to the writer of the Agricultural Report of that district, the comparative calculations of expense and saving stand as below.

Estimate for Wheat.

A man to feed the machine with sheaves, at} 2s. 6d. per day 0 2 6
A woman to throw up the sheaves into the sheaf-shelf, at per day 0 0 8
A girl or boy to hand and unbind the sheaves to the man who feeds, at the same 0 0 8
A man to riddle or sift the corn from cockles, or small chaff, at 2s. 6d. 0 2 6
A woman to sift him 0 0 8
Two men to remove the straw, and to make it up into bundles, at 2s. 6d. 0 5 0
A boy to drive the horses, and attend to their places, at 1s. 6d. 0 1 6

In all eight persons 0 13 6

Four horses, at 7s. 6d. per day, a liberal allowance 1 10 0

Expence of threshing 20 qrs. which is done in the day of 12 hours 2 3 6

Ditto by the flail, at 3s. 6d. per quarter, supposing a man can thresh a quarter in the day, which is too much 3 10 0

Saving by the machine in 20 qrs. 1 6 6

Or by the quarter 0 1 4

Estimate for Barley.

Two men to feed and loose bands, at 2s. 6d. 0 5 0
Two women to pitch up and supply machine, at 8d. each 0 1 4
Two women to riddle, at 8d. 0 1 4
Two men to remove straw, at 2s. 6d. each, and one boy ditto, at 1s. 6d. 0 6 6
One boy to drive 0 1 6

In all nine persons 0 15 8

Four horses, at 7s. 6d. each 1 10 0

2 5 8

Usual price by the flail, 2s. 2d. per quarter, 30 qrs. the quantity done in the day of 12 hours 3 5 0

Saving on the above quantity 0 19 4

Or by the quarter 0 0 8

Estimate for Oats.

Nine persons employed, as for barley, and the same number of horses 2 5 8

Usual price by the flail 2s. per quarter, on 40 qrs. the quantity done in the day of 12 hours 4 0 0

Saving on the above quantity 1 14 4

Or by the quarter 0 0 10

It should be noticed, that these calculations are made fully to the highest, which is so much the more in favour of the machine.

In some of the northern districts, the execution of this fort of business by the machine is sometimes undertaken by labourers, the farmer finding horses. By this method, in Yorkshire, the work costs for wheat 1s. the quarter, and oats 6d. And in Northumberland they make use of a machine, which threshes at the rate of 33 bushels per hour, or 264 in the day of eight hours. In this machine, the expenses in the attendance of the threshing and dressing parts of it being merely that of three women; one to feed in, another to hand the sheaves to the feeder, and a third to take away and riddle the corn after it is winnowed; consequently the threshing and dressing the above number of bushels only costs 1s. 6d., while the threshing the same quantity by the flail would be 19s. 1d., or 10d. bushels, which at 2s. the bushel is 23s.; to which must be added 2s. for the expense of a man and two women to assist in winnowing, which makes in all 25s.

But in the Agricultural Survey of the County of Norfolk, there is an account of the expense of threshing with the machine in comparison with that of the flail, which furnishes a very different result. The machine was built by a person from Leith in Scotland, for Mr. Bevan, and cost 100l.; and strongly shews, it is thought, that bad machines are worse than the old method of the flail.

Estimates of Wheat.

Forty combs of barley, at 7d. come to 1 3 4
To dressing ditto 0 2 0

Fifty combs of oats, at 6d. 1 5 0
Dressing ditto, at 1s. per score 0 2 0

4 7 6

Forty combs of rye, at 9d. 1 10 0
Dressing ditto, at 1s. per score 0 2 0

1 12 0

Forty combs of wheat, at 1s. 2 0 0
Dressing ditto 0 2 0

2 2 0

Threshing by Means of the Flail.

Forty combs of barley take eight horses, at 2s. 6d. 1 0 0
Ten men, at 1s. 6d. each 0 15 0
To dressing ditto, five men one day 0 7 6

Thus barley costs more by 17s. 2d.

Fifty combs of oats take eight horses, at 2s. 6d. 1 0 0
Ten men, at 1s. 6d. each 0 15 0
To dressing ditto 0 7 6

Thus oats cost more by 15s.

Forty combs of rye take eight horses, at 2s. 6d. 1 0 0
Ten men, at 1s. 6d. each 0 15 0
To five ditto, at 1s. 6d. one day dressing 0 7 6

Thus rye costs more by 10s. 6d.

Forty
Forty coombs of wheat take eight horses, at
£ 1 d.
21. 6d. 1 0 0
Ten men, at 11. 6d. each 0 15 0
Five dito to dreeing 0 7 6

2 2 6

And wheat costs more by 6d.

The calculations of the expenses are here made greatly
under the rate of wages and hire of horses which has since
taken place.

The above should lead the farmer to be careful in put-
ting up these machines; and to be certain of their being
contracted in such a way, as to answered the purpose in a
perfect manner before he begins the work.

It is well observed by Mr. Somerville, in the AGRICUL-
TURAL REPORT of East Lothian, in calling the attention
of the public to the unrewarded merits of Mr. Mickle, in
bringing the threshing machine to a state of perfecti,
that it is computed, by those who have paid every possible
attention to the subject, that in Britain about 7,500,000
acres are annually employed in raising grain, the produce
of which, if averaged at three quarters per acre, amounts to
22,500,000 qr. and, as it is admitted that the surplus
quantity gained by the use of threshing machines is at
least a twentieth part more than when the flail is used,
it will appear that 1,112,500 qr. would be saved annually,
were the whole of the grain in the kingdom threshed in that
way; the value of which, if only calculated at 32s. per quarter,
would be 1,781,250l.; to which adding the savings of ex-
perience, at 1s. per quarter, upon 22,500,000 acres, viz.
4,125,000l., it would make the enormous sum of 2,906,250l.
sterling; a fact almost incredible to any but those who
have turned their attention to the subject, and are well acquainted
with the great difference between the threshing-machine and
the flail.

All sorts of grain should be in a proper, hard, dry con-
dition, when it is to be threshed out, otherwise the work
cannot be performed in a clean and perfect manner, whether
it is to be executed by the flail or the machine.

It is a remark of the time of Little, founded on his own
extensive experience, that wheat threshed in damp weather
generally yields but little flour, with a great deal of bran,
when it is ground; and that if it be put into sacks, it will
grow musty in less than three weeks, let the weather be
ever so dry afterwards: but if, on the contrary, it be
threshed when the air is perfectly clear and dry, it will keep
well in sacks for a long time, especially if these are laid
upon treliffs high enough to secure them from the damp-
ness of the ground or floor.

But for keeping of the meal or flour, in general, there
is no better way than first to bolt and clean it from the
bran or husks, which is apt to make it musty, and then to
tread it down as hard as possible, and head it up closely
in clean, dry, tight, and well-bound sacks, which must be
laid in a cool dry place.

It may be noticed, that the beards of barley come off
best, in threshing, when the sheaves or swarts of this corn
have taken the dew before they are being houfed. It will keep
well in the mow unthreshed for one year; but for making
it into malt, which must be done before the heat of the
summer comes on, it should not be kept above a year and
a half, or at most two years: otherwise it will be filled with
cerevis or insect; unless it has been previously cured in a
flow or kiln.

But oats, from their being defended with a double husk,"n
are the grain least subject to harbour vermin. The best way
to keep them after they are threshed, which should be done
when dry, is to dry them well on a kiln, and then to barrell
them up in clean close casks.

As for beans and peas, they always thresh bell after they
have sweated in the mow, which they are very apt to do;
as the whole crop of either of them never ripens altogether,
the green parts heat, and communicate their ferment to the
whole heap. The danger to be guarded against is, that
they do not heat too much. For this reason, farmers gen-
erally choose to stack them without doors, rather than to
house them; that they may be the more thoroughly dried
by the sun and air. As beans are a very large feed, and
consequently full of moisture, it is found best to let those
that are intended for keeping, sweat and season in the mow
until March, when they may be threshed without danger,
for beans never give again, after they have once been
thoroughly dried and hardened.

And vetches, when wanted for sowing immediately after
they are cut, may be threshed very well on a hurdle, with
a cloth; though they then be too soft, notwithstanding their
being ripe, to be threshed on a floor, where the flail and the
threshers feet would bruise and break them.

In general, in the busines of threshing, as the work pro-
ceeds, it will from time to time be necessary to remove all
the long straw from the corn beaten out of it, which last
always lies underneath, with a prong or fork, and then the
pieces of straw, broken ears, &c. with a wooden rake.
The remaining grain should then be shovelled up on one side
of the floor, and the work be repeated till enough be
threshed out to make what is commonly called a clearing.
The heap should then be wholly passed through a wide sieve,
which retains only the bits of straw, and such fragments
or ends of the ears as have escaped the flail. Thencefrequently
contain some good corn, and form an useful fodder for most
forts of animals, being what are commonly called cavings, as
seen below.

Much labour may often be saved in the use of the sieve
by fastening a loop to its rim, and reeling it thereby on
a hook suspended by a rope. This will fullall half the weight
of the corn, and the necessary circular motion may more
easily be given to it.

After much threshed grain has thus accumulated on the
threshing-floor, and the short straw and chaffy matter have
been separated from it, as just noticed, by passing it through
a wide riddle or sieve for the purpose, which should always
be done before too much grain has been collected, as in that
way the bruising of it is more effectually prevented; it must
be put by to afford more room. The short chaffy sub-
stance thus separated from the grain is in some districts
denominated cavings, or caving-chaff, and is capable of being
employed with advantage, as seen above, in the feeding of
horses, or neat cattle and sheep. When this has been done,
the loose grain should be thrown into a chamber or other
place conveniently formed for receiving it, where it should
remain till a sufficient quantity has been collected to render
the clearing and cleaning of it by some kind of machine
for the purpose, requisite. But the improved threshing
machines render this unnecessary, as they drey or clean it
at the same time it is threshing out. See WINNOWING
Machine.

Furze tops in their young flates of growth are in some
northern situations beat or threshed by the fll, and in that
way bruised as horse-food, where property machinery for this
purpose is not at hand. The work-horses during their use
have little other food, it is said, though performing great
labour.

From the whole of what has been said, it is evident that
the farmer should always consider well before he decides on
the mode of threshing which may be the most proper and
advan-
advantages, as well as the most suitable, to the firm which he holds.

**Threshing-Floor,** the floor on which grain is threshed out in the barn or other place. All floors of this sort should be well formed and constructed, of whatever sort of materials they are made, as without it they give way and fall to pieces. When the materials employed in this intention is wood, the timber should always be of the best kind, and well seasoned, being put together in a careful and firm manner; and when of the earthy kind, the different matters be well reduced, wrought together, and laid up for some length of time before the floor is formed, being then laid down in a smooth even manner, and made firm and solid by frequent ramming with a proper tool for the purpose, until the flooring subsides, whatever it may be, becomes quite dry.

It has been observed, that as grain is threshed out by machinery, from the circumstance of its being separated from the straw immediately, and not permitted to remain upon the floor for an hour or two, when brought to market, is always much drier, looks better, and brings a higher price than that which is threshed by the hand, and suffered to remain upon the floor for weeks, where it becomes mummy, loses its colour, and is so raw, that much of it is bruised and rendered useless in the working. Therefore, if the flat-mode of threshing is still pursued, it is supposed that the inconveniences above-mentioned may, in some degree, be remedied, by paying proper attention to the materials of which the floor is made, and raising it sufficiently above the reach of moisture. Where the barns are very extensive, and the price of wood uncommonly high, as is the case at present, a very good and durable threshing-floor may sometimes be made by laying an uniform stratum of round gravel, covering it with a coat of well-tempered clay; above which, a mixture of clay, brick-dust, forgesmash, and a small proportion of lime, will make it a hard uniform floor, proper and suitable for the purpose of threshing upon. It is observed that the brick-dust and forgesmash should previously be beaten very small, and well incorporated with the clay, using a sufficiency of water to bring the whole to the consistency of mortar; in that state, the lime, having been previously flaked, should be incorporated with the other ingredients; the whole smoothed over with the back of the spade, and allowed to remain in a round heap for two or three weeks, at the end of which time it should be turned over in the same manner as plaster lime, and after being rendered sufficiently soft with water, it may be spread upon the floor, an operation that will require some pains on the part of the workman. The floor, in the first instance, should have the coat of clay, that is laid above the gravel, rendered perfectly smooth and uniform, by rolling, beating, or otherwise; the smoothing coat, composed of the mixture above-mentioned, may then be applied, taking care to break the surface of the clay with shallow lines, in the way practised by plasterers, for the purpose of making one coat adhere to another in a firm and perfect manner.

Many other sorts of materials, somewhat of this nature, are made ude of for threshing-floors in different districts of the kingdom.

The following plan has been suggested as the means of excluding rats and mice from the barn and threshing-floors. First, that when the floor is entirely of wood, the space between the fleecers, upon which the boards are laid, should be entirely filled with washed gravel, well beat down, an operation which, when properly done, will effectually prevent the entrance of either rats or mice; where this precaution is not taken, when the floor is laid, openings should be made at the bottom of the wall large enough to admit cats, a contrivance that will have the two-fold effect of destroying the vermin, and affording a free circulation of air. Secondly, that when the floor is of clay, the vermin generally burrow under the foundation, and have the entry to their retreats at the bottom of the wall; in such cases, their access into the barn will be, in some measure, if not entirely, prevented, by mixing a considerable quantity of broken glass with the materials with which the threshing-floor is made. It does not appear necessary to mix the glass with the clay over the whole floor; perhaps two feet from the wall quite round will be sufficient. And thirdly, that the top of the wall, as furnishing a temporary retreat for vermin, deserves also to be noticed: in every instance it is customary for the mason to level the top of the wall previous to the roof being put on, which, when the building is finished, is left in that state, by which a considerable space remains for the shelter of rats and other vermin: to prevent this, as soon as the roof is finished, the building of the wall on the inside should be continued upwards till it joins the roof, to which it should be closely united by hard platttering. It is supposed, by these precautions, and smooth platttering, the walls of barns as well as the threshing-floors may be preserved free from vermin.

**Threshing-Machine,** an engine of the mill kind, contrived for the purpose of threshing grain, seeds, and pulse out of the straw or the ear.

This is a sort of mill or machine that has been chiefly contrived on the same principles as those of the flax-mill, and which is capable of being wrought by different powers, as those of horses, oxen, wind, water, and steam; but those of water and animals are the most proper and convenient in most instances: in some cases, the grain being beaten or swingleed out of the ears by means of beaters attached to a cylinder that has much velocity, while in others it is rubbed out by suitable means against confined cylinders, as will be more fully seen and explained in what is laid below.

There is some reason to suppose, that the original hint or notion of these mills or machines, was derived a long time ago from Holland or the Low Countries, and thence brought into the northern parts of this country, where the different parts of the machinery of them have been gradually undergoing much modification and improvement, to render them more suitable and efficient for the purpose; so that they have now attained a considerable state of perfection in most parts of the kingdom. The first of these improved machines was, as Mr. Somerville says, invented by a Mr. Menzies, brother to the then sheriff depute of the county: the machinery was driven by a water-wheel, which put in motion a number of rails of the same kind with those used in threshing by the hand. Trials made with these machines were so far satisfactory, that a great deal of work was done in a given time, but owing to the velocity required to do the work perfectly, they soon broke, and the invention fell into disuse.

Some time in the year 1758, another attempt was made by a farmer in the parish of Dumbie, in Perthshire. His machine was constructed upon principles similar to the flax-mill, having an upright shaft with four arms inclosed in a cylinder, three feet and a half in height and eight in diameter, within which the shaft and its arms were turned with considerable velocity by a water-wheel. The sheaves, being presented by the hand, were let down from the top upon the ears, by which the grain was beat out, and together with the straw deflected through an opening in the floor, where they were separated by riddles and fansers, also turned by the wheel.

And
And it is added, that, about twenty years after this, a third attempt was made by a Mr. Elderton, near Alnwick, and a Mr. Smart, at Wark, both nearly about the same time. Their machines were so constructed as to act by rubbing, in place of beating out the grain. The sheaves were carried between an indented drum, about six feet in diameter, and a number of rollers of the same description ranged round the drum, towards which they were pressed by springs, in such a way as to rub out the grain when the drum was turned round. Upon trial, this method of construction in these machines was also found defective, as along with its doing very little work in a given time, it bruised the grain, and so materially hurt its appearance, as to lessen its value considerably in the markets.

It is further stated that the machine, in its then imperfect state, was seen by the late Sir Francis Kinloch, bart. of Glenmerton, a gentleman well acquainted with mechanics, and who had paid much attention to country affairs: it occurred to him, that the machine might be rendered more perfect, by inclining the drum in a fluted cover, and fixing on the outside of it four fluted pieces of wood, capable of being raised a little from the circumference by springs, in such a way as to press against the fluted cover, and to rub out the grain as the sheaves passed between them; but after repeated trials, it was likewise found to bruise the grain nearly as much as the model from which it was copied. In that state it remained some time, and was afterwards sent by Sir Francis to a very worthy and ingenious character, Mr. Mickle of Know-Mill, in his neighbourhood, (a millwright by profession,) who had for a considerable time employed his thoughts upon the same subject. After much consideration, and several trials, it appeared to Mr. Mickle, that the purpose of separating the grain from the straw might be accomplished upon a principle different from any that had hitherto been attempted, namely, by sketching acting upon the sheaves by their velocity, and beating out the grain, in place of pressing or rubbing it out. Accordingly a model was constructed at Know-Mill, in which the grain was beat out by the drum, to which it was presented through two plain feeding rollers, which were afterwards altered for fluted ones. The first machine, on a large scale, executed upon this principle, was, it is said, done by a son of Mr. Mickle's, for a Mr. Stein of Kilbagie, in the year 1786, which, when finished, performed the work to the satisfaction of all parties. A patent was afterwards applied for and obtained in 1788. Since that period, as well as the first introduction of these machines, many other improvements have been made upon them by different ingenious artificers in many different places; a screen has been added for the grain to pass through into a winnowing machine, and a circular rake to remove the straw from it; as before this addition, the straw was forced out from the heater upon the upper barn-floor, and required much time and labour in shaking and putting it into order, which by this contrivance is saved. And besides having a sufficient degree of velocity, without its being so great as to injure the machinery, it is found that a point upon which the clear threshing of all sorts of grain materially depends in the use of this machine, is the management of the iron covering, under which the beating-wheel, having six or more beaters, moves: in some machines this is fixed, while the beating-wheel is capable of being raised or depressed at pleasure; but a more late improvement is to render the iron roof moveable and the wheel fixed, the iron being placed so close to the beaters, that the grain is rubbed as well as shaken out of the ear. And in some cases the beaters are somewhat rounded, but the flat form is probably better.

Different machines of this sort are also said to have been lately constructed so as to work with chains instead of cogs, and to perform the business in a satisfactory manner. Another great improvement is likewise believed to have been made on the feeding rollers; which is that of having the upper roller, instead of being one solid cylinder of wood, with rods of iron fixed upon it, as was formerly the case, an octagon or decagon of cast iron, and divided into four parts, which are loosely joined into each other, so that in turning round, each part can rise or fall in a separate manner, according as the corn is spread out in a thicker or thinner way. The advantage is, that by means of this contrivance the corn is regularly held; whereas, by the roller being all of one piece, if at one part the grain should happen to be more in a heap or lump than at another, the whole roller is raised, and a great part of the grain passes through, without having been held sufficiently to the beaters, and is consequently imperfectly threshed out.

This sort of machine is sometimes constructed with a vertical shaft, on which is fixed in a horizontal manner an iron bevel wheel, six feet in diameter, which drives another about eighteen inches diameter upon a tumbling shaft, upon which is also an iron fpur-wheel, three feet six inches in diameter, driving one about ten inches upon a short iron shaft, which likewise carries a drum or pulley, three feet six inches in diameter, from which a fix-inch strap drives one nine or ten inches in diameter, hung upon the iron shaft or spindle which runs quite through the wood-beater or barrel, two feet in diameter, and three feet in length, having fixed upon it, by means of strong screws into its iron bands, twelve wrought-iron bars, about an inch square, which beater making upon its horizontal axis about three hundred revolutions in a minute, and consequently nearly three thousand fix hundred strokes in that space of time; the corn being carried to it by means of a cloth, which is moved forwards by rollers, lying nearly upon a flat surface of six feet long, by three feet wide, two to three feet high from the ground-floor, which is a very convenient position to feed upon, and paling between a pair of fluted rollers, over a bar, comes in contact with the beater, through a cavity, which may be varied by screws, from an inch in width, to the thickness of a grain of corn, when the straw is immediately delivered, perfectly clean upon the floor on the outside of the machine, no more injured for thatch, or other purposes, than by the flail, and the corn in its passage under the beater is filtered through a wooden frame to the floor, where it remains for removal. Upon this kind of threshing-machine many different trials have been made in the view of ascertaining what sort of power, construction, and velocity or speed, would produce the best and most beneficial effects on the work, and many improvements have been suggested which we have not room for reciting.

Some machines of this sort have large wooden fly-wheels, of from twelve to fifteen feet diameter, fixed upon the tumbling-shafts, which run over or above the horse's heads, perhaps made of fir-timber, as cork unfortunately is seldom to be met with; but as their speed, in such a situation, can rarely afford any assistance, the lighter they are, the less impediment, it is supposed, they will produce. The bars or beaters are also sometimes as much as an inch and a half, or two inches thick, from the barrel or roller upon which they are fixed, and the roller itself three feet or more in diameter; but so much of the bar is certainly, it is thought, unnecessary, as exceeds the length of straw drawn in by the rollers, during each interval between the strokes, and which is seldom more than half an inch; consequently, whatever is more than three quarters, produces an increased impediment.
The greater the diameter of the same beater, from meeting with the principal resistance, so much farther from the centre, of course, the proportionately greater power is required to work it; but this last description of beater is said, in general, to be found to make the best work, and the reason is thought obvious: they are necessarily driven by water, stream, or a number of horses, and, it is concluded, calculated to make the same number of revolutions in a minute as one of two feet, in which case their velocity, on which all depends, is, jult half as much more—a most important point indeed. The means of regular steady driving is likewise of material importance in all machines of this nature, where animal labour is necessary.

A very powerful improved machine belonging to Mr. Harbottle, of the Rimingham farm, near Henley on Thames, consists of a horse-wheel which contains 136 teeth, or pinion wheel with 26, a large wheel with 88, another with 21, the same with 88, and a further one with 21, forming the drum. Underneath the drum is the contrivance for winnowing, or the wheel that separates the chaff from the corn, by blowing it back into a bin below the feeder, and allowing the corn to fall into a box, from whence it runs. Every revolution of the horse-wheel in this machine produces eighty-eight and a half of the drum; and as the horse-wheel goes about three rounds of twenty-four yards each per minute, or two miles and a half in an hour, the drum of consequence must revolve on its circumference, of three yards and a half, 265 times in a minute, or 0.27 yards. The feeding-board is five feet four inches wide. The drum-wheel is four feet four inches diameter, being covered with sheet-iron, and has four beaters, which project four inches making the number of revolutions to one of the horse-wheel, and the horses going the above distance in the hour; in a path twenty-four feet diameter. The cogs of the wheels are of white horn properly feathered, working into others of cast-iron; paid only with black lead, not any grease being employed. The level of the flage on which the men stand to feed, is eight feet above the barn-floor in which the machine is fixed.

The drums of threshing-machines, it is remarked, in general revolve from sixty to a hundred times for one revolution of the horse-wheels; and that in proportion as the move flower, the horses must go faster, so that the utmost nicety is necessary to properly adjust this: as if the horses are under the necessity of trottling, they are greatly injured in long continued exertion, and if they move too slowly, the work is imperfectly performed. A steady common walk is the pace at which horses should be kept, and the drums of machines should be formed accordingly, in order fully to effect their work, and at the same time to enable the horses to do a good day's labour without too much fatigue and inconvenience.

This machine will thresh, it is said, from twenty to thirty quarters of wheat in twelve hours in great perfection; from thirty to forty-five of barley in the same time; and from forty to fifty quarters of oats. It threshes every thing perfectly clean when the grain is in sheaves. But though it cleans the corn from chaff, as seen above, winnowing is required afterwards. It was seen with one feeder to thresh twenty-two large and long sheaves in three minutes, without any variation in the ordinary movement of the horses. This machine was constructed by Elliot of Hexham, in Northumberland, and cost about 200l., without the expenses of fitting up, &c.

It is stated, in the Essex Agricultural Report, that Mr. Newman of Hornchurch has a threshing-mill which was built by two young millwrights from Somersetshire, in which there are two new circumstances of improvement, one of which is a movement so prepared, as that the person who feeds the mill, by putting his foot on a pedal can lift one of the fluted cylinders out of its work, so that the wheat-ears having been advanced far enough to be threshed, the flay may be drawn back again and be prevented from being broken; the other is a click, or iron, which admits the horses to be stopped suddenly without stopping the beater; by which the connection is removed for a moment, so that one operates without the other: this is of capital importance in working the machine. Representations of these improvements are given in the above work.

These machines have occasionally grinding-mills combined with them, and are in this way found very convenient and advantageous. The Hon. Newton Fellows, in Devonshire, has been at very great expense, in erecting a threshing-mill connected with one for grinding, both of which are wrought by a never-failing stream of water. The power of this mill or machine is said to be calculated as equal to sixteen horses. And together with its power and capability for threshing, winnowing, and driving every kind of corn, the pair of flanes for grinding attached to it are about four feet in diameter, to which a bolting-machine or apparatus is added.

In working, this threshing-machine is capable of discharging about twenty-five bushels of wheat, and nearly forty bushels of barley or oats in the hour. The barn, or place where the machine is placed, being filled with the wheat or other corn; the manual assistance for performing the duties is distributed through it in this manner: one man and two women for unbinding the theaves of corn and feeding the rollers, which lift are grooved and divided into lengths of six to eight inches: on the flay being discharged from the machine, one person attends to make it well over a large open screen, whence it is tossed over to another person, who removes it out of the way. At and under each of the winnowing-machines, sieves are placed to receive the grain coming directly from the machine, which is then put into the hopper of the fan of the second winnowing-machine, from which it is again received into another sieve and thence discharged into the hopper for grinding, for the market, or for other purposes: in passing through this little fan, such a separation takes place of the chaff, to completely to divide the head from the tail corn. A cylindrical pearl-barley machine or apparatus is also applied and used to cleanse the wheat of the chaff, and thus by taking off the down end of the grain, a much finer sample of both wheat and flour is obtained. This is preferred to the brush apparatus; for although that may cleanse the body of the grain, it will not carry off the dust from its end, which may reasonably be supposed to contain the germ of the grain, or to form the neli of other animalcula, equally injurious to such grain when used as feed on lands.

There is in this machine only one labouring man employed to five women, which is an advantage of great importance in many situations. The introduction of such machinery as this is therefore of great benefit in bettering and improving the rural condition of the country.

But, besides machines of this sort being constructed for performing the different operations of threshing, winnowing, grinding, and bolting, they have sometimes contrivances for other purposes, as an iron hopper axis for grinding apples; and a contrivance for sheellng clover feed, and the haddocks of wheat. These two additions belong to a threshing-machine of Mr. Vinns in the above district; and some others are occasionally met with in other places which are a little different in their nature, but unnecessary to be here described.

In the general construction of these machines, they are commonly,
Mr. Whiting, of Fring, has also a large threshing-mill, built by Mr. Fordyce, an engineer from Scotland. It is called the 200. It is worked by six horses; threshes twenty-four coombs of wheat in the day, fifty-five of barley, and from sixty-three to eighty-four of oats. It has five beaters on the drum-wheel, and the fluted segment of a cylinder which covers the drum in two parts, with an unfluted plate between them, which is raised or sunk by a short lever: this is a guard against hones getting in. In another circumstance also it is angular; there is a long platform, with a rolling cloth bottom: the whole raised or sunk for delivering the corn, across the floor space of the barn, from the gulf in which the corn is flaked, to the other end in which the mill is built; which saves much labour, and works to his satisfaction.

The horse-wheel is here upon a different construction from the common ones, working by a caged-wheel of small diameter below, instead of above the horses; and the communicating spindle under their path; but it is said to be hard work.

And Mr. Coke, of Holkham, is fitted to have a very large machine, which coil about 600. Besides threshing, it grinds corn, works two chaff-cutters, and breaks oil-cake. It threshes sixty-four coombs a day.

Mr. Reeves, of Heverland, has a threshing-mill which is, the writer thinks, still nearer to perfection than any other he has seen; it was made by Aheby, works with two or three horses, and cost a hundred guineas. He found it at work, threshing oats; it does for barley as well as for any other grain, threshing thirty-two coombs in a day of seven hours and a half; more of oats; forty of peas; and thirty of wheat: its day's work of wheat, threshed the day before he saw it, was thirty-one coombs, which were flanding backed in the barn. It varies considerably in the beating-drum cylinder from the others he has seen, it being of a much larger diameter, and has eleven beaters.

At Brightwell-Grove, in Oxfordshire, according to the Agricultural Report of that district, there is a threshing-machine, belonging to Mr. Lownde, which was constructed by Railrick, and in which there is some novelty of convenience: it works by means of four horses; the drum-wheel, in this case, is three feet and a half in diameter, makes two hundred and fifty revolutions in a minute, and, having sixteen beaters, it gives 4160 strokes in that time: there is a rake with four fags of teeth which takes the straw, and delivers it to a second drum-beating cylinder two feet in diameter. This drum is termed the drawer, and turning in an opposite direction to the motion of the straw, beats it down, and in its descent strikes it against a circular board, faced with bars sod with iron, through the space of eighteen inches, by which the straw receives several additional strokes, which, it is conceived, have a great effect in dislodging that corn which has not been completely separated in passing the principal drum. This is the addition not usual in these machines. There are wrought four hours at a time, in which eight quarters of wheat are threshed out. Every thing is threshed perfectly clean; and the straw is not broken more than by the flail. Twelve quarters of barley are threshed in four hours, and sixteen have been done in that length of time. The horses, in this machine, are not attached in the draught, in the manner which resembles pushing, by advancing with the lever before them, but in the common drawing method, with the lever behind them, in which way they are suppos'd by some to do the work much better.

This machine was seen to thresh forty-three flake in ten minutes. It drels at the same time; and there is a chaff-cutter,
eutter, as well as a corn grinding-mill with stones, for farm use, attached, and wrought or not, at pleasure.

It is perhaps only in places situated in the immediate vicinity of a colliery, and where, from the cheapness of fuel, they are capable of being worked at a very trifling expense, that steam can be had recourse to as the moving power of these machines. See Steam, and Steam-Engine.

With regard to small machines, it is said in the East Lothian Agricultural Report, that they have been introduced there, upon a reduced scale, at a price so low as 40l: that these small machines, having little work to do, and that little being, in general, done slowly, answer the purpose tolerably well; but though cheaper in the first instance, they are, in the end, more expensive than larger ones, a certain degree of strength being absolutely requisite to do the work perfectly. If the parts of the machine are below that degree of strength, the work is either ill done, or the machine is destroyed, by being exerted above what it is able to bear.

The writer of the Essex Agricultural Survey too flates, that in that district at present many are made by Balls of Norfolk, the price fifty guineas, and do their work very clean and well for all sorts of corn, but do not drefs. They have been applied to white clover, and have done it to the satisfaction of the growers, by palling it through twice or thrice. In one erected by Mr. Vaisey, which is worked by horses, one man feeds, two supply, a boy drives, and two men clear away the straw. He has threshed sixty quarters of wheat with it in eighteen hours. It cost 52l. 10s., and 10l. putting up; the shed added about 20l., two winnowing machines 15l. 15s., in all, complete, about 100l. But in this a greater number of horses are used than are noticed above. The owner has no fault to find with its performance, but is very well satisfied with it. He has applied it to cobbing white clover with great success; by palling it thrice through the mill, he got from three jars, seven barrels of clean feed in four hours. And one built by Dickson of Ipswich, for Mr. Sanxter, goes with two or four horses, and costs fifty guineas. It is supposéd that it will thresh twenty quarters of wheat per diem. But it is now fifty-five guineas, put up and ready to work. Two horses work it, without hard labour. The last year's wheat, which was very badly threshed at 7l. per quarter, was done by this machine perfectly well. Also at Little Walkering, Dr. Apilin has a machine which the writer saw. Working with one horse, which moved with great ease, driven by a little girl; one man and two boys work it, and it does three quarters of wheat in a day. The writer examined the straw for about a quarter of an hour, and did not find a single kernel in it. The price is sixty guineas. The construction in this machine varies from the others he has seen, in the wheels which communicate the motion. The doctor threshes only wheat with it, though it will do for all sorts of grain. He thinks it answers greatly, and is perfectly satisfied with it. It was made by Turbot, Bankside, Wellminster, but they are now made by Jones, Clement's Lane, Clare-market, London.

There are many other persons who put up these machines at an equally reasonable rate, and so as to work with much perfection.

Where machines of this sort cost about one hundred guineas, the annual expense in interest of capital and repairs cannot be more than from 10l. to 12l. at most, except in the expenses of teams and the labour of the persons employed in the execution of the business and work about them.

The expensive machines which have rollers for rubbing out the grain instead of beaters, are thought in general to perform the business in the most perfect manner, though they require more power to work them.

It is, however, thought by some to be utterly impossible to build threshing-machines which will do justice to the owners for any such sum as 50l., or thereabouts, as their durability and success depend materially on their firmness, strength, solidity, and other circumstances of the same nature, which are by no means attainable for any such money. Yet many of these small machines of one or two horse power, are said to perform their work well, and at the rate of six quarters of wheat, and the relative proportions of other sorts of grain, in the course of the day. They are flated to be made in several different districts, at the prices of from thirty to fifty guineas, so as to thresh well at nearly the above rate, and to have, in some instances, other additions, such as chalk-cutters, &c. made to them. In particular cases, they are thought not to break the wheat-fraw so much as the flail; and though wheat and beans are mostly well threshed by them, barley is under the necessity of being often twice paffed through such machines, as seen above. They do not drefs in general; but sometimes head clover in a pretty perfect manner, as noticed already.

Small threshing-machines have likewise been constructed so as to be wrought by hand, in some districts, both in the northern and southern parts of the kingdom, and been offered by some to perform their work in a clean and satisfactory manner; but from their mortlly wanting that degree of velocity, in being wrought in this manner, which is essential to good work of this kind, they have not yet become in any way general. Indeed, in some districts in the south, the working of them by the hand not being found to succeed well in actual practice, the usual feeding rollers have been applied with the horse-tackle, at the additional charge of about 20l., which has enabled them, it is said, to do the work properly, and in an easy manner, even by the power of one horse. Where the teeth of the iron wheels in such machines have been found too fine for the increased force made use of in this way, vertical wooden wheels and pinions have been put in their place, which have contributed to the strength and preferred the simplicity of the machinery.

Threshing-machines have now been known, and in some measure employed, in the northern parts of this country for more than half a century, and are at present very general in those that are any way improved; but in the more southern districts, they have only been attended to, in any considerable degree, for the space of the last thirty or forty years, yet their use and application are fast becoming general among the more extensive farmers whose farms are of the arable kind. In short, it is not improbable but that in a little time the machine will be the most prevalent method of threshing out corn. And it has been conjectured, that parish machines of this nature, in centrical situations, would perhaps not be less useful or convenient than parish mills, while, at the same time, they might be easily so regulated as to be rendered of great general benefit to the community, as well as advantageous in the way of private speculation to individuals. Something of this sort is said to be already in the case in some districts of the North, and would, I believe, be defirable in all, for the convenience and accommodation of the small farmer; as the same conveyance that brought the corn to be threshed, might take back the straw and grain, and in this way little waste of labour or time be fuitual, while the saving would be considerable and certain.

It may be noticed also, that in all cases where threshing-machines are made use of, they should be well suited to the extent
extent of the farms, and he erected in such a manner as to be convenient for having the contents of the flacks brought to them. In this view it has been suggested, in the Report on Agriculture for the West Riding of Yorkshire, that the barns to which they are attached should extend into the yards in which the flacks are contained; as in that way the labour and time will be considerably lessened of supplying them with corn in the flack for being threshed. And it has been justly remarked, by an intelligent promoter of agricultural improvements, that this machine has not been attended with one-half of the advantage which might have flowed from so useful a discovery, for want of combining the use of it with the various connected circumstances of the farm-yard. The buiness of flaking corn, for instance, mulf, it is conceived, receive an entirely new arrangement in consequence of building a threshing-mill or machine. By means of no other additional expense than that of an iron railway, and placing the flacks on frames resting on block-wheels, two feet in diameter, a very considerable annual expenditure in time and labour mulf, it is supposed, be saved in carting flacks to the barns, in lots of corn, and in waiting for good weather, as well as in the saving of threshing by flails, and all the attendant evils of pilfering and leaving corn in the flack. This is a material object, which it is thought cannot receive too much attention from both landlord and tenant. It is contended that there cannot be the smallest doubt of the propriety or profit of having one of these machines fixed in the principal farm-yard. But that where the farm is large, and flacks consequently scattered over various fields or parts of it, then it may be right to have a moveable one also; but so many operations are wanting at home, that one should certainly be fixed. The circular form of the railway upon which the flacks are brought to the mill or machine, is considered necessary in such cases, as being the only one which permits a choice of any particular flack to the thresh, without waiting for all or many others being done before it can be got at; but a straight line leading to and past the mill or machine is admissible, except for this circumstance, though much inferior, in some other points, to the circular form. In forming this plan, a fort of railway should be so contrived as that a horse or two may be sufficient to draw all common flacks to the mill or machine. And it is directed that the wooden stumps on which the frame rests should be tinned, or laid in the common manner with brafs latten, which is more durable than common tin, to keep out rats. Also, that as the power applied to the threshing-mill in other ways is at hand, and applicable also to the above fort of work of drawing the flacks, it may be used for the purpose in many cafes.

Threshing-Mill Barn or Building, that fort of barn, fixed, or other building which is calculated for receiving, or which contains this kind of mill or machine.

In this intention, an upper floor, raised eight, nine, or ten feet from the ground, in proportion to the height or size of the animals, and the arrangement of the machinery which is to be employed, will be required, and which should reach from end to end of the barn or building, as a repository for the unthreshed corn, which should be there lodged and deposited, at leisure times, from the flack-yard, or other places, in order to be ready to feed the mill or machine with from this upper floor. The ground-floor should contain the large mill-wheel, and a horse-path round it, all the lower parts of the machinery, a dressing-room for the grain, and a wide open space for flack of different sorts, which is there to be piled up, ready for the cattle-sheds, on each side of this repository of fodder.

The expenses of these prepared barns or buildings, will probably not only be much lighten, but wholly done away, in some cafes, by the use of the threshing flack farm-yard, which has been described in speaking of the mills or machines for this use, and much convenience and accommodation be thereby gained to the farmer in the dispatch of the business, &c.

On the whole, by these means the labouring teams and hands will be enabled to perform the work of threshing at such wet, houmy, and leisure periods as will render it the least troublesome and expensive to the farmer. See Threshing-Machine.

Threshold Point, in Geography, a cape on the north-west coast of New Guinea. S. lat. 6° 37'. E. long. 132°.

Threx, among the Romans. See Thraces.

Thrip, in Botany. See Statice.

Thrihing. See Thrihing.

Thrimsa, in Antiquity, a silver coin, the value of which has occasioned a variety of conjectures. Lamhard, who gave the first effum of it, makes it a three-shilling piece, in which opinion he is followed by Sir Henry Spelman. Bifhop Nicholfon apprehends, that it was the name of their common coin, and that the thrimbus, fceata, and penny, were all of them the fame. Somner, from the import of the word, and the value given to the thrimbus in the Saxon laws, rates it at three-pence. Selden, Brady, and Hickes, are of opinion, that this coin was either the half tremis of the Franks and Germans, and conquenently four-pence, or the third part of the Saxon shilling, i.e. three halfpence and one-third of a halfpenny in their money. Mr. Clarke adopts, and endeavours to establish the opinion of Somner, who observed, from the laws of Athelflan, that the price of a threeman's life was, by the Angli, valued at 2000 thrimbus, which, by the Mercian effumne, was 1200 shillings; and if each of these sums denotes the same value, which is probable, then threimbus must be to the shilling as 2000 to 1200, or three parts in five of a Saxon shilling, i.e. three-pence.

The thrimbus was first coined in the reigns before Athelflan, during their greater affluence in cash, and designed merely for the convenience of exchange, as the most proper division that could be made in their money without a fraction, between the shilling and the penny. But when the shilling was reduced, it was of little use, and by degrees entirely laid aside.

Dr. Hikies obserues, that the method of computing by thrimbus was chiefly used in the more mercantile parts of this kingdom, among the East and West and South Saxons, and possibly coined only among them; for it appears that the inland provinces, the Mercians, reckoned generally by the shilling. Clarke's Comm. of the Roman, Saxon, and English Coins, p. 229, &c.

Thrin, in Geography, a river of Norfolk, which joins the Yare at Yarmouth.

Thricia;

site formifolofulve, Linn. Cirrhaces; Juff.

Gen. Ch. Common Calyxx oblong, permanent, imbricated, of several linear, parallel, unequal, longitudinal, incumbent scales; those at the base very small. Cor. compound, imbricated, uniform; the florets numerous, all perfect, equal, monopetalous, ligulate, linear, abrupt, with five teeth. Stam. Filaments five, capillary, very short; anthers united into a cylindrical tube. Peric. none, except the permanent, straight calyx, at length reflexed. Sepals solitary, oblong, truncate, crowned with falcate feathery down, somewhat chafy in the lower part, and often unequal in the marginal florets; somewhat falcate in the central ones, frequently accompanied by shorter hairs or plumes. Recept. dotted, naked, or very flitily hairy.

This genus, though very natural and well defined, has the general habit of Hedyoopsis, or of Hieracium, agreeing with the latter in having some caulescent species, though in most the flowers are radical and single-flowered. The leaves are variously toothed or fimbriated, mostly hairy, rarely villous. Flowers of a full yellow. Root, except in our thirteenth species, perennial, tuberous. We adopt the English name of Hawk-bit from Petiver.

nois pyrenaica; Villars. Dauph. v. 3. 78, from the author. Picris fætalis; Allion. Pedem. v. 1. 211. t. 14. f. 4. Tiri- 

raeum folis integris dentatis, calyce hifidio, pappo plu- 

mbo; Hall. Helm. ed. 1. 741.) — Stalk radical, falcate, single-flowered, fealy; slightly timid, and somewhat hairy, at the top. Calyx hifid. Leaves lanceolate-oblong, slightly toothed, somewhat hairy. — Native of gayly pastures, on the Alps of Auffria, Switzerland, Dauphiny, and Italy. Haller found it on mount St. Gothard, Schleicher on mount Foulry, and the late Mr. Davall on St. Bernard. Our synonymy of Haller's first edition, entitled by Willdenow, rests on the authority of Allioni. We do not find the plant in his subsequent publications. The root is tuberous, perennial, with long fibres. Leaves from three to eight, radical, falcate, erect, obtuse, two or three inches long; tapering at the base; differently toothed about the middle or lower part: rough, with shaggy short hairs, particularly about their rib and footstalk; which latter is sometimes red or purple. Flower-footstalk from three to ten inches high, slender, erect, bearing a few feathery linear scales, and one yellow flower, hardly so big as our common Dandelion, whose calyx-scales are narrow, black with shaggy hairs.
A. erecta. Saffron-coloured Hawk-bit. Wildld. n. 3. (Leontodon croceus; Hafne in Jacq. Cod. v. 2. 16.)—

"Stalk radical, solitary, single-flowered, slightly falcate; tufted and hairy above. Calyx hispid. Leaves smooth, runcinate, with a triangular terminal lobe."—Gathered by Haenke on the alpine heights of Judenberg, in Upper Styria, where it inhabits dry, open, barren places, but is elsewhere rarely to be seen. This is said by Willdenow to be like the preceding, but different in the above-described figure of its leaves, which are only somewhat hairy. Flower an inch and half; or two inches, in diameter, very handsome, and readily distinguished from all the surrounding species of its own tribe, by its colour, which is that of tincture of saffron.

4. A. bistulis. Shining Spear-leaved Hawk-bit. Hoff. Syn. 423. Willd. n. 4. Ait. n. 1. (Leontodon bistulis; Linn. Sp. Pl. 1123. Jacq. Ait. t. 164. L. prothesis. B & C; Villars Dauph. v. 87. Picris n. 26; Hall. Helvet. v. 1. 12.)—Stalks radical, single-flowered, smooth as well as the calyx. Leaves ovato-lanceolate, smooth, with numerous slightly hooked teeth.—Native of the south of Europe; very abundant in Switzerland. The leaves are often a foot long, tapering at the base into purplish, flat, winged footstalks; their surface smooth, even, and somewhat glaucous; their margin cut into many deep, acute, triangular teeth, partly hooked backward. Stalks several, round, very smooth, glaucous, very rarely divided, twelve or eighteen inches high. Flower bright yellow, an inch and half wide, with scarcely any perceptible hairs on the calyx; drooping when in bud. Sometimes the flower-stalks bear a few linear distant scales.

5. A. dubia. Doubtful Hawk-bit. Willd. n. 5.—

"Stalk single-flowered, radical, nearly naked; hairy, as well as the calyx, above. Leaves lanceolate, toothed at the base, slightly clothed with forked hairs."—Communicated to Willdenow by Hoppe, from the Saltzburg Alps, under the above name, which seems to us to but too well applied. We have not indeed seen a specimen of this plant. Willdenow describes it as intermediate between the last and A. bistulis. The stalks are mostly furnished with one small scale, and are tufted under the flower, whole calyx, as well as the upper part of the stalk, beft with short forked hairs. The leaves seem smooth at first sight, but bear scaterred, white, forked hairs.

6. A. tuberosa. Knotty-rooted Hawk-bit. Willd. n. 6. Ait. n. 2. Sm. Fl. Græc. Sibth. t. 797, unpubl. (Leontodon tuberosum; Linn. Sp. Pl. 1123. Dens leonis bulbolus; Ger. Em. 290. Chondrilla altera Dioecorides, &c.; Lob. t. 232.)—Stalks radical, single-flowered, naked, somewhat hairy. Calyx hairy. Leaves pinnatifid, runcinate, somewhat lyrate, rough with forked hairs. Root of many ovate tapering knobs.—Native of the fouth of Europe and the Levant; very common in the fandy meadows of Greece, Cyprus, and Zante. The modern Greeks name it φαδος, or ραδος; and it may be, as some old botanists have thought, the κονιτάκα της of Dioecorides, but this is hard to determine. The perennial root is a clusater of fesilie ovate knobs, above an inch long, tapering into radicles. Leaves numerous, spreading, dark green, obtuse, either finely runcinate, with a large terminal lobe, or deeply, sometimes interruptedly, pinnatifid, and bluntly toothed. Flower-flanks several, a span high, ascending, filrated, more or less hairy; purple, like the footstalks, at their base. Calyx flender, with acute scales. Flowers above an inch wide, full yellow; red underneath.

7. A. incana. Hoary Hawk-bit. Scop. Carn. v. 2. 313. Willd. n. 7. Ait. p. 3. (Hieracium incanum; Jacq. Ait. t. 287. Linn. Sp. Pl. ed. 1. 799. H. fexatum montanum; Clus. Hilt. v. 2. 141. Ger. Em. 302. Leontodon hidpidam; Linn. Sp. Pl. ed. 2. 1124.)—Stalks radical, single-flowered, almoft naked, hoary as well as the calyx. Leaves lanceolate, erect, very minutely and sparsely toothed, hoary with lirary hairs.—Found on hills and mountains in Germany, Switzerland, Carniola and France. The root is long and woody, divided at the crown, where its bears several tufts of straight, upright, more or less acute, very hoary, leaves, tapering at the base, from three to five inches long, with a few little, marginal, glandular teeth. Stalks often foliary in each tuft, a foot high, flowering at the top. Flowers light yellow, an inch and a half broad. Calyces narrow, acute. The uniformly entire leaves, though beft with a few glandular teeth, and the structure of most other parts, when minutely examined, render this plant sufficiently distinct from A. bistulis, hereafter described, with which Linneus subsequefly confounded it as a variety.

8. A. Taraxaci. Dandelion-leaved Hawk-bit. Willd. n. 8. Ait. n. 4. Compend. Fl. Brit. n. 3. (Hedypnois Taraxaci; Villars Dauph. v. 3. 82. t. 26. Fl. Brit. 825. Eng. Bot. t. 1109. Hieracium Taraxaci; Linn. Sp. Pl. 1125. Retz. Obs. ffig. 4. 30. t. 2. Lightf. Scot. 435. Picris n. 27; Hall. Fl. Brit. t. 1. 12. P. Taraxaci; Allion. Ped. v. 81. t. 31. f. 1.)—Stalks radical, mostly single-flowered; tufted and hairy at the top. Leaves smooth, with recurved teeth. Calyx hairy,—Native of wetty pastures on the loftied mountains of Lapland, Scotland, Wales, Switzerland, Savoy, and Dauphiny, flowering in July or Augulf. Root abrupt, with long lateral fimple fibres. Herb very variable in the breadth of its leaves, as well as the number, height and luxuriance of its flower-flanks. The former are either lanceolate, and almoft linear, or spatulate and obovate, sharp or blunt, from two to four inches long, with fhallo or very deep, always runcinate, teeth. The latter are ascenfing or erect, foliary or in pairs, sometimes, though rarely, divided, naked or furnifhed with a few linear scales, fragiary with black hairs at the top, as is likewife the broad and thick calyx. Flowers an inch broad, or more, of a full yellow, with brownifh terminal feet. Germin furmifhed with a taper neck, like a italk, but as the feed fwellis, this appearance vanifhes, and the feathery down is truly fefile. Receptacle naked. Willdenow juftly remarks, that Gouan's fynonym is misapplied to this species in the Fl. Brit. We have now quoted it more correcfly under our fecound A. alpina, to which fome of the flender varieties of the preffent bear a great refeemblance. Solander, as well as Linneus, thought this plant a mule between Hieracium alpinum and Leontodon Taraxacum, merely because its flowers refeembed one, and its leaves the other. The generic character differs from both.

9. A. autumnalis. Autumnal Hawk-bit. Hoffm. Germ. for 1791. 274. Willd. n. 9. Ait. n. 5. Compend. Fl. Brit. n. 4. (Hedypnois autumnalis; Fl. Brit. n. 4. Eng. Bot. t. 830. Leontodon autumnale; Linn. Sp. Pl. 1123. Hieracium minus; Fuchs Hilt. 320. H. minus, five leporiform; Ger. Em. 296.)—Stalks radical, branched; their ultimate divisions falcate. Leaves lanceolate, toothed, or pinnatifid, smooth. —Native of meadows and pastures throughout Europe, flowering in autumn; very common in Britain. The root is abrupt, with very long and copous fibres. Leaves numerous, variably and unequally pinnatifid, or merely toothed, rarely a little rough or shaggy, oblique, or somewhat fterpentine, in their general form or poftion. General flanks one or more, a foot or two in height, spreading, curved and zigzag, alternately branched, not quite without puberfence, terminating in a few long ficaly
10. A. crispus. Curled Hawk-bit. Willd. n. 10. Ait. n. 6. (Leontodon crispum; Villars Dauph. v. 3. 84. t. 25. Hieracium alterum fasicato montanum; Colum. Eecfr. 243. t. 243. H. parvum hirtum, caule aphylo, crispum ab fucetum; Bauh. Hill. v. 2. 1038.)—Stalks radical, almost naked, single-flowered, hairy as well as the calyx. Leaves with various disarticulated teeth and segments, rough with dense three-forked hairs. Seeds with a rough elongated b-sk.—Native of rocks in Dauphiny, Switzerland, and Italy.—The root is said to be very long, thrusting itself deep into the scarcely visible crevices of large rocks, and sending forth many long, simple, lateral fibres. Leaves numerous, in dense spreading tufts, from two to four inches, Columna says more than six, in length, pinnatifid in a rather lyrated manner, some of their segments or teeth turned various ways, especially, as J. Bauhin observes, when dry; they are densely clothed, on both sides, with prominent hairs, whose peculiarly white tips have three or more spreading forks or points. Flower-stalks ascending, a span high, furrowed, bearing a few linear scales near the top. Flower full an inch broad. Seeds uniform, each terminating in a long, tapering, brown, minutely rough beak, which looks like a stalk to the dense feathery down. This species comes very near the following, but appears to be essentially distinguished by the beak of the seeds. Villars confounds its synonyms with those of A. hirta, which differs very materially in having a feally short crown to its marginal seeds, as will hereafter be described.

11. A. bifida. Rough Hawk-bit. Willd. n. 11. Ait. n. 7. Compend. Fl. Brit. n. 1. (Hedyphoia bifida; Fl. Brit. n. 1. Engl. Bot. t. 1554. Leontodon bifida; Linn. Sp. Pl. 1124. Curt. Lond. f. 5. t. 56. Fl. Dan. t. 1562. Hieracium dentis licis folio, hifrutum; Ger. Em. 303.)—Stalks radical, naked, single-flowered. Leaves with recurved teeth, rough. Florets hairy at the orifice; glandular at the tip. Seeds scarcely beaked.—Very common in meadows, pastures, and waste ground, throughout Europe, from Sweden to Greece, flowering in summer. The root is tapering, zigzag, long and slender. Leaves oblong, more or less deeply toothed, or in some measure pinnatifid, their teeth acute, pointing downwards; they are much less densely hairy than those of the leaf, their hairs generally simply forked only; but we are aware of the uncertainty of this character. Stalks several, upright, frayed, clothed with similar hairs. Flowers drooping while in bud; afterwards erect, bright yellow, an inch and half broad. Calyx hairy; its outer scales lax and scattered. Flowers with a tuft of long yellow erect hairs, at the top of their tube externally; their summit terminates in five teeth, at the back of each of which Mr. Sowerby first detected a small triangular cluster of brown glands. These two characters serve admirably to distinguish the present species from every other British one, but the first of them, if not the other, is found in A. crispus. The seeds however have not near so long a beak as in that species, and they differ from A. hirta in being all uniformly furnished with a feathery crown. It is curious to trace an affinity of the seed-down being flaked in this species, published by Wildenow, taken from Haller, on the authority of Reichard. On turning to Halkr, n. 25, we find he trusted to Berkhey, who, in his

Flores Compositi, t. 6. f. 10, has figured a seed, supposed to belong to the plant before us. On examination however its crown proves to consist of simple, not feathery, rays, and therefore it has nothing to do with any Apargia. We mention this circumstance, to shew the mischief of taking things for granted; not only in botanical criticism, but any other inquiry of the human mind.

12. A. hirta. Deficient Hawk-bit. Hoffm. Germ. for 1791. 274. Compend. Fl. Brit. n. 2. (Thrift. Catal. v. 1. 98. Willd. Sp. Pl. v. 3. 1554. Ait. Hort. Kew. v. 4. 447. Hedyphoia hirta; Fl. Brit. n. 2. Engl. Bot. t. 1555. Leontodon hirtum; Linn. Sp. Pl. 1123. Curt. Lond. f. 5. t. 59. Rhagadiulus n. 7. Hall. Hill. v. 5. 5, with some doubtful synonym.)—Stalks radical, naked, single-flowered. Leaves toothed, rough. Calyx nearly smooth. Outer row of seeds definite of down.—Native of gravelly heaths and waste ground throughout Europe. Dr. Sibthorp gathered it, along with our violets and primroses, in Arcadia. Mr. Curtis observes that this species seldom occurs on the same spot with the preceding, of which Mr. Hudson made it a variety. Other botanists have found great difficulty in distinguishing them under all their various appearances, whilst Haller, and more recently Roth and Wildenow, have separated them generically. Linnaeus thought the simple hairs of the plant before us afforded a good mark; but this is fallacious. The herbage of both is nearly the same, or at least their varieties closely approach each other. The flowers of both droop in the bud, but those of A. hirta are the smallest; their florets orange beneath, defunct of hairs about the orifice, and of glands at the summit. The most effential difference of all is found in the seeds of the circumference, which have no feathery down, but instead thereof a crown of short jagged scales. The root is abrupt, or bitten off, not tapering.

13. A. annua. Annual Hawk-bit. (Thrift. Catal. v. 1. 99. Willd. Sp. Pl. v. 3. 1555. Hysteris taraxacoides; Villars Dauph. v. 3. 166. t. 25, excluding the synonyms.)—Stalks radical, naked, single-flowered. Leaves lanceolate, toothed, rough with forked hairs. Calyx hoary and hispid. Outer row of seeds definite of down; those of the disk beaked.—Native of Spain and France, in sandy ground. The annual fibrous root distinguishes this from all the other known species, and especially from the last, with which the short crown of its outer row of seeds agrees. The rest of the seeds however are elongated at the summit into a slender beak, which elevates the feathery down, as on a lengthy stalk, but is not really such. The rough and hoary calyx, and the brighter green of the leaves, are further differences. The name of bifida being preoccupied, see sp. 11, we are obliged to select a new one for the present species.

14. A. Villarsii. Villarsian Hawk-bit. Wild. n. 12. (Leontodon hirtum; Villars Dauph. 82. t. 25, excluding the synonym.)—Stalks radical, naked, single-flowered, nearly smooth as well as the calyx. Leaves deeply toothed, or pinnatifid, rough with simple awl-shaped bristles.—Native of dry funny rocks in Dauphiny, Wildenow, who had a dried specimen, says the leaves are hoary with copious white hairs. We have not seen the plant, nor dare we attempt an illustration of it; Villars having fo confounded various synonyms under this and his Leontodon protheciformes, p. 87. t. 24, that, even with some of his specimens before us, the descriptions are not satisfactory.
grassy pastures on the Caucasian Alps, flowering in August
and September. Root perennial, abrupt. Leaves with
triangular, nearly entire lobes pointed backward, be-
sprinkled on the upper side with decumbent hairs, so
sparingly that they seem altogether smooth. Stalk longer
than the leaves, flared, naked except a minute scale or two;
a little tufted and downy under the calyx, which is blackish,
though hispid, though thickly matted with whitish hairs.
Flower of a full yellow. 

Seeds smooth to the naked eye; their downy, feathery.
This plant has the habit and stature of _A. bifida_, n. 11,
but differs in the want of hairs on the stalk, as well as in
the form and position of the pubescence of the foliage.

Wild. n. 13. (Leontodon coronopifolia; Desfont. Atlant. v. 2. 239. t. 214.)—Stalks radical, single-flowered,
feally, shorter than the leaves, hairy as well as the
calyx. Leaves pinnatifid, with blunt lobes, rough with
forked hairs.—Native of the sandy deserts of Barbary, near
Casfa. The whole plant is rough with branched hairs.
Leaves three or four inches long, spreading on the ground,
unequally, but rather regularly, pinnatifid. Stalks several,
ascending, an inch or two high. Flowers yellow, an inch
broad.

Marlch. a Biebertl. Caucaf. v. 2. 248. (Leontodon his-
pidum; Cavon. 10. v. 2. 39. t. 149, excluding the sy-
nonym.)—Stems leafy, mostly single-flowered, hairy as well as
the calyx. Leaves oblong-lanceolate, toothed or pinnata-
ifid, rough, with forked hairs.—Native of hilly situations
in Spain, flowering the beginning of May. Frequent also
in Tauria. This, as Willdenow remarks, differs as much as
possible from _A. bifida_. The whole herb is even more
soft or finely than that species. Stems six inches high,
with divided lanceolate scales, accompanied by some ob-
long, obtuse, entire or toothed leaves, an inch or inch and
half long. The radical leaves are much more numerous and longer,
tapering at the base, gradually dilated upward, blunter
leafed, or in some degree pinnatifid. Flowers terminal,
foliaceous, pale yellow, near an inch and half broad.

n. 8.—Stems leafy, somewhat branched, hairy. Calyx
smooth. Leaves lanceolate, runcinate, hairy, with forked
bristles.—Native of rocky woods in Hungary, near the
baths of Hercules. Very nearly akin to the last, but
the more branching _flora_, runcinate leaves, and smooth very eleft-
prepared scales of the _calyx_, fringed at the edges only, not lax
and hairy, appear sufficient, as Willdenow thinks, to differ-
ent this species.

Caucaf. v. 2. 249. (Scorzonerla alpifera; Willd. Sp.
Pl. v. 3. 1578. S. bifida; Forsk. Egypt.-Arab. 215.)—
"Stems leafy, hispid, bearing one or two flowers. Calyx
strongly; the margin and keel of its scales fringed with
bristles. Leaves lanceolate, toothed, hispid, with forked
hairs. Seeds rough."—Native of dry open places in Ibn-
ria, and the eastern part of Caucasus, flowering in June.
Forskall found it at Efías, near Marfellhes. We have
already described this under the article _Scorzonerla_, n. 32.

The able author of the _Flora Turcico-Caucasica_ says, "the
leaves and flowers are extremely hispid.; the _calyx_ only hoary,
exto the edges and keels of the scales. Stems bearing
one or two flowers, and from one to three flowers, like _A. his-
picana_. Flowers pale yellow; the outermost purple beneath.

Seeds brown, linear, tapering much at the top, as in the
_Scorzonera_; they are rough with minute prominent points.

Down featherly. The habit of this plant, and its affinity to
_A. hispanica_, n. 17, and _inca_, n. 7, make it rather an
_Apargia_ than a _Scorzonerla_." We have seen no specimen.
The regularly imbricated membranous-edged scales of the _calyx_
in the latter, and the naked tips of its _seed-scales_, are suffi-
cient indications of this genus, and if not found in the
present plant, there can be no doubt upon the subject
but of this we are left in ignorance.

n. 16. (Hieracium variegatum; Lamarck Dict. v. 2.
362.)—Stems nearly leafless, somewhat branched, hairy.
Radical leaves oblong, strongly toothed, hairy towards the
edges. Calyx-scales spatulate, flat; downy at the base and
margins.—Gathered by Commeron at Monte Video. The
root feems rather woody. Stems several, six inches high,
each terminating in one large yellow or orange-coloured
flower, and bearing several linear acute scales, with the
rudi-
ments of branches; but we find none of the pinnatifid
leaves mentioned in Lamarck. The numerous radical leaves
are two inches long, tapering at the base, bluntest, with
coarse blunt unequal teeth, green, not hoary; fringed with
simple black hairs about the margin and mid-rib on both
sides. The dilated, obtuse, smooth scales of the _calyx_ are
more regular and copiously imbricated than usual in this
genus, and are prettily variegated with white marginal cot-
tony down. The _seed-scales_ are feathery, but of the _seeds_
or _receptacle_ we can see nothing.

n. 17.—"Stem branched at the top, hairy. Leaves ob-
long-lanceolate, hairy, toothed. Hairs forked."—Native
of Galatia. Willdenow, who had a dried specimen, de-
scribes this plant as resembling _Hieracium murorum_.
The _stem_ is erect. Leaves feellive, an inch and a half long.
Flower-lasts: feally and hairy. Down feellive, feathery.
Receptacle naked.

THRINNIUM-GILD. See _Trinimum-Gild_.

THRIO, 2 hips, in Antiquity, a festival in honour of
Apollo.

THRIPS, in _Natural History_, a name used among the
ancients to express a sort of worm hatched from the egg
of a beetle: which, while in the worm-state, eats its way
into wood, and forms cells and cavities in it of various
shapes, and in various directions, often resembling the
figures of letters or other things. See _Enxylon_.

The ancient Greeks are said to have used small pieces of
the wood thus eroded in particular forms, as seals, before
the engraving of these utensils was invented; and indeed
they must very well have served this purpose, since it is
fearfully possible to conceive how one of these pieces of
cor-
rodden wood should be counterfeited, or the impression
imitated.

Lucian mentions his marking his olives with a signature
of one of these pieces of wood greatly eroded, and ues
the word _thrips_, not as the name of the animal, but of
the piece of wood eroded by it. Theophratus, Pliny,
and Aristotle, also use the same expression; and we find
that the word _thrips_ was as frequently used to signify
the pieces of wood eroded, as the animal which eroded
them.

Thrills, in the _Linean System of Zoology_, is a genus of
the order of Hemiptera, the characters of which are, that
the rostrum is obsolete, being hidden within the mouth;
the an-
tenna filiform, and as long as the thorax; the body slender,
and of equal thickness; the abdomen reflexible, and often
bent upwards; the four wings extended, incumbent, nar-
row,
row, and crossing one another at some distance from their base. The thrips has six feet, and the tarsus of each foot has only two articulations. Gmelin enumerates the following eleven species.

**Paradoxia.** Brown, with abbreviated wings, and antennæ pectinate, filifide and filiform. Found in China, but Gmelin doubts whether it be of this genus.

**Physalus.** With glaucous elytra or shell-wings, and black body. Found frequently on flowers in Europe.

**Minutissima.** With glaucous elytra and body, and brown eyes. Found as the former.

**Juniperina.** With snowy elytra and brown body. Found in the galls of the juniper.

**Ulm.** Black, with snowy ciliate wings, and acuminate anus. Found gregarious on the bark of the elm.

**Urtica.** Yellow, with whitish elytra. Found solitary on the leaves of the nettle, vine, and hazle.

**Fasciata.** With elytra banded with white and black, and brown body. Found on flowers in Europe.

**Busca.** Blackish, with glaucous elytra. Found in Denmark: the female probably falcated?

**Obscura.** Yellowish, with palish elytra, and eyes and wings of the abdomen black. Found in Denmark.

**Rufa.** Red. Found on the spikes of wheat; if it be not the larva of the minutissima.

**Variegata.** Variegated. Found on flax.

The thrips is highly injurious and destructive to many sorts of fine fruited trees, but particularly so to those of the grape or vine kind. The bell and most effectual means of preventing its mischiefous effects, in such cafes, is probably that of frequent good washing of the trees with common water, by the engine or otherwise. It has lately been advised that this should be done every evening, as, when performed in the heat of the sun, the vines are materially injured. Indeed all such trees should, it is suppos'd, be well washed every evening, until the berries begin to colour, whether infested with insects or not, but especially in the former state; after which it is to be wholly discontinued.

Where there is a neglect of washing the trees in this or some other way, the thrips, for the most part, makes its appearance. In such cafes, these insects may without much difficulty be destroyed by the fumigation of tobacco and damp hay; the plants or trees being well washed after it by pure water.

The *sulphur-bug* is another insect which is often very hurtful to peach-trees and vines in forcing-houses; and the cause of which is believed to be much owing to the trees not being daily properly washed in the above manner.

Each of these sorts of trees stand in need of particular management in clearing them of this insect.

The *brown-bug* too occasionally makes its appearance on, and is hurtful to peach-trees in such situations, especially when they are shaded, or approach near the flues of the houses. Proper washing of the trees, in these cafes, with lime-water, in the winter season; and fyring them with it as soon as the leaves have fallen off, are often very effectual in removing such insects.

The *green-fly* is also very destructive to peach-trees, especially when in the forcing flate. These are the most effectually destroyed by means of well washing the trees daily in a regular manner, after the work of forcing is begun. It is the common practice of most gardeners to discontinue such washings as soon as the flowers begin to make their appearance, but others have lately continued them with supposed advantage, and not found them to prevent the fruit from setting. If any flies of this sort prey on themselves, they may be kept under by proper watering or washing, as above, and by carefully picking off the first buds on which they appear, which is found to prevent them from breeding, and to render the use of tobacco-smoke unnecessary. Fumigations of this substance are, however, sometimes beneficial in these cases in removing the vermin.

This and the *blue-fly* too are often very injurious to plum-trees, especially after they have been affected with the honey-dew. The manner of getting rid of them in such cafes, which has lately been recommended, is that of watering the trees in a plentiful manner two or three times a week, if the weather be dry; and during the continuance of the above fort of dew upon the trees, preparing the water with a little common salt and the fluid part of a good portion of broom that has been boiled. This mixture, it is said, effectually kills the flies, while it does no injury to the trees, if care has been taken not to use too large a proportion of salt. This practice also tends to make the trees shoot stronger, and to hinder such insects from breeding.

There is another insect which has lately been found to be greatly injurious to apple and other fruit trees, but which is yet only little known to gardeners. It is the *Tortrix ovabarea*, which may be seen well described in the second volume of the "Transactions of the Horticultural Society of London." It is there stated to be occasionally very hurtful to such trees, not only in the larva flate, but others; and that its attacks are by no means confined to the diseased parts of such trees. The insect in its perfect flate is a small moth, which is very abundant in gardens and fruit grounds.

In what regards the means of removing and destroying such insects when their attacks become injurious, the hints given below are thrown out. The frill and moist essential procès evidently is, it is thought, to cut away the edges of the canker parts where they are chiefly found, making the wound smooth, and covering it with any composition likely to prevent the moth from depositing her *œva* or eggs there again. One precaution is necessary, which is to put into boiling water, or to bury at a considerate depth, the cut-out pieces of decayed bark containing the larve; which, if left near the tree, would soon crawl from their holes or other places, and remount it; thus defeating the labour of the horticulturalist, who often, from neglecting a flight additional trouble, loses the benefit of many painful exertions. Where the larve are found to have infamated themselves generally into the rough bark of old trees, it would probably, it is thought, be advisable to scrape off the whole of the life-leaves bark, and such portions of the alburnum as are injured, as suggested by Mr. Knight on another occasion; a process which, there can be no doubt, it is said, would be advantageous to the tree in other respects, as pointed out by the above writer. And where projecting fav-dlut-like maffes shew that the larve has attacked even smooth-barked trees, the infection of a blunt prickler into the hole would probably, in moss cafes, suffice to destroy it, and do less injury to the tree than suffering it to attain its growth. But the mode which is most to be recommended in this, as in the cafe of almost all insects hurtful to fruit or other trees, is, it is said, to destroy the moths themselves by collecting them from the trees, or other places, during the summer months, which might be done by children properly directed and provided with suitable means for the purpose, or in other ways. The destruction of every female moth, before the deposition of its eggs, may, it is said, be fairly calculated to prevent the
existence of some hundreds of large; and thus, in any
garden or fruit-ground not in the neighbourhood of others,
where the same methods are neglected, the whole race
might, it is supposed, be exterminated in a few years.

THRISSA, in Ichthyology, the name given by the
Greeks and by the modern Latin writers to the fish which
we call the thad, or the mother of the herring.

THRIVING, in Neat Cattle, a term made use of by
grazers and other flock-farmers to signify the property
they have of doing well on the food they consume, or of
fattening kindly, in contradistinction to that of a flunted
unthrifty growth, or bad sort of feeding. It is mostly
known by the hides or coats of the beasts having a mel-
lowness of feel in handling them, with a fineness and sleek-
ness in their appearance. This depends, in a very great
degree, upon the pile and growth of the coats, for the
shorter and sleeker they are, the more thriving the beasts;
as, on the contrary, in proportion to length and hardness,
is the unthriftiness of the flock.

A coarse, rough, thick hide is an indication too of hard-
ness of flesh in beasts; while, on the contrary, fineness and
cleseness of grain in it, give the feel of fine texture in the
hide.

These circumstances demand great attention in choosing
neat cattle for all purposes.

THRIVING Drinks, such drinks as are prepared and given
to neat cattle, or other beasts, when in a low unthrifty state.
They are mostly composed of the powders of different
sorts of aromatic seeds, such as those of aniseed, cardaway,
seeds, and grains of paradise, in the proportion of about
two ounces of each; which are mixed well together and
put into a quart of warm ale, in which they are given to the
beasts; or of sweet fenel seeds and cummin seeds,
each two ounces, long pepper, ginger, turmeric, and
demecampane, each one ounce, mixed together, to be given in
the same way as above, to which sometimes a little fresh
butter and treacle or coarse sugar are added. Snake-root
and gentian root, in powder, too, are sometimes employed
in such drinks.

As the principal effect of such drinks, for the most part,
depends upon the effential oil the substances may contain,
they will be somewhat preferred and increased by giving
them in the above manner.

The most proper management for the beasts in these cafes,
is to change their food as much as possible for the better,
letting them have occasional good mashes of feedled bran,
ground malt, or other such substances, with a small propor-
tion of ground oats or barley meal put into them: warm
water may also sometimes be necessary.

By the use of drinks of this sort, very reduced cows and
other neat cattle may often be readily restored and brought
into a thriving condition.

THRIXSTEMPERUM, in Botany, so called by Lou-
reiro, from 6, z, a hair, and sperma, seed. We cannot lay
much for the construction of this word, which should have
been Trichospermum, provided there be no dormant chain to
that name; but it is not worth changing, till we are better
affirmed of the genus.—Loureiro. Cochinchin. 510.—Clas.
and order, Monandria Monogyne. Nat. Ord. Orchids?

Gen. Ch. Common Calyx catkin-like, linear, compressed,
flexible, with alternate, acute, single-flowered scales. Pe-
rianth none. Cor. Petals five, linear-awlshaped, long, erect,
nearly equal. Nectary attached to the receptacle, between
the two lowermost petals, deeply divided into two lips; the
inner one three-clitell, embraced by the petals, its lateral
segments short and blunt, the middle segment longest, co-
nical, ascending; outer one ovate, undivided, prominent
beyond the petals. Stam. Filament solitary, thread-shaped,
short, attached to the pistil; another ovate, of two cells,
with a lid. Pist. German thread-shaped, straight, bearing
the flower; style thick, unequal, standing on the base of the
nectary; stigma simple. Peric. Capsule oblong, tri-
angular, the angles acutely emarginate, of three valves and
one cell. Seeds numerous, long, very slender, like hairs.

Eff. Ch. Petals five, linear, erect. Outer lip of the
nectary ovate, prominent.

1. Th. centipes. Nham goi rit of the Cochinchines.
Found in Cochinchina, creeping upon the native trees.
The stem is parifitical, long, compressed, perennial, creep-
ing by means of simple, very short, lateral roots. Leaves
linear-lanceolate, entire, small, sheathing. Flowers
pale yellow, with a reddish nectar, in straight, lateral,
catkin-like, two-ranked spikes.

We guess this to be allied to some of those parifitical
Orchids, formerly referred to Epipedium by Linneus;
and by Swartz chiefly to Cymbidium. The structure of
the whole tribe is so obscure, that Loureiro may very well
be excused if we cannot entirely unravel his description.

THROANA, in Ancient Geography, a town of India,
on the other side of the Ganges, which Ptolemy affigns
to the people called Lelit, or pirates.—Alfo, a town of Serica,
near the mountains in the vicinity of Amfimara. Ptolemy.

THROAT, the anterior part of an animal, between
the head and the shoulders, in which is the gullet.

Physicians include, under the word throat, all that hollow,
or cavity, which may be seen when the mouth is wide open.
It is sometimes also called 1blimus, because it is narrow,
and bears some refeemblance to what is called by geogra-
phers 1blmus.

THROAT, Sore, in Medicine. See Quinny.

THROAT, Wounds of, in Surgery. See Wounds.

THROAT, in Architecture, Fortification, &c. See Gorge
and Cul.

THROAT, in Ship-Building, the inside of knee-timber
at the middle or turn of the arms. Alfo, the middle part
of the floor-timbers; the inner part of the arms of an anchor,
where they join the flunk; and the inner ends of booms and
gaffs, where they traverse round the maff.

The throat is opposed to peak, which implies the outer
extremity of the said gaff, or that part which extends the
fail behind. Hence the ropes employed to hoist up and
lower a gaff, being applied to those parts of it, are called
the throat and peak haliards. Falconer.

THROAT-WORT, in Botany, the name of a perennial
weed common in pasture grounds. The flalk is cornered
and undivided. The flowers grow in bunches at the top of the
flalk. They are erect, of a beautiful purple colour, and
divided in the middle into five acute segments. It is a very
pernicious weed when suffered to get a-head in such lands,
and not capable of being defroyed without considerable
difficulty and trouble. See Trachelium.

This plant yields, when wounded, a milky juice in great
plenty, and this, if received into a shell or other small vesel,
curdles immediately, and the whey runs from the thick
part; this whey is of a brown colour, whereas that of the
wild lettuce is of a fine purple, and dries into a cake that
may be crumbled into a purple powder. The juice of the
throat-wort smells four, and its curdled part, being dried,
burns like resin at the flame of a candle. Phil. Trans.
N° 284.
should never be allowed to become too ripe when intended to be cut in this manner. The term is also occasionally applied to some other purposes in husbandry.

**THROGGY**, in Geography, a river of Monmouthshire, which runs into the Severn, 4 miles S.W. of Chepstow.

**THROMBUS**, from ὀμβρος; coagulated blood, a clot of blood. The term has also been applied to a tumour, formed of a collection of extravasated blood under the integuments after bleeding. When such an extravasation, though of some extent, is not considerable, it is usually called an *echymosis*; which see.

A thrombus sometimes depends on the surgeron having totally divided the vein; but much more frequently on his not having made the opening in the vein properly correspond to that in the skin. The patient's altering the posture of his arm, while the blood is flowing into the bain, will often cause an interruption to the escape of the fluid from the external orifice of the puncture; and, consequently, it insinuates itself into the cellular substance in the vicinity of the opening in the vein. In proportion as the blood issues from the vein, it becomes effused between the skin and fascia in the interstices of the cellular substance, and this, with more or less rapidity, and in a greater or lesser quantity, according as the edges of the skin impede or let the outward escape of the fluid. Sometimes, also, a thrombus forms after venesection, when the usual dressings, compretts, and bandages, have been put over the puncture, and the patient imprudently makes use of the arm on which the operation has been done. This is more particularly liable to happen when a very large opening has been made in the vein.

The accident is not attended with any danger when the extravasation is inconsiderable; for, in this circumstance, the tumour generally admits of being easily resolved by applying to it linen dipped in any stimulant lotion. If the swelling should be more extensive, applying to it a compress wet with a solution of common sea-salt, is deemed a very efficacious plan of promoting the absorption of the extravasated blood. Brandy, and a solution of the muriate of ammonia in vinegar, are likewise eligible applications.

It sometimes happens, that a thrombus induces inflammation and suppuration of the edges of the puncture. The treatment is now like that of any little abscess: a common linseed poultice may be applied, and any considerable accumulation of matter should be prevented, by making an opening with a lancet in proper time. As soon as the inflammatory symptoms have ceased, difficients should be refuted to again, for the purpose of drying the remaining clots of blood and surrounding induration. Cooper's *Dict. of Practical Surgery*.

**THRONE, θρόνος, a royal seat, or chair of state, enriched with ornaments of architecture and sculpture, made of some precious matter, raised one or more steps, and covered with a kind of canopy.

Such are the thrones in the rooms of audience of kings, and other soveigns.

**THRONTION, or THRUMON, or THRUMON, a town belonging to the Locrians, situated according to Strabo, 20 miles from the sea.

**THRUMONIA, a town of the Abantides, was a district of Thespatoria, in Epirus, towards the Ceraunian mountains. On the return from the war of Troy, when the ships of the Greeks were dispersed, the Locrians of Thrumon, and the Abantes of Euboea, were driven with eight vessels towards the Ceraunian mountains. They esta-blished themselves in this place, and built a town, which they called Thrumon, and they gave the country the name of the Abantide. They were afterwards expelled by the Apolloniates.

**THROO, or THROUGH, in *Agriculture*, a term signifying a breadth, lip, or width of corn, which a set of reapers, &c. drive before them at once, whether it consist of one or more lands or ridges. The mode of reaping by means of throats is very common in some of the northern counties of the kingdom, and suppedo by some to greatly expedite the work.

**THROPPLE, among country people, denotes the wind-pipe of a horse.

**THROSTELE, or Song-Thrush, *Mavis, or Turdus muscius* of Linnaeus, in *Ornithology*, is called by authors the *turdus verrisveris minor*, to distinguish it from the larger species, called in English the mistle-thrush, and usually known among us by the simple name of thrush. It is called *vveri- verris* by authors, from its resemblance in colour to the other *vveri-verrius*, not from its feeding on the misletoc-berries, as that does.

It resembles the mistle-thrush in colour, except that the inner coverts of the wings are yellow.

It feeds on worms, frogs, and small insects, and remains with us the whole year. It builds with moss and stubble, and lines the nest with mud. On this it lays five or six eggs, which are of a blueish-green, variegated with a few black spots. It fits on hedges and bulrushes, and sings very agreeably.

The throstle is the finest of our singing-birds, not only for the sweetness and variety of its notes, but for the long continuance of its harmony; as it obliges us with its song for nearly three parts of the year. See Turdus.

**THROSTLING, a disease of black cattle, proceeding from humours gathering under their throats; by which means their throats are fo dangerously swelled, that they will be choked, unless reasonably relieved by bleeding.

**THROUGH-STONE, in *Rural Economy*, a term which signifies a long stone which fills the whole breadth of the wall in making fences of that kind, and which binds them together in a more perfect manner than would otherwise have been the case. It is always of great importance to have plenty of throughs in fences of this nature, from almost the bottom part to near the top.

**THROW, the provincial name of a turner's lathe.

There is a great variety of these sorts of tools in use for different purposes. See Lathe.

**THROW the Glove. See Glove.

**THREWED SILK. See Silk.

**THROWSTER, one who prepares raw silk for the weaver, by cleaning and twirling it. See Milling and Silk.

**THRUM, in *Gardening*, among the cultivators of fine flowers, is a term applied to the thread-like internal bulby parts of them, and which, in some sorts of good flowers, such, for instance, as the auricula and other similar kinds, should be of a bright colour, and the chives, or thready bristles; of which it is composed, clear and shining with spangles, somewhat like gold-dust; and they should also be distinct from each other, leaning inwardly towards the pipe; as when they appear platted together, or look battered or mis-shapen, the beauty of the flowers to which they belong is much impaired; which is not unfrequently occasioned by the wild and other bees, which, when in search of honey or food, are apt to greatly hurt such parts of fine flowers.
flowers. The bees, in such cafes, should be carefully taken
by proper means, and be presented as much as possible from
collecting their food from such fine kinds of flowers.

TRHUM-Cap Island, in Geography, a low woody island,
of a circular form, and not much more than a mile in com-
pass, in the South Pacific ocean, covered with verdure of
many hues, but without inhabitants, discovered and so
called by Cook in April 1769. S. lat. 18° 36'. W. long.
139° 4'.

TRHUM-Wort, in Agriculture, a troublesome weed in
some lands of the rather moist down kind, which is of the
perennial sort.

TRHUMMING, in Rigging, denotes interchanging short
pieces of thrums, or rope-yarn, in a regular manner into
matting, through intervals made by a fid, or large needle.

TRHUST, an affection of the inflammatory and sup-
purring kind in the feet of the horse, and some other
animals. In the horse it is an inflammation taking place in
that part of the foot termed the flable frog, which is
most frequently occasioned from want of due cleanliness in
it, especially in those of the team or working fort, from the heels
being in a contracted state, or from flowing upon erroneous and
bad principles, but most commonly from the last of
these causes. See SHOEING.

The disease may be known to be present in this, as well
as in other animals, by a tenderness and uneasy feel being
shown on pressing the frog, or affected part, and its
being accompanied with a discharge of matter of the pruri-
ient kind, as well as by other similar appearances.

The means of removing the complaint in the horse, when
inflammation is chiefly present, consists in taking away
the shoe, and lowering the heels, in such a manner as that
the frog or discolored part may come in contact with the
ground or floor; after which the animal may be suffered
to stand some days without shoes, the part being well
washed two or three times a day with a common flable
brush, and a solution of soft soap in rain-water, an appli-
cation composed of white vitriol, Armenian bade, and alum,
in fine powder, of each half an ounce, mixed up with com-
mon tar, in a sufficient proportion to make a fort of ointment,
being then had recourse to as a dressing. This may be
used spread upon lint, being applied between the eft of the
frog, or affected part, and renewed as often as there may be
a necessity.

It is likewise advised by some, that all the discolored parts,
in such cases, should be carefully removed by means of a
drawing-knife, and that if the animal be not allowed to have
reft, a bare -hoe must be had recourse to, until the disease
becomes quite removed. It is thought, too, that three or
four pints of blood may often be taken away with advan-
tage in cases where there is much inflammation, and masses
with nitre may be given in the evenings. Much benefit al-
so may sometimes be found from the use of diuretic bales, and
from the foot affected being fomented with warm water,
in which a handful of common salt has been dissolved, juft
before the application of the above dressing. Great utility
is occasionally derived, too, from the infusion of a feoton
or rovel in the eft, or other proper part, and letting it
continue some time. See SHOE.

In cases where the complaint proceeds chiefly from con-
tacted heels, some suppose the only certain and effectual
mode of removing the affection is, perhaps, that of the ufe
of the artificial, or patent frog, not long ago invented by
Mr. Coleman, who has bestowed much attention on the
feet of animals, especially of the horse. See FROG.

In other animals, where the hoofs, claws, or other parts
of the feet are affected with inflammation, and collections
or discharges of matter, in some measure of the thrush kind,
or having some resemblance to it, the best means of relief
are probably those of first trying the effects of difcuent
ificant applications, and if these do not succeed, to have
recourse to warm emuient fomentations or poultices, then
cutting or paring the parts down so as to lay them well
open, and let out any thing they may contain, dressing the
openings with mild echaritics, as there may be occasion.
In this way, very troublesome affections of this fort may
often be speedily removed.

TRHUS, in Medicine. See APHThE and INFANT.

TRHUS, in Ornithology, is the turdus oiseauvus of Lin-
neus, and is the largest of the genus. See TURDUS and MIS-
SELA BIRD.

TRHUSK, See THIBSK.

TRHUST, in Fencing, is an action of which there are
three kinds. To thrust in carte, is to throw your hand as far
as possible on the inside, with the point of your fword to-
wards your adversary's breast: to thrust seconde, is to take
with your arm in a perfect opposition to your adversary's, hold-
ing your head inside: to thrust tierce, differs from carte only
by the position of the hand, which must be reversed.

TRHUSTING, or Hand-preasing, in Dairying, is a term
applied to the practice of squeezing and forcing the liquid
parts contained in the cud out of it by the hand, or
other such means, after it has been properly reduced,
and placed by a cloth in an unheaped or conical manner in the
vat or hoop.

TRHUSTING-Screws, in Rural Economy, a contrivance of
the large screw kind, calculated for affording due pre-
fure in the making of cheefe with facility and con-
venience. These screws are perfectly simple, and capable
of being made either of wood or iron; but the latter mate-
rial is probably by much the best. They may be wrought
in several different ways, but it is commonly done by means
of a fort of lever applied in some manner or other, not un-
usually through a hole for the purpose in the head of the
large screw. In some districts they have them fixed up
in the under-fides of the floors above the preffing-rooms, and
the power of them is managed as to be regulated at plea-
ure. By means of these thrusting-screws, it is evident that
the preflure can be gradually increafed, as there may be
occasion, from the blind application to the concluding hard
or heavy preflure infinishing the work. This command of
power is, of course, a circumstance of great utility and
advantage in such businesss.

TRHUSTINGS, a term applied in cheefe-making, in
some districts, to the white whey, or that which is the last
preffed or forced out of the curd by the hand and other
means, after it has been put into the cheefe vat. In some
influences in the process and practice of making butter
of the whey kind, these thrustings are fet by in earthen pans
for the purpose, in order to acidulgate, or carrve, as it is
called in some places, either by means of the warmth of the
featon, or of a room, for being churned, in the same way
as in the common manner practiced, in many places, for
making butter from milk. See WHEY.

These thrustings, probably, form and constitute the best
butter of the whey fort, though it is made from that fluid
managed in other ways, as seen under the head just referred
to above.

TRHYALLIS, in Botany, an ancient Greek name for soma-
thing of the Mullein kind, whose woolly leaves served
to make wicks for lamps. It is not easy to conceive how Linnaeus came to apply this name here, nor can we trace out any thing to account for his having done so. We must readily agree with De Theis, that the shrub, about to be described has nothing in common with *Verbena*, but its yellow flowers. (See Dioscorides, book 4. chap. 104.)—Linn. Gen. 213. Schreb. 289. Willd. Sp. Pl. v. 2. 570.

Gen. Ch. Cal. Perianth inferior, in five deep, lancelolate, erect, permanent segments. Cor. Petals five, roundifh, spreading. Stem. Filaments ten, awl-shaped, longer than the calyx; anthers roundifh. *Pill.* German obtuse; style thread-shaped, the length of the flavescent; stigma simple. Peric. Capsule with three fides, and three angles, obtuse, separable into three parts; its cells burfting at the external angle. Seeds solitary, very smooth, obovate; obtufe at the bafe, with an incurved point.

1. *Th. brasiliensis*. Brasilian Thryallis. Linn. Sp. Pl. 554. Willd. n. 1. (Fruiticeens herba; Marcgr. Bral. 79. f. 3.)—Native of Brazil. A little *brufb*, with round, jointed, reddifh branches. Leaves on reddifh footstalks, oppofite, ovate, entire, about an inch long; pale green above; whiffifh beneath, with a flender mid-rib. *Sipularis* briffle-shaped. Clifiers terminal, solitary, from fix or seven inches to a foot long, with very flender partial flakes, longer than the flowers, and very short fetteaceous briffes. Flowers small, elegant, yellow, bordered with red, with which colour also their yellow flavescent are fpneckled. Fruit three-lobed. Neither the plant nor its flower has any remarkable odour. Linnaeus apparent to have examined a dry fpecimen of this plant, but it is wanting in his herbarium, as well as in every other that we have been. His idea of its natural order is furely lefs correct than fuffiieu's. Specimens without fruit are not unlikely to have been overlookd for some nondefcript *Bamifleria* or *Malpigia*.

**THRYOCEPHALUM**, in *Botany*, a genus of Forfter's, named from *brufb*, a fort of *ryb*, and *skepia*, a head, because of the habit of the plant, and its little round head of flowers. This genus is the fame as *Kyllingia*. (See that article.) The only species mentioned by Forfter is that ferened by us as *K. monoecephala*. Vahl, in his *Enum. Plant.* v. 2. 381, refers it to *K. triepis*, probabiy because he faw a fpecimen with a compound head. This very circumftance strengthens his own fpuficion, that thefe two fpoked species of *Kyllingia* are not, in reality, diftinct. Our fpecimen from Forfter himfelf has a very flight indication of a small lateral head, by the fide of the principal one, nor can it be otherwife diftinguifhend from *K. monoecephala*. In the ftucture or appearance of any other part, we cannot difcern the leaf diference between *monoecephala* and *tripis*, in separating which we confidered more in thofe who have originally defcribed thefe plants, than it seems they deferved.

**THRYOESSA**, or *Thryon*, in *Ancient Geography*, called from the time of Strabo Epitafium, fitted on the left banks of the Alpheus, E. of Olympia.

Eff. Ch. Calyx-flumes of one valve, two-flowered, spiked, unilateral, on a dilated common flake; the lowermost ones only partly perfect; the reft male only; the inner flor of the lowermost glume male, its outer valve resembling the calyx. Nectary of two scales at the bafe of the germin. Stigmas feathery. Seed wrapped in the corolla, and enfolded in the hardened, clofed, involute flake.

The stems are creeping, very long, with erect, short, undivided, leafy branches. Spike solitary, terminal, short, for a long time half enclofed in a leaf-like fheathe. The common flake is thick and coriaceous, not membranous, as M. du Pet- *tit Thuars terms it, he having, as Mr. Brown supposes, confounded that part with the fheathe. Flowers feffile, in a fimple row, one or two of the lowest only being perfect, the remaining four, five, or fix, in the contracted portion of the spike, males.

Mr. Brown observes, that this genus of graffes is not very diftantly related to *Panicum* (fee that article); espe- cially to *P. dimidiatum*, Retz. Ohb. f. 23; but in *Tbarea*, the calyx-flumes are, with refpect to the flake, in- verted, and want an outer fvalue. In structure this genus agrees, in many particulars, with *Spinefix* (fee that artie- cle), in which the fexes are indeed more fpattered, and therefore a reuique abundance of males is provided. The figure and economy of the common-flake, or *racib*, too is different; though that part is permanent in both genera, and affifts in both, though not in the fame manner, to dif- perfe the fseeds.

The only fpecies of which we can give an account are the three following, though Mr. Brown mentions also a *T. fermentosof*.

'T. media. Br. n. 2.—"Perfect flowers folicitary. Leaves linear-lanceolate; their under fide fmothe, as well as the ftem."—Found by Mr. Brown, in the tropical part of New Holland.

'T. involuta. (Icshemum involutum; Forr. Prodr. 73. Willd. Sp. Pl. v. 4. 741.)—Perfect flowers folicitary. Leaves lanceolate, nearly fmothe on both fides.—Gathered by Forfter in the Society Ifles, and fome other places within the tropics. The fpecimen given by him to the younger Linnaeus is marked Tubicuf. The erect ftems, or branches, are but two or three inches high, fimple, fтратed, fmothe, each bearing at the bottom one lanceolate, acute, fтратed leaf, about its own length; feathing at the bafe; becoming involute in drying. Sometimes there is another leaf, about half as long, with a fheathe almost an inch in length, near the middle of the branch. Spike fcarcely an inch long, termi- nal, of about four flowers, springing laterally from the hollow of a concave pointed leaf, rather shorter than the reft. Calyx ribbed. Corolla fmothe. Feathery ftegmas very confpicuous in the lowermost flower.

**THUBUNA, TUBUNA**, in *Ancient Geography*, a town of Mauritania Sitifenis, according to Ptolemey; fitted in the mountains, between two rivers, S.W. of Igifili.

**THUBURSICA**, a town of Africa, in New Numidia.

**Ptol.**

**THUBUTIS**, a town of Africa Propria, near Bullaria.

**Ptol.**

**THUCCA**, or *Tucca*, *Dagga*, a town of the interior of Africa, mentioned by Ptolemey; fitted at the extremity of a small chain of hills about two miles S. of Tiburicum- bure. On this fte we were found many máufeulums, and the portico of a temple ornamented with beautiful column. Here was also an aqueduct.

**THUCYDIDES**, in *Biography*, a celebrated Greek his- torian, was born in the 77th Olympiad, about 470 B.C. The
The name of his father was Olorus, or Orclus, that of a Thracian prince, indicating a connection with Thrace, in which he seems to have possessed gold-mines, and to have had influence over its chiefs. He belonged to one of the principal families at Athens, and was related to that of Miltiades. His education was that which distinguished Athenians of rank: Anaxiphanes being his preceptor in rhetoric, and Anaxagoras in philosophy.

When he heard Herodotus recite his history at the Olympic festival, he is said to have cried tears; and Herodotus observing it, congratulated Olorus on his son's disposition. At the commencement of the Peloponnesian war he was at Athens, and shared in the calamity of pestilence that then occurred; and in the eighth year of that war he had a command in Thrace, and was opposed to the Spartan general Brasidas, who hurried the town of Amphipolis, for the loss of which Thucydid was punished by banishment, though it does not appear that he could have prevented it. During the twenty years of his exile, he devoted himself to literary researches and observations through different parts of Greece, and thus collected materials for the history which he was projecting. He refuted for a considerable time in Thrace, but the place and time of his death are not ascertained. Dodwell conjectures that he palled his 80th year, and died in Thrace. His history comprehends the transactions of the first twenty years of the Peloponnesian war, diffused in eight books; more limited in its compass than that of Herodotus, but not merely rivalling but surpassing it in historical merit, more especially if we admit that a modern writer says of it, 1 "that the first page of Thucydid is the commencement of real history." The distinguishing characteristics of this historian are diligence of research, and the selection of the best authorities, and perfect impartiality. To these qualities we may add facility in investigating causes and effects, and a philosophical spirit in forming a discriminating judgment of human affairs. His narration is occasionally very interesting, and indicates the writer of genius. His style, which has undergone much criticism, is of that kind which the ancients termed the aurea, aiming at force and brevity rather than harmony, elegance, or peripetia. Its conciseness and frequent transpositions render it frequently obscure, nor is this defect compensated by its energy and elevation. The most valued editions of this work are Hudson's, Oxon. 1696; Walf and Ducker's, Am. ed. 1731; and the Leipzig, 2 vols. 1790—1834. Volf. Hill. Greek. Gen. Biol.

THUDA, in Ancient Geography, a town of Africa, in Mauritania Cæfariana, near Tingis. Ptol.

THUELATH, a maritime town of Africa, on the coast of Libya, between Autolates and Thagana. Ptol.

THUEYE, in Geography, a town of France, in the department of the Ardèche; 18 miles W. of Privas.

THUJA, in Botany, 600: 600, or 600 of the Greeks, the name of a tree, whose very durable wood furred, according to Theophrastus, to make images. Its root in particular, being curiously twisted or veined, was used for the most valuable ornamental works. This plant was probably the Juniperus oxycedrus, very common throughout Greece and the Archipelago, of which Mr. Hawkins is of opinion that the most ancient statues were made. It is the Small Cedar, 40 to 500 of Diochorides, and still universally bears the name of Aro in modern Greek. Our present genus of Thuja has nothing in common with this classical plant, except being an aromatic evergreen tree, of the same natural order, with a very durable wood; but it is not a native of Greece or the Levant.—Linn. Gen. 500. Schreb. 651. Willd. Sp. Pl. v. 14. 508. Mart. Hill. Dict. v. 4. 321. Pursh 646. Juss. 413. Tourn. 1. 358. Lamark

Gen. Ch. Male. Cal. Catkin ovate, composed of a common flalk, on which the flowers stand opposite, in three rows, each flower having for its bace a nearly ovate, concave, obtuse scale. Cor. none. Stem. Filaments in each flower four, but scarcely visible; anthers as many, attached to the base of the scale above mentioned.

Female on the same plant, Cal. Catkin nearly ovate, with opposite flowers, and consisting of two-flowered, ovate, concave scales, converging longitudinally. Cor. none. Pist. German minute; style awl-shaped; stigma simple. Peric. Ovate-oblung, obtuse, beftribed, into oblong imbricated, nearly equal, obtuse, externally convex scales. Seeds solitary, oblong, each surrounded by a longitudinal membranous emarginate wing.

Female, Catkin becoming an imbricated cone, with two-flowered scales. Corolla none. Seed surrounded by a vertical membranous wing.

Obl. Linneus indicates the close relationship of this genus to Capestratus. They are neverthelefs distinguished by the peltate scales of the cone in the latter, and its angular, obtuse, scarcely winged, feel, or nats.

1. Th. occidentalis. American Arbor-vitæ. Linn. Sp. Pl. 1421. Willd. n. 1. Ait. n. 1. Pursh n. 1. "Michaux Arb. For. v. 3. 29. t. 5." (Arbor-vite; Cluf. Hilt. v. 1. 36. Gen. Em. 1366.)—Young branches twoweighted. Leaves imbricated in four rows, compressed, ovate, somewhat rhomboid, dotted. Inner scales of the cone abrupt, tumbid under the point.—Native of North America, from Canada to the mountains of Virginia and Carolina, blooming in May. It is rather scarce in the southern states, and only found on the steep banks of mountain torrents. The branches are extremely tough. Pursh. This tree was introduced into our gardens in Gerarde's time, or before, and is much esteemed for ornament and shelter in shrubberies, or for platted and clipped hedges in nursery-gardens, in which last itate it is really very beautiful. By a strange mistake of Linneus, this species is handed down as a native of Siberia; because Gmelin, Pl. Sib. v. 1. 182, mentions a Thuja, to which he misappplies the synonyms of the present, but which by his own account is different; for he says it is " paler than the garden kind, and smaller in all its parts." It was brought him by a travelling surgeon, from rocks near Pekin in China, and could be no other than the Ts. orientalis, hereafter described. Th. occidentalis is a perfectly evergreen tree, of humble growth, much branched, very different from most others in the compressed vertical aspect of its younger shoots, and their closely imbricated leaves, which are small, obtuse with a point, smooth; those of two opposite rows compressed and keeled; the intermediate ones flat, with a glandular point, or cell of resin, at the back. The flowers appear in May, and are small, solitary, terminal; the males yellowish, and moth abundant. Cones ripened the following year, drooping, each the size of a filbert-kernel, consisting of about half a dozen lax, smooth, coriaceous scales. The smell of the bunting plant is something like Savine, aromatic, but not agreeable. The wood is not hard, but tough and extremely durable, on which last account it is much esteemed in America for making pales and fences.

figures. Very bad.) — Young branches two-edged. Leaves imbricated in four rows, compressed, ovate, somewhat rhomboid, with a central furrow. Inner scales of the cone oblong, with a recurved dorsal point. — Native of rocky situations in China. Celmis. On mountains in Japan. Thunb. Jap. 266. A hardy tree in our gardens, which appears to have been cultivated by Miller in 1752. It flowers at the same time as the former, but though a much more handomc tree, is less common. The very copious and crowded young branches are more erect, more slender, and rather less compressed than the former, and the leaves are furrowed, without any refrinous dot. The differences between these two species are accurately marked in our specific characters, adopted from Linnaeus and Willdenow. The inner scales of the cone in that before us are remarkably hooked. Gartner observes that the wing of its seed is hardly discernible.

3. Th. articulata. Jointed Arbor-vite. Vahl. Symb. v. 2. 96 t. 48. Desfont. Atlant. v. 2. 353 t. 252. Willd. n. 3. (Th. aphylla; Linn. Sp. Pl. 1422, as to the synonym of Shaw, and part of the character taken from thence, but not of Am. Acad. v. 4. 295; see Tamarix. Cypessus fruticu quadrufilvi, folis equifeti infrac articulatis; Shaw Afric. n. 188 f. 188.) — Young branches jointed, rather compressed, with four furrows. Leaves minute, concave, pointed, four, at the top of each joint; glandular at the back. Cones quadrangular, of four hooked scales. — Native of the mountains of Barbary, where it is not uncommon. A tree from fifteen to thirty feet high, with round branches, the younger ones repeatedly subdivided, in a partly opposite, partly alternate manner, moderately compressed, composed of a series of linear, smooth, brittle joints, from a quarter to half an inch long, and marked with four longitudinal furrows, which are continued to the interstices of the four minute feal-like leaves crowning each of these joints. Willdenow, misled by the analogy of other species, and the figures of authors, supposes each joint to be an allomagne of leaves, from which error the faithful descriptions of Vahl and Desfontaines might have guarded him. Callins terminal, solitary; the males ovate-oblong, of many scales; females roundish, of much fewer. Fruit somewhat deflored, about the size of a black currant, with four protuberant angles, and crowned with many intermediate reflexed points. The scales separate at the angles, but are firmly united at their base. Seeds small, with a broad kidney-shaped wing. The late celebrated Broussonet observed the refus called Gum Sandaracze to be procured from this tree. Dole attributes it to the Common Juniper. Such being the history of the species before us, the Th. aphylla of Linnaeus becomes a nonentity.

4. Th. doabratia. Sculptured Arbor-vite. Linn. Suppl. 420. Willd. n. 4. Thunb. Jap. 266. (Quai, vulgar Fi no ki et hibuki; Kämpf. Am. 88.) — Young branches two-edged, jointed; convex on one side; concave and white on the other; joints oblongate. Leaves lateral, opposite, keeled, compressed. — Native of Japan. Thunberg observed it in the countries of Oygawa and Fakonia, between Minae and Jedo; and it was planted along the high road on the hill of Fakonia. He speaks of it as a tree of vast height and dimensions, the most beautiful of all the evergreen trees. The branches are alternate, repeatedly subdivided, compressed and clothed with imbricated leaves. At first sight the young branches appear covered with four rows of leaves, but the analogy of the foregoing species, even of the first of all, leads us to believe the intermediate row, on each side, is an obvolute furrowed joint, insensibly terminating in a short broad leaf, while the more obvious leaves are opposite, laterally inserted into the base of the joint at each side, and about the same length; each of them strongly compressed, with a thick keel, and incurved point. Their great peculiarity consists in being all convex and green on the upper side of the branch; concave and as if whitewashed, like the furrows of the joints, on the under. This gives the plant an artificial, but most elegant, appearance. The flowers we have not seen. Kämpfer says the fruitle is warty, the size of a pea.

5. Th. cupressoide. African Arbor-vite. Linn. Mant. 125. Willd. n. 5. Ait. n. 3. Thunb. Prodr. 110. (Th. aphylla; Burm. Prodr. 27, excluding the reference to Shaw.) — Young branches but slightly compressed. Leaves imbricated in four rows, even. Cones nearly globose, of four acute warty scales. — Native of the Cape of Good Hope, from whence Dr. Roxburgh introduced it to Kew Garden in 1799. The growth of the tree is tall and close, like that of the Cypress. Leaves closely imbricated, not spreading. Fruit of the size and appearance of the Cypress, nearly globular, with four oblique angles, separating into four thick acute valves or scales, tereulate externally, keeled within. Seeds numerous, each terminated by a membranous obvolute wing. Linnaeus adds to this description, "Ramuli minime articulati nec Equast." If minime be not printed by mistake for minimi, we presume this alludes to Shaw's synonym, cited in the "Manufact" with many scurfes, and certainly not belonging to this but to articulata, our third species.

THUJA, in Gardening, contains plants of the hardy, evergreen tree-kind, of which the species cultivated are, the American arbor-vite (T. occidentalis), and the Chinese arbor-vite (T. orientalis).

In the first of these species there are different varieties; as the American sweet-scented, and the variegated-leaved.

Method of Culture. — These plants may be increased by seeds, layers, and cuttings. Good seeds should be obtained from the native situations of the trees, and be sown soon after they are ripe, or as soon as they can be obtained, in autumn or spring, in pots or boxes of light earth, covering them half an inch deep, placing the pots, &c. in a sheltered warm situation, or under the shelter of a frame in bad weather, especially when sown in autumn, that they may be protected from severe frosts; they sometimes come up in the spring, but are frequently apt to remain in the ground till the second year. When the plants are come up, the pots should be placed in a cool border to have only the morning sun, but open to the free air, giving frequent but very moderate waterings all the summer; and in winter removing the pots again to a sheltered place till spring, when they may be pricked out in nursery-rows; or, when they are small and weakly, continued in the pots another year, placing them in a shady situation during summer, and in a sheltered place in winter; and in the spring following planting them out in the nursery, in rows a foot or two asunder, in order to acquire size and strength for planting out where they are to remain.

The layers should be made from the young shoots of one or two years growth, which may be laid down early in autumn, bending down the branches to the earth, and laying all the young wood in by slit or twist-laying, with the tops only appearing a little above ground; shortening any that have much longer tops than the others; they mostly emit roots in the earth, and form proper plants by the autumn following; when, or rather in spring after, they should be separated from the followers, and be planted in nursery-rows, to remain two or three years, or till of a proper size for the shrubbery, &c.

The cuttings should be made from the strong young shoots of the same year's growth, which should be planted in
in the autumn in a shady border, taking the opportunity of flowery weather, if possible, for the busy time; they should be cut off with a small part of the old wood, where practicable, and be planted in rows a foot asunder, closing the earth well about them: they will be properly rooted in one year for planting out in wider nursery-rows: they may also be planted in pots, and placed in a hot-bed, in order to have them more forward.

And they all may be planted out into the borders, &c. in the autumn or early spring months.

These trees in their native situations grow to very considerable sizes and magnitudes, but in this climate they are of much inferior growths, seldom rising to any great height or thickness. They succeed best in the countries from which they are brought, in rather moist soils; but here they thrive perfectly in any tolerably good common kind, and in any situation. They have a beautiful form of growth, being much and finely branched from their very bottoms, and constantly closely adorned with leaves, which are of a very minute fize, and arranged in a curiously compact imbricated manner, displaying a continual verdure and ornamental variety at all times of the year.

They are highly ornamental evergreens, proper for adorning the shrubbery and other parts, having a fine effect also when disposed finely in borders, &c. and in open spaces of grounds; in all of which situations they should be tuffered to grow with their full branches, in their own natural way, except reducing with a knife: any low straggling or rambling branches occasionally: this is all the culture they require afterwards.

They may also be employed as timber-trees, in the evergreen forest-tree plantations.

And those in the pots, as the Chineese arobor-vitae, may be placed among other potted plants to adorn any particular compartment, and in allembage with greenhouse plants for variety.

THUILLIER, VINCENT, in Biography, a learned Benedictine, was born at Concy, in the diocese of Laon, in 1658; and entered into the congregation of St. Maur in 1723, where he was distinguished for his talents. Having officiated as professor of philosophy and theology in the abbey of St. Germain-des-Pres, he was made Sub-prior, and died in 1736. With his extensive literature, he combined a lively imagination and a turn for fancy, which involved him in several controversies. He first opposed, and then warmly defended the bull "Unigenitus," on which subject he published two treatises. But he was more usefully employed in a French translation of Polybius, which appeared in 1724–28, in 6 vols. 4to. His version is elegant and faithful. Moren.

THUIN, in Geography, a town of France, in the department of Jemappes, on the Sambre; 14 miles S.E. of Mons. N. lat. 50° 20'. E. long. 4° 21'.

THUIR, a town of France, in the department of the Laved Pyrenees; 7 miles S.W. of Perpignan.

THULDEN, THOMAS VAN, in Biography, was one of the most distinguished among the pupils of Rubens, whom he assisted in forwarding the pictures of the Lussembourg gallery. He was born at Bois-le-Duc in 1607. He painted a considerable number of large works for the churches and public buildings of the principal towns and cities in Flanders; some of which have been honoured by being considered as from the hand of Rubens. Among the best of them are the Martyrdom of St. Sebastian, at Mechlin; the Martyrdom of St. Adrian, at Ghent, and the Assumption of the Virgin, formerly in the church of the Jesuists, at Bruges. He was engaged at Paris, which he visited in 1633, to paint a series of pictures of the life of the patron saint of the Mathurins, St. John of Matha, which he afterwards etched and published in twenty-four plates. He is also the author of several other etchings from his own works and those of others; particularly of 58 plates of the life of Ulysses, from pictures painted at Fontainebleau by Primaticcio, of most of which there is now no other remembrance but his etchings. He died in 1676, at the age of 69.

THULE, or Thyle, in Ancient Geography, an island of the Northern ocean, described in a very vague manner by the ancients; but which some maintain to have been the Shetland islands. Virgil (Georg. l. i. v. 30.) and Seneque (Medea, v. 379.) call this island "Ultima Thule." It is difficult to ascertain its precise situation. Strabo ascribes the ignorance and uncertainty that prevailed with regard to this island to its great distance, and charges Pytheas with having made many false reports concerning it. Ptolemy places the middle of this island in 63° of latitude, and says, that at the time of the equinoxes, the days were 24 hours, which could not have been true at the equinoxes, but must have referred to the solstices; and, therefore, this island is supposed to have been in 66° 30' lat. or under the polar circle. Stephanus Byzantinus says of this island, "Thula insula magna in oceano sub Hyperboreas partes ubi Aeolus dies ex vigenti horis aequalibus conlat, no vero ex quattuor. Hybernae vero dies e contrario." From this account it appears that the ancients described an island which was situated three degrees on this side of the polar circle; but its situation, if such an island existed, still remained very uncertain. As the ancients have not given us the dimensions of this island, some authors have concluded that the appellation of Thule was given to Scandinavia, of which the ancients had a very imperfect knowledge.

According to Procopius (l. iii. de Bell. Goth. c. 14) a party of the Eutulians, when vanquished by the Lombards, fought an abode towards the extremities of the earth. With this view they traversed the country of the Scelavians; and in their progress entered into the country of the Varbri, and into Denmark, and at length arrived on the ocean, where they embarked, and then landed on the island of Thule. This island, he adds, is ten times larger than Great Britain, and is far remote from the northern coast, a great part of it being desert. The habitable part was occupied by thirteen distinct classes of people, who had their respective kings. Towards the summer solstice, the sun appeared 40 days successively above their horizon; six months afterwards, the inhabitants had 40 days of night, which they passed in a state that was truly deplorable, as their commerce was totally interrupted. By the account of Procopius, it appears that the place to which he refers must have been beyond the polar circle, and of course beyond 63° lat., where Ptolemy placed the middle of Thule. Procopius says, that he wished to visit this island, but was never able to accomplish his object; but he professes to have derived his information from persons who had actually visited the country, and he describes its aspects, productions, and the manners of its inhabitants. His details correspond to the accounts that have been given of the ancient state of Lapland (which see); but this could not have been the Thule of the ancients. The descriptions transmitted to us from the ancients of their pretended isle of Thule are so intermixed with fabulous and incredible relations, that some modern geographers have even doubted whether such an island as they describe ever existed; others have supposed that they refer to Scandinavia, or some country far distant to the north, of which we could have
no certain and satisfactory accounts; and others again have been of opinion, that no island to which modern voyagers have had access, correspond more exactly to their reports than the islands of Shetland, N. of Scotland. See _Zeland Islands_.

**Thule,** in Geography, a town of Westphalia, in the bishopric of Paderborn; 6 miles W.S.W. of Paderborn.

**Thule,** a river of Wales, in the county of Glamorgan, which runs into the Llhogor, near its mouth.

**Thule, Southern,** a part of Sandwich Land, observed by Capt. Cook in January 1775, in S. lat. 59° 13' 30" and W. long. 27° 45'; and so called because it is the most southern land that has ever yet been discovered. It exhibits a surface of vast height, and is everywhere covered with snow. Some thought that they saw land in the space between Thule and Cape Brito: Cook thought it more than probable that the two lands are connected, and that this space is a deep bay, which he called Forster's bay.

**Thum,** a town of Saxony, in the circle of Erzgebirg; 7 miles S. of Chemnitz. N. lat. 50° 37'. E. long. 12° 50'.—Allo, a town of Bavaria, in the bishopric of Bamberg; 3 miles S.S.W. of Forchheim.

**Thumata,** in Ancient Geography, a town of the Arabs, placed by Pliny on the banks of the Tigris, at a considerable distance from the town of Petra.

**Thumatha,** a town situated in the interior of Arabia Felix, between Chabata and Opalstat. Ptol.

**Thumb, Politex,** in Anatomy, one of the members or parts of the hand. See Extremities.

**Thum-Stall,** a ferrule made of iron, horn, or leather, with the edges turned up, to receive the thread in making falls. It is worn on the thumb to tighten the stitches while sewing.

**Thumelitha,** in Ancient Geography, a town of Africa, in Interior Libya, near the source of the river Cydnus. Ptol.

**Thumereville,** in Geography, a town of France, in the department of the Mofelle; 6 miles S.W. of Brie.

**Thumerstone,** in Mineralogy; Asinite, Haity. This mineral was called Thumerstone by Werner, from Thum, in Saxony, the place where it was found; and Asinite by Haity, from the flattened sharp edges of the crystals resembling the edge of an axe. This is the first character which strikes the eye when this mineral is presented for inspection. It is most commonly found crystallized, but sometimes massive or disseminated. The form of the crystals is very compressed oblique rhombohedral prism. The primitive crystal, according to Haity, is a four-sided prism, whole bales are parallelograms with very oblique angles: the larger angle being 101° 32', and the smaller 78° 28'. In the secondary crystals, the acute edges are generally truncated. It is crystallized also in oblique four-sided tables. The form of the crystals is sometimes very difficult to be determined; they not infrequently intersect one another, forming a cellular aggregation. The external luster is generally splendent; internally it is glintening or shining, and is vitreous. It is transparent or translucent. The fracture is fine-grained and uneven; in the translucent varieties, it sometimes approaches to splinterly; and in the transparent varieties, to the small and imperfectly conoidal. It scratches glass; is harder than felspar, but not so hard as quartz; it is fragile, and fusible by the blow-pipe into a greenish-white glass, but if laid on charcoal into a black glass. The specific gravity is from 3.2 to 3.3. The colours of this mineral are most commonly a close-brown of various degrees of intensity, inclining to violet and green.

Vol. XXXV.

It is sometimes green and opaque: according to Brongniart, this is owing to a mixture of chlorite. It has been observed, he remarks, that the crystals which are coloured with this earth are the most regular. The constituent parts are given by Klaproth and Vauqueul as under.

This mineral occurs in Saxony, France, Switzerland, and Spain, and at mount Atlas, in Africa. It is found also massive and crystallized near St. Juft, in Cornwall, at the Bodelch mine, associated with common garnet, and in veins between Marazion and Penzance.

The most beautiful variety is met with in a rock of serpentine, near Balme d'Auris, in Dauphiny, in the department of the Isere, where it generally occurs in well-defined crystals, sometimes colourless and transparent, but more frequently of a dull reddish-violet colour, whence it obtained the name of violet schoorl of Dauphiny. The crystals of thumerstone, which are not symmetrical, become electric by heat; it is indeed a general law, that all minerals which possest the pyro-electric property, are defective in the symmetry of the crystals.

**Thumilitz,** in Geography, a river of Saxony, which runs into the Mulda; 3 miles S. of Grina.

**Thumim,** in the Scripture Learning. See Urim and Thummim.

**Thumna,** in Ancient Geography, the name of two towns situated in the interior of Arabia Felix; one between Mochura and Aluare, and another between Mariama and Vodona. Ptol.

**Thun,** in Geography, a town of Switzerland, in the canton of Bern, at the distance of about 12 miles from the town of Bern. It occupies the bottom and brow of a hill, and stretches on both sides of the Aar. It contains 1200 inhabitants, enjoys considerable immunities, has its own magistrates and courts of justice, in which the bailiff from Bern always presides, and from whose decision an appeal always lies to the capital. The inhabitants employ themselves in carding and spinning silk for the manufactures of Basle. Some of the burghers possess large herds of cattle. To the N.E., on an eminence, stands the church, and the castle, which is the residence of the bailiff. N. lat. 46° 44'. E. long. 7° 31'.—Allo, a lake of Switzerland, in the canton of Bern; about four leagues long, and one broad, and probably very deep: the borders are richly variegated, and present several fine points of view, much heightened by many rugged rocks rising boldly from the margin of the water. The river Aar passes through the lake of Brienz, and then enters that of Thun, from which it is again discharged, passing between two level promontories, prettily sprinkled with trees, on one of which stands the castle of Schadow; 15 miles S.S.E. of Bern.

**Thuna,** a town of Cachemire; 45 miles S. of Ca-chemire.

**Thunbergia,** in Botany, received that name first from Professor Retzius, and next in the Supplementum Plantarum, from the pen of the younger Linnaeus, in honour of their mutual friend, Sir Charles Peter Thunberg, knight of the order of Wafa, by whose discoveries that work was peculiarly enriched with new and curious species, especially from the Cape of Good Hope. This illustrious veteran still
fits in the prefforial chair of Rudbeck and Linnaeus at Upfal, after having essentially added to the general rock of knowledge by his Travels to Japan, his Flora of that country, and of the Cape, and his very numerous academical communications. The liberal communications, and amiable character of professor Thunberg, have secured him no less personal esteem than his extensive application and knowledge.

Gen. Ch. Cal. Perianth inferior, double, permanent: the outermost of two ovate, obtuse, ribbed, equal leaves, as long as the tube of the corolla: inner of one leaf, in many, about twelve, awl-shaped erect segments, not one-third so long as the former. Cor. of one petal, falver-shaped: tube gradually dilated upwards: limb in five deep, nearly equal, ovate, very abrupt segments, about half the length of the tube. Stam. Filaments four, awl-shaped, inserted into the tube, the two lower ones shorter, all included within the tube; anthers arrow-shaped. Pfl. German superior, roundish; style thread-shaped, crept, hardly so long as the tube; stigma of two rounded flat lobes. Peric. Capsule globose with a beak, smooth, or two cells and two valves, burting lengthwise: the beak linear, obtuse, compressed, furrowed; partition ovate, margined, perforated below the summit, membranous at the sides, permanent. Seeds two in each cell, kidney-shaped, rugose, convex on the outside, concave on the inner, with a longitudinal furrow.

Obf. Linnaeus remarks that this genus agrees in many points with Barleria. Thunberg takes the outer calyx-leaves for bracteas, but this is not countenanced by the altogether peculiar appearance of the inner calyx, by no means like an external perianth.

1. T. capensis. Diffuse Thunbergia. Linn. Suppl. 292. Willd. n. 1. Retz. Act. Lund. v. i. 163, with a figure.—Leaves roundish-ovate, obtuse. Stem diffuse.—Native of the Cape of Good Hope. The root seems to be perennial. Stems a finger's length, diffuse, simple, leafy, square, hairy. Leaves opposite, on short hairy stalks, entire or somewhat toothed, hardly an inch long, strongly reticulated with veins: very rough with minute bristles above; hairy beneath. Flowers yellow, on simple, foliary, fistulated, crept, axillary, hairy stalks, twice the length of the leaves. Outer calyx very hairy; inner rigid, with almost pungent points. Corolla about an inch long, its segments somewhat rounded. Capsule rigid, about the same length.

2. T. fragrans. Twining Thunbergia. Roxb. Corom. v. i. 47. t. 67. Willd. n. 2. Ait. Repof. t. 123.—Leaves ovate-oblong, somewhat heart-shaped, acute. Stem twining.—Common in hedges among bushes, on the banks of water-courses, about Simulæth. flowering in the wet and cold seafsons. Dr. Roxburgh never met with it any where else. He says the plant produces a peculiar and agreeable fragrance, and the beauty of its flowers, though not fragrant, entitles it to a place in the flower-garden. No scent has been discovered in any part of this plant in our flowers, where it blossoms freely all summer long. The long

and twining stems readily distinguish this species from the foregoing, as well as the elongated form of the leaves, which are occasionally angular, or toothed, near the base. The flowers are white, larger, and with a narrower tube than the caperina, their segments more abrupt or somewhat notched.

It appears by the Linnean herbarium that the younger Linneus had originally defined the name of Solandra for this genus.

Another Thunbergia was previously established by Dr. Montin, in the Stockholm Transactions for 1773, but the noble plant on which it was founded proved a Gardenia. See that article.

THUNDER, a noise in the lowest region of the air, excited by a sudden explosion of electrical clouds; which, on this account, are called thunder-clouds.

Senea, Rohault, and other authors, both ancient and modern, account for thunder by supposing two clouds impeding over one another, the upper and rarer of which, becoming condensed by a fresh accession of air raised thither by warmth from the lower parts of the atmosphere, or driven upon it by the wind, immediately falls forcibly down upon the lower and denser cloud: by which fall the air interpolated between the two being compressed, that next the extremities of the two clouds is liquefied out, and leaves room for the extremity of the upper cloud to close tight upon the under; thus a great quantity of air is enclosed, which, at length escaping through some winding irregular vent or passage, occasions that noise which we call thunder.

But this could only reach to the phenomena of thunder heard without lightning; and, therefore, recourse has been had to another solution. It has been said, that thunder is not occasioned by the falling of clouds, but by the kindling of fulphurous exhalations, in the same manner as the noise of aurum fulminans.

"There are fulphurous exhalations," says Sir Isaac Newton, "always ascending into the air when the earth is dry; there they ferment with the nitrous acids, and sometimes taking fire, generate thunder, lightning, &c."

That, besides the vapours raised from water, &c. there are also exhalations carried off from sulphur, bitumen, volatile salts, &c. is past all doubt; the salt quantity of fulphurous and bituminous matter all over the surface of the earth, and the volatile salts of plants and animals, afford such an ample flock of them, that it is no wonder the air should be filled with such particles, raised higher or lower, according to their greater or less degree of subtility and activity; and more copiously spread in this or that quarter, according to the direction of the winds.

Now, the effects of thunder are so like those of fired gunpowder, that Dr. Wallis thinks we need not feruple to ascribe them to the same cause; and the principal ingredients in gunpowder, we know, are nitre and sulphur; charcoal only serving to keep the parts separate, for their better kindling.

Hence, if we conceive in the air a convenient mixture of nitrous and fulphurous particles, from the sources above mentioned; and those, by any cause, to be set on fire, such explosion may well follow; and with such noise and light, the two phenomena of thunder, as in the firing of gunpowder; and being once kindled, it will run from place to place, this way or that, as the exhalations happen to lead it; much as is found in a train of gunpowder.

This explosion, if high in the air, and remote from us, will do no mischief; but if near us, may destroy trees, animals, &c. as gunpowder would do in the like circumstances.

This nearness, or distance, may be estimated by the in-
terval of time between the flash and the noise. Dr. Wallis observes, that, ordinarily, the difference between the two is about seven seconds, which, at the rate of 1142 feet in a second of time, gives the distance about a mile and a half; but sometimes it comes in a second or two, which argues the explosion very near us, and even among us. And in such cases, the doctor affuises us, he has more than once foretold the mischief that happened.

Upon the whole, that there is in lightning a sulphurous vapour has been argued from the finell of sulphur which attains it, and from the fultry heat in the air which immediately precedes it; and that there is a nitrous vapour along with it, the same writer concludes hence, that we know of no other body so liable to a sudden and violent explosion. And as to the kindling of these materials, we know that a mixture of sulphur and steel-findings, with a little water, will of itself break forth into actual flame. Nothing, therefore, is wanting to the explosion but some chalybeate or vitriolic vapour; and, among the various effusions from the earth, the doctor does not doubt but there must be some of that kind; but, in proof of what he leaves as a probability, the following facts are alleged.

In history, we meet with instances of its raining iron in Italy, and iron-rains in Germany. Jul. Scaliger tells us, he had by him a piece of iron rained in Savoy, Cardan reports 1200 iron to have fallen from heaven, some of them weighing 30, some 40, and one 120 pounds, all very hard, and of the colour of iron.

The matter of fact is so well attested, that Dr. Lifter, in the Philosophical Transactions, builds a whole theory of thunder and lightning on it; maintaining that they both owe their matter to the vapour or exhalation of the pyrites.

The noise of thunder, and the flame of lightning, are easily made by art. If a mixture of oil or spirt of vitriol be made with water, and some filings of steel added to it, there will immediately arise a thick smoke or vapour out of the mouth of the vessel; and if a lighted candle be applied to this, it will take fire, and the flame immediately descend into the vessel, and this will be burst to pieces with a noise like that of a cannon.

This is so far analogous to thunder and lightning, that a great explosion and fire are occasioned by it; but in this they differ, that this matter when once fired is destroyed, and can give no more explosions; whereas, in the heavens, one clap of thunder usually follows another, and there is a continued succession of them for a long time. M. Hornberg explained this by the lightnings of the air above us in comparison of that here, which therefore would not suffer all the matter so kindled to be dissipated at once, but kept it for several returns.

Ever since the year 1732, in which the identity of the matter of lightning, and of the electric fluid, has been ascertained, philosophers have generally agreed in considering thunder as a concussion produced in the air by an electrical explosion. For the illustration and proof of this theory, see Lightning. See also Electricity. We shall here observe, that Mr. Henry Eales, in a letter written in 1751, and read before the Royal Society in 1752, considers the electrical fire as the cause of thunder, and endeavours to account for it on this hypothesis; and he tells us, that he did not know of any person having made the same conjecture. Phil. Trans. vol. xlvii. p. 524, &c.

That rattling in the noise of thunder, which makes it seem as if it passed through arches, or were broken variously, is probably owing to the sound being excited among clouds hanging over one another, and the agitated air passing irregularly between them.

See this phenomenon particularly accounted for under Lightning.

**Thunder-Bolt.** If what we call lightning acts with extraordinary violence, and breaks or shuts any thing, it is called a thunderbolt, which the vulgar, to fit it for such effects, supposeth to be a hard body, and even a stone.

But that we need not to have recourse to a hard solid body to account for the effects commonly attributed to the thunderbolt, will be evident to any one, who considers those of the pulvis fulminans, and of gunpowder; but more especially the aulofulminating powers of electricity, even when collected and employed by human art, and much more when directed and exercised in the course of nature.

When we consider the known effects of electrical explosions, and those produced by lightning, we shall be at no loss to account for the extraordinary operation vulgarly ascribed to thunderbolts. As stones and bricks struck by lightning are often found in a vitrified state, we may reasonably suppose, with Ignior Boccac 1s, that some stones in the earth, having been struck in this manner, first gave occasion to the vulgar opinion of the thunderbolt.

Placed struck with thunderbolts were held sacred among the ancients. Nigidius has a curious treatise on the thunderbolt.

The ancient painters and poets have armed Jupiter with a fort of flaming dart, called a thunderbolt. Thus, it is said, he became master both of gods and men.

These thunderbolts are forged for Jupiter, according to the poets, by the Cyclops.

The thunderbolt, in antiquity, represented sovereignty, and a power equal to the gods; on this account, Apelles painted Alexander, in the temple of Diana of Ephesus, holding a thunderbolt in his hand; and on medals, the thunderbolt is sometimes found to accompany the emperor's head, as that of Augustus.

Appian informs us, that the thunderbolt was the principal divinity of Seleucia; adding, that it was adored, even in his time, with various hymns and ceremonies.

**Thunder-Clouds,** in Physiology, are those clouds which are in a state fit for producing lightning and thunder. From Ignior Baccar's exact and circumstantial account of the external appearances of thunder-clouds, we shall extract the following particulars.

The first appearance of a thunder-cloud, (which generally happens when there is little or no wind,) is one dense cloud, or more, increasing very fast in size, and rising into the higher regions of the air. The lower surface is black, and nearly level; but the upper finely arched, and well defined. Many of these clouds often seem piled upon one another, all arched in the same manner; but they keep continually uniting, swelling, and extending their arches.

At the time of the rising of this cloud, the atmosphere is generally full of a great number of separate clouds, motionless, and of odd and whimsical shapes. All these, upon the appearance of the thunder-cloud, draw towards it, and become more uniform in their shapes as they approach, till, coming very near the thunder-cloud, their limbs mutually stretch towards one another; they immediately coalesce, and together make one uniform mass. These he calls **adscriptious** clouds, from their coming in, to enlarge the size of the thunder-cloud.

But sometimes the thunder-cloud will swell, and increase very fast, without the conjunction of any adscriptious clouds; the vapours in the atmosphere forming themselves into clouds wherever
which interrupted.

When the thunder-cloud is grown to a great size, its lower surface is often ragged, particular parts being detached towards the earth, but still connected with the rest. Sometimes the lower surface swells into various large protuberances, bending uniformly toward the earth. And sometimes one whole side of the cloud will have an inclination to the earth, and the extremity of it will nearly touch the earth. When the eye is under the thunder-cloud, after it is grown larger, and well formed, it is seen to sink lower, and to darken prodigiously; at the same time that a number of small addititious clouds (the origin of which can never be perceived) are seen in a rapid motion, driving along in very uncertain directions under it. While these clouds are agitated with the more rapid motions, the rain generally falls in the greatest plenty, and if the agitation be exceedingly great, it commonly hails.

While the thunder-cloud is swelling, and extending its branches over a large tract of country, the lightning is seen to dart from one part of it to another, and often to illuminate its whole mass. When the cloud has acquired a sufficient extent, the lightning strikes between the cloud, and the earth, in two opposite places, the path of the lightning lying through the whole body of the cloud and its branches. The longer this lightning continues, the rarer does the cloud grow, and the less dark is its appearance; till, at length, it breaks in different places, and flews a clear sky. When the thunder-cloud is thus dispersed, those parts which occupy the upper regions of the atmosphere are equally spread, and very thin; and those that are underneath are black, but thin too; and they vanish gradually, without being driven away by any wind.

These thunder-clouds were sometimes in a positive as well as negative state of electricity. The electricity continued longer of the same kind, in proportion as the thunder-cloud was simple and uniform in its direction; but when the lightning changed its place, there commonly happened a change in the electricity of the apparatus over which the clouds passed. It would change suddenly after a very violent flash of lightning, but the change would be gradual when the lightning was moderate, and the progress of the thunder-cloud slow. Beccar. Lettore dell’Elettrificus, p. 177; or Priestley’s Hist. Elecr. vol. i. p. 397, &c. See Lightning.

Thunder-House, in Electricity, is an instrument invented by Dr. James Lind of Edinburgh, for illustrating the manner by which buildings receive damage from lightning, and to evince the utility of metallic conductors in preserving them from it.

A (Plate XV. Electricity, fig. 2) is a board about three quarters of an inch thick, and shaped like the gable-end of a house. This board is fixed perpendicularly upon the bottom board B, upon which the perpendicular glass pillar C D is also fixed in a hole about eight inches distant from the basis of the board A. A square hole I LM K, about a quarter of an inch deep, and nearly an inch wide, is made in the board A, and is filled with a square piece of wood, nearly of the same dimensions. It is nearly of the same dimensions, because it must go so easily into the hole, that it may drop off, by the leaf-flanking of the instrument. A wire, L K, is fastened diagonally to this square piece of wood. Another wire, I H, of the same thickness, having a brass ball, H, screwed on its pointed extremity, is fastened upon the board A: so also is the wire MN, which is shaped in a ring at O. From the upper extremity of the glass pillar C D, a crooked wire proceeds, having a spring socket F, through which a double knobbed wire slips perpendicularly, the lower knob, G, of which falls just above the knob H. The glass pillar D C must not be made very flat into the bottom board; but it must be fixed so that it may be pretty easily moved round its own axis, by which means the brass ball G may be brought nearer or farther from the ball H, without touching the part E F G. Now when the square piece of wood I M K (which may represent the shudder of a window or the like) is fixed into the hole so that the wire L K stands in the dotted representation I M, then the metallic communication from H to O is complete, and the instrument represents a house furnished with a proper metallic conductor; but if the square piece of wood I M K is fixed so that the wire L K stands in the direction L K, as represented in the figure, then the metallic conductor H O, from the top of the house to its bottom, is interrupted at I M, in which case the house is not properly secured.

Fix the piece of wood L M K so that its wire may be as represented in the figure, in which case the metallic conductor H O is discontinued. Let the ball G be fixed at about half an inch perpendicular distante from the ball H, then, by turning the glass pillar D C, remove the former ball from the latter; by a wire or chain connect the wire E F with the wire Q of the jar P, and let another wire or chain, fastened to the hook O, touch the outside coating of the jar. Connect the wire Q with the prime conductor, and charge the jar; then, by turning the glass pillar D C, let the ball G come gradually near the ball H, and when they are arrived sufficiently near one another, you will observe, that the jar explodes, and the piece of wood L M K is pushed out of the hole to a considerable distance from the thunder-house. Now the ball G, in this experiment, represents an electrified cloud, which, when it is arrived sufficiently near the top of the house A, the electricity strikes it, and as this house is not secured with a proper conductor, the explosion breaks part or it, i.e. knocks off the piece of wood I M.

Repeat the experiment with only this variation, viz. that this piece of wood I M is situated so that the wire L K may stand in the situation I M; in which case the conductor H O is not discontinued; and you will observe that the explosion will have no effect upon the piece of wood L M, this remaining in the hole unmoved; which shews the usefulness of the metallic conductor.

Farther, unfcrew the brass ball H from the wire H I, so that this may remain pointed, and with this difference only in the apparatus repeat both of the above experiments, and you will find that the piece of wood I M is in neither case moved from its place, nor any explosion will be heard, which not only demonstrate the preference of conductors with pointed terminations to those with blunted ones, but also shews that a house furnished with sharp terminations, although not furnished with a regular conductor, is also sufficiently guarded against the effects of lightning.

Mr. Henly, having connected a jar containing 509 square inches of coated surface with his prime conductor, observed that if it wasfo charged as to raise the index of his electrometer to 60°, by bringing the ball on the wire of the thunder-house, to the distance of half an inch from that connected with the prime conductor, the jar would be discharged, and the piece in the thunder-house thrown out to a considerable distance. Using a pointed wire for a conductor to the thunder-house, instead of the knob, the charge being the...
fame as before, the jar was discharged silently, though sud-
denly; and the piece was not thrown out of the thunder-
house. In another experiment having made a double circuit
to the thunder-house, the first by the knob, the second by
a sharp-pointed wire, at one and one-fourth of an inch di-
tance from each other, but of exactly the same height (as in
fig. 3) the charge being the same; although the knob was
brought first under that connected with the prime conductor,
which was raised half an inch above it, and followed by the
point, yet no explosion could fall upon the knob; the point
drew off the whole charge silently, and the piece in the
thunder-house remained unmoved. Phil. Trans. vol. liv.
part i. p. 136. See Points, in Electricity.

 Thunder-Stone, in Natural History, the same with that
called by authors brontia.

 Thunder-Storm. See Thunder-Clouds.

 Thunder Bay, in Geography, a bay in lake Huron,
about nine miles long, and nearly as many broad. The
Indians who reside near, and all European travellers who
have passed this bay, agree to call it by the present name, on
account of the continual thunder they observe. N. lat. 44°
50'. W. long. 83° 30'.—Also, a bay on the N. part of
lake Superior.

 Thundering Legion, Legio Fulminans, was a
legion in the Roman army, consisting of Christian soldiers,
who in the expedition of the emperor Marcus Aurelius An-
toninus against the Sarmatæ, Quadri, and Marcomanni,
A.D. 174, are said to have faved the whole army, then
ready to perish with thirst, by procuring, with their prayers,
a very plentiful shower on them; and at the same time a
furious hail, mixed with lightning and thunderbolts, on
the enemy, and thus he obtained a decisive victory.

 This is the account commonly given by ecclesiastical hi-
torians; and the whole story is engraved in bas-relieves
on the Antonine column. And hence arose the denomination
thunderers: though some say, that the legion those Chris-
tians were of was called the thundering legion before.

 This deliverance has been thought by many to have been
miraculous, owing to the prayers of the Christians who
were in the Roman army; and it has been supposed,
that the emperor wrote a letter to the senate on this occasion,
which was very favourable to the Christians; others, how-
ever, have thought, that the Christians, by a pious fort of
militia, attributed this unexpected and fearsome shower,
which faved the Roman army, to a miraculous interposition;
and this opinion, says Mothes, is indeed supported by the
weightier reason as well as by the most respectable au-
torities; and the letter of Marcus Antoninus is allowed;
even by the defenders of the miracle of the thundering legion,
to have in it manifest tokens of spuriousness, to be the work
of a man unskilful in Roman affairs, and who probably lived in
the seventh century. Mothes sums up the arguments on
this subject in the following manner: it is certain, he says,
that the Roman army encircled by the enemy, and reduced
to the most deplorable and even desperate condition by the
thirst under which they languished in a parched desert,
was revived by a sudden and unexpected rain. It is also certain,
that both the Heathens and the Christians looked upon this
event as extraordinary and miraculous; the former attribut-
ing it to Jupiter, Mercury, or the power of magic; the
latter to Christ, interposing, thus unexpectedly, in con-
sequence of their prayers. It is still farther beyond all doubt,
that a considerable number of Christians served, at this time,
in the Roman army, and it is extremely probable, that in
such trying circumstances of calamity and distress, they em-
ployed the merciful interposition and succours of their God
and Saviour. And as the Christians of the time looked
upon all extraordinary events as miracles, and ascribed to
their prayers all the uncommon and singular occurrences of
an advantageous nature that happened to the Roman empire,
it will not appear surprising, that upon the present occasion
they attributed the deliverance of Antoninus and his army
to a miraculous interposition which they had obtained from
above. But, on the other hand, it must be carefully ob-
served, that it is an invariable maxim universally adopted
by the wise and judicious, that no events are to be esteemed
miraculous, which may be rationally attributed to natural
causes, and accounted for by a recourse to the ordinary dif-
temperations of providence; and as the unexpected shower,
which restored the expiring force of the Romans, may be
easily explained without rising beyond the usual and ordinary
course of nature, the conclusion is manifest: nor can it be
doubtful in what light we are to consider that remarkable
event. Ecl. Hist. vol. i. 8vo. edit.

 Mr. Moyle and Mr. King had a curious and interesting
controversy on the subject of the thundering legion. The
learned Dr. Lardner has collected into one view every thing
relating to it of importance, in his Collection of Jewish and
Heathen Testimonies, vol. ii. ch. xv. sect. iii. p. 221, &c.

 Thunegen, in Geography, See Thunus.

 Thunoe, a small island of Denmark, between the
coast of Jutland, and the island of Samoe. N. lat. 55° 58'.
E. long. 15° 27'.

 Thunudromum, in Ancient Geography, a town,
with the title of a Roman colony, in Africa, in New
Numidia, according to Ptolemy. It is named Tysiumenien
Oppidum by Pliny.

 Thunusda, a town of Africa Propria, according to
Ptolemy, denominated by Pliny Thunudromum Oppidum.

 Thupe, or Thuppe, a town of Africa, in the interior
of Libya, upon the southern banks of the Niger. Ptol.

 Thuppa, a town of Africa, in the interior of Libya,
upon the northern bank of the river Gira.

 Thur, in Geography, a river of Switzerland, which
rises in the south part of the county of Toggenburg, and runs
into the Rhine, 7 miles S.S.W. of Schaffhausen.

 Thure, a town of France, in the department of the
Vienne; 4 miles W. of Chatellerault.

 Thurer, a river of France, which rises in the depart-
ment of the Upper Rhine, passes by Thann, &c. and joins
the Ill at Ensisheim.

 Thurgau, a country of Switzerland, with the title of
landgrave; bounded on the north by Swabia and the
lake of Constance, on the east by the lake of Constance,
on the south by the territories of St. Gall, and on the west
by the cantons of Zurich and Schaffhausen. It receives its
name from the river Thur, and, in its most extensive sense,
comprehends all the extent of country on both sides of that
river. Though somewhat mountainous towards the south,
yet it affords rich pastures; and its other parts, as approach-
ing nearer to levels, produce plenty of grain, with vegetables
and fruits of all kinds, as also wine. The country is popu-
lous, and well cultivated, containing fix towns, with several
handicome burghs, a great number of fefts, and upwards of
170 villages. About one-third of the inhabitants consists of
Roman Catholics, and in church affairs are subject to the
bishop of Constance. The other two-thirds, ever since the year 1543,
have been Calvinists. The Thurgau is a very ancient land-
grave, which, on the extinction of the counts of Old or
Hohen Frauenfelden, devolved to those of Kiburg, and, on
their failure, to the counts of Habburg, with whom it came
to the house of Austria, which continued possessed of it till
1460, in which year the Switzers, being at war with the
archduke Sigismund, wrested this country from him, which,
by the peace concluded at Constance in the following year, was confirmed to them. The cantons to which the territorial sovereignty of this country belongs, are the eight old cantons of Zurich, Berne, Lucerne, Schwyz, Unterwalden, Zug, and Glarus; but it was not till the peace of Aarau, that the seceded was admitted by the others as a co-sovereign. These eight every two years alternately appoint a landvogt over it, who resides at Frauenfeld; and since the year 1449, the cantons of Friburg and Solureve have also obtained a seat in its criminal court.

THURGOLAND, a township of Yorkshire, in the West Riding; 4 miles S.W. of Barnetley.

THURIA, in Ancient Geography, a town of Meffenia, on the river Aris, S.W. of Alagonia. It had a temple dedicated to the goddess Astarte, a Syrian divinity, supposed to be the same with Venus—Alfo, an island on the Egean sea, near Naxos, according to Plutarch.

THURIBULUM, among the Romans, a cenotaph, or vault, in which incense was burnt at sacrifices.

THURIFICATI, in Church History, a designation given to those who, to avoid the persecution of the Roman emperors, offered frankincense to the heathen gods.

THURII, THURINGIANS, a people of Germany, supposed by some authors to have been a part of the Vandals. They have been scarcely known in history since the fall of the Roman empire.

Towards the end of the fifth or commencement of the sixth century, Thuringia had a king, or at least a warlike chief.

THURINGIA, in Geography, a circle of Saxony, which forms the N. part of the landgrave of that name. The country is well watered, yields good pasturage, and abundance of corn, particularly wheat, which is excellent, as also fine timber, flax, anife, flax, flax, and wine; and has also a considerable breed of horses, horned cattle, and sheep. Of these natural productions of the country, a great part is exported. Thuringia contains in it 60 towns, 674 villages, and 300 noble estates. The modern Thuringia, which lies nearly between the Saale and the Werra, is but a part of the ancient Thuringia, a country formerly comprised under that name, extending itself much farther every way.

In the sixth century, the Franks and Saxons subjected the Thuringians to their dominions, whose country form that time forwards became divided into the North and South. North Thuringia, towards the N., extends itself beyond Harzwalde, quite to the river Elbe, and belonged to the Saxons. It was united with the duchy of Saxony, lost its name, and was at length annexed to Eastphalia, or to the eastern part of the county of Saxony. South Thuringia belonged to the Franks, and comprised in it the modern Thuringia, together with a large share of the modern Franconia, Hesse, &c. Till the eleventh century, it flourished under the emperors and kings, and besides the counts, we find also some dukes mentioned, to whom the German kings entrusted the government of this country. Ever since the thirteenth century, the margraves of Meifen, who afterwards became electors of Saxony, have been in possession of the landgraviate of Thuringia, which was at one time divided among separate lines, but returned again by the extinction of the latter to that of Meifen. It has been ceded to Prussia by the king of Saxony.

THURIS, in Ancient Geography, a town situated in the interior of Arabia Felix. Ptol.

THURIS, in Geography, a post-town of the county of Tipperary, Ireland, situate on the river Suire, which divides it nearly into two equal parts. There was formerly a castle belonging to the knights of St. John of Jerusalem, and there are full some ruins of a monastery. Thurlis is 70 miles S.W. from Dublin.

THURLEMORE, a lake of England, in the county of Cumberland, from whence a river runs to the Derwent; 3 miles S.E. of Keswick.

THURLOE, John, in Biography, secretary of state to the Protectorate, was the son of Thomas Thurloe, rector of Abbot's Roding, in Essex, where he was born in 1616. He was brought up to the law, and in 1644-5, by the intercessions of Oliver St. John, was appointed one of the secretaries to the parliamentary commissioners at the treaty of Uxbridge. Advancing through other offices, he went as secretary to lord chief justice St. John, and Mr. Strickland, in their embassy to the States-General. In 1652 he refe to the office of secretary to the council of state; and when Cromwell, in 1653, assumed the protectorate, he was nominated his secretary, on whom he repose peculiar confidence. In 1655 he was entrusted with the management of the post-office; and in 1656 he represented the isle of Ely in parliament. On the death of Cromwell he signed the order for proclaiming Richard, and in the following parliament was returned member for the university of Cambridge. He retained his office of secretary under Richard, and also under the parliament that deposed him. On the Restoration, he was accused of high treason and examined, but soon let at liberty. He then retired to his seat in Oxfordshire, and visited London, at his chambers in Lincoln's Inn, in term-time. Charles II. often invited him to take a part in his administration: but he declined it, alleging that perhaps he should not be able to serve the king, as he had done the protector, in connection with men of different characters and principles; the protector, as he told his majesty, was used "to seek out men for places, and not places for men." The abilities of Thurloe for public life were distinguished, and his character in private life no less amiable. He died in Lincoln's Inn, where he was mallet of the bench, in 1667-8, and was interred in the chapel. His密封 papers formed a valuable historical collection, and were published by Dr. Birch, in 7 vols. fol. 1742. Biog. Brit. Gen. Biog.

THURLOW, in Geography, a township of Upper Canada.

THURLOW's Island, a narrow island in the Pacific ocean, near the coast of North America, about 24 miles in length from E. to W. N. lat. 50° 24'. E. long. 233° 35'.

THURMAN, a post-township of the United States, in the state of New York, and county of Washington, erected in 1792 from Queenbury, and then comprising a great extent of territory, which has been since subdivided into other towns. Thurman is bounded N. by Chester and Johnsburg, E. by Caldwell and Bolton, S. by Saratoga county, and W. by Montgomery county. The first settlements commenced about 1786, and in 1810 there were about 200 families, mostly Scots, and the soil from the eastern flates, it has one Presbyterian and one Methodist meeting-house, and a pretty competent number of common school-houses and schools. The whole township is well watered, and Cran's mountain in the W. part of it is rich in mineral treasures. Much of this western part is still unsettled.

THURN, a town of the duchy of Slesia; 5 miles S. of Windisch Grätz.

THurn am Hand, a town of the duchy of Carniola; 2 miles S. of Gurkfeld.

THURNAU, a town of Germany, in the principality of Culmbach; 5 miles S.S.W. of Culmbach. N. lat. 50° 2'. E. long. 11° 26'.
THURNEISSER, Leonard, in Biography, a man of great temporary celebrity in chemistry and the occult sciences, was born at Baffe in the year 1530. Having imprudently, in 1547, when a boy, married a widow, who proved unfaithful; and having involved himself in debt, he found himself under a necessity of leaving both his wife and his native place. Accordingly, in 1548 he went to Strabburg, and from thence he proceeded to Constance, having, by different application to his trade of a goldsmith, amassed a considerable sum of money. He employed himself in the construction of mathematical instruments, and in a variety of metallurgic operations with such reputation, that he was entrusted with the direction of the smelting works at Eberfeld in the Tyrol. During his abode at Constance, he married the daughter of a goldsmith by whom he had been employed, and in 1558 retired with her to Tarenz in the Upper Innthal, where he formed metallurgic establishments on his own account, and constructed furnaces, together with a manufactury for the preparation of sulphur. Here he was visited by several persons of eminence, and became known to the emperor Ferdinand; and patronized by the emperor's son, the archduke Ferdinand, he travelled, by his connex, in 1560, to Scotland and the Orkney islands, and in 1561 to Portugal and Spain, and also to some parts of Africa and Asia. On the summit of an island he received the order of St. Catharine; and in his way home he visited Candia, Greece, Italy, and Hungary. When he arrived in the Tyrol, he found his establishments in great confusion; but he was enabled by the government of Innsbruck to revive and support them. He was then deputed by the archduke to examine the mines in Hungary and Bohemia; but notwithstanding this high patronage, he involved himself in debt, and by his pride and extravagance forfeited the favour of his patrons. In 1569 he obtained leave to visit Lower Germany, for the purpose of making some observations in natural history, and of superintending the printing of some of his works. During the leisure afforded by some of his sea-voyages, he had composed, in German verse, a work intituled "Archidoxia," or an account of the influence which the planets have on the human body, and on all the employments of man; together with a secret introduction to alchemy. He had prepared also another work, called the "Quintessence," in which he pointed out the connection between medicine and alchemy, and gave instructions how to extract from all substances their quintessence or subtile parts. He pretended also to have made some other curious discoveries, which we cannot detail.

At Munster he published, in 1569, the first edition of his "Archidoxia," in 4to.; and his "Quintessence" was printed there, also in 4to., in 1570. These works were afterwards enlarged and published in folio. Thurneisser, quarrelling with the bishop, left Munster and removed to Frankfort on the Oder, to print his "Pison," or Description of Rivers, by which, together with his calendar and book on plants, he acquired the greatest share of his reputation. Having cured the margrave of Brandenburg of a dangerous illness, the margrave appointed him his physician, and defrayed the expense of bringing his wife and family from Constance. In 1572 he published his work "On Urine," in which he affirms, that by examining the urine of Sigismund I., of Poland, he had discovered the nature of his disease, and predicted his death, with the day on which it would happen. Under the patronage of the margrave of Brandenburg he went on perpendicularly with his laboratory and printing-premises; and indulged in the most expensive and splendid mode of living. His visitors were numerous, and of the first rank; and among his correspondents were the emperor Maximilian, and Elizabeth queen of England. He was confounded not only in all kinds of difeases, but on witchcraft, magic, and other such matters. His printing-premises was in high estimation. By printing, and the sale of his MSS. and preemptions, he acquired great wealth. For the MSS. the elector, John Gruge, gave him 9000 dollars; and there was formerly in the king's library at Berlin, a MS. entitled "De Transmutatione Veneris in Sollem," for which an annual pension of 600 dollars was settled on him and his children. He was the first person who formed a collection of natural curiosities in the Marche of Brandenburg. He had also a garden filled with plants for the study of botany, and a menagerie, containing a collection of various animals from all parts of the world. In 1575 he lost his second wife, who arranged all his affairs with great prudence; and this was the era of his downfall. From opulence he was reduced to poverty. His reputation as a physician declined. Dr. Hoffman of Frankfort, in his oration "De Barbaricin Imminente," was formidable to his credit, and he contrived means to prevent its being printed till the year 1578. Thurneisser, tearing utterly to lose his character, prepared for his departure from Berlin, and retired to Baffe, where, in 1580, he married a third wife. Withdrawing from domestic quiet into Italy, he is said to have converted, in the presence of the grand duke, Francesco de Medicis, one half of an iron nail into gold. This singular man died in 1595, or 1596, in a monastery at Cologne, after requesting that his body might be interred close to that of Albert the Great. A list of his works is given by Haller in his Bibliotheca. Gen. Biog.

THURTOZ, in Geography, a river of Hungary, which runs into the Waag, 12 miles N. of St. Martin. It gives name to a county.

THURROCK GRAYS, or GREAT THURROCK, a market-town in the hundred of Chafford, and county of Essex, England; is situate 22 miles S.S.W. from Chelmsford, and 24 miles E. by S. from London. It acquired the appellation of Grays from the noble family of that name, who possessed the manor for upwards of three centuries, from the year 1194, when it was granted to them by king Richard I. The town consists principally of one irregular street, on the banks of a small creek from the Thames, navigable for boats and vessels of small burthen. A weekly market is held on Thursdays, chiefly for the sale of corn, and is much frequented: here is also an annual fair. The church is built in the form of a cross, with a tower on the north side. By the return under the population act of the year 1811, this parish was stated to contain 114 houses, and 1055 inhabitants.

In the adjacent parishes of Chadwell and Little Thurrock are various caverns, or holes, of unequal depths and dimensions, formed in the chalk, which here constitutes the upper stratum: they appear to open from the top by a narrow circular passage, which near the bottom begins to spread, and communicates with subterranean apartments of different forms. Dr. Derham measured fix of these caverns, and reports them to be of various depths, from fifty to eighty feet. The origin of these excavations is uncertain; the opinion of some modern writers, that they were the granaries of the Britons, seems by far the most rational supposition. They are also called Dane Holes, and traditionally reported to have been used as receptacles or hiding-places for plunder during the frequent incursions of the Danes into this island.—Beauties of England and Wales, vol. v. Essex; by J. Britton and E. W. Brayley.

THURSDAY, the fifth day of the Christians' week, but the sixth of that of the Jews. See THURSDAY.
THURSDAY, Holy. See Holy.
THURSDAY, Monday. See Monday Thursday.
THURSDAY, store, in Evidences, a species of fish mentioned by Pliny, ib. ix. cap. 9. It is thought by some to be the

place, or porpoise; and by others the

f节目.

THURSO, or Thorsay, in Geography, a market-town

in the burh of Caithness, Scotland, is situated on the northern

side of the coast, at the extremity of a spacious bay, on the

estuary of the river Thurso, at the distance of 279 miles N.

from Edinburgh. The town is irregularly built. A new

town, on a regular plan, has been lately commenced at

Thurso, in consequence of which, the inclosed lands let for

five guineas per acre per annum. Here is a fine bay or

harbour, which is progressively much improved in conve-

nience and security. Eight vessels belong to the town, and

are chiefly employed in conveying salmon to London.

Although the customs of this port are very inconsiderable,

yet the following officers are regularly stationed here; a col-

lector, comptroller, land-surveyor, land-waiter, two esta-

lished tide-men, and one extraordinary tide-man. Thurso

is a borough of barony, holding of Sir John Sinclair as im-

mediate superior. The charter of erection was granted by

Charles I. in 1633, in favour of John Matter, of Berriedale,

by which it was entitled “to all the privileges, immunities,

and jurisdictions, belonging to a free borough of barony in

Scotland.” It is governed by two bailies and twelve coun-

sellors, who are appointed by the superior, and hold their

offices during his pleasure. A well-supplied market is held

on Fridays; and here are two annual fairs, one of which

continues for ten days. The principal manufacture of the

town is coarse linen cloth; in the neighbourhood are a

bleach-field and a tannery, both of which are prospcrouis.

In the population return of the year 1811, the town and

parish of Thurso were estimated to contain 592 houses,

inhabited by 3462 persons. The parish extends about three

miles from the town in every direction, except to the north-

west, where it is bounded by the sea. The rocks that

bound the coast exhibit various scenes of natural grandeur.

The Clett is an inflated rock about 160 yards long and 80

breadth; it is elevated about 400 feet above the level of the

sea; and during the spring season, is frequented by in-

numerable flocks of sea-fowls.

Thurso East, anciently called Thurso Castle, once the

residence of the earls of Caithness, is now the seat of Sir

John Sinclair, bart. a native of Thurso; a gentleman whose

exertions will ever be revered by men of science for “The

Statistical Account of Scotland.” In the park are the ruins

of a small chapel, where earl Harold the younger was buried,

and where a neat modern monument has been erected by the

above-mentioned baronet.—Beauties of Scotland, vol. v.

THURSO, a river of Caithness, which runs into the sea, at

the town of Thurso.

THURS, in Natural History, the name of a creature
defcribed by Géniel, and some others, as a difficult species of

wild bull; but the accounts of it seem either fabulous or

mistaken descriptions of the wild bull.

THURY, in Geography, a town of France, in the de-

partment of the Yonne; 10 miles S.E. of St. Fargeau.—

Also, a town of France, in the department of the Oise; 7

miles S.E. of Crepy.

THUS, a town of Feria, in the province of Khorassan ;

200 miles N.W. of Herat.

Thus, a river of Feria, which rises near Mefghid, in

Khorassan, and runs into the Caspian sea, 40 miles N.W. of

Zaweh.

Thus, See Frankincense.

Thus Judeorum, called also caftarilla and cortex ele-
therris, in the Materia Medica, is the bark probably of the

thurb described by Cato, under the name of vinaeides
eleagni folio or stherris, the corona caftarilla of Linnaeus,

which grows plentifully in most of the Bahamas islands;

thence it is brought to us in curled pieces, or rolled up

short quills, about an inch wide; covered on the outside

with a rough whitish matter; and brownish within; and

exhibiting, when broken, a smooth close blackish-brown

surface. The bark, freed from the outer coat, has a light

agreeable smell, and a moderately bitter tafte, accompanied

with a confiderable aromatic warmth. It is easily inflam-

mable, and yields, whilst burning, a fragrant smell, some-

what resembling that of mufl. Stiffer was the flirt who

employed this bark as a medicine in Europe; who relates

that a tincture of it in alkaliized vinous spirits, or in dulci-

died alkaline spirits, proved carminative and diuretic, and
did service in arthritic and scorbutive cafes. In 1694 and

1695, it was employed by Apinus in an epidemic fever of the in-

termittent kind. The gentlemen of the French Academy

found this bark of excellent service against an epidemic

dysentery in 1719, when the ipecauanha proved ineffec-

tual. At present it is of great esteem among the Germans, as a

warm fomachic and corroborant, in flatulent colics, in-

ternal hemorrhages, dysenteries, the diarrhoea of acute

fevers, and, mixed with the Peruvian bark, in common in-

termittents.—Among us it has been lately received into prac-

tice; but its use, says Dr. Lewis, is not yet become so

general as it well deserves to be. Its virtues are partially

extracted by water, and totally by rectified spirits. Lewis’s

Med. Mat.

Thus, in Sea Language, the order by which the pilot

directs the helmsman to keep the ship in her present situation

when falling with a feant wind, so that the may not approach

too near the direcHon of the wind, and thereby shiver her

fars, nor fall to leeward, and run farther out of her course.

Falconer. See STEERING.

Straits of Sunda. S. lat. 5° 55'. E. long. 105° 43'.—

Also, a small island in a bay on the coAft of New Guinea.

S. lat. 2° 15'. E. long. 136° 54'.

THWATER, Trembling, or Leaping-ill, a disease

in fleep, of the shaking, jumping, and convulsive kind.

These different forms, some of which were formerly par-

ticularly used in one part and another in another, especially in

the northern districts of the kingdom, are now said to be

had recourse to indifferently, and applied indiscriminately to

all diseases which, on a dry foil, proceed from a weak and

enfeebled rate of body and barren feaons. Under this

threefold name, some fay they have been fleep suffering by
diseases, which at leat had much resemblance to those of

several other forts, as the apoplectic, paralytic, rheumatic,

&c.; and that even when an old fleep falls down, and

dies of weeknesses and exhaustion, the manner of its death

differing somewhat from that of the hog-fleep, it is frequently

affected by fhepherd to the thwarter or trembling-ill.

There
There is, on the whole, so much contrariety of opinion, and diversity in the descriptions of the diseafes, its caufes, and the means of cure, that the writer of a paper on some of the diseases of sheep, in the third volume of the "Trans-
actions of the Highland Society of Scotland," has divided and considered it under two different species.

The first variety, it is laid, is much more rare than for-
merly, and is scarcely known in the Highlands of the above
country. It appears mostly in the spring and harveft
seasons. It affects sheepe of all ages and kinds, but never
when in good condition, excfling chiefly on dry farms, which
have a northern exposure, and which are evidently over-
flock'd; but on these only when the spring is feverell and
dry, or when early Aprill grass has been cut down by frofis,
and the sheep can find no succulent food or any thing green.
Its production is favoured by a long continuance of eafierly
winds; and in cold weather, ewes are sometimes attacked by
it, even after they are f深圳ed. In these circumstances they
become extremely emaciated, espefially when heavy with
lamb in many of them, or giving fuck; and when at this
time they get an overfretch in running or leaping, or even as
halfly start, or crurfh in the fold, numbers fall a prey to
this disorder.

The appearances are, that fome sheep, it is faid, will fall
down and die in two or three minutes; others will lofe the
power of one fide, and lie fpawling until they die of hunger;
others again will lie flivering, and very fick at times, until
death alfo comes on; and fome will go a long time quite
fame, until they are likewife quite exhausted. Others defcribe
it as of two kinds; in one, fometimes feizing the whole fyllen,
when there is a general trembling over the whole body, and
in the other, fometimes affecting the legs only, when the
animal immediately falls down, and the fhaking, which is
interrupted, is confined to the legs. Some fay that the
animal gradually lofes the power of its legs and body, until
it becomes quite weak, always lying at falt upon one fide.
Thefe sheep which die off in spring, are lean and ufeless;
but the mutton of fat hog-fheep carried off by it in the
autumn is not uetable. It is sometimes extremely fatal.
In one inftance, out of a flock of forty fcore, feventeen
fcore were, it is flated, loft in one spring. It was formerly
thought to be contagious, and although this can fearely be
the cafe, it is certainly molt deftructive when it ftrikes
among a flock; and when fheepe are brought from a clean
ground to one infected with it, great numbers of them are
fure of dying. Thofe which furvive it one fandon, are fure
to relapfe the next spring.

Udder-locking should be entirely laid afide, as in one in-
ftance, one-twentieth of a large parcel of ewes is faid to
have died of the difeafe, in the course of a week after they
had been udder-locked. See UDDER-Locking.

It is alfo faid to be ufeful during the early fpring months
for to provide them with fufficient food and felter; and to
avoid overflockng, if the early grass has been blighted, to
paffure them in a rich park or other ground, on water-
meadow, or on meaf or early rye-grafs.

The fcranl variety of the difeafe is, it is remarked, chiefly
confined, in the above part of the kingdom, to the flocks in
the south of it, more efpecially about the banks of the river
Tweed, and of tho which difcharge themfelves into it.
It is faid to be a complaint almoft unknown to the farmers
on the Pentland range, and to the north of the Forth.
In those places where it prevails, it is fometimes peculiarly
fatal, and a farmer often lofes more of the flock by it alone,
than all the other difeafes put together.

The appearances when it first comes on, which is gene-
 rally during the summer or harveft months, are, that the
animal turns somewhat flupid and neglects its food, does round,
in some measure, as in the flurdy, and frequently
leaps up, as if to clear any hulf or dikke before it; at times,
it will eat voraciously, and again refufe all influence for a
confiderable time. It continues frequently leaping during the
day, and the neck is often stiff, and turned on one fide;
convolutions take place in the limbs which caufe the animal
to fall down, make curious contortions, and at times run to a
little difance; the body fometimes partakes of thefe, when
the fheepe becomes totally incapable of motion, and dies from
want of food, which the jaws will not open to admit, being
clofely wedged together. In this fteate, it is unable to fol-
low the flock, and the wool claps to the body. It lies for a
long time motionlefs, and at length dies. After lying
motionlefs for a confiderable time, in those cafes where
the difeafe is not to violent, and the fpavin of the jaw not
foucerv, it gradually relaxes, and the sheepe will eat the
whole of the food within reach quite bare, although the
power of the limbs is totally gone, leaving the earth quite
red and naked all round them. If the fhepherd be at-
tentive, and lifts them from place to place, and the fean be
pretty well advanced, they often flowly recover, and are
again refured to the ufe of their limbs. When they lie in
this inactive fteate, if the weather be warm, maggots are very
apt to breed in them; and if not attended to, foon defroy
them.

The difeafe moftly appears at the periods stated above,
especially during hot and fultry weather, and arises either
from the fheepe being put into violent motion by dogs, or
overheated by the fun; in which cafes, in a few hours after-
wards, it makes its appearance by the fluff neck, or fome of
the other figns coming on. When the fheepe are exposed
to fatigue, it will take place, if the weather be warm, inde-
pendent of violent motion. They are commonly the
caffethyl of the flock that are cut off by it. It not un-
frequently arifes from the braxy, of which it is moftly a fa-
vourable fign. It is never fever, however, when it is the
confequence of that difeafe, and the fluff neck never accom-
pnies it.

In regard to the means of cure in the fcranl fort, they
are various. When the fheep fall down suddenly, and are
threatened with immediate death, bleeding, by cutting
the tail, or opening a vein on the inide of the fore-thigh,
will sometimes give immediate relief. In all the other
cases it is proper to take them home and feed them with
ftrongeafing food; and if at this time they be attacked
with a temporary fcoring, they moftly recover very falt, and
foon acquire their former vigour. It is faid that some few
means of cure are occasionally tried, but it is believed with
little fuccefs. Dipping in cold water is not unfrequently
practifed: whisky and gunpowder are sometimes poured
down their throats; and balls of mustard and other hot
pungent medicines are often administered. Others re
commend bringing them into the houfe, giving them a mixture
of equal quantities of fallad oil and spirits, with a little
finely powdered ginger, and at the fame time rubbing into
the back a little black soap broken in warm water, and
feeding them on hay, the produce of dry walks or other
grounds.

The giving of the fheep a decoction of the dewcup and
healing leaf boiled in butter-milk, is faid to have been uni-
formly successful in treating sheep affected with this disorder
during the summer and autumn.

In the removal of the fcranl kind of the difeafe, as it
arifes from the brain being oppress'd, by too much blood
being sent to it by the quickened circulation, the fcranl thing
to be attended to on its appearance is copious blood-letting,
which
which will be more effectual if taken from the veins of the neck, or from a vein on the outside of the eye, mostly well known to shepherds. It may even be taken from the tail, or fore-leg; but opening of the veins of the head is generally considered as the most proper and beneficial in this species of the complaint. As there is too great a determination of blood to the head, it will be attended with advantage to make a determination to the bowels, by illuminating them by means of purgatives, such as those of common salts, one ounce or more: calomel, from ten grains to half a drachm; or, what is supposed more proper, as it also acts upon the kidneys and skin, a dose of half an ounce or more of nitre. These remedies are to be persevered in, until all marks of the disease disappear. But if the sheep be too far gone in the disorder, and has lost all motion, it should be killed for the sake of the carcase, which in this species of the disease is not affected, or at least but very slightly.

In the managing of the cure, much nice attention is necessary in both kinds of this disease.

THY, in Geography, a town of Prussia, in Pomeralia; 7 miles N. of Marienburg.

THYAMIA, in Ancient Geography, a town of the Peloponnesus, in Sicilya. Xenophon.

THYAMIS, a town of Arcachia, founded by Semiramis.—Alfo, a promontory of Epirus, between Theborea and Cethrini.

THYARIS, a river of Asia, in Phrygia Salutaris, which passed through the northern part of this province, and discharged itself into the Sangara.

THYATIRA, A Phoras, a town of Asia Minor, in Lydia. According to Steph. Byz. it was very ancient, and called Pelope, Pelopon, or Pelopia, and afterwards Semiramis. According to Pliny it was also denominated Eupippa. It derived its name of Thyatira, from the Greek word signifying daughter, from Seleucus Nicanor, who received the news, as it is said, at this town of the birth of a daughter. From an inscription found in this city, it appears that Adrian had a temple in it; and medals have been found here that were struck in honour of Adrian. Strabo says that the town of Thyatira was considered by some authors as the birth of the district of Mylia, and that it was a colony of Macedonians. After Scipio had defeated Antiochus near Magnesia and Sipyla, the town of Thyatira sent ambassadors to the Romans, to render them homage. Thyatira was taken by Artilonicus, in the year 140 B.C., but this prince having been taken prisoner in the same year by the confed Perpenus, this town reverted to the dominion of the Romans. Thyatira was much distinguished by the benefactions of the emperor Caracalla; and it appears by a medal of this town, that under the reign of this prince it took the name of Neoecoros. This place was one of the seven churches of Asia, mentioned in the book of Revelations; so that the Chilrian religion was introduced here by the apostles and their immediate disciples; but whether the church was founded by St. Paul or St. John, or by either of them, does not appear.

The inhabitants of Thyatira had a particular veneration for Diana. This appears from many inscriptions found in this town, of which this goddess bears the title of "Diana Montana." The town was situated at the southern foot of a chain of mountains, on the route from Hermus to Sardis, and it was watered by a stream of the river Caucus. The town suffered much by an earthquake in the reign of Tibereus. See AKHISAR.

THYIA, or S, in Antiquity, a festival in honour of Bacchus, celebrated by the Eleans.

THYITAS LAPIS, in the Materia Medica of the Ancients, the name of an indurated clay, approaching to the nature of a stone. It was found in Egypt, and used in different temperatures of the eyes.

This substance has been very much misunderstood by late writers, and by most of them supposed to be lost at this time; but this was wholly owing to their mistaking the clays of bodies among which they were to look for it: some imagining it to have been a species of green marble; and others to have been turquoise-blue, that Dioscorides meant by this name. It is very plain, however, that it was no other than an indurated clay of the morrochus kind, and no more a stone than that substance, that being also frequently called lapis morrochus.

It is of a smooth, even, and regular texture, very heavy, of a shining surface, and of a pale green, without the admixture of any other colour. It does not at all adhere to the tongue, nor stain the fingers in handling; but drawn along a rough surface, leaves a flender white line. It melts slowly in the mouth, and is of a sharp, acrid, and disagreeable taste; and when rubbed down with water on a marble, it melts into a milky liquor of a pure white, not the least greenness being sensible in it. It is found at present in the great mine at Gofidar in Saxony, and seems to owe its colour to particles of copper, to which also it owes the virtues attributed to it by Dioscorides, acting as a weak kind of verdigris. Hill.

THYLACION, a word used by the ancient medical writers, to express the bag formed by the membranes of the eyes at the orifice of the pudenda, before the birth.

THYLLA, of 2nd a, in Antiquity, a festival in honour of Venus.

THYMALLUS, in Ichthyology. See Grayling, and SALMO THYMALLUS.

THYMATERIUM, in Ancient Geography, a town of Africa, in Libya, two days' journey beyond the columns of Hercules, according to the Peripus of Hannon; it is the Thymateriæ of Steph. Byz.

THYMBRA, a town of Asia Minor, in the Troade, according to Steph. Byz., who says that it was founded by Dardanus, who gave it its name after that of his friend Thymbros. Apollo had a temple here under the appellation of Thymbrian. Strabo says that a stream called Tymbrius traversed its canton, and that this stream discharged itself into the Scamander, before the temple of Apollo. Servius says that Achilles was wounded here by Paris; and this circumstance gave occasion to the report that the wound was inflicted by Apollo.

THYMBRÆA, or Tymbra, a mountain of Asia, in Phrygia. THYMBRA, in Botany, a name borrowed from Dioscorides, whose real genus, however, is a species of SATIVA, see that article, n. 3. Linnaeus therefore has adopted the above name for another Greek genus, nearly akin to the original plant.—Linn. Gen. 288. Schreb. 385. Willd. Sp. Pl. v. 3. 46. Mart. Mill. Diæt. v. 3. 471. Gray. Hort. Kew. v. 3. 375. Sm. Prod. Pl. Græc. Sibth. v. 1. 998. Jaff. 115. Lamarck Illutr. t. 512. Clas and order, Didynamia Gymnofermis. Nat. Ord. Verticillata, Linn. Labiate, Jaff. Gen. Ch. Cal. Perianthus inferior, of one leaf, nearly cylin- drical, with a longitudinal hairy keel at each side, the orifices of which are two-lipped; upper lip broadest, cut half way down into three equal converging segments; lower in two deep narrower segments. Cor. of one petal, ringlet, tube nearly cylin- drical; upper lip flat, ascending, obcute; lower in three, nearly equal, flat lobes. Stam. Filaments four, thread- shaped, approaching each other in pairs, two of them shorter than the rest; anthers of two or divided lobes, under the upper lip of the corolla. Pfi. German superior, four- cleft;
cleft; style thread-shaped, cloven a little way down; filaments two, acute. Pericarp none, except the unaltered calyx.

Seeds four.

Eff. Ch. Calyx nearly cylindrical, two-lipped, marked on each side with a hairy prominent line. Style cloven.

1. *Th. ficata*. Spike-flowered *Thymbra*. Linn. Sp. Pl. 795. Willd. n. t. Ait. n. 1. Sm. Fl. Greece. Sibth. t. 546, unpublished. (Th. spicata verior hispanica; Barbel. Ic. t. 1230. Thymus majus longifolium, &c.; Pluk. Phyt. t. 116. f. 5.)—Flowers spike'd. Leaves lanceolate.—Native of the Levant, on dry hills. Dr. Sibthorp met with the plant in Crete, Aia Minor, and Greece, and conceived it to be the *Hymenoptera officina*, or Mountain *Hylyos*, of Dioscorides, which is extremely probable. The *flem* is shrubby, very bushy, about a foot high, with numerous, upright, sessile, leafy, purplish, quadrangular branches, whose opposite sides are often densely downy, in an alternate manner between the different pairs of leaves, the pubescence recurved. *Leaves* opposite, sessile, crowded, spreading, acute, entire, about an inch long, smooth on each side, besprinkled with refrinous dots, and fringed at the margin with conspicuous white hairs. They are accompanied by axillary tufts of smaller and narrower leaves. *Flowers* of a fine reddish purple, in solitary, terminal, dense, leafy, whorled *spikes*, from two to four inches long. Calyx reddish, abounding in essential oil, smooth and naked, without ribs, except the lateral line at each side, which is fringed, as well as the teeth, with strong white hairs. *Braeaces* lanceolate, fringed, purplish. Tube of the corolla twice the length of the calyx, somewhat downy; lower lip deflexed, in three obtuse equal segments, hairy about the throat. The whole herb has the warm pungent flavour of Thyme, and the aspect of *Hylyos*.

2. *Th. verticillata*. Whorl-flowered *Thymbra*. Linn. Sp. Pl. 796. Willd. n. 2. Ait. n. 2. (Hylypos montanus; Dalch. Hist. 934; not 394, as Willdenow, copying Linneus's typographical error, has it.)—Flowers whorled. Leaves linear-lanceolate.—Native of the south of Europe. The *flem* is shrubby, but more slender than the last, hairy in the same manner, but more universally. *Leaves* much narrower, dotted and fringed in the same manner. *Flowers* axillary, from top to bottom of each branch; those of the principal one fix in each whorl; those of the lateral branches only two. In stature, size and colour they agree with the foregoing, only the *calyx* has some appearance in the dried specimen of being more ribbed. Its lateral keels, as well as the teeth, are strongly fringed. Nevertheless, the general hue and aspect of these two plants are so much alike, that there seems great reason for Linneus's substitution of their being varieties of each other. At the back of the original specimen of this last is the following synonymy. *Tragoriganum ceterium*, majorae ciboria alpestris folio; Propr. Alpin. Exot. 79. So confused is this old author, that one can hardly tell which of his plates his loose descriptions refer to; but our plant certainly agrees better with his *Thymbra*, t. 80, than with his *Tragoriganum*, t. 78, though the above synonymy seems to indicate the latter.

3. *Th. cilicia*. Capitate-flowered *Thymbra*. Desfont. Atlant. v. 2. 10. t. 122. Willd. n. 3.—*Flowers* capitate. Leaves linear. *Braeaces* ovate.—Found by Desfontaines, on dry hills and uncultivated spots, near Mafcar, in Algiers. A small bushy *herba*, from eight to twelve inches high, agreeing much in habit with the two preceding species; but the *leaves* are linear; while the *braeaces* are broader and more ovate, as well as the *spikes* much shorter, than in the *Th. spicata*. The *leaves* are equally fringed in all. Nothing is said, or expressed in the figure, of any hairy lateral lines on the *calyx*, the most important character of *Thymbra*. Having seen no specimen of this species, we cannot judge with certainty respecting its genus, nor whether it might not rather be referred to *Satureja*, see that article; but we cannot satisfactorily assent to the opinion of its learned discoverer, that these genera are not sufficiently distinct. The *calyx* in the natural order to which they belong affords, in many instances, clear, though nice, generic differences. At the same time we admit that Linnaeus is incorrect in making a femia of this, &c., &c. until it be understood a style cloven half way down, one of the essential marks of a *Thymbra*.

*Thymbra*, in *Gardening*, furnishes plants of the under shrubby, exotic kind, among which the species cultivated are the spike'd *Thymbra* (*T. spicata*); and the whorled *Thymbra* ('T. verticillata').

Method of Culture.—These plants may be increased by seeds, slips, and cuttings. The seeds should be sown in the early spring in a warm border, and sheltered from bad weather by glasses; or, which is better, in pots filled with light mould, and placed in a mild hot-bed: when the plants have attained some growth, they should be let out or removed into separate pots.

The slips and cuttings should be planted out in the spring and summer, and when well rooted, removed where they are to grow; they also sometimes succeed by bottom offsets, planted out as above.

They afford variety among other potted greenhouse plants; and require the protection of such houses during the winter season; in this climate, in almost all situations and places.

*THYMBAEUS Mons*, in *Ancient Geography*, a mountain of Aia Minor, in the Troade; from which, according to Pausanias, Apollo was denominated Thymbrian.

*THYMBAEA*, a place of Ionia, four fathoms E.S.E. of Myus. The cavern Charon was near Tymbria, which was thought to be one of the mouths of Hell, because from it issued pestilential vapours.

*THYMIBRUM*, a town of Aia, in Phrygia, at the distance of twelve parasangus from Caylfrudum. At this place was a fountain, called the fountain of Midas, king of Phrygia.

*THYME*, in *Botany*. See *Thymus*.

In the *Materia Medica*, the common garden thyme is a moderately warm pungent aromatic. To water it imparts by infusion its agreeable smell, with a weak tinge and yellowish or brown colour; in distillation, it gives over an essential oil, in the quantity of about an ounce from thirty pounds of the herb in flower, of a gold yellow colour if distilled by a gentle fire, of a deep brownish-red if by a strong one, of a penetrating smell like that of the thyme itself, but less grateful, and in taste exceedingly hot and fiery: the remaining decoction, infusible, leaves a bitterish, roughish, sublimate extract. The active matter, which by water is only partially dissolved, is by rectified spirit distilled completely, though the tincture discovers the essence of thyme than the watery infusion; and the spirit brings over, in distillation, a part of its flavour, leaving an extract of a weak smell, and of a penetrating camphorated pungency. Murray has observed, that this plant seems actually to contain a species of camphor.

The virtues of thyme, according to Bergius, are resolvent, emmenagogue, diuretic, tonic, and ramachic. As agreeing, says Woodville, in common with the natural order of verticillata, its aromatic qualities may be found equally useful in some of thefe complaints for which lavender, sage, rotemary, &c. are usually employed.

The *serpyllum*, or mother of thyme, is an elegant aromatic 4 G 2 plant,
plant, similar to the preceding species, but milder, and in flavour rather more grateful; its essential oil is both in smaller quantity and less acute, and its spirituous extract comes greatly short of the penetrating warmth and pungency of that of the others, so that it is less medicinal than the other species. It is said to afford an agreeable distilled water, more durable, but less active and penetrating than pepperment. (Lewis.) This has been much extolled as a nervous stimulant. An infusion of it has been said to do wonders in turnours, lowness of spirits, and head-aches; and it has been much commended for the cure of the night-mare.

The lemon-thyme, which is a variety of the last, is less pungent than the first sort, but more so than the second, and much more grateful than either. Dililled with water, it yields a larger quantity than the other sorts, of a yellowish very fragrant oil of the lemon-flavour, containing nearly all the medicinal parts of the plant. It gives over also, with rectified spirit, its finer odorous matter. Lewis.

Thyme, Cat. See Tueichum Marum.

Thyme, Maftich. See Thumas Maftichina.

Thymelœa, in Botany, from Juvius, thyme, and Makia, an olive, (the first alluding to the leaf, and the latter to the fcape and oilnests of the fruit,) is an ancient Greek name, found in Dioscorides, book 4, chap. 173. His Juvius, there defcribed, is thought to be the Daphne Gnidium of Linnaeus; and must be at least one of that natural order, and, probably, genus. Hence the name has been applied by many botanists, amongst which were the Baulins and Tournefort, to what Linnaeus called Daphne; see that article. This latter appellation was preferred by him and his school, because a name composed of another, already deflabilis, is contrary to a very found law of the Philosophia Botanica; and in the present infrence the word is compounded of two other generic names, though one of them has been made Latin in Ola. The French however still hanker after Thymelea, as appears by Juffieu's choosing it for the title of one of his Orders. See Thymeleæ.

Thymeleæ, the twenty-fifth of Juffieu's Natural Orders, or the second of his fieth clas, thus named from an ancient fynonym of the genus Daphne, which makes a principal figure herein. (See Daphne and Thymelea.) This order is analogous to the Vpeculæ of Linnaeus. For the detailed characters of Jussieu's sixth clas, see Læuri.

The order of Thymelea is defined as follows.

Calyx of one leaf, tubular, inferior. Corolla none; but in some infinaces there are petal-like scales, originating from the mouth of the calyx, which have the appearance of a polypetalous corolla. Stamens definite, inserted into the calyx, and for the most part double the number of its segments, some being opposite, others alternate therewith. Germen superior, simple; style solitary; stigma mostly univalved. Seed solitary, superior, either naked, or pulpy, or clothed with the calyx. Embryo delinated of albumen; its radicle superior. Stem more or less shrubby. Leaves generally alternate.

We may add to these characters of Jussieu the remarkable silky appearance of the inner bark, when a twig is broken. Mr. Brown, Prodr. Nov. Holl. v. i. 358, observes that the general number of flaments is eight, sometimes four, rarely but two; in the latter cases always opposite to the segments of the calyx, which are occasionally five, sometimes, not always, with ten flaments. The fame writer informs us there is sometimes a flight portion of albumen. The leaves are entire, delinated of stipular. Flowers capitate or plicated, terminal or axillary, sometimes solitary.

The genera, as they stand in Jussieu, are Dirca; Lagette; Lamarek Illusrf. t. 281; Canistræ, Jull. append. 448; Daphne; Passengeria; Stellera; Struthiola; Lachna; Dosia; Gnidia; Metandra of Bergius, included under Gnidia by Linnaeus; and Quisquatia. To these is to be added the great diandrous genus of Pimelea, of which Mr. Brown defines thirty-four New Holland species.

The order under consideration is one of those which has most excited the question of what is a calyx, and what a corolla? and is appealed to equally by those who maintain different theories on this intricate subject. It seems to us that the Thymeleæ combine both these parts in one, the coloured inside of their calyx having exactly the nature of a corolla; which is confirmed by the remark of Jussieu, that the tube of Daphne Mezereum is double, formed of two layers. The appendages, in the form of scales, or glands, found in Gnidia and Struthiola, are more evidently petals, and would doubtless be universally taken for such, did not analogy and theory call a doubt over the subject. At any rate it is safe to say that Daphne has a coloured calyx, as well as most of its allies; just like Polygonum, in the generally coloured order of Holocarne, or Arrylees.

Thymeleæ Radis, in the Materia Medica, the dried root of the thymeæ folis lini of Tournefort and other authors.

It is a light root of different sizes, of a reddish colour without, and greyish within, woody, and full of fibres, and taints sweet at first, but is hot as fire when it has been held a little time in the mouth. It loses however both this fiery taste, and its acrid quality, in long keeping, and with them its virtues.

It is to be chosen now, well fed, and not worm-eaten. The fruit of this plant is the granum cuminum of the shops. They are both of an acrid quality, and are not in use in the shops at present.

Thyme, in Biography, a celebrated female Grecian, who invented theatrical dances. It is supposed that the Greeks called their comediens Thymelici from her name.

Thyme, in the Ancient Theatre, a kind of pulpit, where the fingers, called thymelici, performed.

Thymelici, among the Romans, were musicians, who sung in the interludes, or who danced and kept time with their gestures. The place where they performed was called thyme, whence Juvenal, vi. 66.

"Attendit thymeæ, thymeæ nunc rustica dicat."
that the ancients used salutiferous as well as sweet-scented things in these fumigations. Galbanum has a worfe smell than ammoniacum, and yet this alfo we find, together with the myrrh, and other gums, is made an ingredient in the oldest preceptions of this kind.—And Pliny mentions the ammoniacum with the fexenanth, and other fweets, used for this purpofe.

**THYMIATUM**, in *Ancient Geography*, a country of Africa, in Libya, on the coaft of the Atlantic, according to the Peripius of Hannon.

**THYMIC**, in *Anatomy*, arteries, veins, &c. belonging to the thymus; see that article.

**THYMUS**, a wart or excrescence on the skin.

**THYMIAS**, in *Ancient Geography*, a gulf placed by Pliny on the coaft of the Doride, a province of Afa Minor. Here was a promontory of the fame name.

**THYMOSALME**, in the *Materia Medica of the Ancients*, was a compofition used externally in the gout, and many disorders of the limbs, and was given inwardly in diftemperatures of the flomach, a quarter of a pint for a dose. It operated as a purge, and was prepared in the following manner: take two ounces of broofed thyme, as much falt, a little meal, rue, and pencyroyal.—These were to be put into a pot, and three pints of water and fourteen ounces of vinegar are to be poured upon them; after which they are to be covered with a coafe cloth, and let in the fun for fome time. Diofcorides, lib. v. cap. 24.

**THYMUS**, in *Anatomy*, a glandular body, occupying the upper and anterior part of the cheft, and neighbouring portion of the neck, very large in the fucus, and diminished or nearly difappearing in the adult. The name is Greek, θυμος, which Pollux defines "caro famillis tonfille, prope cordis caput;" p. 258. The gland confines of two lobes, a right and left, which are elongated and conical, being broader below and narrow above: they are joined by cellular fubfance, which can easily be defroyed by dilfection, in their inferior two-thirds, but above they are separated by the intervention of the trachea. The thymus, indeed, may be defcribed as forming two elongated horns above, of which the right is fometimes longer than the left: it also forms two horns below; but they are shorter, thicker, and more obtufe. The principal body of the gland occupies the cavity of the mediastinum, or the interval between the right and left pleure, behind the upper part of the ferum. Here it is covered in front by that bone, on the fides by the pleure, and it refts behind on the front of the pericardium, of the aorta at its origin, and of the left fubclavieian vein. The inferior cornua reach to about the middle of the pericardium; and sometimes nearly to the diaphragm: the inferior run into the neck, on each fide of the trachea, between that tuba and the carotid, and reach the thyroid gland, or nearly fo.

The thymus is large in the fucus; nearly equal to the heart or one of the lungs. In a fucus of fix months, this gland was to the kidney as 4 to 6. It not only does not in-creafe after birth, but it becomes lefs, contains lefs fluid, is harder, and is nearly loft in the surrounding fat. In the mature fucus it weighed 160 and 180 grains; at twenty-eight years, 90 grains. In a calf it was 16 ounces; in a full-grown cow, 9 ounces.

In ftructure it reffembles the conglomerate glands: that is, it is composèd of innumerable small portions, united by cellular fubfance. By maceration there may be separated into smaller and smaller lobules. It is however fooner than the pancreas or salivary glands, and of a darker colour. When cut into, a copious white fluid may be fqueezed out from all parts of its texture. If air be impelled into it, the whole is reduced into a fpongy kind of fubfance.

No excretory duct has been discovered in the thymus; although anatomists have fancied that they had discovered passages from it to the oesophagus, trachea, pericardium, &c.

It has several arteries and veins: the former principally from the thyroid and mammary. The veins join the left fubcla-vian, or the jugular, and the internal mammary.

The nerves, if it has any, are extremely fmall twigs from the phrenic. Its absorbing vessels, which no doubt exift, are not much known.

It is of coniferable fize, even in the adult, in fome ani-mals, as the rat: the fame may be observed of the Arctic bear. It is large in fetaeous animals.

We know nothing of its office, nor why it is fo large in the fucus. There is not even a probable conjecture on the fubject.

**THYMUS**, a wary excrescence, especially about the anus or pudenda.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, per-manent, divided nearly half way down into two lips, the mouth clofed with converging hairs; upper lip broaded, flat, erect, with three teeth; lower of two equal oval-shaped segments. Cor. of one petal, ringent; tube the length of the calyx, with a small throat; upper lip rather the shorter, flat, erect, emarginate, obtufe; lower longer and broader, spreading, in three obtufe lobes, of which the middle one is the broadest. Stam. Filaments four, incurved, two longer than the reft; anthers small, two-lobed. Pfl. Germen superior, deeply four-ecleft; ftyle thread-shaped; stigma divided, acute. Peric. none, the feds being concealed in the calyx, whose orifice is con-tracted and hairy. Seeds four, fmall, roundish.

Effi. Ch. Calyx two-lobbed, its mouth clofed with hair. Upper lip of the corolla flat, emarginate.

The trifling gener of old authors, made out of the pre-ent, though indicated by Linnæus, are not worth confidering. It is more defirable to define the limits of *Thymus* itself, which run very clofe upon thoce of *Melissa*; see that article, at the end of which this fubject is defcified. The number of species in Syn. Veg. ed. 14. are eleven; Will-deow has 22. We fhall find fome things among them to correct, and feveral new species to add. The habit of the whole is more or lefs shrubby, but their habit is humble, with spreading or diffuse branches. Root woody, generally per-ennial. Branches square. Leaves opposite, mostly entire. Flowers either whorled or capitate, purple or lilac; sometimes nearly white; never really blue, flaret or yellow. Whole plant abounding with pungent aromatic efential oil. This genus is about almost entirely European, and inhabits dry hilly situations, in the warmer or more temperate climes.

£ Ser-
THYMUS.

Flowers capitulate. Stems decumbent, creeping. Leaves flat, ovate, obtuse; fringed at the base.—Native of dry heaths and hillocks, as well as alpine pastures, throughout Europe, from Sweden to Greece, flowering all summer long. Its entangled branches form an eafy perennial turf, exhaling a warm aromatic odour when trodden upon, which varies in degree, and, in the well-known variety, affumes the grateful flavour of lemon-peel. The hoary or woolly variety we believe to be no more specifically distinct, notwithstanding Willdenow's remark, of its being unchanged by culture; for he does not mention having raised it from seed. The stems of Th. Serpyllum are wiry and flender, always wavy, never straight; their branches leafy and downy, ascending, each terminating in a little round head of numerous purple flowers, whose palate is variegated with white and crimson. Leaves dotted, strongly fringed at the base, are their footstalks throughout. Stipulae none. Bees frequent the flowers in great numbers. Hairy feelings, caused by an insect, are common on the young shoots. The seeds are rarely perfected.

2. Th. levigatus. Smooth Arabian Thyme. Vahl. Symb. v. 2. 65. Willd. n. 3. (Th. Serpyllum; Forsk. Egypt.-Arab. 107.)—"Flowers capitulate. Stems procumbent. Leaves linear, obtuse, sessile; contracted at the base."—Found by Forskall, on mount Chadra, in Arabia Felix. Stems thrubby, thread-shaped; smooth in the lower part, villous above, grey, with jointed annulated branches. Leaves half as long as the nail, very smooth, without ribs, dotted on both sides; fringed at the base. Head of flowers sessile, terminal, hemispherical, surmounted with numerous larger leaves. Calyx marked with elevated hairy lines; its teeth awl-shaped, fringed. Corolla rather hairy. Vahl.

3. Th. montana. Smooth Mountain Thyme. Waldst. et Kitaib. Hungar. v. 1. 72. t. 71. Willd. n. 13, excluding the rest of the synonyms, which belong to our Th. Serpyllum, var. 7. Ait. n. 7.—Flowers in elongated heads. Stem erect, branched. Leaves ovate, obtuse, flat, smooth and naked, entire.—Native of the Carpathian mountains. We received it from the Cambridge garden, in 1803. The root is perennial, with many long branching fibres. Stem a span high, bushy; the angles downy, with fine recurved hairs. Leaves silky, broadly ovate, slightly revolute; very smooth and even above; deficient of fringe at the base. Inflor 8escence like Th. Serpyllum, but rather more elongated, or spiky, and the flowers smaller, with a much less hairy, though not smooth, calyx, the hairs of whose orifice are scarcely prominent at all, by no means to conspicuous as in the Serpyllum.

4. Th. nummularius. Money-wort Thyme. Marsh. a Bieberit. Taur. v. 2. 58.—Flowers capitulate. Stems decumbent, creeping, hairy. Leaves roundish-ovate, flat, obtuse; somewhat fringed at the base and midrib.—Native of mount Caucasus. We received wild specimens from Dr. Fischer. This has a very different aspect from Th. Serpyllum, on account of its almost orbicular leaves, and the hemispherical leafy heads of flowers. Every part moreover is three or four times the size of that common species. The joints of the stem are remarkably villous in their upper part, especially near the flowers. Sometimes, it is said, the whole plant is densely hairy.

5. Th. Marchalianus. Buxby Taurian Thyme. Willd. n. 8. Marchal. a Bieberit. Taur. v. 2. 59.—Flowers in elongated heads. Stem thrubby; its flowering branches erect. Leaves linear-lanceolate, bluntish, flat, somewhat triple-ribbed; fringed at the base. Frequent in dry grassy hilly places, about mount Caucasus, flowering from May to August. This seems from the description more akin to Th. Serpyllum than to Th. Zygis, for which latter it was taken by Pallas. The stem is procumbent, fending up numerous simple flowering-branches, fix inches high, downy in the upper part. Leaves eight inches long, one and a half broad, on very short stalks. Calyx hairy, fringed. It varies with leaves but half as broad.

6. Th. vulgaris. Common Garden Thyme. Linn. Sp. Pl. 825. Willd. n. 4. Ait. n. 2. Woodv. Med. Bot. t. 109. (Thymum durtius; Ger. Em. 573.)—Stem thrubby, much branched, erect. Leaves ovate, revolute. Whors crowded into leafy spikes.—Found on stony hills in Spain, Portugal, the south of France, Greece, and the Archipelago. Common in gardens, flowering during summer. The stem is bushy, woody and rigid. Leaves a quarter of an inch long, various in breadth, downy, of a greyish hue, numerous, with little axillary tufts of smaller ones. Flowers small, light purple, in hairy heads, or short spikes, with two or three remote whors beneath. Calyx-teeth strongly fringed. This has usually a warm pungent flavour, like Winter Savory; but there is a sweet-scented variety, called Frankincense-Thyme, differing in no other respect from the common sort, which is commonly cultivated in Norfolk, and highly grateful to most people. The thymus: of Dicoresides is not, as Bauhin supposed, this plant, but Satureja capitata.

9. Th. Zygis. White Spanish Thyme. Linn. Sp. Pl. 826. Mant. 413. Willd. n. 7. Ait. n. 3. Sm. Pl. Græc. Sibth. t. 574, unpublished. (Thymum angustifolium longiroque folio; Barrell. Lc. t. 777. Serpyllum sylvestre, Zygis Dioecoris; Clus. Hift. v. 1. 358. S. erectum; Ger. Em. 571.)—Stem thrubby, ascending. Leaves linear-lanceolate, obtuse, revolute; tapering and fringed at the base. Whors crowded into leafy spikes.—Native of Spain and the Levant. Dr. Sibthorp gathered it on hills about Athens and Constantinople. Mr. Malcolm is said in Hort. Kew. to have had the plant in his garden in 1771. Linnæus cultivated it at Uplif. The root is woody and perennial. Stems numerous, from four to six inches long, leafy, round, finely downy,
downy, reddish, slightly branched, spreading on the ground before flowering, then ascending. Leaves three-quarters of an inch long, numerous, crowded, spreading, very minutely and densely downy, copiously dotted; ribbed and rather paler beneath; tapering into a short, broad, downy footstalk, coarsely fringed like the base of the leaf itself. Flowers in leafy heads, often with an axillary whorl below. Calyx clothed with recurved hairs; all its teeth tapering and parallel, strongly fringed. Corolla white, with red dots on the palate. Anthers reddish, prominent. Professor Sibthorp adopted the opinion of the old authors, that this might perhaps be the _Thymus alpinus_ of Dioscorides. Its application in modern Greek is _Thymus_, which, if we mistake not, means "the delight of bees."

10. _Th. Ainos._ Basil Thyme. Linn. Sp. Pl. 826. Willd. n. 10. Fl. Brit. n. 2. Engl. Bot. t. 411. Curt. Lond. f. 1. t. 43. (Acinos; Rivin. Monop. Irr. t. 43. f. 2. Ocyamus fylvestre; Ger. Em. 675.)—Flowers on simple footstalks, about fix in a whorl. Stem herbaceous, ascending, branched. Leaves acute, serrate. _Calyx_ gibbous at the base. Native of dry gravelly or chalky pastures, fallow fields, &c. throughout Europe, nor rare in England, flowering from July to September. The _root_ is annual, of a few slender fibres. _Stems_ clothed with recurved hairs, reddish, lax and spreading, hardly a span long; their flower ultimate branches erect. _Leaves_ on short foot-stalks, small, ovate, varying to roundish or oblong, but always acute, more or less deeply and coarsely serrated, rarely quite entire, veiny, hairy; the upper ones tapering much at the base. _Flowers_ light violet; their palate white, with dark purple spots. _Stamens_ short. _Calyx_ deeply furrowed, hairy, fringed, swelling underneath, as is the calix, more or less, with all the species to which this is allied. The herb is rather slightly aromatic, not pungently so.

11. _Th. fruticosus._ Penny-royal-leaved Thyme. Prodr. Fl. Græc. n. 1400. (Chinopodium minus angustifolium, pulegii odor, romanum; Bocc. Muf. v. 1. 50—54. t. 45. A.)—Flowers whorled. _Leaves_ lanceolate-elliptical, pointed, somewhat serrated, hairy. _Stems_ shrubby.—Native of Italy and Greece. _The flāms_ is a foot high, bushy; the branches leafy, rough, with recurved hairs. _Leaves_ with their flāms about an inch long, rigid, ribbed, bristly, often quite entire. _Flowers_ fix or eight in a whorl, on simple flāms. _Calyx_ like the leaf, but longer and more slender. The whole plant smells powerfully of Penny-royal, even after having been dried thirty years. On this subject _Boccone_ has treated us with a long disquisition, quite in the Italian fyle, in which the facts are better than the philosopgy, though some of them want confirmation. He attributes the above scent to particles of sulphur and bitumen communicated by the soil.

12. _Th. patavina._ Marjoram-leaved Thyme. Jacq. Obs. f. 4. t. 87. Willd. n. 11. Ait. n. 5. (Chinopodium perennium, pulegii odor, majorana folio, patavinum; Bocc. Muf. v. 1. 60. t. 45. B.)—Flowers whorled. Leaves ovate, with copious shallow ferratures, slightly hairy. _Stems_ shrubby.—Native probably of the south of Europe, though no botanist who has described this species seems to have known it but from gardens. Hence even its name originated, which is therefore liable to great exception. _Willdenow_ appears to have seen no specimen. The specific character taken by him from the first edition of Hort. Kew. of "the inflated throat of the corolla, extending beyond the calyx," is not in the leaf degree peculiar. Nevertheless, authentic specimens of the plant prove it distinct from the foregoing and the following, in the broad-ovate, almost heart-shaped, figure of the rather fleshy _leaves_, their even surface, and numerous, minute, shallow ferratures. They much resemble some kinds of _Ocimum_, and like those are sometimes concave.

13. _Th. alpinus._ Alpine Thyme. Linn. Sp. Pl. 826. Willd. n. 12. Ait. n. 6. Jacq. Aufr. t. 97. (Chinopodium montanum; Bawh. Pin. 225. Bocc. Muf. v. 1. t. 45. C. C. australicum; Chuf. Pann. 621, 623. Hilt. v. 1. t. 353. Ger. Em. 676.)—Flowers on simple footstalks, about fix in a whorl. Stem herbaceous, ascending, branched at the bottom. Leaves ovate or roundish, bluntish, coarsely serrate. _Calyx_ gibbous at the base.—Native of the lofty mountains of Austria, Switzerland, Italy, and Crete, as well as of the Eichymian Olympus. Nothing is more difficult than to define the difference between this and our _Th. Ainos_, except that the _alpinus_ is in every part larger and more handsome, with a strong reinous scent. The root is either biennial, or perennial, we are not certain which. The _leaves_ are too entire in the cut of Chelius and Gerarde.

14. _Th. exigius._ Small Cyprian Thyme. Sm. Prodr. Fl. Græc. Sibth. n. 1402. Fl. Græc. t. 575. unpublished. _—Flowers very few in a whorl. Leaves rhomboid, pointed, oblique, nearly entire. Stems branched at the base. Tube of the corolla thread-shaped.—Discovered by Dr. Sibthorp in hilly situations in the isle of Cyprus. The root is annual, simple, fibrous. _Stems_ two or three inches high, erect, with leafy hairy branches from the bottom. _Leaves_ one-third of an inch long, smoothish, on long hairy flāms. _Flowers_ either two or four in each whorl, on thick flāms. _Calyx_ slender, furrowed, hairy. _Corolla_ with a very slender white tube, enclosing the _flāmens_, and short, rounded, pale-purple segments in the limb.

15. _Th. pulegiodes._ Penny-royal-leaved Thyme. Linn. Sp. Pl. ed. 1. 592. Sm. Prodr. Fl. Græc. Sibth. n. 1597. (Cunila thymodes; Linn. Sp. Pl. ed. 2. 31. Willd. Sp. Pl. v. 1. 123. Acinos thymi folio annuo, floribus in/exanips; Morif. f. 11. t. 16. f. 6.)—_Whorlsm_ many-flowered, crowded into long, dense leafy spikes. _Leaves_ ovate, obtuse, entire. _Stems_ herbaceous, branched, with four hairy angles.—Native of the south of France, and of hills in Greece. _Root_ fibrous, marked as annual by _Linnaeus_, but the _leaves_ have a thrubby appearance. They are a span high, with opposite branches, leafy, their angles densely clothed with recurved hairs. _Leaves_ falked, from a quarter to half an inch long, deflexed, dotted, smooth, except a few occasional coarle marginal hairs. _Flowers_ on longish, cylindrical, densely downy flāms, ten or twelve in each whorl. _Calyx_ strongly furrowed, hairy, with a broad upper lip, and two long, narrow, fringed teeth in the lower one; the orifice densely hairy. _Corolla_ small; its limb seems to resembbe the falt-described. Sometimes the _flēms_ is clothed with whorls of _flowers_ almost from the bottom to the top, and the upper _leaves_ are larger than the lower. The odour of the plant is that of Thyme, not of Penny-royal.

16. _Th. graveolens._ Strong-scented Greek Thyme. Sm. Prodr. Fl. Græc. Sibth. n. 1403. Fl. Græc. t. 576. unpublished. _—Whorls_ barely fix-flowered. _Leaves_ ovate, rhomboid, obtuse, revolute, somewhat ferrature. Stems much branched, shrubby.—Gathered on mount Parnassus, by Dr. Sibthorp, who supposite it might be the _Thymus_ of Dioscorides, and from whole manuscripts we have adopted the specific name. The strong, woody, branching _root_ bears a tuft of numerous ascending, branched, leafy, reddish, downy _flēms_, about fix inches high. _Leaves_ dark green, paler beneath, smooth, a quarter of an inch long, on foot-flāms of nearly their own length. _Flowers_ on fimple flāms, with a pair of small oval _bractes_ at the base of each flāk, usally
Native of the Balearic islands. Introduced into our greenhouses in 1770, by Mr. Malcolm. The root is perennial, woody. Stems from four to six inches long, trailing, purplish, slightly branched. Leaves flabellate, agreeing with those of n. 17, in their timid margin, but not half so large, and more pointed. Flowers very small. Calyx ovate, narrowed; its three upper teeth broadest and shortest; lower ones fringed.

21. Th. incanus. Hoary Calaminth Thyme. Sm. Prodr. Fl. Græc. Sibth. n. 1405. Fl. Græc. t. 577, unpublished. (Calaminthar orientalis annua, oocym folio, flore minimo; Tour. Cor. 12, by the character.) —Whorls simply flabellate, of about six flowers. Leaves roundish, entire, clothed with hoary down. Beard of the calyx concealed. Stems procumbent. —Common in the islands of the Archipelago, and about Athens. The root is woody, and but for Tournéfort’s synonym, we should judge it perennial. Stems herbaeaceous, numerous, diffuse, a foot long, with opposite leafy branches, clothed, like every part of the herbage, with fine, soft, grey pubescence. Leaves flabellate, convex, ribbed, rounded and blunt, half an inch in diameter. Flowers scarcely projecting beyond the leaves, on simple hairy flanks. Calyx ovate, tumid, ribbed; with lips of equal length; the upper broad, abrupt, three-toothed; converging hairs of the throat concealed in the tube. Upper lip of the corolla pink, hairy; lower white; palate dotted with red.

22. Th. grandiflorus. Large-flowered Calaminth Thyme. Sims in Curt. Mssg. t. 997. (Th. carolinianus; Michaux Boreal-Amer. v. 2. 9. Calamintha grandiflora; Pursh. 414.) —Whorls simply flabellate, of about ten flowers. Leaves ovate, ferrated, nearly smooth. Beard of the calyx concealed. Stems erect, thorny. —On the banks of the river Savannah, in Georgia and Carolina, flowering in July and August. Pursh. Cultivated by John Walker, elq. at Southgate, about 1804. The root is perennial. Stems bushy, with opposite branches, a foot or more in height. Leaves flabellate, deflexed, above an inch long, green, somewhat downy to the touch only. Flowers large, pale purple, with a vaulted upper lip, and a dotted palate. Upper lip of the calyx very broad.

usually three or four in a whorl, sometimes five or six. Calyx with a shortish furrowed tube, very gibbous at the base beneath; its upper lip broad; lower of two awl-shaped fringed teeth; both tinged with red. Corolla of a purplish crimson, large and handome, downy in the mouth, as well as at the back, which latter is the case with Achinos, alpinus, and all of the same tribe.

17. Th. marginatus. Thick-edged Thyme. Sm. in Dickf. Dr. Pl. n. 71. (Th. Piparella; Allion. Pedem. v. 1. t. 37. f. 3, excluding the synonyms.) —Stalks many-flowered, lateral and terminal. Leaves ovate, nearly smooth, ribbed, entire, with a thick cartilaginous margin. Calyx-teeth nearly equal. Stems shrubby, ascending. —On the rocks of the maritime alps of Piedmont very abundantly. Allioni. Of more humble stature than the last, with many round, slender, downy, purplish, ascending stems, about a finger’s length, branched at the base only. Leaves nearly scifice, inclining to heart-shaped, covered with retinous dots, sometimes slightly downy, remarkable for their thick, smooth, pale margin. Flower-flanks chiefly axillary, about as long as the leaves, somewhat corymbose, downy, bearing several small ovate bracteas, and three or four flowers. Calyx cylindric, furrowed; all its segments awl-shaped, and not very unequal, none of them fringed. Corolla with a slender hairy tube, twice as long as the calyx, and a short rounded limb. The whole plant is warm and pungent, highly aromatic. It is very distinct from the following.

18. Th. Piparella. Pepper Thyme. Linn. Syll. Nat. ed. 12. v. 2. 400. Willd. n. 14, excluding the synonym of Allioni, and possibly those of Vahl and Forrill. (Marum hispanicum nigrum, flore purpureo, Piparella hisp.) —Stalks many-flowered, lateral. Leaves ovate, somewhat heart-shaped, obtuse, entire, smooth, strongly ribbed, copiously dotted. Upper lip of the calyx very broad; lower fringed. —Native of Spain. The root is perennial. Stems apparently trailing, a span long, branched, bluntly quadangular, finely downy. Leaves varying in size, but scarcely more than a quarter of an inch long at the root, thick, flat, without any cartilaginous edges, their ribs numerous, parallel and strong. Flower-flanks short, downy. Flowers in axillary, corymbose, downy, leafy tufts, with ovate bracteas. Upper lip of the calyx remarkably broad, and rather the longest, covered with retinous dots; lower strongly fringed. Corolla a little longer than the calyx, pale, dotted with retinous points. The odour of the plant is most like Th. Serpyllum. Vahl speaks of a border to the leaves, which induces a fupicion that he took out marginatus for Piparella.

THYMUS.

August. The habit of this species is like the last, but
with smaller leaves, more conspicuous longer-stalked flowers,
and less upright stems. Its scent is different, and much
stronger, resembling Penny-royal.

" Hoffm. et Link Luft. v. 1. t. 127. t. 13." (Tragori-
ganum dictauni capite, hispanicum; Barcel. Lc. t. 778.
Docq. Mif. 50. t. 43.)—"Heads of flowers with closely
imbricated, large, coloured bracteas, delittute of dots.
Leaves linear, entire.—Native of Spain and Portugal. A
thubby bushy plant, with purplish flowers, and downy branches.
Leaves fringed at the base. Flowers concealed by the
large purplish bractea, forming an ovate head. Upper lip
of the calyx rather the longest; lower fringed. We have
seen no specimen, either of this or the next.

Symb. v. 3. 78. Willd. n. 18.—"Heads of flowers with
closely imbricated, ovate, liriated, dotted bracteas.
Leaves linear-lanceolate, ferrated, dotted in the margin."—Found
by Cyrillo, in the kingdom of Naples. The flerns are shorter
and more upright than the foregoing; not branched in their
upper part. Leaves broader, erect; liriated at the back.
Heads smaller, with smaller green bractea. Vahl.

128. t. 14." Sm. Pl. Græc. Sibth. t. 578, unpubl.-
Heads of flowers with imbricated, fringed, lanceolate,
ternate, keeled bracteas. Leaves lanceolate, hairy, acute.
Stems trailing.—Native of Portugal, Cyprus, and the
carphelago. The strong woody root tends out numerous,
decumbent, branched, thurby flerns, which compose ample
tufts, taking root as they spread, with short, simple, ascen-
ding flowering branches. Leaves clustered, nearly awl-shaped,
dark green, fringed with coarse white hairs. Bracteas
and calyx tinged with a violet purple; the upper lip of the latter
oval, with three sharp teeth. Corolla rose-coloured, with a
flender hairy tube, twice the length of the calyx. Stamens
prominent.

827. Willd. n. 20. Ait. n. 11. (Marum; Rivin. Monop.
rr. t. 49. Ger. Em. 670.)—Whorls flaked, many-flower-
ced, crowded into round heads. Leaves ovate, obtuse,
entire. Calyx-teeth awl-shoulded, taper-pointed, all fringed,
nearly uniform.—Native of woody ground in Spain and
Greece. Dr. Shibthor gathered it on mount Hymetus,
near Athens, fo famous for honey. This plant has been
treasured up in many a rutile garden, or cottage window,
ever since the days of old Gerarde; but will larcely bear
our winters unprotected, for any length of time. It
flowers throughout the latter part of summer. The figure of
Rinvin is cited by milfack, in the usually accurate Hort.
Kew. for Teucrium Marum. The flern of the present species
is thrabby, twelve or eighteen inches high, erect and bulky,
with many roundish, downy, leafy branches. Leaves nu-
erous, flaked, about the size and shape of Th. Scopulum,
but thicker, finer downy, and not fringed at the base;
mott borazy beneath. Flowers white, small, conspicuous for
the long slender teeth of the calyx, which are pectinated
with abundance of long brillock hairs. The tube is closed
with copious white hairs, nor can we see any foundation
for Linnæus's doubts, whether this plant should be referred
to Thymus or Satureja, except the calyx-teeth being nearly
equal, which is the cafe, more or less, with some of the
foregoing. The odor of Th. Maftichina is pleasantly aro-
matic, not very pungent.

Vol. XXXV.

Widtt. n. 21. Ait. n. 13. Turr. Farct. 11. (Tragori-
ganum magus; Alpin. Exot. 79. t. 78. T. fecunda, altera
species; Chit. Hift. v. 1. 555. T. cretenf; Gen. Em.
608.)—"Stem somewhat thurby, erect. Flowers whorled.
Leaves liripaid, pointed."—Native of hills in Crete; as well
of Cyprus and Beoetia, according to Dr. Sibthorps's manu-
scripts, though his herbarium contains no specimen. Neither
does that of Linnæus, whose specific character we are
obliged to copy. He describes it as a sweet-scented plant,
with hairy flerns, a foot high; leaves rather rigid, pointed
at each end. The root appears to be woody and perennial.
It is curious, numerous, dense, of many flowers.

For Th. virginicus, Willd. n. 22, see PYCNANTHUM,
no. 5. The same author has a Th. inodorus, n. 9, adopted
from Desfont. Atlant. v. 2. 51. t. 129. A specimen ap-
parently anwering to this, gathered by Thunberg at the
Cape of Good Hope, is preferred in the Linnean herbarium,
with a note at the back advertting to the singularity of a
plant of the Didynamia Gymnopsomia having alternate
leaves; and it is named Satureja alternifolia. We do not
find that either Linnæus or Thunberg ever published this
plant; possibly because of the uncertainty of its genus; or
it may be among those which the latter has referred in his
Prodromus zu Sicilia, several of which we have no means of
determining. Whether the plant of Desfontaines be the
name or no, we dare not, without examination, confider it as
a Thymus, though he describes the calyx as closed with
hairs, which is certainly not the case with Thunberg's specimen.

Thymus, in Gardening, contains plants of the low, aromatic,
perennial kind; among which the species cultivated are
the wild thyme (T. pcrpillum); the garden thyme (T.
varigala); the maftick thyme (T. maftichina); and the
Virginian or favory thyme (T. virginicus).

In the first fort there are several varieties; as the broad-
leaved, the narrow-leaved, the variegated-leaved, the silver-
striped-leaved, the cliron-scented or lemon thyme, and the
great purple-flowered.

And in the common fort there are different varieties; as the
broad-leaved, the narrow-leaved, and the variegated or
fringed-leaved thyme.

Method of Culture.—These plants may be easily raised
from seed, by flooding the roots and branches, and by cut-
tings; but the seed method is seldom practised, except with
the second fort, or garden thyme. The feed should be
fown in the early spring on light, rich, dry ground, which
should be properly dug over, and the surface be made mo-
derately smooth with the spade. As the feed is small, it
should not be fown too thick, or be covered too deep: the
feed is best fown while the ground is fresh firmed, either
broad-call on the surface, raking it in lightly, or in flat
shallow drills, earthed over thinly: the plants appear in two
or three weeks. It is necessary to be careful to keep them
well weeded, giving occasional light waterings in dry
weather; and by June they will require thinning, especially
if the plants are to grow focky, and with buffy full heads;
in which case they should be let out to fix or eight inches
distance; when those thinned out may be planted in another
place, in rows fix or eight inches alonder, giving water till
fresh rooted, keeping the whole clean from weeds by occa-
sional hoeing between them in dry days, which will also fit
the surface of the earth, and much improve the growth of
the plants: they will be in perfection for use in flower, or
early in autumn.

Sometimes the market kitchen-gardeners raise large quan-
tities in beds, for daily supply, leaving the whole thick:
Some is and people accordingly and place. Some is and fibres. Some is and place, fame variety. The thyme in the garden is used for cuttings in order to form small, fresh, and fragrant plants, which are planted in beds of good earth, in rows half a foot in diameter, giving water directly, and repeating it occasionally in dry weather till they have taken root, and begin to shoot at top; they soon grow, and form good bushy plants in two or three months.

The strong slips of the branches without roots, succeeded in the early spring season in a shady border, in rows four or five inches distant, giving due waterings; and before the plants were in full leaf, and being now divided into separate parts, are put into small, with roots to each, and planted in the beds of the garden, and by taking up the old plants in the autumn, and cutting or dividing them into separate parts, the plants multiply exceedingly. Some plants, however, become rooted from cuttings as master, as being able to form a better and more uniform quality than those cut in the spring.

When planted in any particular varieties, in the best Lewis certainty, it can only be effected by leaf and cutting. The leaves and slips, all the slips multiply by leaf and slipping, and the latter by the old plants. In order to form slips, the plants are set out of the soil in pots, half a foot apart, by taking up the old plants in the spring, and cutting or dividing them into separate parts, and planting them in the beds of the garden, and by taking up the old plants in the autumn, and cutting or dividing them into separate parts, the plants multiply exceedingly. Some plants, however, become rooted from cuttings as master, as being able to form a better and more uniform quality than those cut in the spring.

The thyme being in universal use as a pot-herb for various culinary purposes, it also is employed in the garden for the same purposes, as also in the kitchen garden, in which it is often potted, or placed in small, with roots to each, in the beds of the garden, and by taking up the old plants in the autumn, and cutting or dividing them into separate parts, the plants multiply exceedingly. Some plants, however, become rooted from cuttings as master, as being able to form a better and more uniform quality than those cut in the spring.

Some plants, however, become rooted from cuttings as master, as being able to form a better and more uniform quality than those cut in the spring.
Allo, a place situate on the coast of the Peloponnesus. According to Herodotus, the inhabitants of Hermione gave it to those of Samos.

**THYREUM**, a small town of Arcadia, S. of Megapolis. It was deferted in the time of Paulaniers.

**THYRIDES**, a town of Laconia, S.E. of Messa. Near this place were the ruins of the town of Hippola, in the midst of which was seen, in the time of Paulaniers, a chapel of Minerva Hippoloparias.—Allo, the name of the summit of Tymnus, in the Peloponnesus; 30 stadia from the promontory Tymnus. Phiny gives the name of Thyrides to three islands of the Gulf of Africa.

**THYROID**, in Anatomy, thyroidus, or more properly thyreoideus, from *thyros*, a shield, and *oidos*, form; a name given to one of the cartilages of the larynx (see LARYNX), to a gland situated near that cartilage (see LARYNX), and to the arteries and veins of the gland. See *Artery* and *Vein*.

**THYROID Gland, Diseased.** See *Bronchocele*.

**THYROID Gland, Extirpation of.** It cannot be doubted that this operation is one of the most difficult and dangerous in the practice of surgery; and it ought never to be undertaken, except under the most urgent circumstances, and by operators of connunicate skill and judgment. Were a surgeon, superficially acquainted with anatomy, and little accustomed to attempts of so bold a kind, to undertake the operation of cutting away a diseased thyroid gland, he would run the utmost risk of seeing the patient bleed to death under his hands.

The following is a memorable instance of the successful performance of this operation. In the year 1784, J. Hyons, twenty years of age, experienced an acute pain at the middle and anterior part of the neck, in consequence of a violent extension of the head. This pain, which was only momentary, was followed by some difficulty of motion. About three months afterwards, a small, hard, indolent tumour appeared on the right side of the trachea. The swelling was unattended with pain, or alteration in the colour of the integuments. The tumour seemed to be raised by a pulsatary action, which tended to prove the existence of a large artery underneath, and, in fact, its base was situated on the general course of the carotid artery. The patient feeling no inconvenience, neglected it until June 1788. At this time it was an inch in diameter. Its progress, which in the first instance was slow, now augmented with proportionable rapidity. Internal remedies and topical applications had no effect in preventing its increase. A fluctuation in its centre was soon evident: an incision was then made into this part, and a quantity of yellow serosity discharged. Three months after this operation, which was not of the least service, recourse was had to cauteries, which were repeatedly applied without any advantage. On the 20th of March 1791, she presented herself for admission at the Hôtel-Dieu. At this period the tumour was two inches in diameter, round, hard, and attached to the right and middle part of the trachea; and it pushed outwards the laryngo-mastoideus muscle. Independently of its being sufficiently raised by each pulsation of the arteries, it obeyed the motions of deglutition, and in a slight degree impended the passage of the food aliment. The patient, ill defined the desire of its convenient disposition, determined to submit to its extirpation, which appeared her only resource. The danger, the length of time, and the pain necessarily annexed to the operation, were not concealed from her. The operation, after a few days previous preparation, was performed in the amphitheatre by Defart in the following manner: the patient being laid on her back, a little inclined on the left side, with the head and neck more raised than the rest of the body, the surgeon made a longitudinal incision through the middle of the tumour, beginning one inch above, and finishing one inch below, to allow room to finish the operation with ease: in the first section he cut down as far as the gland, dividing the integuments, the platyma-myoidei, and some fibres of the laryngo-hyoidei and laryngo-thyroidei muscles: an assistant, with the view of fixing the tumour, drew towards the left the inside edge of the wound made by the incision, whilst the surgeon detached it from the laryngo-mastoideus muscle. In dissecting the cellular substance which united the parts, two small arteries were divided, which were raised by a pair of dissecting forceps and secured by ligatures. The external surface of the tumour being thus diffigaged, the internal part was detached in the same way. The tumour was drawn outwards by a means of a hook, that it might be separated with more ease from the anterior part and from the side of the trachea. In the course of this dissection, the branches of the thyroid arteries were successively tied, as fast as they were divided. The assistant, to whom the hook was confided, directed the gland from within and forwards, whilst the surgeon finished the dissection outwards and from above downwards. This part of the operation was the most minute and difficult; it was necessary by means of a sponge continually to wipe away the blood, which necessarily prevented the parts from being easily distinguished, and obliged the surgeon to divide but a little at a time, and previously to feel with his finger those parts he was about to incise. By this cautious dissection of parts, the superior and inferior thyroid arteries were laid bare, and afterwards secured by ligature by means of a blunt crooked needle. They were afterwards transected, divided, and the remaining part of the tumour detached from the trachea, to which it strongly adhered. The wound resulting from this operation was near three inches in depth; it was outwardly bounded by the laryngo-mastoideus muscle, and inwardly by the trachea and oesophagus; posteriorly by the carotid artery, and by the nerves of the eighth pair, which were exposed at the bottom of the wound. After the wound was well washed with warm water, and cleared from the blood, it was filled with coarse lint, powdered with colophony; square comproffes, secured by a bandage moderately tight, formed the rest of the dressing. The extirpated tumour was five inches in circumference; and on examination was found to differ in no particular from fibrous glands, except that in the centre there was a cartilaginous nucius. The patient supported this long, difficult, and painful operation with uncommon firmness: the puffed the rest of the day without experiencing any other symptom than a slight swelling, generally consequent to large wounds. The following night she complained of a sense of heat in the neck, and some difficulty in deglutition. The next day a little cold was obtained by moistening the dressing with a decoction of marshmallows. A weak drink of the herb dog’s-tooth, acidulated with oxymel, was preferred. On the third day the fever was very moderate, but the difficulty in swallowing had considerably increased at this period; the comproffes and the external lint were removed, and fresh applied. On the fourth, the fever ceased, and deglutition became less painful. Suppression now became established. The next day all the lint was detached, and the whole of the dressings renewed. The wound was in a good state; it was dressed with warm lint and comproffes moistened with an emollient decoction; a practice which was continued for the following days. No particular circumstance occurred during the cure. The wound followed the ordinary pro-
grew, and was cicatrized at the end of a mouth. The patient left the hospital, perfectly cured, the 34th day after the operation. See Defaut’s Parisian Chirurgical Journal, vol. ii. p. 292—296.

To the preceding case, the editor of the above work has annexed the few following reflections.

The extirpation of the thyroid gland is an operation extremely difficult, and certainly highly dangerous, when performed by an operator but moderately exercised in the practice of his profession. The number and size of the arteries necessary to divide, the proximity of the trachea, celiacus, and carotid, near which the knife must necessarily pass, are the principal dangers that the operator should avoid. These are the circumstances which have deterred the majority of practitioners from performing it, particularly those who from long established prejudice have been deterred from using ligatures in cases of wounded arteries. Examples of this operation are very rare. The first time that Gooch undertook to perform it, he was deterred from finishing it by the hemorrhage, and his patient died on the eighth day. The second time he succeeded better, but was incapable of curing the veins, and succeeded in flopping the hemorrhage, which would otherwise have been mortal, by cutting the parts to be compressed by the hand of an assistant for the space of eight days. Gooch’s Med. and Chir. Obf. p. 130.

A. F. Vogel and Theden have practised the same operation with the most complete success. All danger from the hemorrhage, or inconvenience arising from the discharge of blood, may be obviated by pinching up the small veins, tying them as fast as they are divided, and by discovering and tying the large vessels previous to their division; other parts that cannot be wounded without danger, are to be avoided by dissection slowly and a little at a time, and feeling with the finger every part previous to its division with the hilory.

THYRO-ARYTENOIDEUS, a muscle of the larynx. See LARYNX.

THYRO-EPICLOTTICUS, a tappused muscle of the larynx. See LARYNX.

THYRO-HYOIDUS, a muscle passing between the os hyoideus and the thyroid cartilage. See LARYNX.

THYRO-PARYNGEUS, a portion of the inferior constrictor of the pharynx. See Description.

THYROIDEÆ Glândule Majuscula. See the description of the thyroid gland in the article LARYNX.

THYRÆUM VITISUM, a fort of wine among the ancients, remarkable for its thickness and dark colour; it was sweet and delicious, and not astringent.

THYRÆUS LAPIS, in Natural History, the name of a fossil, which the writers of the middle ages have called syrah.

It has many virtues ascribed to it; but all the accounts we have of its real properties are from Pliny, who observes, that it swam upon the water while whole; but when broken into small pieces, these sunk to the bottom. It seems to have been a fort of bitumen of a spongy structure.

THYSUS, Oregis, in Antiquity, the sceptre which the ancient poets put in the hands of Bacchus, and with which they furnished the Muses in their Bacchanalia.

The thyrus was originally a lance or spear, wrapped up in vine leaves; with which Bacchus is said to have armed himself and his soldiers in his Indian wars, to amuse and deceive the unpractised Indians, and make them suspect no boflullies.

Hence it was afterwards borne in the feast and sacrifices of that god; and as the Satyrs, who were Bacchus’s followers, were supposed to have fought with it, it became a custom to represent them therewith.

THYSUS, Orlyagnn, in Ancient Geography, a river of the isle of Sardinia, which ran from N. to S. and discharged itself towards the W. into the sea.

THYSUS, in Botany, a Bunch, is a mode of inflorescence, nearly allied to a Racemus, or Clatter, except being compound, in which it agrees with a Panicle. Its form is more or less ovate, and the disposition of the branches and subdivisions is either opposite or alternate; the ultimate one sometimes obscurely umbellate. Examples are found in the Lilac, Syringa vulgaris, and a bunch of Grapes, Ægis vinifera; as well as in the herbaceous plants Tussilago hybrida and Potentilla. Hence it appears that a Thyrus is nothing more than a dense or close Panicle; and in the examples last cited, this mode of inflorescence actually becomes a loose panicle, as the plant perfects its seed. See PANCULA and INFLORESCENCE.

THYSANTHUS, Ægis, fringed, a very descriptive name of Mr. Brown’s, which he applies to his plant, Mr. Salisbury for having knowingly suppressed.—Brown Prodr. Nov. Holl. v. 1. 282. (Chlamysporum; Salis. Parad. 103.)—Clafs and order, Hexandria Monogyne. Nat. Ord. Coronaria, Linn. Aphiobole, Jull.

Gen. Ch. Cal. nom. Gen. inferior, of one petal, in petioles spreading, permanent segments; the three inner ones broadest, fringed at the edges with jointed hairs; the three outermost externally of the texture of a calyx. Stom Filaments six, awl-shaped, smooth, much shorter than the calyx, inserted into its base; anthers linear, incumbent, attached by the funis at their base, a little unequal at the end, the three outer ones generally elongated and reclining. Pet. Germen superior, roundish; style thread-shaped, dehiscing, about the length of the stamens; stigma simple. Peric. Capsule oval, of three cells and three valves, with a partition from the centre of each, enveloped in the withered corolla. Seeds two in each cell, one erect, the other pendulous, roundish, somewhat flattened, inserted into a cup-shaped white appendage; albumen dense, fleshy.

Obs. A few species have only three stamens.

A rather numerous genus of perennial herbaceous plants, natives of different parts of New Holland. The root is either fibrous, or confis of clotted fleshy bulbs. Stem generally branched and leafy. Leaves lance, narrow, often channelled, sometimes thread-shaped, or shortened. Flowers terminal, umbellate; rarely scattered; their stalks jointed in the middle. Corolla blue within; three, at leaf, of its segments green at the back. Anthers purple; the outer ones sometimes whitish, which in the triandrous species are wanting. Seeds black. The permanent corolla, and smooth filaments, principally distinguish this genus from Mr. Brown’s Arthrophorum, Prodr. Nov. Holl. v. 1. 276, by which it is related to the Linnean Anthericum. The learned author whom we follow defines twenty-one species, of which he seems doubtful whether any one has ever been introduced into the English gardens, at least so as to bear flowers; for he thinks the figure in Parad. Lond. was done from
from a dried specimen. On this subject we have no particular information. Several drawings of this genus and its allies, made in New Holland, have passed under our inspection, and display a degree of elegance which renders the plants highly desirable.

Of the twenty-one species, seventeen are hexandrous, four triandrous.

Sec. 1. Stamen six.

Th. tuberosus. Tuberous Fringe-blossom. Br. n. 1.—

"Bulbs falcately, filiform, marked. Radical leaves channelled, lax, smooth, rather shorter than the round, smooth, parallel-fined. Umbels of two or three flowers. Anthers unequal."—Gathered by Mr. Brown, near Port Jackson, New South Wales.

Th. junceus. Rush-leaved Fringe-blossom. Br. n. 9. (Chlamydomphora junceolafum ; Salif. Parad. t. 103.) — "Root fibrous. Stems branched, diffuse, round, fringed; branches slightly anguilar. Radical leaves short; those of the stem straight, slightly spreading. Umbels of few flowers. Anthers unequal."—Native likewise of Port Jackson, from whence we have received specimens by favour of Dr. White. The "flora are about a foot long, diffuse, according to Mr. Brown, smooth, slender, rusby, alternately branched. Flowers about an inch in diameter, their inner segments obulate, delicately fringed. They are said to be very transient.

Th. dichotomus. Forked Fringe-blossom. Br. n. 14. (Ornithogalum dichotomum; Labillard. Nov. Holl. v. 1. 83. t. 109.) — Root fibrous. Radical leaves frilled. Stem round, frilled, with numerous rather spreading branches; forked above. Flowers solitary. Anthers unequal. — Gathered in Lewin's land by M. Labillardiére, from whom we have a specimen. The "flora is 15 or 18 inches high, repeatedly divided from the bottom, so as to afford corystome at the top, roughish to the touch, slightly leafy. Radical leaves numerous, about four inches long, erect, linear, obtuse, entire, channelled, rough with short, rigid, pale, prominent hairs; sheathing at the base; those of the stem solitary under each branch, short, axiled, frilled, clasping the stem with a dilated, membranous margin in the lower part. Flowers terminal, two or three to each branch, but it appears to us that the individual ones are solitary. Three inner segments purple on the inside, with a fringe of the same colour; their outside, like the whole of the outer ones, green. Anthers but lightly, if at all, unequal. Valves of the calyx beaked.

Sec. 2. Stamen three.

Th. triantrtr. Triandrous Fringe-blossom. Br. n. 18. (Ornithogalum triandrum; Labillard. Nov. Holl. v. 1. 84. t. 110.) — Root fibrous. Leaves linear, fringed, the length of the smooth unbranched common flower-flalk. Umbel many-flowered. Lower joint of each partial stalk several times longer than the bracteas. — Gathered by Labillardiére, in Lewin's land. Stalks one or more, compressed, a span high, as well as the numerous, all radical, leaves. Umbel of about nine flowers; its stalks joined below the middle. Stamin but three, opposite to the three fringed segments of the corolla, which are purple on the inside.

Gen. Ch. Cal. Perianth inferior, of five coloured, permanent, lanceolate, concave, hairy, spreading leaves. Cor. bell-shaped, of five spreading oblong petals, the size of the calyx. Stam. Filaments ten, short, reflexed; anthers roundish, crested, of two cells. Pjfl. Germen superior, quadrangular; styles four, thread-shaped, inserted laterally into the four angles of the germ; stigmas slightly elongated. Par. Drupas four, oblong, gibbous, recurved at the point, with a woolly coat, curling laterally. Stems. Nuts solitary, oblong-ovate, smooth, naked at the top, enveloped in their lower part with a hairy, fringed, red tunic.

1. Th. Palala. Deeli Khé of the Cochinchine. —

Native of the woods of Cochinchina. A large, woody, nearly erect, branching furub, without thorns. Leaves pinnate, of about ten pairs of oblong, entire, smooth leaflets. Stalks axillary, many-flowered. Celaxes red. Corella white. Wing, or tunic, of the nuts red.

Such is the description of Loureiro, who quotes, with a mark of doubt, Palala ferruca; Rumph. Amboin. v. 2. 26. t. 6. But that is Myriffica, and has simple leaves. Yet hence the specific name appears to be taken. He more justly indicates the affinity of his plant to Sinuoba; Abl. Guan. 400. t. 153, of which we propose to treat hereafter in its proper place, under Schreber's name of Zwingerä.

We presume Loureiro's Thyfanus to be very nearly related to Cnestis of Jullien and Willdenow; see that article. The number of genera may be very variable or uncertain. What the author terms a drupa, appears, from its burking laterally, to be a true follicle, as is the feed-veil of Gewnfl. Whether the seed of the latter has any thing analogous to the fringed tunic, does not appear.

THYSDRUS, in Ancient Geography, a town of Africa Propria, and one of those which, according to Ptolemy, lay to the S. of Adrumetum.

THYSIUS, (THYS), ANTONY, in Biography, a philologyst, was born at Leyden in 1603, and became professor of eloquence and poetry in the university of his native city, and public librarian. Besides two or three works of his own, he was the editor of several editions of classics called "Variorum," of which were "Valerius Paternus," "Sallust," "Valerius Maximus," "Seneca the Tragedian," "Lactantius," and "Aulus Gellius." He died in 1670.

THYSSETAE, in Ancient Geography, a people who inhabited the territory near the Sarmate, where was the source of the river Tanaes. Ammianus Marcellinus says that these people had their abode in large forests, and lived by the chase. Their wives and children they had, he says, in common. Herodotus says they were a numerous nation, and governed by their own laws. Hardouin, in his notes on Pliny, says that they inhabited the banks of the Tanaes, towards that bend of the river, where it most nearly approaches the Wolga, and which is now the territory of Astrauchan.

THYSSELINUM, in Botany, a name adopted by Lobel in his Icones, 711, for the Selinum sylvestre of Linnaeus. Lobel cites Pliny, but the name in that author is Thyselium. The plant to which it belonged was "not unlike parsley, Apium; its roots when chewed purged humours from the head." Rivinus, Pentap. 1. t. 19 and 20, has the Linnaean Selinum sylvestre and palustre under the generic name of Thysselium, as has Tournefort likewise, in his Institutiones, 319. The latter differing from his genus from Orofelinum solely by its milky juice. As this juice is highly acid, these authors should seem to consider the word as derived from to, to burn, and sylven, parsley. Linnaeus omitted the first syllable as, in his opinion, superfluous.
TI A

TI A

flums, and even Haller follows his example. See Sr-

LAMIN.

THYSSUS, in Ancient Geography, a town of Macedonia, on about Mount Athos. Pliny and Thucydides.

THYSTUM, or THYSTUM, a town of Eotia. Suidas.

TIABA, a town of Asea Minor, in Caria. Strabo.

TIAVAR, a town in the interior of Arabia Felix, between Leptis and Appa. Ptolemy.

TIAVAR, in Geography, a town of Hindoostan, in the Carnatic; 6 miles W.S.W. of Pondicherry. N. lat. 11° 42'. E. long. 79° 12'.

TIGNANUCO, a town, in Peru, in the diocese of La Paz. This is a town of great antiquity, and is said to have received its name from one of the Incas. In it are some ruins, and a colossal pyramid, with a variety of human figures cut out of stone, which, though decayed by time, appear to have belonged to some gigantic nation; 36 miles N.W. of La Paz.

TIGURUS, in Ancient Geography, a town of India, on this side of the Ganges, and E. of the river Nomonias. Ptolemy.

TIGN-POTAO, in Geography, an island of Corea, about thirty miles in circumference, in the Hong-hai. N. lat. 3° 25'. E. long. 124° 52'.

TIANO. See Theano.

TIANO, a small island in the North sea, near the coast of Lapland. N. lat. 6° 42'.

TIANGNIES, a town of France, in the department of Jemappes; 6 miles S.W. of Tournay.

TIANTONG, a town of Upper Slam, on the Mecon; 20 miles N.W. of Perpignan.

TIAYOU-SU, a small island in the Chinefe sea, belonging to the tribe called Lienou-kieou. N. lat. 25° 55'. E. long. 128° 35'.

TIA, 1749, an ornament, or habit, with which the ancient Persians covered their heads; and which the Armenians and kings of Pontus wear on medals: thefe last, however, have been deftined from the Persians.

Latin authors call it in-differently tiara and bidari.

Strabo says, the tiara was in form of a tower, and the feholium on Ariflophanes's comedy, Aspasia, act i. scene 2, affirms that it was adorned with peacock's feathers. Some moderns, however, fancy the feholium is here speaking of the caque which the ancient Persians wore in war, rather than of the habit which they wore on the head in the city.

The kings of Peria alone had the right of wearing the tiara ftraight and erect; the prifles and great lords wore it defpered, or turned down on the fore-fide. Xenophon, in his Cyropedia, fays that the tiara was sometimes encompassed with the diadem, at head in ceremonies; and had frequently the figure of a half-moon embroidered on it: others are of opinion, that the diadem was in form of a moon, and that it was hence the tiara was called luna. Lally, others think that the tiara itself was made fometimes in form of a half-moon. From what we have said, it appears that there were different forms of tiaras; and, in effect, Pachau- lius, De Coreollis, distinguishes no less than five different kinds. See Diadem.

The tiara was also an ornament belonging to the Jewish priefles. Exodus xxviii. 40. xxxix. 26.

TIAR is also the name of the pope's triple crown; ancienfly called regnum.

The tiara and keys are the badges of the papal dignity; the tiara of his civil rank, and the keys of his jurisdiction: for as soon as the pope is dead, his arms are represented with the tiara alone, without the keys.

The ancient tiara of the popes was a round high cap.
Am. Acad. v. 2. 351. — Leaves ternate, lobed and toothed. Stem leafy. Clutter compound. — Gathered by Mr. Menzies on the north-west coast of America, where it is frequent in woods. Linnaeus saw it only in the collection of plants from Kamtschatka, submitted to his inspection by Demidoff, and described in the 2d volume of the *Annates Academiae*; for there is no specimen in his own herbarium. The root is tuberous, and somewhat creeping, perennial. *Stm. above a foot high, erect, simple, leafy, smooth and slender. Leaves all ternate, slightly hairy, paler beneath; the leaflets somewhat rhomboid, acute, more or less deeply lobed, and irregularly notched, an inch or an inch and half in length; the lateral ones often deeply divided; so that they much resemble some of the more delicate species of *Rubus*. The radical leaves have long slender *footstalks*; those on the stem short ones. Clutter many-flowered, from three to six inches long, alternately branched; the branches corymbose, each bearing from three to five or six very small greenish-white flowers. The ball of the *calyx* is concave, or slightly bell-shaped. *Calyx* half an inch long, each valve tipped with a permanent, elongated, capillary *style*.

4. *T. biterna*. Compound-leaved Tarilella. Venetia. Malmaison t. 54. Pursh n. 4. — Leaves twice ternate, lobed and toothed. Stem leafy. Panicle compound, divaricated; its branches somewhat spicaded. — Found on the mountains of South Carolina, flowering in May. *Stem* perennial. *Stem* a yard high. The appearance of the plant is jutly comprised by Ventenat to *Spinea Aruncus*. The leaves consist of nine large ovate *leaflets*, slightly hairy, partly lobed, and all strongly toothed, or notched. *Flowers* very small, yellowish-white, almost fleshy, disjuxtaposed in numerous long *clusters*, forming a large, spreading, repeatedly branched *panicle*. The petals in Ventenat's figure are narrow, elliptical-lanceolate. Pursh says they are sometimes wanting. The appearance of the *calyx* in that figure is very different from the other species, and the valves are of equal length. This plant is said to have proved biennial in the garden of Malmaison; but it may still be perennial in its native country. We have seen no specimen, nor has this curious species, any more than the last, yet found its way into the English gardens.

**TIARINI, ALESSANDRO.** In *Biography*, an historical painter, who was born at Bologna in 1577. He was a disciple of Prospero Fontana, and on the death of that master, he received instructions from Bartolomio Celi, from whom, being obliged to leave Bologna on account of a quarrel, he went to study under Passignano at Florence. After some time, about seven years, as the influence of the circumstance which had driven him from his native city subsided, he ventured to return there, and became a pupil of the Caracci; and he principally attached himself to Ludovico, more for the improvement of his style, than for practice. He had, during his residence at Florence, acquired considerable fame, and painted several pictures for churches and convents in places within and round about that city. On his return to Bologna, his talents acquired him considerable employment there, and many of his principal works still adorn its public edifices. Ferdinand, duke of Mantua, invited him to take up his residence with him; but to him for his portrait, is did all the princes of his family, and many of the nobles of his court.

The colouring adopted by Tiarini in his best time is clear and rich; his design tasteful and agreeable, though of a serious cast; and his expression just and natural; and there are not many artists who have done more credit to the Bolognese school. He died in 1668, at the advanced age of 91.

**TIARIULIA, in Ancient Geography.** a town of Ilif-pania Citerior, in the interior of the country of the Herculis. Ptol.

**TIARP, in Geography.** a town of Sweden, in Welfmankland; 25 miles N. of Upfal.

**TIASSE, in Ancient Geography.** a river of the Peloponnese, in Lacoonia, which ran between Sparta and Amycla. Paus.

**TIASUM, a town of Dacia, in the vicinity of Nantida and Zugna.** Ptol.

**TIASP, a town of India, on this side of the Ganges, W. of this river and near it.** Ptol.

**TIAS, in Geography.** a town of Perfi, in Chufsitan; 135 miles N.W. of Shuter.

**TIBAENS, a town of Portugal, in the province of Entre Duero et Miluo; 4 miles W. of Braga.**

**TIBALDI, PELLEGRINO, in Biography, was born at Bologna in 1527. He was the pupil of Bagnacavallo, and copied with much attention the works of Valari, in the refactory of S. Michele in Bofco. At the age of twenty he went to Rome, chiefly to study the works of Michael Angelo. The pictures he produced at Rome obtained for him the patronage of the cardinal Paggi, who employed him in ornamenting his Vigna, near the Porto del Popolo, with works in fresco, and then sent him back to Bologna, to assist in the completion of his palace there (now the Academic Institute), both as architect and painter; and in both characters it remains as the principal testimonial of his powers remaining in Italy. He also constructed and adorned a chapel for his patron in the church of S. Ciocapo Maggiore. One of the paintings he executed there was the *Presentation of St. John*, and another, the *Last Judgment*; where, in the opinion of the Caracci, he almost equalled the majesty of Michael Angelo, and it was preferred by them to all the other works of Pellegrino, and served them and their scholars as a model of study.

From Bologna, the cardinal sent him to Loretto, to superintend the erection of a chapel in the church of La Madonna, which he also ornamented with frescoes and paintings of the Nativity, the Presentation in the Temple, the Transfiguration, and the Decollation of St. John. From thence he went to Ancona, where he was made a deputy of S. Agostino and Criaco; and in the great hall of the merchants he painted one of his most celebrated pictures, the subject of which is Hercules overthrowing monsters. He also superintended, as military architect, the fortifications of the place, about the year 1560; and two years afterwards visited Pavia, where he constructed the palace of the Saporza; he then went to Milan, and there built the temple of S. Fidele, and before the year 1570 was elected architect of the cathedral.

Here he ditionembered the dome of numerous Gothic monuments, sepulchral urns and trophies, and embellished it in their stead with various chapels and a majestic choir. He soon after received a commission from Philip II. to prepare designs and plans for adorning the Escorial, both architectural and pictorial. He followed them to Spain himself in 1586. There he superintended the work for nine years, painting a great number of pictures, particularly some in fresco in the lower cloister, whence he expunged the unsuccessful productions of F. Zuccherio. The subjects were from scripture, of the Purification; the Flight into Egypt; the Murder of the Innocents; Christ tempted in the Wilderness; The Election of the Apostles; The Resurrection of Lazarus; The Expulsion of the Money Changers from the Temple; and the Resurrection of our Saviour. Besides these, he painted during his residence in Spain several pictures

Hebrew this contains they is r the all fondamento."

The compositions of the chapel Poggi, in St. Giacomo, where the imitation of Michael Angelo is blended with that of Raphael, Coregio, and D. da Volterra, contain the rudiments of their own stylen.

Pellegrino Tibaldi is more known by his works in fresco than by his pictures in oil, which are extremely scarce: one of the earliest is the Nativity, already mentioned, in the Palace Borghese, of which the cartoon still exists in a private collection of drawings. It is painted in a sober unaffected tone, and considered as the work of an artist jealous of his line, with great mellowness of touch. The figures of this are considerably less than the size of life; but there are pictures of his to be met with of diminutive dimensions, with all the finish of miniatures, though rich in figures, touched with great spirit and equal vivacity of colour; they are generally set off by backgrounds drawn from his favourite branch of art, architecture. Fujioli's Pilkington.

TIBARANIA, or TIBERARIA, in Ancient Geography, a country of Asia, in Pontus, in the vicinity of Cappadocia, and adjoining the country of the Chalybes. Steph. Byz.

TIBERIA, a town of Thrace, founded by the emperor Tiberius, whence its name.

TIBERIACUM, a town of Italy, near Ravenna.—Aifo, a town of Lower Germany, upon the route from Colonia Trajana to Colonia Agrrippina, between this latter place and Juliacum, according to the itinerary of Antonine.

TIBERIADIS Water, the water of a hot spring near Tiberiades in Egypt.

Dr. Perry, when on the spot, tried some experiments on this water, which give us a much better idea of its nature than we have from any other accounts of it. Half a dram of oil of tartar being mixed with an ounce and half of the water, it becomes turbid and muddy; and after twelve hours, three parts of the whole appear like white wool, only leaving a small portion of clear water at the top. The white woolly matter dried, produced only a small quantity of yellow ochre.

Spirit of vitriol added to the water in the same quantity, affords a large unifrous sediment of a white colour. A solution of sublimate being mixed in the same quantity, it became turbid and yellowish, and yielded an earthy sediment in small quantity; whence it seems evident, that it contains a salt murale. Saccharum faturini being added in the same quantity, the water deposited a lateritious sediment in a small quantity. Mixt with spirit of fal ammoniac, it turns to a blueish-green turbid liquor, and finally yields a woolly sediment. Sugar of violets mixed with it, turned it to a yellow colour; and the scrapings of gall mixed with it, turned it to a deep purple; and on shaking, this became as black as ink.

It appears from these experiments, that the water contains a good deal of a grofs fixed vitriolic salt, some alum, and a salt murale. It is too salt and nauseous for internal use; but it must be of use as a bath in all cutaneous froulness, especially in scorbutic and leprous cases; for it will powerfully deterge, scour, and cleanse the excrettory pores, and it may be, by its weight and stimuli, restore them to their natural state and tone, and restore the true state of the vitiated solids in general. Phil. Trans. N° 462, p. 52.

TIBERIANI CAMPi, in Ancient Geography, fields of Italy, in the vicinity of Rome, which took their name from the emperor Tiberius, who fixed them at 25 acres.

TIBERIAS, a town of Pale-fine, the capital of Galilee, was situated in a plain, near the lake of Genesareth, which from this city was also called the lake or sea of Tiberias. This city is very famous, and often mentioned by Jewish writers, because, after the taking of Jerusalem, there was at Tiberias a succession of Hebrew judges and doctors till the fourth century. It was a bishop's see in this century. Epiphanius says that a Hebrew translation of St. John, and the Acts of the Apostles, was kept in this city. It was distant about 90 miles from Jerusalem. See TABARIA.

TIBERINA INSULA, the ile of Tiber, situated in the city of Rome; called by Suetonius the ile of &esclapius. Plutarch says that this island was called at Rome the sacred ile and the ile of two bridges, because in consecrating to Mars a field which belonged to the Tarquins, they threw into the
the river the corn and also the trees which grew in this field. These materials, united with the mud brought down by the river, formed an island, on which were built several temples and porticoes.

Tiberina Regia, a country of Asia, in Cappadocia, where was a place named Ariarzus.

TIBERIOPOLIS, a town of Asia, in Phrygia Major. Ptol.—Ala, a town of Bulgaria, upon the coast of the Euxine sea.

TIBERIS, or Tiber, a river of Italy, which had its source in the Apennines, towards a place called Tifernum Tiberinum. Its course was first towards the S. passing by Perusa, as far as Tuder, where it turned towards the S.W. as far as the Volturno. Having received the Claneis, it turned towards the S.E., received the Nar at Hortamont, and continued in this direction as far as a point that lies between Capena and Cures. Assuming a direction towards the S., it falied to Rome, and then proceeded towards the S.W. to the sea before Olia, i.e. the mouths, of which it has many. This river was inconsiderable till it reached Hortamont; but afterwards it was augmented by the Nar, the Volturno, and the Anio, so that at Rome it was large and deep. The ancients, by way of enhancing its celebrity, represented it as receiving twenty other rivers; but under this general denomination they must comprehend several small streams. It was called by various names.

TIBERIUS CLAUDIUS NERO, in Biography, a Roman emperor, so called after his father, his mother's name being Livia Drusilla, was born in the year B.C. 42. He was at an early age so well instructed in Greek and Roman literature, as to be able, when nine years old, to pronounce a funeral oration for his father, which gained great applause. His temper was naturally refined and gloomy, and yet, with the advice of his mother Livia, who was married to Augustus, he conducted the usual spectacles with a magnificence which gave satisfaction to the Roman people. His first appearance in a military character was as a tribune in the Cantabrian war; he next fulfilled the office of commander-in-chief in placing Tigranes on the Armenian throne, and on his return was made praetor. He was afterwards sent to join his brother Drusus, and gained a decisive victory over the Rhetsians and Vindelicians. He became consul in the twenty-eighth year of his age, and thus rapidly advanced to the rank which, as the emperor's step-son, he was likely to obtain, and his elevation was accelerated by the death of Agrippa, B.C. 22. Previously to his being admitted into a partnership of the empire, Augustus obliged him to divorce his wife Vitania, the daughter of Agrippa, and the object of his choice and affection, and to marry his own daughter Julia, of doubtful reputation.

The next object of his military career was the reduction of the Pannonians, in consequence of which he was honoured with triumphal ornaments. From his successful prosecution of the war in this part of the empire he was suddenly called to attend his brother Drusus in his last moments; and he afterwards accompanied his remains on foot in a funeral procession to Italy. After his victories had been celebrated by an ovation, he was deputed to make peace in Germany, and being a second time made consul, B.C. 7, he triumphed on the day when he took possession of his dignity. At the expiration of the year, Augustus conferred upon him the tribunitian power for five years. At this time Caius, one of the emperor's adoptive sons, though under age, was raised to the pontificate, and introduced into the senate. Jealous of Caius as a rival, and disgusted by the open gallantries of his wife Julia, he resolved to ask permission to withdraw from public business, and to live in retirement at the island of Rhodes. Accordingly he failed for Rhodes. His wife's conduct became so notorious, that he was banished by her father to the isle of Pandataria, and divorced from her husband. Having obtained leave of the emperor, though reluctantly granted, to return from Rhodes to Rome, he lived privately till the death of the two Caesars, Caius and Lucius, opened to him new prospects. The emperor, whose declining age needed an associate, adopted Tiberius A.D. 4, renewing his tribunitian power, and then placing him next to himself in the empire. Having brought the war against the Pannonians and Dalmatians, as much by policy as by force, to an honourable termination, he obtained a triumph, A.D. 9; and as a recompense of other services, his tribunitian authority was prolonged: but the emperor terminating his life at Nola, Tiberius, without opposition, succeeded to the empire, in the fifty-fifth year of his age. Past experience had taught him the art of dissimulation, and this art he practiced during the progress of his reign. Although he was very jealous of his authority, he was moderate in the exercise of it, and always paid great deference to the senate, and respect to the consuls. He was zealous in the administration of justice, and avoided oppressive imposts even in the most distant provinces, for which he had the less occasion, as he was not avaricious of money; a virtue which, as Tacitus says, he retained, when he had renounced all others. To which we may add, that he was munificent in his relief of public calamity and private distress. These qualities, combined with his found fene, rendered the earlier part of his reign as prosperous as perhaps any in the annals of the empire.

The popularity of Germanicus rendered Tiberius jealous, and vigilant of his conduct; and in order to restrain his authority, he employed Piso, a man of ancient family and imperious spirit, as his subordinate agent for this purpose. Germanicus, however, died of a lingering disease, and Piso was suspected, if not accused, of having given him poison. Piso was impeached in the senate for his conduct towards Germanicus. In the course of his trial, Tiberius acted with apparent impartiality; but the accused, despairing of an acquittal, put an end to his own life. Tiberius, in the seventh year of his reign, withdrew from Rome to Campania, in order to accustom Drusus, who was then consular, to the exercise of the supreme power. Notwithstanding several influences, in which he manifested a moderate exercise of power, a stern unfeeling tyranny was becoming the settled character of his reign, to which his growing confidence in the detestable Sejanus very much contributed. The death of Drusus, A.D. 23, occasioned by poison, administered in consequence of the seduction of his wife, was borne by his father Tiberius with a degree of self-possession, which was imputed to want of natural affection. After this event he appeared in the senate; and the two elder sons of Germanicus were preferred to him. Taking them by the hand, and delivering a speech which melted the whole assembly into tears, he recommended these orphans, who had lost both their uncle and father, to the guardianship of the senate. Two years after the death of Drusus, Tiberius took an opportunity, which a proposal for erecting a temple to him and his mother afforded him, of giving his sentiments on that subject which disgraced the reigns of the Roman emperors. Recognizing himself as a mere mortal, subject to all the infirmities of the human condition, and sufficiently honoured in holding the first place among men, he was detestable that posterity should know his sentiments on the subject, and that he wished for no other honours paid to his memory than to be thought to have worthily performed the duties of his station. The whole speech, replete with wisdom and
TIB
