In the northern hemisphere, a curve of no variation moved from west to east during two centuries prior to 1662. This curve first passed the Azores, then the meridian of London, and, after a certain number of years, the meridian of Paris. But in the southern hemisphere, there was another curve of no variation moving from east to west. This curve first passed Cape Aguilas, and then the Cape of Good Hope; the westerly variation following the easterly, the same as in the northern hemisphere, but in a contrary direction.

And from the observations that have since been made, it appears that the curve of no variation in the northern hemisphere, after passing the meridian of London and Paris, has discontinued its easterly progress; while the curve of no variation in the southern hemisphere, still continues its course north-westward.

The variation on the east side of the curve of no variation, which passed the meridian of Aguilas in 1600, and extended north and south to a high degree of latitude in both hemispheres, being westerly; and the curve which passed the meridian of London in 1662 being easterly; it follows, that the curve which passed London could not reach beyond the 18th degree of east longitude, as the denomination of the variation was the same easterly of that meridian in 1600 that it now is, namely, westerly. The exact point where the southern curve of no variation passed the northern curve cannot be satisfactorily ascertained; but it is known, that while the northern curve passed London eastward, the southern curve passed westward in nearly the same longitude.

Dampier, in his voyage to the East Indies in 1669, found, that from 6° south latitude and 25° west longitude, to the point where the 37th degree of south latitude was intersected by the meridian of Greenwich, the variation was easterly, but never exceeding 13°; at which latter point the easterly variation was 0°, and thence became westerly, and continued to increase to 49° E. long., and 25° S. lat., where it appears to have attained its maximum; i.e. 25° or 26° W.; and from this point the variation gradually diminished, till it again assumed another denomination in S. lat. 10°, and E. long. 125°; and from this point, the lat. point, as far north of the equator as 10°, the variation appears to have then been, as it still is, influenced by local attractions; the quantity being always small, sometimes east, and at others west.

Captain Cook, in 1772, in S. lat. 6°, and W. long. 16°, found 6° 30' westerly variation; and in S. lat. 24°, and W. long. 23° 51', found only 30' westerly variation. From this point the westerly variation gradually increased, as the southern latitude and eastern longitude augmented to 96° of east longitude, and 60° 49' south latitude, where it attained its maximum; i.e. 43° 45' west. From this latter point it rapidly decreased, and became east in S. lat. 58° 53', and E. long. 143° 40'. But as the tract of D'Entrecaults, in 1791, nearly coincides with Dampier's in 1669, the change in the position of the curve of no variation, will be illustrated by a comparison of their respective observations.

D'Entrecaults found the variation in S. lat. 6°, and W. long. 25°, to be 7° 15' west; and in S. lat. 25°, and W. long. 25°, only 1° 56' west; from which last point it again increased as the west longitude diminished, till the meridian of Greenwich intersected the 33rd degree of south latitude, where the variation was 15° west; and it attained its maximum of 30° 48° 9' in S. lat. 34° 54', and E. long. 38° 14' 18" from Paris; and from hence, to S. lat. 44°, and W. long. 133°, the variation continued westerly, but it thence changed and became east.

The space between the two curves observed by Dampier in 1669, reached from the meridian of Greenwich to 130° E. long.; and the distance between them, according to D'Entrecaults, in 1791, must be 155°. Dampier having cut the curve in 80° E. long., and the other in 25° W. The curve of no variation must therefore have advanced from the westward annually about 1°, in the parallel of 34° south latitude, to have shifted its place 25° in ninety-two years, and at a yearly rate of 14' 80' from the time it passed Cape Aguilas in 1660 to 1791. This curve is now known to extend across the magnetic and terrestrial equators, to a point in N. lat. 37° 27' and W. long. 76° 44'.

From a comparison of the above results, and others drawn from the observations of captain Flinders, and the Russian navigator Krufenstern, it appears, that a curve of no variation bending westward, extends from the highest degree of southern latitude, in about 144° E. long. to 52° N. lat.; the curve parallel, intersecting the equator in 150° E. long. Now from the observations of La Perouse and Krufenstern, the westerly variation ceased, and the curve of no variation terminated in about 52° N. lat., and 143° E. long.; for the variation north-eaft of this point assumes another character; and 18° farther north, and 52° to the east, captain Cook found near 56° of easterly variation.

It appears also, from a comparison of observations made in Peria and the frontiers of China by Schubert, with those of Peroue, Krufenstern, and others, made on board his majesty's ship Sybille, that the curve of no variation again takes its rite in about 52° N. lat., and 143° E. long., and terminates a little east from Spitzbergen, extending in a direction nearly east by south, and west by north, through 67°80 miles of longitude.

Biott, in speaking of this subject, says, "that a curve of no variation seems to take its rite in the great Southern ocean, passing through the western part of New Holland, traverses the Indian ocean, enters the continent of Asia at Cape Corom, and thence passes through Persia and West Siberia, and proceeds towards Lapland. But what is more remarkable, that line divides itself into two in the great Asian archipelago, and gives rite to another branch, which, pointing directly from the south to the north, passes that archipelago, traverses China, and is again found in Eastern Siberia. The existence of this branch, and its separation from the former, are clearly indicated by the observations made in the Chinese seas; but I am able to offer a still further confirmation of it, by the observations made in Ruffia and the frontiers of China, by the celebrated astronomer Schubert, who has been kind enough to communicate them to me;" which latter are the observations spoken of above.

We have seen that a curve of no variation, extending from 60° of south latitude to 52° of north latitude, in about 143° east longitude, but taking a small head to the westward, is intersected by the meridian of Ambouyn; and by comparing with each other different observations made by Mr. Wales, in his voyage with captain Cook, and those of Vancouver in 1791, and others made by Mr. Home Popham, and by Humboldt, it appears, that from the weftly part of the curve of no variation, found in about 130° eall of the meridian of Greenwich, where the weftly changes to an easterly variation, to the meridian where the easterly variation...
tion was found to terminate by captain Cook. S. lat. 58°
27'. W. long. 13° 10', the distance east and west will be
216° 50'.

To the meridian of Peru, S. lat. 20° 39'. W. long.
28° 36', the distance is 201° 22'.

To the meridian of Vancouver, S. lat. 35°. W. long. 28°,
the distance is 202°.

To the meridian of sir H. Popham, S. lat. 30°. W. long.
26°, the distance is 204°.

To the meridian of Humboldt, N. lat. 13°. W. long. 59°,
the distance (taking the mean) is 171°.

And if the curve of no variation extends to N. lat. 37°
27'. W. long. 70° 40', the easterly variation in that parallel
will only measure 15° 16'.

These different distances point out, under different paral-
lels of latitude, the direction which the curve of no variation
at present affirms; and we may perhaps conclude, that the
variation of the magnetic needle is caused by two different and
distinct systems of magnetic forces; the one producing a
weasterly variation in the northern hemisphere, over the space
of 200° 44'; and in the southern hemisphere, in the same
parallel of latitude, of 143° 10'; and the other an easterly
variation in the northern hemisphere, over a space of 159°
16'; and on the southern, of 216° 50'.

From these facts it would seem, that the north end of the
curve, which passed Cape Aguilas in 1600 north-westward,
was in 1804 found to extend from S. lat. 60°. W. long. 15°
10', to N. lat. 57° 27'. W. long. 70° 40', intersecting the 13th
degree of northern latitude, and the 21st, 30th, and 35th of southern
latitude; whence the medium rate of its motion is found
about 26° annually; but it is extremely probable, that the
south end of this curve has during the same period remained
stationary; and this difference in the motion of the two ex-
tremes of the curve in the southern hemisphere, may perhaps
point out to us the reason why the quantity of variation
should have continued the same off Cape Horn during 133
years, while at the Cape of Good Hope, Paris, and London,
it should have increased 25° or 27° in the same period.

The curve of no variation which passed through London
eastward, about the same time the curve in the southern
hemisphere passed the meridian of Greenwich westward,
appears to have been lost among the smaller magnetic powers
at present found in the continent of Europe and Asia.

The view which we have given of this perplexing subject,
deduced from actual observation, renders it obvious that all
trials, by theory, to fix on charts the exact positions of the
curves of no variation, or lines of given variation, must prove,
as they have always hitherto done, entirely abortive. There
are indeed places in the world, such as Spitzbergen, Cape
Horn, Chili, and Mexico, the great Alpin archipelago, the
cost of Coromandel, Peru, Brazil, &c., where the curve of
variation, and the variation itself, has not undergone any perceptible
change since first observed; but we have good rea-
sons to believe, that at all the above-mentioned places the
variations are regulated by incidential magnetic attractions,
which are lost or merged in the two great powers already
debated, at a little distance from their respective spheres.
In all other places of the globe, it is continually undergoing
a regular and progressive change; but it is impossible ac-
curately to determine when this change may cease, or to foresee
what quantity our present westward variation may attain,
though there is some reason to believe it has very nearly or
entirely arrived at its maximum.

At present, we have spoken only of those great and in
some measure continued changes in the variation which takes
place, and become very obvious after a long period; but
there are others of a more minute quantity, and of daily,
and we might add of hourly occurrence, to which it will be
proper to refer in the present article.

Mr. George Graham made several observations of this
kind in the years 1722 and 1723, professing himself alto-
gether ignorant of the cause of the variation which he ob-
erved. Phil. Trans. N. 385, or Abr. vol. vii. p. 290, &c.

About the year 1750, Mr. Wargentin, secretary of the
Royal Academy of Sciences in Sweden, took notice both of
the regular diurnal variation of the needle, and also of its
being disturbed at the time of the aurora borealis, as record-
ed in the Phil. Trans. vol. xlvii. p. 126, &c.

About the year 1756, Mr. Canton commenced a series of
observations, amounting to nearly 4000, with an excellent
variation-compas, of about nine inches diameter. The
number of days on which these observations were made was 605,
and the diurnal variation on 574 of them was regular; i.e.,
the absolute variation of the needle westward was increasing
from about eight or nine o'clock in the morning till about
one or two in the afternoon, when the needle became sta-
tionary for some time; after that, the absolute variation
westward was decreasing, and the needle came back again
to its former situation, or near it, in the night, or by the
next morning. The diurnal variation is regular when the
needle moves slowly eastward in the latter part of the mor-
ing, or westward in the latter part of the afternoon; also
when it moves much either way after night, or suddenly both
ways in a short time. These irregularities seldom happen
more than once or twice in a month, and are always accom-
panied, as far as Mr. Canton observed, with an aurora
borealis.

Mr. Canton lays down and evinces by experiment the fol-
lowing principle, viz. that the attractive power of the mag-
net (whether natural or artificial) will decrease while the
magnet is heating, and increase while it is cooling. He then
proceeds to account for both the regular and irregular vari-
ations. It is evident, he says, that the magnetic parts of the
earth in the north on the east side, and the magnetic parts of
the earth in the north on the west side of the magnetic meri-
dian, equally attract the north end of the needle. If then
the easterly magnetic parts are heated faster by the sun in
the morning than the western, the needle will move westward,
and the absolute variation will increase: when the attracting
parts of the earth on each side of the magnetic meridian have
their heat increasing equally, the needle will be stationary,
and the absolute variation will then be greatest, but when the
western magnetic parts are either heating faster, or cool-
ing slower than the easterly, the needle will move eastward,
or the absolute variation will decrease; and when the easterly
and western magnetic parts are cooling equally, the needle
will again be stationary, and the absolute variation will then
be least.

By this theory, the diurnal variation in the summer ought
to exceed that in winter; and accordingly it is found by ob-
ervation, that the diurnal variation in the months of June
and July is almost double that of December and January.

The irregular diurnal variation must arise from some other
cause than that of heat communicated by the sun; and here
Mr. Canton had recourse to subterranean heat, which is gen-
erated without any regularity as to time, and which will,
when it happens in the north, affect the attractive power of
the magnetic parts of the earth on the north end of the
needle. That the air near the earth will be much warmed
by the heat of it, is obvious; and this has been frequently
noted, that of in the morning, before day, by means of
thermometers at different distances from the ground. Phil.

Mr. Canton has annexed to his paper on this subject a
complete
complete year's observation; from which it appears that the
durnal variation increases from January to June, and
decreases from June to December. Phil. Trans. vol. i.
p. 398, &c.

It has also been observed, that different needles, especially
if touched with different loadstones, will differ a few min-
utes in their variation. See Poleni Epit. Phil. Trans.
N° 421.

We shall here subjoin a method practised by M. Du Hamel,
who was one of those who attempted, and succeeded in
the preparation of artificial magnets, for enlarging the scale of
the variation. At each extremity of the needle, composed
of two magnetic bars, and which is fourteen inches long, a
slender pointed piece of steel is erected perpendicularly; and
at the distance of fifty-two feet, in the direction of the
needle, he has placed on two pillars, and in a line perpendi-
cular to that direction, a graduated limb fix feet long; being
a segment of a superseded circle, described from the centre
on which the needle turns. The observer, placing himself so
as to bring the two pieces of steel at the extremities of the
bar into a line with the eye, observes where that line
prolonged, or the visual ray, points to the graduated arc. As,
at this distance, each of these degrees measures a foot, the
true direction of the needle is ascertained with the greatest
precision; and left the observer's eye may not be good
enough to enable him to see distinctly the particular divisions
at that distance, an assistant occasionally moves a certain
index, conformably to his direction. Hift. de l’Acad.

On the Effect of the Local Attraction of the Ship upon the
Variation of the Needle.—We have already had occasion to
notice the necessity of attending to the direction of the ship's
head, in observations made on ship-board relative to the
direction of the compass; and that this may have a very
favourable effect will appear very obvious, when we recollect
the quantity of iron with which a ship of war, in particular,
is generally loaded; and that this is mostly forward, while the
compass is generally aft. The great attraction between the
iron and the needle is generally known; and consequently,
if we could imagine the magnetic power of the earth to
cease entirely, we should have no difficulty in conceiving
that the attraction of the guns, &c. would incline the needle
towards the direction of that of the vessel; and consequently,
when the magnetic meridian and the direction of
the ship's head are the same, that is, when the vessel
lies north and south, both forces acting in the same manner, the
position of the needle will be the same as if no local
attraction existed. But if the ship's head is put over to
the east or west, then the local attraction of the ship will
incline the needle to the east and west, and consequently
will draw it towards the north; and it will, therefore,
assume a direction which corresponds with the
resultant of these two distinct forces; and we may observe,
that the direction of this resultant would furnish, if well
observed, most important data towards determining the inten-
sity of this mysterious power.

Simple and obvious as this idea is, it does not appear to
have been formed till Mr. Wales, the astronomer in captain
Cook's voyages, was struck with certain irregularities,
which he could in no way account for, and of which we
have the following account in the Introduction to the
astronomical observations in the Second Voyage.

'In the English Channel, the extremes of the observed
variation were from 148° to 25°; and all the way to
the Cape of Good Hope, I had frequently observed differences
nearly as great, without being able in any way to account
for them; the difference in the situation being by no means
sufficient. These irregularities continued after leaving the
Cape, which at length put me upon examining into the cir-
cumstances under which they were made. In this examina-
tion it soon appeared, that when most of these observations
were made, wherein the greatest variation had happened,
the ship's head was north and easterly; and that when
the ship had been taken, it was south and westerly. I mentioned this to captain Cook, and some of
the officers, who did not at first seem to think much of it;
but as opportunities happened, some observations were
made under those circumstances, and very much contributed
to confirm my suspicions; and throughout the whole voyage,
I had good reason to believe that observations varied,
with the ship's head in different positions, and even in different parts
of her, will differ very materially from one another, and
much more will observations made on board different ships,
which I now find fully verified, on comparing those made on
board the Adventure with my own, made about the same
time in the Resolution.'

Mr. Wales again recurs to this subject, in the course of
his astronomical observations made in Cook's third voyage,
and points out the quantity of the deviation in several cases;
yet the true cause of these anomalies does not appear to have
furnished itself to this able astronomer: he merely states the
results, but offers no explanation of them. Nor does it appear
that they were afterwards particularly noticed by any
navigator, till captain Flanders's attention was called to the
subject in the early part of his last voyage. Here that experienced
navigator found such unaccountable differences in the quantity
of variation, deduced from the different observations he
occasionally made, that he determined on instituting an
inquiry into their causes; and, if possible, to ascertain the
laws by which they were regulated.

"Several instances," he observes, "have been mentioned
in the course of this voyage, where the compass shewed a
different variation, on being removed from one part of the
ship to another. Thus, observations on the binnacle gave
29° off the Start, where the true variation was 25½°;
whilst others taken from the booms before the main-mast,
68 miles lower down the Channel, gave only 24°; and in
the experiments made with five compasses, the mean variation
on the binnacle was 4° 37', greater than on the booms.

"It soon became evident, however, that keeping the
compass to one spot was not alone sufficient to secure accu-
racny: a change in the direction of the ship's head was also
found to make a difference in the needle; and it was neces-
sary to ascertain the nature and proportional quantity of this
difference, before a remedy could be applied. This inquiry
was attended with many difficulties, and no satisfactory
conclusion could be drawn, until a greater variety of obser-
ations was collected. It then appeared, that whereas
the ship's head was on the east side of the meridian, the
differences were molly one way; and when on the west side,
they were the contrary: whence I judged that the iron in the
ship had an attraction on the needle, which drew it forward.
But there was this remarkable direction: in the northern
hemisphere, it was the north end of the needle which was
attracted; and in the southern hemisphere, it was the south
end. In the instances off the Start, before cited, when
the ship's head was westerly, the north end of the needle
drew forward; or to the left of the north, nearly 4°; and
the west variation thereby increased to 29½°; with the head
at easterly, it would be drawn to the right of its natural position.
and the variation diminished to about 21½°; but at north,
the attraction of the ship was in the same line with the mag-
netic poles of the earth, and would, therefore, produce no
change.
change. The same thing took place at south, for the two attractions were still in the same continued line, though on opposite sides of the compass; and throughout the voyage, I found the variation, taken with the head at north and south, agreed very nearly in themselves, and with the observations themselves near the same place, when such observations were not affected by local attractions."

The following table contains a few of the instances, where the change in the variation was observed by Captain Flinders.

**Table of Variations observed in a Voyage of Discovery to Terra Australis, in 1801 and 1802, by Captain Flinders, in His Majesty's Ship Investigator.**

</tbody>
</table>

After various other observations, and much examination, (for the needle was not always deflected the same quantity, when the position of the ship was the same,) captain Flinders found that the errors had a close connection with the dip. When the north end of the needle had dipped, it was the north point of the compass that had been attracted by the iron of the ship; and that dip diminished, so had the attraction, until at the magnetic equator; where the dipping-needle stands horizontal, there seemed to have been no attraction; and, upon the whole, it seemed probable that the error produced at any direction of the ship's head would be to the error at east or west, at the same dip, as the sine of the angle between the ship's head and the magnetic meridian was to the sine of eight points or radius.

After captain Flinders's arrival in England, he made application to the lords commissioners of the Admiralty to have experiments tried on board some of his majesty's ships, that the observations made during his voyage might be verified; and a series of observations was accordingly made on board five different ships at Sheerness and Portsmouth, which fully established the accuracy of his former conclusions.

Should this rule, upon further trial, be found to answer under all circumstances, we must consider it as a most important acquisition to our present knowledge of navigation; but those who with folly to appreciate all the consequences of this discovery, should consult Bains's treatise on the "Variation of the Compass," to which work we have been much indebted in the composition of this article, and where they will find every information of a practical kind connected with the subject.

**Theory of the Variation of the Needle.**—Dr. Halley, as we have already stated, was the first who attempted any theory relative to the variation of the compass; and from the observations which he collected, many of which are included in our preceding remarks, he conceived "that the whole globe of the earth is one great magnet, having four magnetical..."
etical poles, or points of attraction: near each pole of the equator two; and that in those parts of the world which lie nearly adjacent to any one of these magnetic poles, the needle is governed thereby; the nearest pole being always predominant over the more remote."

The pole which at present is nearest to us, he conjectures, to lie in or near the meridian of the Land's-End of England, and not above 9° from the Arctic pole: by this pole the variations in all Europe and Tartary, and the North Sea, are principally governed; though still with some regard to the other northern pole, whose situation is in the meridian passing about the middle of California, and about 15° from the north pole of the world, to which the needle has chiefly respect in all North America, and in the two oceans on either side thereof, from the Azores, westwards, to Japan, and farther.

The two southern poles, he imagines, are rather farther distant from the south pole of the world; the one about 16°, in a meridian 20° to the westward of Magellan's straits, or 95° west from London; this commands the needle in all South America, in the Pacific sea, and the greatest part of the Ethiopic ocean. The other seems to have the greatest power, and the largest dominion of all, as it is the most remote from the pole of the world, being distant from it little less than 20°, in the meridian which passes through New Holland, and the island Celebes, about 120° east from London; this pole is predominant in the south part of Africa, in Arabia, and the Red sea, in Persia, India, and its islands, and all over the Indian Sea, from the Cape of Good Hope eastwards, to the middle of the Great South Sea that divides Asia from America.

Such appears to have been the disposition of the magnetic attraction in the time of Dr. Halley; and from these data this author draws the following conclusions; viz.

1. Then, it is plain that, as our European north pole is in the meridian of the Land's-End of England, all places more easterly than that will have it on the west side of the meridian; and, consequently, the needle, respecting it with its northern point, will have a westerly variation, which will still be greater as you go to the eastward, till you come to some meridian of Russia, where it will be the greatest, and from thence will decrease again. Accordingly, in fact, we find, that at Breil the variation is but 13°; at London, 41° (in 1683); and at Dantzic, 7° west. Again, to the westward of the meridian of the Land's-End, the needle ought to have an easterly variation, were it not that, by approaching the American northern pole, (which lies on the west side of the meridian, and seems to be of greater force than this other,) the needle is drawn thereby westward, so as to counterbalance the direction given by the European pole, and to make a small westward variation in the meridian of the Land's-End itself. Yet, about the isle of Tercera, it is supposed our nearest pole may so far prevail as to give the needle a little turn to the east, though but for a very little space; the counterbalance of those two poles admitting no material variation in all the eastern parts of the Atlantic ocean, nor upon the west coasts of England and Ireland, France, Spain, and Barbary. But to the westward of the Azores, the powers of the American pole overcoming that of the European, the needle has chiefly respect to this, and turns still more and more towards it as we approach it. Whence it happens, that on the coast of Virginia, New England, Newfoundland, and in Hudson's Straits, the variation is westward, that is, it decreases as you go from thence towards Europe; and that it is lefs in Virginia and New England than in Newfoundland and Hudson's Straits.

2. This westerly variation, again, decreases as you pass over North America; and about the meridian of the middle of California, the needle again points due north; and from thence westward to Yedzo and Japan, it is supposed the variation is easterly, and half-half over, not less than 15°; and that this east variation extends over Japan, Yedzo, Tartary, and part of China, till it meets with the westerly, which is governed by the European north pole, and which is the greatest somewhere in Ruflia.

3. Towards the south pole the effect is much the same, only that here the south point of the needle is attracted. Whence it will follow, that the variation on the coast of Brazil, at the river of Plata, and so on to the straits of Magellan, should be easterly, if we suppose a magnetic pole, situated about 20° more westerly than the straits of Magellan. And this easterly variation extends eastward over the greatest part of the Ethiopic sea, till it be counterpoised by the virtue of the other southern pole, as it is about mid-way between the Cape of Good Hope and the isles of Tristan d'Alcunha.

4. From thence eastwards, the Asiatic south pole becoming prevalent, and the south point of the needle being attracted thereby, there arises a west variation, very great in quantity and extent, because of the great distance of this magnetic pole from the pole of the world. Hence it is, that in all the Indian Sea, as far as Hollandia Nova, and farther, there is constantly a west variation; and that, under the equator itself, it rises to no less than 11°, where it is most. And that, about the meridian of the island of Celebes, being likewise that of this pole, this westerly variation ceases, and an easterly one begins, which reaches to the middle of the South Sea, between Zelandia Nova and Chili, leaving room for a small west variation, governed by the American south pole.

5. From the whole it appears, that the direction of the needle, in the temperate and frigid zones, depends chiefly upon the counterpoise of the forces of two magnetic poles of the same nature; as also why, under the same meridian, the variation should be in one place 29° 1/2 west, and in another 20° 1/2 east.

6. In the torrid zone, and particularly under the equinoctial, respect must be had to all four poles, and their positions must be well considered, otherwise it will not be easy to determine what the variation shall be, the near pole being always stronger; yet not so as necessarily to be counterbalanced, sometimes, by the united forces of two more remote. Thus, in failing from St. Helena, by the isle of Ascension, to the equator, on the north-west course, the variation is very little easterly, and in that whole tract is unalterable; because the South American pole, (which is considerably the nearest in the aforesaid places,) requiring a great easterly variation, is counterpoised by the contrary attraction of the North American and the Asiatic south poles; each of which, as it were, lies in those parts, weaker than the American south pole: and upon the north-west course, the distance from this latter is very little varied; and as you recede from the Asiatic south pole, the balance is still preferred by an accese towards the North American pole. In this case, no notice is taken of the European north pole; its meridian being a little removed from those of these places, and of itself requiring the same variations which we here find.

After the same manner may the variations in other places, under and near the equator, be accounted for, upon Dr. Halley's hypothesis.

But in order to account for the variation of the variation, it was observed, that from many of the observed phenomena, it seemed to follow that all the magnetic poles have a motion
motion westward: but if it be so, it is evident that it is not a rotation about the axis of the earth; for then the variations would continue the same in the same parallel of latitude (the longitude only changed), as much as the motion of the magnetic poles: but the contrary is found by experience; for there is no where, in the latitude of 51° North, between England and America, a variation of 11° East, at this time; as it was once here at London. Wherefore it seems, that our European pole is become nearer the Arctic pole than it was heretofore; or else, that it has lost part of its virtue.

But whether these magnetic poles move altogether with one motion, or with several, whether equally, or unequally; whether circular, or libratory: if circular, about what centre; if libratory, after what manner; are things yet unknown.

This theory seems yet somewhat obscure and defective: to suppose four poles in one magnetic globe, in order to account for the variation, is a little unnatural; but to conceive those poles to move, and that by such laws as to solve the variation of the pole, is still more extraordinary. In effect, the solution appears not much less implicit and arbitrary than the problem.

The learned author of the theory, therefore, found himself under a necessity to solve the phenomena of his solution; and with this view, he presented the following hypothesis. The external parts of the globe he considers as the shell, and the internal as a nucleus, or inner globe; and between the two, he conceives a fluid medium. That inner earth, having the same common centre and axis of diurnal rotation, may turn about with our earth each twenty-four hours. Only the outer sphere having its turbinating motion some small matter either swifter or slower than the internal ball; and a very minute difference in length of time, by many repetitions, becomes sensible; the internal parts will, by degrees, recede from the external, and not keeping pace with one another, they will appear gradually to move either eastward or westward, by the difference of their motions.

Now, suppose such an internal sphere, having such a motion, the two great difficulties in the former hypotheses are easily solved; for if this exterior shell of earth be a magnet, having its poles at a distance from the poles of diurnal rotation; and if the internal nucleus be likewise a magnet, having its poles in two other places, different also from the axis; and these latter, by a gradual and slow motion, change their place in respect of the external, we may then give a reasonable account of the four magnetic poles afore-mentioned, as likewise of the changes of the needle's variation.

The period of its motion being wonderfully great, and there being hardly a hundred years since these variations have been duly observed, it will be very hard to bring this hypothesis to a calculus; especially since, though the variations do increase and decrease regularly in the same place, yet in different places at no great distance, there are found such casual changes thereof, as can no ways be accounted for by a regular hypothesis; but seem to depend upon the unequal and irregular distribution of the magnetic matter within the substance of the external shell, or coat of the earth, which deferts the needle from the position it would acquire from the effect of the general magnetism of the whole. Of which the variations at London and Paris give a notable instance; for the needle has been constantly about 1° more easterly at Paris than at London; though it be certain that, according to the general effect, the difference ought to be the contrary way; notwithstanding which, the variations, in both places, do change alike.

Hence, and from some other things of like nature, it seems plain, that the two poles of the external globe are fixed in the earth, and that if the needle were wholly governed by them, the variations thereof would be always the same, with some irregularities, upon the account just now mentioned. But the internal sphere having such a gradual translation of its poles does influence the needle, and direct it variously, according to the result of the attractive or directive power of each pole, and, consequently, there must be a period of the revolution of this internal ball; after which the variations will return again as before. But if it shall in future ages be observed otherwise, we must then conclude that there are more of these internal spheres, and more magnetic poles, than four; which, at present, we have not a sufficient number of observations to determine, and particularly in that vast Mar del Zor, or South sea, which occupies so great a part of the whole surface of the earth. If, then, two of the poles be fixed, and two moveable, it remains to ascertain which they are that keep their place.

The author thinks it may be safely determined, that our European north pole is the moveable one of the two northern poles, and that which has chiefly influenced the variations in these parts of the world; for, in Hudson's Bay, which is under the direction of the American pole, the change is not observed to be near so far as in these parts of Europe, though the pole be much farther removed from the axis. As to the south poles, he takes the Atlantic pole to be fixed, and, consequently, the American pole to move.

This granted, it is plain that the fixed poles are the poles of this external shell, or cortex, of the earth; and the other the poles of the magnetic nucleus, included and moveable within the other. It likewise follows, that this motion is westwards, and, by consequence, that the aforesaid nucleus has not precisely attained the same degree of velocity with the exterior parts in their diurnal revolution; but so nearly equals it, that, in 365 revolutions, the difference is scarcely sensible. That there is any difference of this kind arises hence, that the impulse by which the diurnal motion was impressed on the earth, was given to the exterior parts; and from thence, in time, communicated to the internal; but not so as yet perfectly to equal the velocity of the first motion impressed on, and still conferred by the superficial parts of the globe.

As to the precise period, we want observations to determine it, though the author thinks we may, with some reason, conjecture, that the American pole has moved westward 4° in ninety years, and that the whole period thereof is performed in about seven hundred years.

Mr. Whitson, in his "New Laws of Magnetism," raises several objections against this theory. See Magnetism.

M. Euler, the fon of the celebrated geometer of that name, has also controverted and conftrued the above theory; he thinks that two magnetic poles placed on the surface of the earth will sufficiently account for the variation; and he then endeavours to shew, how we may determine the declination of the needle, at any time, and on every part of the globe, from this hypothesis. But we must refer for the particulars of this reasoning to the "Histoire de l'Académie Royale des Sciences et Belles-Lettres de Berlin," for 1775.

Various other theories have been fugggled by later authors, but most of these have been already alluded to under our articles Magnetism, Dipping-Needle, &c.; we shall, therefore, here conclude this article, by referring the reader for a more minute account of the various theories, particularly that of Coulomb, to Hail's "Elementary Treatise on Natural Philosophy," translated by Gregory, and to the first chapter of the third volume of Biot's "Traité de Physique."
VARIATION.

VARIATION or Declination of the Needle. To observe the.—

Draw a meridian line, as directed under MERIDIAN, then, a style being erected in the middle of it, place a needle thereon, and draw the right line which it hangs over. Thus will the quantity of the variation appear.

Or thus: as the former method of finding the declination cannot be applied at sea, others have been thought of, the principal of which follow: suspend a thread and plummet over the compass, till the shadow falls through the centre of the card; observe the rhumb, or point of the compass, which the shadow touches when it is the shortest. For the shadow is then a meridian line; consequently the variation is shown.

Or thus: observe the rhumb in which the sun, or some star, rise and set; bifect the arc intercepted between the rising and setting; the line of bisection will be the meridian line; consequently the declination is had as before. The same may be had from two equal altitudes of the same star, observed either by day or night.

Or thus: observe the rhumb in which the sun, or some star, rise and set; and from the latitude of the place find the eastern or western amplitude, for the difference between the amplitude, and the distance of the rhumb observed, from the eastern rhumb of the card, is the variation sought. See Azimuth Compass.

Note, to have the eastern or western amplitude accurately, regard must be had to the refraction. See Refraction.

For the more commodious observing in what rhumb of the compasses the sun, or a star, is seen, it will be proper to have two little apertures, or glafs windows, opposite to each other, under the limit of it, with a telescope-fight fitted to one of them, and to the other a fine thread.

The use of the variation is to correct the courses a ship has steered by the compasses: e.g. given the course set, and the variation of the compasses, and let it be required to find the true course the ship steers: if the variation is west, call the N.W. quarter the 1st, the S.W. the 2d, the S.E. the 3d, and the N.E. the 4th; but if the variation be east, call the N.E. quarter the 1st, the S.E. the 2d, the S.W. the 3d, and the N.W. the 4th. Then, if the course be set in the 1st or 3d quarters, add the variation to the points or degrees in the given course; but if in the 2d or 4th quarters, subtract, and the sum in the former, or the difference in the latter case, will be the course corrected by the variation.

VARIATION of Curvature, in Geometry, is used for that inequality, or change, which happens in the curvature of all curves, except the circle. And this variation or inequality constitutes the quality of the curvature of any line.

Sir Isaac Newton makes the index of the inequality or variation of curvature, to be the ratio of the fluxion of the radius of curvature to the fluxion of the curve: and Mr. Maclaurin, to avoid the perplexity that different notions, connected with the same terms, occasion to learners, has adopted the same definition; but he suggests, that this ratio gives rather the variation of the ray of curvature, and that it might have been proper to have measured the variation of curvature rather by the ratio of the fluxion of the curve itself to the fluxion of the curve; so that the curvature being inversely as the radius of curvature, and, consequently, its fluxion as the fluxion of the radius itself directly, and the square of the radius inversely, its variation would have been directly as the measure of it, according to Sir Isaac Newton's definition, and inversely as the square of the radius of curvature.

According to this notion, it would have been measured by the angle of contact contained by the curve and circle of curvature, in the same manner as the curvature itself is measured by the angle of contact contained by the curve and tangent. The reason of this remark may appear from this example: The variation of curvature, according to Sir Isaac Newton's explication, is uniform in the logarithmic spiral, the fluxion of the radius of curvature in this figure being always in the same ratio to the fluxion of the curve; and yet, while the spiral is produced, though its curvature decreases, it never vanishes, which must appear a strange paradox to those who do not attend to the import of Sir Isaac's definition. Newton's Meth. of Flux. and Inf. Series, p. 76. Maclaurin's Fluxions, art. 386. Phil. Trans. N.S. 4th. p. 342.

The variation of curvature at any point of a conic section, is always as the tangent of the angle contained by the diameter that passes through the point of contact, and the perpendicular to the curve at the same point, or to the angle formed by the diameter of the section, and of the circle of curvature. Hence the variation of curvature vanishes at the extremities of either axis, and is greatest when the acute angle, contained by the diameter, passing through the point of contact and the tangent, is least.

When the conic section is a parabola, the variation is as the tangent of the angle, contained by the right line drawn from the point of contact to the focus, and the perpendicular to the curve. See CURVATURE.

VARIATION of Ratios. In the investigations of the relation which varying and dependent quantities bear to each other, conclusions are frequently more readily obtained by expressing only two terms in each proportion, than by retaining the four. But although in considering the variation of such quantities two terms only are expressed, it will be necessary to bear constantly in mind that four are supposed, and that the operations by which our conclusions are in this case obtained, are in reality the operations of four proportionals.

1. One quantity is said to vary directly as another, when their magnitudes depend wholly upon each other, and in such a manner, that if the one be changed, the other is changed in the same proportion; thus, let A and B be mutually dependent upon each other in such a way, that if A changes to any other value a, B is changed to another value b, such that A : a :: B : b; then A is said to vary directly as B, which is denoted by the symbol of general proportion \( \alpha \) placed between the two quantities. Thus, for example, while the altitude of a triangle remains constant, the area varies directly as the base, or the area \( \propto \) base; for if the base be increased or diminished, the area is increased or diminished in the same proportion.

2. One quantity is said to vary inversely as another, when one cannot be changed in any manner; but the reciprocal of the other is changed in the same proportion. A varies inversely as B, or A \( \propto \frac{1}{B} \), if when A is changed...
VARIATION.

To $a$, $B$ is changed to $b$, in such a manner, that

$$A : a :: \frac{1}{B} : \frac{1}{b}; \text{ or } A : a :: b : B.$$  

For example, if the area of a triangle be given, the base varies inversely as the perpendicular altitude; for let $A$ and $a$ represent the altitude of two triangles of equal areas, and $B$ and $b$ their bases; then

$$\frac{A \times B}{2} = \frac{a \times b}{2}; \text{ or } A \times B = a \times b;$$

therefore,

$$A : a :: b : B; \text{ or } A : a :: \frac{1}{B} : \frac{1}{b}.$$  

3. One quantity is said to vary as two others jointly, if, when the former is changed in any manner, the product of the other two is changed in the same proportion; that is, $A$ varies as $B$ and $C$ jointly, or $A \propto BC$, when $A$ cannot be changed to $a$, but $BC$ is changed to $b$, such that $A : a :: BC : cb$. The area of a triangle, for example, varies as the base and altitude jointly; for let $A$, $P$, $B$, represent the area, perpendicular, and base of one triangle, and $a$, $p$, $b$, the corresponding quantities in another; we know that $A = \frac{1}{2}Pb$, and $a = \frac{1}{2}pb$; consequently $\frac{A}{a} = \frac{Pb}{pb}$, or $A : a :: BP : bp$.

4. One quantity is said to vary directly as a second, and inversely as a third, when the first cannot be changed in any manner; but that the second, multiplied by the reciprocal of the third, is changed in the same proportion. That is, $A$ varies as $\frac{B}{C}$, or $A \propto \frac{B}{C}$, when $A : a :: \frac{b}{c}$; $A$, $B$, $C$, and $a$, $b$, $c$, being corresponding values of these quantities. For example, the base of a triangle varies as the area directly, and as the altitude inversely; for as in the preceding example, $\frac{BP}{A} = \frac{a}{b}$; if we multiply both sides by $\frac{P}{a}$, we have $\frac{BP}{b} = \frac{Pb}{pa}$, whence $B : b :: \frac{A}{P} : \frac{a}{p}$.

The following are some of the principal propositions relating to the ratio of variable quantities.

If $A \propto B$, and $B \propto C$; then $A \propto BC$.

If $A \propto B$, and $B \propto \frac{1}{C}$; then $A \propto \frac{1}{C}$.

If $A \propto C$, and $B \propto C$; then $A \pm B \propto \sqrt{BC}$.

If $A \propto B$, and $m$ is any given number, $A \propto mB$.

If $A \propto B$; then $A^a \propto B^{b}$; or $A^{\frac{a}{b}} \propto B^{\frac{a}{b}}$.

If $A \propto a$, and $M \propto m$; then $AM \propto am$.

If $A \propto BC$; then $B \propto \frac{A}{C}$, and $C \propto \frac{A}{B}$.

If $A \propto B$; then $A \propto \frac{1}{B}$, and $B \propto \frac{1}{A}$.

If $A \propto B$, and $C \propto D$; then $AC \propto BD$.

Wood’s Algebra.

VARIATION, Calculus of, is a department of the modern analysis, which we owe, as a distinct branch, to the inventive genius of Lagrange, who published his first memoir on this subject in the second volume of the Transactions of the Academy of Sciences of Turin, in 1762; and his second memoir, published in the fourth volume of the same Transactions, in 1770, gave to this theory a perfection and generalization far beyond what it was supposed capable of possessed. This method was also in the interval illustrated in the most simple and elementary manner by the celebrated Euler, in the Memoirs of the Academy of Sciences at Peterburgh for 1764, as it was afterwards in the third volume of his Calcul Integral, and again in the Acta Petro, for 1771. Since that time it has been treated of by different authors at greater or less extent; and to Mr. Woodhouse, of Cambridge, we are indebted for a very neat little volume, in which this subject is handled in a very clear and perspicuous manner, from which work we have already given a few extracts under the article ISOPEIMETRY. Boffut, also, in vol. ii. of his “Traité de Calcul Differentiel et de Calcul Integral,” has a very periphrastic chapter on the calculus of variations, of which we shall avail ourselves in the present instance.

Let there be any indefinite expression or function compounded of variable and constant quantities, which changes its value by the increase or diminution of one or more of the elements which it contains: it will thus undergo a variation, and the method of finding this is what is called the calculus of variations.

In the same manner as $x$ is made to denote the fluxion of $x$, and $d$ the differential of $x$; so $\delta x$ is used to indicate the variation of $x$; and the fundamental rules of this calculus are founded on the same principles as those of the differential calculus: at the same time, however, it is necessary to guard against confounding the one with the other. A very simple example will shew clearly the distinction that must be made between the two cases.

Let us suppose the equation $y^2 = ax$, which denotes the relation between the absciss $A P = x$, and ordinate $PM = y$, of a parabola $AM$ (Plate XIII. Analyse, fig. i.), $a$ being the parameter. By drawing $PM$ indefinitely near to $PM$, and $MR$ parallel to the axis $AV$; the line $LP$, or $MR$, will represent the differential $dx$, and $MR$ the differential $dy$; and the relation of these differentials is found by the differentiation of the equation $y^2 = ax$, which gives

$$2y dy = ad x, \text{ or } dy = \frac{a dx}{2y}, \text{ or } dy = \frac{ad x}{2 \sqrt{ax}}.$$

Let us conceive now that the equation $y^2 = ax$, vary by the indefinitely small augmentation of its parameter $a$, which is one of its elements; and let us construct a second parabola $AN$, which has $a + \delta a$ for its parameter. Then supposing the absciss $AP$ to continue the same for both parabolas, it is obvious that the ordinate $PN$, of the parabola $AN$, will have for its value the primitive ordinate $PM$, augmented by the small quantity $MN$, which therefore represents the variation that the ordinate $PM$ undergoes in consequence of the variation of the parameter $a$; hence, in representing by $\delta y$ the variation of $y$, as that of $a$ is denoted by $a + \delta a$, the new equation will be $(y + \delta y)^2 = (a + \delta a)x$; from which subtracting the original equation $y^2 = ax$, we shall have (neglecting, as in the differential calculus, the variations of the second order) $2y \delta y = ax \delta a$, or $\delta y = \frac{ax \delta a}{2y}$, or $\delta y = \frac{\sqrt{ax} \delta a}{2\sqrt{ax}}$, an equation which exhibits the relation of the variations $\delta a$ and $\delta y$.

If, also, we make the absciss $AP$ vary by the indefinitely small quantity $Pp = \delta x$, the corresponding ordinate for the parabola $AN$ will be $q\eta$, and the line $\delta x$ will represent the variation of the primitive ordinate $PM$. Now to find the relation between the variations $\delta x$, $\delta y$, $\delta p$, we must substitute in the equation $y^2 = ax, (a + \delta a)$ for $a$, 

$$\sqrt{x + \delta x} = \sqrt{a + \delta a},$$
(x + \delta x) for x, and (y + \delta y) for y, and the equation becomes

\[(y + \delta y) = (a + \delta a) (x + \delta x)\]

from which subtracting \(y = ax\), we shall have

\[2y \delta y = x \delta a + a \delta x\]

therefore,

\[\delta y = \frac{x \delta a + a \delta x}{2y}\]

which is an expression for the variation \(\delta y\) of the ordinate \(PM\).

In this example, (and the same has place for all similar equations,) the parameter \(a\), and its variation \(\delta a\), are constant quantities for the entire parabolas, while those of the co-ordinates \(P\) and \(A\) continually change; the changes, therefore, relative to the same parabola belong to the differential calculus, and those which result from the passage of one parabola to another, to the calculus of variations. Any one of the variations \(\delta x, \delta y, \delta a, \delta y\), may be arbitrarily assumed; as, for example, we may suppose \(\delta x = dx\), but this supposition being once made, the values of the other variations must be subordinate to this, and we cannot therefore afterwards make \(\delta y = dy\), or \(\delta y = \delta a\).

There is no difficulty in determining the variations of every order for algebraical and circular quantities, and common exponents; the operations being exactly the same as in the differential calculus; we therefore obtain the variations by the same rules, and have only to write \(\delta\) instead of \(d\), and in this respect the calculus of variations return again to the differential calculus; but this latter will not be sufficient when it is required to determine the variation of a function, which contain in themselves the sign of integration; thus, for example, let the integral formula be \(\int V \, dx\), where \(V\) is any function of \(x, y, z\), and \(x, y, z\), constant quantities; we difference this by omitting the sign \(f\); that is, \(d (\int V \, dx) = V \, dx\); but the expression \(\delta (\int V \, dx)\) is very different, as we shall see in what follows.

Now the principal object of the calculus of variations, is to determine the variation of these sorts of integral formulae; let us, therefore, endeavour to establish the principles which are to serve as the basis of this research.

First Principle.—The variation of a differential is equal to the differential of a variation, and reciprocally; that is, we shall have \(\delta dx = d\delta x\).

For let us suppose that the variable \(x\) represent the ordinate of a curve; then this ordinate will change by differentials while it belongs to the same curve, and by variations in passing from the proposed curve to the curve indefinitely near to the first. In the primitive curve, let \(x\) be the concentric value to \(x\), and consequently \(x' = x + d\, x\), or \(x = x' - d\, x\). Now taking the variation of this last equation, we shall have \(\delta x = \delta x' = \delta x\); and in the same manner \(x\) and \(x'\) are concentric values in the series of \(x'\)'s, we may consider \(x\) and \(x'\) as concentric values in the series of \(x'\)'s, so that \(\delta x = x' + \delta x\), or \(\delta x = x' - \delta x\); thus in equating these two values of \(x' - \delta x\), we shall have \(\delta x = dx\).

Hence if we express which contains any number of \(dx\) and \(dy\)'s affecting one and the same variable, we make these characteristics change place at pleasure; for we have seen that \(\delta dx = dx\); and in the same manner, we may for \(\delta dx\) write \(d\delta x\), or \(d\delta x\); and for \(\delta dx\) we may write \(d\delta x\), or \(d\delta x\), or \(d\delta x\), and so on of others.

Second Principle.—The variation of an integral formula is equal to the variation of its differential; that is, \(\delta f = f'\delta x\).

Let \(f = z\), and consequently \(\delta z = dz\), we shall have by taking the variations \(\delta z = d\, z\), or \(\delta z = dz\); and integrating this last equation, we obtain \(\delta z = dz = \delta f\).

Hence in general integrations, we change at pleasure the signs \(f\) and \(\delta z\); for we have seen that \(\delta f = f'\delta x\); and in the same manner, \(\delta f = f'\delta x\); so also \(\delta f'\delta z = f'f'\delta x\); and so on of others.

On the Method of determining the Variations of indefinite integral Formulas.—By indefinite integral formulae, is here to be understood those expressions which contain the sign \(f\), and such at the same time that the integration cannot be effected; these formulae are said to be simple, when they contain only one sign \(f\), and compounded, when they contain two or more such signs, or when they are any function of simple integral formula, combined or not with algebraical quantities, by addition, multiplication, or division.

Let us begin by considering those formulae which contain only two variable quantities \(x\) and \(y\), and between which we shall always suppose the relation \(d\, y = p\, dx\), \(d\, q = q\, dx\), \(d\, r = r\, dx\), \&c., a supposition which it will be very necessary to bear in mind.

Problem I.

To investigate a general rule for determining the variation of any indefinite integral formula \(f \, dx\).

Whatever may be the quantity \(\pi\), we have always from the second principle given above, \(\delta f = \frac{x}{\pi} = f'\delta x\); but \(\delta f = \delta (\pi \, dx) = \pi \, dx + \pi \, d\, x\); and the first principle gives \(\delta d\, x = \delta x\); whence \(\delta f = f'\delta x = f' \, d\, x + f'_d \, dx\).

Now by the method of integrating by parts, the last term

\(\int f' \, dx = \pi \, dx - \int f \, dx\)

whence by substitution,

\[\delta f = \frac{\pi}{\pi} \delta x = \pi \, d\, x + f' \, d\, x \]

Now the different values that we may attribute to \(\pi\), will give rise to different general problems; of which we shall develop a few of most common use, and which will open the way to others of a higher kind.

Problem II.

To determine the variation of the indefinite simple integral \(\int V \, dx\), \(V\) being a given function of \(x, y, z, p, q, r, \&c\).

Firstly, by the preceding problem we have

\[\delta \int V \, dx = V \, dx + \int (d\, x \, dV - d\, V \, dx)\]...

Again, the quantity \(V\) being a function of \(x, y, z, p, q, r, \&c\).

Multiply the first of these equations by \(\delta x\), the second by \(d\, x\), and subtract the first product from the second, and we shall have

\[d\, x \, \delta V - d\, V \, \delta x = N \, (d\, x \, \delta y - d\, y \, \delta x) + P \, (d\, x \, \delta p - d\, p \, \delta x) + Q \, (d\, x \, d\, q - d\, q \, dx) + R \, (d\, x \, \delta r - d\, r \, \delta x) + K\]
If now we put for $\frac{dy}{dx}, \frac{d\delta y}{d\delta x}, \frac{d\beta y}{d\beta x}, \text{ &c.}$ their values
\[ \begin{align*}
\frac{d}{dx} \delta V &= \frac{d\beta V}{d\beta x} = \\
\{ N \frac{d}{dx} (\delta y - \beta \delta x) + P \frac{d}{dx} (\delta y - \beta \delta x) + Q \frac{d}{dx} (\delta y - \beta \delta x) + &c. \\
& \int N \frac{d}{dx} (\delta y - \beta \delta x) + P \frac{d}{dx} (\delta y - \beta \delta x) + Q \frac{d}{dx} (\delta y - \beta \delta x) + &c.
\end{align*} \]
Consequently our equation (A) becomes
\[ \begin{align*}
\int \delta V \frac{d}{dx} &= V \frac{d}{dx} + \int \{ N \frac{d}{dx} (\delta y - \beta \delta x) + P \frac{d}{dx} (\delta y - \beta \delta x) + Q \frac{d}{dx} (\delta y - \beta \delta x) + &c. \\
& \int V \frac{d}{dx} + \int \{ N \frac{d}{dx} (\delta y - \beta \delta x) + P \frac{d}{dx} (\delta y - \beta \delta x) + Q \frac{d}{dx} (\delta y - \beta \delta x) + &c.
\end{align*} \]
This being established, let us make $\frac{d}{dx}$ and $\frac{d}{d\delta x}$, (a substitution that will be employed in what follows,) and differencing, we shall have
\[ \delta y - \beta \delta x = d \frac{d}{d\delta x} w. \]
But the formula $\delta y = \beta \frac{d}{d\delta x}$ gives, by taking the variations,
\[ \begin{align*}
{\delta d y} &= \beta \frac{d}{d\delta x} \beta \delta x + \beta \frac{d}{d\delta x} \beta \delta x, \text{or} \\
{\delta d y} &= \beta \frac{d}{d\delta x} \beta \delta x + \beta \frac{d}{d\delta x} \beta \delta x, \text{or} \\
{\delta d y} &= \beta \frac{d}{d\delta x} \beta \delta x + \beta \frac{d}{d\delta x} \beta \delta x.
\end{align*} \]
Whence, making the necessary substitutions, we obtain finally
\[ \begin{align*}
\int \frac{d}{dx} \delta w \left( N \frac{d}{dx} + \frac{d^2 Q}{d x^2} - \frac{d^2 R}{d x^2} + &c. \right) \\
+ V \frac{d}{dx} \beta \delta x + \beta \frac{d}{d\delta x} \left( P \frac{d}{dx} + \frac{d^2 R}{d x^2} - &c. \right) \\
+ \frac{d^3 Q}{d x^3} + \frac{d^3 R}{d x^3} + &c. \ldots \ldots (D)
\end{align*} \]
a formula in which $\frac{d}{dx}$ is supposed constant.
It will be seen from this expression for the variation $\delta V \frac{d}{dx}$, that it includes two distinct orders of terms, the one affected with the sign $\delta$, and the other free from it. And further, that the integration by parts necessarily introduces certain constant quantities which must be annulled to the terms of the latter species. The aggregate of the terms affected with the sign $\delta$ extends through all the variation, viz. from its commencement to its termination, while the other quantities answer only to the beginning and end of the variation. This remark finds its application in the treating of the maxima and minima of quantities.

**Prob. III.**

To determine the variation of the indefinite compound integral $\int Z \frac{d}{dx}$, $Z$ being a given function of the indefinite simple integral formula $\int V \frac{d}{dx}$, where again $V$ is a function of $x, y, z, \beta, \gamma, \delta, \text{ &c.}$ as in the preceding problems.

First by Prob. 1.
\[ \delta Z \frac{d}{dx} = Z \frac{d}{dx} + \int \left( d \frac{d}{dx} Z - d Z \frac{d}{dx} \right) \ldots \ldots (E) \]
And supposing $\int V \frac{d}{dx} = t$, or $V \frac{d}{dx} = d t$; since $Z$ is by hypothesis a function of $t$, we shall have $d Z = T \frac{d}{dt} t$; therefore
\[ \begin{align*}
\delta Z \frac{d}{dx} &= T \frac{d}{dt} t - T \frac{d}{dx} \frac{d}{dt} t. \\
\text{Consequently we have} \quad \delta \int Z \frac{d}{dx} &= Z \frac{d}{dx} + \int \left( \frac{d}{dx} \frac{d}{dt} V - d V \frac{d}{dx} \right) \ldots \ldots (F)
\end{align*} \]
Now integrating the last term by parts, and representing the integral $\int T \frac{d}{dx} b$ by $b$, for the sake of abbreviating, the preceding equation becomes (F)
\[ \delta \int Z \frac{d}{dx} = Z \frac{d}{dx} + b \int \left( \frac{d}{dx} \frac{d}{dt} V - d V \frac{d}{dx} \right) - b \int \left( \frac{d}{dx} \frac{d}{dt} V - d V \frac{d}{dx} \right). \]
This being premised, and making here for the values of \(dV\) and \(\delta V\) the same suppositions, and the same calculations as in the preceding problem, we shall obtain
\[
b \int (dx \delta V - dV \delta x) = 
\]
\[
b \int dx \delta w \left( N - \frac{dP}{dx} \frac{d^2 Q}{dx^2} - \frac{d^3 R}{dx^3} + &c. \right) + 
\]
\[
b \delta w \left( P - \frac{dQ}{dx} \frac{d^2 R}{dx^2} + \frac{d^3 R}{dx^3} - &c. \right) + 
\]
\[
\frac{bd^2 \delta w}{dx} \left( Q - \frac{dR}{dx} + &c. \right) 
\]
\[
\frac{bd^3 \delta w}{dx^3} \left( R - &c. \right) \ldots \ldots (G) 
\]

And we shall find in the same manner, by putting \(b\) \(N\) for \(N\), \(b\) \(P\) for \(P\), \(b\) \(Q\) for \(Q\), &c.

\[
b \int (dx \delta V - dV \delta x) = 
\]
\[
b \int dx \delta w \left( bN - \frac{d(bP)}{dx} \frac{d^2 (bQ)}{dx^2} - \frac{d^3 (bR)}{dx^3} + &c. \right) + 
\]
\[
b \delta w \left( bP - \frac{d(bQ)}{dx} \frac{d^2 (bR)}{dx^2} + \frac{d^3 (bR)}{dx^3} - &c. \right) + 
\]
\[
\frac{bd^2 \delta w}{dx} \left( bQ - \frac{d(bR)}{dx} + &c. \right) + 
\]
\[
\frac{bd^3 \delta w}{dx^3} \left( bR - &c. \right) 
\]

Finally, substituting in Equation \((G)\), instead of \(b \int (dx \delta V - dV \delta x)\) and \(b \int (dx \delta V - dV \delta x)\), their values, which we have found above, we shall have the expression for the variation of \(\delta f/Z \, dx\).

As in these sorts of problems, it is required to find the variation which answers to a given absciss \(a\), it is evident that in denoting by \(H\) the integral \(f/T' \, dx\), corresponding to this absciss, we may regard \(H\) as a given constant quantity relative to the total variation, while \(b\) constantly represents the indefinite integral \(\frac{f}{T'} \, dx\), that is to say, the integral for an indeterminate part of the absciss \(a\).

Then, in writing \(H\) for \(b\) in the part
\[
b \int (dx \delta V - dV \delta x), 
\]
and passing \(H\) under the sign of integration, the expression
\[
b \int (dx \delta V - dV \delta x) - \int (dV \delta x) = 
\]
will become
\[
\int (H - b) (dx \delta V - dV \delta x). 
\]

If, for the sake of abridging, we make \(H - b = k\), which gives \(d(H - b) = dk\), \(H\) being constant; now, making conformably to these remarks, and to these abbreviations, the substitutions indicated at the end of the preceding article for equation \(G\), we shall find that this equation becomes

\[
\delta f/Z \, dx = \left\{ f \frac{dx}{dV} \left( kN - \frac{d(kP)}{dx} \frac{d^2 (kQ)}{dx^2} - \frac{d^3 (kR)}{dx^3} + &c. \right) + 
\right.
\]
\[
+ Z \delta x + k \delta w \left( kP - \frac{d(kQ)}{dx} \frac{d^2 (kR)}{dx^2} + &c. \right) + 
\]
\[
+ \frac{k \delta^2 w}{dx} \left( kQ - \frac{d(kR)}{dx} + &c. \right) + 
\]
\[
+ \frac{k \delta^3 w}{dx} \left( kR - &c. \right) \ldots \ldots (H) 
\]

and thus Equation \(I\) becomes
\[
\delta f/Z \, dx = Z \delta x + f \left\{ L' \frac{dx}{dV} \left( dx \delta V - dV \delta x \right) \right\} + 
\]
\[
+ f \left\{ N' \frac{dy}{dx} \left( \delta y - \frac{dP}{dx} \delta x \right) \right\} + 
\]
\[
+ P' \frac{dx}{dV} \left( \delta p - q \delta x \right) + Q' \frac{dx}{dV} \left( \delta q - r \delta x \right) + 
\]
\[
+ R' \frac{dx}{dV} \left( \delta r - s \delta x \right) + &c. \ldots \ldots (K) 
\]

Prob. IV.

To determine the variation of the indefinite integral formula \(\int f/V \, dx\), \(Z\) being a function of \(x, y, p, q, r, &c.\); and of the indefinite simple integral formula \(\int V \, dx\), where \(V\) is the same as before.

First, we have
\[
\delta f/Z \, dx = Z \delta x + f \left\{ dx \delta Z - dZ \delta x \right\} \ldots \ldots (I) 
\]

Let us suppose \(f/V \, dx = t\), or \(V \, dx = dt\). The quantity \(Z\) being given in \(t\), \(x, y, p, q, &c.\), we shall have
\[
dZ = L'dt + M'dx + N'dy + P'dp + Q'dq + &c. 
\]
\[
\delta Z = L'd \delta t + M'd \delta x + N'd \delta y + P'd \delta p + Q'd \delta q + &c. 
\]

expressions in which the quantities \(L', M', &c.\) are functions of \(t, x, y, p, q, &c.\).

When we draw, by a proceeding similar to that which has been employed in the second problem,

\[
dx \delta Z - dZ \delta x = L'(dx \delta t - d \delta dx) + N' dx \delta y - p \delta dx \right) + 
\]
\[
+ P' dx \delta (\beta p - q \delta x) + Q' dx \delta (\beta q - r \delta x) + 
\]
\[
+ R' dx \delta (\beta r - s \delta x) + &c. 
\]

But \(dt = V \, dx\), and \(dx \delta t = f/V \, dx = \delta V \, dx + f(dx \delta V - dV \delta x)\); therefore
\[
L'(dx \delta t - d \delta dx) = L'dx (dx \delta V - dV \delta x); 
\]
If now, as in the second problem, we make
\[ dV = Mdx + Ndy + Pdp + Qdq + \&c. \]
we shall have
\[ dx \delta V - dV \delta x = Ndx(\delta y - p \delta x) + Pdx(\delta p - q \delta x) + Qdx(\delta q - r \delta x) + Rdx(\delta r - s \delta x) + \&c. \]
Substituting, in equation (K), instead of \( \int_1^2 dx \) (\( d \times \delta V - dV \delta x \)), its actual value \( \int_1^2 (dx \delta V - dV \delta x) \), and instead of \( \delta x \delta V - dV \delta x \), the value assumed above, reuniting the several parts, and for the sake of abridging, making \( N' + N'' = N' + N'' + K'P + P' = P'' + K'Q + Q' = Q'' \&c. \) this equation will become
\[ \delta \int Z dx = Z dx + \{ N'' dx (\delta y - p \delta x) + P'' dx (\delta p - q \delta x) \}
\[ + Q'' dx (\delta q - r \delta x) + R'' dx (\delta r - s \delta x) + \&c. \}
\[ = Z \delta x + \int N'' dx (\delta y - p \delta x) + \int P'' dx (\delta p - q \delta x) \]
\[ + \int Q'' dx (\delta q - r \delta x) + \int R'' dx (\delta r - s \delta x) + \&c. \]
An equation which, being of the same kind as Equation (B), Prob. II, will give in the same manner, by making \( \delta y - p \delta x = \delta w \), and supposing \( dx \) constant,
\[ \delta \int Z dx = \left\{ \begin{array}{l}
\int dx \delta w (N'' - \frac{d P''}{dx} + \frac{d^2 Q''}{dx^2} - \frac{d^3 R''}{dx^3} + \&c.)
\int Z dx + \int \frac{\delta w}{dx} (P'' - \frac{d Q''}{dx} + \frac{d^2 R''}{dx^2} - \&c.)
\int Z dx + \int \frac{\delta w}{dx} (Q'' - \frac{d R''}{dx} + \&c.)
\int Z dx + \int \frac{\delta w}{dx} (R'' - \&c.) + \&c. \ldots \ldots (L)
\end{array} \right. \]
It may be remarked here, the same as in Problem II, that the expression of this variation includes two distinct species of terms; viz. those which are affected with the sign \( \delta \), and those that are free from it; and moreover, that the integrating by parts introduces certain constant quantities, which are additive to the terms of the second species; and that the aggregate of the terms affected with the sign \( \delta \) extends through all the variation, viz. from the place where it commences to that where it finishes; while the other terms answer only to the beginning and end of the variation.

Probl. V.

To determine the variation of the indefinite simple integral \( \int V dx \), where \( V \) is any given function of three variables \( x, y, z \), and their differentials.

We shall have at first, the same as in the formula of two variables,
\[ \delta \int V dx = V \delta x - \int (dx \delta V - dV \delta x) \ldots \ldots (M) \]
Let us suppose \( dx = P dx, \delta p = q dx, \delta q = r dx, \delta r = s dx, \&c. \) the letters \( p, q, r, \&c. \) \( \delta p, \delta q, \delta r, \&c. \) \( \delta p', \delta q', \delta r', \&c. \) expressing functions of \( x, y, z \), and their differentials.

Now making
\[ dV = \left\{ M dx + Ndy + Pdp + Qdq + Rdr + \&c. \right\} \]
\[ + F dx + Gdp + Hdq + Idr + \&c. \]
and hence, also,
\[ \delta \int V dx = \left\{ M \delta x + N \delta y + P \delta p + Q \delta q + R \delta r + \&c. \right\} \]
\[ + F \delta x + G \delta p + H \delta q + I \delta r + \&c. \]
expressions in which \( N, M, P, Q, R, \&c. \) \( F, G, H, I, \&c. \) are given functions of \( x, y, z, p, q, r, \&c. \) \( p', q', r', \&c. \) \( \&c. \) we shall find
\[ dx \delta V - dV \delta x = \]
\[ N dx (\delta y - p \delta x) + P dx (\delta p - q \delta x) + Q dx (\delta q - r \delta x) + R dx (\delta r - s \delta x) + \&c. \]
\[ F dx (\delta p - q \delta x) + G dx (\delta q - r \delta x) + H dx (\delta r - s \delta x) + I dx (\delta s - t \delta x) + \&c. \]

To which it will be necessary to add certain terms, in order to complete the integral, as stated in the conclusion of our second and last problem.

The formulæ above considered are the simplest of their kind, and the solution of them is found by a calculation comparatively direct and easy to perform; but it may happen, that in the general expression \( \int Z dx \), of which the variation is required, the quantity \( Z \) is a function of many variables, consisting of algebraical expressions and various indefinite simple integrals; or the quantity \( Z \) may depend upon the integration of an equation of any order; it may also, in some cases, be required to find the variation of a formula under a double...
a double or triple, &c. sign of integration, as \( \int f(x) \, dx \), in which \( Z \) is any function of \( x \) and \( y \), and so of others. In all these cases, except the last, the variations are determined in the same manner, but the calculus of finite becomes more long and intricate, which our limits will not allow of our entering upon in this place. On this head, therefore, the reader is referred to the several works mentioned in the introduction to the present article. We only propose giving here one problem, by way of illustrating the preceding calculus; viz.

To determine the curve OMD (Plate XIII. fig. 2.) through which a body will pass from the point \( O \) to \( D \), not in the same vertical line, in the shortest time possible.

Let \( A \) the vertical plane, in which are situate the two given points \( O \) and \( D \); \( A \) the axis of the abscissas; and the horizontal line \( A \) that of the ordinates. Also, let us suppose an abscissa \( A = x \), the ordinate \( P \) \( M = y \), and consequently the element of the arc \( \sqrt{dx^2 + dy^2} = \sqrt{(1 + p') \cdot dx} \), making \( dy = p \, dx \).

Now whatever may be the nature of the curve OMD, the velocity of the body along and in the direction of the element of the curve \( Mm \), is equal to that which would have acquired in falling from a certain vertical height; all these heights deriving their origin in the same horizontal line, which we may suppose to be the axis of the ordinates \( A \), the position of this axis being arbitrary.

Thus, calling \( g \) the gravity of the body, the velocity along \( Mm \) will be expressed by \( \sqrt{2 \, g \times} \), and consequently the time in passing \( \sqrt{dx^2 + dy^2} = \sqrt{(1 + p') \cdot dx} \); therefore we shall have

\[
\int \sqrt{(1 + p')} \, dx = a \, \text{minimum},
\]

or, simply

\[
\int \sqrt{\frac{dy}{dx}} = a \, \text{minimum}.
\]

Now generally, when a quantity becomes a maximum or a minimum, its variation is equal to zero; consequently we shall have

\[
\frac{d}{dx} \int \sqrt{(1 + p')} = 0.
\]

Now this agrees with our formula \( \int \sqrt{\frac{dy}{dx}} \, dx \) in the second problem; viz. in the present case \( V = \sqrt{(1 + p')} \); consequently we shall have \( dV = -\frac{p}{2 \, \sqrt{(1 + p')}} \cdot dx + \frac{\sqrt{\frac{dy}{dx}}}{\sqrt{(1 + p')}} \cdot dp \); an expression which, being compared with the general value

\[
dV = M \, dx + N \, dy + P \, dp + \text{&c.}
\]

gives here

\[
M = -\frac{\sqrt{(1 + p')}}{2 \, \sqrt{(1 + p')}}; \quad N = 0;
\]

\[
P = \frac{p}{\sqrt{\frac{dy}{dx}} \cdot \sqrt{(1 + p')}}; \quad Q = 0, \quad R = 0, \quad \text{&c.}
\]

Now the expression of the variation \( \frac{d}{dx} \int \sqrt{\frac{dy}{dx}} \, dx \) comprehends generally, as we have seen in Equation (D), two parts, the one indefinite, containing the sign \( \int \), and the other definite, in which that sign is not found; and it is evident that these two parts are wholly independent of each other; and consequently, if the whole is equal to zero, these two parts are each also equal to zero; thus the equation \( \int \sqrt{\frac{dy}{dx}} \, dx = 0 \), gives in general the two following equations, of which the one is definite, and the other indefinite; viz.

\[
(1) \quad 0 = \int d \sqrt{(N - \frac{dp}{dx} + \frac{dp^2}{dx^2} - &c.)}
\]

\[
(2) \quad 0 = \left\{ \begin{array}{l}
\sqrt{\frac{dy}{dx}} \left( P - \frac{dQ}{dx} + \frac{d^2R}{dx^2} - &c. \right) \\
\frac{dp}{dx} \left( Q - \frac{dR}{dx} + &c. \right) \\
\quad & + \frac{d^3R}{dx^3} & + C, \, \text{correction.}
\end{array} \right.
\]

Equation (1) is that on which depends the nature of curves, since the second member of this equation is an indeterminate expression, which, being made equal to zero, gives to the curve OMD the character of a maximum or a minimum.

As to Equation (2), it belongs only to the extreme points of the curve OMD, which may be subject to particular conditions, wholly independent of the nature of the curve.

Now differencing Equation (1), and dividing the whole by \( \frac{dx}{dx} \), we shall have

\[
(3) \quad 0 = \frac{dp}{dx} - \frac{d^2Q}{dx^2} - \frac{d^3R}{dx^3} + &c.
\]

which gives generally the solution of the problem, where only the nature of the curve is required, that renders \( \int V \, dx \) a maximum, or a minimum; \( V \) being a function of the perpendicular co-ordinates \( x \) and \( y \) of the curve, and of the quantities \( p, q, r, &c. \) which are given by the hypothesis \( dy = p \, dx, dp = q \, dx, &c. \) remembering that the differential \( dx \) has been supposed constant.

Now to apply these general results to our problem; since we have \( N = 0 \), and \( P = \frac{dp}{dx} \cdot \sqrt{(1 + p')} \); also \( Q = 0, R = 0, &c. \) our Equation (3) becomes

\[
\frac{dp}{dx} = \frac{1}{\sqrt{x} \cdot \sqrt{(1 + p')}} \cdot \sqrt{\frac{dy}{dx}}, \quad \text{or}, \quad \frac{dp}{dx} = \frac{1}{\sqrt{x} \cdot \sqrt{(1 + p')}} \cdot \sqrt{\frac{dy}{dx}}.
\]

which is the differential equation of the curve OMD; consequently, by integrating we shall have

\[
\frac{1}{\sqrt{a}} = \frac{1}{\sqrt{x} \cdot \sqrt{(1 + p')}} \cdot \sqrt{\frac{dy}{dx}} = \frac{1}{\sqrt{a}} \cdot \sqrt{\frac{dy}{dx}}
\]

which gives

\[
\frac{dy}{dx} = \frac{x}{\sqrt{a - x}}.
\]

the equation of the reversed cycloid, its base being horizontal, and its generating circle having for its diameter the constant quantity \( a \).

This equation being integrated, will receive a second arbitrary constant \( b \); and we shall have then, in the final equation, two constants, \( a \) and \( b \), which will be determined from the condition that the cycloid passes through the two points, 0 and D.
O and D, given in position. For other examples illustrative of this calculus, see the article Isoperimetry.

Variation, in Music, is the different manner of playing or fingling the same air, tune, or song, either by subdividing the notes into several others of less value, or by adding graces, in such a manner, however, as that the tune itself may still be discovered through all its embellishments, which the French call broderies.

Thus, great masters of the last century, flattering the bad taste of the public, have condescended to make variations to old tunes; as Corelli to Tartini's ground, or "All Joy to great Cæsar," which the Italians call "La Follia d'Espagna," and which he has made the theme of his whole twelfth folio. Handel and Tartini have composed simple airs on purpose to be the ground-work of variations. The late John Christian Bach, Fitcher, Giardini, &c., have varied Scotch and Irish tunes to corrupt the public taste, instead of improving it by new compositions, which would have done them more credit, and given them less trouble. See Theme and Double.

"All Paris," says Roux, "used to go to the concert spirituel, to hear the variations of Mefiers. Guignon and Mondenville; and still at a more recent period, those of Meffis. Guignon and Gaviniès, to the tunes of the Pont-neuf, which had no other merit than that of being trifled with by the two greatest performers on the violin in France."

VARICA, in Ancient Geography, a town of Abatic Iberia, according to Ptolemy.

VARICELLA, in Medicine, a diminutive of Varicela, (the small-pox,) signifying a vesicular eruption, accompanied with flight febrile symptoms, and occurring but once in the period of human life, which is popularly termed chicken-pox and small-pox.

It will not be matter of surprize if this disease should bear the name of a lesser small-pox, and that it should have been described by the elder writers as a modification of that distemper, under various simlar appellations, such as varicela varicellae, varicelle, &c.; when we are informed by a late acute investigator of disaeas, Dr. Willan, that, from the year 1800, to the time of the publication of his essay on vaccination, in 1806, he had seen seventy-four cases of chicken-pox that had been mistaken for small-pox, after vaccine inoculation. It is true, indeed, that the diffion has been rendered somewhat more difficult, in consequence of the milder degree, shorter duration, and modified form, which the small-pox itself has been made to assume by the influence of the previous cow-pox, in the fewcases where it has occurred after this disease. Nevertheless, the remembrance is sufficient at all times to mislead ordinary observers; and the foreign nofolists, from Sauvages down to Burfeurius, have confidered the diseaee as a species of varicela. (See Sauvages Nofol. Method. clafs iii. gen. 2. Vogel, De Cognocendo. et Curand. Hominum Morbis, § 128. Burfeurius, Inf. Med. vol. ii. cap. 9.) It is singular, however, that not only some of the earliest Italian writers on the small-pox, who lived three centuries ago, have distinctly described the chicken-pox under a specific name, corysphili, and with the mention of the scarcely perceptible fever, and absence of all danger (see Vidus Vidianus, De Crystallis; and Ingraffias de Tumoribus pronter Naturam, lib. i. cap. 11;) but that the vulgar, in several countries of Europe, had distinguished it by popular appellations, even while physicians were regarding it as a modification of small-pox. Thus Daniel Senett, who was a professor at Wittemberg at the commencement of the seventeenth century, observes, in his Treatise on Small-pox and Measles, that there are other varieties, "prater cornmunes variolos et morbillos," which are popularly known in Germany by the terms schaffsklattern (sleep-pox, or sleep-bles or blains) and windbollen (wind-pox). (See his Med. Pract. lib. iv. cap. 12.) And Riverius, who was professor at Montpellier at the same period, speaks of it as familiarly known by the common people in France by the name of varicelle. (See his Praxis Med. cap. ii.) In Italy it was also known to the vulgar under the appellation of ravaoglone. Again, in our country, Fuller, who published his "Examinations" in 1730, acknowledges himself indebted to the old women for his appellation. "I have ventured to think," he says, "this is what among our women goeth by the name of chicken-pox." (P. 161.) Other popular names have been given to this disease in different parts of this country. Thus it is in many places called small-pox; in some, hives; and at Newcastle and Sunderland, water-jugs. (See Dr. Wood in the Med. and Phyf. Journal, vol. xii. p. 58.) In some places, however, the different forms which this disease itself assumes, three of which have been distinctly described by the late ingenious Dr. Willan, are designated by the terms chicken-pox, small-pox, and hives, respectively.

The character of each of these varieties, under which the varicella occasionally appears, we shall copy from the work of that excellent observer of diseases, as there is no other description of them extant of equal accuracy; and it is highly necessary to be able to discriminate between this eruption and the milder forms of small-pox, as especially that modified and altered varicella which sometimes succeeds vaccination. The only other account of the chicken-pox in our language, which bears the stamp of observation, is a paper of the late excellent Dr. Heberden, another physician of the true Hippocratic school, written in the year 1767, and published in the first volume of the Transactions of the College of Physicians, and which we shall have occasion also to quote, on the point of diagnosis, in the sequel of this article.

Dr. Willan observes, "there are three varieties of the varicella, which, from the different forms of the vehicles, may be entitled the lenticular, conoidal, and globate." And he adds, in a note, "In the northern parts of England, and in some counties of Scotland, these varieties are denominated the chicken-pox, the small-pox, and the hives. In the south, the latter varieties are called flame-pox.

1. "The lenticular varicella exhibits, on the first day of eruption, small red protuberances, not exactly circular, and having a flat shining surface, in the centre of which a minute vehicle is soon formed. This, on the second day, is filled with a whitish lymph, and it then somewhat resembles a milky vehicle, but is not so prominent, so tenue, or so regularly circumscribed: its diameter is about the tenth of an inch.

2. On the third day, the extent of the vehicles continues the same, but the lymph which they contain becomes straw-coloured. On the fourth day, many of the vehicles are broken at the most prominent part; the rest begin to shrive, and are puckered at their edges. Few of them remain entire on the fifth day, but the orifices of several broken vehicles are closed, or adhere to the skin, so as to confine a little opaque lymph within the puckered margins. On the fifth day, small thin brown scabs appear universally in the place of the vehicles.

3. The scabs, on the seventh and eighth days, become yellowish, and gradually dry from the circumference towards the centre. On the ninth and tenth days they fall off, leaving for a time red marks in the skin, without depression.

"The eruption is generally first observed on the breast and back, and afterwards on the face and extremities. As fresh vehicles arise during two or three successive days, and go through the same stages as the first, the duration of the disease is sometimes longer than I have stated above."

2. "In the conoidal varicella, the vehicles rise suddenly, and have a hard inflamed border. They are, on the first day of their
VARICELLA.

their appearance, acuminated, and contain a bright transparent lymph. On the second day they appear somewhat more turgid, and are surrounded by more extensive inflammation than on the preceding day; the lymph contained in many of them is of a light straw-colour. On the third day, the vesicles are distended; those which have been broken exhibit at the top fibrillated, and formed, by a concretion of the exuding lymph. Some of the softened vesicles, which remain entire, but have much inflammation round them, evidently contain on this day purulent fluid. Every vesicle of this kind leaves, after scabbing, a durable cicatrix or pit. On the fourth day, thin dark-brown scabs appear intermingled with other vesicles, which are rounded, yellowish, and semi-transparent. These scabs gradually dry and separate, and fall off in four or five days.

"A fresh eruption of vesicles usually takes place on the second and third day, and as each set has a similar course, the whole duration of the eruptive stage in this species of varicella is six days; the last-formed scabs, therefore, are not separated till the eleventh or twelfth day.

3. "In the small-pox, or hives, the vesicles are large and globated, but their base is not exactly circular. There is an inflammation round them, and they contain a transparent lymph, which, on the second day of eruption, resembles milk-whey. On the third day, the vesicles subside, and, as in the former species, become puckered or distended. They likewise appear yellowish, a small quantity of pus being mixed with the lymph. Some of them remain in the same state till the following morning, but, before the conclusion of the fourth day, the cuticle separates, and thin blackish scabs cover the bafes of the vesicles. The scabs dry and fall off in four or five days.

"The eruption is usually completed in three days, but I have sometimes observed a few fresh vesicles on the fourth day; in which case, therefore, the eruptive stage occupied eight days.

"The fever in varicella commences two or three days before the eruption appears, and it sometimes continues to the third day of the eruption, but is generally very slight. Its symptoms are, languor, with disposition to sleep, loss of appetite, thirst, heat of the skin, occasional flushing of the cheeks, a severe cough, soreness of the throat, a white fur on the tongue, a quick but unequal pulse, pains in the head, back, and limbs, sometimes pain in the mouth and bowels, with nausea, or vomiting of bile.

"The eruption usually commences on the breast and back, appearing next on the face and scalp, and lastly on the extremities. It is attended, especially in children, with an incessant tingling or itching, which leads them to scratch off the vesicles, so that the characteristic of the disease are often destroyed at an early period. Many of the vesicles, thus broken and irritated, but not removed, are presently surrounded by inflammation, and afterwards become pustules, containing thick yellow matter. These continue three or four days, and finally leave pits in the skin. The eruption is usually fullest in the conoid form of varicella: I have seen the vesicles close together, or coherent, but seldom confluent. When they are numerous on the scalp, some of the glands below the base of the cranium are enlarged.

"The incidental appearance of pustules among the vesicles sometimes occasions a doubt respecting the nature of the eruption." See Dr. Willan’s "Treatise on Vaccination," page 86.) Dr. Heberden says, "the principal marks by which the chicken-pox is distinguished are:

1. "The appearance, on the second or third day from the eruption, of the vesicle full of serum upon the top of the pock. The pustules which are full of the yellow liquor resemble what the genuine small-pox are on the fifth or sixth day, especially when there is a larger space than ordinary occupied by the extravasated serum. It happens to most of them, either on the first day that these vesicles are formed, or on the second day, that their tender cuticle is broken; a thin scab is then formed at the top of the pock, and the swelling of the other part abates, without its ever being turned into pus, as it is in the small-pox.

2. "Slight scabs cover the chicken-pox on the fifth day; at which time the small-pox are not at the height of their suppuration.

3. "The inflammation round the chicken-pox is very great, and the contents of them do not seem to be owing to suppuration, as in the small-pox, but rather to what is extravasated immediately under the cuticle by the fleshy vessels of the skin, as in a common blister. No wonder, therefore, that this liquid appears so soon as on the second day, and that upon the cuticle being broken, it is presently succeeded by a flight scab. Hence too, as the true skin is so little affected, no mark or scar is likely to be left." See Med. Trans. of the Coll. of Physicians, vol. i. art. 16.

To these remarks Dr. Willan adds, that "various pustules, on the first and second day of their eruption, are small, hard, globular, red, and painful. The sensation of them to the touch, on passing the finger over them, is similar to that which one might conceive would be excited by the pressure of small round seeds under the cuticle. In the varicella almost every vesicle has, on the first day, a hard, inflamed margin, but the sensation communicated to the finger in this case, is like that from a round seed, flattened by pressure." He also observes that, "on the third and fourth days, the distended or wrinkled state of the vesicles which remain entire, and the radiating furrows of others, whose ruptured apices have been closed by a flight inflammation, fully characterize the varicella, and distinguish its eruption from the firm and durable pustules of small-pox. As the vessels of the chicken-pox appear in succession during three or four days, a partial examination will not always dis¬cover the characteristic here specified. In order to form a proper judgment, practitioners should inspect the eruption on the face, breast, and limbs, attending more especially to the places in which it was first observed. If the whole eruption be viewed on the fifth or sixth day, every gradation of the progress of the vesicles will appear at the same time. This circumstance may be added to the diagnostics of varicella, as it cannot take place in the flow and regulated progress of the small-pox.

"The globated vesicles not having any resemblance to various pustules, distinguish the varicella from the small-pox, whenever they appear; for it is to be remembered, that these large vesicles are occasionally intermingled, both with the lenticular and conoid vessels of the chicken-pox. It may be said, that an acknowledged co-existence of different species, of vesicles in the same pock, tends to aggravate the distinction I have made. The vesicles, however, are, in many cases, all of the same kind; or, where they are intermingled, one sort greatly predominates. I do not contend for the perfect accuracy of nosological arrangement, but I adopt it because it is in many respects convenient. SYSTEMS OF BOTANY AND ZOOLOGY are useful, though they have not been yet brought to perfection, for we find some species which break the order of every classification proposed." Loc. cit. p. 95.

With respect to the treatment of varicella, under any of its forms, very little need be said: since it is seldom attended by any severe indisposition, and often by scarcely any perceptible disorder of any of the functions, except a little lassitude and inability for the usual exertions, a quiet,
tongue, and some loss of appetite. In these cafes, the treatment consists rather in avoiding all causes of irritation, especially in the way of diet, than in the actual administration of medicines. Where the fever is more considerable, however, not only are these cautions necessary, but it will be proper also to evacuate the bowels, by gentle means, as by a little rhubarb, or neutral salts, to take dibent drinks, and gently diaphoretic medicines.

VARICOCELE, in Surgery, derived from varis, a dilated vein, and ceple, a tumour, sometimes denotes a varicoce enlargement of the veins of the spermatic chord; but, more commonly, a similar dilatation of the veins of the scrotum; the term cirrocsele being usually applied to the other affection.

Varicocele, or a varicoce enlargement of the veins of the scrotum, is a subject of but little importance; because these vessels are never thus affected, except in consequence of some other more serious dilatation of the testicle and its coats. Indeed the varicocele is to be regarded as the mere effect of another complaint, the removal of which is the only necessary indication. This having been attended to, the swelling of the scrotal veins, which was never itself a source of much inconvenience, always subsides without further trouble.

Varicocele, considered as a varicoce enlargement of the spermatic veins, is a disease that demands greater attention; but as it has been explained in a previous volume (see Circocsele), we do not mean to detain the reader with it in the present place. One remark, however, appears to merit particular attention; a varicoce swelling of the spermatic veins is more frequently than any other disease mistaken for an omental hernia. Mr. Aylo Cooper has given the following rule, by which the two diseases may be distinguished. Place the patient in a horizontal posture, and empty the swelling by prelusion upon the scrotum; then put the fingers firmly upon the upper part of the abdominal ring, and define the patient to rise; if it be a hernia, the tumour cannot reappear as long as the prelusion is continued at the ring; but if it be a circocsele, the swelling returns with increased size, on account of the return of blood into the abdomen being prevented by the prelusion. See Cooper on Inguinal Hernia.

VARICOSE VEINS. The term varis is applied by surgeons to the permanently dilated flate of a vein, attended with an accumulation of dark-coloured blood, the circulation of which is materially retarded in the affected vessel. When venas are varicoce, they are not only dilated, but they are also evidently elongated, presenting a cylinder larger than natural, irregular, and in several places fluided with knots. They likewise make a variety of windings, and, coiling themselves, form actual tumours from the assemblage of their convolutions in one particular place. The trunk and branches of a vein, thus dilated and elongated, constitute a very distinct swelling, when they are numerous, and confined to a certain part of the body. Indeed, when the dilated vessels are situated near the integuments, the surgeon can feel, and even see the outlines of their tortuous course. These things, for instance, are remarkably obvious in the vena saphena interna, where the affection is particularly common. This vessel may be observed to form in its course several of these swellings, in the interspaces of which it runs in a very serpentine tortuous manner.

Varices are most commonly observed in the lower extremities, reaching sometimes as far up as the abdomen. They have, however, been noticed in the upper extremities, and it is probable that the whole venous system is susceptible of the affection. As a well-informed writer observes, "the great venous trunks sometimes become varicocele. When the diseased vein is situated near the heart, it is attended with pulsation, which renders it liable to be mistaken for aneurism. Morgagni observed that the jugular veins were occasionally very much dilated, and possest a pulsation. (Letter xxi. art. 3, 9, 10, 11.) He also relates a case in which the vena azzygos, for the length of a span, was so much dilated, that it might be compared with the vena cava. The patient died suddenly in consequence of the rupture of this varix into the right side of the chest. (Letter xxv. art. 29.)" A similar case is related by Portal, who also mentions an instance, in which the right subclavian vein was excessively dilated, and burst into the chest. (Cours d'Anatomie Medicales, tom. iii. pp. 354-372.) Mr. Cline des cribed in his lectures the case of a woman who had a large pulsating tumour in her neck, which burst, and proved fatal by hemorrhage. A case proceeded from the internal jugular vein; the carotid artery was lodged in a groove at the posterior part of this face. The veins of the upper extremity very rarely become varicocele. Excepting cases of aneurismal varix, the only instance of this disease with which I am acquainted is mentioned by Petit. (Traite des Maladies Chir. tom. ii. p. 49.) In this case a varix was situated at the bend of the arm; the patient was so fat, that no other vein could be found for the purpose of venesection, which operation Petit repeatedly performed by puncturing this varix. The superficial epigastric veins sometimes become varicocele; but the most frequent seats of this disease are the vena saphena, the spermatic and hemorrhoidal veins."

(See Hodgson's Treatise on the Diseaues of Arteries and Veins, pp. 358, 359.) The deep-seated veins of the extremities seldom become varicocele.

The disease rarely occurs before the adult period of life, and its progress is extremely slow. It is very frequently remarked in pregnant women, who have passed a certain age; but it is particularly unusual for it to happen in young women, even during a series of repeated pregnancies. Surgeons have not hitherto made out any very precise information respecting the places, climates, and kinds of constitution which promote the occurrence of a varicoce enlargement of the veins. Nor has it been well proved, that the disease often proceeds from swellings of the abdominal viscera, or any other species of tumour capable of mechanically obstructing the venous circulation. One or more veins of the same limb are at first most commonly affected with a slight degree of dilatation, without pain, or any sensation of uneasiness. This beginning change ordinarily advances with a great slowness, except in cases where it accompanies pregnancy, in which circumstance one or both the lower extremities, as early as the fifth months, are frequently seen covered with largely dilated veins, or even with tumours formed by an assemblage of varices. The veins gradually become more and more dilated, lengthened, coiled up, and tortuous. The patient then begins to complain of a feaue of heaviness, numbness, and sometimes of very acute wandering pain through the whole of the affected limb. In a more advanced stage, in proportion as the varices increase, and especially when the dilated veins actually form tumours, the limb swells, and becomes more or less oedematous, according to the extent of the diseaue, and the time which it has existed. M. Delpech thinks, however, that the oedema in this cafe is not such as to justify the conclusion, that the increased size of the veins, and the way in which they distend the integuments, produce a mechanical interruption of the function of the absorbent system. For, says he, we meet with, though not often, enormous varices, which are not attended with any swelling of the cellular substance; and we find more frequently fee cafes, in which there is a considerable degree of oedema, while the varices are scarcely remarkable. When the latter have prevailed a long while, and made much
much progress, the coats of the affected veins are not unfrequently thickened, swelled, and indurated, forming a fort of half canal, or fold tube, which has been regarded as an excavation made by the preasure of the varix against the neighbouring bone. But the same phenomena are equally observable, when varicose veins lie at a distance from any bone, against which it can be pressed.

As Mr. Hodgson remarks, "the blood occasionally deposits stringers of coagulum in varicose veins: when this is the case, the vessel is incapable of being emptied by preasure, and is firm to the touch. The deposition does not in general fill the vessel, but, by diminishing its calibre, it retards the flow of blood, and causes the dilatation to increase in the inferior portion of the vein, and in the branches which open into it." (On the Diseases of Arteries and Veins, p. 541.) This gentleman has seen four cafes, in which the coagulum accumulated to such an extent, that the canals of the dilated vesseis were obliterated, and a spontaneous cure was the consequence.

The excessive dilatation of the coats of a superficial vein produces an inflammatory irritation, at first in the adjoining cellular membrane, and afterwards in the integuments. These organs become at first connected together by the adhesive inflammation; and if the dilatation continue to operate, they may at length ulcerate, and burst, and hemorrhage be the consequence. In such cafes, the effusion of blood has sometimes been very considerable; but, says M. Delpech, we have no example of its having proved dangerous. The lyncope following it, or a moderate compression, has sufficed for its stoppage. A more common occurrence than bleeding, is the coagulation of the blood in the cavity of a varicose vein. The veiil then becomes hard and incomprehensible, and it loses that elastic yielding softnefs, which renders it capable of being diminished by gentle preasure. If the parts be already inflamed, Delpech conceives, that the clot in the diseased vein may act as an extraneous body, and bring on ulceration, by the effects of which it is at last brought into view. In this fort of cafe, it is extremely uncommon for hemorrhage to occur; for, in general, the veiil has been already obliterated by the preceding inflammation. But the ulcer itself is very difficult to heal, and may be kept up a long while by the edematous swelling of the limb. Varicose, or rather the edema which is the consequence of them, has the same effect upon every other species of ulcer, and even upon the most simple solution of continuity. While the swelling of the limb cannot be dispersed; while the edges of a solution of continuity are kept afunder by the tenfe flate of the skin; and while the divided parts are irritated by this painful tension; every thing is unfavourable to cicatrization. Thus, we fee the most simple wounds, which have been allowed to suppurate, and ulcers, which should have healed rapidly, continue u.ncured a great many years, merely because the limbs, on which they are situated, are affected with an edematous swelling, the consequence of varices. Such is the condition of things in the cafe which has been improperly named the varicoce ulcer. Delpech Traité des Maladies Chir. tom. iii. fect. 8. art. 3.

In the investigation of the causes of varices, it is usual to dwell very much upon the mechanical obstructions which may affect the circulation of the blood in the veins. Surgeons have thought themselves justified in regarding this as the only cause, because a circular, moderate compression incontestibly retards the course of the blood in these vessels, and produces a temporary dilatation of them. The opinion has seemed also to derive confirmation from the knotty appearance of varicose veins, a circumstance which has been accounted for by supposing, that the dilatation is greatest in the situation of the valves. Lastly, the idea is further supported on the well-known fact of the frequent occurrence of varices during the flate of pregnancy. But it has not been remembered, that the use of garters, for example, is extremely common; but varices of the legs infinitely less frequent; that very large varices are met with in persons who have never employed any kind of ligatures, to which the origin of the complaint can be imputed; that when the dilatation of the veins extends to the thighs and patientes of the abdomen, no causes of this description even admit of sufficion; that varicose veins are observable round several kinds of tumours, especiably fibriui, when there is no possibility of pointing out any mechanical obstruction to the circulation of the blood; that varices sometimes make their appearance at the commencement of pregnancy, and long before the enlargement of the womb can impede the free return of the blood through the veins in the pelvis; that nothing is more unusual than a varicose dilatation of the veins of the lower extremities, in consequence of swellings of the abdominal viscera; and lastly, it has been forgotten that the knots of the dilated veins are far too numerous to admit of being ascribed to the refilience of the valves. It cannot be denied, that preasure applied in the track of the veiils, tends to promote their dilatation; but it can neither be considered as the only cause, nor as the principal one. The foregoing observations made by Delpech, render it probable, that some unknown general cause is concerned in producing varices, the formation of which may also be facilitated by the impediments to the free return of the blood, occasioned by certain attitudes, and particular articles of clothing.

Mr. Hodgson conceives it probable, that in some instances, the valves are ruptured in consequence of muscular exertions, or external violence, in which cafes, the preasure of the column of blood is the first cause of the dilatation of the veins. Sometimes, also, the disease appears to arise from preternatural weaknes in the coats of the veins, as in those instances in which, without any evident cause, it exists in various parts of the same person. Treatise on the Diseases of Arteries and Veins, p. 537.

Experience proves, says Delpech, that there is no certain mode of curing varices, strictly so called, which he thinks cannot be wondered at; since the nature and causes of the disease are completely unknown. The same source of knowledge, however, also proves, that the increase in the dilatation of varicose veins may be retarded, and that the edematous swelling attendant on the complaint may be beneficially opposed. But these effects cannot be produced by refulvent, tonic, astringent applications, nor by aperient, diuretic, and purgative remedies, as some even of the latest writers so inconsiderately assert; but only by means of methodical and permanent compression. When the whole of a limb affected with varices is subjected to this last mode of treatment, the dilated veins subside, the circulation is more regularly performed, and the edema and pain cease. There is not, says Delpech, any better method of healing the solutions of continuity in the soft parts produced or kept up, by the varicose flate of the limb and its consequences. But as soon as the compression is discontinued, the varices make their appearance again, the pain recurs, the edema returns, and the ulcers which were healed break out afresh. Compression, therefore, which absolutely required to be constantly employed, can be regarded only as a palliative, the more useful indeed, inasmuch as the changes which it brings about in the flate of things are nearly equivalent to a perfect cure.
Inflammation of the integuments covering a varix, or varicose tumour, cannot invariably be prevented by compression, nor will this treatment always succeed even in removing the intolerable pain which sometimes attends numerous clutters of varicose veins. In the first case, rest and relaxing applications will often succeed; and in the second, the topical use of sedatives frequently gives relief. It has been proposed to puncture and empty varicose veins; but if a temporary empiema and relaxation of these vessels, which are rendered painful by their distention, could remove the pain for a time, things would fall into the old state again in the course of a few days. If it should appear also, that the clotted blood had the effect of keeping up the unfavourable symptoms, it would be necessary to make a very considerable opening into the dilated vein, in order that the coagulum might be extracted. In such a case, it would be useless to tie the vessel above and below the opening, as has been recommended: the flight of compression is afterwards sufficient for the stoppage of the bleeding, and by the subsequent inflammation the vessel is certain of being obliterated.

We learn from Celsus, that the ancients were accustomcd to remove varices by excision, or destroy them with the cautery. (De Ré Médica, lib. vii, cap. 3.) When the vein was much convoluted, extirpation with the knife was preferred; but in other cases, the dilated vessel was exposed by an incision, and then cauterized. Petit, Boyer, and many surgeons in this country, have also sometimes practised the operation of cutting out clutters of varicose veins.

Delpech remarks, that the extirpation of tumours composed of numerous varices, has been practised either for the purpose of removing the pain in the situation of the diseased, or other inconveniences. This operation has been successfully performed; but it appears also not to have constantly had the effect of preventing the formation of new varices, and it has sometimes proved tedious, difficult, and feverly painful in its execution. In fact, an erroneous judgment must necessarily be formed of the extent of these swellings, when they are judged of only from the appearance which they present under the skin. When we attempt to operate, says Delpech, we may be led to organs which ought not to be meddled with, and a long and extremely painful dissection may be found requisite. Besides, varices are not always confined to the superficial veins, and a relapse would be inevitable. These reflections tend to the conclusion, that operations of this sort should never be undertaken, except when the disease is accompanied with perilous symptoms, or nearly deprives the patient of the use of his limb.

It has been thought, that one of the established principles in the treatment of aneurysms might be advantageously extended to the cure of varicose veins. By tying the principal venous trunk above the point to which the varicose affection reaches, it is said that the course of the blood in the morbid vessels may be totally stopped; the column of this fluid contained in them made to coagulate; and the consequent obliteration of the vessels themselves accomplished.

The practice of tying veins for the cure of varices appears to have been employed in the days of Paré and Dionis, (Cours d'Opérations de Chirurgie, p. 610.) who have accurately described the operation of tying and dividing the vein between the two ligatures. Sir Éverard Home has related many cases of varicose veins in the leg, some of them being accompanied with tedious ulcers, in which, after tying the varisaphena major, where it passes over the inside of the knee, not only the dilatation of the veins of the leg was relieved, but the ulcers were readily healed. This proceeding has unquestionably been sometimes followed with success; but it has also had its failures. Among other evils, an inflammation of the tied vein has been observed extending very far in the vessel, and succeeded by convulsions and death. Indeed, the dangers arising from an inflammation of the internal coat of the veins are now generally acknowledged, and every endeavour should be made to avoid them. A cafe which lately happened in one of the large hospitals of this metropolis, has fully proved them: we allude to the example, in which the femoral vein happened to be wounded in the operation for aneurysm, and had a ligature applied round the small aperture accidentally made in it. Inflammation of its internal coat took place to a considerable extent, and the patient is supposed to have died of the indisposition resulting from it.

As Mr. Brodie observes, it seems to be now established by the experience of modern surgeons, that a mechanical injury inflicted on the trunk of one of the larger veins, is liable to be followed by inflammation of its internal membrane, and a fever of a very serious nature; and the occasional occurrence of these symptoms after the ligature, or even the simple division of the varisaphena, has made surgeons less confident than formerly, of the propriety of attempting these operations for the relief of a varicose state of the branches of that vessel in the leg. Certain reflections, however, induced Mr. Brodie to think, that the same ill effects would not follow a similar operation performed on the branches themselves. "Where the whole of the veins of the leg are in a state of morbid dilatation, and the dilects produced by the disease is not referred to any particular part, there seem to be no reasonable expectations of benefit, except from the uniform preflure of a well-applied bandage. But not unfrequently, we find an ulcer which is irritable, and difficult to heal, on account of its connection with some varicose vessels; or without being accompanied by an ulcer, there is a varix in one part of the leg, painful and perhaps liable to bleed, while the veins in other parts are nearly in a natural state, or at any rate are not the source of particular uneasiness. In some of these cases, I formerly applied the caustic panth, so as to make a slough of the skin and veins beneath it; but I found the relief which the patient experienced from the cure of the varix, to afford but an inadequate compensation for the pain to which he was subjected by the use of the caustic, and the inconvenience arising from the tedious healing of the ulcer, which remained after the separation of the slough.

"In other cases, I made an incision with a scalpel through the varix and skin over it; this destroyed the varix as completely as it was destroyed by the caustic, and I found it to be preferable to the use of the caustic, as the operation occasioned less pain, and as, in consequence of the being no loss of substance, the wound was cicatrized in a much shorter space of time. I employed the operation, such as I have described it, with advantage in several instances; but some months ago I made an improvement in the method of performing it, by which it is much simplified, rendered less formidable, not only in appearance, but also in reality; and followed by an equally certain, but more speedy cure.

"It is evident," says Mr. Brodie, "that the extensive division of the skin over a varix, can be attended with no disadvantage. On the contrary, there must be a disadvantage in it, as a certain time will necessarily be required for the cicatrization of the external wound. The improvement to which I allude consists in this; the varicose vessels are completely divided, while the skin over them is preserved entire, with the exception of a moderate puncture, which is necessary for the introduction of the instrument with which the incision
incision of the veins is effected. Thus the wound of the
internal parts is placed under the most favourable circum-
stances for being healed, and the patient avoids the more
tedious process, which is necessary for the cicatrization of a
wound in the skin above.

"For this operation, I have generally employed a narrow
sharp-pointed bistoury, slightly curved, with its cutting-
edge on the convex side. Having ascertained the precise
situation of the vein, or cluter of veins, from which the
diseases of the patient appears principally to arise, I intro-
duce the point of the bistoury through the skin on one
side of the varix, and pass it on between the skin and the
vein, with one of the flat surfaces turned forwards, and
the other backwards, until it reaches the opposite side. I then
turn the cutting-edge of the bistoury backwards, and in
withdrawing the instrument, the division of the varix is ef-
fected. The patient experiences pain, which is occasionally
severe, but subsides in the course of a short time. There
is always hemorrhage, which would be often profuse if
neglected, but which is readily stopped by a moderate
pressure, made by means of a compress and bandage care-
fully applied." Mr. Brodie particularly enjoins the neces-
sity of keeping the patient quietly in bed for four or five
days after the operation, and removing the bandage and
first dressings with the utmost care and gentleness. He also
cautions surgeons not to make the incision more deeply
than absolutely necessary. Inflammation of the coats of the
veins has not occurred in any of the cases in which Mr.
Brodie has adopted this method of treatment. This
gentleman wishes it to be understood, however, that he does
not recommend the practice indiscriminately, but with a
due attention to the circumstances of each individual case.
"The cases for which it is fitted, are not those in which
the veins of the leg generally are varicose, or in which
the patient has little or no inconvenience from the complaint;
but those in which there is considerable pain referred to
a particular varix; or in which hemorrhage is liable to
take place from the giving way of the dilated vessels; or
in which they occasion an irritable and obstinate varicose

On the subject of cutting through veins affected with
varix, it is proper to observe, that even this plan has been
known to bring on severe and fatal symptoms. Cases con-
firming this fact are recorded in a valuable modern work,
which should be in the hands of every practical surgeon. (See
Hodgson's Treatise on the Diseases of Arteries and Veins,
p. 555, et seq.) It is but justice to flate, however, that
in these examples, Mr. Brodie's manner of doing the oper-
ation was not adopted.

As we have already noticed, cases of spontaneous varix in
the veins of the arm are rarely observed. When these
vessels become varicose, it is almost always in consequence of
a communication being formed, in the operation of vena-
dication, between the brachial artery and one of the veins at
the bend of the arm. The superficial veins in this situ-
ation then become more or less dilated by the impulse of the
stream of arterial blood which is thrown into them. There
is, however, a good deal of difference between those acciden-
tal varices actually induced by a mechanical cause, and
those which originate spontaneously, or from causes not
very clearly understood. The former never acquire the size
which the latter often attain; they never exceed a certain
magnitude, whether preasure be employed or not; they
never form tumours composed of an assemblage of varicose
veins; they are never filled with tough coagula of blood;
their coats are never thickened, nor constitute the solid
half canal remarked in the other species of varices; the
skin which covers them is not disposed to inflame and ul-
erate; they are not subject to occasional hemorrhage; and
the limb is not affected with any edematous swelling.
(See Delpech Traité des Maladies Chim. tom. iii. p. 261.)
These circumstances must render it sufficiently evident that
all surgical interference in such a case would be entirely
unnecessary.

For additional observations connected with the subject of
varicose veins, see the article ANEURISM, where the aneu-
rismal varix is described; CIRROCELE, where the varix of the
spermatic cord is treated of; HEMORRHOIDAL, where the
diseased and enlarged veins of the rectum are considered;
and WARTIECELE, where those of the scrotum are noticed. Del-

province of Beira; 14 miles S.E. of Lameg."
making shoots of extraordinary vigour, which soon overtop and exclude the variegated parts of the same individual.

VARIETIES, in Natural History, a word used to express an accidental change in some body, which is not essential to it, and therefore does not constitute a different species.

The naturalists of former ages have run into great errors, in mistaking the accidental varieties of plants, animals, and minerals, for distinct species. Many of them have called a plant a new species, because its flower, which should have been blue or red, is white, on account of the poorness of the soil, or some other such reason. Mr. Ray has established a very good test for varieties in botany; he allows every thing to be a distinct plant, which will propagate itself in its own form by its seeds; but such as, when sown, lose their difference, and run back to the old standard, he accounts varieties, however great their distinctions may appear.

In the history of fish, as much confusion has been introduced, by mistaking varieties for distinct species, as in botany. Arctedi is the only author who has rationally attempted to bring this part of natural history into order in this respect, and to settle regularly the rules by which to distinguish real and essential from accidental differences.

The principal grounds of the error of supposing varieties distinct species of fish have been these: the variable and inconstant colour of fish hath been mistaken for a specific difference; in this manner Rondeletius has defcribed many varieties of the turdi, labri, and other fish, under the names of distinct genera.

Others have paid the same too great regard to the more constant varieties of colour, which are found only to differ in degree in the several individuals of the same species, and their differences to be only in the degrees of the same colour, which is much more intense in some, and more remiss in others. These differences can only make varieties of the same fish, the species remaining always the same. Of the same kind are the mistakes of those who esteem size or magnitude a specific character; and thus, out of the varieties of the same fish, occasioned by scarcity or plenty of food, or other such occasions, make larger or smaller species.

The place where fish are caught is also another cause of making new species with these authors: thus, though the perca fluviatilis of Bellonius, and the perca marina of other authors, be the same fish, yet they are pretended to be different species. The time of spawning is also with some made a distinction of species; and thus we find the common pike divided into three species, according to its spawning, in spring, summer, and autumn, which it does according to the heat or coldness of the climate. See Specific Names.

All these differences are false and frivolous, and the utmost they can do is to make what are properly called varieties, though few of them are sufficient even for that. A salmon caught at sea is not different from one of the same brood caught in a river; and if the perca marina, falsely so called, be a little different from the perca fluviatilis, yet if its spawn will produce regular perca fluviatilis, its difference can only amount to a variety, not a distinct species.

The time of spawning is no essential difference; for we daily see the change of climate make changes of that kind in all creatures; and even in the same climate, and under the same circumstances, the same species of birds will afford some individuals much earlier or later in laying their eggs than others. Artedi Ichthyol.

VARIETIES, in Botany and Vegetable Physiology, are certain differences between individuals of the same species, which are not sufficiently important to constitute a specific distinction, nor, however important or striking, are they permanent, except in offsets, buds, cuttings, or layers of the same individual. Even these are observed, sooner or later, to wear out; while, on the other hand, some varieties do appear to be continued, by seed, through successive generations, at least in annual plants; but a very slight degree of observation will shew that these gradually return to their original nature; sometimes very speedily. Varieties amongst edible fruits seem to be the most numerous and the most lasting; but whether they are more so than others, which, being unimportant to mankind, pass unnoticed, as in the Fungus tribe, may be doubted. Mr. Knight, the learned and experienced President of the Horticultural Society, has convinced himself, and we believe most of his intelligent readers, that varieties of Apples and Pears have only a limited duration. (See Species of Plants.) Thus the most valuable, perhaps, of all, the Golden Pippin, and particularly the rufted-coated kind of that fruit, is generally wearing out. It may be propagated by grafting; but the young trees, thus obtained, quickly canker, and cease to bear any fruit worth notice. Numbers of Apples and Pears, celebrated in the horticultural works of the French, and many known to have existed formerly in England, are no more to be found. Those who plant orchards draw out admirable plans upon paper, buy trees, and wait with great complacency for the produce, till they find themselves miserably deceived. Half their trees, possibly, bear something different from what was promised. So far they have a right to complain of an ignorant, careless, or diabolical nurseryman. The greater part of their whole stock, whether the fruit be good or bad in quality, canker and die, or dies, in a few years. Some few hardy trees only, of ordinary fruits, perhaps remain. The foil is concluded to be unfit for apples, and the polleffor bears his disappointment as well as he can. This is the literal history of several orchards, which have passed under our observation. We have also seen fine trees of Golden Pippins and Nonpareils, which twenty years ago bore full crops of excellent fruit, canker and die, without any apparent cause, so that "the places which knew them, know them no more." Such is the melancholy history of our orchards. But it is still more grievous to observe, that new varieties, which Mr. Knight, and some other patriotic cultivators, are obtaining every year from seed, prove far more transient than their predecessors, canker and disappearing in four or five years. Some, however, we hope and trust, will remain, and that our descendants will not be defitute of the most valuable of all English fruits. With this important end in view, we cannot sufficiently recommend, to those who have the means, the raising of apple-trees from seed, every year, on a large scale. It has usually been the practice of such experimentals to select the kernels of good apples, for their purpose; thinking such more likely to yield something analogous to their parent fruit. Perhaps they may inherit too much of the same constitution, and this may be the latent cause of their own short existence. Might it not be worth while to sow the seeds of healthy wild crab-trees, whose vigour might remain in their offspring? From such, doubtless, all our valuable varieties must, at first, have originated. Who can tell that the degeneracy so prevalent among the new-raised stocks, as to duration, may not be owing to the repeated crofs impregnation of diseased wrought-out varieties, which must take place in a garden? The ornaments of our courts and drawing-rooms may descend from the heroes of Crofley and Agincourt, but our modern heroes commonly rise from the ranks, and the quarter-deck.

In the ornamental department of horticulture, varieties
VARIETIES.

are much attended to. Cape Geraniums are raised, by crofs impregnation, which often excel their parents in size and beauty, and for a while are continued by cuttings, if not by seed. Nothing, however, can be more tranitory than these ephemeral productions. We have adverted to some of them under the article Pelargonium. Double-flowered varieties are produced from time to time, either by nature or by some accident of cultivation, for which we cannot in any manner account. Thus, if we sow an hundred seeds of the common Annual Stock, Cheiranthus annuus, one, or perhaps many, of the plants may bear nothing but completely double flowers, all the rest being quite single. When such a variety occurs in any perennial, or shrubby, species of plant, it is justly prized, being capable of multiplication by cuttings, layers, &c.; and when variations of colour are superadded, as in the favourite Camellia japonica, the treasures of the conservatory are still more multiplied. We must be content, in the present state of knowledge at least, to seize each vegetable Proteus as it comes in our way, without attempting to explain, or to imitate, the cause of its transformation.

Colour is, of all things, most liable to vary in the petals of flowers. Almost every blue flower is capable of changing to white, and it appears that in several instances the seeds of the white variety more generally produce their like, than those of the natural-coloured flowers change to white. But this rule is not invariable. The seeds of Canterbury Bells, Campanula Medium, whether taken from a white or blue flower, appear, as far as we can judge, to produce a great majority of blue-flowered plants, with a few white ones. The elegant varieties of the Sweet Pea, Lathyrus odoratus, seem more constant; but they are comparatively of recent introduction amongst us, and it is probable they may in time wear out, like other more short-lived beauties.

Varieties in the luxuriance or flavour of annual herbs, or their seeds, which make the riches of a kitchen garden, require, of all things, the most affidious attention of a cultivator. These are the most casual and fugacious of all things. They do, however, appear to be more within the control of a skilful gardener, than many above-mentioned; especially with regard to soil, or manure. An eminent London seedman assured the writer of this, that he found it expedient to fend lettuce seed to a remote country, the south of France, for instance, one seafon, and its produce to Holland, or Germany, perhaps, the next, in order to preserve or improve its quality. Change of crops every body knows to be essential in farming, as well as change of seed. What are the various degrees of excellence in Wheat, Barley, or other grain, but varieties, in what possibly, when originally wild, refembled but an ordinary grafs. Thefe excellencies are kept up by culture, that is, by attention to the circumstances just detailed. Such attention is infinitely more requisite in the cultivation of high-fed, pampered, and delicate culinary vegetables, which, if at all neglected, soon return to their original kind, or more frequently vanifh altogether. Varieties of Peas, obtained by crofs impregnation, are a late improvement in horticulture, which promises a more durable success. For this acquirement to our tables we are indebted to the skill and indefatigable exertion of Mr. Knight, who has also extended his philosophical inquiries and experiments to Strawberries. It is much to be wished that the test of divifion between a variety and a species, which this gentleman has affumed, or rather adopted from animal physiologists, may hold good. This is, their power of generating together, without limitation. That unqueftionably different species in the vegetable king-
VARIETIES.

VARIETIES, in Gardening, the different variations of 
plants of the same general nature from that of the parent 
or particular fort from which they came. They are, of course, 
the offspring of certain peculiar determinate forts, which 
vary in some accidental particular of their habits of growth, 
or some other circumstance, from the natural original fort, 
or parent plant. But although this is the case, as their 
variations are, for the most part, confined to some particular 
part or parts, they still retain the specific mark or marks of 
differentiation of the parent plant, which differentiates them 
from those of other different forts. Consequently there are 
frequently numerous varieties from the same fort, all of 
which differ from it, either in their manners of growth, 
foliage, flowers, the economical qualities which they possess, 
or some other particular of a similar nature. All kinds of 
plants, both of the annual, biennial, and perennial descriptions, 
as well as those of the herb and tree fort, are liable to 
vary in this way. This is effected by different modes and 
kinds of culture, by the nature of the climate, by that of 
the soil, by the use of particular forts of manure and other 
materials, by frequent changes in their situation, by age, 
and in many other methods, and respects their differences in 
size and magnitude, their luxuriant, dwarfish, erect or 
trailing growths, their being smooth or prickly; the nature and 
shape of their leaves, as broad, narrow, entire, divided, 
curled, spotted, variegated, round, oval, sharp, blunt, &c.; 
smooth, hairy, downy: in their flowers, as single, double, 
proliferous, white, red, blue, yellow, variegated, &c.: in 
their smell, as sweet-scented, rank-scented, &c.: also in the 
form, size, colour, taste, quality, &c. of the fruit; in some 
cases, as round, oval, oblong, smooth, furrowed, warty, 
hairy, downy, large, small, red, green, yellow, variegated, &c.: 
in their smell, as sweet-scented, rank-scented, &c.: also in the 
shape and appearances of the roots, as in the carrot, the 
radish, the turnip, the potato, &c.: in the manner of 
their producing their seeds, fruits, &c.; as in the hop, 
spinach, hemp, &c.; and the cucumber, melon, &c. And 
it takes place in many other circumstances.

However, notwithstanding these different modes of variation 
in the particular parts of the varying plants of a 
peculiar fort, if those of each such fort still maintain the 
same specific mark of differentiation as that which characterizes 
and differentiates the respective natural forts from all others, 
it shews them all the offspring, or varieties, of the same 
original fort. For as every different and distinct fort, in 
any particular kind of plants, is discriminated from some 
peculiar, uniform, constant mark or appearance in some 
part of its growth, all the plants of the same particular kind 
unchangeably bearing exactly the same, are, notwithstanding 
their accidental variation in other parts of their growth, all 
varieties of one fort. Consequently all the plants which 
are produced from the seed of the same particular fort, 
however they may put on different forms and appearances, 
are to be considered as the real varieties of it.

The difference between any particular fort and that of 
a variety, is, that a really true fort, raised from seed, will, 
though it may sport into many variations, still retain and 
keep its true and invariable mark of differentiation through 
all its varieties; and although there may be varieties of that 
particular fort with different sized leaves, and colours of 
the flowers, &c.; if the seed of any one be sown, it will 
probably produce young plants of all these kinds, each 
having the characteristic discriminating mark of the parent.

It is, indeed, in a great measure, from plants of the 
feeding kind, that the different varieties of particular forts 
were first obtained, as in the case of the auricula, polyanthus, 
&c. each being a distinct fort of the same kind, and 
each of which consists of innumerable varieties, in the colours 
and variegations of the flowers, still gained in this way, 
the seed of the same plant often producing a great diversity in 
this respect, each variation of colour, &c. forming a real 
variety; but probably not one of them with a flower 
exactly like that of the original parent plant: yet each 
variety retains the specific difference of its respective 
particular fort, the auricula, for instance, never changing to 
the polyanthus, nor that to the auricula, but the varieties 
of each keep their proper differentiation; as the auricula, in all 
its varieties, continues its smooth finely serrated leaves; 
and the polyanthus, its rough-toothed leaves. And the same 
is the case with the carnation, the ranunculus, the anemone, 
the tulip, and a great number of other flower-garden plants.

The tree kind, especially those for the production of fruit, 
are particularly disposed to form varieties, equally in their 
modes of growth, their foliage, and the fruit: for instance, 
one original fort of apple-tree is only admitted, but which 
furnishes an almost endless variety of fruit, in regard to 
shape, size, colour, taste, quality, &c. as well as in the 
growth of the trees, so far as respects their size or magnitude, 
the dimensions and colours of the foliage, &c.; the 
specific differentiation of which is, serrated leaves, and clove- 
futing flowers in the form of an umbel, which runs through all 
the numerous varieties, however different the trees may be 
in size, growth, leaves, and fruit. And the same takes 
place in the pear, the plum, the common cherry, the peach, 
and many others, there being only one principal fort of each 
of these, but the varieties of the fruit are many in number, 
which, in all these sorts of trees, were originally obtained 
from feeding plants, that is, such trees as were raised by 
setting the fleshes or kernels of the fruit. Almost all the 
fruit-tree kind sport greatly in their feeding plants, so that 
out of hundreds of trees raised from the seeds of the best 
fruits, very few, if any, will produce fruit exactly like that 
of the parent plant, or which posses any good perfection.

Therefore, on account of the uncertainty of producing and 
continuing the approved sorts of fruit from feeding plants, 
recourse is constantly necessary to be had, in the practice of 
gardening, to the modes of grafting, budding, and, in some 
instances, the making of layers and cuttings, in order to 
propagate the intended and desired sorts, or to continue 
and increase any good newly acquired variety.

The greater number of varieties in herbaceous plants, as 
well as many kinds of fruit and other trees, are of a variable 
and sportive nature, so that when raised from seed, there is 
no dependance on having the feeding plants coming again of 
the same fort, but varying into different sorts of one another. 
In cases of this nature, the propagation of such of them as
are perennial, to continue them with certainty, is to be accomplished either by means of planting their suckers, or the offsets or slips of the roots, and in some by layers and cuttings, or in the woody descriptions by layers, cuttings, grafting, and budding; but in the annual tribe there is no other means than by sowing or setting the seed, except in some few forts, by the planting of their cuttings, as in the chrysanthenum, nauturium, and some others; however, in a great number of kinds, where particular attention has constantly been bestowed in sowing the seeds from only the most perfect, they will continue tolerably permanent, and frequently come again the same, or with but very little variation.

In many sorts of plants of the kitchen-garden and annual flower kind, though there be a number of varieties in each, yet by good care, and constantly sowing seed from the most perfect plants, which show no signs of degenerating, they remain, year after year, permanent from seed.

But most of the perennial tribe, the herbaceous as well as the woody sorts, as being in general more variable from seed, afford great opportunities of continuing the permanency of any particular variety, by making use of the offsets from their roots, the suckers, layers, and cuttings, as well as by grafting and budding, as has been already seen.

It sometimes occurs, however, that plants, although not immediately raised from seed, will, on account of some accidental cause, vary materially from their usual natural growths, and assume quite different appearances, arising in consequence either of culture, climate, exposure, soil, age, disease, abundance, or deficiency of nourishment, contusions, or other similar circumstances; and by such means produce accidental varieties in some particular parts of their growth.

The ascertaining of the reality of the varieties is, in many sorts, readily and easily accomplished by a comparison of the variable plant with the specific distinctions of the natural sort; and the variations of growth of the variety with the same parts in the natural plant. But still there are many varieties that require all the skill and knowledge of the most expert gardener to fully distinguish and ascertain them. It is, however, of material importance, in many cases of practical gardening, to have a nice and correct notion of the varieties of the plants which are to be cultivated, as the work can thereby be performed with greater certainty and advantage, as well as with more and better effect.

In the first volume of the Transactions of the Horticultural Society, T. A. Knight, esq., makes the following conclusions on the means of raising new and early varieties of fruits: after stating that "variation is the constant attendant on cultivation, both in the animal and vegetable world," and that "in each the offspring are constantly seen, in a greater or less degree, to inherit the character of the parents from which they spring," that as every particular sort of fruit acquires its greatest rate of perfection in some peculiar sort of soil or situation, and under some similar mode of culture; the proper choice of such "must be the first object of the improver's pursuit; and that nothing should be neglected which can add to the size, or improve the flavour of the fruit which it is intended to propagate. Due attention to these points will, it is contended, in almost all cases, be found to comprehend all that is necessary to introduce the introduction of new varieties of fruit, of equal merit with those from which they spring,"; but that, at the same time, "the improver, who has to adapt his productions to the cold and unsteady climate of this country, has still many difficulties to contend with; he has to con-
more often indebted to accident than to any plan of systematic culture; and contents himself with merely selecting and propagating from the plant of the earliest habits, which accident throws in his way, without inquiring from what causes those habits have arisen; and few efforts have been made to bring into existence better varieties of those fruits which are not generally propagated from seeds, and which, when so propagated, of necessity exercise during many years the patience of the cultivator, before he can hope to see the fruits of his labour, industry, and attention."

The attempts which the writer has made to produce early varieties of fruit are, it is believed, all that have yet been made; and though the result of them is by no means sufficient decisive to prove the truth of the hypothesis he is endeavouring to establish, or the eligibility of the practice he has adopted, it is amply sufficient to encourage future experiments on the subject.

It is noticed, that the first sort of fruit which was subjected to experiment in this way, was the apple; some young trees of the desired varieties of which for propagation were trained to a south wall, until they afforded buds containing blossoms. The branches of which then, in the following spring, were detached from the wall, and removed to as great a distance from it as possible, in which state they continued till so far advanced in their blossoms in the following spring, as to be in danger from fruit. Then the branches were trained to the wall, where each blossom allowed to remain quickly expanded, and formed fruit, that in a few months attained perfect maturity; and the seeds produced plants that have ripened the fruit much earlier than other trees raised at the same time from seeds of the same fruit grown in the orchard. In this trial, the blossoms of each variety were fecundated by the farina of another kind; from which is supposed to have been attained in this as well as other similar instances a greater vigour and luxuriance of growth; but no earlier ripening of the fruits than in the plants grown by the ordinary modes of culture. The early maturity of those mentioned, is consequently ascribed to the other peculiarities of circumstances under which the fruit and seeds ripened from which they sprang.

By the same method of culture, several new varieties, that are the offspring afforded by the Siberian crab and the richly-apples of this country, were obtained in the intention of providing fruits for the press that might ripen well in cold and exposed situations. The plants furnished in this manner posses, a remarkable hardiness and luxuriance of growth, appearing in every way perfectly suited to answer the intended purpose. In each of these trials, some of the new varieties inherited the character of the male, and others of the female parent, in the greatest degree; and of some varieties of fruit, especially of the golden pippin, a better example was obtained by the introduction of the farina into the blossom of another apple, than by frowing their own seeds. The new variety of the Downtown pippin, obtained in this manner from the farina of the golden pippin, will, it is believed, be found, in a favourable feason and situation, little if at all inferior to the golden pippin, when first taken from the tree; but it is a good deal earlier, and probably cannot be preferred so long in a perfect state.

The next trials were on the grape, which, though less successful than the above in producing new varieties, were not less favourable to these conclusions. After supposing a vineyard without fires in the winter, to afford a climate to the vine similar to that afforded by the southern parts of Siberia to the apple or crab-tree; the same extensive variation of temperature taking place in it, and the sudden transition from great comparative cold to excessive heat, as productive of the same rapid progress in the growth of the plants and the advancement of the fruit to maturity; he states that his first attempt was to combine the hardiness of the blossom of the black chuckler, or Burgundy grape, with the large berry and early maturity of the true sweetwater, often confounded with the white chaffelas and white muscadine. In this case, the seeding plants produced fruit in his vineyard at the age of three or four years, and in some of them it was very early; but the bunches were short and ill-formed, and the blossoms did not set by any means so well as he had expected.

On substituting the white chaffelas for the sweetwater, many varieties were obtained whose blossoms appeared perfectly hardy, and capable of setting well in the open air; and the fruit of some of them ripening a good deal earlier in the year than that of either of the parent plants. But the berries are smaller than those of the chaffelas, having fewer tender and delicate skins: and though not without much merit for the dessert, they are generally better calculated for the press. In the latter intention, in a cold climate, it is supposed that one or two of them possess the greatest excellence. From the white chaffelas and sweetwater, plants have since been obtained, the appearance of which is greatly more promising; and the earliest variety of the grape he has ever yet seen was produced from a seed of the sweetwater, and the farina of the red Frontignac. It is a very fine grape, resembling the Frontignac in colour and the form of the bunch; but it is feared that its blossoms will prove too tender to succeed in the open air in this country; a single bunch consisting of a few berries is, however, all that has yet existed of this kind. Two new varieties of the grape, with striped fruit and variegated autumnal leaves, have also been produced from the white chaffelas and the farina of the Alupi vine: one of these has ripened extremely early, and is thought a good grape. As in all attempts to obtain new varieties of fruit, the propagator is at a loss to know the kind which are best suited to answer his purpose, those varieties of the grape which he has employed with the most success are mentioned. In short, the facts which he has obtained on this subject, leave no doubt in his mind that varieties of the grape capable of ripening perfectly in our climate, when trained to a south wall, as well as of other fruits better suited to this climate than those which are now cultivated, may be readily produced; but whether the method of cultivation which he has adopted and advised be the most eligible, must be left to the decision of future and more extensive practice and experience.

Trials similar to these have been made on the peach; but it is stated that nothing more can yet be said of the result of them, than that the plants are perfectly healthy and luxuriant in their growth, affording sufficient evidence in their leaves of the good quality of the future fruit. And though he is uncertain at what age plants of this sort become capable of producing blossoms, the sudden changes in the character of the leaves and growth of those raised by him, which are now in their third year, lead him to believe that they will be in a state to produce fruit at the age of three or four years.

Upon the whole, from these and a close attention to the subject for years, it may be maintained that new varieties of every particular sort of fruit will in general be better obtained from the introduction of the farina of one variety of it into the blossoms of another, than by propagating from any single kind. Where trials of this nature are made between varieties of different size and character, the farina of the
VARIETIES.

the smaller kind should be introduced into the blossoms of the larger, as under these circumstances it has generally, though with some exceptions, been found that there is a prevalence in the fruit of the character of the female parent, probably on the following account. The seed-coats are wholly generated by the female parent, and these regulate the bulk of the lobes and pedicells; and it has been noticed, in raising new varieties of the peach, that when one flower contained two seeds, the plants these afforded were inferior to others. The largest seeds, procured from the finest fruit, and from that which ripens most perfectly and most early, should constantly be chosen. When it is intended to propagate new varieties in this manner, it will be necessary for the gardener to extract the stamina of the blossoms from which he purposes to propagate some days before the farina begins to dry. After young trees have riven from seed, a certain time must elapse before they become capable of bearing fruit, which, it is believed, cannot be shortened by any means of cultivation. Pruning and transplanting are equally hurtful, and no alteration in the character or merits of the future fruit can be effected during this length of time, either by manure or any sort of culture. The young plants should be suffered to extend their branches in every direction, in which they do not interfere with each other in a hurtful manner; and the soil must be kept sufficiently rich to promote a moderate degree of growth, without exciting the plant to a premature exertion, which constantly brings on diseases. The soil of an old garden is particularly destructive in this way. The length of time that different sorts of fruit-trees require to attain the age of puberty, admits of great variation. The pear demands from twelve to eighteen years; the apple, from five to twelve or thirteen; the plum and cherry, from four to five years; the vine, three or four; and the raspberry, two years. The strawberry, if its seeds be sown early, affords an abundant crop in the following year; and he has produced several new and excellent varieties of this fruit; but the half-blow strawberry does not seem to propagate readily with the other varieties, possibly belonging to an original distinct sort. He has, however, obtained several offspring from its farina; but they have all afforded a feeble and abortive blossom, and been of little value.

In another paper in the same volume, the same writer, in speaking of raising new and early varieties of the potato, says that those who have cultivated early varieties of this plant, must have noticed that they never afford seeds or even blossoms, and that the only mode of propagating them is by the division of their tuberous roots. Altogether, that each variety has been found by experience, when long propagated, to gradually lose some of those good qualities which it possessed in the early stages of its culture; the duration of a variety in the state of perfection, being limited to about fourteen years. A good new variety of an early potato is, of course, considered highly valuable by the person who raised it; and as such early varieties, according to any method of culture heretofore practiced, can only be gained by chance from seeds of late kinds, they are not very frequently produced. But by the method here directed, seeds are readily obtained from the earliest and best varieties; and the seeds of these may possibly, in successive generations, finally afford much earlier and better varieties than have yet appeared.

The cause of the constant failure of the early potatoe to produce seed has been suspected, and found to be the premature early formation of the tuberous root, which draws off for its support that portion of sap, which in other plants of the same sort affords nutriment to the blossoms and seeds.

After taking several methods of placing the growing plants so as readily to prevent this, he found the following to be the best. He fixed strong stakes into the ground, and raised the mould in a heap round the bases of them, in perfect contact with their bottom parts; and then planted on their south sides the potatoes from which seeds were defied. As soon as the young plants were about four inches high, they were fastened to the stakes by means of lead and nails, and the mould washed away, by a strong current of water, from the bases of their stems, so that the fibrous roots only of the plants entered into the soil. As the fibrous roots of this plant are perfectly distinct organs from the runners, which give existence and subsequently convey nutriment to the tuberos roots; and as the runners spring from the stems only of the plants, which are, in this mode of culture, placed wholly out of the soil, the formation of tuberos roots is easily prevented. Whenever this is therefore done, numerous blossoms will soon appear, and almost every blossom will afford fruit and seeds. It is also suggested as not improbable, that by introducing the farina of the small and very early varieties into the blossoms of those of larger sizes, and somewhat later habits, moderately early varieties, adapted to field culture, and winter use, may be obtained, the value of which to the farmer in the colder parts of the kingdom, whose crops are of this root are followed by one of wheat, would be extremely great.

It is likewise stated by Mr. Biggs, in the above work, that the different varieties of the apple-tree may be raised in a ready manner by means of cuttings, and that the trees so produced, "from healthy one-year old branches, with blossom-buds upon them, will continue to go on bearing the finest possible fruit, in a small compass, for many years. Such trees are also peculiarly proper for forcing, by way of curiosity or luxury, and, it is believed, that they are less liable to canker than when raised by grafting. This has been more than once experienced in the golden pippin, cuttings of which have remained seven years in perfect health, when grafted, taken not only from the same tree, but from the very branch, part of which was divided into cuttings, cankered in two or three years. This mode of raising young apple-trees was discovered by accident, from flicking cuttings of these kinds of trees into the ground, as flower-marks during the wet season, which took root.

In raising new varieties of carnations, much advantage has lately been found from ripening the feed of the old plants by means of placing them in the artificial heat or warmth of some sort of hothouse, frame, or other contrivance of these kinds, as they naturally flower late in the season, and, of course, fully ripe feed can seldom be procured in that way for the purpose.

VARIETIES OF LAND, IN AGRICULTURE, the different sorts or qualities of it, as they relate to the nature and manner of its cultivation, or the uses to which it is applied. Though no general principles are probably yet capable of being laid down in regard to the comparative value or utility of different sorts or plans of cultivation, or of the different methods of proceeding in respect to crops that are had recourse to in different cases and situations, as the real nature of it, and the particular circumstances to which it is exposed and liable, in every instance, are not sufficiently known; it is evident that all the sorts of clofe, field, and fallow sorts of land are not so greatly benefited by much working over, as those of the finest and cohefive kinds, in which minute division of their parts and full aeration are essentially necessary,
necessary, effects which are produced in the most extensive manner, under the drill practice of culture; but the labour, trouble, and expenditure attending its use, in some cases, may not be adequate to its benefits. Thus, the former and all the dry and least moist forts of land are commonly well fitted for the purposes of tillage and those of sheep-patuheit; while the latter and those of the more wet and retentive kinds are more fitted to the raising broad-leaved crops, and those of the artificial and natural grafts forts. Stiff clayey or alluvious lands are mostly best suited for wheat crops, and those of the lime-stone or calcareous descriptions for producing saffron and clover crops. The varieties of land, too, are considerable, as they relate to different practices, such as those of draining, watering, and many others.

See Soil, Spring and Surface-Draining, Tillage, and Watering of Land.

VARIGNON, Peter, in Biography, was born at Caen, in France, in 1564, and originally intended for the church; but imbibing an early taste for the mathematics, this kind of science became the object of his attention, in the prosecution of which he was discouraged by his relations, who obliged him to devote some part of his time to theology. With the abbe St. Pierre, who studied philosophy in the famous college, he formed an intimacy; and they mutually encouraged and aided each other in their favourite studies. The abbe took him to his house, and in order to render him more independent, bestowed upon Varignon out of his own income, which was only 1800 livres a-year, 300. In 1686 the abbe took him to Paris, where he wholly employed himself in the study of mathematics, and where he formed an intimacy with Du Hamel, Du Verney, and De la Hire. From Du Verney he acquired a considerable knowledge of anatomy, whilst in return he taught him the application of mathematical reasoning to that subject. In 1687 Varignon became known by his "Projet d'une nouvelle Mechnanique," dedicated to the Academy of Sciences. This treatise was much admired, and served to introduce him to two considerable places, viz. that of geometrician to the Academy of Sciences, and that of professor in the college of Mazarine. In 1690 he published "Nouvelles Conjectures sur la Pendante;" and he became one of the most early cultivators of the science of infinitesimals. Of his application and industry we have ample evidence in the volumes of the Academy of Sciences; his papers are numerous, and contain complete theories on the laws of motion, central forces, and the refraction of different media. In 1703 he suffered much from his intense application, which impaired his naturally strong constitution, and reduced him for three years to a very languishing state. His physicians prohibited study, from which, however, he could not totally abstain. Having conferred Dr. Wallis for affecting that there are certain spaces more than infinite, ascribed by this celebrated geometer to hyperbolas, whilst Varignon maintained that they were finite, his criticalism was shewn to M. Carré, and by him cauful to be printed in the Memoirs of the Academy, without his knowledge. After his recovery, he refounded his application, by republishing his "Projet d'une nouvelle Mechnanique" in a new and enlarged form, by an extensive correspondence, and by reading lectures to his scholars in the college of Mazarine, as well as in the royal college, in each of which he occupied a professor's chair. In the latter part of his life, much as he valued peace, he was engaged in a scientific dispute with an Italian monk on the subject of tangents, and the angle of contact in curves. In the two last years of his life he laboured under an arithmetical complaint, which baffled all remedies. At length, having finished his lecture at the Mazarine college, on the 22d of December 1722, he died suddenly on the following night. His character, says Fontenelle, was as simple as his superior understanding could require. He had no jealousy of the fame of others; for, indeed, he was at the head of the French mathematicians, and one of the first in Europe. In the discharge of every personal and social duty he was confidingly strict. On the theory of the mathematics few mathematicians have laboured more successfully than Varignon; introducing into this science that mode of generalization which characterizes it, simplifying many of its principles, and resolving many questions that had not before been confounded; such, especially, as relate to the doctrine of motion. His works, published separately, were "Projet d'une nouvelle Mechnanique," 4to. Paris, 1687; "Des nouvelles Conjectures sur la Pendante," 12mo. 1692; "Nouvelles Mechnaniques," 2 tom. 4to. 1725; and his papers in the different volumes of the Academy of Sciences are very numerous. Montucla Hist. des Mathém. Fontenelle's Eloge des Academicians.

VARILHES, in Geography, a town of France, in the department of the Arriege; 10 miles W.S.W. of Mirepoix.

VARILLAS, Antony, in Biography, was born in 1624 at Gueret, in the Upper La Marche, and upon his settlement at Paris, Gaillon, duke of Orleans, made him his historiographer; and in 1655 he obtained a place in the royal library, very favourable for the prosecution of his historical studies. Huet says of him, that no man ever brought to the illustration of French affairs so rich a provision of valuable observations, or so copiously a store of domestic narrative. But he adds, that his excellent qualifications were disparaged by his immoderate assurence, which led him to confide in his own conjectures and speculations, and to relate with as bold affection the things for which he had no authority, and which were altogether fictitious, as if he had been an eye-witness of them. In fact, Varillas was delitute of the most essential and estimable quality of an historian, a love of truth; and this has rendered his voluminous labours of inferior value. His leading object seems to have been the gratification and amusement of his readers. In the prosecution of this object he at first succeeded; his books were much read, and Colbert gave him a pension, which was afterwards withdrawn. In lieu of this, he contented himself with a pension which the French clergy granted him, as the reward of his services to the Catholic cause, obtained for his "Histoire des Révolutions arrivées en Europe en Matière de Religion," a mere party performance, concerning which Menage said to the author, "You have given a history of hereby full of heresies!" Bishop Burnet published a critique on part of it, which is said to have prevented Dryden from translating it; a talk which was proposed to him, after his conversion to Popery, by James II. of Bavle, and many others, have detected the errors and falsifications of Varillas. As his writings, which chiefly relate to French and Spanish history, are scarcely ever read or cited, it is needless to copy their titles. Varillas died in 1696, in easy circumstances, so that he left several legacies for pious purposes. Moreri. Huet. Nouv. Dict. Hist. Gen. Biog.

VARINAS, in Geography, a province and city of South America, which in the year 1787 was detached from the government of Maracaibo, and made a separate government, confeiated at the expense of those of Venezuela and Maracaibo. The chief has only the title of political governor, although his functions, in the district affiged to him, are the same as those of other governors, in the civil, military, and religious
VARIAN, a small island in the Spanish Main. N. lat. 11° 10’. W. long. 83°.

VARIOLE, in Surgery, the small-pox. See INOCULATION and SMALL-POX.

VARIOLE, Vaccina, the cow-pox, sometimes termed by modern medical writers vaccina. See COW-POX and VACCINATION.

Eff. Ch. Receptacles cup-shaped, with a torn border from the crust, powdery, with a fertile disk beneath.

The whole of this genus was confounded by Linnaeus under his Lichen fagineus, and L. laetius, so far at least as its species were then noticed. They now amount, in the last work of Acharius, to ten, all of a crustaceous nature, found, some on the trunks of trees, others on rocks or walls, one on the ground. We have several, of British origin, to add to this list.

1. V. velata. Veiled Variolaria. Achar. n. 1. (Lichen velatus; Engl. Bot. t. 2652. Parmelia velata; Trum. Tr. of Linn. Soc. v. 9. 143. t. 12. f. 1.)—Crust limited, tartaceous, thin, rugged, greyish, with a pale edge. Receptacles small, crowded; disk yellowish, veiled with a white membrane; border thick, even, of the substantiae of the crust.—Found by Mr. W. Borrer, but rarely, on the bark of ash-trees in Suffolk. The crust is thin, spreading in roundish patches, two or three inches broad, of a greenish-grey, corrugated in the disk, minutely fibrous at the edge. Receptacles numerous, sessile, shield-like, about a line in diameter, pale fumon-coloured, with a thick smooth border, from which a white membrane is drawn across the disk, so as entirely to conceal that part.

2. V. multipuncta. Many-dotted Variolaria. Turn. Tr. of Linn. Soc. v. 9. 137. t. 10. f. 1. (Lichen multipunctatus; Engl. Bot. t. 2661.)—Crust ash-coloured, warty, rugged, tartaceous, thin, with a fibrous edge. Receptacles hemispherical, with a white, aggregate, powdery disk, and smooth, lobed border.—Found, not uncommonly, on the trunks of beeches in Suffolk, by Mr. W. Borrer. Nearly akin to the last, but the crust is more of a grey hue, and lfts uneven, though becoming rugged and warty by age. It changes nearly to white in drying. Fructifications the size of the leaf, but essentially differing in the want of a separate membranous cover, and in having each receptacle marked with three or four depressions, making to many distinct disks, in one thick lobed border. The surface of these disks is white and powdery; their minute pale chesnut.

3. V. globulifera. Vehicle-fruitied Variolaria. Turn. Tr. of Linn. Soc. v. 9. 139. t. 10. f. 2. Achar. n. 3. Prodr. Fl. Grece. n. 2432. (Lichen globulifera; Engl. Bot. t. 2008.)—Crust spreading, faintly bordered, rugged, greyish with white powdery warts. Receptacles spherical, closed; at length burbling, with a thin rugged border, and blackish disk.—This also was discovered by Mr. W. Borrer, growing on the trunks of beeches and oaks in Suffex, but rarely. Dr. Sibthorp met with it in Greece. The crust agrees in appearance with the following, but the globular veicles, of the size of small peas, scattered over the disk, and each lodging a blackish receptacle of seeds, are peculiar to the present species.

4. V. faginea. Common Bitter Variolaria. Perf. in U. Ann. f. 7. 24. Achar. Meth. 12. Prodr. Fl. Grece. n. 2433. (V. communis; Achar. n. 4. Lichen fagineus; Linn. Sp. Pl. 1063. Achar. Prodr. 27. Hoffm. Enum. 18. a. 1. 2. f. 4.)—Crust cartilaginous, rugged, polished, greyish, bordered with brown. Receptacles prominent, hemispherical, mealy, very white, with a pale, flatthih, at length naked, disk.—Very common on the trunks of beech, fycamore, oak, &c. throughout Europe, from Sweden to Greece. The crust, in a perfect slate is circular, grey or greenish when young, corrugated, but with a smooth polished surface, and circumcised by a thin border, elegantly coloured with concentric shades of brown. Numerous, prominent, almost flattened, tubercular receptacles are scattered over the central part, which are very white, especially in wet weather; powdery and somewhat convex in their disks, with a clumsy indistinct kind of border. By age the flesh-like, the crust, become of a dirty white. Mr. W. Borrer has first observed a very bitter taste in this species, not immediately perceptible, but after a while very strong, disagreeable and permanent, like the flavour of the Cyclamen root. No other species of Variolaria has been found to have this bitternes.

We know not by what accident the learned Acharius, generally so accurate, has transferred it to our difcidea, which he has therefore called amara. His specific characters of the two species leave no doubt of what he intends under each, though we do not presume to decide on all his synonyms. This being the case, we do not feel authorized to change the old Linnean name, though we readily allow that Linnaus here confounded two species.

5. V. difcoidea. Flat-capped Variolaria. Perf. in U. Ann. f. 7. 23. Achar. Meth. 14. (V. amara; Achar. n. 5. Lichen difcoidea; Achar. Prodr. 28. Engl. Bot. t. 1714. L. fagineus; Hoffm. Enum. 19. B. C. D. t. 7. f. 3. 5. L. albescens; Hudd. 539. L. carnieus; Lightf. 607. Lichenioles candidus et farinaeacum, scutellii feri planis; Dill. Mufc. 131. t. 18. f. 11.)—Crust cartilaginous, cracked, somewhat rugged, polished, greyish, bordered with brown; at length powdery. Receptacles flatthih, mealy, very white; at length concave, deprehit, with a dilated torn border.—This is probably as common as the preceding, with which it has been confounded. The chief mark of distinction consists in the little elevation of its receptacles, which, after discharging their powdery contents, become quite concave, with a thin expanded margin. Hence the present plant has been separated by several botanists from fagineus, even without their advertitious to its insipidity, remarked by Mr. Borrer,
Borrer, and which obliges us to retain the old name difcoidea, that of amara being only applicable to the former, where it is not wanted. On the trunks of old trees, particularly in wet weather, V. difcoidea is very conspicuous for its whiteness. No proper receptacle, of a different colour from the ground, has been detected in this species.

6. V. conglobata. Conglobate Variolaria. Achar. n. 6. — "Cruft tartareous, thick, milk-white, plated and conglom- erated, with a smooth cartilagineous surface. Warts of the receptacles close-preffed, of the same colour. Dilk powdery. Margin elevated, tumid. Nucleus thick, included, yellowish; flattened above." —Native of France. This appears by its colour, and the different habit of its parts, to be distinct from all the other known species. Acharius.

7. V. gelisio-congress. Greyish-green Variolaria. Turner and Borrer Lich. Brit. t. 51, unpublished. Engl. Bot. t. 2400. — Cruft elliptical, thin, slightly tartareous, rugged, grey, scarcely limited. Receptacles roundish, with a narrow border. Powder greyish. — Gathered by Mr. Borrer, on the smooth cuticle of the bark of birch and cherry trees, in Norfolk. The patches, about an inch or two in length, and half as broad, look like a dirty flaw, or some decayed Leparia; but when accurately examined, prove to consist of a continued, rugged, though thin, crust, of a dirty greenish-grey, bearing very distinct mealy receptacles, of a yellowish rather bright green when wet, bordered with white.

8. V. Cinchona. Smooth Green Variolaria. — Cruft elliptical, thin, cartilaginous, polished, nearly even, olive-coloured, slightly bordered with black. Receptacles round, white, mealy, with a smooth pale border. — Found on the bark of Cinchona floribunda from the island of St. Lucia. Our only specimem is above an inch in diameter, of a brighter more olive-brown than the bark, but otherwise fearfully diftinguishable to the touch. The whitish fructifications, scattered all over it, smaller than pins' heads, are very conspicuous.

9. V. aspergillus. Sprinkled Variolaria. Achar. Meth. 13. — Turn. and Borr. Lich. Brit. t. 67. Engl. Bot. t. 2401. (V. communis g; Achar. Syn. 131. Lichen aspergillus; Achar. Prodr. 28, excluding the reference to Persoon.) — Cruft orbicular, tartareous, thickish, dull white, wrinkled, with a smooth, white, polished edge. Receptacles scattered, elevated, hemispherical, with an oblong border. Powder very white. — Found by Mr. Borrer in Suffolk, more commonly on rails than on trees. This gentleman and Mr. Turner have, on the authority of an original specimen, determined the synonym of Acharius. That learned botanist has sent us, under the name Fame, what has a different aspect, being whiter and full of cracks; and such may perhaps have induced him to refer his plant to V. communis (fagina) as a variety. However this may be, our aspergillus is inferior, and clearly distinct from fagina; yet, though like difcoidea devoid of bitterness, it cannot be confounded with this latter. The edge is polished and white; the rest of a pale greyish or blueish hue, unaltered by moisture. Receptacles neither numerous nor crowded, but scattered, convex, very prominent; their border minute, and soon obliterated; their internal disk, or nucleus, pale flesh-coloured, concealed by the copious white powder, which forms a dense mass, and turns greenish by rubbing.

10. V. cirreus. Ash-coloured Variolaria. Engl. Bot. t. 2411. — Cruft orbicular, tartareous, thin, ash-coloured, cracked; its circumference indeterminate. Receptacles orbicular, very small, white, with an elevated margin, and a flesh-coloured concealed disk. — Discovered by the Rev. Mr. Harrism of whinfone rocks, in the county of Durham. We conceive it to be of all things most distinct from the following, with which it is said to have been confounded. The colour and great tenuity of the crust; the want of an expanded or zoned border; the more evident red nucleus; and the much smaller receptacles; all mark it with precision. The white powder of the latter is easily abraded, and then the disk or nucleus becomes inconspicuous.

Mr. Turner found a pale brown nucleus, which we have not seen.

12. V. dealbata. White-wash Variolaria. Decand. France. v. 2. 525. Engl. Bot. t. 2519. (V. corallina; Achar. n. 8. Lich. Univ. 319. t. 5. f. 6. Lichen dealbatus; Achar. Prodr. 29. Indium corallinum, a supposed variety; Achar. Meth. 138. t. 3. f. 75. D. E. Red. T. paradoxum; and Borr. Lich. Brit. t. 97.) — Cruft tartareous, thickish, greyish-white, cracked, cutaneous, papillary and rugged; obscurely zoned at the circumference. Receptacles orbicular, prominent, white, with an aggregate internal disk. — Not rare on rocks in mountainous countries. Differs from the last in having a very narrow, imperfectly zoned, border, and especially in the cylindrical, papillary, cretaceous processes, sometimes in pairs, scattered over the crust. The receptacles when young are small, concave, powdery, white cups; but the few which arrive at maturity become raised, convex, the size of hemp-seed, their surface still white and powdery, but finally displaying several little, concave, brownish or flesh-coloured, separate disks. We are not quite free from doubts, as to the plant of Acharius being the same as our's, and therefore we would not hastily follow him in altering the name, by which we have already adopted this most distinct and curious species in the English Botany.

Acharius.

14. V. gaditana. Spanish Variolaria. Achar. n. 10. — "Cruft nearly orbicular, tartareous, continued, rugged, grey, powdery powdery; its circumference somewhat crenate, with little imbricated lobes. Receptacles hemispherical, or partly cylindrical, crowded in the centre, and of the same colour."

—Gathered on walls near Cadiz, by Don Simon de Roxas Clemente. The sorts, or receptacles, whether hemispherical or somewhat cylindrical, become concave with age.

VARIOLITE, in Mineralogy, a name given by some mineralogists to porphyritic rocks, in which the imbedded substances
fustances are imperfectly crystalized, or are rounded, giving the tone a spotted appearance.

**VAR**

**VARORUM** in *Maters of Literature*, a term or phrase of abbreviation, used for an edition of a classic author, printed in Holland, with the notes of divers authors upon it: *Cum notis variarum, or cum fidelis variarum observationibus.*

In this sense we say, Plantus variarum; a set of Dutch *variorum*, &c. Many of the *variorum* are valuable editions.

The word is the genitive plural of the Latin *variis*, different, divers.

**VARIS**, in *Ancient Geography*, a place of the ille of Al- bion, on the route from Segontium (Caernarvon) to Deva (Chester), between Conovium (Caer-Rhyon) and Deva; supposed to be Bodvary; 32 miles from Deva, or Chester.

**VARUS**, in *Ichthyology*, a name used by most authors for a small fresh-water fish, common in brooks and running waters, and well known in England by the name of the **minnow**.

**VARUS Mus**, in the old authors of *Geography*, a name used for the same creature they otherwise called *mus ponticus*; which seems to have been no other than the European flying squirrel.

**VARIX**, from *variis, irregular*, in *Surgery*, denotes an uneven swelling of a dilated vein. The tumor is fishish, generally not painful, and presents an appearance as if fluided with several knobs, or tubercles, which correspond to the valves in number and situation. The diseased vein is also elongated as well as dilated, and describes in its course a variety of windings or convolutions. A particular account of the symptoms, causes, and treatment of this common disease, will be found under the head of *Venicose I'iens*.

**VARIX**, in *Animalis*, a sort of fluffy dilatation or enlargement in some part of a vein, forming a kind of knot. It mostly happens in the veins of the legs, and is of the nature of spavin. It may readily be removed, on its first appearance, by the use of cold solutions, and applications of that sort, frequently applied, and suitable bandages.

**VARLER**, in *Geography*, a town of Germany, in the biphorphic of Munster; 4 miles N.N.W. of Coesfeld.

**VARLET.** See *VALET*.

**VARMAT**, in *Geography*, a town of Hungary; 12 miles N.N.W. of Zatar.

**VARIO**, a river of Italy, which runs into the Taja- mento, 2 miles N. of Ladiifana, in the country of Friuli.

**VARNA**, in *Geography*, a sea-port town of European Turkey, in Bulgaria, situated on a gulf or bay of the Black sea, to which it gives name, at the mouth of the river Vrana; the fee of a Greek archbishop. In the year 1444, Ladiifana, king of Hungary, was defeated and slain by Amurath I emperor of the Turks, near this town; 144 miles N. of Confitantinople. N. lat. 43° 14'. E. long. 27° 16'.

**VARNA.** See *VRANA*.

**VARNAVA**, a mountain of Greece, near Athens.

**VARNAVIN**, a town of Ruflia, in the government of Kolrom, on the Vetiluga. N. lat. 57° 16'. E. long. 45° 14'.

**VARNI**, in *Ancient Geography*, a people of Aia, in Baetria. *Ptolemy*.

**VARNISH, or VERNISH, VERNIX**, a thick, viscous, glossy liquor, used by painters, gilders, and various other artificers, to give a gloss and luster to their works, as also to defend them from the weather, dust, &c.

There are divers kinds of varnishes; some of the principal of which are as follow:

**VARNISH, Amber**, is prepared in the following manner: Put four ounces of amber into a crucible, and melt it with a small degree of heat, and pour it out upon an iron plate; when cold, reduce it to powder, and add to it two ounces of drying oil, that is, linseed oil thickened by boiling it up with litharge, and one pint of oil of turpentine, and dissolve the whole together into a liquid varnish.

This simple amber varnish is of great use for many purposes, and is said to be the basis of the fine varnishes which we fee on coaches, and may be prepared without drying oil, by boiling the powder of amber in linseed oil, or in a mixture of linseed oil and oil of turpentine. Drying oil is commonly used by the workmen; but Dr. Lewis thinks it more eligible to take the oil unprepared, that the boiling requisite for giving it the drying quality may be employed at the same time in making it act upon the amber. It has generally been thought, that amber will not at all dissolve in oils, till it has suffered a degree of decomposition by fire. But Hoffman relates an experiment, in his *Observations Physico-Chemica*, which discovers the solubility of this concrete in its natural state. Powdered amber, with twice its quantity of oil olive, was put into a wide-mouthed glafs; and a digestor, or strong copper vessel, being filled about one-third with water, the glafs was placed in it, the cover of the digestor screwed down tight, and a moderate fire continued an hour or more: when cold, the amber was found dissolved into a gelatinous, transparent mass. In Dr. Stockar's *Specimen Inaugural* de Succineo, printed at Leyden in 1760, we have an account of other experiments made by himself, in conjunction with M. Ziegler of Winterthur; from which we learn, that by continuing a simmering heat twelve hours, and confining the vapour as much as stone-ware vessels would bear without burbling, (the danger of which was avoided by making a small notch in the cork-foppers,:) powdered amber dissolved perfectly in expressed oils, in turpentine, and in balsam of copaiba; a strong copper vessel, with a cover screwed on it, seems most eligible; and for the greater security, a valve may be made in the cover, kept down by a spring, that shall give way before the confined vapour is of sufficient force to endanger burbling the vessel. Moreover, by digestion for a week in clofe-opped glafs vessels, in which the compreffure could not be very great, solutions equally perfect were obtained. The solution in rape-feed oil, and in oil of almonds, was of a fine yellowish colour; in linseed oil, gold-coloured; in oil of poppy-feeds, yellowish-red; in oil olive, of a beautiful red; in oil of nuts, deeper coloured; and in oil of bays, of a purple-red. The solutions made with turpentine and with balsam of copaiba, were of a deep red colour, and on cooling, hardened into a brittle mass of the same colour. All the solutions mingled perfectly well with spirit of turpentine. Those made with the oils of linseed, balsam, poppy-feeds, and nuts, and with balsam of copaiba and turpentine, being dilated with four times their quantity of spirit of turpentine, formed hard, tenacious, glossy varnishes, which dried sufficiently quick, and appeared greatly preferable to those made in the common manner from melted amber.

An amber varnish may also be made by boiling down some colophony, or turpentine, till it becomes black and friable, and melting this in a glazed earthen vessel, sprinkling in, by degrees, thrice as much amber in fine powder, with the addition of a little spirit or oil of turpentine now and then. When the amber is melted, sprinkle in the same quantity of sarcocolla, continuing to mix them, and to add more spirit of turpentine, till the whole becomes fluid; then strain out the clear
VARNISH.

clear through a coarse hair bag, preffing it gently between hot boards. This varnish, mixed with ivory-black in fine powder, is applied, in a hot room, on the dried paper pa[le] of which the *papi er mâché* is made; which is then fat in a gently heated oven, next day in a hotter oven, and the third day in a very hot one, and let stand each time till the oven is grown cold. The paste thus varnished is hard, durable, glossy, and bears liquors hot or cold. Lewis's Com. Phil. Techn. p. 367.

An amber varnish may be otherwise made by melting eight ounces of Chio turpentine, and when fluid, pouring into it, by degrees, a pound of fine powdered amber, and stirring it; and when it is properly mixed, setting it on a fire for half an hour, taking it off, and stirring it well, and adding to it two ounces of the white colophony. It is again to be put on a brisk fire, and covered close; when the mafs is perfectly fluid, and taken off too cool, a pound of linseed or poppy oil, made drying, is to be poured in boiling hot, and stirred till it be incorporated with the mafs; and then a quart of hot turpentine is to be added, and the whole well stirred. Let it then cool, and strain it off for use; when, if it has been properly made, it will be quite clear. See Gilding on Enamel and Glass.

VARNISH, Black, for japanning on wood or leather, is prepared by mixing lamp-black or ivory-black with a proper quantity of a strong solution of gum lac in spirit of wine. (See Japanning.) The lamp-black is commonly preferred to the ivory-black, on account of its uniting better with the fluid, and working smoother. The thicker part of the varnish, which settles at the bottom, is used with the lamp-black for the first coatings, and the mixture applied at different times, in a hot room, one layer after another, is dry, till a full body of colour is obtained; after which, the piece is washed over in the same manner several times, with the finer part of the varnish, just tinged with the black, so as to make a coating of sufficient thickness to bear polishing with tripoli. Iron snuff-boxes, mourning buckles, &c. are coloured black, by making them considerably hot, and applying on them in this flate a thick mixture of lamp-black, with a certain varnish called gold-size, confifting of drying oil, turpentine, and the pigment called Naples yellow; but the yellow might be omitted, and the varnish formed at once by mixing lamp-black with a proper quantity of turpentine and drying oil. The workmen, as Dr. Lewis says, frequently employ, as varnish for metals, a mixture of lamp-black, with the flavumings, &c. of different oil paints; the mixture is applied with a pencil, and the piece afterwards baked in an oven with a heat somewhat greater than is used for the *papier mâché*. Naples yellow, a superfluous ingredient in the black varnish, is the basis of the dark-brown which we see on some iron snuff-boxes; this pigment changing to a brown in baking with the varnish. Lewis.

See LACQUER.

The excellent black varnish of China and Japan, which has been hitherto but imperfectly imitated in Europe, and which was formerly thought to be an artificial composition of reinos bodies coloured with black pigments, has been discovered by the later travellers into those countries, to be a native juice, exuding from incisions made in the trunks of certain trees. Mr. Miller, in confequence of a letter from the abbé Mauret to Dr. Hales, containing a communication of the discovery of a plant by the abbé de Sauvages, which he calls *troidendron Cardinianum folis pinatis, florus mini- mis herbaceus*, and the black juice of which adheres, without the least acrimony, to cloth with more force than any other known preparation, takes occasion to shew, that this American toxiodendron is the fame species of plant from which the inhabitants of Japan procure the varnish with which they fit all their utensils; adding, that the Calicuts are also painted with the juice of this shrub. This American toxiodendron (see Poison-tree) is the fame plant, as he affirms, which is mentioned by Kämpfer, in his Amoenitates Exoticae, by the title of *arbor vernacifera legumina, folio pinato juglandis*, *fruita racemofe cireos facie*; i.e. the true varnish-tree, with a walnut-tree leaf, and a branching fruit like cicers. It is called by the inhabitants of Japan *sato*, or *fehiz-sa,yu*, and also *uru, e uru-nabi*. Kämpfer has also described the wild or fpurious varnish-tree, called *faji-no-ki* by the natives, which he says agrees with the other in every part, except that the lobes of the leaves are narrower; but Mr. Miller is of opinion that this is a distinct species, if not a different genus, from the true fort; and says, that the varnish yielded by it is of little esteem. The account which the Jefuits at China have given of the manner in which the varnish is procured, is as follows: they first fill the back of the branches of the shrub, in different places, with a knife; and thus there flows out a white clammy juice, which is received into wooden vefels; and when these become dry, they tap the stems of the shrubs near the roots, so that all the juice is drawn out of them. The shrubs are then cut down to the ground, and from their roots new ftems arife, which in three years will be fit for tapping. The juice turns black when exposed to the air; it heats without turning foud; but being of a poisonous nature, it is dangerous to handle it. This native varnish wants hardly any preparation; but if any dirt should happen to mix with it, it is cleansed by being strained through coarse gaze, put into wooden vefels, and covered with an oil called *toi*, and a skin, in order to prevent its evaporating. In this state it is carried over to China and Japan for sale. The shrub is chiefly cultivated in the provinces of Tü-kocko and Figo; and the best varnish, according to Kämpfer's account, is produced about the city Jaffino; but there is an ordinary fort of varnish, called *num-rak*, brought from Siam, which is collected in the province of Corefama, and in the kingdom of Cambodia, from the tree anacardus, called by the inhabitants *tong, ot tu-rak*, the fruit of which is called in our shops *anacardiun*. To collect this liquor, they bore a hole in the trunk, and insert a tube. By this method they procure as much of it as is sufficient, not only to varnish all the utensils of China, Tonquin, and Japan, but it is even exported in clofe wooden vefels to Batavia, and other parts of India. This varnish, says Kämpfer, is not only fold quite pure, but likewise coloured, with Chinese native cinnamon, and a kind of red earth, which the Dutch formerly, but now the Chinese bring them, and also with the materials of which they make their common Japan ink. Mr. Ellis has controverted the opinion of Mr. Miller, and endeavoured to shew that the American toxiodendron is not the fame with Kämpfer's *arbor vernacifera legumina*; alleging, that Kämpfer's defcription of the true varnish-tree does not agree with this toxiodendron; and he inclines to the opinion, that the Carolina pinuted toxiodendron, or psifen-she, is the fame with the *faji-no-ki*, or fpurious varnish-tree of Kämpfer. Mr. Ellis also thinks it is not improbable, that the varnish mentioned by Kämpfer, as obtained from the oriental anacardum, is the fame with that mentioned by father d'In- careville, in the Phil. Tranf. vol. xviii. p. 254, called *tong- yau*; which is fo universally used in China for preferving and ornamenting their furniture. See this controversy between Mr. Miller and Mr. Ellis at large, in Phil. Tranf. vol. xli. part i. p. 577—166. part ii. p. 806—876. vol. i. p. 420—456. See Poison-tree, Linen, and Japanning.

VARNISH, Brown, for Metals. See Black Varnish, fupra.

Varnish,
VARNISH.

VARNISH, Copal Oil, called in France vernis martin, is made by pouring into a well-glazed strong earthen pot, in shape resembling a chocolate pot, and in size large enough to hold about a gallon, and made warm, four ounces of Chio or Cyprus turpentine, and when this is dissolved, eight ounces of finely powdered amber; mingling them well, and setting them on the fire for a quarter of an hour; take off the pot, and pour gently into a pound of copal, finely bruised, but not powdered; stir the mass, and add four ounces of Chio turpentine, and a Gill of warm turpentine oil; then let it on a brisk fire for about half an hour, and taking it off, stir the contents well, and add two ounces of the finest and whitest copal. Let the pot be put on a very brisk fire, and remain till the whole is dissolved, and become as fluid as water; let it be removed from the fire, and remain for a few minutes, and then gradually pour in twenty-four ounces of poppy, nut, or hinseed-oil, made drying, and boiling hot, and stir the mass with a deal flick. When the gums and oil are thoroughly incorporated, let them over the fire for a few minutes, fill them stirring them, and let them boil once up; and having taken off the pot, pour into it a quart of hot turpentine; stir them together, and give them one boil up; take off the pot, and pour into it a pint more of hot turpentine, still stirring it well. If the gums are thoroughly melted, and well incorporated, the varnish is made; which, being cool, is strained through a close cloth into another vessel, and, if it be too thick, thinned with oil of turpentine, till it becomes of the consistence of linseed-oil; strain it a second time, bottle it for use, and let it stand a month, at least, before it is used. This varnish is used for coaches, cabinets, &c.; and the piece, whatever it be, after having been varnished smoothly, and dried in the intervals half a dozen times, and suffered thoroughly to dry, must be rubbed with a wet coarse rag, dipped in pumice-stone, powdered and sifted, till the streaks of the brush and all blemishes are removed. When it is perfectly smoothed, washed, and dried, the coats of varnish are to be repeated, for ten or twelve times, till there be a sufficient body. After having again used the powdered pumice-stone, and washed it off as before, let it be rubbed with fine emery, till the surface becomes even and smooth as glass; then with powder of fine rotten stone, till by polishing the palm of the hand two or three times over the same place, you discover a gloss equal to that of glasses: having dried it clean, dip a rag, or piece of flannel, in sweet oil, and rub the surface a few times over, and clear it off with fine dry powdered flour, or the hand; and a piece of fine flannel, dipped in flour, and rubbed over it, when cleared of the oil, will give it an excellent lustre. Between every coat of varnish it will be advisable, if the subject admits of it, to let it in a warm oven; or to heat the varnished pieces by roves. See Copal.

VARNISH, Gold-coloured. See Lacquer.

The composition of a gold-coloured varnish, used by the English artists for brs and silver, was communicated to some of the French academicians in 1720, by Mr. Scarlet, and in 1738 by Mr. Graham, and published in the volume of the French Memoirs for 1761. It is as follows: Take two ounces of gum lac, two ounces of yellow amber, forty grains of Dragon's blood in tears, half a drachm of lafiron, and forty ounces of good spirit of wine: infuse and digest in the usual manner, and then strain through a linen cloth. The piece to be varnished must be heated before the liquid is applied: it receives from the varnish a gold colour, and may be cleaned, when fullled, with warm water.

VARNISH for preserving polished Iron from Rust. See Iron.

Many methods have been used for preserving iron utensils from rust, as animal fats, oils, boiled oil mixed with melted lead, &c. Homberg's salve for this purpose consists of two pounds of hog's-lard, an ounce of camphor, and as much black lead as will render the mixture of an iron-colour; when this is used, the iron must be previously heated. M. Reaumur has discovered a better composition for this purpose: it is oil, inflam'd by being exposed to the air in flat shallow vessels, so as just to cover the bottom, mixed with a solution of copal in spirit of wine: this forms an elegant hard varnish, which, rubbed on polished iron, made a little hotter than the hand can bear, will cover it with a solid, thin, transparent coat, without any injury to its colour or appearance. See Rust.

VARNISH; Lacca, is made of gum lacca and spirit of wine, frequently shaken till the gum be disolved, then strained, and the clear liquor decanted off.

The lacca ought to be of the kind called feed lacca. (See LACC.) Three ounces of this, well purified by repeated ablation of water, dried and powdered grofsly, should be put into a bottle with a pint of rectified spirit of wine, so as to fill about two-thirds of it, and the bottle placed in a gentle heat; proceeding as above: though for varnishing ordinary woods, shell lacca is often used. For this purpose, five ounces of the best shell lacca should be grossly powdered, and put into a bottle, holding about three pints or two quarts, with one quart of rectified spirit of wine; and placed in a gentle heat: the mixture must be filtered through a flannel bag. To this varnish, the colours used in varnish painting may be added, and properly diluted with rectified spirit, and kept in phials, or tin vessels closely stopped for use. But this will not stand against the weather.

For various preparations of this kind, see Japanning and Lacquer.

VARNISH, Mastic, is made by putting five ounces of powdered mastic into a proper bottle, with a pound of spirit of turpentine, and letting them to boil in balsam Marie, till the mastic be disolved, and straining the solution through flannel. This varnish may be converted into a proper varnish for painting, by grinding one ounce of gum anime on a stone with water; till it becomes an im-palpable powder; then drying it, and grinding it again with half an ounce of turpentine, and afterwards with the proper colours, and moistening it with the mastic varnish, till the mixture be of a due consistence for working with the pencil. It must then be kept in phials or tin vesicles, and diluted, as there may be occasion, with spirit of turpentine.

VARNISH for preserving Paintings. See Picture.

For this purpose some have recommended the following composition: viz. half a pound of gum fandarac; an ounce and a half of Venice turpentine; three-quarters of an ounce of each of the gums anime and copal; half an ounce of mastic; benzoin, gum elemi, and white refin, each two drachms, and one pound of rectified spirit. The benzoin and gum anime powdered, are put with the Venice turpentine into a phial, with eight ounces of the spirit of wine; the copal and refin powdered are also put in a phial with fix ounces, and the powdered gum elemi, with two ounces of spirit of wine. The several phials are frequently shaken, till the gum, &c. are disolved; then the solutions are strained through a fine linen in one bottle, and when the mixture has stood some days, it is decanted off clear, and kept in a separate bottle for use. Some have substitute the farcocola for the copal. Another composition is formed, by dissolving mastic and fandarac, grossly powdered,
Varnish

and discovered others must His Greek, work the glibby a in fusceptible Rodopa. and 1542, is died medal but thoroughly naval turcois blue, a and He others fine pencil. pound In separate alfo in inventor, one varnifh, Venice turpentine half an ounce, by olibanum, fhould dering not fofter them time, varnifhing by the attraction of the cloth on the oils mixed with them. An oil of turpentine varnish may be added by grossly pow- dering maffic and fandarac, of each four ounces; two ounces of white reffin; and farcocolla, anime, copal, and olibanum, of each one ounce; and putting them into a phial with two pounds of oil of turpentine, flopping the phial gently, and placing it in any heat, fo that the mafs may not boil, and flaining off the solution for use. Or, a varnifh more simple, and equally good, may be made by pow- dering two ounces of fandarac, maffic and olibanum, of each an ounce and a half; or three ounces of maffic, and Venice turpentine half an ounce; and diffolving them in half a pound of oil of turpentine, and proceeding as before. Handmaid to the Arts, vol. ii. p. 227, &c.

Varnish for Printers' Ink. See Printing-Ink.

Varnish, White, is usually made of gum fandarac and gum maffic, diffolved in fpirits, left to fettle two days, then flained through a linen cloth, and, after flanding some time, the clear poured off, and bottled for use.

The more curious artists difolve the two gums separa- rately; and having made a feparate varnish of each, mix them occasionally, as their work requires a thicker or a fottier varnish.

But for the left white varnish more gums are required; viz. Venice turpentine, gum copal, elemi, benzoin, anime, and white reffin.

Besides these, there are hard and soft varnishes, or grounds, used by the etchers and engravers. See Etching.

Varnish is also used for a kind of glibby coat, with which potter's-ware, Delf-ware, China-ware, &c. are covered, to give them a smoothness and luftre. Some prepa- ration of lead is the varnish ordinarily used for the firft; and earths for the second. See Glazing and Pottery.

The true varnish used by the Chinese and Japanefe, to give that inimitable luftre to their porcelain, is one of the grand feats in that manufacture; and is one of the great things wanting, to make Delf and French ware vie with the Chinese. Several have described the preparation of it, particularly Kircher; but none ever succeeded in the trial. See Porcelain and Varnish, supra.

Varnish is also a term applied to the colours which antique medals acquire in the earth.

The value of a medal is heightened by a beauty, which nature alone was able to give, and art has never yet attained to counterfeit; we mean the colour or varnish with which certain foils tinge the medal; some with a blue, almoft as beautiful as that of a turcois; others with an inimitable vermilion colour; and others with a glibby shining brown, infinitely beyond any of our figures in bronze.

The moft usual varnish, however, is a fine green, which hangs to the moft delicate strokes without effacing them; much more accurately than the finest enamel does on metals. Brats alone is fulcceptible of it; for as to silver, the green

ruit that gathers on it, always spoils it; and it muft be scoured off with vinegar, or lemon juice.

There is also a falfe, or modern varnish; which the fal- fiers of medals give to their counterfeits, to give them the air of antiquity: it is discovered by its being fottier than the natural varnish, which is as hard as the metal itself.

Some lay their fpurous medals under ground, where they contract the degree of varnish, that they impose on the lefs knowing: others use ful ammoniac, mixed with vinegar; others the acid spirit of nitre, &c.

VARODOPA, or VERODOPA, in Ancient Geography, a pro- vince in the environs of Macedonia, according to Europius. Ortelius makes it a country of Thrace, writing it Rodopa.

VAROE, in Geography. See VARIOE.

VAROLI, Costanzo, in Biography, was born at Bo- logna in 1542, and became a professor of phyfic and fur- gery in his native city. In 1572 he was invited by pope Gregory XIII. to settle at Rome as his fair physician, and professor in the college of Sapienza. He was advancing in reputation by his anatomical discoveries, as well as in his practice of medicine and surgery, when a premature death cut him off in 1575, in the 33d year of his age. He was particularly distinguished in the anatomy of the brain, which he described in his work "De Nervis Opticis nonnullis quibus præter communem Opinionem in Humano Capite operatvs Epiftola ad Hieronymum Mercuriam," Patav. 1570. Among the parts of the brain which he dis- covered, or more accurately described, was that known by his name, the "Pons Varoli," formed by the union of the crura cerebri and cerebelli, and the place whence several nerves originate. After his death was published "De Re- solutione Corporis Humani," a work which is a com- pendium of anatomy, chiefly according to the ancients, but with several new observations by himself. Haller. Eloy. Varoli Pons, in Anatomy. See Pons.

VARORE, in Geography, a town of Hindooftan, in Baramaul; 14 miles N.N.W. of Darempour.

VAROTARI, Dario, in Biography. See Paduanino. VARPA, in Geography, an innland near the N.E. coast of Sumatra, about 30 miles in circumference. S. lat. 6° 30', E. long. 103° 25'.

VARO, Marcus Terentius, in Biography, the most learned of the ancient Romans, received from Pompey the Great, in the piratical war, a naval crown, and joined this chief in the civil war agains Cæfar; but afterwards submitting to the latter, he was employed by him in making a collection of books for the public library which he proposed to establish at Rome. The death of Cæfar prevented the accomplishment of this design; and Varro, being involved in the proscription by the triumvirates, escaped with his life, but with the loss of his library. After the restoration of tranquillity, he retired for the prosecution of his studies, and composed books till his 88th year. His life was prolonged to the age of 90, and he died about the year B.C. 27. He is highly extolled for his various talents and literary performances by ancient writers, and par- ticularly by Cicero in his "Academics." Anius Gellius cites a passage from Varro, in which he declares of himself, that to the 78th year of his life he had composed 400 books, and he continued to write to his 90th year. The subjects on which he wrote, as we learn from Fabricius, were grammar, eloquence, poetry, the drama, history, antiquities, philosophy, politics, agriculture, nautical affairs, architecture, and religion. He was also the first Latin author of that species of satire called the Menippian, from Menippus, a Greek, its inventor, which was written in prose, with a mixture of verse in different measures. (See

Menipean.)
V A R

MENIPANE.) Such and so pre-eminent was the reputation of Varro, that when Aemilius Pollio, in the reign of Augustus, opened the first public library at Rome, and placed in it the effigies of various learned persons, he was the only living writer who had the honour of this distinction. The only relics of his numerous works are six books, in an imperfect state, out of twenty-four, which he composed on the Latin language, with three books on agriculture, and a few fragments of his epigrams. The former are printed among the "Auctores de Lingua Latina," and the latter among the "Auctores de Re Rutilia."

Gen. Ch. Cal. Perianth of one leaf, inferior, tubular, with five long, slender, recurved teeth, permanent. Cor. of one petal, tubular; tube cylindrical; limb in five deep spreading segments. Stem. Filaments five, awl-shaped, the length of the corolla, inserted into its tube; anthers oblong, incumbent. Petf. German superior, ovate; style thread-shaped, the length of the corolla; stigma four, bristle-shaped. Pet. Drupa ovate, of one cell, inclosed in the swelling calyx, but not connected with it. Seed. Nut roundish, of four cells.

A West Indian genus of shrubby plants, with simple, alternate, rarely almost opposite, rough leaves; and terminal, aggregate, rather ornamental, flowers. They are little known in our flowers, nor has any one species as yet been exhibited in our popular periodical works. Variocina is next akin to Tournefortia (see that article;) but the leaves are divided, and each leaf of six leaves, and four slender bristles, are sufficient to mark the present genus, without advertizing to their fruits, which are not in all cafes well understood.

1. V. lineata. Round-spiked Varroina. Linn. Sp. Pl. 275. Willd. n. 1. Ait. n. 1. Swartz Obs. 87. (V. fruticosa, folia rugosae, ovatis, subfibrifitas, ferratis, alternis, capitulis subfubrosis; Browne Jam. 172. t. 13. f. 2. V. humilis; Jacq. Amer. 41. Ulmi angustifolii facie Bacchus jamaceif. folio purpureo fructi botryoide monopermo; Pluk. Almag. 393. Phyt. t. 328. f. 5.)—Leaves lanceolate, minutely hairy, marked with straight defrived veins. Flower-flaks mostly axillary, combined with the footstalks. Spikes globose.—Common in the lower woody lands of Jamaica. The stem is three or four feet high, with many slender, round, downy, crooked, entangled, leafy branches. Leaves spreading, or rather dependent, two inches long, taper-pointed, daintly and irregularly serrated; roughish, like a very fine file, with minute rigid hairs, above; denely downy and hoary beneath. Footflaks hairy, a quarter of an inch long, united for half their length, to the base of each simple, solitary, downy flower-flak, which is about half the length of the leaf, and bears a round head of small white or yellowish flowers. Plukent's figure is a much better representation of the Linnaean specimes from Browne himself, than his own plate, particularly with respect to the situation of the flowers. We cannot but suspect some error, and that the said plate may represent a species not hitherto well defined.

2. V. bullata. Blotted Varroina. Linn. Sp. Pl. 276, excluding Jacquin's synonim. Am. Acad. v. 5. 394. Willd. n. 2. Swartz Obs. 88.—Leaves ovate, venous, rugose, rough with callous tubercles and bristles. Spikes globose, on long rough stalks, from the forks of the stem.—Native of Jamaica. The Linnaean specime is from Browne, but does not answer to the description of either of his species. The branches are forked, extremely rough with minute warts, and rigid ascending bristles, as are likewise the footstalks and flower-flaks. Leaves an inch and a half or two inches long, about four times the length of their stalks, nearly elliptical, acute, serrated, reticulated with copious veins, and minutely blotted in the interstices; beakned on the upper side with callous tubercles and bristles, which turn white by age, when the leaf becomes tawny; paler, with hairy veins, beneath. Flower-flaks from the forks of the branches, solitary, from one inch to two inches and half a long, erect, simple, very rough, quadangular upwards. Spike globose, of six or eight flowers. Calyx corrugated, bristle, with linear recurved teeth. Corolla not much longer than the tube of the calyx, with five plait in the limb. Fruit tuberculated. Many doubts have arisen respecting this species. What we have here, with all possible precisio, described, is certainly the Linnaean authentic specime, which we should suppose to be the Lantana Radulata of Swartz, Ind.occ. 1557. Willd. Sp. Pl. v. 3. 317; to judge at least by the description, not having seen the plant. Nevertheless our's has the calyx and corolla of a Varronia, and the habit of the plant is so near V. mirabiloides, as figured by Jacquin, that Linnaeus may well be excused for supposing them one and the same. In the Linnaean herbarium are two other specimes, sent by Roderer, and marked likewise V. bulbata. It must be to these that Swartz alludes, when he says, in his Obs. 88, "there is a specime of V. globosa in Herb. Linn. under the name of bulbata." Whether this be correct or not, these have never been described as bulbata, though, by mistake, so named.

3. V. mirabiloides. Salver-flowered Varroina. Jacq. Amer. 41. t. 33. Willd. n. 3. Swartz Ind. occ. 465.—Leaves ovate, rough, serrated. Spikes roundish, unequal. Corolla salver-shaped; its tube three times the length of the calyx.—Native of Hispaniola, even in hedges near the town of Port-au-Prince. Jacquin. The most elegant of its genus, often twelve feet high. Leaves two inches long, rough on both sides. Flower-flaks lateral and terminal, measuring three or four inches, and bearing each a simple or divided round-headed spike, of numerous white inodorous flowers, very hardy, the size of Marvel of Peru. Segments of the calyx small, ovate, ending in long bristles. Drupa red, the size of a pea, full of sweet glutinous pulp. Nut defrived. Such is the plant of Jacquin, and we must suppose Swartz's the same, in spite of some flight incongruities of description. We have never seen either.

4. V. martinicensis. Martinico Varroina. Jacq. Amer. 41. t. 32. Willd. n. 4. Ait. n. 3.—Leaves ovate, pointed. Spikes oblong, dense. Calyx-teeth linear, half the length of...
of the tube.—Native of Martinico. Sent to Kew by Sir Joseph Banks, in 1795. It is said to flower in the flow the two months of August and September.—A shrub as tall as a man; the young branches only rough with close-prefixed hairs. *Leaves* three inches long, sharply serrated; rough above, with minute deprefened hairs; soft and downy at the back. *Flower-flanks* solitary, a little above each fork of the branch, silky and a half long, each bearing a dense *spikes*, about an inch long, of many funnel-shaped, probably white, flowers. *Calyx* silky, with broader and shorter teeth than any of the foregoing.

5. V. *globofa*. Globofe Varronía. Linn. Sp. Pl. 276. Willd. n. 5. Jacq. Amer. 41. — *Leaves* lanceolate-oblong. Stem forked. *Flower-flanks* axillary, elongated, naked. Spikes globose.—Native of the West Indies. An obscure species, of which we can only give the Linnaean specific character, the author of which adds pedunculus e diebotomia nuda; meaning, probably, that whenever a flake springs from the fork of the stem, it is accompanied by a leaf. Linnaeus further says, that the *calyx-teeth* are long, linear, and recurved. Whether the specimen above-mentioned from Rolander (see n. 2) be this species or not, we have no authority to say. Sir Joseph Banks has favoured us with what he considers as *V. globofa*, from Von Rohr, which may be the same; the *leaves* and *flummets* are much blunter, but hardly enough to make a specific distinction.—In this the *leaves* are scarcely above an inch long, rough and rather hoary, especially beneath, as are also the *branches* and *footsflaks*. *Flowers* numerous, in denes, globular, silky, flaked heads, either from the forks of the younger branches, or opposite to a leaf. *Calyx-teeth* as described by Linnaeus.

6. V. *curassavica*. Long-spiked Varronía. Linn. Sp. Pl. 276. Willd. n. 6. Jacq. Amer. 40. n. 1. Swartz Ob. 88? (V. auffurgenus farmenta, folis et capitulis oblongis; Browne Jan. 1722)—*Leaves* elliptic-oblong, minutely toothed. Spikes oblong. *Calyx-teeth* triangular, slightly pointed.—Sent by Von Rohr from the West Indies, and given by us to the late Mr. Dryander, as the authentic plant of Jacquin, compared doublets with his specimen. Yet the *calyx-teeth* have lefs evident points than he describes, and the *spikes* are rather lax. Whatever our intelligent friend Dr. Swartz may have had for *V. curassavica*, we can assert that our is certainly different from *martinicus*. (See his Obs. 88.) Jacquin describes it fifteen feet high, with round rough *branches*, roughy when old. *Flowers* small, white, without scent, in denes terminal *spikes*, two or three inches long. *Drupa* small, red.

8. V. *alba*. White-flowered Varronía. Linn. Sp. Pl. 276. Jacq. Amer. 41. Willd. n. 8. (Melipus americana, alni vel coriyli folis, fructu mucaginolio albo; Comm. Hort. v. 1. 155. t. 80.)—*Leaves* heart-shaped, pointed, flowers cy- mole.—Native of South America, about Cartagena and in Curaslaw. A tree, often thirty feet high, with an ample spreading head, and a trunk fix inches in diameter; though in hedges it is scarcely more than a shrub. *Leaves* four or five inches-long, ferrated, rough; somewhat heart-shaped at the base. *Cymes* large, not uncommon extending fix inches, of numerous, white, scented *flowers*. *Calyx* at first entire, but, as the *corolla* protrudes, it is pushed aside horizontally, splitting into two valves, the upper withering, the under permanent, and the margin is seen to have five very flight teeth. Limb of the *corolla* bell-shaped. *Drupa* oblong, measuring half an inch, whitish, termepellucid, sweet, but inodorous and glutinous, eaten by the inhabitants of Curas-
fow. *Nuc* oblong, fritated, black.

9. V. *monosperma*. Single-seeded Varronía. Jacq. Hort. Schoenbr. v. 1. 18. t. 39. Willd. n. 9.—*Leaves* ovate; entire at the base. *Cymes* lateral. Flowers capitulate.—Native of the Caracas. It flowered in the flow at Schoenbru all summer long, and bore fruit. The *stem* is twelve feet high. *Leaves* three inches in length, flaked, ferrated from about the middle only. *Flowers* small, white, in little globular heads, collected into flaked *cymes*, which spring laterally from the branches, about half way between the leaves. *Calyx-teeth* triangular, scarcely pointed. *Corolla* bell-shaped, abrupt, crested. *Stigma* dilated, obtuse. *Drupa* scarlet, the size of a pea. There being but one kernel, is probably owing to the plant not being in a natural situation, and therefore is wifely omitted by Will- denow in the specific character. For the same reason, the name may probably prove exceptional.

In studying this genus, we cannot but observe that the species are not fo distinctly known, nor so well defined, as could be wished, nor do we pretend to have placed them all beyond the reach of uncertainty, our materials being, in several instances, defective on the score of authority.

VARRONIAN SATIRE. See SATIRE.

VARS, in Geography, a town of France, in the department of the Charente; 6 miles N. of Angoulême.

VARSAKA, a town of Imiretia; 10 miles S.E. of Cotatis.

VARSETCH, a town of Ithria; 8 miles E. of Pedana.

VARSHNEYA, in Mythology, a name of the Hindoo deity *Krishna*; which fee.

VARSOVIA, in Geography. See WARS.

VARU, an island in the Caribbean sea, near the coast of South America, about sixteen miles long, and three broad. N. lat. 10° 12'. W. long. 75° 25'.

VARVELS, in Falconry, small rings about a hawk’s leg, with the owner’s name on them.

VARUNA, in Hindoo Mythology, is the genius or regent of the waters, corresponding with the Neptune of Western heathens. As light is thought to be excluded from the deep, Varuna is also deemed the governor of the night, or of darkness; in this character, as well as in that of lord of punishment, coalescing with the Hindoo *Pluto*, who is named *Yama*; which fee. Still he is one of the twelve funs, called *Aditya*, of which see our article *SUREYA*. As lord of punishment, the wealth of criminals is directed to be offered to him; or, in other words, thrown into the waters; or it may, instead, be bestowed on a learned priest. The latter, we may suppose, is likely, on most occasions, to outshine the deity. In the Institutes of Menu, ch. ix. v. 243; 45. 5, these texts occur. “Let no virtuous prince appropriate the wealth of a criminal in the highest degree; for he who appropriates it through covetousness, is contaminated with the same guilt. Having thrown such a fine into the waters, let him offer it to Varuna; or let him bestow it on some priest of eminent learning in the scripture. Varuna is the lord of punishment; he holds a rod even over kings, and a priest who has gone through the whole Vedas, is equal to a sovereign of the world.” In another text, c. ix. v. 398, it is said that “Varuna most assuredly binds the guilty in fatal cords.” Like other Hindoo deities, Varuna has a consort, or falki, assigned him. She is called *Veruni*; which fee. He has likewise a terrestrial palace or paradise, situated far in the

VAS, VESSEL. See VESSEL, VESICULA, and ANGIOLOGY.

Hence, in the phrase of anatomists, the vasa adiposa, preparatoria, &c.

VAS Chyliiferum, in Anatomy, the thoracic duct. See ABSORBERS.

VAS DEFERENS, the excretory tube of the testis. See GENERATION.

VASA Brevia, the short arterial and venous ramifications proceeding from the splenic trunks to the great end of the stomach. See ARTERY, and VEIN.

VASA EFFERENTIA et INFERENTIA; the latter are the lymphatic vessels, which enter an absorbing gland; and the former, those which go out of it. See ABSORBERS.

The tubes which pass from the upper end of the testis, and unite to form the epididymis, are also called vasa efferentia. See GENERATION.

VASA LACTEE, or Vena Lactee, the absorbents which take up the chyle from the small intestine. See ABSORBERS, and INTESTINE.

VASA VENOSORUM, the vessels which belong to the coats of vessels. See HEART.

VASA CONCORDIA, in HYDRAULICS, are two vessels, so constructed, as that of one of them, though full of wine, will not run a drop; unless the other, being full of water, do run alto. Their structure and apparatus may be seen in Wolluss, Element. Math. tom. ii. Hydraul. Vasa, in Geography, a town of Turkistan, on the Sirr; 70 miles W. of Taraz.

VASA, or Wafa. See WASA.

VASAGUDA, or VAGAGUDA, in Ancient Geography, a town of Africa, in Mauritania Cazeria. Ptol.

VASANTA, in HINDOOS Mythology, is the name of the bolom friend of their Kama, god of love. Among the Maharattas and low people he is called Bellant, Bellent, or Buftant; he is a perifonification of the feafon of spring; and fongs in his honour are chanteed by minbrods of both sexes at vernal and other festivals. See under KAMA for fome mention of his infeparable attendant.

VASARHELY, in Geography, a town of Hungary, on a small river, which runs into the Tisza; 50 miles N.N.W. of Temeswar. N. lat. 46° 27'. E. long. 20° 33'. Alfo, a town of Hungary; 22 miles E. of Câșimâr. Alfo, a town of Transylvania; 40 miles E. of Colovar. N. lat. 46° 37'. E. long. 25° 5'.

VASARI, GIOSTGO, in Biography, was born at Arezzo in 1512, and was first instructed in design by a glafs-painter, called il Prete Gallo, but afterwards, being taken to Florence by the cardinal Pafferini, studied under M. Angelo and Del Sarto. Another friendly cardinal conveyed him to Rome, the cardinal Ippolito di Medici; and under his protection he acquired riches and honours. In Rome he laboured assiduously, attacking himself particularly to M. Angelo, of whom he appears, by several letters preferred by Bottari, to have been very sincerely esteemed. He was employed in several public works at Rome, both as a painter and an architect, particularly in the Vatican, in the Sala della Cancellaria, where he painted, by the direction of the cardinal Farnese, a series of frescoes, representing the principal actions of Paul III. and in the church of S. Giovanni Dicollato, he painted for the principal altar the martyrdom of that saint, one of his most highly esteemed performances.

He was invited by Cofmo I. to Florence in 1553, and employed by that prince as superintendent of the important works then going on in the Palazzo Vecchio, where he executed, with the help of numerous disciples, the decoration of the principal apartments. Of his paintings there, pope Clement VII. crowning the emperor Charles V. was the most important, and it was accompanied, in other compartments in the same hall, by representations of the actions of that monarch.

There are many other works of Vafari scattered about Italy, as at Bologna, Arezzo, and Rimini, &c.; but after all he was a tame copyist of Michael Angelo's manner, and a very indifferent colourist. He is far more endeared to us by his writings than his pictures. His work, entitled "Lives of the most excellent Painters, Sculptors, and Architects, from the Period of Cimabue till his own Time," is the fountain of knowledge concerning the greater part of them; and though in many points he appears to have been too facile of belief, and to have related histories without sufficient inquiry into their correctness, yet upon the whole the world is indebted to him for an ingenious and useful work; without which, the history of the art would not now have been so distinctly understood, nor the profession so justly known and honoured. It was first published at Florence, in two volumes, in 1550, and afterwards republished, with considerable additions, and heads engraved in wood of most of the artists mentioned, in 1568, and has since been re-edited with copious notes by Bottari. Vafari died at Florence in 1576, at the age of 64.

VASAVA, in Mythology, a name of the Hindoo god Indra: which see.

VASBARA, in Ancient Geography, a town of Africa, in the interior of Mauritania Cazeriafci. Ptol.

VASBUHL, in Ancient Geography, a town of Africa, in the interior of Mauritania Cazeria. Pтол.

Vasco, or VASORUM CIVITAS, in Ancient Geography, a town of Gallia Narbonensis, according to Ptolomy and Pliny.

VASCONES, a people of Hispania Citerior, at the foot of the Pyrenees. These people, who in later times passed into Gaul, where they assumed the name of Gaeons, lay to the east of the Cantabr, in the country now called Navarre; and they extended from the Pyrenees as far as the Iberus towards the south. Their principal towns were Pompelo, Calaguris, and Gracarius.

VASCULAR, VASCULARIS, in Anatomy, is applied to any thing consisting of divers vessels, veins, arteries, &c.

We say, the vascular and valvar texture of the lungs.
All the flesh, in an animal body, is found to be vascular, none of it parenchymous, as the ancients imagined.

Vascular Glands. See Gland.

Vascular, Vascularius, in Antiquity, was the denomination of a kind of artificers among the ancient Romans; who made silver and gold vases without relieves, or figures embossed on them.

Hence, according to Salmantius, it is, that Cicero, in his sixth oration against Verres, distinguishes vascularius from calato, engraver.

In the art called by the Greeks τέχνη κόσμου, which was the art of superadding ornaments of precious stones, or rich metals, to vases of other metals; the vascularii and calatores were different; the first being the goldsmiths who made the vase; the second, the sculptors who added the ornaments. But in the art called τέχνη κόσμου, or the art of cutting bas-reliefs, or stamping figures on metal, the vascularii were also calatores, or engravers; that is, they who made the vase, made also the relieves, or figures, with which it was enriched.

Vasculariues Plants, in Agriculture and Gardening, are all such the seeds of which are contained in vases, divided in the cells. There are several of these in both these departments. See Seed.

VASE, a term of equal import with the Latin vas, whence it is formed; and with the English vessel; which see.

It is applied to the ancient vessels dug from under ground, or otherwise found, and preferred in cabinets, &c. as vases of sacrifice, urns, &c.; and to other more modern vases, which are rather of curiosity and show than use; as those of crystal, porcelain, &c.

In the curious collection of ornamental works, made by Meifs, Wedgwood and Bentley, after the antique, there are vases of various kinds; some formed of a composition of terra cotta, refining agate, jasper, porphyry, and other variegated stones, of the vitreous or crystalline kind; others of black porcelain, or artificial basaltes, highly finished, with bas-relief ornaments; others of the painted Etruscan kind; and others again ornamented with encaustic paintings. The art of painting vases in the manner of the Etruscans has been lost for ages; however, these ingenious manufacturers set themselves to revive it; and, having carefully examined the original Etruscan vases, and having perused with attention the writings of the late count Caylus upon Etruscan antiquities, they were convinced that the colours of the figures could not be successfully imitated with enamel; and that their success must chiefly depend upon the discovery of a new kind of enamel colours, to be made upon other principles, and to have effects essentially different from those that were then in use, and are of the nature of glass; the Etruscan colours being burnt in, smooth and durable, but without any glassy lustre. In consequence of this observation, and by a great variety of experiments, they invented a sort of encaustic colours, not only sufficient to imitate the paintings upon the Etruscan vases, but to give the beauty of design the advantages of light and shade in various colours; and to render paintings durable, without the defect of a varnished or glassy surface. These encaustic colours may be applied with great ease and certainty; they change very little in the fire, are not liable to run out of drawing, are perfectly durable, and not glassy, and possess the advantages of enamel, without its essential defects. Catalogue of Cameos, &c. by Wedgwood and Bentley, 1773.

Vases, in Architecture, are ornaments of sculpture, placed on foci, or pedestals, representing the vases of the ancients; particularly those used in sacrifice, as the praefer clericum simpulum, incens-pots, flower-pots, &c. and occasionally enriched with baso-relievo.

They are commonly placed there to crown or finish façades, or frontispieces. They are frequently also called acroteria; and are usually infixed.

In forming and decorating vases, fancy has great scope. Many excellent inventions of these ornaments are transmitted to us from the ancients. A vase differs from an urn, as it is in general of a more elegant contour, and is lofty; whereas an urn should be low and wide, and always covered.

Vitruvius mentions a kind of theatrical vases, made of brafs, or earthen-ware, called echeia, υψαν. (See Echeia and Vitrivius); which they disposed in private places, under the steps and seats of the theatres, to aid and increase the reflection and resonance of the actors' voices, &c. It is said, there are also vases of this kind in the cathedral church of Milan.

VASE is particularly used in architecture to signify the body of the Corinthian and Composite capital; called also the tambour, or drum; and sometimes the compana, or bell.

VASE is also sometimes used among Florists, for what they otherwise call the calyx.

The vase, or rather calyx of a tulip, is the top or head of a tulip; the leaves of which form a kind of vase, or cup.

Goldsmiths, brauers, &c. also use vases for the middle of a church-candlestick; which is usually of a roundish figure, bordering somewhat on that of a vase.

VASE River, in Geography, a river of America, which runs into the Mississippi, 55 miles above the mouth of the Ohio.

VASEN. See Wesen.

VASH, a river of Grand Duchy, which gives name to the country it waters; and runs into the Gihon near Jerusalem. Also a province of Great Britain; which see.

VASHAN, a town of Hindoostan; 30 miles S.W. of Dindigul.

VASHCERD, a town of Grand Duchy, and principal town of a district watered by the Vash; 200 miles S.E. of Samarcand. N. lat. 39° 25'. E. long. 65° 50'.

VASHON'S ISLAND, an island near the west coast of America, at the bottom of the Admiralty Inlet, and eastern branch of the gulf of Georgia. N. lat. 47° 10'. E. long. 23° 25'.

VASL, a town of Russia, in the government of Nizegorod, on the Volga; 60 miles E. of Nizne Novgorod. N. lat. 56° 16'. E. long. 45° 44'.

VASILICA. See Basilica.

VASILKOV, a fort of Russia, in the government of Kiev; 28 miles S.S.W. of Kiev.

VASINA, a town of the island of Corea; 4 miles N. of Bafla.

VASIR. See Servent.

VASICHT'HA, in Biography, is the name of a celebrated person of Hindo o History and mythology: one of a class called Rishi, meaning a sage. Of these divine persons we have given a list, and some remarks, under the articles Rishi and Krkika; the latter being the Pleiades of the Hindoos, who have many very curious tales of their "shedding sweet influences." Vasicht'ha is a character frequently mentioned in the historical histories of the Hindoos, as being referred to for advice by royal and other persons requiring spiritual or other consolation. He is, indeed, called the preceptor of the inferior gods. A very celebrated commentary on the Veda, the Hindoo scripture, is ascribed to Vasicht'ha. It is in prose, with poetry intermixed; and is quoted as a high law authority. (See Veda.)
His wife, named Arundhati, is represented to have been exemplary in regard to holiness and sanctity, and to have been translated to the skies with her hapless husband: she is still quoted as proverbial for virtue and constancy. Vasiț'st'ha is a star of the second magnitude, in N. lat. 60°, and Arundhati is a smaller star near it.

In the Agni Purana, a hymn is addressed to Vasiț'st'ha; affording some clue to the relative antiquity of the poetical romances bearing the common denomination of Purana; which are.

**VASIȚ, or Wasiț, in Geography, a town of the Arabian Trak, on the Tigris. This town was built in the beginning of the eighteenth century, by Al Hejaz, the Arabian general. A mint was established, and in 707, money was coined there by order of the caliph. In 1401 it was plundered by Timur Bec; 96 miles S.E. of Bagdad. N. lat. 32° 19'. E. long. 45° 38'.**

**VASKINA, a gulf or bay of Ruffia, on the south coast of the island of Kalguev.**

**VASKOVNIA, a town of Ruffia, in the government of Pikov; 120 miles S.S.E. of Pikov.**

**VASLUI, a town of European Turkey, in Moldavia, on the Birlat; 32 miles S. of Jaffy. N. lat. 46° 40'. E. long. 27° 45'.**

**VASOKY, in Hindoo mythological Legend, is a name of a mighty serpent, more commonly called Sētha; which is. The name of Vasok, however, frequently occurs in the extravagant legends of the East. See KALIA and KURMA-VATARA.**

**VASON, in Geography, a town and castle of Hungary; 20 miles W.S.W. of Stuhl Weifenburg.**

**VASPINGE, a town of Perîa, in the province of Adir-betzan, containing about 600 houses; 9 miles from Tauris.**

**VASQUEZ, a town of the island of Cuba; 66 miles N.W. of Villa del Principe.‖ Alfo, a river of Mexico, which runs into the Spanish Main, N. lat. 11° 30'.**

**VASSAL, VASSALLE, in our Ancient Cullions, a person who vowed fidelity and homage to a lord, on account of some land, &c. which he held of him in fee.**

Du-Cange will have the word to come from vaffus, which anciently signified a servant or domestic of a prince, and sometimes also the comites, or officeres, in public trials. Menage, after Cujas, takes vaffal to have been formed of gassul, an ancient German word, signifying companion. Calene ởve derives it from the Gafful gassus, a brave man, from gassus, or gessum, or jessum, a kind of javelin used among them. Volfius derives vassal from vaut, vados, pledge; whence also he will have it to be, that they are sometimes called fidèles.

The vassal was also called piratus, lord's-man, and see-man; but now the denomination is changed into that of tenant in fee.

Accordingly the vassal, or feudatory, was only another name for the tenant or holder of the lands; though, on account of the prejudices we have justly conceived against the doctrines that were afterwards grafted on this system, we now use the word vassal opprobriously, as synonymous to slave or bondman. The manner of the grant, on the part of the proprietor or lord, who retained the dominion, or ultimate property of the feud, or fee, was by words of gratuitous and pure donation, de et concilis; which are still the operative words in our modern indentures, or deeds of seisin. This was perfected by the ceremony of corporeal inversion, or open and notorious delivery of possession, in the presence of the other vassals, which perpetuated among them the era of the new acquisition, at a time when the art of writing was very little known; and, therefore, the evidence of property was repose in the memory of the neighbourhood: who, in case of a disputed title, were afterwards called upon to decide the difference, not only according to external proofs, but also by the internal testimony of their own private knowledge.

They sometimes also used the term vaflour for vassal; whence vaflage.

If a vassal offended his lord grievously, either in person or in honour, he committed the crime of felony; which carried with it a confiscation of his fee.

VASSAL, a Rear, is he who holds of a lord, who himself is vassal of another lord.

VASSAL was anciently used for soldier; by reason fees, at first, were given to none but military men.

VASSALAGE, the state of a vassal; or a servitude and dependency on a superior lord.

Anciently, they distingushed between liege vassalage, and simple vassalage.

Lige vassalage only belonged to the king; as carrying with it an obligation on the side of the vassal to serve his lord in war, against all persons whatever. See LIEGE.

In all simple vassalage, the fealty, or liege vassalage, was still referred to the king.

Some also distingushed active vassalage, and passive: the first is the right of fealty reposing in the lord; the second, the service and duties incumbent on the tenant.

**VASSALBOROUGH, in Geography, a town of the province of Maine, on the Kennebeek; 204 miles N.E. of Boston.**

**VASSEN, or Waessen, a town of Holland, in the department of Guelderland; 12 miles S. of Hattem.**

**VASSIETTE, a river of America, which runs into lake Michigan, N. lat. 44° 38'. W. long. 86° 18'.**

**VASSY, a town of France, in the department of the Calvados; 8 miles E. of Vire.‖ Alfo, a town of France, and seat of a tribunal, in the department of the Upper Marne. In the year 1563, a bloody persecution against the Protestants began in this town; 9 miles S. of St. Dizier. N. lat. 48° 30'. E. long. 5° 2'.**

**VASTÂN, a town of Curdifan, on lake Van. In 1386, it was taken by Timur Bec; 20 miles S.W. of Van.**

**VASTANFORS, a town of Sweden, in Weftmanland; 32 miles N.N.W. of Stroemsholm.**

**VAŠAÚNA, in Ancient Geography, a town of Asia, situated in the S.E. part of the lake Arifi, towards the 38th degree of latitude.**

**VASTO, in Law, a writ that lies against the tenant for life, or years, for making waife.**

**VASTUS, in Anatomy, the name of two very large muscles belonging to the thigh. The body of the femur is completely enveloped, except at the linea aspera, by a thick muscular mass: this may be distingushed at its-ori gin into three portions, which soon become blended together, so as not to admit of separation. The part which covers the outside of the bone is called vastus externus; that which covers the inside, vastus internus; and the middle, cruralis, or cruræns. These have usually been described as three distinct muscles; but some modern anatomists have more properly considered them as one, under the name of triceps femoris: they form the tri-femoro-rotulien of Dumas.**

The triceps cruris then is a very thick flethy mass, of a rounded or convex figure, covering the thigh-bone, and extending from the hales of the trochanters to the patella and tibia.

The anterior surface is covered, towards the outside, by the tendon of the gluteus maximus, the tenor vaginae, the falcia
fasca lata, and the short portion of the biceps; at the middle, by the illicus internus, rectus extensor cruris, and the external circumflex veffels; on the infe, by the fartorus, the femoral artery, and the fasca. The posterior surface covers the body of the femur, with the exception of the linea alpea; it is attached to the anterior, external and internal surfaces of the bone, from the bafes of the trochanters to within four fengers breadth of the knee; then it is separated from the femur by a loofe and fatty cellular fubftance, and laftly, it covers the fynovial membrane of the knee-joint.

The outer margin is fixed to the rough line, which defcends from the great trochanter to the linea alpea, together with the gluteus maximus, to which it is clofely con- nected: it is then fixed to the external edge of the linea alpea, in its whole length, and to the upper two-thirds of that line, which defcends from the linea alpea to the external condyle of the femur, being connected in the latter situation with the fasca lata. The internal edge is fixed to the correffponding inner edge of the linea alpea, from the trochanter minor downwards; and to the upper two-thirds of the line defcending from it to the external condyle, being connected here with the tendon of the triceps adductor. Its upper extremity is divided into the three portions already mentioned. The external (vafus externus) and moft con- siderable is fixed to the circumference of the basis of the great trochanter; it defcends on the outside of the thigh, increasing in size to the middle of the limb, and then diminifhing again. At firft it is separated from the middle portion by a thin stratum of cellular fubftance; but they are fon confounded in one mass. The internal portion (vafus internus) is not in general very diftinft from the middle. Commencing at the root of the little trochanter, it defcends on the infe of the femur, firft increasing in size, and then diminifhing again. On its outide it is defparated from the middle portion, if at all, by a very feftile cellular line, for about an inch or two, after which they are confounded in one mass. The middle and smallfeft division (cruralis) commences at the basis of the neck of the thigh-bone, by an at- tachment to the rough line, which reaches from the great to the small trochanter: it defcends perpendicularly, increasing in size, refeated at firft from the lateral portions, but foon infeparably joined with them into one mass, surrounding the body of the femur, and ending in a tendinous extremity, attached to the bafes and fides of the patella, and to the tu- berofties of the tibia.

The laft-mentioned attachment is effected by means of a broad and thick tendon, connected in front to that of the rectus extenor cruris, and expanded laterally into aponeurofes fixed to the tuberofties of the tibia. Of these aponeurofes, the outer is clofely connected to the fasca lata. The tendon of the triceps is divided above into three broad portions, which ascend on the three divisions of the muscle. A thick and broad aponeurotic fHEET commences from the bafis of the trochanter major and the linea alpea, and covers the upper half of the vafus externus: a fimilar but smaller aponeurotic defcends from the linea alpea on the vafus internus. The muscular fibles of the vafus externus passes obliquely downwards and forwards from its superior aponeurofis, and from the aponeurotic septum, which separates it from the fhort head of the biceps to the inferior tendon. Of these fibles, the upper are the longest and moft perpendicularly; the fucceeding ones become more and more oblique, and the lowest approach to the tranverse direftion, accompanying the tendon to within an inch of its infertion.

Thick fibres of the vafus internus pass with a corre-
prefixed by some of his hearers, collected by Robert Stephens, and added to his publication in 1545; of Leo Judae's Latin version of the Bible. But as they contained some free passages, they were condemned by the doctors of the theological faculty in Paris, who, imperfectly acquainted with Hebrew, reposed their confidence in the Vulgate. However, the university of Salamanca reprinted the text and notes in Spain, R. Stephens defended them against the Paris theologians, and they have since been approved by men of learning. He not only encouraged Clement Marot to translate the Psalms into French verse, but assisted him in the undertaking. Vatable, though suspected of heresy, was an orthodox Catholic, and opposed the discipline and opinions of the Calvinists. He died in 1547, pollied of the abbacy of Bellezane. Dupin.

VATAN, in Geography, a town of France, in the department of the Indre; 11 miles N.W. of Issoudun. N. lat. 47° 7'. E. long. 1° 54'.

VATERIA, in Botany, was so named by Linnaeus, in honour of Abraham Vater, professor of Medicine at Wittenberg, and author of Catalogue Horti Wittenbergensis, (a mere catalogue,) as well as of some botanical dissertations, on the Ballam of Mecca, on Hippomane, &c. This gentleman was born in 1683, and died in 1751. He succeeded his father in the professorship, who died in 1752, aged eighty-one, and was also a naturalist. Linn. Gen. 269. Schreb. 359. Mart. Mill. Dict. v. 4. Julf. 258. Lamarck Ill. t. 475.—Clafs and order, Polyandra Monogyna. Nat. Ord. akin to Gutiferæ, Juff.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five acute segments, permanent, at length reflexed. Cor. Petals five, ovate, thick, entire, spreading. Stam. Filaments numerous, very short; anthers vertical, sgl-flaped, much longer than the filaments, with two capillary points. Filg. German superior, roundish; fylle simple, short; frigga capitate. Peric. Capsule turbinate, coriaceous, seated on the reflexed calyx, marked with three furrows, separating into three valves, with one cell. Seed solitarly, ovate, with a reddish skin.

Obf. Retzius and Vali have removed this plant to Eleo- carpus, fee that article; but without giving any sufficient reason. On the contrary, they describe the petals as entire; nor have they thrown any light upon the fruit, which, as de- scribed in the Hortus Malabaricus, cannot accord with Eleocarpuis. The large figure, on the right hand, in that book, cannot be reconciled with the rest, unless it be a seed vegetating. Jussieu seems staggered as to the character of this fruit, by finding the rudiments of three seeds in the germen. But this may very well be, and yet only one may ever come to perfection. The fame learned author remarks, that Lin- naeus, in his Syllena, attributes three seeds to Vateria. This is true; but we believe it a typographical error, originating in the tenth edition of Syll. Nat. especialy as the synoptical table, at the head of the clas, remains with the character of a single seed. This contradiction, whichever of the two characters be correct, is heedlessly perpetuated through every following edition. On the whole, there appears more reason to retain than to abolish the genus in question.

1. V. indica. Copal Vateria. Linn. Sp. Pl. 734. (Eleo- carpus copalliferus; Retz. Obs. fae. 4. 27. Vahl Symb. v. 3. 67. Willd. n. 5. Pœno; Rheed. Hort. Malab. v. 4. 33. t. 15.)—Native of Malabar and Ceylon. A tall and handsome tree, generally sixty feet high, with wide extended branches, and a thick bark, which when wounded discharges a clear, pellucid, fragrant resin, acidic and bitter to the taste, at length becoming yellow and brittle like glafs. This, according to Kernig, is one kind of Copal; see that article. Perfons experienced in the ufe of this gum, fo useful for varnishing anatomical preparations, know that there are, as Kernig says, several different things imported under the same name, which are not all equally soluble, even in oil of lavender. The blooms of this tree are alternate, flaked, a span long, elliptical, acute, coriaceous, entire, smooth. Flowers in large terminal, downy panicles, white with yellow flumens; their fcent feet, like a lily. Fruit the size of a walnut in its green coat, swelling and blunt at the extremity, dark purple; its kernel white, bitterish and rather astringent, inclosed in a reddish skin, like that of a filbert. This de- scription, taken from the Hortus Malabaricus, is precise; and as nothing is faid of any hard shell, we do not fee bow the fruit can agree with that of Eleocarpus. The above-mentioned kernel, triturated with hot water, is reckoned strengthening to the stomach, and is given to flop vomiting or nausea.

Having formerly examined at Sir Joseph Banks's a specimen of Vateria, in order to dilugnith this genus from Vatica, (fee that article,) we have corrected the generic char- acters from observations then made, particularly respecting the anthers, of which Retzius and Vahl have also given a faithful account. Linnaeus had no specimen, but described the genus from one in Hermann's herbarium, now at Sir Joseph Bank's. Vahl is surely mistaken in faying the corolla and fruit agree with Eleocarpus!

VATES, in Mythology, the name of a clas of Druids.

VATII, in Geography, a town on the north coast of the island of Samos, in a bay called the Gulf of Vathi. N. lat. 37° 40'. E. long. 26° 54'.

VATIIA, or Berrathi, anciently Tyrins, a town of European Turkey, in the Morea; 16 miles N.E. of Napoli di Romani.

VATI, a town of the island of Sifanto. N. lat. 36° 57'. E. long. 24° 40'.

VATICA, in Botany, an unexplained name of Linnaeus, apparently derived from the same source as vaticination, a prophesying. Hence the writer of the present article ventured to fuggit, as a query, whether the plant might have any superstitious use among the Chinese, from whole country it is faid to have been brought. This conjecture appears in the form of a general opinion in De Theis, strengthened by a reference to Boehmer's Lexicon, p. 268, a book not within our reach. Notwithstanding all this, there is great doubt whether the plant comes from China, the specimens being marked India, just like many others, known to have been received from Java by Linnaeus. In fact, these specimens are fo like Vateria (fee that article) in appearance and char- acter, that if it were pooffible to fuppofe the anthers could vary fo remarkably, we should fuppofe these plants might be only sexual differences of one species. Having flared this difficulty without having the means of overcoming it, we proceed to defcribe Vataea.—Linn. Mant. 2. 152. Schreb. Gen. 318. 831. Willd. Sp. Pl. v. 2. 847. Mart. Mill. Dict. v. 4. Sm. Plant. Ic. 36. Julf. 259. Lamarck Ill. t. 397.—Clafs and order, Dodecandria Monogyna. Nat. Ord. akin to Gutiferæ, Juff.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, erect, ovato-lanceolate, acute segments. Cor. Petals five, fylline, obovate, entire, thrice the length of the calyx, folded over each other, in some flowers to the left, in others to the right; their inner surface smooth; outer, in the exposed half, hoary. Stam. Filaments none; anthers fifteen, fylline, three on the bafe of each petal, small, ovate, smooth, of four
four obtuse cells, the two outer cells terminated by a small, intermediate, upright spine, the two inner but half as long, without any spine. *Pij. German superior, conical, with five angles, obtuse, hoary; fylle cylindrical, with five angles, twilled; fligma flathithi, obscurely three-lobed. *Petric, unknown, but the gemem has three cells, with the rudiment of a solitary feed in each.

Wild. n. 1. Sm. Plant. t. 56.—Native of China, according to Linneus, but his authority, as we have said, does not appear. This seems to be a tree, very near *Vateria indica, from which it chiefly differs in the number and form of the flaments. As to the fruit, Jussieu's having found three cells and as many seeds, in the gemem of *Vateria, renders the supposed distinction in the ripe fruit very doubtful. The leaves, inflorescence, &c. discover no difference, and the flower-flalks and calyx, as well as flower-flalks, are clothed with the same fine, short, clofe, hoary pubeffence, in both. It is much to be wished that some East Indian botanift would clear up these doubts refpefting two very fine, and liitherto little-known plants. We must add, that if this be *Vateria, nothing can be more diftinét in its petals from Elaeocarpus; for instead of the thin texture, and curiously incarinated margin, appropriate to the latter, their thick undivided fubflance, and partial hoarfines at the back, prove that these genera ought never to be confounded together.

Vatica, in Geography, a sea-port town of European Turkey, in the Morea, situated in a large bay, to which it gives name; 44 miles S.E. of Misftra.

VATICAN, Vatica, is properly the name of one of the seven hills on which Rome flands; on the foot of this is the famous church of St. Peter, hence called the Vatican; and a magnificent palace of the pope, which has the fame denomination. Hence arise divers figurative expreffions; as the thunderbolt of the Vatican, q. d. the pope's anathema, &c.

The word, according to Aulus Gellius, is derived from vatricium, prophecy; by reaon of the oracles and predictions which were used to be delivered there by the inspiration of an ancient deity, called Vaticanus; who was suppoTed to unbind the organs of speech in new-born children; and whom others will have to be no other than Jupiter, confidered in that capacity.

Vatican, The Library of the, is one of the most celbrated in the world: it is particularly remarkable for its manuscripts. It was first erected, according to Petaus (Rat. Temp. lib. ix. cap. 9) by pope Nicholas V., who succeedcd to the papal chair in 1447. It was re-established, after the books had been difpersed, under the pontificate of Calixtus III., by Sixtus IV.; and after having been almost entirely destroyed by the army of Charles V. it was not only restored to its former flate by Sixtus V., but greatly enriched with books and manuscripts. It was finally fixed in the Vatican, under the pontificate of Martin V.

Towards the beginning of the 17th century, it was greatly augmented by the addition of that of the elector palatine. It is open to all the world three or four times a week. In it are shown a Virgil, Terence, &c. above a thousand years old; as also the manuscript on which the edition of the Septuagint was made; and abundance of rabbinical manuscripts.

Vatican Manuscript, is one of the most celebrated manuscripts of the Greek version of the Bible now extant in the world. It was polished at Rome by cardinal Carafa, at the command of Sixtus Quintus, in 1587; and in the preface, it is said to have been written ante millenium ducen-
VAVAO, or Vavou, in Geography, one of the Friendly islands, in the South Pacific ocean, seen by Perouze in 1787, who says, "this island, which Capt. Cook never visited, is almost equal in size to Tongataboo, and has the advantage of being never in want of water, with a good harbour."

It had been before discovered by the Spaniard pilot Maurelle, and with a number of islands almost as considerable as those already explored by Capt. Cook, which he called the islands of Majorca. S. lat. 18° 34' of the western point. See Tonga.

VAVASOR, Valvasor, Vavasour, or Vavasour, in our Ancient Cymry, a diminutive of vaffal, or vassal; signifying a vaffal or a vassal, or one who held a fee of another vassal.

Yet Camden, and others, hold vavasor to be a dignity, next below that of a baron: he adds, that the word is formed of vas fertum ad valitudinem, a vessel chosen for safety and health. Others derive it à valesis, quasi obligatus fit adfere ad vassus domini, vel indignis fuit eam intrare; as being a peron obliged to wait at his lord's door, or as unworthy to enter thereat; but this etymology is ridiculous enough.

Du-Cange distinguishes two sorts of vassals under this denomination: the great, called vassuferes, who held of a king; such were counts and barons; and the lesser, called vavafonii, who held of the former.

The vavafortes are mentioned by our ancient lawyers as viri magna dignitatis; and Sir Edward Coke speaks highly of them. But they are now quite out of use; and our legal antiquarians are not agreed upon even their original or ancient office.

VAVASORY, Vavasoria, the quality of the land, or fee held by a vavasor.

"Quod dicitur de baronia non eft observandum in vavaforia, vel allis minoribus feclis quam baronia, quia caput non habent ficut baronia." Bract. lib. ii. cap. 39.

There are vafe vavafortes, and frank or noble vavafortes: according as it pleased the lord to make his vavasor. Vafe vavafortes are those for which the lord of the fee owes fummage, light-horse, rents, or other services. Free vavafortes are such as are exempt from these services.

VAVASSEUR, Francis, in Biography, was born in 1605, at Paray, in the diocese of Autun; and entering into the society of the Jesuits in 1621, and acting as regent in the schools for some years, he was called to Paris to occupy the chair of positive theology, the duties of which he discharged honourably for thirty-fix years; and he died in this city in 1681, aged seventy-six years. He has been reckoned one of the most elegant and correct Latin writers, and wrote several theological pieces, some against Jansenius, and one of a singular subject, "On the personal Beauty of Jesus Christ," and also poems chiefly on sacred subjects. The work which has chiefly distinguished him is a treatise "De Ludicara Dictione," or on the burlesque style, dedicated to Balzac. He also wrote a treatise "On the Epigram," and "Remarks on the Poetics of Father Rapin." Moreri.

VAUBAN, Sebasfian le Prestre, Seigneur de, marshal of France, and an eminent engineer, was born in 1633, and began to bear arms at the age of seventeen under the prince of Conde, general of the Spanish army. Being taken prisoner by a French party, he was engaged by cardinal Mazarin on the royal side, and employed in 1653 at the second siege of St. Menehould, by which it was recovered to France. He also served as engineer in the five following years at several other sieges. After the peace of the Pyrenees, he was employed in demolishing some places and fortifying others; and he also fuggled a variety of ideas, by the maturity and development of which he contributed in a high degree to the improvement of the science of fortification. On the renewal of the war in 1667, he conducted several sieges, at which Lewis XIV. attended in person, and he was commissioned to fortify several places, and in 1668 nominated governor of the citadel of Lille, which he had constructed. After the peace of Aix-la-Chapelle, he visited Piedmont, and gave designs to the duke of Savoy for some important fortresses. In the war of 1672 he again distinguished himself, particularly at the siege of Maelrich, in which he introduced his famous method of attack by parallels and places of arms; and also on other occasions, when an opportunity offered for the display of his inventive genius. In carrying his schemes into execution he was anxious for saving life, and therefore preferred a slow and regular advance in sieges. The peace of Nimfeuen afforded him leisure for fortifying towns; and of these, his master-piece was the port of Dunkirk. On the commencing of war, he again resumed his active services, and had the honour of taking Luxembourg, which was regarded as impregnable. Upon the whole, he fortified one hundred old places, constructed thirty-three new fortresses, and had the principal direction of fifty-three sieges. In recompence of his various exertions, he was advanced to several petty honours, and in 1703 appointed marshal of France. At Dunkirk, whither he was sent in a state of great alarm, he died of a fluxion in his lungs, in March 1707, at the age of seventy-four years.

The character of Vauban, as a man and a citizen, was no less estimable than his superior talents and achievements in his professional capacity. Loyal and faithful to his sovereign, he studied to serve more than to please, and he manifested on all occasions an inviolable attachment to truth. As a liberal and zealous patriot, he made such observations, and collected such facts in his various travels, as contributed most effectually to the improvement and prosperity of his country. These were comprised in twelve large MS. volumes, which he modestly denominated "Mes Œuvrées," and Fontenelle observes of him in relation to these, that if all his projects could be executed, his "idlenes" would be more useful than his labours. In 1699, he was nominated an honorary member of the Academy of Sciences. The following works were either written by himself, or in conference of ideas which he suggested: viz. "Manière de Fortifier, par M. de Vauban, mille en ordre par le Chevalier de Cambray," Amft. 1689 and 1692, printed at Paris under the title of "L'Ingénieur Français," with notes by Hectbert, professor of mathematics; and afterwards with notes by the Abbé du Fay; "Nouveau Traité de l'Attaque et de la Defence des Places, suivant le Systéme de M. de Vauban," par M. Despréz de Saint-Sevin," Paris 1736; "Essais fur la Fortification, par M. de Vauban," Paris 1740; "Projet d'un Dime Royale," Rouen, 1707, often reprinted. This last work is attributed by Voltaire to Bois-Guillebert, author of a "Téfantment Politique" in the name of Vauban. Fontenelle Eloge. Moret.

VAUBECOURT, in Geography, a town of France, in the department of the Meuse; 9 miles N. of Bar-le-Duc.

VAUCHERIA, in Botany, is so named by M. Decandolle, in his Flore Française, in honour of the discoverer of the genus, the Rev. M. Vaucher of Geneva, author of an excellent work in quarto, entitled Histoire des Conflernes d'Eau douce, where this genus is established by the name of Eeo-ferma. The latter appellation has very properly given way to the above, previously chosen by M. Decandolle.—Sm. Engl. Bot. v. 25. 1765. "Decand. Rapport fur les Con-

1. V. suffult. Seifille-fruited Vauclera. Engl. Bot. t. 1765. (Ectoptera suffult; Vauch. Conf. 25. t. 2. f. 7. Confera veficata; Dillw. Conf. t. 74, without the anther. Ceramium cefitum; Roth Catal. v. 3. 170).—Floating. Capsules in pairs and solitary, feiffle on each side of the anther.—Found floating on the surface of pools, in large green patches, about February; and confifting of capillary, branched, smooth, rather claffic, tubular filaments, filled with a green pulpy fubftance, which separates in oblong portions, giving the filament a jointed appearance. Capsules lateral, feiffle, pellucid, commonly in pairs, each containing one large green feed, and having next to them an awl-shaped body, affeeted by Vaucler to be the anther. Yet sometimes this fbody feems to shoot out into a branch. Veficles are often found on the branches, perhaps of the nature of galls, inhabited by the aquatic animacule called by Muller Cyclops Lapula, in coniderable numbers, with one dark-coloured animal befoles.

2. V. geminata. Twin-flalked Vauclera. Engl. Bot. t. 1766. (Ectoptera geminata; Vauch. Conf. 25. t. 2. f. 5).—Floating. Capsules in pairs and solitary, on opposite partial flalks, growing out of one common flalk with the anther.—Sent by Mr. W. Borrer, along with the preceeding, from Suffex. The habit is the fame in both, but the frutification, furnihered with partial flalks, and with a common flalk for both organs, appears to afford a good specific character. Some botanists nevertheless, and among them, if we mistaft not, Mr. Dillwyn, confider these two plants as mere varieties of each other.

3. V. velutina. Velvet Vauclera. (Confera velutina; Engl. Bot. t. 1556. Dillw. Conf. t. 77. Byfius velutina; Linn. Sp. Pl. 1638. B. tenerrima viridis, velutum referens; Dill. in Rall Syn. 56. Mouc. 7. t. 1. f. 14. B. terreliris viridis herbaee et mollifima, filamentis ramosis et non ramosis; Mich. Gen. 211. t. 89. f. 5).—Erect, tufted. Filaments beaded, somewhat rigid. Capsules fefille.—This covers the earth, in moft fhashy places, with a moft beautiiful fine green velvet carpet, fragrant like feveral of the Jungermannias, even for a long time after it is dried. It appears to be perennial, occurring in fummer as well as winter, but has been thought more common than it really is, because Dillenius and others have confounded with this plant a much more general one, Confera muralis, Engl. Bot. t. 1554, which is proflrate, refting with fatin rather than velvet, and has no fweet fcent. M. Vaucler is our authority for re-moving this species hither. Micheli has but imperfectly figured the capfules, and in fuch a manner that they may belong either to thofe Conferae which make Roth's genus of Ceramium, or to Vauclera. Of the anther we know nothing.

We have here limited ourselves to the British species, which may poflibly prove but a small part of the genus, when the fubject has been sufficiently examined.

VAUCCLAIN, L.E. in Geography, a town of the ifland of Martinico, fituated in a bay on the N.E. coaft. N. lat. 14° 36'. W. long. 66° 46'.

VAUCLUSE, a town of France, in the department of the Doubs; 8 miles S.W. of St. Hypolite.

VAUCLUSE, formerly Venaisin, and the principality of Orange, on the left hand of the Rhone, in N. lat. 44°, one of the twelve departments of the S.E. region of France, bounded on the N. by the departments of the Drôme and Ardéche, on the E. by the department of the Lower Alps, on the S. by the department of the Mouths of the Rhone, and on the W. by that of the Gard. It derives its appellation from the fountain of Vaucluse, (see Fontaine de Vauclus, which is the fource of the river Sorgues, and made memorable by the near residence of Petrarch and Laura. Its territorial extent is 3700 kilometres, or 186 square leagues, and its population consists of 190,180 inhabitants. It is divided into 4 circles or districts, 22 cantons, and 150 communes. The circles are, Orange, including 54,293 inhabitants. Avignon, 47,351; Carpentras, 39,714; and Apt, 48,822 inhabitants. According to Haffenratz, its length in French leagues is 15, and its breadth 10; its circles are 4, its cantons 52, and its population consists of 200,500 persons. Its capital is Avignon. Its contributions, in the eleventh year of the French era, amounted to 1,367,701 francs; and its charges, administrative, judiciary, and for public instruction, were 227,109 francs, 14 cents. This department consists of plains, marshes, gentle eminences, and hills. Mont-Ventoux is upwards of 6000 feet above the level of the sea. The soil is various, and indifferently cultivated. The products are grain, silk, fruits, and roots. In this department coal is impregnated with sulphur, a few metallic subfiances, potter's-earth, mineral springs, &c.

VAUCLUSE, a town of France, and principal place of a district, in the department of the Meuse; 8 miles N.E. of Gondrecourt. N. lat. 48° 36'. E. long. 5° 44'.

VAUD, PAYS DE, a country of Switzerland, of which travellers and historians speak with rapture, particularly of that part which borders on the lake of Geneva. It is almost wholly a gradual ascent from the edge of the lake, richly laid out in vineyards, corn-fields, and luxuriant meadows, and chequered with continued hamlets, villages, and towns: the shores are generally of the clearest gravel, and the water of the finest transparency. This country is one of the two great divisions into which the canton of Berne is divided; the other being the German district. The Pays de Vaud, after the decline of the Roman empire, made a part of the kingdom of Burgundy, from which it fell to the empire of Germany, under which the dukies of Zaringen held it as a fief, and at the extinction of that family, it became annexed to the eftates of the counts of Savoy. It was conquered from the house of Savoy by the canton of Berne in 1536, and in this year the reformation was introduced. From that period the whole Pays de Vaud, excepting the common baililages of Grenchon, Orbe, and a small portion of which was ceded to Friburgh, has been subject to Berne, and forms a part of that canton. The German district was gained by conquest from the eftates of the empire. In each of these divisions justice is administered and taxes regulated by peculiar laws and customs. Each division has its treasurer and chamber of appeal resident in the capital; the chamber of appeal belonging to the Pays de Vaud judges in the last resort; but the inhabitants of the German district may appeal to the sovereign council. During the French revolution, the Pays de Vaud was separted from the canton of Berne, and formed into an independent republic under the protection of France, in January 1798. In the new division of Switzerland, it forms the canton or department of Leman, of which Laufanne is the capital. The Pays de Vaud is estimated to be about 60 miles long, and as many broad; bounded on the N. by the county of Neuchatel, on the E. by the canton of Friburgh, on the S. by the lake of Geneva and the river Rhone, and on the W. by France. It includes the towns and baililages of Lausanne, Yverdon, Mondon, Avenches, Vevey, Morges, and several others.

VAUDE-
VAUDEMONT, a town of France, in the department of the Meurte; 4 miles S. of Vezelise.

VAUDEVILLE, a song sung in the streets by ballad-singers, the subject of which is generally jocose or factitious. The origin of this little kind of poem is traced up to the time of Charlemagne. But according to the more general opinion, it was invented by a certain man of the name of Baffelin, Foulon de Vire in Normandy; and in order to dance, as people used to assemble in the Val de Vire, they were called Vaux de Vire, and afterwards, by corruption, Vauvileil.

The air of these Vaudevilles is generally very unmusical. But as people merely listen to the words, the tune only helps to enforce the voice and render the words more audible. But, as music, there is in general neither taste, melody, nor measure in their tunes. The Vaudevile, with respect to the words, belongs exclusively to the French, and they are sometimes very piquant and pleafant. Rouleau.

VAUDIER, in Geography, a town of France, in the department of the Stura, late in the province of Coni; 5 miles S.E. of Demont.

VAUDOIS, Valdenses, or Waldenses, in Ecclesiastical History, a name given to a sect of reformers, who made their first appearance about the year 1160.

Of all the sects that arose in this century, none was more disdained by the reputation it acquired, by the multitude of its votaries, and the tellimony which its bitterest enemies bore to the probity and innocence of its members, than that of the Waldenses, so called, says Moheim, from their parent and founder Peter Waldis, or Valdus. They were also called Leonitis, from Leonis, the ancient name of Lyons, where their feast took its rise. The more eminent persons of that sect manifested their progress towards perfection by the simplicity and meanness of their external appearance: hence, among other things, they wore wooden shoes, which, in the French language, are termed pagots, and had imprinted upon these shoes the sign of the cross, to distinguish themselves from other Christians; and on these accounts they acquired the denomination of Saccatois and Infiikatais.

The origin of this famous sect, according to Moheim, was as follows: Peter, an opulent merchant of Lyons, surnamed Valdus, or Valdus, from Vaux, or Waldum, a town in the marquisate of Lyons, being extremely zealous for the advancement of true piety and Christian knowledge, employed a certain priest, called Stephanus de Evifa, about the year 1160, in translating from Latin into French the four Gospels, with other books of Holy Scripture, and the most remarkable sentences of the ancient doctors, which were so highly esteemed in this century. But no sooner had he perused these sacred books with a proper degree of attention, than he perceived that the religion, which was now taught in the Roman church, differed totally from that which was originally inculcated by Christ and his apostles. Struck with this glaring contradiction between the doctrines of the pontiffs, and the truths of the Gospel, and animated with zeal, he abandoned his mercantile vocation, distributed his riches among the poor (whence the Waldenses were called poor men of Lyons), and forming an association with other pious men, who had adopted his sentiments and his turn of devotion, he began, in the year 1180, to assume the quality of a public teacher, and to instruct the multitude in the doctrines and precepts of Christianity.

Bexa, and other writers of note, who are followed by Dr. Maclean, the learned translator of Moheim's History, give different accounts of the origin of the Waldenses; alleging, that it seems evident from the best records, that Valdus derived his name from the true Waldenses of Piedmont, whose doctrine he adopted, and who were known by the names of Vaudois and Valdenfes, before he or his immediate followers exiled. If the Waldenses or Waldenfes had derived their name from an eminent teacher, it would probably have been from Valdo, who was remarkable for the purity of his doctrine in the eleventh century, and was the contemporary and chief counsellor of Berengarins. But the truth is, that they derive their name from their valleys in Piedmont, which in their language were called vaus, and hence Valdois, their true name; hence also Peter, or, as others call him, John of Lyons, was called in Latin Valdus, because he had adopted their doctrine; and hence the term Valdenses or Waldenfes, used, by those who write in English or Latin, in the place of Valdois. The bloody inquisitor, Reinierus Sacco, who exerted such a furious zeal for the destruction of the Waldenses, lived but eighty years after Valdus of Lyons, and must, therefore, be supposed to know whether or not he was the real founder of the Waldenses or Leonitis; and it is remarkable, that he speaks of the Leonitis as a sect that had flourished above five hundred years; and mentions authors of note to make their antiquity ascend to the apostolic age. See the account given of Sacco's book by the Jesuit Groser, in the Bibliotheca Patrum. See also Leger's Histoire Gen. des Eglises Vaudoises, cap. 2. 25, 26, 27.

But to return to the history of Peter Valdus. Soon after Peter had assumed the exercise of his ministry, the archbishop of Lyons, and the other rulers of the church in that province, vigorously opposed him. However, their opposition was unsuccessful; for the purity and simplicity of that religion which these good men taught, the spotless innocence that shone forth in their lives and actions, and the noble contempt of riches and honours, which was conspicuous in the whole of their conduct and conversation, appeared so engaging to all such as had any sense of true piety, that the number of their followers daily increased. They accordingly formed religious assemblies in France, and afterwards in Lombardy, from whence they propagated their sect throughout the other provinces of Europe with incredible rapidity, and with such invincible fortitude, that neither fire, nor sword, nor the most cruel inventions of merciless perfecution, could damp their zeal, or entirely ruin their cause.

The attempts of Peter Waldis, and his followers, were neither employed nor designed to introduce new doctrines into the church, nor to propose new articles of faith to Christians. All they aimed at was, to reduce the form of ecclesiastical government, and the manners both of the clergy and people, to that amiable simplicity, and primitive sanctity, that characterized the apostolic ages, and which appear so strongly recommended in the precepts and injunctions of the divine Author of our holy religion. In consequence of this design, they complained that the Roman church had degenerated, under Constanine the Great, from its primitive purity and sanctity. They denied the supremacy of the Roman pontiff; and maintained, that the rulers and ministers of the church were obliged, by their vocation, to imitate the poverty of the apostles, and to procure for themselves a subsistence by the work of their hands. They considered every Christian as, in a certain measure, qualified and authorized to instruct, exhort, and confirm the brethren in their Christian course, and demanded the restoration of the ancient penitential discipline of the church, i.e. the expiation of transgressions by prayer, fasting, and alms, which the new-invented doctrine of indulgences had almost totally abolished. They, at the same time, affirmed, that every pious Christian was qualified and entitled to prescribe to the penitent the kind or degree of satisfaction or expiation.
expiation that their transgressions required; the confession made to priests was by no means necessary, since the humble offender might acknowledge his sins, and testify his repentance to any true believer, and might expect from such the counsel and admonition which his case demanded. They maintained, that the power of delivering sinners from the guilt and punishment of their offences belonged to God alone; and that indulgences, of consequence, were the criminal inventions of fordid avarice. They looked upon the prayers and other ceremonies that were instituted in behalf of the dead, as vain, useless, and absurd, and denied the existence of departed souls in an intermediate state of purification; affirming, that they were immediately upon their separation from the body, received into heaven, or thrust down to hell. These, and other tenets of a like nature, composed the system of doctrine propagated by the Waldenses. It is also said, that several of the Waldenses denied the obligation of infant-baptism, and that others rejected water-baptism entirely; but Wall has laboured to prove, that infant-baptism was generally practiced among them. Hist. of Infant-Baptism, p. 387, &c.

Their rules of practice were extremely austere; for they adopted, as the model of their moral discipline, the sermon of Christ in the mount, which they interpreted and explained in the most rigorous and literal manner, and, consequently, prohibited and condemned in their society all wars, and suits of law, and all attempts towards the acquisition of wealth, the inflicting of capital punishments, self-defence against unjust violence, and oaths of all kinds.

The government of the church was committed by the Waldenses to bishops, called also majorales or elders, profbyters, and deacons; for they acknowledged that these three ecclesiastical orders were instituted by Christ himself. But they thought it absolutely necessary that these orders should resemble the apostles of Christ, and be, like them, unlearned, poor, and furnished with some laborious trade or vocation, in order to gain by constant industry their daily subsistence; and indeed most of the Waldenses gained their livelihood by weaving; whence in some places the whole fact was called the fact of the weavers. The laity were divided into two classes, viz., the perfect and the imperfect Christians: the former divested themselves of all worldly possessions, manifested in the wretchedness of their apparel, their extreme poverty, and emaciated their bodies by frequent fasting; the latter were less austere, and approached nearer to the method of living generally received, though they abstained from all appearance of pomp and luxury.

The Waldenses were not without intrigue divisions; for such of them as lived in Italy differed considerably in opinion from those who dwelt in France, and the other European nations. The former considered the church of Rome as the church of Christ, though much corrupted; they acknowledged, moreover, the validity of its seven sacraments, and solemnly declared they would continue always in communion with it, provided that they might be allowed to live as they thought proper, without molestation or restraint. The latter affirmed, on the contrary, that the church of Rome had apostatized from Christ, was deprived of the Holy Spirit, and was in reality, that whore of Babylon mentioned in the Revelation of St. John. They were also divided in their sentiments concerning the possession of worldly goods. In the fourteenth century, the Waldenses, though they were everywhere exposed to the fury of the inquirers and monks, baffled all the attempts that were made to extirpate them. Many of them fled out of Italy, France, and Germany, into Bohemia, and other adjacent countries, where they afterwards associated with the Hussites, and other separatists from the church of Rome. In the fifteenth century theyubmitted in several European provinces, more especially in Pomerania, Brandenburg, the district of Magdeburg, and Thuringia, where they had a considerable number of friends and followers; though, it is said, that many adherents of this sect, in the countries now mentioned, were discovered by the inquirers, and delivered over by them to the civil magistrates, who committed them to the flames. After the Reformation, in the sixteenth century, the descendents of the Waldenses, who lived shut up in the valleys of Piedmont, were naturally led, by their situation in the neighbourhood of the French, and of the republic of Geneva, to embrace the doctrines and rites of the reformed church. So far down, however, as the year 1630, they retained a considerable part of their ancient discipline and tenets; but being much reduced by the plague in that year, and deprived of many of their clergy, they applied to the French churches for spiritual succour; and the new teachers, sent from thence, introduced several changes into the discipline and doctrine of the Waldenses, and rendered them conformable, in every respect, to those of the Protestant churches in France. In this century they suffered much from the persecution of Phillibert Emanuel, duke of Savoy, who at the solicitation of the pope resolved to force his subjects to return to the communion of the church of Rome; and in 1561 sent a Dominican friar, as an inquisitor, with forces to effect his purpose. After ineffectual supplications, they took up arms, and so far prevailed, after enduring very severe distress, as to obtain some degree of liberty and peace.

During the greatest part of the seventeenth century, those of them who lived in the valleys of Piedmont, and who had embraced the doctrine, discipline, and worship of the church of Geneva, were oppressed and persecuted, in the most barbarous and inhuman manner, by the ministers of Rome. This persecution was carried on with peculiar marks of rage and enormity in the years 1655, 1656, and 1656, and seemed to portend nothing less than the total extinction of that unhappy nation. The most horrid scenes of violence and bloodshed were exhibited in this theatre of papal tyranny; and the few Waldenses that survived, were indefatigable for their existence and support to the intestine made for them by the English and Dutch governments, and also by the Swifs cantons, who solicited the clemency of the duke of Savoy in their behalf. Molinie's Eccl. Hist. vol. iii. iv. Eng. ed. 8vo. Dupin's Eccl. Hist. of the Sixteenth Century, vol. ii. p. 414.

VAUDREVANGE, in Geography, a town of France, in the department of the Meurte, on the Sarre; formerly a confederate town, but ruined by the wars in Lorraine; 3 miles N. of Sar-Louis.

VAUDREUIL, a town of France, in the department of the Essonne, on the Sarthe; formerly a confederate town, but ruined by the wars in Lorraine; 4 miles W. of Meurte.

VAUGELAS, in Biography. See Claude Faure.

VAUGIRARD, in Geography, a town of France, in the department of Paris; 2 miles S.W. of Paris.

VAUGNERAY, a town of France, in the department of the Rhone and Loire; 8 miles W.S.W. of Lyons.

VAULT, FORMIX, in Architecture, an arched roof, so contrived, as that the several ranges of which it consists, do, by their disposition, sustain each other.

Vaults are to be preferred, on many occasions, to soffits, or flat ceilings, as they give a greater rife and elevation; and, besides, are more firm and durable.
The ancients, Salmasius observes, had only three kinds of vaults: the first, the *forma*, made cradle-wise; the second, the *tessellato*, tortoise-wise, called by the French *cul de four*, or oven-wise; the third, the *contre*, made shell-wise.

But the moderns subdivide these three Arts into a great many more, to which they give different names, according to their figures and use; some are circular, others elliptical, &c.

The epochs of some, again, are larger, and others less portions of a sphere: all above hemispheres are called high, or surmounted vaults; all that are less hemispheres, are low, or unfixed vaults, &c.

In some, the height is greater than the diameter; in others, it is less: there are others, again, just flat, only made with haunches; others oven-like, or in form of a *cul de four*, &c. and others growing wider, as they lengthen, like a trumpet.

Of vaults, some are single, others double, cleft, diagonal, horizontal, overriding, dependent, angular, oblique, pendent, &c. There are likewise *Gothic* vaults, with pendencives, &c.

**Vaults, Majler**, are those which cover the principal parts of buildings; in contradiction to the left, or subordinate vaults, which only cover some little part, as a passage, a gate, &c.

**Vault, Double**, is such an one as, being built over another, to make the exterior decoration range with the interior, leaves a space between the convexity of the one and the concavity of the other: as in the dome of St. Paul's at London, and that of St. Peter's at Rome.

**Vaults with Compartments**, are such whose sweep, or inner face, is enriched with pannels of sculpture, separated by pilasters: these compartments, which are of different figures, according to the vaults, and are usually gilt on a white ground, are made with stucco, or brick vaults; as in the church of St. Peter's at Rome; and with plaiter, on timber vaults.

**Vaults, Theory of.** A semicircular arch, or vault, standing on two piers, or impost, and all the stones that compose it being cut and placed in such manner, that their joints, or beds, being prolonged, do all meet in the centre of the vault; it is evident, all the stones must be in form of wedges, i.e. they must be wider and bigger at top than at bottom; by virtue of which they fulfill each other, and mutually oppose the effort of their weight, which determines them to fall.

The stone in the middle of the vault, which is perpendicular to the horizon, and is called the *key* of the vault, is sustained on each side by the two contiguous stones, just as by two inclined planes; and of consequence, the effort it makes to fall, is not equal to its weight.

But still that effort is greater, as the inclined planes are less inclined; so that if they were infinitely little inclined, i.e. if they were perpendicular to the horizon, as well as the key, it would tend to fall with its whole weight, and would actually fall, but for the mortar.

The second stone, which is on the right or left of the key-stone, is sustained by a third; which, by virtue of the figure of the vault, is necessarily more inclined to the second, than the second is to the first; and, of consequence, the second, in the effort it makes to fall, employs a less part of its weight than the first.

For the same reason, all the stones, reckoning from the key-stone, employ still a less and less part of their weight to the last; which resting on an horizontal plane, employs no part of it's weight; or, which is the same thing, makes no effort to fall; as being entirely supported by the impoil.

Now, in vaults, a great point to be aimed at is, that all the several stones make an equal effort in order to fall: to effect this, it is visible, that as each (reckoning from the key to the impost) employs a still less and less part of its whole weight, the first, for instance, only employing one-half; the second, one-third; the third, one-fourth, &c.; there is no other way to make those different parts equal, but by a proportionate augmentation of the whole, i.e. the second stone must be heavier than the first; the third, than the second, &c. to the last; which should be vastly heavier.

M. de la Hire demonstrates what proportion is, in which the weights of the stones of a semicircular arch must be increased, to be in equilibrio, or to tend with equal forces to fall; which gives the firmest disposition a vault can have.

Before him, architects had no certain rule to conduct themselves by; but did all at random. Reckoning the degrees of the quadrant of the circle from the key-stone to the impost; the extremity of each stone will take up so much the greater arch, as it is farther from the key.

M. de la Hire's rule is, to augment the weight of each stone above that of the key-stone, as much as the tangent of the arch of this stone exceeds the tangent of the arch of half the key. Now, the tangent of the last stone, of necessity, becomes infinite, and of consequence, its weight should be fo too; but as infinity has no place in practice, the rule amounts to this, that the last stones be loaded as much as possible, that they may the better resist the effort which the vault makes to separate them; which is called the *floor*, or *drift*, of the vault.

M. Parent has since determined the curve, or figure, which the extrados, or outside of a vault, whose intrados, or inside, is spherical, ought to have, that all the stones may be in equilibrio. See ARCH.

**Vault, Key of a.** See Key and VOUSSOIR.

**Vault, Reins or Fillings-up of a.** are the sides which furnish it.

**Vault, Pendentive of a.** See PENDENTIVE.

**Vault, Impoll of a.** is the stone on which the first voussoir, or arch-stone of the vault, is laid. See IMPOSTS.

**Vault, in the Manege.** To vault a horse-flooe, is to forge it hollow, for horses that have high and round foles; to the end that the shoe, thus hallowed or vaulted, may not bear upon the sole that is higher than the hoof; but after all, this sort of shoe spoils the feet; for the sole, being tenderer than the shoe, affames the form of the shoe, and becomes every day rounder and rounder. In Mr. Solleyföld's Complete Horfeman, may be seen the true method of shoeing high and round foles. See SHOE and SHOEING.

**Vault, or Volte.** See VOLTE.

**Vault, Going to the.** a term used by sportmen for a hare's taking the ground like a coney, which the sometimes does.

**Vault, Le, in Geography, a town of France, in the department of the Yonne:** 3 miles W. of Avallon.

**VAULX, a town of France, in the department of the Straits of Calais:** 4 miles N.E. of Baupain.

**VAULX MILieux, a town of France, in the department of the Ile de France:** 12 miles N.E. of Vienne.

**VAUNIA, in Ancient Geography, a town of Italy, belonging to the Bucchani.** Potelamy.

**VAUNING, in Mineralogy.** See VAN, VANNING, SHEVEL, and Tin.

**VAUNT, or VANT. See VAN.

**VAUNT-LEGS, among Hunters, a setting of hounds, or beagles, in a readiness where the chase is to pass:** and calling them off before the rest of the kennel come in.
VAUQUELIN, in Biography. See IVETEAUX.

VAUQUELINIA, in Botany, a genus dedicated by M. Correa de Serra, now the Portuguese minister to the United States of America, to the honour of the celebrated French chemist M. Vauquelain, whose discoveries have been extended to the vegetable kingdom. Humboldt and Bonpland, Plantes equinoxeales, falc. 6. De Theis 475. We regret that we are furnished with no further account of this genus, nor with any of its characters.

VAUS, in Geography, a river of West Florida, which runs into the St. Mark, N. lat. 30° 10'. W. long. 84° 36'.

VAUVENARGUES, a town of France, in the department of the Monts of the Romé; 6 miles E.N.E. of Aix.

VAUVERT, a town of France, in the department of the Gard; 9 miles S. of Nîmes.

VAUZ, a small seaport-town of France, in the department of the Channel, on a bay to which it gives name; 9 miles W. of Cherbourg. N. lat. 49° 39'. W. long. 1° 37'.

VAUVILLERS, a town of France, in the department of the Upper Saône; 12 miles N.W. of Luxeuil.

VAUVINCOURT, a town of France, in the department of the Meuse; 5 miles N. of Bar-le-Duc.

VAUX, in Geography, a district of Switzerland, in the Pays de Vaud, between Launanne and Vevey, which contains the two pleasant little towns of Lutry and Cully, with the villages of St. Saphorin and Corfier. This district is entirely hilly, rising abruptly from the lake; above the vineyards are rich meadows and a continued forest. In the church of St. Saphorin is an ancient Roman mile-stone with an inscription, which contains two circumstances often questioned; viz. that the banks of the lake of Geneva, which border this part of Switzerland, were comprised within a Roman province, even so early as the time of Claudius, and also that Aventicum was the chief town of this part of Helvetia; for the mile-stones always referred to the capital of the province in which they were placed, and the distance from St. Saphorin to Avences is nearly 37,000 paces. The inscription is as follows:

TI. CLAVTIUS. DRUSI. F.
CÆS. AUG. GERI.
PONT. MAX. TRIB. FOT. VII.
IMP. XII. P. P. COS. III.
F. A.
XXXVII.

VAUXHALL GARDENS, a well-known place of public amusement in the parish of Lambeth and county of Surrey, which belonged, in 1615, to Jane, widow of John Vaux, between whose two daughters the estate was divided, and passed through various hands, till both moieties were purchased, about the middle of the last century, by Jonathan Tyers, esq. It does not appear at what time this place was first opened for public resort; but we are led to conclude from a paper in the Spectator (No. 388.), and another in the Connoisseur (No. 68.), that it must have been so appropriated in or before the time of Queen Anne. Mr. Tyers, who held the premises on lease many years before he bought the estate, opened the Spring Gardens, as they were then denominated, in 1730, and expended large sums in embellishing them. After his death they fell into the possession of several proprietors, of whom the principal is Mr. Barratt. Thele gardens were, till of late years, opened every evening during a great part of the summer, for the reception of company; but they are now admitted only three times a week. The entertainments consist of music, vocal and instrumental, illuminations, and fire-works, and other exhibitions. See LAMBETH and TYERS.

VAUZ, in Geography, a town of Pennsylvania, on the Susquehanna; 12 miles N.W. of Harrisburg.

VAYHENCE, a town of Wurttemberg, on the Entz, with a castle. This town had formerly counts of its own; 11 miles N.W. of Stuttgart. N. lat. 48° 58'. E. long. 8° 59'.

VAYLOR, a town of Hindoostan, in Barmaul; 11 miles S.S.W. of Namaul.

VAYPAR, a town of Hindoostan, in the province of Madura; 25 miles E. of Coimbatmore.

VAYRES, a town of France, in the department of the Gironde; 3 miles S.W. of Libourne.

VAYU, in Hindoostan Mythology, is a name of the regent of the winds, more commonly called Paeana; (see Vayu.) Vayu is the Eolus of the East. One of the Puranas is named after him, being called Vayu Purana. (See Purana.) Yah is another of his names.

VAYWODE, or Vaiwode. See WAYWODE.

VAZABU, in the Materia Medica, a name by which some authors have called the Acorus Afiticus, or Asiatic sweet-flag.

VAZCUSE, in Geography, a river of Louisiana, which runs into the Mifflin, N. lat. 38° 31'. W. long. 94° 5'.

VAZUA, in Ancient Geography, a town of Africa Propria, between the river Bagrada and the town of Thabraca, according to Poltemy.

UIBALDI, GUIDO, in Biography, an eminent mathematician of noble extraction from a branch of the family of Bourbon, studied under Condamine, and made early as well as rapid proficiency. Mathematics and mechanics were his favorite objects; but in the latter science he published a work, entitled "Mecanicius Liber, in quo hac continentur:— de Libra, Veete, Trochlea, Axe in Peritrochio, Cuneo, Cochlea," Venetii, 1615, fol. In the last work he reduces all machines to the lever, applying the same principle with advantage to some of the other mechanical powers, particularly to the pulley and its combinations. He also explained the structure of the fere of Archimedes, and its application to the rife of water, in a treatise "De Cochlea, Libri quatuor," Venet. 1615, fol. He illustrated the principles and practice of perspective more fully and clearly than other preceding writers had done, but with needls proximity, in his "Perspectiva, Libri sex," Papiling, 1600, fol. His other works, mentioned by Kiltner, are "Guidi Ubaldii e Marchionibus Montes (of the Marquilles del Monte) in duos Archimedes Equiponderant libros Paraphrasia, scholiosis illustrata," Papiling, 1688, fol.; "Probationum Astronomicorum Libri septem," Venet. 1508, fol. The time of his birth and also of his death is unknown, Montuca.

UBAMBA, in Geography, a town of Brail, near the coast of the Atlantic; 80 miles S.W. of Rio Janeiro.

UBARCO, CAPE, a cape on the N.W. coast of the island of Iviça. N. lat. 39° 5'. E. long. 1° 18'.

UBATUBA, in Geography, a river of Brail, which runs into the Atlantic, S. lat. 23° 20'.

UBAYE, a river of France, which runs into the Durance, near Brumun.

UBEDA, a city of Spain, in the province of Jaen, containing 10 parishes, 8 convents, and about 2900 inhabitants. In 1233, Ubeda was taken from the Moors; 3 miles E. of Jaen. N. lat. 38° 31'. W. long. 3° 31'.

UBENITZ,
UBENITZ, a town of Bohemia, in the circle of Prachatitz; 7 miles E. of Prachatitz.

UBERAU, a town of Heife Darmstadt; 6 miles S.E. of Darmstadt.

UBERE, a town of Sweden, in Velt Gotland; 15 miles S.W. of Skara.

UBERLINGEN, a town of Bavaria, in the territory of Ulm; 13 miles S.W. of Ulm.

The burgh of Darmstadt, the Upper Town, and the Hallenberg in the heart of which are vineyards. It contains in it a collegiate church, a house of the order of St. John, a hospital, three convents, and two other churches. Near the town is a good mineral spring. Uberlingen was an imperial town so early as the time of the emperors of Swabia. Charles IV. and Wenceslaus engaged to maintain it in its immediate independence on the empire; but in 1802, it was given to the duke of Baden; 22 miles N.W. of Lindau. N. lat. 47° 45'. E. long. 8° 49'.

UBERSKO, a town of Bohemia, in the circle of Chrudim; 10 miles E.N.E. of Chrudim.

UBERTI, Fazio, (Bonifacio,) De glia, in Geberography, an Italian poet, born at Florence, who flourished in the 14th century. His character is represented as amiable, allowing for his disposition to frequent the courts of tyrants and to pay adulation to the great; but his poverty in a state of exile, as one of the Ghibelline party, has been ascribed as an apology for his conduct. He wrote various poems, and according to the account given of him by Villani, he was the first who employed with effect that species of poetical composition called by the vulgar 'trattelle,' or ballads. His principal work, however, written in his advanced age, was a description of the world in verse, entitled 'Ditta Mondo.' This is divided into six books, but was left in an unfinishing state, though written at different periods from the year 1355 to 1364. It was first printed at Verona, and afterwards at Venice in 1501. He is reckoned superior to the Italian poets of his time in energy of style. Some of his Canzone have been published in collections. He died and was interred at Verona.

UBES, St., in Geography. (See Setuval.) This town would be more considerable if it were not so near to Lisbon, and the trade carried on through Lisbon houses; for here, it is said, there are only mercantile firms. Its trade consists in wine, of which various kinds are exported. Oranges are likewise exported: but the chief commercial article of St. Ubes is salt, which is taken principally by Danish and Swedish ships. The salt-pans lie in great numbers along the Sado or Sandoa, and its branches, being called in Portuguese 'marinas.' They are dug square, about three feet deep, and salt-water is introduced on one side from the sea, at flood, through canals which extend in innumerable branches, and are shut when the pans are full. The water is often previously collected in large resevoirs called 'governos,' from which it is afterwards distributed into the marinas, where being evaporated, the salt is collected in the month of June, and kept either in wooden sheds, or in heaps, which are protected from the rain by thatches. This salt is large-grained, becomes but little moist by the air, and excels in purity the marine salt collected in other provinces of the south of Europe, or in other parts of Portugal. The fisheries of St. Ubes were formerly celebrated, but have of late much declined.

Opposite to St. Ubes, on the narrow strip of land that forms the entrance of the harbour, are the remains of an ancient city, called Troya. Tradition reports that this place was buried in sand; and that the inhabitants removed and built St. Ubes on the opposite side.

UBI, or UBA, an island in the East Indian ocean, in the gulf of Siam, near the coast of Cambodia; about 21 miles in circumference, with plenty of wood and good water. N. lat. 8° 26'. E. long. 105° 56'.

UBIGAU, a town of Saxony; 6 miles N.W. of Liebenwerda. N. lat. 51° 34'. E. long. 12° 20'.

UBI, in Ancient Geography, a people whose first abode was on the other side of the Rhine, being separated from Gaul by the river. Being afterwards pressed by the Suevi, they had recourse to Caesar. Agrippa passed the Rhine, according to Dion Cassius, and transported them to the other bank of the river and established them, with a view to the security of the adjoining frontier of the empire. Under the reign of Claudius, an Agrippine colony was founded among them, and they voluntarily assumed the name of Agrippinenses, as their attachment to the Romans excited the envy of Civilians. Their territory extended along the Rhine, from the Treveri to the borders of the Gugerni, who had been a branch of the Menapii. The Ubians, on the right bank of the Rhine, were continually harassed by the Sicambri, and in order to avoid the hostility of such neighbours, they were induced to cross the river. Agrippa caused them to build a town, which was called 'Civilitas Ubiorum,' in which he planted a Roman colony, denominated 'Colonia Agrippina.' This town is the present Cologne. The Ubii formed a part of the Germanic body, which they abandoned in order to enter into a league with the Celtic people. This separation of the Ubians is referred to about the thirty-seventh year before our era. They worshipped the god Mars.

UBIQUITISTS, UBQUITARIES, or UBQUITARIANS, formed from ubiique, every where, in Ecclesiatical History, a sect of Lutherans, which rose and spread itself in Germany, and whose distinguishing doctrine was, that the body of Jesus Christ is every where, or in every place.

Brentius, one of the earliest reformers, is said to have first broached this error, in 1560. Luther himself, in his controversy with Zuinglius, had thrown out some unguarded expressions, that seemed to imply a belief of the omnipresence of the body of Christ; but he became sensible afterwards, that this opinion was attended with great difficulties, and particularly that it ought not to be made use of as a proof of Christ's corporal presence in the eucharist. (Luther, Oper. tom. viii. p. 375. ed. Jenenf.) However, after the death of Luther, this absurd hypothesis was renewed, and dressed up, in a specious and plausible form, by Brentius, Chemnitz, and Andraes, who maintained the communication of the properties of Christ's divinity to his human nature.

Melanthon declared against it; maintaining that it introduced, with the Eutychians, a kind of confusion into the two natures of Jesus Christ; and protestted, that he would oppose it as long as he lived.

On the other hand, Andraes, Flacius Illyricus, Schmidelein, Oifander, &c. espoused Brentius's party; and asserted the body of Jesus Christ to be every where.

The universities of Leipsic and Wurtemberg, and the generality of Protestants, felt themselves against this new heresy, but in vain: the Ubiquitarians grew stronger and stronger. Six of their leaders, Andraes, Schneecer, Muffel, Chemnitz, Chytreaus, and Cornerus, having a meeting in 1576, in the monastery of Berg, they there com-
pofed a kind of crede, or formula of faith, called the "Form of Concord;" wherein the ubi-quitity was established as an article. See Form of Concord.

Muculus, one of these leaders, and the most zealous advocate of the ubiquity, expressly maintains, that the ascen-
dedion of Christ into heaven was nothing more than a ceafing to be visible, and that it is not performed by any physical
motion, or change of place: and in 1552 he published a book to prove that it is by no means necessary, that the
glorious body of Christ should physically fill up any space.

And he declares in a fermo in 1564, that they who teach
that Jesus Christ died only as to his human nature, belong
to the devil, both body and foul; and that the true doctrine
is, that he died as to his human and divine nature.

All the Ubiquists, however, are not agreed: some of
them, and among the rest the Sweden, hold that Jesus Christ,
even during his mortal life, was every where: others main-
tain, that it is only since his ascension that his body is every
where.

G. Hornius only allows Brentius the honour of being the
first propagator of ubiquitism; its first inventor, accord-
ting to him, was John of Wetphalia, or Wellephalus, a minister
of Hamburg, in 1552.

But according to Hopeffian, Wetphalus opposed the
opinion concerning the ubiquity advanced by Brentius and

UBIQUITY, in the University of Paris, is a term applied
to fuch doctors in theology, as are not restrained to any
particular houfe; either to that of Navarre, or Sorbonne.

The Ubiquists are called, simply, doctors in theology;
whereas the others add, of the houfe of Sorbonne, or Navarre,
&c. See Sorbonne.

UBIQUITY, Omnipresence; an attribute of the God-
head, whereby he is always intimately prefent to all things;
gives the effe to all things; and knows, prefers, and does
all in all things.

For since God cannot be faid to exift in all places, as
placed therein, (beauf, then, he would need something to
his effe, viz. place; and would have extension, parts, &c.) he muft be conceived to be every where, or
in all things, as a firit, univerfal, efficient caufe, in all his

effects.

He is prefent, therefore, to all his creatures, as a pure
act, or an exercife of an active virtue, which knows, pref-
ferves, governs, &c. every thing. Nor are even finite minds
prefent otherwise than by operation. See God.

UBIRRE, in Ichthyology, a name given by fome to the
anguilla marina, or small sea-eel.

UBIUM, in Botany, altered by Rumphius, Herb.
Amboin. book 9. 346, from the Malay name Ubi, a synonym
of fome fpecies of Dioscorea; see that article. Forster
defires all the kinds of Ubium, mentioned by Rumphius,
to belong to D. alata. These differ chiefly in the fhape of
the roots, and in the items being furnished or not with flefhly
buds, or bulbs, of different forms. These roots confitute
one of the moft important articles of food, in the remote
islands of India and the South Seas.

UBNI, in Geography, a town of Wolachia; 10 miles N.
of Viddin.

UBOA, a town on the west coaft of the ifland of Lucon.
N. lat. 16° 57'. E. long. 120° 48'.

UBRAYE, a town of France, in the department of the
Lower Alps; 9 miles N.E. of Caffelane.

UBRILEN, a town of the Arabian Irak; 5 miles S.E.
of Baffora.

UBRIX, in Ancient Geography, a town of Africa, on the
coast of Libya. Ptolemy.

UC, a town of Afn, in the interior of Media. Pto-
lemy.

UCCANO, in Geography, a town of Portugal, in the
province of Beira; 2 miles N. of Lamego.

UCAYALE, UCALAL, or UCAYALE, a river of South
America, formed by the union of the Apurimac and Ene,
in S. lat. 10° 50'. It purfues a northerly courfe to S.
lat. 4° 15', where it joins the Maranon, near St. Joachim
de Omaguis, and then takes the name of the Amazons.

See MARAXON.

UCENA, in Ancient Geography, a town of Afn, in Ga-
latia, belonging to the Trochimi. Ptolemy.

UCENI, a people placed by the inscription on the trophy
of the Alps, mentioned by Pliny, near the Medulli and the
Caturiges, and fpofded by Saxon to be the fame with the
Sicomin or Iconii, mentioned by Strabo.

UCETIA, a town of Gallia Narbonnenfis.—Alfo, a
town of Gallia Transpadana. Strabo.

UCHALIGES, a people of Africa, in Libya Interior.

UCHENDEGE, in Geography, a town of the principality
of Georgia, and chief place of a diocfe, situated to the eft
of Telies. In 1395, this town was taken by Timur Bec,
and the whole garrifon put to the sword.

UCHINCHIR, one of the small Kurile iflands, in the
North Pacific ocean. N. lat. 48° 30'. E. long. 155° 44'.

UCHKILISSA, a town of Perfhon Armenia; 18 miles N.W. of Erivan.

UCHT, a river of Brandenburg, which runs into the
Aland, near Olferburg.

UCHTLHAIUSEN, a town of the duchy of Wurz-
burg; 6 miles E. of Schweinfurt.

UCIBI, in Ancient Geography, a town of Africa Pro-
pria, in Numidia Nova. Ptolemy.

UCIMATH, a town of Africa, in Libya Interior,
upon the northern bank of the river Gir. Ptolemy.

UCKER, in Geography, a river of Pomerania, which
empties itself into the Fribe-Haff, 1 mile N. of Ucker-
munde.

UCKER Mark. See BRANDENBURG.

UCKER See, a confiderable lake of Brandenburg, in the
UCKER Mark, fitated to the fouth of Premzlow.

UCKERMUNDE, a town of Anterior Pomerania, fitated
on the river Ucker, near its entrance into the Fribe-Haff.
This town was furrounded with walls in 1190. In the 17th century it fuffered greatly by fieses,
and the vicifitudes of war; and in 1713, was facked by
the Russifis. It has good fisheries, pastures, and woods;
29 miles N.N.W. of Old Stettin. N. lat. 53° 48'. E. long.
13° 57'.

UCKEWALLISTS, in Ezekifical History, a fect of
rigid Anabaptifts, fo called after its founder Uke Wallis, a
native of Frieland. This fectary not only exhorted his
 followers to maintain the primitive and auftere doctrine of
Menno, but took it into his head to propagate, in connec-
tion with one John Leus, in 1637, a fingular opinion con-
cerning the falvation of Judas, and the ref of Chriff's
murderers; alleging, that the period of time, which ex-
 tended from the birth of Chriff to the defcent of the Holy
Gholf, and was, as it were, the diflinfive term that fepa-
rated the Jewifh from the Christian dispensation, was a time
of profound ignorance, during which the Jews were delti-
tute both of light and divine succour; and that, confi-
ently,
quently, the sins and enormities, that were committed during this interval, were in a great measure excusable, and could not merit the severest displays of the divine justice. This pale fiction met with no indulgence either from the Mennonites, who excluded its inventor from their communion, or from the magistrates of Groningen, who banished him from the city. In Earls Frieland he drew after him a considerable number of disciples, whose descendents still subsist in the neighbourhood of Groningen, Frieland, and also in Lithuania and Prussia, and have their own religious assemblies, separate from those of the other Mennonites. They re-baptize all who leave other Christian churches to embrace their communion; they studiously avoid every appearance of elegance or ornament; suffering their beards to grow to an uncommon length, and their hair to lie uncombed over their shoulders; their countenances are marked with melancholy; and their houses only adapted to answer the demands of necessity. Their inspectors or bishops, whom they distinguish from the ministers whose office is to teach, are chosen by an assembly composed of all the congregations of the sect. The ceremony of washing the feet of strangers is considered by them as a rite of divine institution. They carefully avoid even the aspect of learning and science, and thus prevent all attempts to alter or modify their religious discipline. Molhem's Eccl. Hist. vol. v. 8vo.

UCLES, in Geography, a town of Spain, in New Castile. In 1108, a battle was fought near this place between the Christians and the Moors, in which the former were defeated with great loss; 20 miles S.W. of Huete.

UCO, a town of Chili; 9 miles E.S.E. of St. Yago.

UCRIA, a town of Sicily, in the valley of Demona; 8 miles W.S.W. of Pati.

Gen. Ch. Cal. Perianth superior, of one leaf, short, cup-shaped, with five angles, and five small, erect, acute teeth, permanent. Cor. of one petal, tubular; tube extremely long and slender, cylindrical, pervious; limb bell-shaped, with five rather short, ovate, acute, equal, slightly spreading, marginal segments. Stam. Filaments five, very short, inserted into the limb between the segments; anthers incumbent, oblong, pointed, of two cells. Pila. Germen inferior, elliptical; style the length of the tube of the corolla, thread-shaped; swelling and hairy at the top; stigma of two rounded lobes. Peric. Berry elliptical, fleshy, of two cells, crowned by the permanent calyx. Seeds: numerous, roundish, inserted into the middle of the partition at each side, and surrounded with viscid pulp.

1. U. scirpoidea. Willd. n. 1. (Tocoyena longifiora; Aenl. t. 50.)—Native of woods in Guiana, bearing flowers as well as fruit in August. Stem shotty, simple, about three feet high, obtusely quadrangular, leafy. Leaves opposite, stalked, fifteen inches long, lanceolate, acute, entire, smooth, contracted at the base, with one rib and many transverse veins. Stipular in pairs, intrafollicaeous, ovate. Flowers about fourteen, crowded at the top of the stem, sessile, opposite, erect, very fragrant, white, with a yellow tube, nine inches and a half long, the thickness of a goose-quill. Calyx very small. Berry yellow, an inch in length.

This plant comes very near to Gardenia, or at least to Thunberg's Rothmannia. (See Gardenia.) We do not profess to have had sufficient opportunities of comparing them and their allies, to form an accurate judgment. Willdenow has changed the specific name without any authority or reason.

UCUBIS, in Ancient Geography, a town of Spain, in Bética.

UDA, in Geography, a river of Russia, which runs into the Velika, 12 miles N.W. of Onega, in the government of Piskov.—Also, a river of Russia, which joins the Tchiuna, N. lat. 55° 50'. E. long. 99° 22'.—Also, a river of Ruflia, which runs into the Selenga, near Verch Udiuk.—Also, a river of Russia, which runs into the sea of Ochotz, N. lat. 55° 15'. E. long. 136° 44'.

UDACENSES, in Ancient Geography, mountains of Asia, in Corduena, south of the lake Ar thìa, lat. 37° 30'.

UDAL. See Odial.

UDASSA, in Geography, a town of Hindoostan, in Goondwana; 12 miles N.W. of Nagpaur.

UDWANTANAGUK, a town of Hindooftan, in Bahar; 5 miles S.S.W. of Arrah.

UDDALAKA, in Hindoo Mythology, is the name sometimes given to a theologian, who is said to be the son of Aruna, the charioteer of the sun. He is not often read of. Respecting his parent, who corresponds with the Aurora of western fables, notice will be found under our article Surya, the common name of the Hindoo Phobus.

In the theogonies of the Puranas (see Purana), when describing the procees of churning the ocean, as mentioned in our article Kurmayata, a goddess, named Jyeftha, was produced. She is deemed the goddess of poverty and misfortune, and having rove from the sea earlier than Lakshmi, the goddes of riches and fortune, is called her elder sister. Vishnu, enamoured of the latter, wished to espouse her; but the objected, saying her elder sister, agreeably to the injunctions of the Veda, ought to be married first. And this we may remark, in paling, is a rule in force at this day, though not invariably observed. Vishnu, after much difficulty, prevailed on Uddalaka the Rishi, who was unmarried, to take the undeferrable damsel to wife; and Sagara, her father, sealed the nuptial ceremony by pouring water into the hands of the Rishi. (See Sagara.) Jyeftha, like Lakshmi, is called the daughter of the ocean, and is celebrated as being ever faithful to her comfort. She is sometimes called Sretha.

Under the article Rishi will be found an account of the holy men so designated. One of them taking the goddef of poverty to wife, means, we may suppose, the usual profession of poverty by pious perfons. It was no small sacrifice of comfort to be linked to such a rib: for Jyeftha is described to have arisen in black garments, with yellow hair, red eyes, wanting many teeth, those remaining of repelling appearance, her tongue lolling out of her mouth, potbellied, &c. &c.; so that gods and demons were amazed at the sight of such a figure. Such a one is described, from an image in the East India Houfe, in our article Kal. Her younger sister, on the contrary, is described as superlatively fascinating, but fickle; being a personification of Fortune.

UDDEN, in Geography, a town of Arabia, in the province of Yemen; 44 miles E.S.E. of Zebid. N. lat. 13° 58'. E. long. 43° 50'.
UDDER, in Rural Economy, a term applied to the glandular organ, which is defined for the preparation and secretion of the milk in cows, mares, ewes, fows, or any other kinds of domestic animals, and which is often much subject to disease.

It is to be noticed, that the udders of young cows which are in a high condition, are sometimes very greatly swollen and inflamed for several days before they calve; in which cases, it is mostly proper to milk them frequently in repetition, and alternately to anoint the distended parts, with some severe inunction, with a faturine cooling ointment, and brandy, or some other quickly evaporating spirit; as, by such means, these swellings are often speedily removed, without much danger or inconvenience. But, besides these sorts of swellings, the udders of cows are liable to injures, which are often of a more serious consequnce, as from falls, blows, the wounds of sharp instruments, or such as are pointed, and the violent sucking of calves, as well as from the injudicious or rough treatment of harsh and inexperienced milkers. In such cases, while the inflammation in the glands remains in a hard and indolent state, the parts so affected should be repeatedly anointed in the course of the day with some gentle cooling sub stance, such as fresh lard, or with a solution consisting of one ounce of Calamine soap, dissolved in a pint and a half of new milk, over a moderate fire, constantly stirring it until it becomes thoroughly mixed and incorporated. An ointment, too, prepared from the juice of the leaves of the common thorn-apple, by mixing it with fresh hog's-lard, is said by fome to be an excellent application in cases of this nature. Such tumours may likewise, in many inclusions, be anointed with a little of a composition, consisting of camphor dissolved in spirit and blue ointment, with great benefit; and about half a dram of calendul may be given in a boaln of treacle and warm beer, three or four mornings together, if the swelling should continue to increase. Where, however, the udder and teats are considerably inflamed and swelled, other internal remedies may be had recourse to; for which purpose, it has been recommended to mix four ounces of nitre with one pound of common salt, and to give two tablespoonfuls of the powder in a gallon of thin water-gruel every three hours. But in cases the affection, in such instances, should have made, from neglect, such progress as to display large hardish tumours in the parts, fomentations of the fort given below may often be applied with advantage. Boil in a sufficient quantity of water one handful of the leaves of common hemlock, the fame quantity of the dwarf or round-leaved mallow, and an equal proportion of common melilot, and diligently apply the liquid, by means of cloths wrung out of it, to the part or parts, as warm as the breast can bear it. As soon as the tumour or tumours, in this case, burst or opens, the wound should be well and properly cleaned, and then covered with a pledge of lint, and a plaster of common cerate or basilicon laid over all.

The remedy directed below, it is said, has been employed with great success in very obstinate cases of ulcerated cattle udders: one ounce of gum ammoniacum, the fame quantities each of gum galbanum, Calamine soap, and extract of hemlock; reduce the gums into powder, and form them with the soap and extract into eight small balls, one of which is to be given to the beast every night and morning. In cases where the teats only are fore, they may first be washed well with clean warm soap-fuds, and then rubbed with an ointment, composed of finely powdered ceruse or white lead, which has previously been saturated with brandy, and well mixed and united with a proper quantity of elder ointment or grose-grease.

In the case of sheep too, these parts are often much affected, when the lambs are yeaned in the ewes, the lactiferous ducts in the udders of which are liable to become attacked with various obstructions, which are the consequence of hard tumours or swellings being formed, which are accompanied with inflammation, and which, if not speedily relieved, will terminate in mortification, not unfrequently in the course of twenty-four hours. As soon as such swellings or tumours are discovered, the wool should be torn off closely in a careful manner, and the part affected be frequently wetted and rubbed well with camphorated spirit of wine. If, however, suppuration should ensue, the part should be laid open by a strong lancet or sharp knife, and the matter be discharged, when a pledge of lint should be laid over the part, and secured by a plaster spreaded with some soft ointment, or the common cerate rubbed with a little oil. Ewes, when thus affected, should be kept separate from the rest of the flock, and though one of the nipples may be lost, they may be allowed to suckle their lambs; but in cases where both are affected, there is, of course, no alternative but that of fattening them off for sale, and to bring up their lambs by hand in the best manner possible.

The udders and nipples of ewes are likewise very apt to be heated, chafed, and fretted, by which the lambs are prevented from being let suck in a proper and ready manner; consequently, in all such cases, the parts so affected should be kept as cool as possible, and be well washed with a weak solution of white vitriol in rain-water, or be anointed with some mild softening ointment, such as that of elder, or common cerate softened with oil, once or twice in the day; care being taken to have them well removed by the use of warm water and a little soft soap, before the lambs be again admitted to them for suckling.

The diseases of the udders, in the other sorts of domestic animals, are, for the most part, to be treated in a similar manner, according as the nature of them may be; always having the parts carefully cleaned, before the young are suckled.

UDDER-LOCKING, a term used in the management of sheep, to signify the practice of clearing away the locks of wool from about the udders, and other parts, where the lambs suck, in ewes. Some sheep-farmers have a very high opinion of the necessity and utility of this custom, while others as strongly condemn it, and consider it to be quite unnecessary, as well as dangerous and hurtful both to the ewes and the lambs. It may, however, be useful in different cases and circumstances. The former, or those in favour of the practice, recommend that, immediately before the ewes begin to drop their lambs, they should be carefully driven into the yards, folds, or pens, and have a small part of the locky wool pulled off from about their udders, in order to give the lambs more easy and ready access to the teats or nipples, by which they come forward faster, and succeed better. But the latter, or those who object to the custom, think that they have seen instances where it occasioned not only the death of nearly one-twentieth part of the ewes, but that many of those which survived it lambed dead lambs at the danger and hazard of their own lives. They suppose that there is naturally a sufficient space left bare about these parts, so as to enable the young lambs to find the ducts or nipples; and that the uncovering more, or a larger extent of parts, serves only to starve and expose the ewes in the most tender and delicate parts; as, although they have been engaged among sheep the whole of their lives, they have never seen a single lamb die from the want of its dam or mother being udder-locked, even though the
may have been ever fo young, or ever fo rough in such parts: nor have they ever met with any persons who could be certain that they had seen any. How far some breeds of sheep, as those of the Cheviot, may have their lambs more readily or more easily killed or destroyed in this way, or whether it may not be owing to the shape of the udders in their dams, which being more full and exposed in such parts, is not by any means well known; but far less injury or exposure, in this or in any other way, will make that breed of sheep lamb dead lambs, it is said, than in the forest, or probably some other breeds.

But though this practice may often be found prejudicial in the more northern parts of the kingdom, in the southern sheep districts it may not unfrequently be had recourse to with very considerable utility and advantage in different respects.

**UDIVALLA**, in *Geography*, a sea-port town of Sweden, in the province of Bohus, with a strong fort and convenient harbour. The inhabitants carry on a considerable trade in iron, planks, and herrings; their number is about 9000; 205 miles W.S.W. of Stockholm. N. lat. 58° 21'. E. long. 11° 45'.

**UDEBODE**, a town of the island of Ceylon; 60 miles S. of Candi.

**UDEGHUR**, a town of Hindoostan, in the Carnatic; 43 miles N.W. of Nellore. N. lat. 14° 43'. E. long. 79° 16'.

**UDEM**, a town of France, in the department of the Roer; 7 miles S.S.E. of Cleves.

**UDEPIRCONDA**, a town of Hindoostan, in Myfore; 20 miles N.W. of Anantpour.

**UDEWANGEN**, a town of Prussia, in Natacen; 12 miles S.S.E. of Konigberg.

**UDI**, a town of Egypt; 10 miles N. of Attieb.

**UDJARMA**, a town of the principality of Georgia, in the province of Kakhet; 24 miles E. of Tiflis.

**UDICA** denotes the projecting part of a barges stern, on which its name, &c. is printed.

**UDINA**, or **UDINE**, in *Geography*, a town of Italy, and capital of Friuli; to which, on the decline of Acquileia, the patriarch removed his seat. It has several churches, convents, and hospita!s, a college for the study of law, and a military academy: and it is said to contain between 17,000 and 18,000 inhabitants; 35 miles N.W. of Triele. N. lat. 46° 10'. E. long. 13° 14'.

**UDINE, Giovanni da**, in *Biography*, was the cognomen of an affidavit of Raphaelle in the works of the Vatican, whose real name was Nanni. His family resided at Udine, where he was born in 1494, and had there followed the occupation of embroiderers with so much excellence, as at length almost to have lost their own name in that of Ricamatori, by which Vaffari often calls him. His father, become rich, amused himself with hunting; and his son Giovanni found his sport, at a very early period of his life, in drawing the animals, birds, &c. brought him from the chase. This indication of taste for painting was encouraged, and the youth was placed under the tuition of Giorgione, at Venice, with whom he acquired a knowledge of colour and chiaro-scuro. About the time of the death of Giorgione he went to Rome, and being furnished by his protector, the patriarch Grimani, with letters to count Baldassare Cafliglione, he was introduced to Raphaelle, who admitted him into his school, and employed him in painting the grotesque and ornamental accessories of his larger works. The imagination of his master Raphaelle, and of himself, was led to the introduction of this species of ornament, by the discovery of the painted chambers in the baths of Titus, then recently opened, when Giovanni was employed in making designs of the beautiful ornaments in tusco found there, and thence denominated * grotesque*. In pursuance of these studies, he discovered the composition of the tusco upon or rather in which they were painted; and with the fame materials, he, by order of Raphaelle, prepared the walls and ceilings of the Loggie, and painted upon it the beautiful series of ornamental combinations of flowers, fruit, animals, vases, &c. since then so much employed in adorning the dwellings of the rich and great. This part of the work was entirely entrusted to Giovanni da Udine, under whose directions a number of ingenious young men were employed; and the taste and ability, the freedom and truth, without minuteness, with which the whole is managed, has ever since been a constant subject of praise and admiration. After the death of Raphaelle, he was employed by Clement VII., in conjunction with Pierino del Vaga, to ornament that part of the Vatican called the Torre di Borgia. When he was compelled to leave Rome by the faking of that city, he was employed for a time at his native place, and afterwards was engaged at Florence in adorning the palace of the Medici; and returning to Rome in the pontificate of Pius IV., left in various places there mementos of his admirable ingenuity. He died there, at the age of seventy, in 1564, and had the honour to be buried in the church of La Rotonda, (the Pantheon,) near the tomb of his renowned master.

**UDINE, Martino da**, called Pelegrino di San Danielo, was born at the castle of San Danielo, near Udine, about the year 1480, and was a disciple of Giovanni Bellini. He purveyed the style of that master in the many religious subjects he treated for altar-pieces at Udine and his native place, where his works are principally to be found; though it is said, in addition to his fame, that something of Giorgione's breadth may be discovered in his latter productions. He died about 1545.

**UDINSK, Niznii**, in *Geography*, a town of Ruffia, in the government of Irkutsk, situated on the river Uda; 260 miles N.W. of Irkutsk. N. lat. 54° 15'. E. long. 98° 50'.

**UDINSK, Verehuchi**, a town of Ruffia, in the government of Irkutsk, on the Selenga; 88 miles E. of Irkutsk. N. lat. 51° 50'. E. long. 105° 20'.

**UDINSKA**, a town of Ruffia, in the government of Irkutsk, at the conflux of the Uda and the Angara; 140 miles W.N.W. of Irkutsk. N. lat. 54° 12'. E. long. 103° 14'.

**UDINSKA, Nov.,** a town of Ruffia, in the government of Irkutsk, on the Uda; 24 miles S.E. of Udinska.

**UDITTA,** in *Ancient Geography*, a town of Africa Propria, between the Two Syrites. Polemy.

**UDNON,** in *Botany*, the name by which Theophrastus and Dioscorides have called the truffle commonly used at table in their times: but we find that they were not acquainted with a better kind of truffle, which we cultivate at present.

This smooth reddish-coated truffle is common in Italy at this time, and is esteemed of no value, and called the wild truffle; the fort that is eaten there, and in all other parts of Europe, is the blackish and rough-coated kind. In Africa they have a yet finer kind than our's: it has a white coat, and is of the most delicious flavour. The Greeks were also acquainted with this, and denominated it Cyprian, as they did almost all the things they had from Africa: they also gave it the name *mush.*

**UDO,** in the *Materia Medica*, a name given by the Portuguese to the lignum aobis.

It seems only a corruption of the monosyllable *ud,* by which
which the Arabian physicians have called that drug; and even this ad posibly was only a contraction of the orthography of the word herb; which seems to have been the original name of this drug among the Arabs.

UDON, in Geography, a town of Japan, in the island of Niphon; 60 miles W. N. W. of Jedo.—Also, a town of Japan, in the island of Ximo. N. lat. 32° 30'. E. long. 123° 30'.

UDORIGILL HEAD, in Geography, a river of Aegadian Sarmatia; the mouth of which, according to Ptolemy, was in the Caspian sea, between that of Alontas and that of Rha.

UDSOKI, a town of Japan, in the island of Niphon; 15 miles S. W. of Meaco.

UDSTEIN, a small island near the coast of Norway; 9 miles N. W. of Stavanger.

UDUAR, a town of the island of Ceylon; 26 miles S. S. E. of Columbo.

UDVARHELY, a town of Transylvania; 22 miles N. E. of Scheiburg. N. lat. 46° 30'. E. long. 24° 54'.

UDUMNAEVSKOI, a fort of Russia, in the government of Irkutsk; 88 miles S. W. of Nertchinsk.

UDURA, in Ancient Geography, a town of Hippania Citerior, belonging to the Taccetani. Ptolemy.

VEA, in Geography, a town of Peru, in the province of Segedion; 52 miles N. of Zaragoza.

VEADAR, in Chronology, the thirteenth month of the Jewish ecclesiastical year, answering commonly to our March; this month was intercalated, to prevent the beginning of Nisan from being removed to the end of February.

VEAGUES, in Geography, a town of France, in the department of the Cher; 6 miles S. W. of Sancerre.

VEAL TOWN, a town of New Jersey; 14 miles N. N. W. of New Brunswick.

VEAS, a town of Spain, in the province of Seville, on the Odiar; 8 miles N. N. E. of Gibraleon.

VEASCION, in Ancient Geography, a town of Italy, allied to the Romans; it was attacked by the Gauls on their departure from Rome, but they were surprized and routed by Camillus. Plutarch says, that the Gauls, on leaving Rome, encamped eight miles from this town in Latium.

VEBRON, in Geography, a town of France, in the department of the Lozere; 6 miles S. of Florac.

VECCHI, Orazio, in Biography, born at Milan, and many years master di capella at Mantua, gained great reputation, not only as an able musician, but a poet. His numerous canzonets for three and four voices, published at Milan and Venice, from 1580 to 1613, were reprinted and sung all over Europe. Our countryman, Peacham, who had received instructions in music from this composer, during his residence in Italy, speaks of him in the following manner: "I bring you now mine own master, Horatio Vecchi, of Modena, who, beside goodnes of voice, was most pleasing of all other for his conceit and variety, wheresoever his works are singularly beautified, as well his madrigals of five and six parts, as thole his canzonets, printed at Norimberge."

(Complete Gentleman, p. 102.) He then infinaces and points out the beauties of several of his compositions, that were most in favour during that time. Besides secular music, Vecchi composed two books of faced fongs, in five, six, seven, and eight parts; masses of six and eight voices; and four-part lamentations.

Vecchi has been erroneously suppos'd by many of his countrymen the inventor of the burletta or comic opera in Italy; and it was the opinion of the learned Muratori (La Perfetta Poetica, lib. iii. cap. 4.), that a musical drama or farce, called Aniparnasia, written and set by the celebrated Orazio Vecchi, and acted and printed at Venice, 1597, was the origin of the OPERA BUFFA; which see.

VECCHIA, Pietro, born at Venice in 1605, was a painter, educated in the school of Paduanino, but more an imitator of Giorgione and Pordenone; and some of his pictures have been mistaken for works of those masters. Sandrart relates a story of his having been deceived by a picture of Vecchia, which he mistook for one by Giorgione. From this talent of imitating others, the doge and senate of Venice employed him to copy the ancient works in mosaics which are preferred in the church of St. Marc. And in that church are also two original and very able pictures by him, representing the Crucifixion, and Chirli driving the money-changers from the temple. His colouring is rich and warm, and his execution free and full, but sometimes apt to be incorrect. He died in 1678, aged seventy-three.

VECCELLI, Titiano. See Titiano.

VECCELLI, Orazio, son of Titian, born at Venice in 1540, practised the art of painting under his father's tuition, but became distinguished only as a painter of portraits, some of which were esteemed as little inferior to those of his father. He died in the same year with his father, 1576.

VECELLI, Marco, called Marco da Tiziano, was the nephew and disciple of Titian, and born at Venice in 1545. He appears to have been regarded by his great instructor with peculiar favour, and certainly his talent gave him the fairest claim to such distinction; for he approached the nearest to Titian, both in colour and composition, of all his discipiles, and has left several original works, very defervedly esteemed, in the Palazzo di San Marco. He also executed several considerable works for the churches in Venice, Trevisi, and in the Fruli. He died in 1611, leaving a son, known by the name of II Tizianello, who obtained much repute by his paintings, but they are in a loose and mannered style: his bell productions are his portraits.

VECHT, in Geography, a river which rises in the bosphoric of Munster, about six miles N. E. of Coesfeld, crosses Bentheim and Overfifel, and runs into the Zuyder See at Gelmuyden.—Also, a river which passes by Utrecht, and runs into the Zuyder See at Muyden.

VECHTA, a town and fortress of Germany, in the bosphoric of Munster; 60 miles N. E. of Munster. N. lat. 52° 43'. E. long. 8° 18'.

VECS, a town of Transylvania; 16 miles E. S. E. of Biltritz.

VECTIS, in Ancient Geography, an island of the British ocean, S. of the Portus Magnus, or Great Haven, according to Ptolemy and Pliny.

VECTIS, in Mechanics, one of the powers, more usually called the lever; which see.

VEXTOR, Heterodromus. See HETERODROMUS.

VECTOR, in Astronomy, a line supposed to be drawn from any planet moving round a centre, or the focus of an ellipsis, to that centre or focus.

This, by some writers of the new astronomy, is called vector, or radius vector, because it is that line by which the planet
planet seems to be carried round its centre; and with which it describes areas proportional to the times.

VEDA, the name by which the Hindoos designate the collective body of their scripture. They enumerate eighteen parts of true knowledge, as follow: four Vedas, four Upavedas, six Angas, and four Upangas. The prefixture up infers a work deduced from its principal; like our sub, implying inferiority.

The first four, according to a native writer, quoted by Sir W. Jones, are the immortal Vedas, evidently revealed by God, which are entitled, in one compound word, Rig-yajya-samanyaarthavara; or, in separate words, Rig, Yajya, Saman, and Atharvan. The Rigveda consists of five fecciones; the Yajurveda, of eighty-six; the Samaveda, of a thousand; and the Atharvaveda, of nine; with eleven hundred sūtras, or branches, in various divisions and sub-divisions. The Vedas in truth are infinite; but were reduced by Vyāsa to this number and order. The principal part of them is that which explains the duties of man in a methodical arrangement; and in the fourth is a yṣṭham of divine ordinances.

From these are deduced the four Upavedas; viz. Ayūth, Gandharva, Danuth, and Sthapatya. The first of which was delivered to mankind by Brahma, Indra, Dhanwantari, and five other deities; and comprises the theory of divinities and medicines, with the practical methods of curing diseases. The second, on music, was invented and explained by Bharata; it is chiefly useful in raising the mind by devotion to the divinity of the cubic nature. The third Upaveda was composed by Vishwamitra, on the fabrication and use of arms, and implements handled in war by the tribe of Khatriya. Vishvakarma revealed the fourth, in various treatises on forty-four mechanical arts, for the improvement of such as exercise them. Of the personages named above, viz. Brahma, Indra, Vishvakarma, Vishwamitra, and Vyāsa, are under those words respectively. Of Dhanwantari, some mention is made under our article Kurmanatha.

The six Angas, or bodies of learning, are also, according to the fame native authority, derived from the same source. We omit their names and contents; their subjects chiefly are: 1. Of the pronunciation of vocal sounds. 2. Detail of religious arts and ceremonies. 3. Grammar. 4. Prophesy. 5. Astronomy. 6. On the significature of difficult words and phrases in the Vedas.

Lastly, continues the same author, there are four Upangas, called Purana, Nyaya, Mimana, and Dharma. (See Purana, Nyaya, and Mimansa.) Eighteen Puranas were composed by Vyāsa, for the instruction and entertainment of mankind in general. Nyaya is a collection of treatises in two parts, on metaphysics, logic, philosophy, &c. Mimana is similarly divided into two parts; the latter, abounding in questions on the divine nature, and other sublime speculations, was composed by Vyāsa in four chapters and sixteen fecciones. It may be considered as the spring of all the Angas; it expounds the heretical opinions of sophists; and, in a manner suited to the comprehension of adepts, it treats on the true nature of Ganea, Bhāskara or the sun, Nilakantha, Lakṣmī, and other forms of One Divine Being. Of Ganea, the god of prudence and sagacity, see under Pollear. Bhāskara is a name of Surya. Nilakantha is a name of Siva, the fame as Shitakouta. Lakṣmī is the comfort of Viṣṇu.

The body of law, called Smriti, consists of eighteen books, &c. delivered for the instruction of the human species by Men, and other sacred personages. As to ethics, the Vedas contain all that relates to the duties of kings, the Puranas, what belong to the relation of husband and wife; and the duties of friendship and society (which complete the triple division) are taught fancifully in both. This double division of Angas and Upangas may be considered as denoting the double benefit arising from them in theory and practice.

To the above native account of the Vedas, Sir W. Jones adds an ingenious commentary. He says that the Vedas consist of three kandas, or general heads; viz. Karma, Jnyana, and Upațana; or works, faith, and worship. To the first of which, the author of the Vidyadeva, or View of Learning, a rare Sanscrit book, wisely gives the preference; as Menu himself prefers universal benevolence to the ceremonies of religion.

After all, continues this instructive writer, the books on divine knowledge, called Veda, or what is known, and Śrutī, or what has been heard from revelation, are still supposed to be very numerous; and the four here mentioned are thought to have been selected as containing all the information necessary for man. It must not be omitted, that the commentaries on the Hindu scriptures, among which that of Vafiṣṭha (see Vasiṣṭha) seems to be reputed the most excellent, are innumerable.

From the Vedas are immediately deduced the practical arts of chirurgery and medicine, music and dancing; architecture, which comprises the whole art of war; and architecture, under which the system of mechanical arts is introduced.

Next in order to these are the fix Vedangas: three of which belong to grammar; one relates to religious ceremonies; a fifth, to the whole compass of mathematics; and the sixth, to the explanation of obscure words or phrases in the Vedas. Subordinate to these Angas, though the reason of the arrangement is not obvious, are the series of sacred poems (see Purana), the body of law, and the fix philosophical fātras or shaftas. See Philosophy of the Hindoos, and Silastah.

In the commentary whence we quote parts of this article, Sir William Jones gives some of the reasons that induced him and Mr. Wilkins to believe, notwithstanding the mythological fable of Brahma’s four mouths, each of which uttered a Veda, that the fourth, or Atharva, was written or collected after the other three: but Mr. Colebrooke, in the eighth volume of the Asiatic Recherches, after noticing some texts and arguments on which that belief might be reasonably grounded, gives his own reasons and proofs in support of a contrary opinion. He thinks it probable that some portion at least of the Atharvāsa, is as ancient as the compilation of the three others; and its name, like theirs, is anterior to Vyāsa’s arrangement of them; but the fame, he adds, must be admitted of the portion called Itihaṣa and Purana, which constitute a fifth Veda, as the Atharvāsa does a fourth.

The Hindoos believe that the original Veda was revealed by Brahma, and to have been preferred by tradition until it was arranged in its present form by a sage, who thence obtained the name of Vyāsa, or the compiler; or Vedavyāsa, that is, compiler of the Vedas. He distributed the Indian scripture into four parts, as already enumerated; each bearing the common denomination of Veda.

With the Hindoos it is an article of their creed, that the Vedas were composed by no human author. It must be understood, therefore, that in affirming the primaeval existence of their scripture, they deny these works to be the original composition of the editor (Vyāsa), but believe them to have been gradually revealed to inspired writers.
VEDA.

It appeared to Mr. Colebrooke from several other passages, and from the received opinion of the Hindoos themselves, that the Rich, Yajush, and Saman, are the three principal portions of the Veda; and the Atharvana is commonly admitted as a fourth; and that divers mythological poems, entitled Itahafa and Purana, are reckoned a supplement to the scripture, and as such constitute a fifth Veda.

The Vedas are a compilation of prayers, called Mantra; with a collection of precepts and maxims, entitled Brahmana: from which last portion, that called Upanihad is extracted. The prayers are properly the Veda, and apparently preceded the Brahmana. Each Veda consists thus of two parts, the Mantras and the Brahmanas; or prayers and precepts. The complete collection of the hymns, prayers, and invocations belonging to one Veda, is called its Sanhita: every other portion of Indian scripture is included under the general head of divinity (Brahmana): this comprises precepts, which inculcate religious duties; maxims, which explain those precepts; and arguments, which relate to theology. But in the present arrangement of the Vedas, the portion which contains passages called Brahmana, includes many which are strictly prayers, or Mantras. The theology of the Indian scripture, comprehending the argumentative portion entitled Vedanta, is contained in the tracts denominated Upanihiad; some of which are portions of the Brahmana, properly so called: others are found only in a detached form; and one is a part of a Sanhita.

Prayers, employed at solemn rites, called Yajuya, have been placed in the three first Vedas: those in prose are named Yajush; such as are in metre are denominated Rich; and some which are intended to be chanted are called Saman; and those names, as distinguishing different portions of the Vedas, are anterior to their separation in Vyafa's compilation. But the Atharvana, not being used at the religious ceremonies above-mentioned, and containing prayers employed at oblations, at rites conciliating the deities, and as imprecations on enemies, is essentially different from the other Vedas. This is adduced by Mr. Colebrooke as the true reason why the three first Vedas are often mentioned without any notice of the fourth; which must be sought, he says, not in their different origin and antiquity, but in the difference of their use and purport. The fourth, or Atharvana, is known to contain many forms of imprecation for the destruction of enemies. These are called Mantra (see that article), but it must not be inferred that such is the chief subject of that Veda; for it contains also a great number of prayers for safety, and for the averting of calamities; and, like the other Vedas, numerous hymns to the gods, with prayers to be used at solemn rites and religious ceremonies, excepting, as above-mentioned, such as are named Yajuya.

Mr. Colebrooke gives a passage from that part of the second, distinguished by the title of the White Yajurveda, the other being called the Black, confirming his opinions as above indicated, and important, as containing an enumeration of the Vedas, and of the various sorts of paffages which they comprise:—

As smoke and various substancces separately issue from fire lighted with moist wood, so from this Great Being were reprieved the Rigveda, the Yajurveda, the Sama-veda, and the Atharva and Angiras; the Itahafa and Purana; the sciences and Upanihiads; the verbs and aphorisms; the expostions and illustrations: all these were breathed forth by Him.”

The commentators remark, that four sorts of prayers (Mantra), and eight kinds of precepts (Brahmana), are here stated. The fourth description of prayers comprehends such as were revealed to, or discovered by Atharvan and Angiras, meaning the Atharvana Veda. The Itahafa designate such passages, in the second part of the Vedas, as narrate a story. The Purana intends those which relate to the creation, and similar topics. “Sciences” are meant of religious worship; “verbs” are memorial lines; “aphorisms” are short sentences in a concise file; “expositions” interpret such sentences; and “illustrations” elucidate the meaning of the prayers.

The Puranas here meant are not the mythological poems bearing the same title; but, as already mentioned, certain paffages interperfed throughout that part of the Vedas called Brahmana, or divine precepts. This distinction is important. Under our article PURANA a pretty full account of those mythological romances will be found.

The subjets and uses of the prayers contained in the Vedas, differ more than the deities which are invoked, or the titles by which they are addressed: every line is replete with allusions to mythology, and to the Indian notions of the divine nature and of celestial spirits. For the numerous ceremonies to be performed by a householder, and full more for those endless rites enjoined to hermits and ascetics, a choice of prayers is offered in every stage of the celebration. It may be here sufficient to observe, that Indra, or the firmament, fire, the sun, the moon, water, air, the spirits, the atmosphere, and the earth, are the objects most frequently addressed; and the various and repeated sacrifices with fire, and the drinking of the milky juice of the moon-plant, or acid acleptias (see SOMALATA), furnish abundant occasion for numerous prayers adapted to the many stages of those religious rites.

In describing the Vedas so replete with mythological allusions, Mr. Colebrooke does not mean a mythology which avowedly extols deified heroes, as in the Puranas; but one which personifies the elements and planets; and which peoples heaven, and the world below, with various orders of beings. He observed, however, in many places, the groundwork of legends which are familiar in mythological poems; such, for example, as the demon Vritra, slain by Indra, who is thence furnished Vritravan (which fee), but he did not remark any thing, except some detached portions, the genuineness of which appeared doubtful, that correspond with the favourite legends of these feats which worship either the Linga or Sakti, or else Rama or Krishna. Such portions, he reasonably suspects have been compounded in more modern times, when compared with the other parts of the Vedas. This suspicion is chiefly grounded on the opinion, that the feats which now worship Rama and Krishna as incarnations of Vishnu, are comparatively new; he did not find in any other part of the Vedas the least trace of such a worship. The real doctrine of the whole Indian scripture is the Unity of the Deity, in whom the universe is comprehended; and the seeming polytheism which it exhibits, offer the elements, and stars, and planets as gods. The three principal manifestations of the Divinity, with other personified attributes and energies, and most of the other gods of Hindoo mythology, are indeed mentioned, or at least included, in the Vedas. But the worship of deified heroes is no part of that system; nor are the incarnations of deities figured in any other portion of the text which he had seen, though such are hinted at by the commentators.

On the point of unity in doctrine, inunvclated with great fulness and purity, we may refer to some translations from the Vedas by Mr. W. Jones, in the last volume of his Works.

After giving strong reason for believing the Vedas to be genuine compositions, in opposition to some allegations of their being forgeries, or grossly interpolated, Mr. Colebrooke avows his opinion, that the greater part of the books received by the learned among the Hindoos will affurdly be found genuine.
The idea of impurity arising from the chanting of the Samaveda, is not uniformly held. Mr. Colebrooke informs us, "that a peculiar degree of holiness seems to be attached, according to Indian notions, to the Samaveda, if reliance may be placed on the inference suggested by the etymology of its name, which is expounded as denoting something which defrays sin." And this inference, we may remark, is countenanced by the circumstance of Krishna, when enumerating, in the Bhagavat Gita, various orders of beings and things, to the chief of which he compares himself, declaring, that "among the Vedas, I am the Saman." It may be said, however, that this Veda more especially relating to music, over which Krishna, the Hindoo Apollo, presides, he may advert only to its harmonious pre-eminence.

262. "Let the learned," Menu commands, "read the Veda on every lawful day, having first repeated in order the pure essence of the three Vedas, namely, the Pranava, the Vyahrta, and the Gayatri." Of these fee under O'M. xi. 262. "A priest who should retain in his memory the whole Rigveda, would be absolved from guilt, even if he had slain the inhabitants of the three worlds, and had eaten food from the fouleit hands."

263. "By thrice repeating the Mantras and Brahmanas of the Rig, or those of the Yajuth, or those of the Saman, with the Upanishads, he shall perfectly be cleansed from every possible sin."

264. "As a cloud of earth, cast into a great lake, sinks into it, thus is every sinful act submerged in the triple Veda."

266. "The primary trilateral syllable, in which the three Vedas themselves are comprised, must be kept as secret as another triple Veda: he knows the Veda, who knows the mythic fence of that word." Of which see under O'M.

In the above texts from Menu, we see the propeney of the Hindoos to bring every thing into a ternary arrangement. The three Vedas, and the triple Veda, are ever recurring. In a hymn by Sir W. Jones to the fun, or rather to its ruler, Suria, he says,

"Nor e'en the Vedas three to man explain
Thy mystic orb triform, though Brahma turn'd the tritron."

See SURYA. See also TRIMURTI for many instances of this disposition for trine classification.

The philosophical writers and their disciples, who professed to adhere closely to the doctrines of the Veda, are called Vedanta; which see.

On the age of the Vedas, we have to observe, that Sir W. Jones (Af. Ref. vol. i.) rejects their claim to the very high antiquity that some warm advocates were disposed to affix to them: he could never believe that they were actually written before the flood; but ventures to assert, that they are far older than any other Sanscrit composition. And in vol. ii. he says, that he "firmly believes, from internal and external evidences, that three of the Vedas are more than three thousand years old." And in vol. iii. that they appear to stand next in antiquity to the five books of Moses. In the preface to the Institutes of Menu, the learned translator deems the three first Vedas to have been composed about three hundred years before the Vedantins, and about five hundred before the Puranas, which is fully corroborated not the production of Vyasa. The Institutes he supposes to have received their present form about 880 years before Christ's birth. By one mode of reckoning, the highest age of the Yajurveda is carried to 1580 years before the birth of our Saviour, (which would make it older than the Pentateuch,) and the Institutes must then be ascribed to about 1280 years before the fama epoch: but Sir W. Jones deemed the former date of 880 years B.C.

Veda.

The following is the concluding paragraph of Mr. Colebrooke's very instructive paper on the Vedas, in the eighth volume of the Asiatic Researches, to which we have already acknowledged our obligations for a portion of this article.

"The preceding description may serve to convey some notion of the Vedas. They are too voluminous for a complete translation of the whole; and what they contain would hardly reward the labour of the reader; much less that of the translator. The ancient dialect in which they are composed, especially that of the three first Vedas, is extremely difficult and obscure; and though curious, as the parent of a more polished and refined dialect (the classical Sanscrit), its difficulties must long continue to prevent such an examination of the whole Vedas as would be requisite for extracting all that is remarkable and important in those voluminous works: but they defer to be occasionally consulted by the Oriental scholar." See SHANKAR.

We shall now proceed to notice, as briefly as we can, the fabled and believed origin of the Vedas; the reverence in which they are held by Hindoos; their supposed antiquity; and some other points that may incidentally arise in the course of such considerations.

In the Institutes of Menu, chap. i. v. 23, it is laid down, that "from fire, from air, and from the fun, He (the supreme Ruler) milked out, as it were, the three primordial Vedas, named Rich, Yajuth, and Saman, for the due performance of the facricles."

Chap. iv. 124. "The Rigveda is held sacred to the gods; the Yajurveda relates to mankind; the Samaveda concerns the manes of ancestors; and the found of it, when chanted, raises therefore a notion of something impure."

A commentator on the fifth of these texts explains it by remarking, that the Rigveda opens with a hymn to fire, and the Yajurveda with one in which air is mentioned. Another commentator has recourse to the popular notions respecting the renovations of the universe, at the end of the periods called Kalpa. "In one Kalpa the Vedas proceeded from fire, air, and the fun; in another, from Brahma at his allegorical immolation." See KALPA and PARUSHA.

The most general belief is, that the four Vedas issued from the four mouths of Brahma, as the like number of individuals did in whom originated the four great civil sects, from appropriate parts of his body (see sects of Hindoos); the Brahman, or divine, from his mouth. Now Brahma is fabled to have once had five heads, and in this article we have noticed a fifth Veda. Siva, in one of his forms, is also five-headed; hence called Panchamuki; which see. (See also SIVA.) Some authorities attribute the Vedas generally to PAVAKA, the god of fire. (See PAVAKA.) Others to Sarafwati, the goddess of literature, &c. comfort of Brahma. (See SARASWATI.) No female, however, is permitted to read the holy volumes. Sir W. Jones tells us (Af. Ref. vol. iii.), that "the Veda is called also Agama; but this title refers more particularly to a mysterious book, or set of books, so named from having come from the mouth of Siva, as the Vedas proceeded severally from the four mouths of Brahma. The same word means also the Veda." The word Agama, and similar words in other tongues, seem to imply something mysterious. See OGHAM and O'M.
B.C. for the Institutes the more probable. This would give the Yajurveda an age, in 1815, of about 2995 years.

Mr. Colerbrooke (Af. Ref. vol. vii.) infers, from several data there given, the probability that the Vedas were not arranged in their present form earlier than the 14th century before the Christian era; but cautiously marks the inference as vague and conjectural: about 3200 would hence be affirmed as the maximum of elapsed years since the present arrangement of the Vedas. And deducing, by sir William Jones's method, the comparative age of the Puranas, they will be 2500 or 2600 years old at most; and the Institutes 2800. See Purana and Menu.

As to the relative age of the different Vedas, some differences of opinion will have been seen to exist. We shall only remark farther, that Mr. Wilkins, in the preface to the Gita, observes, that Krishna throughout the whole makes mention of three Vedas only; and those, the three first in their present order; the fourth, proving itself a posterior work, mentions him. On this being noticed to some Pandits who affiled in the translation, they expressed great astonishment at it, as it had escaped all the numerous commentators on the Gita. It may be remarked, in passing, that Menu is often mentioned in the Veda, and the Veda by Menu; a proof of interpolation somewhere.

It is evident that the Vedas are anterior to the hereof or reformation of Buddha; one of his leading innovations being the condemnation of the practice of killing and eating animals, as enjoined in the Veda, and by Menu. See Sects of Hindus, and Sra dhia.

So holy are the Vedas esteemed by the Brahman, that no individual of the fourth, or servile tribe of Sudra, is permitted to read them. In this interdict are included several other divine works. Both the poems entitled "Mahabarat" and "Ramayana," are likewise esteemed to contain passages and descriptions too awful for the eye of a Sudra: he may bear them read by a Brahman, who is likely to be careful as to what he communicates. Of this fee under Mahabarat, Ramayana, Sects of Hindus, Sudra, and Vaidya.

The Yajurveda is declared by Menu, in a text quoted above, to "relate to mankind." It is, as already noticed, ascribed to a celestial physician: it contains an entire Upanishad on the internal parts of the human body; with an enumeration of nerves, veins, and arteries, a description of the heart, spleen, and liver, and various disquisitions on the formation and growth of the fatus. From this, and from many texts of Menu, we may perceive that the ancient Hindoos were fond of reasoning, in their way, on the mysteries of animal generation; and on the comparative influence of the sexes in the production of perfect offspring. The physiological disputes on this latter point exacerbated, by mythical warmth, appear to have led to violent schisms in religion, and even to bloody wars. See Sarasanwati and Yoni.

There can be little doubt but the learned world would thankfully receive a faithful interpolated translation of such portions of the Vedas as tend to throw light on the state of knowledge among a people who so early engaged in such disquisitions as are contained in the Yajurveda, above indicated. These would, doubtless, be valuable, and are, indeed, necessary to complete the history of universal philosophy, and to supply the scholars of Europe with authentic materials for an account of the opinions anciently formed on this head by the philosophers of Asia. We will not say how far the Atharvana Veda may deferve the honour of translation. It contains a most complete system of incantations and magical devices; and would be so far curious, as to evince that, both in antiquity and ingenuity, the demagogues of Europe are vastly outtripped by their fainter brethren of the East.

We are not able to state the exact size or extent of the Hindoo scripture, or Veda. The following is as near an estimate as can be made.

The first, or Rig-Veda, contains about 10,000 verses, or rather flanças, of various measures. The second, or Yajur-Veda, is divided into two; the white and the black; together, they include about 9000 verses. The third, or Sama-Veda, about 3000. The fourth, or Atharva-Veda, about 6000. Of glosses, or commentaries, it is not easy to form any but a vague estimate: but we are, we think, warranted in the opinion, that, supposing the whole could be collected and printed in the manner of our dictionary, they would form a work larger than this!

In all Hindoo writings connected in the leart with theology, and, indeed, in many others, extracts from, and allusions to, the Veda, frequently occur. Several articles in this work contain such, and are farther explanatory of the contents of those revered volumes. Those, therefore, dearth of more information herein, are referred to the following: leolatriy, Krishna, Matsyavatara, Saraswati, (in which is an extract of some length descriptive of the powers or energies of that goddes,) Shastri, Subtan, Sects of Hindus, Sani, Sring, Sutra, Trimurti, Upanishad.

Veda is the correct way of writing the title of the Hindoo scripture collectively. In different parts of India it is variously pronounced; and it is variously spelt by European writers. Vedam and Bedam are occasionally seen; these are the modes of pronunciation in the Carnatic. Among the Maharratas, Bede, or Blade, is uncommon; and its reputed compiler is called Beafs, and Beafs Muni. (See Muni.) The Bengali alphabet having no v, Bed or Beda is the usual pronunciation in that quarter.

VEDAM, a name sometimes given to the Veda; which fee.

VEDANGA, in Hindoo Mythology, a name of the fun, more commonly called Surya; which fee. The name of Vedanga seldom occurs, as of the fun; but it is applied to certain portions of books of divine knowledge, as they call them, derived from the Vedas. Of this fee under our article Veda.

VEDANTA, in Philosophy, a sect among the Hindoos, so named from their theory being professedly founded on the doctrines contained in the Veda, or scripture, in a degree exceeding that of any other of the philosophical schools or sytems. (See Ved.) The fundamental tenet of this school consists, not in denying the existence of matter, but in correcting the popular notion of it; and in contending that it has no existence independent of mental perception; that existence and perceptibility are convertible terms; that external appearances and sensations are illusory, and would vanish into nothing, if the divine energy, which alone sustains them, were suspended but for a moment. This opinion seems to have been adopted by Epicurus and Plato, and was maintained in the last century by a writer of our own nation. The founder of this school is named Vajra (which fee), and his theory is comprised in a little tractate in four chapters. An attempt has been made to elucidate the obscurity of this writer by the judicious and learned Sankara, in his commentary on the Vedanta. (See some account of him under the article SANKARA CHARYA.) His esteemed work is entitled "Baha." Sir W. Jones, after reading this commentary with great attention,
tention, affirms that it is not possible to speak in too high terms of so excellent a work; and that until an accurate translation of it shall appear in some European language, the general history of philosophy must remain incomplete. See MIMANSA.

The elegant author whom we have already named, touching on the Indian metaphysics of natural bodies, according to the most celebrated of the Asiatic schools, from which the Pythagoreans are supposed to have borrowed many of their opinions, remarks, that as the old fages of Europe had, as we learn from Cicero, an idea of centripetal force, and a principle of universal gravitation, which indeed they never attempted to demonstrate; so he would venture to affirm, without meaning to pluck a leaf from the never-fading laurels of our immortal Newton, that the whole of his theology, and part of his philosophy, may be found in the Vedas, and even in the works of the Sufis. (See Sufi.) That most subtle spirit, which he suspected to pervade natural bodies, and, lying concealed in them, to cause attraction and repulsion; the emission, reflection, and refraction of light; electricity; cælefaction; sensation and muscular motion, is described by the Hindoos as a fifth element, and endured with those very powers. The Vedas abound with allusions to a force universally attractive, which they chiefly ascribe to the fun, thence called "Aditya," or the Attractor.

Sir W. Jones, in his instructive essay on the philosophy of the Asiatics, proceeds to observe, that from all the properties of men and of nature, from all the various branches of science, from all the deductions of human reason, the general corollary admitted by Hindoos, Arabs, and Turkeys, by Perians and by Chinees, is the supremacy of an all-creating and all-preserving spirit, infinitely wise, good, and powerful, but infinitely removed from the comprehension of his most exalted creatures. Nor are there in any language (the ancient Hebrew always excepted) more pious and sublime adresses to the Being of beings, more splendid enumerations of his attributes, or more beautiful descriptions of his visible works, than in Arabic, Persian, and Sanscrit, especially in the four Vedas, and in many parts of the Puranas. But supposition and praise would not satisfy the boundless imagination of the Vedanti and Sufi theologians; who, blending uncertain metaphysics with undoubted principles of religion, have premised to reason confidently on the very nature and essence of the Divine Spirit, and affirmed in a very remote age, what multitudes of Hindoos and Muslumans affirm at this hour, that all spirit is homogeneous; that the spirit of God is in kind the same with that of man, though differing from it infinitely in degree; and that, as material subsistence is mere illusion, there exists in this universe only one generic spiritual subsistence, the sole primary cause, efficient, substantial, and formal, of all secondary causes, and of all appearances whatsoever; but enlarged, in its highest degree, with a sublime providential wisdom, and proceeding by ways incomprehensible to the spirits which emanate from it.

This doctrine, as it is grounded on the belief of an immaterial Creator supremely wise, and a constant preserver supremely benevolent, differs widely from the pantheism of Spainza and Toland. Our limits will not allow our enlarging on the principles of the Vedanta philosophy.

We have already noticed the admirable commentary by Sanakaracharya on the Vedanta doctrines of Vyasa. In Bengal this work is highly esteemed; but on the western side of India, it is rivalled, in the estimation of the learned, by a more concise gloss, entitled Pauchadahi, thought to be not inferior in clearness and accuracy to the Balnea of Sankara.

From a statement of the fundamental doctrine maintained by the disciples of the Vedanta school, it has been inferred that their philosophy is founded on the contemplation of one infinite Being, existing under two states or modifications. The first is that of a pure, simple, abstract Essence, immovable and quiescent; the second is that of a Being displaying motion or active qualities. Under the first modification he is called Brimh, or the Great Being, and Kuthal, or He who sitteth on high; under the second, he is named Eeh, the Lord, or Jiv, the Soul: or we may say, that Brimh is Being in its state of simple essence; Eeh is Being exciting energy, and causing the phenomena of the material universe; Kuthal is Being existing in sensuous creatures in its pure simple state; and Jiv is Being in a sentient active state.

It is rare to find in Vedanta works any attempt to establish its doctrines by any process of reasoning. The authors announce the principles of their sect in a dogmatical authoritative style, as indubitable truths; or establish their affections by the authority of the sacred text alone, and attribute disbelief to passion and ignorance. Sometimes, indeed, we do perceive an appearance of reasoning and argument, in support of the denial of a material world.

It will be perceived by those who investigate the Vedanta philosophy, that it does not correspond closely either with the Berkeleian, or with any other system known in the western world. (See Berkeley.) It does not teach that the Supreme Being is the soul of the universe, as was taught by Virgil (see Maya); that animate beings are separate detached portions of his essence, or that the visible extended material frame of things is God; but it affirms that the world is one living, unextended, indivisible Being, who produces his energy, and excites in himself the phenomena of sensible things, as well as of sensation, passion, &c. In explaining this syllogism, however, the writers frequently make use of such figures as may mislead one who reads only detached passages of Vedanta works, without examining closely the nature of their doctrines. Hence the Vedantas have been supposed to teach the doctrine of emanations; and it must be admitted that passages occur, even in the Vedas, apparently countenancing this supposition. (See Murty.) In the fourth or Atharva Veda it is said, that "as the sparks proceed from fire, so various kinds of animate and inanimate beings proceed from the incorruptible Being." But the best commentators say, that these expressions do not mean that there are separate individual beings, but only whatever is beheld or perceived is the Divine Essence. The Vedanta opinions cannot be represented by any figure; they must be deduced from plain and simple declarations.

The Vedanta philosophy will be found to correspond with the Berkeleian in this important particular: both deny a material world, referring sensible things to the energy of a living Being. But the analogy appears to extend no farther. In another important particular they are strongly opposed: in maintaining and denying the existence of separate beings, upon whom this energy operates, existing in their minds the ideas of external things. See more on this subject under our articles Mystical Poetry, and Sufi.

Having offered this sketch of the Vedanta theory, the practical maxims of this very extended sect will be easily understood. They teach that perfection consists in reit; that motion or action is the origin of the moral distinctions of good and evil, both of which must be renounced, as they involve and imply each other. To the attainment of this sublime state, it is required that the active faculties be annihiliated, and the passions and affections subdued; that the individual be totally indifferent to external things, animate and inanimate, to parents, wives, children, relations, goods,
or to whatever causes pleasure, pain, &c. This furnishes a reason why, in some Veda works, language very dif-
respectful is held towards such relatives and friends; so dif-
ter to the general rule and usage of the Hindoos. When
by the practice of rigid austeritie, retirement from the world,
and contemplation, this quiescent state is attained, the soul
perceives that it is Being, and that Being is all things; and
thus the soul becomes the one Infinite Eeeence. Some
branches of this rigid austeritie and contemplation are called
Tapas and Jap. (See under those words for some account
of these practices; and under Sects of Hindoos, and Yooi,
of those who practise them.) Action, say the Vedantis, or
religious performances, do not conduct the soul to the state
of the Eternal but to Swarga (which fee), where it con-
tinues, until the holiness it hath accumulated be nearly ex-
pended by the enjoyment of happiness; when it returns to
earth, and takes a body corresponding to its remnant of
virtue. Agreeably to this notion, action is condemned, as
it tends to retain the soul in the prison of passion and affec-
tion. Still, while a person continues to perform the com-
mon acts of life, it is incumbent on him to attend to religious
duties and rites.

It has been found expedient farther to modify the doc-
trine, in such a manner as to reconcile it with the ordinary
avocations of life, on which depend the existence of society.
Accordingly it is held, that the renunciation of the world
does not require that a person cease or depart from those
avocations; but only that he preserve his mind in a state of
perfect indifferency and tranquility. "If it be alleged that
the Puranas declare, that Bharata and others did not per-
form the acts of life; we would ask," says the Panditdahi,
"why do you not liken to the Vedas, which declare that
wife men eat, act, and procreate?"

It will be necessary to keep in mind that the Vedanta is
a philosophical, not a religious system; and that a profession
of its tenets is compatible with all the religious sects who
admit the authority of the Veda. This may be said like-
wise of the Sankya, Nyayai, and other philosophical sys-
tems. The religious distinctions of the Hindoos result
from the peculiar or exclusive veneration paid to a particular
deity; and the adoption, as a spiritual guide, of those
books which celebrate that deity as the great Being. On
this point the reader may consult our articles Krishna,
Saraswati, Sects of Hindoos, Sankya, Siva, and
others hence referred to, connected herewith.

VEDENSKAIA, in Geography, a town of Russia, in the
government of Irkutsk; on the Irkut; 34 miles W. of
Irkutsk.

VEDENSKOI, a town of Russia, in the government of
Vologda, on the Ulia; 66 miles E.S.E. of Vielik.—Alfo,
a town of Ruffia, in the government of Archangel, on the
Vokcha; 200 miles E.S.E. of Archangel. N. lat. 58° 43'.
E. long. 46° 44'.—Alfo, a town of Ruffia, in the govern-
ment of Tobolok; 36 miles S.E. of Tomfil.

VEDETTE, in the Military Art, a sentinel on horse-
back, detached from the main body of the army, to discover
and give notice of the enemy's designs.

VEDIANTHII, according to the orthography of Pliny,
written Vefhiatii by Ptolemy, in Ancient Geography,
the name of a people, whose capital was Camelon (Pliny),
or Cemelchon (Ptolemy), situated in the province of the
Maritime Alps, according to the Notitia of the provinces
of Gaul.

VEDRA, a river of Britain, the mouth of which is
placed by Ptolemy on the south-east side, bounded by
the German ocean. Horley differs in opinion concerning
this river from Camden and Baxter: he supposes it to be the
river Tyne, and they conjecture it to be the Were.

VEDRA, Cape, in Geography, a cape of Spain, on the
cost of Galicia. N. lat. 42° 19'. W. long. 8° 51'.
VEDRO, or WEDRA, in Commerce, a liquid meafeure
in Ruffia. The caf, farokowo, or pipe of wine, contains
40 vedros; the vedro, 8 ofmuki or kruihkas; and the
kruihka, 11 7charkays or cups. The vedro in Petersburg
contains 621 French, or 752 English cubic inches; hence
1 vedro = 3¾ English wine gallons, and 3 kruihkas =

VEENE, in Geography. See VEENE.

VEER, in Sea Language, is variously used. Veeing out
the rope, denotes the letting it go by hand, or letting it run
out of itself: thus, they say, Vee more cable; that is, let
more run out.

Veer is also used in reference to the wind: for when
it changes often, and suddenly, they say, the wind veers.—
Or, the wind is said to veer and haul, when it alters its
direction, and becomes more or less fair: thus it is said, to
veer aft, and to haul forward.

Veer and haul, To, is to pull a rope tight, by drawing
it in and slackening it alternately, till the body to which it
is applied requires an additional motion, like the increased
vibration of a pendulum, so that the rope is straightened
to a greater tension with more facility and dispatch. This
method is particularly used in hauling the bow-lines.

Falconer.

VEERAPATCH, in Geography, a town of Hindooftan;
18 miles W.N.W. of Dindigul.

VEERE, or Vere, or Terwve, a fea-port town of Zea-
land, situated on the northern coast of the ile of Walcheren,
communicating with Middelburg by means of a canal. The
name given it signifies, in the language of the country,
"Passage," and was probably acquired by its being the place
from whence they ordinarily pass over to North Beve-
land. Its ancient name was Kamp Vere. The place is reg-
ularly fortified towards the land with strong bulwarks, and
a broad ditch; and towards the sea is a strong wall. The
harbour is very good, but lies much exposed to inundations.
The arsenal is one of the best in Zeeland, and furnished with
all manner of stores for a considerable fleet. This is the
third walled town in the iland of Walcheren, and has the
sixth place in the assembly of the iles of Zeeland. It has
got three gates towards the land, and one towards the sea, where
veffels come from Dort, Ziericz, and other places. The
inhabitants are chiefly occupied in the herring-fishery, which
is their harvef. There is little to be observed in the town
but the fladthoufe, began in 1704, and the great church,
the fleepe of which is low and uninfinifhed; 4 miles N.
of Middelburg. N. lat. 51° 37'. E. long. 3° 35'.

Veer Channel, a channel between the Dutch iles of
Walcheren and Schouwen.

VEERING, in Sea Language, denotes the operation by
which a ship, in changing her course from one board to the
other, turns her helm to windward. Hence it is used in
opposition to tacking (which fee), wherein the head is turned
to the wind, and the ftern to leeward. A ship, having
made the neceffary dispositions to veer, bears away gradually
before the wind, till it blows obliquely upon the opposite
fide, which was before to leeward; and as the ftern necef-
sarilly yields to this impression of the wind, affifted by the
force of the helm, and the action of the waves upon the
fame quarter, the fide which was before to leeward foon be-
comes to windward. Since, by this movement, a ship loifes
ground considerably more than by tacking, it is rarely prac-
tifed except in cafes of neceffity or delay; as, when the
violence of the wind and sea renders tacking impracticable;
or when her course is slackened to wait for a pilot, or fome
other ship in company, &c.
When it becomes necessary to veer the ship, the sails towards the stern are either furled or brailed up, and made to shiver in the wind; whilst those near the head are spread abroad, so as to collect the whole current of air which their surfaces can contain. Hence, while the whole force of the wind is exerted in the fore-part of the ship to turn her about, its effect is considerably diminished, or altogether destroyed, on the surfaces of the after-falls. The fore-part, accordingly, yields to the above impulse, and is put in motion; and this movement, confining with that of the wind, pushes the ship about as much as is necessary to produce the effect required. When he is turned so that the wind will act upon that quarter, which was formerly to leeward, her circular motion will be accelerated by extending some of the falls near the stem, as the mizen, and by placing those at the prow more obliquely, which will wheel the vessel round with her bow to the windward; in the same situation, with regard to the wind, as when close-hauled, or tacking. When the tempest is so violent as to prevent the use of sails, the effort of the wind operates almost equally on the opposite ends of the ship, so that the masts and yards situated at the head and stern counter-balance each other. The effect of the helm is also considerably diminished, because the head-way, which gives vigour to its operations, is at this time feeble and ineffectual. Hence it is necessary to destroy this equilibrium which subsists between the masts and yards afore and abaft, and to throw the balance forward, in order to veer. This is accordingly performed by bracing the foremost yards across the direction of the wind, and arranging those on the main-mast and mizen-mast directly in the line of the wind. If this expedient proves unsuccessful, and it is absolutely necessary to veer, in order to save the ship from destruction, by overbearing or running abroad, the mizen-mast must be instantly cut away, and even the main-mast, if the stem remains incapable of answering the helm by bearing away before the wind. Falconer.

Veering, in Husbandry, a term borrowed of the sailors, and used for the turning of two furrows toward each other, as they must do to begin a ridge; they therefore call the top of a ridge a veering; and they call the two furrows that are turned from each other at the bottom between two ridges, a walking, that is, an ending, because it makes an end of plowing ridges.

VEERSE, in Geography, a town of Germany, in the county of Verden; 10 miles E.N.E. of Rotenburg.

VEGA, LOPEZ DE LA, or LOPE-FELIX DE VEGA-CAPRIO, in Biography, a celebrated and voluminous Spanish poet, was born of a noble family at Madrid, in the year 1562. Having been educated in the university of Alcala, he occupied several honourable posts, and served on board the grand armada defined against England. After the death of his second wife, he took holy orders at Toledo, and obtained admission into the congregation of priests at Madrid; acting as prefident, and professing himself as one of the third order of Franciscans. By favour of pope Urban VIII. he was honoured with the insignia of the knights of Malta, and with the title of doctor of theology. He died in 1635, at the age of 73. He was eminently distinguished as a poet, and regarded as the father of the Spanish drama, excelling, as some have alleged, all poets, ancient and modern, in this kind of composition. His "Theatre" occupies twenty-five volumes, each of which contains twelve plays of various descriptions. One of his biographers lays of him, that "the inundation of Vega's fancy seems to have been more than a deluge of very ordinary matter, in which there is little to be praised but an easy eloquence of language, and a faculty of dramatizing, after a manner, stories of every kind. Three hundred pieces could not possibly have been composed otherwise. Nor was this the principal portion of his literary labours; for he has himself affirmed, that upon a calculation it would appear, that he wrote five leaves of MS. for every day of his life." The high degree of admiration he inspired in his own country appeared from the numerous eulogies of which he was the subject after his death. Morel. Gen. Biog.

VEGA, in Geography, a town of Spain, near the N. coast of Altarias; 34 miles N.W. of Oviedo.

VEGA, Lo, a town of the island of Hispaniola; 24 miles S.E. of St. Jago de los Cavalleros.—Alfo, a town of the island of Hispaniola; 62 miles N. of St. Domingo.—Alfo, a town of Spain, in the province of Leon; 40 miles W.N.W. of Alforaga.—Alfo, a town of Spain, in the province of Leon; 18 miles N.N.E. of Leon.

VEGAMAN, a town of Spain, in the province of Leon; 24 miles N.N.E. of Leon.

VEGENOE, a small island in the North sea, near the coast of Norway. N. lat. 65° 45'.

VEGESELA, in Ancient Geography, a town of Africa, in Numidia, upon the route from Theveste to Sitifus, between Malecula and Timphadis, according to the Itinerary of Antonine.—Alfo, a town of Africa, in the Bybacener territory, on the route from Thene to Theveste, between Sufetula and Meneges. Itin. Anton.

VEGETABLES, in Agriculture and Gardening, are all such plants as are found capable of affording useful products as food for man, and different sorts of live-flock. They are constituted and composed of soft and fleshly and solid parts, the latter of which are formed and arranged in such a manner as to afford proper firmness and support in their different growths; and from which proceed those which are often considered as, in some measure, distinct and different in their nature and uses, as the roots, the stumps, the leaves, the flowers, the fruits, the seeds, and some others.

The first of these, which differ greatly in different sorts of vegetables, are the parts which connect them with the earth or soil, and the main source of their nourishment and support. They are, in all cases, more or less fibrous in some of their parts; and the more perfectly this takes place, the more capable they are of drawing nourishment from the ground on which they grow. It is, consequently, the fibrous radicles and the leaves that constitute the media through which the growth and increase of vegetables are effected. The fixing of these parts in the earth, too, by the ramifications which they send forth, prevents the vegetables from being overturned by winds and other causes. The form or shape and uses of these parts in different kinds of vegetables differ very materially, having in some cases a branching lateral growth, in others a knobby, and sometimes that which is directly downward, in some instances is soft and starchy, and in others woody or sticky, and of no value.

They are very similar in the nature of the different divisions of their parts to the stem or trunk and branches; and may, indeed, be said to be a fort of continuation of the former, terminating in minute ramifications and filaments, and not in leaves; as by burying the branches of certain trees, as the willow, in the earth or soil, as practised by Woodward, and since repeated by many others, and elevating the roots in the atmosphere, there is, as it were, an inverion of the functions of them, the roots producing and becoming buds and leaves, and the branches floating out into radical fibres and tubes, and forming roots. See Root.
VEGETABLES.

The second of these parts are those which stand next in importance in vegetables, when considered merely as such, and which include the branches as well as all the more solid parts of them, consisting principally of different coats, as bark, fleth or wood, according to the nature of the vegetable, and pith, or the middle part. These coats or coverings are differently formed, modified, and constituted, so as to be of different uses in their economy. The part, or layer, which is placed next to the wood, is composed, in vegetables of the tree kind, of a soft white substance, not easily discernible in some sorts of trees, but harder and more apparent in others. It is, as it were, an imperfect wood, or in the state between bark and wood. The wood is the compact, fibrous, hard part or substance which is diffused in the middle of trees, which in annual and biennial vegetables is called the fleth, as has been seen already. Between the above coat and the wood, a new ring of a softer nature is formed every year, which gradually loses its softness as the cold season advances, and which towards the middle of winter is converted into a solid ring of wood. These annual rings, which are visible in most trees when cut through transversely, serve as marks by which to determine their ages in some cases. They seem to decrease in breadth as the trees advance in age; and as they are found to be very unequal throughout in their dimensions, their breadth probably varies as the season may be favourable or otherwise. The wood, however, does not only differ from the coats or bark in the degree of hardiness, but likewise in its structure, which is essentially different; and the seeming conversion of bark into wood, is imagined by some to be entirely a deception.

Thus, if the branch, item, or the root of a tree be cut in a transverse manner, it usually displays three distinct bodies or parts: the bark, the wood, and the pith; each of which is again susceptible of a new division. The bark, where perfectly formed, has a thin covering, that may easily be separated; is in laminae or scales, which, in old trees, are mostly in a loose and decaying state. It is not hollow, but merely defends the interior parts from injuries. It is supposed to be a part of little importance in forest-trees, and the larger shrubs, the bodies of which are firm and of strong texture; but in the reeds, the grasses, and the plants which have hollow stalks, it is of great use, is of very great strength, and appears constituted of a sort of glairy network, which is chiefly fibrous earth, as has been lately ascertained. This is the case in wheat, in the oat, and in different other plants; in some of which it exists in large quantities, and is general in this part of the tribe of the hollow kind. It is serviceable as a support as well as protection from insects in such cases.

The most interior part of the bark is composed of layers, the numbers of which vary with the age of the tree; so that on cutting this part of a tree of several years standing, the productions of different periods may be distinctly seen, though the layer of every particular year can rarely be exactly defined or ascertained. The functions of the different parts of the bark are of great importance to vegetables.

In regard to the wood in trees, it is composed of an external or living part, called sapwood, and of an internal or dead part, termed heart-wood; the former of which is white, and full of moisture, and in young trees and annual shoots reaches even to the pith. It is the great vascular system of the vegetable through which the sap-juice rises, the vessels in it extending from the leaves to the most minute filaments in the roots. Its structure has different important uses in producing new arrangements, and forming new wood.

In respect to the arrangement of the fibres of the wood, there are two distinct appearances in them: as the series of white shining laminae, which shoot from the centre towards the circumference, and which constitute what is termed the silver grain of the wood; and the numerous series of concentric layers, which are commonly denominated the spongy grain, the number of which denotes the age of the tree, as already suggested. The former has many important functions, and is the most distinct in forest-trees; though annual shrubs have even a fymet of fibres similar to it. See Timmer, Sap, and Alburnum.

The item parts of some vegetables are quite hollow; partly, it is supposed, from such vegetables requiring a more than ordinary supply of air in their support, as they are generally those which are of a quick growth.

The pith is the white, innermost substance of vegetables of the tree and other kinds, that is situated in the centres of the items.

In the very infancy of the vegetable it occupies but a small space, but gradually dilates; and in shoots of the annual kind, and in young trees, offers a considerable diameter. Being acted on by the heart-wood, as pressed by the new layers of the sap-wood, in the more advanced age of the tree, it begins to diminish, and in very old forest-trees wholly disappears. As it has lately been wholly removed in different young trees, which continued to live and increase; it is evidently only an organ of secondary importance. In early shoots, in vigorous growth, it is filled with moisture, and is a reservoir of fluid nourishment, perhaps, at the time when it is most wanted. As the heart-wood forms, it is more and more separated from the living part, the sap-wood; its functions become extinct, it diminishes, dies, and ultimately disappears. See Stalk and Trunk.

The third, or the leaves, are parts which are essential to the excellence of vegetables; as when, either of the plant or tree kind, wholly divelved, or only stript of a considerable part of them, they do not shoot in a vigorous manner. They are produced from the coats of the stalks or items, and are of the soft flethly thick kind, or the more thin, bony, or woody sort. They are capable of affording nourishment, and of being of use to vegetables, by the nutrient fluid matters which they hold in reserve in their soft substances, and by the dew, air, and moisture, which they take in and throw off.

In all cases the leaves are similar in their interior organization, and perform the same functions as the above parts, only their structure is finer and more minute. The sap-wood spreads and extends itself from the footstalks into the very extremities of the leaves; it forms a vascular system, and its living powers; some parts of the former of which may be distinctly seen in the leaf. A material use of the leaves is, the exudation of the sap to the influence of the air, heat, and light; for which their surface is extensive, the tubes and cells very delicate, and their texture porous and transparent. In the leaves, much of the water of the sap is evaporated; it is combined with new principles, and fitted for its organizing functions, and probably stalls, in its prepared state, from the extreme tubes of the sap-wood into the ramifications of the cortical tubes, and then descends through the bark. On the upper surface of the leaves, which is exposed to the sun, the external covering is thick but transparent, and is said to be composed of matter polishefit of little organization, which is either principally earthy, or consists of some substance of the homogeneous chemical kind. That in the grasses it is partly fibrous, in the laurel reenous, and in the thorn and maple principally constituted by a substance analogous to wax.
By these arrangements, any evaporation, except from the appropriate tubes, is, it is thought, prevented. On the lower surface of them, the external coat is a thin transparent membrane full of cavities; and it is probably altogether by this surface, it is said, that moisture and the principles of the atmosphere necessary to vegetation are absorbed or taken up.

The leaves in the greater number of plants annually decay, and are reproduced; their decay takes place either at the close of the summer, as in very hot climates, when they are no longer supplied with sap, on account of the dryness of the soil, and the evaporating powers of heat; or in the autumn, as in the northern climates at the commencement of the frosts. In common cafes, the leaves preferre their functions no longer than there is a circulation of fluids through them. The colour assumed in the decay of the leaf, seem, is said, to depend upon the nature of the chemical change; and that as acids are generally developed, it is usually either reddish-brown or yellow; yet there are great varieties. Thus, in the oak it is a bright-brown; in the beech, orange; in the elm, yellow; in the vine, red; in the fycamore, dark-brown; in the cornel-tree, purple; and in the woodbine, blue. The cause of the preservation of the leaves of evergreens during the winter is not well known. It is found that the force of the sap is much less in vegetables of this sort, and there is probably a certain degree of circulation throughout the winter season; their juices are less watery than those of other plants, and probably less liable to be congealed by cold, and they are defended by stronger coatings from the action of the elements. The production of the other parts of the plant may be noticed to take place at the time the leaves are most vigorously performing their functions. If the leaves of a tree be stripped off from it in the spring, it uniformly dies; and when many of those of forest-trees are injured by blights, the trees are said always to become flag-headed and unhealthy in their growth.

The leaves, it is said, are necessary for the existence of the individual tree; the flowers, noticed below, for the continuance of the species.

In the flowers there are several different organs or parts, the forms, vascicular nature, texture, and organization of which serve different important uses and functions. That which contains the rudiments of the seed has it never formed as reproductive, without the aid of the influence of the pollen, or fecundating fluid provided for the purpose. This mysterious impregnation is, of course, necessary to the continued succession of the different vegetable tribes.

It has been noticed, that all the parts of a vegetable seem to contribute to the formation of the flowers and fruits of plants; as, although the latter do not swell and ripen until after the former have fallen, their rudiments or leaf beginnings are in the flowers, of which they properly make a part. These last are conseqently temporary parts of vegetables, allotted to the purposes of generation, terminating, as it were, the old vegetable, and beginning the new one. Fruits confit of nearly the same parts as the flemens of vegetables, as a fort of skin or fine coat, which is a production or continuation of that of the bark of an outer soft pulpy substance, and is the same as that continued from the bark, only that its cells or vessels are larger, and it is more succulent and juicy. There is commonly an inner pulp, which is next to the core; and the core itself is nothing more than a hard woody covering, that includes the seed. It is to be noticed, however, that the formation of the fruit is very various: in some scenes, the fruits are diffiered through the pulpy substance; in some, instead of a core, a strong woody material is met with, including the seed or kernel, which, from its great hardness, is termed a stone; in some, there is a number of seeds; and in others, only a single seed, inclosed in a large mass of pulpy matter. See Fruit.

The seeds are the deciduous parts of vegetables, each seed including the rudiment of a new plant, imbued with the vital principle, which it is capable of retaining for a vast length of time. A seed consists of different parts, as that which is necessary to the production of the new plant or vegetable within the seed, termed the corcule; which is divided and distinguished into the fcaly or ascending part, named the plumule, and the plain defending part, called the rothle; with different others of less importance, some of which are perishable. It has been commonly supposed, and not without probability, that the perfect plant, or the organization necessary to it, exilts in the seed, surrounded by a quantity of farinaceous matter, which serves to absorb moisture, and to furnish nourishment to the corcule, until its parts are sufficiently unfolded to draw support from the soil in which it is placed. This is finely illustrated in the dwarf kidney bean, which, when reaped some time in water, and it begins to swell, may be easily separated into its two lobes, between which is seen the naifant plant or vegetable. The flem, and its connection with the lobes, too, are clearly seen; and numberless vrellas ramify through the lobes, which directly communicate with the embryo plant or vegetable.

And on the external surface of the seed are abforbent vessels, that take up moisture, by which a sort of fermentation is produced, and a liquid material formed, elaborated and prepared by a particular procefs, which is proper for the nourishment and support of the plant or vegetable, in its frist tender growth. In this early growth, the lobes of the seed, which are provided with a mealy material, are likewise found necessary. And the frist leaves, or those which are called seminal, are thought to appear not lefs necessary than the lobes to the perfection of the plant or vegetable; as, if they happen to be broken off or defroyed, the plant or vegetable experiences a proportional loss of strength and vigour in its growth.

There is, therefore, to be distinguished in every seed an organ of nourishment, a naifant plant, and a naifant root. The frist of these, in wheat and many grasses, is a single part; in other instances, it consists of more than two parts; but in the greater number, it is simply divided into two.

The feed, which is the last production of vigorous vegetation, is wonderfully diversified in form. That being of the highest importance to the resources of nature, it is defended above all other parts of the plant, it is said, by soft pulpy substances, in the efculent fruits; by thick membranes, in the leguminous vegetables; and by hard thells, or thick external coverings, in the palms and graffes. Though the matter of the seed, in its common state, may appear wholly inert and inactive; when acted upon by moisture, heat, and air, it soon distinctly develops itself, and becomes a complete plant in root and flem.

The above observations have been chiefly taken from the works of Hooper and Davy, to which the reader may be referred. See Seed.

As vegetables are supplied with proper vrellas, those of the abforbent kind on the surfaces of them take up the nutritious fluid or material, and convey it to the different parts. The surface of a plant has two sets of abforbents, as already seen, which constitute the abforbent organ of vegetables; as the mouths of the vrellas of the radicles of the roots, and those on the surfaces of the leaves. The root, as long as it remains soft and tender, imbibles and takes up the nutritious juices from the earth, by means of the abforbent mouths of its vrellas; but as soon as it be-
VEGETABLES.

comes ligneous, it emits radicles on every side, which continue the absorption, and convey the matters first to the root, and then to the whole plant or vegetable. Thus, if a plant or tree be transplanted, it succeeds with greater certainty, the more absorbent radicles are preferred with the root. The leaves absorb matters from the surrounding atmosphere, in the same manner as the radicles do from the earth, and convey them to the other parts of the plant or vegetable. It is supposed that, by means of the absorbents, water is distributed to every part of the plant or vegetable, and constitutes its principal aliment; as, deprived of this universal fluid, it droops and dies; but, by its influence, is not only nourished, and the vascular parts of the whole fabric diluted, but it contributes greatly to excite the languishing fibres, and in this way to increase the vital power of the vessels. By means of this system of vessels, too, the atmospheric air, which is essential to the growth of vegetables, is absorbed or taken up; as plants in vacuo cannot be evolved from the earth, nor can they afterwards vegetate. This is most probably the reason why seeds, buried very deep in the earth, do not vegetate, but die. See Sap and Vegetable.

There are many matters or principles in different kinds of vegetables, which render them particularly useful in the way of food, or beneficial in the products which they afford. The starch and saccharine principles are particularly important, as potting the qualities of fattening animals in a high degree. See Starch, Saccharine Matter, and Vegeto-animal Matter.

The bitter principle prevails very extensively in vegetables, and the natural fort of it is of great importance and utility in the art of brewing, as checking fermentation, and preferring fermented liquors, &c. And there are many other principles in them, which contribute to different useful purposes in several ways. See Oil, Volatile Oil, Wax, &c.

The particular nature and properties of the several different principles or parts of vegetables may be seen explained in Davy's Elements of Agricultural Chemistry.

The quantities or proportions of nutritive or soluble matters, which are contained in different vegetables, or substances of that kind, are very different, as shown in the table given below from the above work, which comprehends the quantities of this sort of matters which are afforded by a thousand parts of different vegetable substances, when submitted to experiment, green, and in their natural states.

These
VEGETABLES.

These substances comprise some of the most important articles of food in different intentions, and it is suggested as probable, that the excellence of them in this view will be found, in a great measure, to be in proportion to the quantities of this sort of matters they yield or afford; though they cannot be regarded as absolutely denoting their value in this way. Some of the matters have the characters of animal substances, as the albuminous and glutinous; sugar is more nourishing, and extractive matter lets fo, than any other principles composed of carbon, hydrogen, and oxygen. Certain combinations of these substances, too, may be more nutritive than others. It is stated likewise, on the authority of Sir Joseph Banks, that the miners in Derbyshire, during winter, prefer oat-cakes to wheaten bread, as they find that this kind of nourishment enables them to support and keep up their strength, and perform their labour better at that season. But that in summer, they say that oat-cake heats them, and they then confume the finell wheaten bread they can procure. It is suppos'd, that even the skin of the kernel of oats has probably a nourishing power, and is rendered partly soluble in the flomach with the flarch and gluten. It is noticed, that in most countries of Europe, except Britain, and in Arabia, horses are fed with barley mixed with chopped straw; and that the straw in this state seems to act the fame part as the husk of the oat. Hard thin-skinned wheats are preferred in some parts to those of the soft thick-skinned kinds, as containing a larger quantity of gluten and nutritive matter. See WHEAT.

In regard to vegetables of the gras kind, the only substances which have been detected in the soluble matters procured from them, are mucilage, sugar, bitter extract, a substance analogous to albumen, and different saline matters; with feeble indications of the tanning principle in some products from after-math crops. The albumen, sugar, and mucilage, probably, it is thought, when cattle feed on gras or hay, are, for the most part, retained in the body of the animal; and the bitter principle, extract, saline matter, and tannin, when any exists, are probably in common voided in the dung, with the woody fibre. From the great similarity of the extractive matter procured from the fresh dung of cows, to that existing in the soluble products from grasses, and some other facts of the fame nature, it appears probable, it is said, that the bitter extract, though soluble in a large quantity of water, is very little nutritive; but probably serves the purpose of preventing, to a certain extent, the fermentation of the other vegetable matters, or in modifying or affording the function of digestion, and may thus be of considerable use in forming a constituent part of the food of cattle. A small quantity of bitter extract and saline matter is probably all that is needed, and beyond this quantity, the soluble matters must be more nutritive in proportion as they contain more albumen, sugar, and mucilage, and less so in proportion as they contain other substances.

In comparing the composition of the soluble products afforded by different crops from the same gras, it was constantly found, that the largest quantity of truly nutritive matter, was in the crop cut when the feed was ripe, and least bitter extract and saline matter; most extract and saline matter in the autumnal crop; and most fecacious matter, in proportion to the other constituent parts, in the crop cut at the time of flowering. It is suppos'd that the greater proportion of leaves in the spring, and particularly in the late autumnal crop, accounts for the difference in quantity of extract; and the inferiority of the comparative quantity of sugar in the summer crop, probably depends upon the agency of light, which always tends in plants to convert fecacious matter into mucilage or flarch.

No differences have been found in the nutritive produce of the crops of different grasses cut at the same season, which could render it possible to establish a scale of their nutritive powers, but probably the soluble matters of the after-math crop are always from one-sixth to one-third less nutritive than those from the flower or seed crop. In this crop, the extractive and saline matters are certainly usually in excess; but the after-math hay, mixed with summer hay, particularly in that which the fox-tail and soft grasses are abundant, would, it is thought, produce an excellent food or fodder.

In the clovers, the soluble matter from the Dutch clover is said to contain much mucilage, and most matter analogous to albumen; all the clovers contain more bitter extract and saline matter than the common proper grasses. When pure clover is to be mixed as fodder, it should, it is said, be with summer hay, rather than after-math hay.

Other observations on this intercellsing subject may be seen in the appendix to the above work.

In cultivation, much use and advantage may, in many cases, be derived from changing the natural habits of vegetables, by fowing the seeds of them or planting them at unusual seasons, by placing them in more dry and warm, or more cold and moist situations, and by altering the time of their flowering, or the length of their duration, by cutting parts of them, or in other ways; as by such means some of them, though annual in their nature, may be made to last and afford crops for two or for several years. Others may furnish two or three green crops the same season, and an early one in the succeeding; and so on in a variety of instances in the garden as well as in the field.

VEGETABLES, Injuries or Destruction of Parts of, the affections and mischiefs which are produced in them by different causes, as those of frost, lightning, insects, and some others. It is well known, that trees of the apple and some other kinds, in field fruit-grounds, orchards, and gardens, have their buds, blossoms, and other parts, often affected or destroyed by a frost of slight or canker induced by such causes; in consequence of which there are great failures in the crops of them. The mischievous effects of frost in this way may frequently be clearly traced, though they are seldom greatly injurious, when it is of the dry kind, unless it be very severe; but most certainly, when it succeeds to large falls of rain. Sudden transitions from heat to cold are hurtful to vegetables; by warmth the vessels of them are expanded, and their juices flow freely: a sudden application of cold causes a sudden contraction of their parts, without a proportionate diminution of the fluids which they contain, which being thus unnaturally checked in their current, become flagrant and diseased. Rain is congenial to the growth of vegetables; and while Nature dispenses them to open all their pores, by which its influence can be received, when overtaken by frost in such a situation, the consequence must be injurious or fatal. It has been said by a philosophical writer, in speaking of the action of cold or frost, that besides its opposition to the adequate fluidity of the vegetable juices, it must be unfriendly to the animation of the fluids, causing either local canker, or death of the whole vegetable. That when the vegetable fluids are chilled, and converted into ice, their bulk is vastly enlarged, and this enlargement sometimes takes place with such extreme violence as to rend them in pieces. In this way, frost, it is thought, destroys those parts of vegetables which are most succulent, particularly in that form of it which is called hoar-frost, or rime, so common in the spring season. The moisture of fog too is said to be equally mischievous, as far as it extends. Thus, in a fruit district, in one night at this season, a mott promi-
ING BLOOM HAS BEEN CUT OFF; THE ELM, OAK, AND ASH, BEING INJURED AT THE SAME TIME; THE LINE OF DEVASTATION WAS PRECISELY MARKED, PROCEEDING IN A HORIZONTAL MANNER THROUGH A CERTAIN VALE TRACT, TO THE HEIGHT OF ABOUT THIRTY-FIVE FEET; THE TREES THAT GREW ON HIGHER GROUND NOT BEING TOUCHED. THE EXPLANATION OF THIS CIRCUMSTANCE FEEMS, IT IS SAID, TO BE, THAT THE FOG, WHICH RIFES MORE OR LESS EVERY EVENING, ESPECIALLY AFTER A WARM DAY, WAS, DURING THE NIGHT, IN THIS INSTANACE, SUDDENLY SUCCEEDED BY A SMART FROST, WHICH FREEZED THE MOIST ENDED PARTS TO THE POINT OF ELEVATION OF THE FOG, AND PRODUCED THE MISCHIEF. COLD WINDS COMING ON AFTER A DAY OR TWO OF FROSTY-SHINE, MAY LIKELY PROVE DESTRUCTIVE OF THE BLOOM IN SUCH CASES OF APPLE-TREES IN THESE FRUIT-GROUNDS. ON THIS ACCOUNT, IN A NORTHERN EXPOSURE, THE FRUIT IS NOT UNFREQUENTLY PRESERVED, WHILE IN OTHERS IT IS DESTROYED; FOR THE FUN, NOT HAVING MUCH INFLUENCED THE TREES IN THIS SITUATION, THEY ARE LEFT TO THE PREVAILING TEMPERATURE OF THE LEAFON, AND THIS ENABLED TO BEAR THE COLD NORTH-EASTERLY BLASTS OF THE NIGHT WITHOUT BEING HURT.

THOUGH THE SECONC OF THE ABOVE CAUSES IS MUCH BELIEVED TO BE HURTFUL TO THE TREES IN FRUIT-GROUNDS BY THOSE ENGAGED IN THEM, THE OPINION HAS BEEN CONSIDERED AS UNFOUNDED BY SOME. IF, HOWEVER, THE PARTIAL MANNER IN WHICH SOME TREES AND HEDGES ARE AFFECTED BE CONSIDERED, IT WILL BE DIFFICULT, IT IS THOUGHT, TO ACCOUNT FOR THE EFFECT IN ANY OTHER WAY. THIS CAUSE, LIKE THAT OF FROST, MAY AFFECT VEGETABLES BY ITS EXPANSIVE POWER, BURLING THEIR VEILS AS IT PALES THROUGH THEM. IN SOME CASES, A LINGLE LIMB OF A TREE, IN ONE NIGHT, LOSES ALL ITS FOLLAGE, AND CAUSES TO VEGETATE: IN OTHERS, ONE TREE OF MANY IN A FRUIT-GROUND; OR A ROW OF TREES IN THE SAME DIRECTION; AND SOMETIMES WHOLE FRUIT-GROUNDS ARE AFFECTED IN THE SAME MANNER, AND ARE DIFFICULT OF RECOVERY. THE MISCHIEF IS MOSTLY DONE IN A NIGHT, AND WITH GREAT UNCERTAINTY, AS NEIGHBOURING TREES IN THE SAME DIRECTIONS OFTEN ESCAPE.

IN RESPECT TO THE LAST OF THESE CAUSES, IT HAS BEEN OBSERVED, THAT FROSTY NIGHTS, WITH A NORTH-CAST WIND, IN THE SPRING, FOLLOWING A WARM DAY, ARE PARTICULARLY INJURIOUS TO THE BLOOM OF THE APPLE; THE WARMTH OF THE DAY HATCHES THE OVA OR EGGS OF THE INSECT WHICH BREEDS IN IT, WHILE THE COLDRNS OF THE NIGHT, BY CHECKING THE PROGRESS OF THE FAP, KEEPS THE BLOOM IN ITS HALF-EXPANDED STATE, TO FORM A NIDUS FOR THEM. THE OPINION OF APPLE-GROWERS, TOO, IS IN SUPPORT OF THIS IN MOST DISTRICTS AND SITUATIONS. BUT WHETHER INSECTS ARE CAUSED IN THIS WAY, OR BY THE DISEASED FLATE OF THE TREES, THE MOST PROMISING MODE OF PREVENTING THE RAVAGES AND DESTRUCTION WHICH THEY COMMIT ON THE LEAVES, BUDS, AND BLOOMS OF SUCH TREES, IS THAT OF SMOKING THEM Well BY MEANS OF SOME PROPER SUBLUSTANCE, TO WHICH A LITTLE SULPHUR HAS BEEN ADDED. IN THIS WAY THEY MAY MOSTLY GET THE BETTER OF WITHOUT MUCH TROUBLE.

THE OTHER CAUSES OF MISCHIEF HAVE BEEN NOTICED UNDER THEIR PROPER HEADS.

MANY OTHER Sorts OF VEGETABLES OF THE TREE AND OTHER KINDS ARE LIKELY TO BE AFFECTED, INJURED, OR DESTROYED IN THEIR PARTS BY THESE CAUSES, THE PREVENTION OF WHICH MAY BE ATTEMPTED BY SIMILAR MEANS. SEE DISCUSES OF PLANTS IN SMITH'S INTRODUCTION TO BOTANY.

VEGETABLE ACID. SEE ACID, AND VINEGAR.

VEGETABLE AFHES, IN AGRICULTURE, THE SUBLUSTANCES OF THIS SORT WHICH ARE PRODUCED FROM VEGETABLES OF DIFFERENT KINDS BY INCINERATION. THEY DIFFER MUCH IN THEIR NATURE AND QUANTITIES AS AFFECTED BY DIFFERENT VEGETABLES. IN GENERAL, THOSE OF THE HERB SORT FURNISH FOUR OR FIVE TIMES, AND THOSE OF THE SHRUB KIND TWO OR THREE TIMES AS MUCH ASHES AS THOSE OF TREES. THE LEAVES IN COMMON PRODUCE MORE THAN THE BRANCHES, AND THE BRANCHES MORE THAN THE TRUNKS. THOSE BURNED IN A GREEN FLAME AFFORD MORE ASHES THAN SUCH AS ARE CONSUMED IN A DRY CONDITION. THE QUANTITIES OF ASHES THAT ARE AFFECTED BY SOME COMMON VEGETABLES ARE, IN 1,000 PARTS OF THE THISTLE, 53 OF ASHES; IN THE NAME NUMBER OF FERM, 62; IN THAT OF THE LOW-THISTLE, 190; IN WORMWOOD, 730; IN VETCHES, 275; IN BEANS, 200; AND IN FUMITORY, 790; WHILE IN THE NAME NUMBER OF PARTS OF THE POPULAR TREE, 7 OF ASHES ARE ONLY AFFECTED; IN THE BEECH, 12; IN THE OAK, 15; IN THE ELM, 39; AND IN THE CACE, 55. SUCH VEGETABLE ASHES AS CONTAIN ALKALIES, ARE CAPABLE OF BEING APPLIED TO LAND WITH ADVANTAGE IN SOME CASES. THE OXYS OF METALS ARE SOMETIMES FOUND IN THE ASHES OF VEGETABLES, BUT ONLY IN VERY MINUTE QUANTITIES. IN CASES WHERE THE VEGETABLE ASHES ARE OF A REDDISH-BROWN APPEARANCE, THEY ARE MOSTLY IMPREGNATED WITH THE OXYS OF IRON; BUT WHERE THEY HAVE A BLACK OR PURPLE CAST, WITH THAT OF THE OXYD OF MANGANESE; AND WHERE THESE DIFFERENT COLOURS ARE BLENDED, THEY CONTAIN BOTH SUCH SUBLUSTANCES OF THE OXYD KIND.

THE DIFFERENT SUBLUSTANCES CONTAINED IN VEGETABLES, OR AFFORDED BY THE INCINERATION OF THEM, ARE EXTREMELY VARIOUS, AND HAVE BEEN CONSIDERED UNDER THEIR SEVERAL PROPER HEADS. SEE SULPHATE OF POTASH, &C. PHOSPHATE OF LIME, &C.

THE QUANTITIES OF SOLUBLE SUBLUSTANCES, METALLIC OXYS, AND OTHER SUBLUSTANCES WHICH ARE AFFECTED BY THE ASHES OF DIFFERENT VEGETABLES, MAY BE SEEN IN A TABLE INSERTED IN THE "ELEMENTS OF AGRICULTURAL CHEMISTRY."

THESE POINTS MAY SERVE TO DIRECT AND AFFICT THE FARMER IN THE PREPARATION AND APPLICATION OF VEGETABLE ASHES IN THE MOST ECONOMICAL AND BENEFICIAL MANNER, WHERE THEY CAN BE HAD RECURSIVE TO THE PROPERTY AS A DRESSING ON LAND OR OVER CROPS OF SOME KINDS. SEE ASHES AND WOOD-AFHS.

VEGETABLE EARTH, OR MOULD, THAT SORT OF Fine REDUCED EARTHY MATERIAL, WHICH IS FORMED AND PRODUCED BY THE DESTRUCTION AND DECAY OF DIFFERENT VEGETABLE PRODUCTIONS AND MATTERS, EITHER UPON THE SURFACE, OR IN THE MORE INTERIOR PARTS OF THE LAND. THE TERM IS, HOWEVER, MORE GENERALLY APPLIED TO THE PECULIARY EARTHY SUBSTANCE, OR BODY, WHICH CONTRIBUTES THE SUPERFICIAL LAYER OF FIN BLACK OR DARK COLOURED MOULD, IN WHICH PLANTS, FOR THE MOST PART, SITTE OR TAKE ROOT, AND GROW IN EVERY SORT OF GROUND OR SOIL, AND WHICH VARIES GREATLY IN DIFFERENT SITUATIONS AND CIRCUMSTANCES.

IN CONSEQUENCE OF THE VARIATIONS THAT HAPPEN IN RESPECT TO ITS DEPTH, AND THE PROGRESSES THAT HAS MADE TOWARDS THE STATE OF PERFECT COMPOSITION AND DESTRUCTION, AS WELL AS FROM THE NATURE OF THE VEGETABLE SUBLUSTANCES AND MATTERS OF WHICH IT IS CONTRIBUTED AND COMPOSED.

IT HAS BEEN SUSPECTED TOO, AS ACQUIRING SOME DIVERSITY OR DIFFERENCE OF QUALITY ON ACCOUNT OF ITS BEING MORE INTIMATELY OR MORE LOOSELY MIXED AND INCORPORATED WITH THE OTHER BODIES AND MATERIALS THAT ARE FOUND TO COMPOSITION, AND, LIKEWISE, THAT THE EARTHY MATERIAL WHICH IS FORMED FROM THE DESTRUCTION OF SOME PARTICULAR FORMS OF VEGETABLE MATERIALS, MAY BE BETTER SUITED FOR THE PURPOSES OF VEGETATION THAN THAT WHICH PROCEEDS FROM OTHERS.

IT IS AN EARTHY MATERIAL, WHICH, BEING PRODUCED BOTH BY THE DISSOLUTION AND REDUCTION OF VEGETABLE MATTERS, AS ABOVE, MAY PROBABLY BE PARTIALLY ACQUIRED FROM THE AIR, WATER, AND LIGHT; BY THE PROCESSES OF VEGETATION, AND PARTLY FROM THE PROPERTIES OF THE LAND IN OR ON WHICH IT EXITS. IN SOME CASES IT IS OF VERY CONSIDERABLE DEPTH, WHILE IN OTHERS IT FORMS MERE A THIN SUPERFICIAL COAT OF COVERING OF THE LAND; AND THERE ARE STILL OTHER CASES, WHEREIT IS SCARELY VISIBLE, OR MET WITH AT ALL.

IT MAY BE NOTICED, THAT VEGETABLES, IN CONSEQUENCE OF THEIR HAVING IN THEIR COMPOSITION A LARGE PROPORTION OF MEALAGINOUS MATTER IN A STATE OF MIXTURE WITH THEIR OTHER MATERIALS OR SUBLUSTANCES, ESPECIALLY IN SOME SORTS, ARE IN SOME DEGREE...
greek capable of being dissolved in water, though the external coats or coverings of living plants, principally on account of the resinous material that enters into their composition, are preferred from its action and effects. It is plain, that in consequence of the first of these circumstances, and that of earthly matters being contained in them, which had been taken up in the state of solution or diffusion with their fresh fluids or juices while growing, that considerable quantities of vegetable earth or mould must be continually formed and deposited on lands by the natural dissolution and decay of such bodies. But its formation and provision are much more abundantly effected by means of the putrefaction and destruction of such vegetable productions as are cut down, or otherwise defrayed, on the surface of the land, and the laying of different kinds of manures and compost materials upon it. In cases where these have been in great abundance for a long time, there is mostly, it is said, a deep rich surface bed of this earth or mould; but that where few vegetable products, and those of the less luxuriant kind, have been left to undergo the above process, or little affittance given by means of manures, the crust of surface earth or mould is commonly very thin and poor. In all cases, it is evident that the dissolution and decay of vegetable materials must be greatly promoted and expedited by a proper degree of moisture, and suitable state of heat; the atmosphere being at the same time in a proper condition for the purpose. The close and stagnated state of different sorts of luxuriant tall growing crops of the grass, herb, plant, or other kinds, have likewise much effect in the forming and elaborating of this mouldy material, by the decaying foliage thereby promoted, falling down and being so much deposited on the land.

All these materials, during the state of decay, undergo different changes in their constituent principles or parts; the water which they contain being decomposed, pure air or oxygen is absorbed, heat digested, and new compositions of the aerial and fafie kinds formed; by which means a number of matters are prepared and fitted for the use and support of vegetable life, which could not have been supplied in any other way, as well as rendered much more extensively applicable in this intention than they could otherwise possibly have been.

It is advised, that in order to promote the formation and production of vegetable earth or mould, recourse should be had not only to such substances as accelerate the putrefactive process, but also to such as have a tendency to increase the solubility of the vegetable earth or mould of the land itself; and that the first of these purposes may be promoted and attained by the application of such substances and materials as have been found useful in changing vegetable matters into the state of mucilage, such as the carbonate of lime, or effeite lime, marle, chalk, and calcareous matters in general, and likewise some earthy fafie substances, as the refuse of salt manufactories, and of other kind. That the latter of such intentions is to be attempted by the use of different substances and matters that are of an alkaline nature; such as the ashes produced by the burning of various green vegetable materials, the urine of animals, the liquor of dunghills and pits, night-soil, and many other such animalized matters and substances. There are many other ways, too, in which vegetable earth or mould may be made and rendered more abundant in land; such as the frequent growth of those kinds of crops that cover the ground in a close full manner, so as to produce a confined state of the air, as already suggested; the confuming upon, or turning down into the ground, full, rich, and succulent green crops, by which much vegetable matter is brought into a state of decay; and by the causing of the destruction and evacuation of insects of various sorts, which are predominant in land, by the use and application of such substances and matters as have the power of effecting these different purposes and intentions.

It must be noticed, however, that it has been remarked by the writer of the work on the "Connection of Agriculture with Chemistry," that too large a proportion of vegetable matter in land, particularly where it is exposed to be much acted upon by the oxygen principle of the atmosphere, is liable to render the ground too loose and open in its nature for the growth of most sorts of crops of the grain kind; winter corns being, especially from the sudden alterations of frost and thaw, frequently thrown out of such lands, and almost wholly destroyed. In cases of this nature, great advantage may, it is said, be derived from the use of different matters of the fafie kind, and lime in its satu rated state, as by such means the vegetable parts of the land will be brought to their most proper and productive state, in so far as the growth of crops is concerned.

It has been conceived too by the same writer, that the ab sorption of the oxygen principle from the surrounding atmosphere, or what is termed the process of oxygenation, is the principal cause of the retention of vegetable matter on the surface of the earth, in deep peaty lands as well as others, but especially in such as have been long in a state of tillage, or under the plough. This process having the power, it is supposed, of rendering the vegetable matter less destruc tile, scarcely any of it being carried away in a state of di solution by rains, or water in other ways, an accumulation takes place, which, under other circumstances, could not have happened. The indestructible state of vegetable matters under these circumstances, and their constant accretion, may, it is thought, be referred to the insoluble compounds produced by the action of pure air on such inflammable substances. The insolubility, to a certain degree, of this system adopted by nature, is undoubtedly, it is supposed, to be preferred to one more completely soluble; for it is evident, it is said, that if putrefaction or oxygenation had pos sed the power of rendering all the vegetable matter, by a speedy process, soluble in water, two pernicious confequences must have followed: the rains would have washed down such extracts, and soluble matters, as flax as formed, into the rivers and springs, contaminating the waters, and rendering them unfit for the existence of fishes, or for the use of terrestrial animals. The fee in process of time would thereby receive all the vegetable and animal produce of the dry land, and the earth would ultimately become barren, confining alone of the simple earths, without any admixture of vegetable matter; consequently there could be no accumulation of this substance on the surface, as is the case to an immense degree at present. As such, there cannot, it is conceived, be a doubt, but that the present incomplete processes of putrefaction, oxygenation, or solution of organic bodies, has been established by the great Creator of all things for wise and benevolent purposes; especially when it shall be understood, that the apparatus and manures of this, to a certain degree, insoluble system, are, as they respect agriculture and vegetation, to be remedied, when necessary, by the ingenuity and industry of man. It is consequently sup posed that the vegetable matters which exist in lands, from their admitting different degrees of this proceeds, and, of course, becoming more or less insoluible, have different powers in forwarding the growth and support of plants. Where the exposure to these causes has been long, they are generally more insoluible in their nature than where the contrary has been the case. See Oxygenation.

Upon the whole, vegetable earth or mould should be accumulated
nulated in grass lands as much as possible; but where grain-crops are to be raised, a proper mixture of other earths is necessary, to give them stability, and prevent their being thrown out of the ground.

**Vegetable Fly**, in *Natural History*, an insect found in the island of Dominica, and (excepting that it has no wings) resembling the drone in size and colour. In the month of May this insect buries itself in the earth, and begins to vegetate. By the latter end of July the tree is arrived at its full growth, and resembles a coral branch; being about three inches high, and bearing several little pods, which dropping off become worms, and afterwards flies, like the English caterpillar. Dr. Hill, in his account of this production, to whose examination it was submitted, observes, that the *cicada* is common in Martinique, and in its nymphal state, in which the old authors called it *cittigmata*; it buries itself under dead leaves to wait its change; but when the season is unfavourable, many perish; and that the feeds of the *clavaaria sobolifera*, which is a fungus producing foboles or shoots from its sides, and growing in putrid animal bodies, find a proper bed on this dead insect, and grow. This, he says, is the fact; though the untought inhabitants suppose a fly to vegetate, although there exists a Spanish drawing of the plant's growing into a trifoliate tree; and it has been figured with the creature flying with this tree upon its back. Phil. Trans. vol. lxx. p. 270, &c.

**Vegetable Oil.** See OIL.

**Vegetation.** In *Vegetable Physiology*. See Germination, Circulation of Sap, Spiral Vessels, Leaf, &c.

Vegetation, as it relates to Agriculture and Gardening, is of considerable importance, by explaining the nature and means by which plants and crops receive nourishment and support, and are the best promoted in their different growths. In respect to grain, seeds, and fets, it seems evident, from the experimental enquiries of Mr. Gough and others, that during the act or process of their germination or infant vegetation, they draw the oxygen principle from the surrounding atmosphere, part of which is retained, and the remainder thrown off, charged with a portion of carbon; and that, in this process or operation, the substances of the feed-lobes, or other parts that answer the same purpose, of course undergo a considerable change, an additional proportion of the oxygen principle entering into their composition, while a portion of their carbon is dissipated and destroyed; that by this alteration in the proportion of their constituent principles and parts, the saccharine fermentation is induced to take place, and sugar is formed, as demonstrated in the operation of malting grain; and that the sugar and carbonic acid, from their being more soluble in water than in the oxyd of farinaceous matter, easily combine with the moisture in the capillary vessels of the feed or other substances, and find a ready passage to the germ; the vegetative principle being thus brought into action by a stimulus suited to the particular nature of it; and that by the decomposition of the feed-lobes, or other parts, a nutritious fluid being thus formed and distributed through the infant plant, its organs are excited to exert their peculiar specific actions in decomposing the nourishment conveyed to them, and in forming new oxyds from the elementary principles of it, in order to the increase and evolution of the vessels and fibres.

As it is in this manner that the first states of germination or vegetation is suppose to commence, it would appear that in such feeds and fets, in order to their undergoing these different changes the most readily, and in the most perfect manner, on which, probably, healthy growth may materially depend, they should not only be properly deposited in the earth or foil, but, in the case of grain and feeds, be so well ripened and filled with farinaceous or mealy matter, and poils such a degree of moisture, as may dispose them to undergo such changes in a suitably speedy manner; while, at the same time, a due supply of proper nutritious matter is afforded for the perfect germination and early growth of the infant vegetables or plants. They should not confluence be put too deep in the ground as to be too much excluded from the action of the air, or be sown or set when in too dry a condition from the state of the feason or other causes, but be constantly suffered to have as much of the agency and influence of such forwarding powers as may be necessary for the perfect vegetation and growth of the plants or crops.

Others conclude on the grounds, and for the reasons that are stated below, that two of the airs of which the atmosphere is compounded, are absolutely necessary to the nourishment and proper growth of vegetables; those of vital air or oxygen, and mephitic air or azote. It is found from different trials, that plants placed in vital or oxygen air grow larger, become more powerful, and are greener than those put in that of the atmospheric kind. That if the feeds of the kidney-bean and the pea be put into earth of the fellous kind, and be sprinkled with water mixed with a small portion of the oxygenated muriatic acid, in which oxygen the utmost abound and the most loosely adheres, they germinate much sooner than if sprinkled with pure water; but that if feeds be immered in diluted muriatic acid, they become black and rugous, and never germinate. That in no kind of air deprived of oxygen do plants vegetate; for if they be placed in azotic or mephitic air, in carbone or fixed air, they become fiscid and drooping, it is said, by the heat of the fun, and gradually die away. And that in nitrous air, plants become inactive in a few hours. It would appear from this, it is thought, that the portion of vital or oxygen air imparts a natural stimulus, which is highly necessary to excite the fibres and sustain the living power and strength of the vessels of plants; and that, lastly, this air, with the peculiar acidifiable bals, generates the various acids which are found in plants or vegetables.

As the gluten of the fibres of vegetables consis of carbon, chemically combined with azote, it follows, it is sup-posed, that the azotic air is absorbed or taken up by the plants; and that it is by this means that vegetables increase so rapidly in rich soils, cemeteries, and other places where animal and vegetable matters putrefy and decay in large quantities in or on the ground.

Carbonic air too dissolved in water is absolutely necessary to the vegetation of plants in order to provide their carbonic principle, which is a constituent part of the fibres, oil, mucilage, and other vegetable principles.

It is suggested, that plants appear to derive their caloric or matter of heat from the surrounding atmospheric air. Hence it is that the shades of trees are so cool; and that nothing is more healthy for almost all plants in their vegetation and growth, than mild tepid flowers, by which they obtain water together with this principle. That, lastly, feeds do not vegetate in the cold, and many plants die in it. Heat too is evidently of much benefit in vegetation, as giving the natural colour to the foliage, flowers, and fruits of plants, causing or promoting the flow and circulation of the sap-juice, increasing the saccharine matter, and promoting the favour of most sorts of fruit.

Light too contributes to the life and healthy growth of plants; for those which vegetate in atmospheric air deprived of its light, as in the night and dark places, become pale and weak; but in the day-time, strong and coloured.

The
The rays of light, likewise, appear to contribute to stimulate plants, with the various gases or vapours they absorb and take up from the air.

Pure air has also been found by many to be essential to the production of perfect seeds, pulp, grain, and fruit, and that by its action upon or being taken up by the soil, it has very powerful and beneficial effects in promoting vegetation and the perfect growth of plants and crops.

Thus, water, air, and these other matters, appear to have a very great share in the vegetation and nourishment of vegetables, but especially the two former. The first has been considered as indispensably necessary to the process, and as supplying the principal materials of vegetable juices. It is unquestionably the chief medium through which the various nutritive matters derived from the soil, is conveyed to the plants which grow upon it. But it has been supposed more favourable to the vegetation and growth of grains plants or crops than those of the grain kind; as crops of grains may be continually produced by watering, while with those of grain it has been found to be wholly impossible. It is found, however, that soft water, such as that of rivers, rain, or which has been exposed to the action of the sun for some time, is more favourable to vegetation, than such as is hard, as that of springs, or which is impregnated with metallic substancess and other such matters. The author of Phytologia considers the first three things necessary to the infant vegetation and growth of plants to be heat, water, and air, as furnishing the general cause of dryness, the menurium in which vegetation is conveyed, and the principle of excitability to perpetually necessary to all organic life.

However, besides these different matters, other agents are necessary, after the plants have been formed and evolved, to the perfect vegetation and growth of the crops, as those of earth or other such matters, which are not only useful and essential for the purpose of holding and supporting the plants in a steady and erect manner, but also for containing and conveying, at least, some portion of the food on which they live, as derived from the atmosphere or other sources, and for the regular ramification and extension of their fibrous roots, in order that it may be more certainly provided and supplied. They are beneficial too in receiving, retaining, and distributing moisture to them, as well as in receiving, reflecting, and dispersing the heat of the sun, dews, and exhalations of different kinds, by which their growth and perfection are greatly promoted. For though some plants of the aquatic kind grow in water, most of them have their roots in earth. Even marine plants, although they grow upon bare rocks or stones, are well known to be fixed to them, and that they derive their food from the seawater in or near which they exist. It has been contended by some, that plants are actually nourished by earth alone, but numerous experiments have the opinion to be erroneous, and that it is perhaps only the medium of their existence. It is well ascertained that they are capable of acquiring a great accession of weight, without almost any loss of weight of the earth in which they have been planted.

The aid and assistance of dead organized materials are, likewise, requisite in the process of vegetation and the growth of crops, as it would seem to be a part of the beautiful and orderly arrangement of Nature, that nothing should have life in vain, and that the destruction of one plant or animal should furnish food for others: consequently, that however useful air, water, light, heat, and earth may be to the growth of plants and crops, it is, if not certain, at least questionable, it is thought, whether they could ever come to perfection without the help of matter that had been formerly in an organized state. The richest soils, it is well known, are full of dead animal and vegetable matter, and there is no soil that will not produce plants or crops if a sufficient quantity of dead animal or vegetable substance be added to it. Under this denomination are comprehended all those manures which are found so useful in cultivation, more especially those to which some authors give the name of manurogenus, enriching, or nutritive. These substances and materials are greatly beneficial, by correcting the tenacity of stiff soils or lands, and the over-porosity of light ones, by producing a fermentation in them, and by affording nutritive matter to the roots of vegetables, as well as by retaining moisture in dry and expelling it in wet lands. Saline substances have been supposed too of much importance in vegetation by some, but they do not appear essential to the growth of any sort of plants except the marine; and there are many productive soils in which little or no saline matter can be discovered. Such matters may, however, be of use to vegetation, though not essential to it. That of common salt may operate upon plants as it does upon the human body, by afflicting to digest the food, without furnishing nutrition to itself. It is of use, mixed with dung, as an affixture to putrefaction, and it may act in the same way in promoting vegetation. It is serviceable too by attracting moisture, detroying vermin in the soil, and decaying and reducing the roots of any plants it may fall meet with, thus furnishing nourishment to the succeeding ones.

It is found likewise, that the culture of the earth is essentially necessary for the vegetation and growth of plants and crops to perfection, the health and vigour of both the roots and branches being thereby greatly increased. By dividing and reducing the particles of soils, the roots of the plants and crops put into them can more easily and readily penetrate and spread out in them, as well as in moderate by more expeditiously the nourishment which they contain. By proper and efficient culture too, such weeds or useless plants as are apt to rise, are extirpated and destroyed, whilst stirring the earth admits air and moisture more freely to the soils, and to those plants and crops the seeds or sots of which have been sown or put in them. It is evident likewise, that young trees thrive and succeed much better, if the soils in which they are planted have been previously ploughed in so deep a manner, as readily to admit their roots and suckers. Even after they are planted, it is supposed to be of great service to have potatoes and other such roots cultivated among the young trees in the plantations with a view to kill weeds, and loosen the soil for the free admissio of air and water. And the practice seems to be generally well received, and to have much effect in promoting vegetation in most sorts of vegetable.

The management of the farmer and gardener should, of course, and assist these views and intentions in every way as much as possible, in raising and producing plants and crops of different kinds; as by the suitable cultivation of the ground, the proper application of manure or other substances of that sort to it, the preservation of the moisture of it by different modes of cropping, and by every other practicable method in their power; as by such means the perfect vegetation and growth of them may be the better promoted and assisted. See FALLOWING Land, PULVERIZATION, SEED, &c.

It may be observed, that the substances or matters in land which have hitherto been found injurious to vegetation, are chiefly those of the metallic, sulphurous, aluminous, and altringent kinds. It has been noticed, that where mines of iron, lead, or copper, are near the surface, no plants will grow to perfection, as is well ascertained to be the case in different
different mining districts. Schilffus too, in which there is generally a great deal of iron and alum, is found to unfavourable to vegetation, that any considerable quantity of it would destroy the fertility of the richest forts of land. The noxious, corroding, and weakening effects of such substances on the tender roots of vegetables being such in some cases as to cause their decay, dissolusion, and destruction. Frequent fluirring, or the exposure of new surfaces of land to the action of the air, and the use of lime, chalk, or other dissoluing matters, will, it is supposed, correct the injurious qualities of this substance, and promote the vegetation and growth of plants and crops in such sites of land. The astringent principle or acidity in peat is often so great and so noxious to vegetation, that until any quality of that nature which may exist be subdued, though that sort of land be a perfect mas of vegetable matter, nothing but heath and other such miserable plants are capable of growing in it. Vegetation is consequently in such cases only to be allisted by breaking the parts of the land well down, and the application of earthly and other matters to it, so as to wholly destroy its astringent property, and in fact change its nature. See Soil.

It may be noticed too, that the vegetation or growth of plants and crops is frequently much injured and impeded by the various forts of vermin with which the earth as well as the air abounds. Those which inhabit the earth, it has been suppos'd, may be destroyed and got quit of by the use of fatal substances, lime, and other different substances, operations, and arts, as are seen under their several proper heads. See Grub, Mole, Slug, Worm, Vermin, &c. also Turnip.

But in regard to the myriads of those of the insect kind with which the air abounds, it is more difficult and uncertain to propoz or point out any remedy or means of prevention that may be effectual. It is not ascertained that the smell of any plant, in its natural growing state, is destructive of insects, but there are several plants which are, when dried and reduced to powder, or when burnt near to certain insects, destructive of them, as those of tobacco, hemlock, henbane, rue, wormwood, and others. Sometimes, however, vermin of this sort are occasioned by the weakness and unhealthful growth of the plants, and the poverty of the soil of the land where they grow; the best remedies in such cases are, of course, those of more perfect tillage and cultivation, so as to render them strong and healthy in their vegetation.

Vegetation, Artificial. Many of the processes and operations in chemistry afford productions, whether of salts or metals, or of whatever other substances, which very much resemble plants of one kind or other, whence they have been called metallic vegetation. But though many have been hence induced to believe, that these productions were formed in the manner of vegetables, there is not the least ground for such an opinion from reason or experiment.

M. Homberg, who has treated very accurately of the several kinds of these chemical vegetation, divides them into three different classes. Those of the first class are such as consist of a pure mafly metal, without the mixture of any foreign matter whatever. Those of the second class are composed of a diffolved metal, which, though it has concreted afterwards, yet retains a part of the menftrum in it; and the third class contains those which have no metal in them, but are merely composed of salts, oils, or earths, or of combinations of these.

All the productions of the first kind are made without the admixture of any liquor, and are merely owing to the force of fire. These are of a firm and solid texture, and may be taken out of the vessels in which they were made, without danger of breaking them. On the other hand, the vegetation of the second kind are all formed in a fluid, and are all so brittle, that they are not to be touched without breaking. Of the third kind, some are formed, or will supfiff at least, in the dry air; others are very tender, and are formed only in fluids, the very fluirring about of which destroys them. See Arbon.

Vegetation of Salts, a name given by M. Petit of the Academy of Paris, to the concretions which salts form, after solution in water, when set in the air to evaporate. These concretions always appear round the surface of the liquor, affixed to the sides of the vessel, or arising above its top, and are very different in the different salts, and in most of them very beautiful.

One of the most ready and most beautiful of all the saline vegetation, is that formed by a solution of the salts in the caput mortuum of aquafortis with common water. If a pint of water be put to half a pound of this caput mortuum, and the whole boiled together, that the salts may be diffolved, and the liquor afterwards filtered, and exposed in an earthen vessel, there will be formed, in about eight and forty hours, vegetables wholly like those from the mixture of spirit of nitre and oil of tar, except that those from the caput mortuum are more ramified and more beautiful. When the solution is exposed in a glass vessel, they form themselves on the surface into very beautiful figures of trees, shrubs, and bushes; and this not only on the surface, but on both the inside and outside of the glasses. These can be compared to no known concretion, except to the vegetation of iron, described by M. Lemery; they differ indeed in nothing from these, but that the vegetation of the metal are of a brownish colour, whereas those of the salt are white.

This impregnation succeeds best in dry weather, for in a moist season the vegetables form themselves more slowly, and are much less beautiful. Glass vessels are also essential to the vegetation being formed in their greatest beauty; they are never nearly so beautiful in earthen ones; and even in the former, the vegetables succeed much better in some sort of glasses than in others. The caput mortuum of aquafortis also is very different, from the different diffulations; and all of it does not succeed alike in this vegetation of the salt. That which looks lightest, and of the reddest colour, seems the best for this purpose. An impregnation of this caput mortuum in red-water produces no vegetables, but only forms a crust with small eminences on the sides of the vessel; and faltpetre, diffolved in the impregnation of this caput mortuum in water, produces a much more beautiful vegetation than that of faltpetre alone; but at the same time much less beautiful than that of the impregnation alone.

Salt-water, diffolved in the same impregnation, sometimes will produce beautiful vegetables, but sometimes only a rough crust. Common rough faltpetre forms no vegetables, but only crusts over the vessel; as is the case with the solutions of many of the metals in different acid menstruums. And the fame is the case in regard to many salts from which it might be natural to expect concretions of this kind. Memoirs Acad. Par. 1722.

Vegetius, Flavius Renatus, in Biography, lived in the reign of the emperor Valentinian, to whom he dedicated his treatise "De Re Militari." Although he was probably a military man, his Latin style was pure, considering the age in which he lived. The best editions of his work are the Variorum, Leyd. 1644, and Velaf. 1670. Turpin's Commentary was printed in French, Paris 1783, in 2 vols. 4to.
A work on the veterinary art, by a writer of the same name, is printed with the "Scriptores Rei Rufii." More. Gen. Biog.

VEGETO-ANIMAL Matter, in Agriculture, a term formerly applied to one of the principal constituent parts of the farina, meal, or flour of some vegetable seeds. It is found in the greatest proportion in grain, especially that of the wheat kind, existing in a state of mechanical union or mixture with mucilage or starch. On cautiously washing wheaten flour in the form of paste, in a kneading manner, under a small stream of water, until the whole of the starchy matter is removed, this substance or material is found in an elastic, ductile, tenacious flake, but incapable of being dissoved in it. It has none or scarcely any taste, readily draws out and contracts, and is of a whiteish-grey colour. When fully drawn out, it extends to the length of about twenty times its diameter before it breaks, and appears as if composed of fibres placed beside each other, according to the direction in which it has been drawn. If the force ceases, it recovers its original form by its elasticity; when dry, it is semi-transparent, and somewhat resembles glue in its colour and appearance. If it be drawn out thin when first obtained, it may be dried by exposure to the air, and in that state a polished surface, somewhat resembling that of animal membranes. If it be exposed to warmth and moisture while wet, it putsrefies like an animal substance; it crackles, swells, and burns, exactly in the manner of a feather or piece of bone. By dilatation it affords, like animal substances, alkaline water, concrete volatile alkali, and an empyreumatic oil. Its coal is very difficultly incinerated, and does not afford fixed alkali. From these facts, it is said to be obvious, that it is a substance totally different from all the others known to exist in vegetables, except albumen, which has lately been discovered in some of them, and in many of its characters resembles the fibrous part of the blood. It does not appear to exist in any considerable quantity in other farinaceous substances, such as rye, barley, buck-wheat, rice, and others of the same kind. M. Berthollet, however, thinks that it contains phosphoric acid like animal matters, and that this is the reason of the difficulty with which it is incinerated: and the younger Rouselle found a glutinous substance in the seuda of plants analogous to that of wheat. It is now commonly called gluten, and said to be of a brown colour by exposure to the air, to be very slightly soluble in water, and to differ from albumen in being infinitely less soluble in that fluid. When burnt, it affords similar products to that substance, and probably differs very little from it in composition. It is found in a great number of plants. Proul is said to have discovered it in acorns, chestnuts, horse-chestnuts, apples, quinces, barley, rye, peas, and beans; likewise in the leaves of rue, cabbages, créches, henshock, borage, fennon, in the berries of the elder, and in the grape. It appears, it is said, to be one of the most nutritive of the vegetable substances; and that wheat seems to owe its superiority to other grain, from the circumstance of its containing it in larger quantities.

In the work on the "Connection of Agriculture with Chemistry," it is said that different kinds of grain contain mucilage or starch, and this substance in different proportions, and that the same kind of grain contains them in different quantities, according to the climate, season, and soil. But that good wheat generally contains two-fifths of amalized matter, and three-fifths of starch. And that good and well-raised bread depends on flour containing a due admixture of these two substances. Hence, it is thought, by mixing the flour of different sorts of wheat, better bread may at times be produced than from one sort only. Extensive benefits, too, may arise to the proceeds of brewing, distilling, and making of vinegar, by a mixture of the different sorts of grain; and that to that of distilling, a further advantage would be derived by a mixture of different sorts with the grain, such as potatoes, parsnips, carrots, and many others, if prepared in a proper manner.

VEGETO-MINERAL Water of Goulard, in Medicine. See Water of Lead.

VEGGIANI, in Geography, a town of the island of Corfica; 12 miles W. of Bonifacio.

VEGI, or Veli, the names given by the Arabian physicians to the acorus. These writers seem never to have been acquainted with the plant itself in its growing state, but only to have known that part of it which was used in medicine in their time; but the Greeks deferred the plant in some form.

VEGIA, in Geography, a town of Africa; 45 miles W. of Tunis.

VEGIANO, a town of Naples, in Basilicata; 12 miles S. of Potenza.

VEGIO, Maffeo, in Biography, was born at Lodii in 1406, and studied at Milan and Pavia, manifesting in the former place an attachment to poetry, and in the latter directing his attention to civil jurisprudence. He obtained some honorary and lucrative appointments under the popes Martin V., Eugenius IV., and Nicholas V. Highly respected and esteemed for his genius and learning, as well as for the sanctity of his life, he died in 1458. As a Latin poet, he composed with facility, but without being distinguished for elegance or purity. He began, in his early age, with profane poetry, composing, among other works, an additional book to Virgil's Æneid; but after he entered into the priesthood, he confined himself to sacred subjects. The best of his works in this class, highly commended by Dupin, was his treatise "De Educandae Liberatorum et eorum claris moribus." His prose style is accounted elegant and polished for his time. More. Gen. Biog.

VEGLSENSKOI, in Geography, a town of Russia, in the province of Uliung, on the Wim; 72 miles N.N.E. of Varenik.

VEGLIA, an island in the gulf of Venice, near the coast of Dalmatia, about 30 miles in length, from 6 to 14 broad, and 90 in circumference, anciently called Curia and Fulfinio. In the decline of the Greek empire, it obtained the name of Buca, of which the present is a corruption. It is situated in the innermost part of the gulf of Quarnara, and separated from the continent by a small canal only. There are many harbours, but unfit for the reception of large vessels, on account of the storms by which they are agitated. Its soil is mountainous and rocky, towards the north stferile, but very fertile to the south, and the valleys are extremely fruitful. The greater part is covered with woods, which occasion a considerable trade in fire-wood. Agriculture is not so much attended to here as the culture of the vine, which produces excellent wine. The culture of silk is insignificant: the breeding of horses is more important. The breeding of sheep and goats is likewise considerable. The quarries produce a red spottet marble, not unlike that of Verona, which is much known by the name of Mandolate of Venice. This island in inhabited by 17,000 souls. N. lat. 45° 16'. E. long. 14° 42'.

VEGLIA, a fea-port town, situated on the S.W. coast of the island so called, surrounded with walls and defended by a castle, in which the governor resides. It is the seat of a bishop, suffragan of Zara, and contains about 3,600 inhabitants. N. lat. 45° 11'. E. long. 14° 38'.—Alfo, a town of Naples, in the province of Otranto; 15 miles S. of Brindisi.
VEGLIANA, a town of France, in the department of the Po, near the Little Doria, where the French obtained a victory over the Piedmontese and Spanishs, in the year 1630; 11 miles N. of Turin.

VEGLIONELLA, a town of Naples, in Basilicata; 20 miles S.S.W. of Turin.

VEGRE, a river of France, which runs into the Eure, near Yvre.

VEHAILEK, a town of Arabia, in the province of Nedsje; 70 miles S.W. of Jamana.

VEHICLE, Vehiculum, in its literal sense, signifies somewhat that carries, or bears a thing along. See Carriage, Wagon, Wheel, &c.

Thus, in Anatomy, the liver is said to be the vehicle that conveys the globules of the blood.

In Pharmacy, any liquid serving to dilute another with, or to administer it in, more agreeable to a patient, is called a vehicle.

In Painting, vehicles denote certain fluids, which are added to colours, in order to give them an unctuous confidence while used, that they may be laid on and spread properly, adhere to the grounds on which they are laid, acquire a proper degree of tenacity when dry, and defend them from being injured by accidents. The principal vehicles hitherto used are oils, water, spirit of wine, and turpentine. But as water and spirit of wine want the unctuous confidence necessary for spreading the colours, and dry away totally without leaving any glutinous substance to bind and fix such of the pigments as are of an earthy or incohering texture; gums, fixes, fugus, and other such viscid substances have been superadded to supply their defects, and render them of a due confidence and body.

VEHNE, or Veene, in Geography, a river which rises in the bishopric of Munfter, and joins the Solte, near Stickhauen.

VEIA. See Veglia.

VEICAMA, a town of Spain, in the province of Guipuzcoa; 12 miles from Tolofa.

VEIENTANA GEMMA, in Natural History, the name of a gem described by Pliny, and faid to be found in Italy; he says it was black, but surrounded with a circle of white: it was probably a stone of the camea kind.

VEJER, in Geography, a town of Spain, in the province of Seville, near the Straits of Gibraltar; 9 miles S. of Medina Sidonia.

VEI, in Ancient Geography, a town of Italy, in Etruria, S. of the Falceri, but nearer the Tiber and Rome. This was a very ancient town, and very considerable on account of the wealth and the valour of its inhabitants. Its original name was Veja, which was also, among the Olci, the name of one of those carriages in which they refted before they had houses. Its vicinity to Rome was one principal cause of its misfortunes; for the jealousy and envy of that city were excited by its opulence and prosperity. From the time of Romulus, the inhabitants of these rival towns contended. At length Veii was taken by Camillus, after a siege of ten years, in the year of Rome 356 or 357. The booty was very considerable; and part of it was lodged in the temple of the Pythian Apollo. It is a sufficient evidence of the eligible situation of Veii, that after the capture of Rome by the Gauls, it was a subject of deliberation whether this town should not be made the capital of the republic.

VEII, Velum, a piece of fluff, serving to hide or prevent the sight of any thing.

In this fenfe, we read of a large veil, or curtain, in the temple of Jerufalem, miraculously rent at the paflion of our Saviour. In the Roman churches, in time of Lent, they have veils, or curtains, over the altar, crucifix, images of the saints, &c.

Veil, in Botany, see Calyptra. These terms are now exclusively appropriated to the membranous covering of the germin in Musci and Hepaticæ, through the summum of which impregnation takes place, and which therefore must be considered as a peculiar organ, partly perhaps, but not exactly, analogous to a corolla. It is elevated with the ripening capsule in Musci, but splits irregularly, to let the fruit pass, in Hepaticæ. The reader is requested to correct two important errors of the press in the 8th column of the article Musci: line 18th, for fisks, read fibrils; line 60th, for sexual, read sexual.

Veil, Charles Marie de, in Biography, the son of a Jew at Metz, and a profelyte to the Roman Catholic religion by Boffuet, became a monk of the Augustine order, and entered among the canons-regular of St. Genevieve. Pursuing his theological studies at Angers, he took the degree of doctor in theology, and taught in the public schools. In 1679 he visited England, and abjured Popery, conforming to the English church. He had previously distinguished himself by his scriptural researches, and published Latin commentaries on the gospels of St. Matthew and St. Mark, on Joel, and the Canticles. During his stay in England he addressed a letter to Mr. Boyle, the design of which was to prove, against Father Simon, that the Scripture is the only rule of faith. In London he reprinted his commentary on the Canticles, giving a literal explanation of that book; and he also published commentaries on the twelve minor prophets, and on the Acts of the Apostles. At this time he stylized himself a prebyster of the English church, but in consequence of marrying the daughter of a Baptist, he became connected with persons of that persuasion, and preached among them in the year 1685. His death is supposed to have happened about the close of the century.

The brother of the preceding, Louis de Combridge de Veil, was also a converted Jew, and distinguished for his knowledge of Hebrew literature. He was interpreter of Oriental languages to the king of France, when he accompanied his brother to England, and joined in communion with the English church. The principal works he published were "The Jewish Catechism of Abraham Jangel;" a Latin translation, with notes, of "Maimonides Sacrificis," and also of Abarbanel's "Exordium in Leviticum." Moreri. VEILLANE, in Geography. See Vegliana.

VELLY, or Vesley, a town of France, in the department of the Aisne, on the Aisne; 9 miles E. of Soissons.

VEIN, in Anatomy, the name of those vessels which convey back to the heart the blood carried out from it by the arteries. All the details relating to the structure of these tubes, to their arrangement in the body, and to their office in the circulating system, are considered in the articles Heart and Circulation.

The veins are naturally arranged in three divisions: viz. 1st, the general venous sytem, commencing from the capillaries all over the body, and pouring the black blood into the heart by three large trunks: 2dly, the pulmonary veins, which
which are concerned only in the minor circulation: and 3dly, the system of the vena portarum, in which the blood that has circulated through the organs of digestion is conveyed to the liver, and distributed through the sublance of that organ. The umbilical venous system of the fœtus, with its ramifications in the placenta, its trunk in the umbilical chord, and its subsequent course and distribution in the liver, is not included under either of these divisions. It belongs to the extra fetal state of existence, and is described under Embryo.

On the subject of the pulmonary veins, we have nothing to add here to what is stated in the articles Lung, Circulation, and Heart: the vena portarum is described under Liver; and the peculiarities of arrangement, belonging to the veins of any organs, are noticed in the account of those organs: so that the present article will include simply a description of the situation and course of the veins of the general system. These we shall trace, according to the course of the blood in them, from the branches to the trunks; as, on the same principle, the arteries have been traced from the trunks to the branches.

The veins of the general system may be arranged in three divisions, according to the great trunks which terminate in the right auricle; viz. the cardiac veins, those belonging to the superior, and those to the inferior vena cava.

I. The veins of the heart do not all end in one trunk: besides one large vein, there are some smaller. The great coronary vein of the heart (grande veine cardiaque pollière) runs in the groove between the left auricle and ventricle; and opens on the left of, and below the fossa ovalis and valvula Eustachii, in the right auricle. A middle coronary vein runs on the inferior flat surface of the heart, between the two ventricles, to open by a common orifice with the former, or close to it. At this opening into the auricle, a valve is placed, differing considerably in size and appearance; sometimes reflector and broad, covering the whole aperture, at other times smaller and hardly distinguishable; sometimes perforated or reticulated. See Heart.

Some smaller veins open by one or more trunks in the anterior part of the right auricle. See the plates of Senac, sur la Structure du Cœur, &c. on these veins.

II. The superior vena cava receives the veins of the head, neck, thorax, and upper extremities. The superficial veins of the head and face end for the most part in two trunks, an anterior and a posterior.

The anterior facial vein (frontal or angular) commences on the forehead, runs along the inner angle of the eye, and then pursues its course obliquely along the face from the corner of the eye to the bafs of the jawbone, which it passes at the same point with the external maxillary artery. It joins, behind the angle of the jaw, the trunk of the posterior facial vein. This anterior facial vein, which is a large and very constant trunk, receives a vast number of venous ramifications from all parts of the forehead and face, which are covered by one universal venous net-work or plexus. (See two excellent plates by Walter, Observat. Anat. 1775.) The following are enumerated as the vesel which open into it: 1. vena frontales; 2. v. suprâ orbitalis; 3, 4, v. doralis nasi, superior and inferior; 5, palpebralis inferior interna; 6, 7, alaris nasi, superior and inferior; 8, palpebralis inferior externa; 9, 10, labiales superiores; 11, 12, two from the zygomatic and levator labii superioris; 13, ramus profundus venae facialis interna, formed by the junction of, a. vena ophthalmica facialis, which, communicating by its opposite end with the cavernous sinus, receives branches from some parts in the orbit; b. nalis posterior interna; c. alveolaris superior; d. veins of the buccinator, &c.; 14, labialis media; 15, 16, vena labii inferioris, superior and inferior; 17, 18, buccalis, superior and inferior; 19, 20, two, three, or four vene mastoideae; 21, submentalœ; 22, glandulae digastrici.

The posterior facial vein is much larger than the anterior; it arises on the side of the head by branches accompanying the ramifications of the temporal artery, descends in front of the ear, through the parotid gland, behind the angle of the jaw, and unites with the former. It receives several deep temporal veins: the maxillaris inferior; several pterygoïd veins: these join its deep-leaved trunk. The superficial trunk is joined by three superficial temporal branches; articularis anterior and posterior; auriculares anteriores and profundus; transversalis faciei; auriculares posterior; several parotid veins.

The common trunk, formed by the union of the anterior and posterior facial veins, behind the angle of the jaw, terminates in the internal jugular near the point, at which the common carotid divides into the external and internal branches. It also anastomoses with the external jugular: this trunk receives the superior thyroid vein.

Veins of the Brain.—They possess no valves: their coats are much thinner than those of other veins; their capacity very much exceeds that of the arteries. Their great and most distinguishing peculiarity consists in the circumstance, that they do not accompany the arteries, either in their great or smaller branches. Their trunks are collected in the pia mater, and run either in the interval of the convolutions, or over the convexities of the latter. They pour their blood into receptacles formed in the dura mater, and called sinus; and in this respect again they differ from all other veins. The sinuses are composed, externally, of the dura mater, which holds the place of the external coat of other veins; internally, of a smooth thin membrane, corresponding to the internal membrane of the veins, and continuous with it. The cerebral veins open in large numbers into these sinuses, of various sizes, from that of a crow's-quill to a writing quill; and they enter, for the most part, very obliquely, and with an obliquity contrary to the direction of the blood in the sinuses.

These receptacles, being formed in the dura mater, which is attached to the bone, are fixed in their situations. They are generally of a triangular figure: the interior is lined by a smooth membrane, but, in many instances, it presents small transverse fibrous bridles going from side to side. They receive not only all the cerebral veins, but also those of the dura mater and the ophthalmic.

There are four large sinuses, of which the others appear to be subordinate dependencies; they are the superior longitudinal, the two lateral, and the fourth sinuses.

The superior longitudinal sinus (falciformis superior) begins near the criûta galli, where it is small; it runs from before backwards to the internal occipital tuberosity, along the middle line of the cranium, occupying the superior or convex edge of the falx, and increasing to the size of the little finger. A vertical section of it, from side to side, is exactly triangular; the base of the triangle being upwards, and corresponding to the excavation in the bone, the sides of the triangle being lateral, or turned towards the hemispheres, inclined towards each other, and united below so as to form the apex, which is downwards. Several fibrous bridles cross its cavity, which contains a greater or smaller number of the granular bodies called glandulae Pacchioni. Numerous small veins enter the sinuses from the cranium, and others from the dura mater; through the parietal foramina it receives veins from the integuments: blood may be expressed from these, when they have been lacerated by detaching
taching the skull-cap. But the principal veins it receives come from the superior or convex surface of the hemispheres. These are spread irregularly over the convexities, advance from the sides towards the middle, uniting into larger and larger trunks, and open in considerable numbers on each side of the sinus; they receive the veins from the opposed flat surfaces of the hemispheres. The anterior branches are the smallest; the middle and posterior much larger. They are directed at their termination obliquely from behind forwards, and sometimes pass for half an inch, in the substance of the coats, before they open.

The two lateral sinuses, right and left (sinus transversi), are produced by the division of the superior longitudinal at the internal occipital protuberance. They are usually of equal size, but sometimes differ in this respect, the right being often larger. They proceed along the internal transverse ridge of the occiput, at the posterior attachment of the tentorium, as far as the commencement of the petrous portion of the temporal bone, where they descend along the internal surface of the mastoid portion of that bone to the foramen lacerum in bafi crani, through which they quit the skull, taking the name of the internal jugular veins. These sinuses are as large as the termination of the superior longitudinal; and are generally uniform on the internal surface. The cavity is triangular, where it occupies the posterior attachment of the tentorium: the base of the triangle being turned backwards, and corresponding to the skull, and the two sides being inclined towards each other, and joining at an acute angle in the tentorium. Where it lies in the mastoid portion, it consists of a layer of membrane lining the bony channel, and another palling directly over it.

The lateral sinus receives veins from the back of the cerebrum and cerebellum, and some meningeal veins; large branches from the integuments of the skull through the mastoid foramina, and from the muscles of the neck through the posterior condylar holes; veins from the cavity of the tympanum, according to Soemmering; the superior and inferior petrous sinuses; and the occipital sinuses.

At the upper or concave edge of the falx, there is found the inferior longitudinal sinus (falciformis inferior). This is very small, just admitting a probe, and it opens behind into the following: it may rather be regarded as a vein than a sinus.

The fourth sinus (perpendicularis, torcular Herophilis, sinus droit) is placed at the junction of the falx and tentorium, has a triangular figure, the basis being formed by the tentorium, and the sides by two oblique layers of the falx, and exhibits internally several prominent fibrous fasciculi. In size it is about equal to a goose-quill. It receives in the front the small vein called the inferior longitudinal sinus, and a large vein, called vena magna Galeni, which brings back the blood from the choroid plexuses and inferior of the ventricles: it also receives, at its under surface, the superior veins of the cerebellum. It opens behind into the bifurcation of the superior longitudinal sinus; sometimes having a double termination.

The superior petrous sinus runs along the sharp ridge of the petrous portion, at the attachment of the tentorium, and opens into the lateral, just where that begins to descend from the tentorium. Besides some small meningeal veins, it has some from the anterior lobe of the cerebrum, and from the cerebellum.

The inferior petrous sinus is larger than the preceding, and runs in the junction of the bafal procefs of the occipital bone and the petrous portion of the temporal. Its anterior end joins the cavernous sinuses, while the posterior opens into the lateral sinuses, just before it enters the foramen lacerum. The right and left are united by one or more transverse communications on the basifal procefs. This transverse communication unites the two inferior petrous sinuses just where they communicate with the cavernous: it is placed at the anterior end of the basifal procefs, is broad, and is described by Bichat to contain the fame kind of cellular substance as the cavernous sinus.

The cavernous is the most complicated in its structure, and altogether the most remarkable of the cerebral sinuses. It occupies the side of the pphenoid bone, reaching behind to the infure which separates the end of the petrous portion from the pphenoid, and in front to the foramen lacerum: above, to the summits of the clinoid procefses, and below, to the openings through which the nerves of the fifth pair pass. The dura mater, in this situation, is divided into two layers, one of which adheres to the bone, as in other situations, and forms the internal side of the sinuses; the other, which is much thicker, forms its external side, and is part of the internal surface of the cranial cavity. In this latter layer the nerves of the third, fourth, and fifth pairs are placed, contained in sheaths of the membrane. The interval of the two layers is occupied by a soft kind of filamentous cellular substance, through which the nerve of the fifth pair and the internal carotid artery pass. The ophthalmic vein, returning the blood from the orbit, opens into this sinus, which receives also meningeal veins, and communicates with the veins on the side of the bafes cranii. It opens behind into the inferior petrous sinus. The right and left cavernous sinuses are said to communicate sometimes with each other under the pituitary gland.

The circular sinus is a small one occupying the superior aperture of the sella Turcica, and describing a circular course round the edge of the pituitary gland. It communicates on each side with the cavernous; and it receives veins from the dura mater and the pituitary gland. The anterior or posterior semicircle, or even the whole sinus, is sometimes wanting.

Occipital Sinuses.—These are very small; they begin at the sides of the foramen magnum, run backwards and upwards, and open into the lateral sinuses close to their origin. Anterior occipital sinuses are described, communicating with the inferior petrosal and the cavernous, and opening into the lateral near its exit from the head: they are not constant.

For representations of the veins and sinuses of the brain, see Haller, Icon. Anat. fascic. 1.; Vicq d'Azyr, Traité d'Anat. et Physiol. avec des pl. color. pl. 33-35-36. Santorini, Tab. Posthum. 3.

The meningeal veins, or veins of the dura mater, receiving innumerable ramifications from the substance of the cranial, form trunks, which accompany the arteries, and often on each side, being lodged with them in bony channels of the skull; these veins open into the sinuses, particularly towards the basis of the skull, and are said to communicate with the pterygoid veins.

Veins of the Eye.—(See Walter, Epitola Anatomica de Venis Oculi.)—The vena ophthalmica cerebral begins about the internal canthus, communicating with the ophthalmica facialis, goes outwards and downwards behind the globe, and ends in the cavernous sinus. The following veins enter it; viz. vena nasalis, ethmoidalis anterior, infraorbitalis, ciliaris interna, ciliaris superior, lacrymalis, ciliaris petrosus, ciliares longae, ethmoida posterior, centralis retina. The arrangement and distribution of these vessels in the eye are described under Eye.

There are free communications between the external and internal veins of the head, in various situations, which have been already noticed; viz. at the parietal, the mastoid, and the
the posterior condyloid foramina. The veins of the orbit also constitute a communication between these two sets of veins, as they are connected on one side with the facial veins, and on the other with the cavernous sinuses.

It appears from the preceding description, that all the sinuses end, either medially or immediately, in the right and left frontal, and consequently that all the blood conveyed to the brain is returned by these veins. Having passed the foramen lacerum, the tube is called the internal jugular vein; it swells out into a dilatation received into the fossa jugularis of the temporal bone, descends perpendicularly along the neck, in company with, and on the outside of the internal carotid, and, afterwards, of the common carotid artery, and of the par vagum, with which parts it is enclosed in a common cellular sheath. Just behind the anterior extremity of the first rib it ends, by joining at a right angle the subclavian vein. The internal jugular is a very large vein; when distended in the living subject, or by injection after death, it is nearly as large as the thumb. It receives the following veins, viz. - the pharyngeal, the lingual, the common trunk formed by the union of the anterior and posterior facial, the superior and middle thyroid.

The external or superficial jugular vein is formed by two or three principal trunks, and by smaller branches, which form a kind of venous plexus on the side of the neck, covered by the skin and by the external jugular vein*. These trunks are the occipitalis superficialis, which commences, in company with the occipital artery, from the integuments of the back of the head, and receives branches from the muscles of the neck; the internal jugular vein, which accompanies the artery of the same name; the deep-seated veins of the cervical muscles; the subclavian vein towards the front of the neck; and smaller twigs from the external and lymphatic glands. The trunk terminates at the angle of union of the internal jugular and subclavian, or in the subclavian itself.

For the veins of the neck, see Walter's plates in the Observat. Anat. already quoted.

Veins of the Upper Extremities.—The arteries are everywhere accompanied by corresponding veins, which lie close to them, and are generally double, one on each side. These it is not necessary to describe. In addition to these, which may be called the deep-seated, there is a cutaneous set of veins in the fingers, the subclavian, and arm, forming large trunks placed merely under the skin, not accompanied by any arteries. Both the deep-seated and cutaneous veins pierce the skin. The superficial veins of the arm lie between the skin and the fascia, and form a venous net-work, composed of larger and smaller branches, over the whole limb. There is great variety in the size and arrangement of the trunks, which, however, are regular and constant in the arm. The digital veins run in trunks at the backs of the fingers, completely covering them after successful injection; they form a plexus (dorsalis manus) on the back of the hand, from which a large trunk (subcapitalis interna, or ulnae superficialis) or two, with smaller ramifications, run in the course of the ulna to the elbow. It passes over the tendon of the biceps, and assumes the name of basilic vein; it ascends along the arm, on the inner edge of that muscle, in company with the brachial vessels, and enters the axilla, where it ends in the axillary vein.

A large vein on the back of the hand, arising from the little finger, was called by the ancients faucella. A venous plexus arises from the thumb, of which the largest branch is sometimes called cephalica pollicis: this plexus, containing one or two larger trunks, (radialis externa, or cephalica minor,) is continued along the radial side of the fore-arm to the bend of the elbow, where it divides into two branches; the largest, under the name of median vein, passes obliquely in front of the joint to join the basilic vein; the other is called the cephalic, (cephalica major,) ascends on the outer edge of the biceps, runs in the cellular interval between the pectoralis major and deltoid to the edge of the scapula, then dips under the bone, and ends in the axillary vein.

There is considerable variety in the median vein, which is sometimes merely an oblique communication between the basilic and cephalic; in other instances, a large branch comes from the middle of the forearm, (mediana communis,) and divides at the elbow into two trunks, which separate like the branches of the letter V, and join, one the basilic, and one the cephalic. These branches are then called mediana subclavia, and mediana cephalica. There is always a large communication at the elbow, between this median vein and the radial and ulnar veins.

The axillary trunk, in which all the veins of the upper extremity end, is placed in front of its corresponding artery, on the side and anterior part of the chest; it passes in front of the anterior scalenus muscle, and ends at the clavicular extremity of the first rib, by joining the internal jugular at a right angle. In this angle the thoracic duct ends behind, on the left side; and the minor trunk in front, on the right side.

For representations of the veins of the upper extremity, see Camper, Demonstrationes Anatomico-Pathologicae, lib. i. Klint de Nervis Brachi.

The axillary trunk receives the superior and inferior thoracic veins, the external and internal scapular, the dorso-lumbar, the vertebral, and the superior intercoastal vein.

The trunk of the latter accompanies its corresponding artery in the transversus processus of the cervical vertebrae, commencing about the foramen magnum, and receiving numerous branches, of which the most remarkable are from a large plexus of veins lying close on the vertebrae before and behind, and connected with the transversus colli, the occipital, and the internal jugular veins, from the sinuses of the medulla spinalis in the neck, (circular venosi cervicales medullae spinalis,) and communicating with the cerebral veins, at the foramen magnum. The vertebral and superior intercostal veins end in that part of the trunk called subclavian.

The right superior intercostal is sometimes deficient; that is, the veins of the two or three superior intercostal intervals, instead of uniting into a separate trunk, join the vena azygos. The left is always a considerable vein, formed by the veins belonging to the five or six superior intervals, which join into a trunk ascending on the left side of the vertebral column, receiving the left bronchial vein, and some other small branches.

The subclavian vein, having received the internal jugular, descends on the right side almost perpendicularly, and on the right of the arteria innomina is, receives the internal mammary vein, and very soon receives the left subclavian at a right angle. It now takes the name of superior or descending vena cava, continues its course in the same direction, receives the vena azygos from behind, and after a farther perpendicular descent of about an inch, having penetrated the pericardium, terminates in the right auricle.

The left subclavian vein crosses the chest, immediately behind the upper edge of the first bone of the sternum, and in front of the trachea and primary branches of the aortic
aortic arch, proceeding transversely from left to right, and joining the right subclavian above the pericardium, as already described. It receives in this course the left internal mammary, the mediastinal, azygos, superior pericardiac, and inferior thyroid veins.

The internal mammary vein accompanies the artery. The azygos veins are connected with the mediastinal, pericardiac, &c. They end either in the subclavian, internal mammary, bronchial, superior intercostal, or thyroid.

The superior and posterior pericardiac veins generally end in the subclavian; but they may terminate in the bronchial or internal mammary. The vein accompanying the left phrenic nerve ends in the bronchial; on the right side, in the internal mammary.

The vena azygos returns the blood from the piaeties of the chest, except in so far as the superior intercostal veins are concerned, which, as we have already described, join the subclavian. This vein connects the superior and inferior veins of the body: for its inferior ramifications anatomico with the lumbar or other abdominal veins. Hence, where the inferior cava has been obstructed, the blood has found its way through the vena azygos into the superior.

The minute origins of the vena azygos on the right side of the body are connected with the vena cava, the lumbar, or the renal veins. The trunk, at this part small, enters the chest, either with the aorta, or through an interval in the right crus of the diaphragm. It ascends on the right side of the vertebral column, in front of the right intercostal arteries, covered by the pleura, with the trunk of the aorta on its left, and the thoracic duct in the cellular substance between it and that artery, receiving the intercostal veins, and increasing in size. About the third dorsal vertebra it quits the spine, passing forwards over the right bronchus and pulmonary artery, receiving the right bronchial and some esophageal veins, and, at a considerable size, and opens into the back of the superior vena cava.

The intercostal veins, which it receives in its course, accompany the arteries of the same name, and return the blood from the intercostal muscles, and those of the back, from the medulla spinalis, from the vertebrae, pleura, integuments, &c.

About the seventh or eighth rib, the vena azygos receives a large branch from the left side, called hemi-azygos. This begins by roots, which communicate with the abdominal veins, from a trunk entering the chest through the diaphragm, ascending on the left side of the chest, receiving four, five, or more left inferior intercostal veins, and then crooking to the right side, to join the trunk. Sometimes the hemi-azygos joins the common trunk by two or three branches; sometimes it is not formed, and the left intercostals proceed straight to the right side. See Wrisberg, Observat. Anat. de Vena azygos duplici, aliquique hujus vena varietatibus. Gotting. 1778.

111. The inferior Vena Cava.—The veins of the lower extremities of the pelvis, and the abdomen, terminate in this trunk.

The veins of the lower, like those of the upper extremity, consist of a deep-felt set accompanying the arteries, and therefore not requiring a separate description; and a superficial order, covered only by the skin, and intervening between it and the fascia. The femoral vein is the common channel for the blood of both these systems of veins.

The superficial veins of the leg compose two principal trunks, called saphenae: there is indeed, as in the upper limb, a plexus covering nearly the whole of the foot and leg, of which the different branches every where communicate.

The saphena externa or minor arises from the venous plexus of the sole and back of the foot towards the outer edge; it runs below and behind the outer ankle, then rises over the calf, and having frequently communicated with the deep-seated veins, terminates in the trunk of the popliteal.

The saphena externa or major is made up by the veins coming from the backs of the toes, and from the inner side of the foot, which form a considerable trunk, ascending in front of the internal malleolus, on the infide of the leg, knee, and thigh, communicating frequently with the deep-seated veins, and ending in the trunk of the femoral, about an inch below the crural arch. Just before its termination, it receives some veins from the external organs of generation (pudicis externa); and a considerable trunk, which descends from the integuments of the abdomen.

The femoral vein passes under the crural arch, on the outside of the corresponding artery, and continues in company with the artery, under the name of the external iliac, along the side of the psoas magnus, until it meets with and joins the internal iliac or hypogastric vein from the pelvis, at the sacro-iliac symphyses, or the point where the common iliac artery bifurcates into its external and internal branches. Immediately above the crural arch, the external iliac receives the epigastric and circumflex iliac veins.

The internal iliac or hypogastric vein is made up by the union of venous trunks, corresponding to the various arteries which are given off from the internal iliac artery. These veins accompany their respective arteries; but they are remarkable for forming thick and intricate plexuses, which surround the prostate, vesicle feminales, neck, and fundus of the bladder, urethra and vagina, and rectum.

A large vein runs along the back of the penis, in its middle, between the two artery dorifae, and returns the blood from the glans, corpus spongiosum, bulb, and corpora cavernosa. It passes under the arch of the pubes, and divides into a right and left branch, which run into the plexus about the prostate and vesicles feminales.

The superficial veins of the penis and scrotum find their way under the arch of the pubes, communicating with the internal pudic vessels, and end in the plexuses about the neck of the bladder.

They are united on the outside with branches of the spermatic vein, and of the femoral. The prostatic and vesicle feminales, the lateral and inferior parts of the bladder, are covered by numerous ramifications of a dense plexus, from which the trunks of the vesical veins convey the blood to the hypogastric.

The veins in the labia are numerous, and communicate frequently: these and the veins of the clitoris pass under the arch of the pubes; the front of the vagina and urethra are covered by a thick plexus, which is the common termination of the external and internal pudic vessels. These plexuses envelope the sides of the vagina, the anterior, lateral, and inferior parts of the bladder, and end in the vesical veins.

The external hemorrhoidal veins end in the pudendal; the middle occupying a space of three or four inches, and united with the plexuses already mentioned, join the hypogastric. These latter are interpolated between the internal hemorrhoidal, which joins the vena portarum, and the external, from which the hemorrhoidal flux proceeds.

Large veins proceed from the vagina and uterus to the internal iliac: there are also the lateral facial veins, corresponding in number to the facial foramina, out of which they proceed, and united with the middle facial vein. The other vessels contributing to the hypogastric vein are, the obturator, ileo-lumbar.

The primary or common iliacs, formed by the junction,
at nearly right angles, of the externa and internal, are very considerable venous trunks, differing slightly on the right and left sides of the body. The right is much the shorter, and proceeds obliquely behind, and rather above its corresponding artery. The left, placed behind and below the left common iliac artery, proceeds obliquely upwards and towards the right, across the front and upper part of the facrum; then goes between the fifth lumbar vertebra and the right common iliac artery, to join its corresponding vein, at an acute but open angle, on the right side of the vertebral column, at the interval between the fourth and fifth lumbar vertebra; forming by this union the great trunk of the inferior or ascending vena cava.

One or two lumbar veins sometimes join the common iliac. The facra media, a small vein, terminates, either at the angle of union, or in the left common iliac.

The inferior vena cava lies at its origin, close to the aorta, on its right, and on the right side of the vertebral column: it ascends in the same relative position, first connected to the spine, then to the right crus of the diaphragm, but more and more distant from the aorta, as it rises higher in the body. It leaves the vertebral column towards the upper part of the abdomen, and enters a deep fissure in the posterior or thick edge of the liver, which covers two-thirds, and sometimes the whole vein. From the joins upwards the size of the trunk is considerably increased; it will easily admit a large thumb. Quitting the liver, it penetrates the tendon of the diaphragm (see DIAPHRAGM), and immediately opens into the right auricle of the heart. (See HEART.) In its passage it receives the following veins.

1. The facra media has already been mentioned.
2. The lumbar veins correspond to the arteries of the same name, and return the blood from the parts supplied by those vessels. They form about four trunks on each side, which end in the lateral and posterior part of the inferior cava.
3. The spermatic veins. They come from the testicles, in the male subject, from the uterus and ovaria in the female; receive various branches from the ureter (ureterica), fat of the kidney (adiposum), &c., and communicate with veins in the mesentery and mesocolon; form first a considerable plexus, with several trunks communicating together, and afterwards a single vein, which ends in the front of the vena cava on the right side, and in the renal vein on the left.
4. Renal or emunctory veins. Of these large trunks, the right is much shorter than the left, on account of the relative position of the vena cava and the kidneys. The latter crosses the vertebral column in front of the aorta. There are rarely more than one on each side.
5. Capillary veins. These often end in the renal, particularly on the left side, otherwise they terminate in the cava.
6. Hepatic veins. They are numerous, and of different sizes. Usually there are from three to five large ones, and several smaller. They return the blood of the vena portarum and that of the hepatic artery.
7. Inferior diaphragmatic veins; accompanying the arteries, and ending either in the cava, or in an hepatic vein. Soemmerring states that some diaphragmatic veins join the vena portarum.

Besides the works to which we have referred in the course of this article, for plates illustrating particular veins, we may refer in general to the Fasciculi of Haller, to the plates of the veins in Loder's collection, and to Mayer's Anatomische Beschreibung der Blutgefäße des menschlichen Körpers; mit kupfern, 1788, 8vo. See also Walter Angiologisches Handbuch, 1779. Soemmerring, De Corporis Humani Fabrica, t. 5. Bichat's Anatomie Descriptive, t. 4.

Veins, Dissection of. Veins (says Mr. Hodgson) are liable to all those morbid changes which are common to soft parts in general; but the membranous lining of these vessels is peculiarily susceptible of inflammation. When a vein is wounded, the inflammation, which is the effect of the injury, sometimes extends along the lining of the vessel into the principal venous trunks, and, in some instances, even to the membrane which lines the cavities of the heart. This inflammation sometimes produces an effusion of coagulating lymph, by which the opposite sides of the vein are united so as to obliterate the tube. In this manner, a great extent of the vein is occasionally converted into a solid cord. In some instances, the secretion of pus into the cavity of the vein is the consequence of inflammation of the membranous lining of veins; under these circumstances, the matter is either mixed with the circulating blood, or the inflammation, having produced adhesion of the sides of the vessel at certain intervals, boundaries are formed to the collections of pus, which in this manner form a chain of abscesses in the course of the vein.

When the inflammation of veins is not very extensive, its symptoms are the same as those of local inflammation in general; but when the inflammation extends into the principal venous trunks, and pus is secreted into the vessel, it is accompanied with a high degree of constitutional irritation, and with symptoms which bear a striking resemblance to those of typhus fever. See Hodgson's Treatise on the Dissection of Arteries and Veins, p. 511, 512.

In the first volume of the Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge, Mr. Hunter has published an extremely interesting paper on the subject of inflammation of veins, and he has particularly adverted to that common case, an inflamed arm after bleeding. By some, he observes, this complaint has been imputed to the wounding of a tendon; by some, to the injury of a nerve; and by others it has been ascribed to a bad constitution.

Mr. Hunter expresses his doubts of the accuracy of these opinions, and he remarks, that the manner in which these fore arms come on, plainly proves that they arise from the wound not healing by the first intention; for, in most cases, the external wound first fester or inflames, and then suppurates or ulcerates, the cavity of the vein becoming subfequently impervious. In some instances, this suppuration is only superficial, the vein and parts below having united. In other examples, the skin appears to be united, but not close to the vein, so that a small ab- seses forms between the vein and the integuments. This bursts and discharges a thin watery fluid, and no further mischief happens. When, however, this imperfection of union is continued on to the cavity of the vein, this vessel inflames both upwards and downwards, frequently to a considerable extent, and the surrounding parts join in the inflammation.

We find, says Mr. Hunter, all these variations in different cases. Sometimes the difcuse goes no further than an inflammation near the orifice of the vein, and the case often ends in resolution. At other times, the inflammation is carried further, but suppuration is prevented by the adhesive inflammation taking place in the affected portion of the vein, and, in such cases, the veins may be plainly felt, like hard cords, after the surrounding tumefaction has subsided. But this salutary effect is not always produced, and suppuration in the vessel is the consequence, but often in so limited a degree, that only a small abscess forms in the cavity of the vein, near the puncture. The confinement of the matter in this part of the vein, arises from adhesions in the vessel, a little above and below the orifice. But, in many cases,
adhesions do not occur, and then the inflammation and suppuration are not confined to the vicinity of the wound. On the contrary, an abscess is frequently produced, occupying a considerable length of the vein in both directions; and, says Mr. Hunter, we often have more than one abscess; nay, sometimes there is a series of them, generally in the direction towards the heart; but not always in this course; for, occasionally, these abscesses are observed between the orifice in the vein and the extreme part of the limb.

In consequence of a wound in the foot, Mr. Hunter saw the vena saphena inflamed all up the leg and thigh, nearly as high as the groin; and he was obliged to open a chain of abscesses, which reached nearly the whole course of the vessel.

In cases in which the inflammation had been violent, and in which the opportunity of examination was afforded, Mr. Hunter found the inflammation at some distance from this violence in the adhering state; in some places, the sides of the vein were adhering; and, in others, the inner surface of the veins was covered with coagulated lymph. When different abscesses had formed, he always found, that the spaces of the vein between them had united by the adhesive inflammation, and it is this union which circumferibes such abscesses.

In examining the arm of a man who died at St. George's hospital, Mr. Hunter found the veins, both above and below the orifice, united in many places by the adhesive inflammation. He also found in many parts of the veins the commencement of suppuration, without ulceration having actually begun; while, in several other places, ulceration had occurred, and destroyed the surface of the vessel next the skin, a circumferibed abscess being produced. The vein near the axilla was in a state of suppuration, and as no adhesions were formed beyond the part affected, Mr. Hunter conceived that the matter had passed freely into the circulation, and most probably been the occasion of the man's decease.

When larger abscesses had come on than those arising from the ulceration of the wound of the lancet, Mr. Hunter always found that the vein was afterwards obliterated, having united and healed up as any other cavity does, so that the patient could never be bled in the same vein again.

Inflammation of a vein is a common effect after bleeding horses, which is to be ascribed to the carelessness and rough manner of closing the puncture with a pin. Mr. Hunter has seen the jugular veins of horses inflamed through their whole course, the swelling extending to all the side of the head, and the inflammation reaching even to the chest. In these cases there is always an abscess formed at the wound, and often several along the vein, as in the human subject; and whenever the complaint is carried as far as this stage, the vein is rendered for ever afterwards impervious. Many horses die of this disease; but what is the particular circumstance which occasions their death, Mr. Hunter was not able to determine. It may (says he) either be that the inflammation extends itself to the heart, or that the matter secreted from the inside of the vein passes along that tube in considerable quantity to the heart, and mixes with the blood.

Although the operation of venesection, which is the most frequent cause of this complaint, is to appearance trifling, yet, as it is often of very serious consequence, both to the life of the patient and the character of the surgeon, the operator should use the utmost care to prevent an evil of such magnitude. He should be particularly attentive to the mode of closing the wound and binding up the arm. This is to be done by bringing the two sides of the wound together, in order that they may unite by the first intention. To accomplish this, let the surgeon, with the thumb of that hand which holds the arm, push the skin towards the orifice, while he draws it on the other side to the same point with the comprefs, which is then to be immediately applied. The comprefs should be broad, so as to keep the skin better together; and thick, in order that the compression may be more certain. Mr. Hunter preferred a comprefs of linen, or lint, to sticking-plaster. He very properly thought, that the blood which dried over the orifice was a more natural and effectual bond of union than any other application. This conclusion, he observes, is drawn from practice; and he had seen more fore arms, in consequence of bleeding, where the puncture had been dressed with plasters, than under other circumstances.

When inflammation takes place beyond the orifice, the surgeon should endeavour to promote adhesion of the inflamed sides of the vessel by means of compression. If it be suspected that suppuration has happened, the prefrure should be applied just above the suppuration, with a view of producing an obliteration of the vessel in that situation. (See Trans. of a Society for the Improvement of Med. and Chir. Knowledge, vol. i. p. 19, &c.) As Mr. Hodgson observes, the treatment of the inflammation, when only the punctured vein is affected, should be the same as that of local inflammation in general; namely, the application of leeches, the use of evaporating washes, purgatives, and low diet. Although the constitutional irritation, which takes place in extensive inflammation of veins, is attended with more debility than usually accompanies acute inflammation, yet the case can hardly be relieved without recourse to copious bleedings, and the usual antiphlogistic remedies.

For additional information on the foregoing subjects, we refer to Mr. Hodgson's excellent Treatise on the Diseases of Arteries and Veins, a publication which reflects the highest credit on its intelligent author. Some other affections of the veins are noticed in distinct articles of this Cyclopaedia. See CIRCOLECCE, HEMORRHIDOS, VARICOCELLE, VARICOSE VENAE, VARIX, &c.

Veins, Method of opening, for the purpose of taking away blood. See BLEEDING.

Vein, in Botany and Vegetable Physiology, vena, is a term used for all those-semblances of tubes, through which the sap of a plant is transmitted along the leaves, and by some of which also the secrete fluids must be returned into the bark and wood, for the increase of both. Hence Hedwig, for the sake of precision, has invented the term ductusfuscius, a cluster of ducts, for the ribs of the foliage in Molluscs; but we see no improvement in this phraseology. The larger, primary, or more direct, semblances of vessels have obtained the name of ribs, capul, or nerves, nervi; but the limits between these and veins are not always very certain. Large transverse veins, as well as the great longitudinal ones, are often called ribs or nerves, especially if they feed off finer and more complex ramifications, interbranching with each other like net-work, to which the name of veins is evidently more suitable. We could wish to apply the term refia to the great central rib, and nervi to the lateral ones, whether longitudinal or transverse, but this has not been adopted with any regularity. See COSTA and LEAF.

Veins are also found copiously in the petals of flowers, and are exactly analogous to the veins, ribs, or nerves of leaves, except being generally more pellicid and homogeneous. When the petals undergo any changes of colour, in their progressive flages of growth, the veins partake remarkably of such changes, and most of the iris is not.

Ribs, rather
VEIN.

rather than veins, are most apparent in the calyx of many plants.

Veins, Metallic and Mineral, in Geology, are fissures intersecting rocks or strata, filled more or less completely with mineral or metallic matter, different from the substance of the rock. When veins are seen on the surface intersecting or traversing a mountain, they have been supposed to resemkle the veins of animals; but the resemblance is only superficial, for veins are not tubular, except in a few instances; but their thickness is small, compared with their length and depth.

Metallic veins are the principal repositories of most of the metals, except iron and manganese, which occur more frequently and abundantly in beds than in veins. The thickness of metallic veins varies from a few inches to several feet; the same vein varies also in thickness in different parts of its course, sometimes contracting to a narrow string of ore, and then expanding again to the width of several yards. The depth to which they descend is unknown, for we believe no instance has occurred of a considerable vein being worked out in depth, though it may sink too deep to render the operation of the miner profitable; or it may branch off in a number of strings, which are too much intermixed with the rock to be worked to advantage. In caves where the metallic ores have disappeared at considerable depths, the veins are still continued, though they are filled exclusively with the mineral matter or vein-stone which accompanied the ore in the upper part of the rock. Some veins appear to grow wider, and others to contract as they descend. The direction of veins downwards inclines more or less from the perpendicular; but they sometimes run for a certain distance parallel with the dip of the beds or strata in a mountain, and then strike down through the lower beds.

The length of metallic veins has rarely, if ever, been accurately determined; they have frequently been traced several miles, but their further progress has been concealed by the intervention of valleys, rivers, or accumulations of land and alluvial deposits. Some of the metallic veins in South America have been traced to the distance of eighty miles. Large veins generally take a nearly direct line through a country, except where they are turned aside by cross veins, or what are called in Cornwall cross courses: it is also remarkable, that the metallic veins in England generally run nearly east and west, and the cross courses north and south. To what cause this is owing we are perfectly ignorant. Large metallic veins frequently feed off smaller veins, or strings of ore, from their sides, which penetrate the rock to a considerable distance on each side of the large vein. Veins are seldom entirely filled with ore, but sometimes it extends in a compact mass from one side to another. More frequently, the ore is intermixed with mineral matter called vein-stone, matrix or gangue; this, according to the rock which it intersects, will be either calcareous spar, fluor spar, barites or quartz. The vein-stone and the ore are frequently arranged over each other, lining the sides of the vein with alternate layers of metallic and mineral matter, and filling up the whole vein. In the mines of Cornwall, the ores of copper and tin commonly occur in detached masses, which are called bunches of ore; and the other parts of the vein, being unproductive, are called deads.

The vein is generally separated from the rock which it intersects by a thin layer of mineral matter distinct from the vein, and from the rock itself, and also by a thin lining of clay. Sometimes there are large cavities in veins called drys, which are generally lined with crystals. In other instances the vein divides, inclosing a piece of rock, which is called the rider; but it is observed, that the included mass, or rider, differs in its quality from that of the rock through which the vein passes.

The superficial part of a vein generally contains the ore in a decomposing state; and it frequently happens that the ores in the upper and lower part of the vein are different: thus in Cornwall, blende, or the sulphuret of zinc, often occupies the uppermost part of the vein, to which succeeds tin-stone, and at a greater depth, copper pyrites. See Zinc, Tin-Stone, and Copper.

When Mr. Pryce wrote his "Mineralogia Cornubiensis," the mines of Cornwall had not been worked to a great depth, for he says the richest state of a mine for copper was from eighty to one hundred yards deep, and for tin, from forty to one hundred and twenty yards. This account by no means corresponds with the present state of the Cornish mines. The Dolecoth copper-mine, near Redruth, is worked to the depth of four hundred and fifty-six yards, and is very productive at that depth.

Veins generally decline from the perpendicular, and descend into the earth obliquely. The sides, or, as they are called, the walls or cheeks of the vein, are differently denominated, the upper side being called the hanging-side, the upper cheek, or hanger; and the under side, the bolding-side, the down-side, or the ledger. The veins we have been describing are called rake veins in some parts of England, and in Cornwall, they are denominated lodes; which fee. These metallic veins have commonly the same direction, or nearly so, in the same district, and the veins which cross them are generally unproductive, or contain metallic ores of a different kind. They are called cross courses, or north and south veins.

Metalliferous rake veins intersect most of the mountains called primary, such as granite, gneiss, and mica-slate. (See Granite, &c.) But they are more abundant in slate-rocks than in rocks of granite or porphyry. (See Granite, Slate, and Porphyry.) They also intersect the rocks of transition and mountain lime-stone, which rest upon slate, or alternate with it; but they rarely rise into the secondary strata which contain coal. This fact seems to prove that veins were formed prior to the deposition of the upper secondary strata. When a metallic vein in its descent passes through different kinds of rock, it is frequently observed that the products of the vein vary in each bed; and when it passes through regularly stratified beds of the same rock, there are particular strata in which the veins are always found most productive, and these in the north of England are called bearing strata. If the nature of the rock seems to have produced a change in the quality of the ore, it is no less remarkable that the rock itself is also frequently changed or decomposed in the immediate vicinity of a vein. This change is more apparent in some rocks than in others, particularly in granite, schistus, gneiss, mica-slate, argillaceous schistus, or slate, and porphyry. In such instances, according to Werner, it is only one of the component parts of the rock that is decomposed, either the felspar, the hornblende, or the mica, but never the quartz. This change sometimes extends to a considerable distance on each side of the vein, even to a fathom or more; it extends farther in some places than in others, and is most general in those parts where the vein contains sulphur. Sometimes this change in the rock may be perceived to far, that it serves as a guide to the miner; and in following a sterile vein, when he comes to a place where the rock is decomposed, he concludes that the metal ore will soon be found. In Cornwall, the felspar is frequently changed in the vicinity of a vein, and tin-stone is sometimes disseminated through the rock to some distance on each side of it.

The
The crofs courses or veins which intersect the metalliferous
veins, frequently occasion a considerable derangement in the
position of metalliferous veins, and, what is still more
remarkable, occasion a change in the quantity or quality of
their contents. When a vein is cut through by another,
either in its line of bearing along a country, or crofses it by
declining in a different direction, the vein which is cut
through is suppozed to be of more ancient formation than
the vein which crofses and cuts through it; but it may be
doubted, from various circumstances, whether many of these
veins were not formed at the same time with the rock itself,
or were fissures passing through the rock in different direc-
tions, into which the various metallic subfances were re-
created, during its condifiliation. To form a more diftinct
idea of the ftricture of a vein and its interfection by crofs
courses, we refer to Plate IV. Geology. Fig. 4. a a repre-
sent a rake-vein defending obliquely; b b, the rock; c c,
the walls or fhecks of the vein; d, an interpofig piece of
rock, called the rider; e e, e, the division of the vein into
numerous small veins or frings of ore. If the fpace at d,
which is suppozed to be filled with rock, were empty, or
filled with water, it would constitute what is called a druffe;
and it is in these cavities or druffes that all the moft beaufiful
and regular crystallizations of the mine occur. Fig. 5. re-
prefents the fection of a rock containing a metallic vein cut
through, and displaced by crofs courses or veins of another
metal; a a is a vein which appears to have been once con-
tinuous, and contains tin; b b, b b, reprefent fifferent veins of
copper, which cut through the former, and have upheaved
the lower part, and brought them nearer the furface. In
Plate II. Geology. fig. 10. reprefents the ground plan or
horizontal fection of a plot of ground traversed by a vein and
a crofs course; E.W. reprefent the eai£ and weft fides of
the ground. It is in this direction the vein a a pafses, but
it is cut through by the crofs vein b b, which has carried the
feftern fide of the vein and the ground along with it confi-
derable to the north of its original position. Such a ftructure
and removal of the vein can only be conceived to have taken
place by a lateral or horizontal motion of a portion of the
ground. Such a motion has been frequently observed during
violent earthquakes. For though the ground is heaved up-
wards, the greater refiftance which certain parts offer to this
motion must occafion a lateral prefure on other parts of the
earth's furface, and to fuch a prefure we muft also refer the
remarkable contortions of the coal flara near Valenciennes.

See Plate II. fig. 9.

Metallic veins frequently occafion a displacement of the
flara when they pass through regularly stratified rocks;
and it is obferved, that when this displacement is con-
siderable, so as to bring a bed of lime-flone on the
fame fide with a bed of fland-flone or flake, the vein
is never fo productive as when the oppofite fides or walls
of the vein are in the fame kind of rock. See Plate II.
Geology. fig. 8. where the different flara a, b, c, d, e, f, g,
reprefent different flara on each fide of a vein or fault.
If d, d, are suppozed to reprefent parts of a bed of lime-
flone broken by the vein, and g, g a bed of fland-flone
below the lime-flone, but brought on the fame fide with it
by the upheaving of the flara,—in that part of the
vein where the lime-flone, d, and the fland-flone, g, form
the walls oppofite to each other, the vein will be unproductive,
though in other parts of the flara, when the vein paffes
through the fame bed of lime-flone, on each fide of it, at
the fame fide, it will be remarkably productive. These
facts may be commonly obferved in the mining flara of the
ueftern parts of Northumberfand and Durham, where
the flara confift of different beds of mountain lime-flone,
fand-flone, and flake. See Strata, under which article
the fuccedion of the different beds is enumerated.

As crofs veins generally difplace and injure the quality of
veins, on the contrary, when eai£ and weft veins in a diftrict
meet, by a flight variation in their direcHon or dip, the part
where they join is frequently very rich in ore; and where
a number of metallic veins crofs each other at the fame
place, they frequently produce a large irregular conical mass
of ore of vallt extent, from which the different veins diverge,
like radii from a common centre. The main ſtart of fuch
a vein, which Mr. Williams, in his Mineral Kingdom, calls an
accumulated vein, "refembles," he says, "the infide of a
flafts-house; and the vallt capacity of this vein is frequent-
y flored with a rich body of metallic ore, often imbedded
in foft mineral fols; but the veins and branches which join
and diverge refemble rake-veins, or perpendicular mineral
fifures. When the ore is worked out of an accumulated
vein, it exhibits a frightful gulf, fometimes fifty or sixty
feet wide below, and is often worked down to a great depth
from the furface." A number of thefe accumulated veins
have been worked at Pike-Law, in the county of Durham.
Crofs courses fometimes contain ore to a fmall diftance from
their junction with metallic veins, and in other fituations
they become fo rich as to be worked with advantage. The
Botallock mine, on the sea-coaft near St. Juft, in Cornwall,
offers a striking illuftration of this, though we believe its
ftructure has not been generally known or undertood. The
vein which is worked is a north and south vein, varying in
width from nine to twelve feet, and extending under the sea.
The vein-flone is quartz, with a small quantity of fluor fpar.
It is found to contain ore of copper and tin only in those
parts where the eai£ and weft veins enter it, and for thirty
or forty fathoms on each fide of the junction. This mine
produces the richest ore of copper in Cornwall, the grey
fulpheur yielding twenty per cent. of this metal. It is de-
serving notice, that the metalliferous veins which enter this
lode on the eai£ fide and render it producfive, have never
been found on the weft fide, fo that they appear to termi-
nate in it. The rock near the great north and south vein is
a foft killas or flate, but beyond this it is a very indurated
flinty flate. This vein may properly be considered as a crofs
course, rendered rich in ore in various parts by a number of
small veins which fall into it, like brooks into a large river
where they are loft. The fition of this mine is truly re-
markable, at the foot of a precipitous cliff that overhangs
the Atlantic ocean. If ever a spot feemed to bid defiance
to the efforts of the miner, it was this. At the very com-
 mencement of his labours, he was required to lower an im-
meas furne-engine down a precipice of more than two
hundred feet, with a view of extending his operations under
the bed of the sea, where the workings are at preient con-
tinued for seventy fathoms in length and eighty-five fathoms
in depth. In these caverns of darknes, many human beings
for a small pittance, and that even of an uncertain amount,
are contantly digging for ore, regardless of the horrors
which furrond them, and of the roar of the Atlantic ocean,
whose boiferous waves are inceafantly rolling over their
heads. In fome places the sea actually penetrates through;
and it is worthy of obfervation, that the water is deprifed of
a great portion of its falt; but whether this arises from
filtration, or whether fome portion of the fresh water from
the land percolated through intertenadow flifures in the rocks,
we could not aertain when we vifited this fingular mine.
If the filtration be more abundant after heavy rains, it
would prove the intermixture of rain-water. The thin crofs
courses filled with clay called flucan, leave the eai£ and weft
veins, and also hold up the water. The vein which is see
in ore on one side of the fracture, will be poor on the other side. This fact, which we believe has not been sufficiently noticed, is well discerning, and would indicate that the presence of water affected the contents of veins.

Some veins contain little diversity in the nature of their contents, being filled principally with one kind of ore or vein-tone. Other veins contain a great variety of minerals, without any apparent regularity of arrangement; there are also numerous veins which have a regular structure, the different minerals being arranged in parallel layers, coating each other: the same succession of different minerals occur on each side and meet in the middle, filling up the vein, or sometimes leaving an empty space between. Thus calcareous fsp, flour fsp, barytic fsp, lead-ore, blende, and grey copper-ore, form different layers over each other in the same succession on each side of the vein. In the Botallack mine, before described, copper-ore is frequently found lining each side of the vein, and this is covered by tin; but in other parts of the mine the tin covers the walls, and is succeeded by copper.

**Irregular Veins.**—Belides rake-veins, which may be considered as regular, there are other veins which present a great variety of structure, and are called belles, pipes, &c. according to their form. If a rake-vein be regarded as a tubular mass of mineral matter intersecting mountains, if this vein become irregular, and have its sides closed, or, as the miners call, *twisted in*, it forms what they denominate a pipe-vein, or mafs of ore and vein-tone sometimes of a tubular shape, depending to a considerable distance like a pipe. In other instances, the sides are closed in both above and below, as well as on the sides, inclining what the miners call a *belly*, or mafs of ore of considerable magnitude. Sometimes a small rib of ore is continued through that part of the rock where the sides of the vein are twitched in, until the vein expands again and produces another mafs of ore. In some instances there is no ore between, a rib of vein-tone or rider of clay being carried through the narrow part or *twitch* of the vein, but many of these twitches contain neither ore, clay, nor rider. In such cafes, it becomes exceedingly difficult to follow the vein through the rock, to where it opens out again.

The veins in general do not close suddenly, but the sides gradually approach each other, and the ore terminates in the form of a wedge at the *twitch.*

These contractions or twitches are of various lengths, and no miner can tell, when the vein is so squeezed in, how many fathoms he must pass through before it opens again, unless the same twitch has before been cut through above or below the part where he is working. The intervening space between two mafs of ore is called a *bar*, and sometimes extends ten, twenty, or even a hundred fathoms or more; and when it is cut through, the ore makes its appearance, and begins gradually to widen and form another mafs or belly. When one of these bellies of ore proves pure and solid, it generally happens that all the contiguous bellies prove so in the same vein. According to Mr. Forster, bellies have been known of eight hundred *lings* of ore being raised by six miners from one of these bellies in the space of nine weeks.

When the matrix in these large bellies of ore is soft, the ore is generally found in a globular form, more or less irregularly imbedded in the soft materials, and these globular masses of ore are of various dimensions. It is an uncommon thing to find the soft openings in this kind of vein swell to an enormous width, so as to make it difficult to find the real sides of the vein. Working these veins is the most difficult part of mining, as there is no proceeding a foot without advancing timbers as far as they go, in the form of a paffle in a house, composed of two side-poles, a lintel and a fole. The miners stand within this square frame, where they work and erect more timber as they proceed. It frequently happens that the ore is so plentiful and rich in this kind of metallic repository, as abundantly to compensate for all the labour and expense.

**Flat Veins and Beds.**—When a vein runs parallel with the *strata*, it is called a flat vein. If the *strata* are soft, and the metallic matter is widely distributed, such veins do not differ from beds, being regular beds or *strata* impregnated with metallic matter. If flat veins run between hard *strata*, they are also liable to contractions, or *twitches*, and again expand, forming *pipes* or tubular masses of ore, which extend in an inclined position, having the same dip as the *strata*. Flat veins may be distinguished from beds by this character; proper flat veins appear to be openings between the *strata* which have been filled with metallic matter from a rake-vein, or are at least connected with it, as they seldom are productive of ore, except in the vicinity of the vein; whereas beds are regular *strata*, having the same elevations and depressions as the other *strata* in a mountain, but containing metallic matter more or less abundantly scattered through them. Iron ores and ores of manganese frequently occur in beds, forming regular parts or layers of the mountain. Other metallic ores, which occur less frequently and abundantly in beds, are, we believe, for the most part veins which have taken the course of the softer beds and distributed their contents through them. It is well known, that when a vein descends through *strata* of different kinds of rock, it grows wider in the softer *strata*, and contracts in the harder beds of rock.

The metalliferous beds in Cumberland appear, in many instances, to be soft beds, rendered productive of ore by a number of small veins running through them. There are few metallic beds in England, except in that county. Manganese occurs in beds in red sand-iron in the vicinity of Exeter, but the metallic matter decreases as the beds dip from the surface. Metallic beds, in primary countries, occur most frequently among the schistose mountains, composed of gneisfs, mica-slate, and slate. (See Rock.) It is observed, that the ores and minerals which occur in beds are seldom crystallized, as these beds contain few druses or cavities to admit the formation of crystals. The minerals in beds are accompanied with garnet, actinolite, and hornblende, which never occur in rake-veins. See Garnet, &c.

**Stock-works.**—When a rock is crossed and penetrated by a great number of small veins in every direction, the whole mafs is worked as an ore, and is called by the Germans a *stock-worke*, or *werke*, the rock being afterwards separated from the ore by pounding and washing, in the same manner as the vein-tone is cleared from the ore in other mines. When the ore is disseminated in particles through the rock, such rocks are also worked for the ore when it exists in sufficient quantity. In some instances, mafs of ore of great magnitude are found imbedded in rocks, without any apparent connection with veins, which mafs must have been formed at the same time with the rock itself.

Rocks and *strata* are sometimes penetrated by metallic falls or oxids, diffused through the mafs in the same manner as we frequently observe *strata* of sand-iron abounding with the red oxyd of iron. Where the metals are valuable, such impregnated rocks or *strata* are sometimes worked as ores. At Alderley Edge, a hill near Macclesfield, in Cheshire, the sand-iron, which is in some parts a kind of breccia, is impregnated with the black oxyd of cobalt, with the carbonate and oxyd of copper, and with particles of sulphuret and
and carbonate of lead, and has formerly been worked for
the lead and copper, and more recently for the cobalt.
Mr. Williams, in his "Natural History of the Mineral King-
dom," describes a singular stratum of flint near Loughmough,
in the shire of Moray, of about eight feet thick, which is
composed of several species of hard and fine flintes of various
beautiful colours. "This stratum is a kind of pudding-flint,
in the composition of which there is blended about an eighth
part of good blue lead-ore or galena.

"This curious bed of flint is nearly horizontal, but dips
away with an easy slope towards the north of the Moray
Firth. The lead is found in larger and smaller grains and
flowers, blended through the whole body and composition
of the flint, in the same manner as the small mafies of
agates and coloured cystals, and other species of flint, are
found blended through the whole body of the stratum."

Where metallic ore is thus intermixed with fragments of
rock forming a conglomerate or breccia, it may probably be
referred to the same kind of metallic repository as stream-
works, (ice Stream-Work,) in which particles and maffes
of ore are intermixed with loose pebbles and sand, forming
beds at the bottom of valleys, or on the sea-foote, the met-
thal matter, as well as the pebbles, being derived from the
disintegration of rocks containing metallic veins; but in the
instance cited by Mr. Williams, the parts have become united,
forming a solid stratum.

The manner in which metallic veins were filled with ore
has greatly divided the opinions of geologists. George
Agricola, a Saxon, who died in 1555, appears to have been
the first writer who had any distinct knowledge of the struc-
ture of metallic veins, which he published in a work entitled
"De Rö Metallica," and another work entitled "Berman-
us." His theory of veins is in some respects similar to that
of Werner, who has lately excited much attention. Accord-
ing to Agricola, the rents or fissures which are filled with
metallic matter were partly formed at the same time with
the rocks themselves, and partly afterwards, by the waters
penetrating the softer parts; so that where there has been a
larger quantity of water, or where theibusance of the rock
has been much softened, there the largest fissures occur.
With respect to the earths and flones found in veins, he con-
ceives the former to have been detached from the rocks and
carried into the veins by water; the latter he considers as
arising from the earthy matter, hardened partly by change
of temperature and partly by a lapidific juice. Minerals
and metals he regards as being deposited from a solution in
water, containing the earthy parts intimately mixed and combined
with it in certain proportions. The solution of these me-
tal flubances he conceives to have been greatly promoted
by heat, on the abstraction of which they assume their pre-
ent solid form; the precious metals being the reftult of a
more pure and perfect solution.

Becher, in his "Physica-Subterranea," published in 1669,
ascibes the formation of metals and minerals to certain sub-
terranean vapours which arise from the bowels of the earth,
and penetrating the flubance of veins, produce a peculiar
change in the earthy or flomy matter they meet with. He
regards the earth as a hollow body, filled with clay, water,
fluphureous and bituminous flubances, from which arise
certain exhalations that form the metals. The celebrated
German phyfician Stahl, confiders veins, as well as the sub-
stances they contain, to have been formed at the same time
with the earth itself, and of course as being contemporaneous
with the rocks they interfet; but he is disposed to attri-
bute some effect to the action of air and other caufes.

Henkel, in his "Pyritologia," has given an ingenious theory
of the formation of metallic veins, which has been adopted,
VEIN.

From the third letter of that work we make the following extract.

"In explaining the phenomena which are observable in the interior of mountains (it must however be remembered, that I do not include such as are evidently of volcanic origin), I do not allow myself of those great causes which, by their magnitude, the suddenness of their action, and by their effects, produce sudden changes which take place under our eyes, such as subterranean fires, earthquakes, and the like. I refer these phenomena to natural causes, which, though left evident and flower in their operation, are no lefs certain of producing a radical transformation. Of this kind are putrefaction and fermentation. It is of little consequence by what name we distinguish this peculiar action exerted by Nature in the mineral kingdom; it consists in an infinite motion in the central parts of the globe, and appears to be produced by water combined with heat in different degrees of intensity. I observe such changes still going on, and can conceive them to continue so long as the same series of operations exist in nature. I am persuaded that there is constantly going on in our mountains a variety of transformations, compositions and decompositions, which not only take place at present, but will continue to the end of time.

"Fermentation, if I may be allowed to call by that name this quality which acts by indescribable degrees, produces the most perfect transformations in the bowels of the earth; fermentation I say may, according to my theory, alter the entire mass of a mountain; it may convert granite into gneis, as this last only differs from the former in its structure, which is flaty or schistofe; gneis indeed has no other distinctive character than its structure, namely, the regularity and parallelism of its beds, and in some places a decomposed felspar approaching to clay. This fermentation may also convert greywacke into an argilaceous schist, which last may again by inundation become jasper, when this process is either diminished or flopt. By it, also, quartz may be converted into clay, carbonaceous substances into quartz, and the whole mass of a mountain into inflammable or saline matter, or even into ores, metals, or ferrimetallics. To it I ascribe the power of producing, preserving, and continuing to form the different beds and mineral repositories, which are found both in primitive and felsztz mountains; finally, the effects which the waters produce in filtering from above to below, and which in their passage through the different rocks may undergo some peculiar modification, appear to me the principal cause why this fermentation may act with more force in one part of the same mountain than in another."

Patrin, a celebrated French mineralogist, considers the changes taking place in the mineral kingdom, as effected by a process somewhat similar to secretion in the animal and vegetable kingdoms, and ascribes a kind of mineral life to the earth itself, differing perhaps as much from vegetable life as the latter differs from that of animals. According to this theory, each kind of mineral substance is capable of converting metals of mineral matter into its own peculiar nature, as animals convert their aliment into flesh and blood. Whatever may be thought of this theory, we believe that those who are most practically conversant with the various phenomena and transmutations that occur in mines, will readily admit that many changes are taking place, which cannot be explained on any known chemical or mechanical principles, and which bear a strong resemblance in their effects to the processes of secretion. Nor can it, even in the present state of chemical science, appear improbable that the different earths and metals may be converted into each other by natural processes. The different beds of rock intersected by metallic veins, are themselves metallic substances combined with oxygen; or, in other words, all the rocks and strata which form the earthy parts of the globe, consist of oxygen combined with metallic bases; and as these metallic bases may perhaps be compounded of the same elementary parts united in different proportions, the transmutation of one earth or metal into another, may be effected by a simple change in the arrangement of the elementary molecules.

The theory of veins proposed by Von Oppel, and in part supported and extended by Werner, supposes veins to have been fissures originally formed by the deflection of mountains, and the sinking in of the mafes. These fissures, being open at the top, were afterwards filled with their contents by metallic solutions poured in from above. Mountains, according to Werner, have been formed by a successive accumulation of different beds and layers, placed or heaped over one another. "The substance of these beds was at first wet, and possessed little solidity; so that when the accumulation of matter had attained a certain height, the mafes of the mountain yielded to its weight, and must consequently have sunk and cracked. As the waters which filled in supporting the mafes began to retire, and lower their former level, these mafes then left their support, and yielded to the action of their weight, opening, and falling to the side where the least resistance was opposed. The sinking of the mafes of a mountain produced by deflection, and still more the fractures by earthquakes, and other similar causes, may also have contributed to the formation of fissures.

"The same precipitation, which in the humid way formed the strata and beds of rock, furnished and produced the subvention of veins. This took place when the solution, from which the precipitation was formed, covered the existing rents, which were as yet wholly or partially empty, and open in the upper part. Veins, whether considered as rents, or as the subvention constituting the vein, have been produced at very different times; and the antiquity or relative age of each can be easily determined."

Such, in Werner's own words, are the great outlines of his theory, a theory which we conceive to be decidedly opposed by all the most striking appearances existing in the mineral kingdom, and equally opposed to the simplest known and acknowledged laws of nature. If metallic veins were once open fissures, filled by precipitations from a solution that covered the whole globe, with the highest mountains in which metallic veins are found; it is obvious that these metallic precipitations would be most considerable in the lower parts of the surface, in valleys and plains, where the fluid must have been much deeper than on the summits and sides of mountains. We ought, therefore, to find thick beds of metallic matter covering and incrusting the low and level parts of the globe; but nothing is more rare than to find beds of metallic matter in low plains. Where beds of metallic matter exist, it is always in comparatively high countries, abounding in veins; and it is much more probable that the beds and veins were formed by local causes, and not from a solvent covering the whole globe. The metallic parts of this metalliferous ocean must have possessed the greatest specific gravity, and instead of floating on the top of the fluid, to be deposited in the fissures of lofty mountains, it would have descended by the laws of gravity, forming crusts of different degrees of thickness from the bottom to the top, increasing downward. The reverse of this is the fact. It is principally in alpine districts, and at enormous heights, that metallic matter is accumulated in the greatest abundance. It is in the heights of the Cordilleras of Peru that the productive mines of Potosi are situated: it is in the same chain of mountains, more
than 14,000 feet above the level of the sea, that the prodigious mass of mercurial ores is found at Guanaca Velica, where, in the space of two centuries, more than 15,000 quintals of this metal have been procured.

But the facts most opposed to the theory of Werner are those which we have stated, namely, that when a metallic vein passes through different strata, the mineral substances it contains generally vary in each stratum, either in kind or quality. Sometimes an entire change takes place, as from tin to copper or lead; in other instances, the vein will contain the same kind of ore in the different strata, but it will be invariably richer or poorer in some of the strata than in others, and there will be certain strata in which scarcely any ore occurs. Very frequently where the same kind of metallic matter is contained in the vein, it will be mineralized or combined with different substances, as the vein passes through different beds; thus we find a metallic sulphuret more prevalent in one part, and a metallic silt or oxidel in another part of the vein.

In Derbyshire, where the veins of lead pass through different beds of mountain lime-flone, which alternates with beds of bafalitic ormydoid, provincially called toad-flone, it is found that the vein scarcely ever contains lead as it passes through the toad-flone, where it is always much narrower, and in some places appears to be entirely cut off by it; but on sinking into the beds of lime-flone, the vein is found again, and is as productive as in the upper beds. Where the vein can be traced through the toad-flone, it contains calcareous spar, and sometimes a few particles of lead-ore. If veins had been filled from above by metallic solutions, it is impossible to conceive that the nature of the rock could change the quality of the ore; much less could the ore disappear in one stratum, and appear again in a stratum below it. Professor Jameson, in a paper published in the Memoirs of the Wernerian Society, has attempted to explain the difficulty presented by the interruption of the veins in Derbyshire, on the supposition that the different beds of lime-flone and toad-flone, together with the metallic veins, were contemporaneous, and that the toad-flone cut through the veins at the period of their formation. On this hypothesis, Mr. Bakewell, in his Introduction to Geology, remarks: “The existence of different organic remains in the upper and lower beds of the mountain lime-flone in Derbyshire, precludes the possibility of these beds having been all formed at the same time. The zoophytes in the lower beds of rock could not be living and co-existent with the shell-fish in the upper, nor with the vegetables, the remains of which are occasionally found in the sand-flone that covers the whole, and into which the veins sometimes shoot. Cuvier has well observed, that the existence of different organic remains in the upper and lower strata offers incontestible proofs that they were formed in succession over each other.” In point of fact also, the veins are not always cut off by the toad-flone; but they are never productive of ore, where they pass through it, except in very small particles.

These facts are not less opposed to the igneous theory of metallic veins than to that of Werner. If metallic veins had been filled with their contents by the operation of subterranean fire, which cracked the surface, and injected the metallic matter in a flate of fusion, it is impossible to conceive that the nature of the rock, through which the veins pass, could have produced any material change in the quality of the ore. Metallic ores may, in some instances, have been formed slowly by exhalations from subterranean fires; as specular iron-ore, and even gold, has been found in the craters of volcanoes; and the phenomena, presented by the lava which destroyed Torre del Grecco in 1794, indicate the manner in which such ores are formed. The lava had buried entire houses for more than twelve months, at the latter end of which time it had considerably cooled; and when the houses were opened, pieces of iron were found converted into a plate of black, red, and magnetic oxides, having the hollow parts and interfaces filled with a brownish-red transparent oxid of iron, and with specular iron-ore. In the articles made of iron, which had undergone this change, the external form was scarcely altered, which evinces that the crysals had been produced by sublimation. Copper articles were changed into crystralized red oxid of copper, and red oxid with green and blue carbonate. From the absence of metallic sulphures, it is inferred that the lava contained little, if any, sulphur. These changes shew that metallic matter may be sublimed and converted into the state of ore by subterraneous heat, at a much lower degree of temperature than has been suppos'd.

There is a circumstance on which those who contend for the aequous formation of metallic veins have laid much stress. In some instances, rounded pieces of flone, apparently resembling water-worn pebbles, have been found in mines at a considerable depth; but as many veins contain hollow spaces, through which water is continually running, the formation of pebbles might admit of a satisfactory explanation, without supposing that these pebbles had fallen in from above. The pebbles which we have seen of this kind, from the mines in Cornwall, are all of a chlorite fchilitus, and the form oblate, presenting the appearance which may frequently be observed in rocks of the same kind. It is in all probability an original formation, and not a breccia from pre-existing rocks.

There is another circumstance which appears to have escaped the attention of geologists. The water in the mines of Cornwall, particularly in the vicinity of copper veins, has a temperature considerably above that of the natural temperature of the earth; it is said to be at 70° Fahrenheit; and the working miners, from its sensible warmth, can predict with certainty the vicinity of a copper vein. The increase of temperature, if any, in the vicinity of tin veins is less sensible.

From hence, as well as from various appearances in mines, we are led to infer that there are certain chemical changes now going on in the interior of the earth; and it is from a more enlarged acquaintance with these phenomena, that we can alone expect to obtain a satisfactory theory of the formation of metallic veins.

The following is a summary account of the rocks and situations in which metallic ores are generally found.

Platina, and the recently discovered metals, palladium, rhodium, olimium, and iridium, have not been hitherto found in veins, but in the sands of rivers. The four latter metals are found as alloys in the grains of platina. See Platina, Palladium, &c.

Gold and silver are found in veins, and diffeminated in primary and transition rocks, in porphyry, sienite, and the lower sand-flone. Gold has been occasionally discovered in coal, and is very abundantly diffeminated in the sands of some rivers. See Gold and Silver.

Mercury is found in slate, in lime-flone, and in secondary strata. See Mercury.

Copper occurs in veins and beds in primary and transition rocks, in porphyry and sienite, and occasionally in sand-flone. Masses of native copper, of large size, are found on the surface of the ground, in the interior of North America. See Copper.

Lead and zinc occur in veins, and diffeminated in primary
VEIN.

and transition rocks, except trap and serpentine, in the lower secondary flata, and in porphyry and diabase. See Lead and Zinc.

Antimony occurs in veins in primary and transition mountains, except trap and serpentine.

Bismuth, cobalt, and nickel, occur in primary and transition mountains, except line-flone, trap, and serpentine. Cobalt and nickel also occur in transition mountains, and in sand-flone. See Bismuth, &c.

Arsenic occurs in veins, either as a sulphuret or mineralizer of other metals, in primary and transition mountains, and in porphyry. See Arsenic.

Tellurium occurs in veins in porphyry, combined with gold. See Tellurium Mines.

Manganese occurs in beds and veins in primary and transition mountains, and in beds, and disseminated in red sand-flone. See Manganese.

Molybdenum, tungsten, and titanium, occur in granite, gneiss, mica-flone, and argillaceous schistus. Theses metals, with chromium and cerium, are very rare, and can only be reduced to the metallic state with great difficulty. See Molybdenum, &c.

Mineral veins differ from metallic veins, being destitute of ores, and filled with the same substances which compose entire rocks, or with earthy minerals.

Quartz veins (see Quartz) resemble in their structure and position many metallic veins; and it not unfrequently happens that a vein, which contains metallic ore in one part, intermixed with quartz and other vein-flones, will, in another part, be entirely filled with quartz. Quartz veins intersect almost all primary and transition rocks, but are particularly abundant in rocks of argillaceous schistus and greywacke. (See Rock.) The quartz in veins is most frequently white, and nearly opaque; and being much harder than the rocks which it intersects, it remains on the summits of mountains, after the surface of the rock is decomposed, until it is carried down by diluvial currents into the beds of rivers, where it becomes rounded by attrition, and is transported to distant districts. Most of the white quartz pebbles in England have probably been formed from the quartz veins of decomposed rocks, as no quartz of a similar kind exists as a rock in any part of England or Wales; but the same mineral abounds in veins.

Granite, argillaceous schist or flake, porphyry, green-flone, pitch-flone, basalt, and various other rocks, frequently form veins in mountains of the same kind with themselves, or in different rocks. Where a vein of one kind of rock intersects a rock of a similar kind, the substance of the vein generally differs from that of the rock in texture, colour, and other characters. The granite in veins, which passes through granite rocks, will generally be coarser or finer grained than the rock which it passes through, and have the constituent parts differently mixed. The followers of Werner assert, that veins which contain rock substances have been filled from above by matter poured into the fissures, and that the granite in veins is of a secondary formation. They further maintain, that the lower rocks, which they consider as the older, never rise into the upper rocks in the form of veins. In opposition to this opinion, it has been discovered that veins of granite, in Cornwall, may be distantly seen rising into the schist or killas which covers the granite rocks in many parts of that county, particularly at St. Michael's mount, east of Penzance, and at Moudefhole, two miles west of that town. Where the junction of the granite and schist is exposed by the action of the sea, veins of the former rock may be traced, at low water, running in a zigzag form for many yards into schist, gradually growing narrower, and terminating in small branches and fringes. One circumstance we observed in these granite veins at Moudefhole, which may deserve notice: the same vein which penetrated the schist, when it entered the granite, was different in texture from the granite rock, though it had the same constituent parts; it might be distinctly traced for a considerable distance into the granite. The granite also, in the vicinity of the schist, was smaller grained than the general body of the rock; and the fclay, where in junction with the granite rock or granite veins, was changed to a kind of very fine-grained gneiss. These facts seem to indicate that both the granite and the schist, to a considerable distance from their junction, had been in a softened flate at the same time, and that their consolidation was contemporaneous. Similar appearances, with an intermixture of veins of schist in granite, are frequent at Glenilt, and other parts of Scotland. Veins of granite, porphyry, or schist, never penetrate the upper secondary flata, but veins of basalt and trap (see Trap) have been found in every kind of rock, even penetrating chalk. These veins are sometimes of vast extent and width, and frequently occasion great diffcations and derangements in the stratified rocks, particularly in the coal flata, where they have been most observed: hence they are called faults. (See Fault and Strata.) The dislocation of the flata by a vein of this kind is represented in Plate II. Geology, fig. 8, where the different flata, c, d, e, f, &c., on the left-hand side, are separated from the corresponding flata on the right, and considerably elevated.

As the veins of trap or basalt are nearly vertical, and often several yards in width, and the subsidence with which they are filled being frequently harder than the flata which they intersect, these veins remain when the surface is decomposed to a considerable depth, rising like a wall or fence, which, in the language of North Britain, is synonymous with dyke; hence such veins have been called dykes, or whin-dykes, the term whin-flone being used to denote basaltic rocks. (See Whin-stone.) Basaltic veins, or whin-dykes, vary in width from a few inches to several yards, and are sometimes more than one hundred yards wide. They often extend many miles in length; in other infinences they terminate at shorter distances, forming irregular wedge-shaped masses. When basaltic dykes are of considerable width, the basalt is interfaced by fissures; and sometimes the central parts and sometimes the sides are harder or softer than the other; and in some parts the basalt graduates into a dark ferruginous clay. Masses of basalt from the dyke are frequently found wedge in between the flata, extending from some distance, and where basaltic dykes intersect coal flata, the coal in the immediate vicinity of the dyke has frequently the appearance of being charred. At Corkfield-shield, in the county of Durham, the coal flata are cut through by a basaltic vein or whin-dyke, which is about seventeen yards wide. Where it comes in contact with the coal, the latter subsidence, for several feet, is converted into a pulvulent flate, like foot. At a greater distance from the basalt, the coal is reduced to a coke or cinder, which burns without smoke, and with a clear durable heat. At the distance of fifty feet from the basalt, the coal is found in the flate of common mineral coal. The roof over the coal is lined with bright crystals of sulphur, probably sublimed by heat from the pyrites common to coal. In these appearances we recognize every circumstance which might be expected from the agency of heat, but which would be extremely difficult to reconcile with the aqueous formation of basalt. We have seen similar appearances near basaltic dykes in Northumberland. The vein, or dyke, of basalt
at Cockfield-fell, is part of the longest dyke which has been traced in England, or perhaps in any other country. According to the description of it in Mr. Bakewell’s Introduction to Geology, “it extends from the western side of Durham in an eastward direction, to Bewick in Yorkshire, crossing the river Tees at this place, and proceeding in the same direction through the Cleveland hills, in the East Riding of Yorkshire, to the sea-coast between Scarborough and Whitby. It rises to the surface, and is quarried, in many parts of its course, for flone to repair the roads. It crosses the turnpike near the seven mile-flone from Whitby to Pockering, where there is a quarry funk in it. The vein, or dyke, is here about ten yards wide; the flone is a dark greyish-brown basalt, and is the principal material for mending the roads in the district called Cleveland. The extent of this dyke has been traced in a direct line about seventy miles. In its course it intersects the metalliferous lime-flone of Durham, the coal district, and the aluminous schistus. The circumstances attending this and other extensive dykes, which have not hitherto been regarded by geologists, completely invalidate,” says Mr. Bakewell, “the theory, that these dykes were originally open fissures, formed by the drying or shrinking in of the rocks. As the different rock formations through which it passes contain different organic remains, they must have been formed in succession at different periods, and the metalliferous lime, with the lower flata, must have been consolidated long before the upper flata were deposited; and the caudes which might dispose the upper flata to shrink and open, cannot be supposed to act on the lower rocks. It is also remarkable, that the width of this vein is more than twenty yards in the lower rocks on the east; but in the upper rocks it is not more than ten yards. The dyke must have been filled with its contents at the time of its formation, otherwise it would contain fragments of the rocks which it intersects. As it passes through the lime-flone, it has rendered it more crystalline in its vicinity, and the effects in charring the coal, before defibed, point to subterranean fire as the original cause of its formation, and as the source whence the basalt that fills it was supplied. The close resemblance between the basalt and compact lava, add probability to the opinion that this great dyke was originally formed by an expansive force operating from below, which opened a chasm in the surface of the earth, and ejected the contents in a flote of fufion. A volcanic dyke was formed on the western side of Vesuvius, June 12, 1794, two thousand three hundred and seventy-five feet in length, and two hundred and thirty-seven feet in breadth, through which lava rose to the surface. This lava, when cooled, formed a wall of flone intersecting the former beds of lava, and constituting a real dyke. The flone has a dark-grey colour, and is in some parts so compact as to resembile horn-flone.” See Volcano.

The effects of basaltic veins on the contiguous parts of the flata of sand-flone which they intersect, are no less remarkable. In some instances, the sand-flone appears very considerably indurated, and converted into a subflata resembiling horn-flone.

It is observed by Mr. Allan, Transact. of the Royal Society of Edinburgh, vol. vii. that the sand-flone which is thus indurated, contains calcareous earth, which appears to have promoted its semi-vitrification; but where the sand-flone remains unchanged in the vicinity of a dyke, the calcareous earth is wanting. Sir G. Mackenzie observed basaltic dykes in Iceland, the walls or sides of which were lined with a glassy subflata resembiling obsidian. These effects offer further illustration of the igneous origin of basaltic veins. A very interesting account of the effect produced by basaltic veins on the different beds of rock at the Giants’ Cauflway, and on other parts of the same range on the north coast of Antrim, is given in the third volume of the Transact. of the Geological Society.

Various beds of columnar basalt, argillaceous lime-flone, and chalk, are interfaced by perpendicular dykes or veins of basalt. The chalk in the vicinity often undergoes a remarkable change, extending eight or ten feet from the wall on each side, and thence gradually decreases. The part nearest the basalt is converted into a dark-brown crystalline lime-flone, like coarse-grained primitive lime-flone. The next flate is that of finer-grained primitive lime-flone, or faccharine lime-flone; then fine-grained arenaceous lime-flone. A compact variety, having a porcelain aspect, and a blue-grey colour, next succeeds; this, towards the outer edge, becomes gradually white, and insensibly graduates into unaltered chalk. The flints in the altered chalk assume a greyish-yellow colour. The altered chalk is highly phosphoreous when subjected to heat. In other parts of the range, the argillaceous beds of chalk appear converted into horn-flone by contact with the basalt, and contain in that flate the imbedded fossils peculiar to the flia stratum. (See Strata.) The basalt in some of the veins is columnar; but the columns lie horizontally. It has been conjectured, with some probability, that this has been caused by its falling from a flate of igneous fluidity, and the refrigeration commencing from the sides. From the same cause, in the beds of columnar basalt in that range, (see Giants’ Caufway,) the columns are perpendicular, the cooling commencing from the top and the bottom of each bed. The marine organic remains in the flata over the basalt, prove that the whole were formed under the sea. In some instances, basaltic veins appear to have been opened, and the intervening space filled with debris from the upper flata; and there are basaltic dykes in Northumberland, in which the basalt being divided into irregular masses, the interspaces are filled with iron-clay, and contain impressions of ferns, like those in the coal flata which these dykes or veins intersected. On the whole, no country in the world which has yet been examined presents so many interesting appearances of basaltic veins as the northern parts of Great Britain and Ireland, nor are they anywhere exposed to the eye of the observer with so much distinctness as on many parts of the sea-coast, where the ocean has bared the surface, and exposed the most magnificent and instructive sections of entire mountains, penetrated by these veins to the height of many hundred feet. The veins may often be seen extending from the mountains into the sea, rising up like enormous walls, which serve as monuments of the ravages of the ocean upon the coast. The great hardness of the subflata which fills the veins has prevented their destruction by the waves that have broken down and removed the mountain mafles in which these veins were once imbedded.

Messrs. Lewis and Clarke, the American travellers, describe extensive walls of dark columnar flone ranging through the interior of North America; these walls were undoubtedly dykes or veins of columnar basalt, remaining where the surface of the ground had been washed away. There are also instances where the subflata of basaltic veins has been softer than the surrounding rock, and is washed out wherever the rock is exposed, forming deep fissures, with perpendicular walls of rocks on each side. Such appearances are not uncommon on the sea-coast in various parts of Scotland.

For an account of basaltic rocks, see Trap.

Vein is also applied to the streaks, or waves, of diverse colours appearing on several sorts of woods, flones, &c.
VELAINE, in Geography, a town of France, in the department of the Meurte: 6 miles E.N.E. of Nancy.

VELAM, a town of Hiadooftan, in the country of the Navys: 34 miles E. of Calicuit.

VELAMEN, is used, by some Surgeons, for the bag, skin, or bladder, of an impomithome, or swelling.

VELAMENTUM BOMBYCINUM, a name which some anatomists give to the velvet membrane, or inner skin of the interlines.

VELANGOODY, in Geography, a town of Hindooftan, in Marawar; 7 miles W. of Trumian.

VELANI, in Botany and the Arts, sometimes called Valonia, a name given by the modern Greeks to the acorns of a species of oak, (see Quercus Égloph, and Quercus Infestoria,) denominated the "Velanida." The tree grows on the western coast of Notolia, in the islands of the Archipelago, in those of Corsa and Cephalonia, and throughout all Greece. For an account of the galls of this oak, we refer to the article Galls. The Oriental fakes care to gather the galls at the precise time which experience has proved to be most favorable, or in which the excrence has acquired its full size and weight. For this purpose, they visit the hills and mountains that are covered with oaks. The first galls that are picked up are laid apart; these are known in the East under the name of "Yerd," and distinguished in trade by the terms of "black galls" and "green galls." These which have escaped the first searches, and which are gathered a little later, called "white galls," are of a very inferior quality. The galls of the environs of Moful and Tocat, and in general those which come from the eastern part of Turkey, are less esteemed than those of the environs of Aleppo, Smyrna, Magnesia, Karabfaff, Diarbekir, and the whole interior of Notolia. The former are sold at Smyrna and at Aleppo two or three paisles les per quintal than the others. The inhabitants neglect to gather the acorns, which serve as food for the wild boars and goats; the latter contribute very much to render the oak small and stunted, by devouring, with its fruit, a part of its foliage and young boughs.

The diploepis which produces these galls has a body of a fawn-colour, with the antennae dark, and the upper part of the abdomen of a shining brown. It is sometimes found, under its latter form, in the inside of the galls which are not yet pierced. On the same oak are found other galls in great numbers, which the inhabitants neglect to gather, because they are not fit for dyeing.

The valani, or valonia, is gathered in the autumn, and dried under sheds, which protect it from rain, and is in a proper state for shipping about the beginning of March: that which is gathered on the mountains is preferred to that of the valleys. There is also a difference with respect to its age or size; the small and young is taken from the trees before it has attained its full growth, and is reckoned better than the large, or that which remains till it is full grown. Those of the best quality are usually sent to England, and the inferior to Ancona and Trieste. This gall is used for dyeing and tanning, and in Turkey a considerable quantity is consumed for the latter purpose.

The quantity shipped annually from the different Turkish ports may be calculated at from 4000 to 5000 tons. It is sent to several places in Europe; particularly London, Liverpool, Leghorn, Trieste, Ancona, and Genoa. The nut, or kernel, of the valonia is not reckoned of any value, and is sometimes picked out to save freight and charges. The lofs in weight thus occasioned, together with garbage, (that is, freeing it from dirt, flones, &c.) is from 10 to 25 per cent., according to the quality of the article, and the expense
The more resident then pays, liberal abridgment thoughts Spanish London its this specimen and fifteen painters painting, author. manca, and of the may here residence or his ferries, and theirrier.”

It was considered that the distance from which valonia, or valenii, is brought, and the heavy duty it pays, compared with oak-bark, discourage its use; but if the duty should be taken off, it is probable that the consumption would be greatly increased.

VELANIDA, in Botany. See QUERCUS, n. 68.

VELARIUS, in Antiquity, an officer in the court of the Roman emperors, being a kind of usher, whose post was behind the curtain, velai, in the prince’s apartment; as that of the chancellors, cancelli, was at the entry of the baletrade, and that of the oftiiarii at the door.

The velarii had a superior, of the same denomination, who commanded them; as we find in two inscriptions, quoted by Salmarius in his notes on Vopiscus, and by a third in Gruter.

VELASCO, DON ANTONIO PALOMINO, in Biography, was a Spanish painter and historian of the artists of his country. He was a native of Valencia, where he flourished about 1700. He was painter to Philip V., and painted many pictures for the churches and convents of Valencia, Salamanca, and Grenada, but is much better known to us as an author. He published an elaborate treatise on the art of painting, in two folio volumes, in which he notices 250 painters and sculptors who had flourished in Spain previous to the conclusion of the reign of Philip IV. Of this work, there was an abridgment published in London in 1742, entitled “Las Vidas de los Pintores y Statuarios eminentes Españoles,” of which there is an English translation.

VELASCO, in Geography, a town of North America, in the province of Mexico.

VELASQUEZ DE SILVA, DON DIEGO, in Biography, the most distinguished painter of the Spanish school, was born at Seville in 1594. His parentage was noble, being of a family originally of Portugal, which had established itself in Andalucia. Though confined in fortune, they gave him a liberal education, and, as he had evinced much inclination for drawing, placed him with Francisco de Herrera, the elder; but he afterwards became the disciple of F. Pacheco, an artist of very considerable ability, and a scholar, then residing at Seville. With him Velasquez studied attentively, and his talents displayed themselves in a variety of imitations of natural objects, particularly of peafantry in their peculiar habits and occupations. Of these we have now a specimen in England, which had at all times been esteemed as a master exhibition of his early acquirements, and celebrated under the appellation of the “Water Carrier.” It was stationed in the new palace at Madrid, but was removed from thence by Joseph Bonaparte, and was found, with a great number of other pictures, in the imperial carriage taken at the battle of Vitoria. It is now in the possession of the duke of Wellington, among the numerous other trophies of that great man’s fame. Still, however, it is considered by his grace as the property of the Spanish crown. Velasquez continued attached to this particular application of his art, conscious of his superiority, and declining to extend his views to a more elevated class of subjects, till at length the sight of some pictures by Guido and Caravaggio, which Pacheco had received from Italy, excited his emulation, and he then turned his thoughts to history and portraiture. After he had been five years with Pacheco, that master bestowed upon him the hand of his daughter in marriage, and he continued still to prosecute his art under the guidance of that able instructor. In 1622, Velasquez left Seville, to visit the metropolis of Spain and the Ecuestri, and there his talents recommended him to the notice of the count De Olivarez, the favourite minister of Philip IV., who patronized and befriended him; taking him into his own palace to dwell. Soon after he introduced him to the king, who immediately ordered him to paint his portrait. From the completion of this picture, which was upon a grand scale in armour, and on horseback, the reputation of Velasquez was elevated above all his contemporaries, and his patron was ordered to inform him, that from that time the royal perufu would be intrusted to no other painter but himself. He received the royal permission to make a public exhibition of it, when it was loudly applauded by all about the court, and held up to public estimation by laudatory verbes in its honour from the poets.

After this successful commencement of his public career, he was employed to paint the portraits of the infants Don Carlos and Don Fernando; and that of the minister, his patron, mounted, like his royal master, on a noble Andalussian charger, richly caparisoned. He now, therefore, began to enjoy the blessings of fortune, as well as those of fame. He was appointed principal painter to the king, with a liberal salary, besides receiving munificent remuneration for his pictures, and being busily occupied in portraits.

He now also, in emulation of other Spanish painters, determined to undertake a work upon a more extended scale than he had before done, and took for his subject the expulsion of the Moors from Spain by Philip III. But, if we may judge by the description given of the picture, it does not appear to have possessed much interesting matter of a high historic quality; however, he gained great reputation from the skill with which he executed it. The composition represented the king armed, and in the act of commanding a party of soldiers, who are escorting a group of Moors of different sexes and ages to the sea-shore for embarkation. On the other side is personified the kingdom of Spain, as a majestic matron, with a stately edifice. This picture, as appears by an inscription upon it, was painted in 1629, and it was no sooner completed than he again experienced the munificence of his sovereign, who made him one of his chamberlains, and allowed him an additional stipend.

It was at this time that Rubens visited Madrid. He formed an intimacy with Velasquez, and first inspired him with a desire to visit Italy; and he obtained from his royal patron every advantageous means of going there, with recommendatory letters to render his residence in Rome and Venice as useful and agreeable to him as possible.

He embarked at Barcelona in 1629, and first landed at Venice, where he was received and entertained by the Spanish ambassador. In this delightful birth-place of colouring, the works of its great master Titian, in the palace of St. Marc, excited his warmest admiration, and he made several copies of them; and no one ever more thoroughly imbibed the principles upon which they are constructed. But perhaps it is of Titoreto that Velasquez is more the imitator, than of Titian. His freedom of pencil appears to have been more congenial with the taste of the Spaniard, than the sober and more correct hand of the former. After remaining at Venico
nice a few months, he went to Rome, where he was most generously received by the cardinal Barberini, nephew to Urban VIII., who procured for him apartments in the Vatican, and access at all times to the works of Raffaelli and M. Anguissola. During his residence at Rome, he painted his celebrated history of Joseph's coat brought to Jacob; and also another very able work, of Apollo informing Vulcan of the infidelity of Venus; in which he had an opportunity of displaying his power of handling, and his admirable skill in colouring. Vulcan is at his forge, the light and shadow proceeding from which are most skilfully conducted; the strong and molecular forms of the Cyclops gracefully contrasted with the pure form of the Apollo; and the whole composition arranged with infinite judgment. Both these pictures were sent to Spain, and honoured by having distinguished, places affixed to them in the palace of the king.

On his return home he went to Naples, and there painted the portrait of Donna Maria of Austria, queen of Ferdinand III. After about the lapse of a year and a half, he arrived at Madrid, and found his favour with his royal master undiminished. He was again lodged in the royal palace, and the king kept a key of his painting room, that he might have free access to him without ceremony; and this he frequently indulged himself with, as his great predecessor, Charles V., had done with Titian. And so strong were the reminiscences in his pictures, that it is said the king, going into his room one day, expressed some surprise, that a nobleman, to whom he had given a commission which required his absence from Madrid, had not departed, imagining that he saw him in the room, when it was in reality only his portrait.

In 1638, Velasquez painted his most celebrated picture of our Saviour on the Cross, for the convent of St. Placido, at Madrid; and about the same time, that of the general Pescara receiving the keys of a Flemish citadel from the governor of the place. The management of all the different characters, the officers, &c. and the effect of the fortification, &c. of the town and landscape in the back-ground, is altogether eulogized by Mengs as the chef-d'œuvre of Velasquez.

Though his patron d'Oliveres fell into disgrace in 1643, yet Velasquez maintained his interest at the court; and in 1648, was commissioned by the king on a particular embassy to pope Innocent X., and at the same time was empowered to purchase for his majesty the finest works of art, both of sculpture and painting, which he could procure in Italy. On this occasion he embarked at Malaga, and having landed at Genoa, passed through Milan and Padua to Venice, where he was well pleased to renew acquaintance with the great masters of art, whom he had before beheld with so much admiration. He afterwards visited Bologna; and on his arrival at Rome, was received with great favour and distinction by the pope; and in the unengaged moments of his more serious business, he painted a very fine portrait of his holiness, of which there is a capital exemplar at Luton, the seat of the marquis of Bute, which has every character of originality. For this painting, the pope gave him a gold medal and chain; and the academicians of St. Luke elected him of their body.

After a lapse of nearly three years, Velasquez took his departure from Genoa, in a vessel freighted with a magnificent collection of pictures, statues, busts, &c. which he had collected, and on his arrival was most graciously received by the king, and honoured with further marks of his royal favour and bounty; among which the order of Santiago was not the least, as being confined to persons of the highest rank, or the most eminent abilities. He thus lived, in honour and riches, till 1660, when the ruthless hand of death put an end to his labours and enjoyments. He was buried with great funeral pomp in the church of San Juan.

VELATODURUM, or Velatudurum, in Ancient Geography, a place on the route from Belfancio to Epamandodurum or Mandura.

VELAUNI, a people of the Maritime Alps near the sea, E. of the Nerufii.

VELAUR, in Geography, a river of Hindoostan, which rises near Attore, in the Mylore country, and runs into the bay of Bengal, near Portonovo.

VELAY, before the revolution, a country of France, in Languedoc, situated to the W. of the Vivarais, and the E. of Auvergne. It is mountainous, but fertile: Le Puyen Velay was the capital. It now constitutes the department of the Upper Loire.

VELAZGHERD, a town of Persea, in the province of Kerman; 54 miles N.E. of Goornon. N. lat. 28° 10'. E. long. 56° 34'.

VELBERG, a town of Germany, in the territory of the imperial town of Hall; 7 miles E. of Hall.

VELBERT, a town of the duchy of Berg; 5 miles N.N.E. of Medman.

VELBURG, a town of Bavaria, in the principality of Neuburg; 12 miles N. of Dietfort. N. lat. 49° 10'. E. long. 11° 28'.

VELCERA, in Ancient Geography, a town on the coast of Illyria, between the mouth of the river Genes and the town of Senia. Ptolemy.

VELDEN, in Geography, a town of Bavaria; 6 miles S.S.W. of Landhut.—Allo, a town of Germany, in the territory of Nuremberg, on the Pegnitz; 21 miles N.E. of Nuremberg. N. lat. 49° 37'. E. long. 11° 31'.

VELDENTZ, a town of France, in the department of the Sarre, formerly capital of a county, in the circle of the Upper Rhine, united with the palatinate; the environs are celebrated for an excellent Moselle wine; 17 miles E.N.E. of Treves. N. lat. 49° 55'. E. long. 6° 50'.

VELEIA, a town of Hispia Citerior.—Allo, a town of Italy, S. of Placentia, in Gallia Cispadiana; now in ruins.

VELEN, in Geography, a town of Germany, in the bishopric of Munster; 22 miles W. of Munster.

VELETRI, a town of the Popedom, in the Campagna di Roma. This was a very ancient town, and considerable in the time of the first Roman kings. It was taken by Ancus Martius, fourth king of the Romans, and retaken by the Volscans, under the command of Coriolanus. The Romans took it again some time after, and, removing the inhabitants, filled it with a Roman colony. It is the see of a bishop, united with Ostia, who is called the bishop of Ostia, but his residence is at Veletri; 28 miles N.N.W. of Terracina. N. lat. 41° 42'. E. long. 12° 50'.

VELEZ, a town of South America, in New Grenada; 100 miles from Santa Fe de Bogota. N. lat. 5° 50'. W. long. 73° 16'.

VELIZ, de Gomeria. Sec Gomeria.

VELEZ MALAGA, a sea-port town of Spain, in the province of Grenada, near the coast of the Mediterranean. The chief article of trade is raisins. In 1487, this town was taken from the Moors by Ferdinand, king of Castile and Aragon; 13 miles E. of Malaga. N. lat. 36° 47'. W. long. 4° 18'.
VEL

VELEZ el Rubio, a town of Spain, in the province of Grenada, near the Guadalentin. This town was, in the time of the Moors, a strong place, and furnished with a garrison; 14 miles S. of Huéca.

VELEZAR, a river of Spain, formed by the union of the little rivers Bercia and Sil, on the confines of Leon, which, after receiving several other small streams, unites with the Minho, a little above Ornde.

VELEZIA, in Botany, was so named by Linnaeus, at the recommendation of his pupil Lejjling, in honour of Dr. Christophal Velez, examiner, first physician, and demonstrator of botany, at Madrid, who gave Lejjling his manuscript Flora of the environs of that capital, which we do not find to have ever been published.—Linn. Gen. 176.

Gen. Ch. Caryophyllum. Velizianum, one of the flims, long and slender, with five angles, five intermediate furrows, and five pointed, erect, small teeth, permanent, without any appendages at the base. Cor. Petals five, well defined, small, narrow, the length of the calyx; limbs spreading, oblong-wedge-shaped, clavate or toothed, hairy at the base, much shorter than the claws. Stam. Filaments ten, cylindrical, about the length of the calyx, inserted into the receptacle; anthers roundish, incumbent. Ptl. Petals superior, cylindrical, short; styles two, thread-shaped, hardly so long as the stamens; stigmas simple. Peric. Capsule cylindrical, fleshy, of one valve and one cell, opening with four teeth at the summit. Seeds numerous, oblong, alternate, imbricated downwards, concave in front, convex at the back, inserted in a simple row, by the dorsal furrow, into a thread-shaped, unconnected receptacle.

Eff. Ch. Calyx of one leaf, nearly cylindrical, furrowed, naked. Petals five, with very long claws; limb bearded at the base. Capsule superior, cylindrical, of one cell. Seeds imbricated.

A small genus of slender campion-like plants, with numerous little pink flowers, nearly related to Saponaria, (see that article,) and certainly to be placed next to it in the artificial, as well as natural, families. Linnaeus knew but one species. We have a new one found by Dr. Sibthorpe in Ais Major.

2. V. quadridentata. Four-toothed Velezia. Sm. Prodr. Fl. Græc. Sibth. n. 954. Fl. Græc. t. 591, unpubl.—Calyx club-shaped, smooth. Petals with four teeth. Gathered by Dr. Sibthorpe in Ais Minor, and, if we are not mistaken, in the island of Patmos. This has the peculiar habit of the foregoing, but is rather larger, and quite smooth. The flowers are flaked. Calyx angular, swelling upwards. Limb of the corolla marked like V. rigida, with a central flare; but each petal has four strong teeth, or acute lobes, instead of being only simply clavate. Each claw is crowned, in both species, with a tranverse row of white hairs. Stamens in the present all of equal length. Capsule rather flatter, shorter, and less accurately cylindrical, than the former.

We have no doubt of this genus being equally distinct from Saponaria and Gypsophila, (see those articles), though the first species betrays a slight affinity to the former, the second to the latter. An ovate, even calyx, and oblong capsule, are proper to Saponaria; a bell-shaped angular calyx, and almost globular capsule, to Gypsophila. Velezia is perhaps more naturally akin to Dianthus, but wants the scales at the bottom of the calyx.

VELHAS, in Geography, a town of Brazil, which runs into the Parana.

VELIA, or HELIA, in Ancient Geography, a town of Italy, in Lucania, westward, on a small gulf of the same name, formed by the small stream Helis, from the Greek Ἡλία, signifying a marsh.—Alfo, a town of Hilipan Citerior, belonging to the Carif. Ptolemy.

VELICALA, in Geography, a town of California, near the coast of the Pacific ocean. N. lat. 26° 35'. W. long. 115° 5'.

VELIDIA, a town of Morocco, on the coast of the Atlantic; 25 miles S.W. of Mazagan.

VELIKA, a town of Moldavia; 25 miles S.E. of Segna.—Alfo, a river of Croatia, which runs into the Save, near Cralioa Velika.—Alfo, a river of Russia, which runs into the Viafka, 10 miles N.E. of Orlov, in the government of Viafka.—Alfo, a river of Russia, which runs into the Tchudikoi lakes, near Pilov.

VELIKIE LUKI, a town of Russia, in the government of Pilov, on the Lovat; 124 miles S.E. of Pilov. N. lat. 56° 28'. E. long. 30° 14'.

VELIKOJ, a small island of Russia, in the White sea. N. lat. 66° 45'. E. long. 34° 20'.

VELILLA, a town of Spain, in the province of Aragon. The author of the "Continuation of Mariana's History of Spain," speaks of a bell in this town of great celebrity, which rung sometimes without the help of man; and that a particular description of its wonders was printed at Madrid in 1657.

VELINO, a mountain of Naples, in Abruzzo Ultra; 12 miles S. of Aquila. This is one of the Apenines, and probably the highest of them. Its summit, 8979 feet above the Mediterranean, is covered with snow in June: about 46 geographical miles N.W. of Rome.—Alfo, a river of the Popedom, which runs into the Nera, about four miles from Termi, in the duchy of Spoleto.

VELINUS, (VELING,) in Ancient Geography, a small river in the country of the Sabines, in the northern part; its sources were about twenty miles from Reate, towards the E., in mountains abounding with water. It passed southward, by a place called Vacunia, afterwards by Intercrce, where it turned towards the W., to the plain on which was situated Cutilix. Changing its direction towards the N.W., it entered an immense plain, in which were high mountains, and formed a large lake. These
flagrant sulphureous waters were found very inconvenient. M. Curius pierced a mountain and made a canal to the Vellina, so that its waters had a free passage to the sea, by a valley, which Cicero compared to the valley of Tempé. The inhabitants of Reate found here abundance of roes, whence they called it Rosea. The Velinius discharging itself into the Nar near Interamna.—Allo, one of the seven mountains of Rome.

**VELLACOMAS.** Vellicasses of Cæsar, Vellicasses of Pliny, and Vellicasses of Ptolemæus, were a people joined by Cæsar to the Cætuli, and others among the Belgæ, separated by the Seine from the Celts. But in the division of Gaul by Augustus, the Vellicasses, as well as the Cætuli, are placed in the Lyonnæ, and they are referred to in that province by Ptolemæus and Pliny. Their capital, Rotomagus, became the metropolis of the second Lonnæ, when the Lyonnæ of Augustus was divided into two provinces.

**VELIUSCUM,** a place of Africa, in Mauritania Cæsariensi, upon the route from Ruficurrum to Celama, between Carte and Taramatau. Anton. Itin.

**VELITES,** in the Roman Army, one of the four kinds of foot soldiers that composed a legion, who were armed lightly with swords, bows and arrows, slings, and javelins. For defensive armour they had only a small target, and a helmet or head-piece. These were commonly young men of mean condition, and took their name à volando, or à velocitatem, from their swiftnes and expedition: and they were designed for skirmishing with the enemy before a battle, and pursuing them after a defeat.

They seem not to have been divided into any distinct bodies or companies, but to have hovered in loose order before the army.

The other classes of the Roman infantry were the batai, principes, and triarii. In the day of battle, the batai were placed in the first line, the principes in the second, and the triarii in the third. The Velites formed small flying parties both in front and rear. See **BATTLE.**

**VELITTIS,** in the Natural History of the Ancients, the name of a peculiar sort of sand used in the manufacture of glases; for which purpose they always chose such as was found washed clean on the banks of rivers; and this they therefore called glases-sand, or velites, or hyalitis.

**VELITRÆ, or VELITRIS,** in Ancient Geography, a town of Italy, in Latium, in the country of the Volcicns.

It was at some distance from the Appian way, S.E. of Alba, and became considerable under the Romans. It had an amphitheatre, of which no trace now remains. Two roads led to Velitrae; one to the W. detached itself from the Appian way, the other to the E. communicated with the Latin way. See **VELITRÆ.**

**VELIZ,** in Geography, a town of Russia, in the government of Polotsk; 88 miles E. of Polotsk. N. lat. 55° 20'.

E. long. 31° 4'.

**VELLY,** in Rural Economy, a term applied in some districts to the bag or stomach of the calf, which is used in making running or rummet; or to the prepared stomaches of the animals or renet for curdling the milk in cheese-making, which are often called wells. In some dairies, instead of making the rennet ready some time previous to its being used, a small piece, proportioned to the quantity of milk to be coagulated, is cut from the yell over-night, and put into half a pint of water, or whey, to infuse until the morning. In this case, the vell are to be suppos'd to be equal in goodnes; and it is probable, that the virtue may not be so fully extracted as by a longer infusion. It is suggested too as not improbable, but that the strength of the rennet might be ascertained by means of experiment, by the application of alkaline salt, and by such means be rendered more certain in its use. See **DAIRYING.**

Gen. Ch. Cal. Perianth inferior, cylindrical, creft, of four linear, obtuse, closely converging, deciduous leaves. Cor. crenulate, from four obovate spreading petals, whole claws are the length of the calyx. Stam. Filaments furcifer, as long as the calyx, the two opposite ones rather shorter; anthers simple. *Piñ.* German superior, ovate; lyle greatly dilated, bordered, leafy, ovate; stigma obtuse. *Peric.* Pouch orbicular, tumid, entire, of two cells, crowned with the permanent, ovate, erect, rigid flyle, which is a continuation of the membranous partition. *Seeds* several, roundish; *their cotyledons folded;* *Brown.*

Obf. *V. Pseudo-cyrtis* has the four larger filaments deftinate of anthers, and combined together in pairs. *Linnaeus.*

2. *V. Pando-cyrtis.* Shrubby Cref-rocket. Linn. Sp. Pl. 895. Wildf. n. 2. Ait. n. 2. Cavan. Ic. v. 1. 32. t. 42. (Cytisus facie Alcyon fruticos quorundam; Linn. Ic. v. 3. 49. *Cytisus aderliaus,* five Alcyon fruticos; Ger. Em. 1506.)—Leaves undivided, obovate, fringed. Pouches erect.—Native of the neighbourhood of Araujue in Spain, flowering in May. Sometimes kept for curiosity as a hardy greenhouse plant, but not remarkable for beauty. The *flum* is shrubby, branched, roughish, two feet high. Leaves alternate, rather lefthy, entire, rough, scarcely an inch long, tapering down into a short *footstalk,* and generally accompanied by two smaller leaves. *Flowers* in long spikes, yellow, with pale veins. Permanent *flyle* broad, nearly
nearly orbicular, scarcely longer than the poucb. Ca-
venilles says he found all the authors correct, though Lin-
næus is correct in his description of the combined filaments.

VELLA, or Verra, in Geography, a river of the Ligurian
republic, which runs into the Magra, three miles above
Sarzana.

VELLACHERY, a town of Hindoostan, in the Carn-
atic; 10 miles S.E. of Madura.

VELLADY, a town of Hindoostan, in Myfop; 14
miles S. of Dammicotta.

VELLAS, a town of the island of Ceylon; 44 miles
W.N.W. of Candi. N. lat. 7° 45'. E. long. 80° 16'.

VELLATOOOR, a town of Hindoostan, in Mysop;
5 miles E. of Coimbetore.

VELLECHYPALEAM, a town of Hindoostan, in
Mysop; 13 miles N. of Coimbetore.

VELLEIA, in Botany, received its name from the au-
thor of the present article, in honour of his highly valued
friend Col. Thomas Velley, F.L.S., author of a descrip-
tive work on the Submarine Plants of Britain, with coloured
plates, in folio, confifting of only one fasciculus. This
amiable and accomplished botanist was unfortunately killed
by accident, a few years since, in the town of Reading, as
he was travelling between Bath and London.—Sm. Tr. of
580. Labillard. Nov. Holl. v. 1. 54. (Euthales; Brown
—Clas and order. Pentandria Monogynta. Nat. Ord. Cam-
Gen. Ch. Cal. Perianth inferior, unequal, either of
three or five roundish, or of one leaf in five segments,
the upper division largest, permanent. Cor. of one petal,
irregular; tube rather longer than the calyx, split longitud-
inally at the back, almost to the base, more or less tumid,
or spurred, underneath; limb in five rather unequal, spread-
ing, bordered, broad-keeled segments, almost two-lipped.
Stam. Filaments five, thread-shaped, shorter than the tube,
inferted into its membranous base, alternate with the seg-
ments of the limb; anthers erectile, oblong, unconnected,
of two cells, bearing a large, prismatic, filamentous, 
filament thick, obtuse, encompassed with a membranous,
cup-shaped, abrupt integument. Peric. Capsule of one
cell and four rigid valves. Seeds several, orbicular, com-
pressed, roughish, imbricated on both sides of a central re-
cepctacle, shorter than the valves.

Eff. Ch. Calyx inferior, three or five-cleft, unequal.
Corolla tubular, five-cleft, two-lipped; tube cloven at
the back. Capsule of four valves and one cell. Seeds imbric-
ated, orbicular, compressed.

Obf. Mr. Brown's Euthales is so strictly united in habit
and character, except the calyx, with our Velleia, that we
cannot but consider it as of the same natural genus. Our
learned friend, from whom we always scruple to differ, has
discovered some acknowledged Velleia with five leaves to the
calyx, instead of three, originally attributed to it. Here
then is an approach toward the five-cleft, though single-
leaved, calyx of Euthales. Linnaeus has declared, Phil.
Bot. sect. 170, "Karo observatur genus in quo pars atque 
frutescens non aberrat." The calyx appears to be the
part in Velleia which runs wild, if we may so translate it,
and flinkingly confirms the above maxim. We may ex-
tend this observation to the whole order of Mr. Brown's
Goodenovia, in which even the situation of the calyx,
whether superior or inferior, is not uniform; which cir-
cumstance must lead us to mistrust other differences in
the same part, when not supported by other characters.

Without attention to such principles as these, we may
almost, as Linnaeus says, make as many genera as species
of plants.

Sect. 1. Calyx of one leaf, in five segments. Euthales-
Brown.

Holl. v. 1. 54 t. 77. (Euthales trineriav; Brown Prodr.
t. 466. Curt. Mag. t. 1197.)—Calyx tubular, of one leaf,
in five acute segments. Leaves downy.—Native of the
south coast of New Holland. Sent to Kew garden in
1803, by Mr. Peter Good. A perennial greenhouse herb,
flowering most part of the year. The root is fibrous. Stem
none. Leaves all radical, numerous, downy, more or less
acute, tapering at the base; sometimes entire; sometimes
toothed, or partly runcinate. Flower-stalks numerous, a
span high, nearly erect, forked, with a pair of opposite lan-
colate bracteas at each division. Flowers stalked, erect,
yellow; keel of each segment green underneath; two
upper ones marked in front with a dark brown spot; all
marginate; tube white, enclosing the flaments and styles.
The flowers seem variable in size. We should hardly, with-
out Mr. Brown's authority, have supposed all the above
fynonyms to belong to the same species.

Sect. 2. Calyx of five leaves. Corolla with a spur at
the base, which is permanent. Menoceras (a fention of Velleia).
Brown.

1. n. 1.—"Downy. Leaves bluntly toothed."—Native of
New South Wales, Van Diemen's island, and the south

2. n. 2.—"Smooth. Leaves sharply toothed."—Gathered by
Mr. Brown, on the south coast of New Holland.

Sect. 3. Calyx of three leaves. Corolla a little gibbus,
on one side, at the base. True Velleia. Brown.

4. V. lyrata. Lyrate Velleia. Br. n. 3.—Smooth.
Bracteas distinct. Leaves orbicular, or sharply toothed at
the base. Calyx-leaves roundish-ovate.—Native of Port Jack-
fon, New South Wales. This is our original species of
the genus. The leaves, all radical, much relumb thofe of
Crypta tetragon. Stalks a span high, rigid, once or twice
forked; one branch at each fork being sometimes wanting.
Bracteas ovato-lanceolate, acute, entire, separate at the
base, with a small internal tuft of hairs. Flowers yellow,
on short partial stalks. Calyx-leaves quite distinct, acute,
nearly entire, a quarter of an inch long, downy within;
the upper one rather broadest, and almost orbicular.

Bracteas distinct. Leaves spinate, almost without teeth;
quently entire at the base; with auxillary tufts of hairs."—
Observed by Mr. Brown near Port Jackson, as well as in
the tropical part of New Holland.

Bracteas distinct. Leaves toothed. Calyx-leaves oblong-
ovate, acute."—Native of the tropical part of New Hol-

Bracteas very large, combined, roundish, toothed."—
Found by Mr. Alexander Gordon, in the neighbourhood
of Port Jackson, but seen by Mr. Brown in a dried state
only.

The whole genus is stenemies, and we believe the flowers
are all yellow.—None but the first species has hitherto made
its appearance in the European gardens, though some of
them might possibly prove hardy annually, if not perennial
with us.
VELLEIACUM, in Ancient Geography, a town of Italy, in the midst of the hills of Gallia Cilpadanca, according to Pliny.

VELLEITY, Velleitas, in the School Philosophy, is usually defined a languid, cold, and remsi will.

Others say, it implies an impotency of obtaining what we require. Others will have it, a slighc desire for something, which a perfon does not esteem much, or is too indolent to seek; as Catus amat pigem, sed non vult tangere lympham.

VELLEIUS, in Biography. See Paterculus.

VELLEKAT, in Geography, rocks in the East Indian sea, about 15 miles E. from the island of Myfol. S. lat. 2° 1’. E. long. 131° 2’.

VELLEPEKONDA, a town of Hindooftan, in Golconda; 15 miles S. of Warangole.

VELLIA, in Ornithology, a name used by some authors for the lanius minor, or lanius tertius of Aldrovand, called in England the flæther.

VELLIAM, in Geography, a town of Hindooftan, in Coimbetore; 16 miles S.E. of Errood.

VELLICA, in Ancient Geography, a town of Hispania, in the territory of the Tarragonone. Ptolemy.

VELLICATION, among Physicians, the act of twitching or stimulating. The word is more particularly applied to a sort of sudden convulsions that happen to the fibres of the muscles.

VELLICULA. See Varicula.

VELLIN, in Geography, a town of Pomerania; 4 miles N.N.E. of Polnow.

VELLING, in Agriculture, a term applied to the operation or process of ploughing or cutting up and taking off the turf or upper surface of the land, in order to its being burnt, or for other purposes. It is usually performed nearly in the same manner as baulking or rell-baulking, except that instead of being turned over, the furrow-slice is, in some cafes, cut with its turf upwards; and the work in this process is in effect the same thing; but as the outer point of the wing of the furrow in the plough is turned upwards, there is less necessity for holding it an oblique position. The plough too in executing this operation, is always turned to the right upon the headland, which is contrary to that which is practised in ploughing, the slice or furrow being turned towards the ploughed instead of the unploughed land. In velling, the plough is thrown so far into the land from the line of drainag, as to enable the ploughman to carry with ease about twice as much land as is displaced by the ploughed slice, which is pared very thin and even, and on the land fide not cut so deep as in the operation of skirting, but gradually lifted and turned neatly on its green side upon the baulk, left on the right-hand or furrow side of the plough. This manner of ploughing, in contradistinction to splitting, is called, in some districts, gathering of the land; and the day-work five or six roods. See Splitting.

In cafes where the furrow-slice is not turned, it is in some places drawn out with small hooks, by the labour of women and boys, or harrowed, and then raked together in heaps, and burned. This is a mode of velling which is commonly adopted in cafes where there is not time to permit the turf to rot, as is the cafe in other methods of practice. See Paring and Burning, and Turning to Rot.

VELLO, in Geography, a town of Italy, in the Veronese; 10 miles N. of Verona.

VELLON, in Commerce, a kind of money, in which accounts are kept in many parts of Spain. The real vellon is the most general money of account: it consists of 8½ quarts, 17 ochavos, or 34 maravedis vellon. Madrid, and all Castile, with most of the adjacent provinces, and also Bilboa, Malaga, and Galicia, keep accounts in reals and maravedis vellon. See Maraved and Real.

VELLOUL, in Geography, a town of Hindooftan, in Gucerat, on the coast; 9 miles W.N.W. of Puttan Sumnaut.

VELLUM. See Velon.

VELLUM, in Geography, a town of Hindooftan, in the Carnatic; 5 miles S.W. of Tanjore. N. lat. 10° 43’. E. long. 79° 7’.

VELLY, Paul-Francis, in Biography, was born near Fifines, in Champagne, in 1711. Quitting the society of Jefuits after having belonged to it for about eleven years, he devoted himself to historical researches. His chief work was his “Histoire de France,” in 6 vols., written in an easy and correct style, and polishing the character of candour and truth. He is charged, however, with too often attacking the privileges of the clergy, and with having borrowed freely from Voltaire’s Eloge on General History, and with having been milled in some instances by adopting his sentiments. This history, which he terminated with Charles le Bel, was continued to the 16th volume by Villaret. He also published a translation of Swift’s “History of John Bull.” He was virtuous and amiable, and of a very cheerful disposition. His death happened in 1750.

VELMES, in Geography, a town of France, in the department of the Dordogne; 15 miles S.W. of Mucidan.

VELOCE, Ital., in Music, swift; Velocissimo, superl. very swift.

VELOcity, in Mechanics, swiftness; that affection of motion, by which a moveable is dispelled to run over a certain space in a certain time.

It is also called celerity, and is always proportional to the space moved.

Huygens, Leibnitz, Bernouilli, Wolfius, and the foreign mathematicians hold, that the momenta, or forces, of falling bodies, at the end of their falls, are as the squares of their velocities into the quantity of matter: the English mathematicians, on the contrary, maintain them to be as the velocities themselves into the quantity of matter. See Motion.

Velocity is conceived either as absolute or relative: the velocity we have hitherto considered is simple or absolute, with respect to a certain space moved in a certain time. Relative or respectif velocity is, that which with two distant bodies approach each other, and come to meet in a longer or less time; whether only one of them moves towards the other at rest, or whether they both move; which may happen two ways, either by two bodies naturally approaching each other in the same right line, or by two bodies moving the same way in the same line, only the foremost slower than the other: for, by this means, this will overtake that; and as they come to meet in a greater or less time, the relative velocity will be greater or less.

Thus, if two bodies come nearer each other by two feet in one second of time, their respective velocity is double that of two others, which only approach one foot in the same time.

Velocity is also uniform or equal, when a moving body passes through equal spaces in equal times; or unequal, when in equal times it passes through unequal spaces; in which case it is either accelerated or retarded; and this acceleration, or retardation, may also be equal or unequal. See Acceleration and Motion.
VELOCITY.

In the doctrine of fluxions, it is usual to consider the velocity with which magnitudes flow, or are generated. Thus the velocity with which a line flows, is the same as that of the point which is supposed to describe or generate the line. The velocity with which a surface flows, is the same as the velocity of a given right line, that, by moving parallel to itself, is supposed to generate a rectangle, always equal to the surface. The velocity with which a solid flows may be measured by the velocity of a given plane surface, that, by moving parallel to itself, is supposed to generate an erect prism, or cylinder, always equal to the solid. The velocity with which an angle flows, is measured by the velocity of a point, supposed to describe the arc of a given circle, which subtends the angle, and measures it. See Macl. Fluxions, book i. chap. i.

All these velocities are measured at any term of the time of the motion, by the spaces which would be described in a given point of time, by these points, lines, or surfaces, with their motions continued uniformly from that term.

The velocity with which a quantity flows at any term of the time, while it is supposed to be generated, is called its fluxion. See Fluxion.

VELOCITIES of BODIES moving in CURVES. According to Galileo's system of the fall of heavy bodies, which is now admitted by all philosophers, the velocities of a body falling vertically are, each moment of its fall, as the roots of the heights from whence it has fallen; reckoning from the beginning of the fall. Hence that author inferred, that if a body fall along an inclined plane, the velocities it has, at the different times, will be in the same ratio; for since its velocity is altogether owing to its fall, and it only falls as much as there is perpendicular height in the inclined plane, the velocity should be measured by that height as if it were vertical. See Inclined Plane.

The same principle, likewise, led him to conclude, that if a body fall through two contiguous inclined planes, making an angle between them, much as a flock when broken, the velocity would be regulated after the same manner, by the vertical height of the two planes taken together; for it is only this height that it falls; and from its fall it has all its velocity.

This conclusion was universally admitted till the year 1693, when M. Varignon demonstrated it to be false. From his demonstration it should seem to follow, that the velocities of a body falling along the cavity of a curve, for instance, of a cycloid, ought not to be as the roots of the heights, since a curve is only a series of an infinity of infinitely little contiguous planes, inclined towards one another; so that Galileo's proposition would seem to fail in this case; and yet it holds good, only with some restriction.

All this mixture of truth and error, so near akin to each other, flowed that they had not got hold of the first principle; M. Varignon, therefore, undertook to clear what related to the velocities of falling bodies, and to fet the whole matter in a new light. He still supposes Galileo's first system, that the velocities, at the different times of a vertical fall, are as the roots of the corresponding heights. The great principle he makes use of to attain his end, is that of compound motion.

If a body fall along two contiguous inclined planes, making an obtuse angle, or a kind of concavity between them; M. Varignon flows, from the composition of those motions, that the body, as it meets the second plane, loses somewhat of its velocity, and, of consequence, that it is not the same at the end of the fall, as it would be, had it fallen through the first plane prolonged; so that the proportion of the roots of the heights affected by Galileo does not here obtain.

The reason of this loss of velocity is, that the motion, which was parallel to the first plane, becomes oblique to the second, since they make an angle: this motion, which is oblique to the second plane, being conceived as compounded, that part perpendicular to the plane is lost, by the opposition thereof, and part of the velocity along with it; consequently, the loss of the perpendicular there is in the oblique motion, or, which is the same thing, the lefs the two planes are from being one, i.e. the more obtuse the angle is, the less velocity does the body lose.

Now all the infinitely little, contiguous, inclined planes of which a curve consists, making infinitely obtuse angles among themselves; a body falling along the concavity of a curve, the losses of velocity it undergoes each instant is infinitely little; but a finite portion of any curve, how little forever, consisting of an infinity of infinitely little planes, a body moving through it loses an infinite number of infinitely little parts of its velocity; and an infinity of infinitely little parts makes an infinity of a higher order, i.e. an infinity of infinitely little parts makes a finite magnitude, if they be of the first order or kind; and an infinitely little quantity of the first order, if they be of the second, and fo in infinitum. Therefore, if the losses of velocity of a body, falling along a curve, be of the first order, they will amount to a finite quantity in any finite part of the curve, &c.

The nature of every curve is abundantly determined by the ratio of the ordinates to the correspondent portions of the axis; and the essence of curves in general may be conceived as confulting in this ratio, which is variable in a thousand ways. Now this same ratio will be, likewise, that of two simple velocities, by whose concurrence a body will describe any curve; and, of consequence, the essence of all curves, in the general, is the same thing as the concourse or combination of all the forces, which, taken two by two, may move the same body. Thus we have a most simple and general equation of all possible curves, and of all possible velocities.

By means of this equation, as soon as the two simple velocities of a body are known, the curve resulting from them is immediately determined. It is observable that, according to this equation, an uniform velocity, and a velocity that always varies according to the roots of the heights, produce a parabola, independent of the angle made by the two projectile forces that give the velocities; and, consequently, a cannon-ball, shot either horizontally or obliquely to the horizon, must always describe a parabola. The best mathematicians, hitherto, had laboured much to prove, that oblique projections formed parabolas as well as horizontal ones.

To have some measure of velocity, the space is to be divided into as many equal parts as the time is conceived to be divided into; for the quantity of space corresponding to that division of time, is the measure of the velocity. For an instance: suppose the moveable A passes through a space of 80 feet in 40 seconds of time: dividing 80 by 40, the quotient 2 gives the velocity of the moveable to be such, as it passes over an interval of two feet in one second; the velocity, therefore, is rightly expressed by \( \frac{1}{2} \); that is, by 2. Suppose, again, another moveable B, which in 30 seconds of time travels 90 feet; the index of the celerity will be 3. Wherefore, since in each case the measure of the space is a foot, which is supposed every where of the same length, and the measure of time a second, which is conceived every where of the same duration;
VELOCITY.

the indices of the velocities $2$ and $3$ are homogeneal, and therefore the velocity of $A$ is to the velocity of $B$, as $2$ to $3$.

Hence, if the space be $s$, and the time $t$, the velocity may be expressed by $\frac{s}{t}$; the space being in a ratio of the time and the velocity. See Motion.

Velocity, Circular. See Circular.

Velocity, Initial, in Gunnery, denotes the velocity with which military projectiles issue from the piece by which they are discharged. This is now known to be much more considerable than was formerly apprehended. For the method of estimating it, and the result of a variety of experiments by Mr. Robins, Dr. Hutton, &c. see Gun, Gunnery, Projectile, and Resistance.

We shall here add, that Mr. Thompson (Count Rumford) has lately published the result of a variety of experiments upon gunpowder, and also an account of a new method of determining the velocities of all kinds of military projectiles. From the equality of action and reaction, it appears, says Mr. Thompson, that the momentum of a gun must be precisely equal to the momentum of its charge; or that the weight of the gun, multiplied into the velocity of its recoil, is just equal to the weight of the bullet and of the powder (or the elastic fluid that is generated from it) multiplied into their respective velocities; for every particle of matter, whether solid or fluid, that issues out of the mouth of a piece, must be impelled by the action of some power, which power must re-act with equal force against the bottom of the bore.

It is easy to determine the velocity of the recoil in any given case, by suspending the gun in a horizontal position by two pendulous rods, and measuring the arc of its ascent by means of a ribbon, according to the method which Mr. Thompson has described, and this will give the momentum of the gun, its weight being known, and consequently the momentum of its charge.

But in order to determine the velocity of the bullet from the recoil, it will be necessary to find how much the weight and velocity of the elastic fluid contribute to it. That part of the recoil which arises from the expansion of this fluid is always very nearly the same, whether the powder is fired alone, or whether the charge is made to impel one or more bullets, as Mr. Thompson has determined by various experiments.

If, therefore, a gun, suspended according to the method proposed, is fired with any given charge of powder, but without any bullet or wad, and the recoil is observed; and if the same piece is afterwards fired with the same quantity of powder, and a bullet of a known weight; the excess of the velocity in the latter case above that in the former, will be proportional to the velocity of the bullet; for the difference of these velocities, multiplied into the weight of the gun, will be equal to the weight of the bullet multiplied into its velocity.

Accordingly, if $W$ is put for the weight of the gun; $U$, for the velocity of its recoil, when it is fired with any given charge of powder, without any bullet; $V$, for the velocity of the recoil when the same charge is made to impel a bullet; $B$, for the weight of the bullet, and $v$ for its velocity; we shall have $v = \frac{V - U \times B}{W}$. Let $B = 580$ grains, $W = 336,000$ grains; and therefore, $B : W :: 580 : 336,000$; $i.e. :: 1 : 579.31$ nearly, and $V - U$ is found by experiment to be equal to $1.8522$; and, consequently, $v = 1.8522 \times 579.31 = 1073$ feet in a second; which is very near $1083$ feet in a second, the mean of the velocities determined by the pendulum after the manner of Mr. Robins.

But the theorem will be rendered more simple by putting $e$ for the chord of the recoil in English inches, when the piece is fired with powder only, and $C$ for the chord when a bullet is discharged by the same charge; and then

$$C - e \text{ will be as } V - U; \text{ and consequently, } \frac{V - U \times W}{B}$$

which measures the velocity of the bullet, the ratio of $W$ to $B$ remaining the same.

Supposing, therefore, $C - e = 1$ inch, and the velocity of the bullet to be computed from that chord; the velocity in any other case, in which $C - e$ is greater or less than one inch, will be found by multiplying the difference of the chords $C$ and $e$ by the velocity that answers to a difference of one inch. Or the velocity of the bullet, expressed in feet per second, may in all cases be found by multiplying the difference of the chords $C$ and $e$ by $118.35$; the weight of the barrel, the length of the suspending rods, and the weight of the barrel, remaining the same, whatever be the charge of powder or its strength.

According to this rule, Mr. Thompson has computed by several experiments the velocities of bullets from the recoil, and compared them with the velocities obtained by the pendulum. The result, making the necessary allowances for the difference in the conclusions arising from these two methods, leads Mr. Thompson to infer, that there is the greatest probability that the velocities of bullets may in all cases be determined by the recoil with great accuracy; and if this method succeeds with musket-bullets, it may also be applied as well to cannon-balls and bomb-shells of the largest dimensions: he apprehends also, that it will be much preferable to any other method hitherto known, not only as it may be applied indifferently to all kinds of military projectiles, with little trouble or expense, but also because by this method the velocities with which bullets are actually projected are determined; whereas, by the pendulum, their velocities can only be ascertained at some distance from the gun, after they have lost a part of their initial velocities by the resistance of the air through which they are obliged to pass to arrive at the pendulum.

Those who advert to what has been delivered under the article Gunnery, will find that, according to Mr. Robins's theory, farther confirmed by Dr. Hutton's experiments, when bullets of the same diameter, but different weights, are discharged from the same piece by the same quantity of powder, their velocities should be in the subduplicate ratio of their weights.

But this theory, says Mr. Thompson, is founded upon a supposition, that the action of the elastic fluid generated from the gunpowder, is always the same in every given part of the bore when the charge is the same, whatever may be the weight of the bullet; and as no allowance is made for the expenditure of force required to put the fluid itself in motion, or for the loss of it by the vent, he concludes that the theory is defective. And from a variety of experiments, made with a view of ascertaining this point, he infers, that the ratio of the velocities of bullets to their weights is different from that which Mr. Robins's theory supposes; and from other experiments he finds, that the velocities computed, according to the reciprocal sub-triplicate ratio of the weights, agree much better with the conclusions deduced.
duced from those experiments, than those computed upon Mr. Robins's principles; though, in this mode of computation, the difference between the actual and computed velocities was in some of the experiments considerable. But as the powder itself is heavy, it may be considered as a weight put in motion along with the bullet; and if the density of the generated fluid be supposed always uniform from the bullet to the breech, the velocity of the centre of gravity of the powder, or of the elastic fluid, and the gross matter generated from it, will be just half as great as the velocity of the bullet; putting, therefore, $P$ to denote the weight of the powder, $B$ the weight of the bullet, and $v$ its initial velocity; then $B \dfrac{1}{2} + \dfrac{1}{2} P v = B + \dfrac{1}{2} P v$ will express the momentum of the charge at the instant when the bullet quits the bore. Instead, therefore, of ascertaining the relation of the velocities to the weights of the bullets, we propose to add half the weight of the powder to the weight of the bullet, and to compute the velocities from the reciprocal sub-triplicate ratio of the quantity $B + \dfrac{1}{2} P$: and the result of several experiments shews an agreement between the actual and computed velocities that is very remarkable.

We shall only add, that Mr. Thompson disputes the justness of Mr. Robins's conclusion with respect to the force of gunpowder, which makes it 1000 times greater than the mean pressure of the atmosphere; whereas, from the result of one of his experiments, its force appears to be at least 1308 times greater than the mean pressure of the atmosphere. Phil. Trans. vol. lixxi. part ii. p. 229-321.

**Velocity of Light, Sound, Wind, &c.** See **Light, Sound, Wind, &c.**

**VeloM., or VellUM.**, is a kind of parchment (which see), that is finer, evener, and more white than the common parchment.

The word is formed from the French velin, of the Latin vitulus, belonging to a calf. See **Abortion.**

For regulations relating to makers of vellum, and duty on the same, see **Leather.**

**VELORE, in Geography, a town of Hindoostan, in the Carnatic; 14 miles W. of Arcot. N. lat. 12° 54'. E. long. 79° 15'.**

**VELOSO, a town of Portugal, in the province of Beira; 14 miles S. of St. Joao da Figueira.**

**VELPE, a river of Brabant, which joins the Demeer, at Halen.**

**VELPI, in Ancient Geography, mountains of the Cyrenaica, on the confines of Africa Propria. These mountains were inhabited by the Macatutes, according to Ptolomy.**

**VELSHER, or Welscher, Mark, in Biography, was born at Augsburg, of an ancient and opulent family, in 1558, and educated at Rome under the celebrated Muret. Upon his return to his native city he procified at the bar, and became a senator in 1592, and having attained the highest rank in the government of the city, he was regarded as its chief ornament; nor was he less distinguished as the promoter of literature and science. He died in 1614, at the age of 56. The principal of his works, which were numerous, are "Re- rum Augvltanarum Vindelicarum Lib. VIII." Venet. 1594, and "Rerum Boicarum Libri V." Aug. Vind. 1602. He was a principal contributor to Gruiter's Collection of In- scriptions, and he aided many others in their publications. A collection of his writings was published in a folio volume at Nuremberg, in 1682. Bayle. Gen. Biog.**

**VELT, or VELTE, in Commerce, a measure for brandy in several parts of France. At Bourdeaux, brandy is con- tained in casks of 50 velts, more or less; but it is sold by the barrel of 32 velts, or about 60 English gallons: 5 velts proof of Bourdeaux make 4 velts proof, by which it is sold in London. At Cognac, it is sold by the 27 velts; and 11 velts proof of Cognac make 10 velts proof, by which it is sold in London. At Rochelle, brandy from this place, Cognac, Ile de Ré, and the river Charente, is in casks of 3 barriques, containing in all 75 or 90 velts, and is sold by the 27 velts: 16 velts = about 31 English gallons. At Bourdeaux, 1.14 barrique = 100 English gallons, and each barrique measures 14.033 cubic inches: 52.74 velts = 100 English gallons, and each velt = 438 cubic inches. At Cognac, 51.68 velts = 100 English gallons, and each velt measures 447 cubic inches. At Nantes, 67.34 velts = 100 English gallons, and each velt measures 536 cubic inches; and 51.79 brandy velts = 100 English gallons, and each velt measures 446 cubic inches.**

**VEL TE, in Ancient Geography, a people of European Sarmatia, in a part of the Venedic gulf.**

**VELTHAUSEN, in Geography, a town of Germany, in the county of Beitham; 2 miles N.E. of Nienhuis.**

**Gen. Ch. Cal. none. Cor. of one petal, tubular, nearly cylindrical; limb regular, in six very short, broad, orho- equal, segments. Stam. Filaments six, thread-shaped, in- fered into the tube and not projecting beyond it; anthers ovate, cloven at the base. Pfl. German superior, roundish; style thread-shaped, decucling; stigma filiform, acute. Peric. Capsule membranous, somewhat pellucid, three-doubled, three- celled, each lobe extended into a compressed rounded wing. Seedsably foliate, obovate, rather compressed.**

**Eff. Ch. Corolla tubular, with six teeth. Stamens inserted into the tube. Capsule membranous, with three wings, and three cells, with folialyte buds.**

**Ob. Ch. This genus, confounded by Linnaeus with his Abeliris, is well separated therefrom, as well as from Tri- toma, (see those articles,) both on account of their habits and characters. The genuine Abeliris is a funnel-shaped corrugated corolla, into the base of whose segments the filaments are inserted; and many seeds in each cell of the cap- sula. Triptoma is distinguished by its long flaments, inserted into the receptacle, and projecting far out of the flower.**

1. V. wacholskia. Waved-leaved Veltheimia. Willd. n. t. Ait. n. 1. Jacq. Hort. Schoenbr. v. 1. 41. t. 78. (V. cap- pensis; Redout. Lilia. t. 1. 5. 195. Abeliris capensis; Linn. Sp. Pl. 456. Curt. Mag. t. 501.)—Leaves lanceolate, ob- tuse, with wavy edges. Teeth of the corolla rounded, creaf.,—Native of the Cape of Good Hope, from whence its bulbs are said to have been first imported into this country in 1768, by the late Mr. Malcolm. The plant is now frequent in most good greenhouses, flowering copiously in the winter and spring, yet it is not easily increased, either by root or by seed. The bulb is ovate, larger than a hen's egg. Leaves numerous, all radical, spreading, smooth, a span long.
long, entire, broadly undulated; of a deep grays-green above; pale and glaucous beneath. Stalk solitary, erect, straight, naked, eighteen or twenty inches high, elegantly spotted and streaked with blood-red or purple, bearing a long, dense, ovate cluster, of pendulous nodorous flowers, each accompanied by an awl-shaped pink bract, much longer than its stalk. The corolla is of a waxy pink, or glaucous rose-colour, pale yellow, or greenish, about the extremity; its length about an inch and a half. Capsules nearly the same length, of a tender bladdery texture, pale and pellucid, so as to show the black seeds within.

2. V. glauca. Glaucous-leaved Veltheimia. Willd. n. 2. Ait. n. 2. Curt. Mag. t. 1091. Jacq. Hort. Schoenbr. v. 1. 4o. t. 77. (Apletris glauca; Ait. ed. 1. v. i. 463.)—Leaves lanceolate, tipped with a small point; somewhat crisped at the margin. Teeth of the corolla spreading.—Native-like of the Cape of Good Hope, from whence it was brought to Kew garden by George Wyench, esq. in 1781, being among the many new species of plants, chiefly from that country or from America, for the knowledge of which the botanical world is indebted to the late Mr. Aiton, and his learned coadjutors, in the first edition of the Hortus Kewensis. The number of such is greatly increased in the second edition, principally from New Holland and the East Indies. No work of the kind has furnished so many. The plant before us differs from the preceding in having a more oblong pointed bulb; much straighter and more erect leaves, glaucous on both sides, whose marginal undulations are slight and very small. The flowers are smaller, paler, and less showy; their marginal segments more expanded. This is much more rare than V. viridifolia, being more difficult of culture and less handsome. It flowers from January to April. For the two other species referred to this genus by Willdenow, Uvoria and pumila, see Tritoma.

VELTZEN, or ULENZ, in Geography, a town of Westphalia, in the principality of Luneburg; 20 miles E. of Lucko.

VELVALEG, a town of Grand Duchy; 5 miles S. of Arlenck.

VELUCA, in Ancient Geography, a town of Hispania Citerior, belonging to the Arvaci. Ptolemy.

VELVET, a rich kind of fluff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being very strong and close. The word is formed of the French velours, which signifies the fame, and which comes from velu, a thing covered with hair.

The knap or shag, called also the shelving, of this fluff, is formed of part of the threads of the warp, which the workman puts on a long narrow channelled ruler, or needle, or wire; and which he afterwards cuts, by drawing a sharp steel tool along the channel of the needle to the ends of the warp.

The principal and best manufactories of velvet are in France and Italy, particularly at Venice, Milan, Florence, Genoa, and Lucca; there are others in Holland, let up by the French refugees, of which that at Haarlem is the most considerable.

Velvets are now made to great perfection at Manchester and other parts of England. There are some brought from China, but they are the worst of all.

There are velvets of various kinds, as plain, that is, uniform and smooth, without either figures or stripes; figured, that is, adorned and worked with divers figures, though the ground be the same with the figures; that is, the whole surface velveting;—ramages, or branched, representing long stalks, branches, &c. on a fattin ground, which is sometimes of the same colour with the velvet, but more usually of a different one. Sometimes, instead of fattin, they make the ground of gold and silver, whence the denominations of velvets with gold grounds, &c.:—uncut, that in which the threads that make the velveting, have been ranged over the channelled ruler, or wire, but not cut there:—striped, that in which there are stripes of divers colours running along the warp; whether those stripes be partly velvet and partly fattin, or all velveting:—cut, that in which the ground is a kind of taffety, or gros de Tours, and the figures velvet.

Velvets are likewise distinguished, with regard to their different degrees of strength and goodness, into velvet of four threads, three threads, two threads, and a thread and a half: the first are those where there are eight threads of fagg, or velveting, to each tooth of the reed; the second have only fix, and the reed four.

In general, all velvets, both worked and cut, shorn and flowered, are to have their warp and shag of organzine, spun and twisted, or thrown in the mill, and their wool of silk well boiled, &c. They are all of the same breadth.

VELUM, in Ecclesiastical Writers, the fame with what is otherwise called brandew.

VELUM Quadragesimale, a veil or piece of hangings, anciently drawn before the altar in Lent, as a token of mourning and sorrow.

VELUM, in Anatomy, a part in the brain. See Brain.

VELUM Palatii, or Pendulum, the soft palate. See Digestion.

VENA, in Mythology. See Vena.

VENA, Vein, in Anatomy. See Ven.

VENABULUM, in Antiquity, a long kind of spear, used in hunting wild beasts.

VENÆ LACTEA, in Anatomy, the abserving vessels, so called because they were suppos'd to be veins. See Lacteal Vasa.

VENÆ Lympathica. See Lymphatics.

VENAFRO, in Geography, a town of Naples, in Lavoria, the fee of a bishop, fullragan of Capua; 14 miles N. of Sezza. T. l. 41° 30'. L. long. 13° 58'.

VENAFRO, (Venafro,) in Ancient Geography, a town of Italy, in Campania, northwards, towards the Sannin, which became a Roman colony. It was famous for its olives and oils.

VENAISSIN, Comtat du, County of Venaisin, in Geography, a country of France, bounded on the N. by the department of the Drôme, on the E. by the department of the Lower Alps, on the S. by the department of the Mouths of the Rhone, and on the W. by the Rhone, which separates it from the department of the Gard, about 12 leagues in length, and 7 in breadth. It takes its name from Venaque, the Vendanca or Vendica of the ancients, and was poisseld, after the 11th century, by the counts of Touloufe.
Touloufe, but reasserted again in the 13th century, and held by count Raymond the elder. The papas lai claim to the sovereignty of this country from the time of count Raymond de St. Gilles, although it is certain that the emperors, as kings of Arles, had exercised that power. In the year 1234, the emperor Frederick II. transferred the imperial rights of the county of Venaissin to Raymond the younger. And the pope found himself compelled to relinquish them to him. From the descendants of Raymond, it came to Philip the Bold, king of France, who in the year 1275, restored it to pope Gregory X. as a fief of the see of Rome, and it has been governed under the popes, by officers called rectores. The soil is fertile, the climate mild, and the air pure; the productions are corn, olives, silk, saffron, and excellent wine. Carpentras was the capital. This country now belongs to France, and forms part of the department of the Vaucluse, being formally ceded by the pope on the 10th of February 1797.

VENAL, or VENOUS, among Anatomy, something that bears relation to a vein.

The extremities of the cava and pulmonary veins, where they enter the auricles of the heart, are called venous sinusae. See Vein.

VENAL, formed from venalis, to be sold, is also used for something bought with money, or procured by bribes.

Thus we lay, venal bards; courtzans and flatterers are venal; even justice, in Turkey, is venal, and must be bought of the bathaws.

In England, there are several offices in the revenue, policy, &c. venal; but this venality of offices is no where so considerable as they were in France, where all offices of judicature were bought of the king, and only municipal officers are elected. Offices in England are venal only by a kind of connivance; in France it was a thing solemn and authorized. The venality was first introduced by Louis XII. who, to clear those immense debts contracted by his predecessor Charles VIII. without burdening his people with new taxes, betook himself to sell the offices of finance; and, in reality, he made a vast sum by it; but he forbade, by an edict in 1508, the sale of offices of judicature. Francis I. made an advantage of the same expedient to get money, and sold his poits, not excepting the offices of judicature, openly: under this king, it was only accounted a kind of loan; but that loan was no more than a name to dignify a real sale. However, it is said, that the sale of offices of judicature was established by edicts of Charles IX. and that military offices were sold under the reign of Henry III.

The parliament, not being able to reft the venality of offices, always made the buyer take an oath that he did not buy his poit, either directly or indirectly; but there was a tacit exception made, of monies lent the king for being put into them. At length the parliament, finding its oppositions were in vain, and that the traffick of offices was publicly authorized, abolished the oath in 1597.

VENAMALI, in Mythology. See Vanamali.

Gen. Ch. Cal. Perianth inferior, of one leaf, cup-shaped, short, with five rounded marginal lobes. Cor. Petals five, regular, obovate, rounded, spreading, thrice the length of the calyx. Stam. Filaments five, awl-shaped, dilated at the base, the length of the petals; anthers oval, verfatile, incumbent. Pfl. German superior, ovate; style short and thick; stigma obtuse, nearly triangular. Recept.
citron in bulk, being in size equal to, and sometimes exceeding a man's head; the rind is like that of the golden
remnet; the pulp is of a reddish colour, and its taste parts
of sweet and acid, refembling that of grapes not fully
ripe. A liquar is preflled from it, as in Europe from apples,
pears, &c. It will keep for a whole year.

VENDEE, in Law, the person to whom any thing is
sold, in contradiftinction to vendor, or the fellor.

VENDEE, in Geography, a river of France, which rises
about eight miles N.N.E. from Fontenai-le-Comte, and
runs into the Sevre Niortoise, about a mile E. of Marans.

VENDEE, one of the nine departments of the western
region of France, formerly Lower Poitou, lying between
Charente and Lower Loire, in N. lat. 46° 30'; bounded
on the N. by the departments of the Lower Loire and
Mayne and Loire, on the E. by the department of the
Two Severes, on the S. by that of the Lower Charente, and
on the S.W. and W. by the sea. Its territorial extent is
7242½ kilometres, or 373 square leagues, and the number
of its inhabitants is 270,271. It is divided into 3 circles
or districts, 29 cantons, and 324 communes. The three
circles are, Sables d'Olonne, including 87,653 inhabitants;
Montaig, 65,649; and Fontenai-le-Peuple, 116,075. Accord-
ing to Hasslerat, its extent in French leagues is 24 in
length, and 21 in breadth; its circles are 6, its cantons 58,
and its population 305,610. Its capital is Fontenay. Its
contributions, in the eleventh year of the French era, were
2,438,463 fr.; and its expenses for administration, judi-
ciary, and for public instruction, were 251,615 fr. 33 cents.
This department, watered by many copious streams, is one
of the most fertile in France. It is divided by nature into
the thicket, the marsh, and the plain. The thift, so called
on account of the great quantum of wood that covers it,
includes nearly five-ninths of the whole territory. Its soil
is of various qualities, yielding grain, wine, and excellent
pastures. The second, lying on the W. and S. coasts,
formerly covered by the sea, is impregnated with saline
substances. Nevertheless it is fertile, producing plentiful
crops of grain, flax, hemp, and pastures. The third is a
fertile and well-cultivated strip of land, included between
the thicket and the S. border of the department. Bouin,
an island containing about three square leagues, participat-
es in all the qualities of the marsh. It was separated, not many
years ago, from the main land by a narrow channel, which
has now almost disappeared. Noirmontier (which fee) is a
fertile island containing about three square leagues, oppo-
site to the N. extremity of the department. It has a port
capable of receiving vessels of fifty or sixty tons. But
down of fine soil, near its N.W. coast, are frequently
raised by the wind, and driven into the interior part of the
island. Ille Dieu is a very small island, covered with a thin
bed of vegetable soil, mixed with sand, and not producive.

VENDÉLA, in Ancient Geography, a town of Hispam
Citerior, belonging to the Autrigones. Ptolemy.

VENDELOS, in Geography, a town of the island of
Ceylon; 64 miles N.E. of Candi.

VENDEN, a mountain of the Tyrole; 14 miles
N.N.E. of Brixen.

VENDEN, a town of Ruffia, in the government of Riga,
on the Aa. In the year 1577, Magnus, duke of Holstein,
was brought to this town by Ivan Vassilевич II. czar of
Ruffia, to be made king of Livonia; but the new monarch
was prevailed upon by his subjects, ever averse to the Ruflia
yoke, to form a secret alliance with the king of Poland, and
to counteract the czar's progress in Livonia. Ivan, soon
apprized of this negotiation, laid immediate siege to Venden,
with so numerous an army, that the inhabitants, finding all
opposition ineffectual, proposed to capitulate. Magnus
himself carried the terms of capitulation, and advancing to
suffocate the incensed monarch, threw himself at his feet,
and interceded for the town. The czar, spurning at him
with his foot, and striking him in the face, loaded him with
reproaches for his ingratitude, and ordered him to prifon;
then entering the town, his troops committed every species
of horror and devastation. Many of the principal inhabi-
tants, retiring into the citadell, determined to defend it to
the last extremity; but soon perceiving all resistance to be
fruitless, and expecting no quarter, they calmly assembced,
received the sacrament, and then destroyed themselves, by
blowing up the citadell; 36 miles N.E. of Riga. N. lat. 57°
12'. E. long. 25° 14'.

VENEDINUS, in Ancient Geography, a town of Upper
Moedia, at a disance from the Danube. Ptolemy.

VENDEVIU, in Geography, a town of France, in the
department of the Aifine; 8 miles S. of St. Quintin.

VENITIONI EXONAS, in Law, is a judicial writ,
directed to the sheriff, commanding him to fell goods, which
he has formerly, by commandment, taken into his hands,
for the satisfying of a judgment given in the king's court.

VENDITOR REGIS, the king's salseman, or person who
exposed to sale goods or chattels seized or disdained to
answer any debt to the king. This office was granted by
king Edward 1. to Philip de Lardimer, in the county of
York, "Ita quod ipse, vel certus suus aturnnatus, ibit ad
mandatum vicicumitis de loco in locum infra com. pred.
sumptibus suis, ad videntiones facienda, & capiat de una
quaque venditio pro feodo fuso xxxi. den.;" but the office
was feized into the king's hands for the abufe thereof,
anno 2 Ed. IT.

VENOEUVRES, in Geography, a town of France,
in the department of the Aube; 11 miles W. of Bar-sur-
Aube.

VENEDOME, a town of France, and principal place of
a district, in the department of the Loir and Cher, on the
Loir. Before the revolution, it gave name to a county in
Beauce, called Vendomois; 18 miles N.E. of Tours. N. lat.
40° 28'. E. long. t° 8'.

VENDRE, le Port, a small sea-port town of France,
in the department of the Eastern Pyrenees; 12 miles S.S.E.
of Perpignan.

VENDRELL, a town of Spain, in the province of
Catalonia; 25 miles W.S.W. of Barcelona.

VENDRESSE, a town of France, in the department of
the Ardennes; 9 miles S. of Charleville.

VENDUE, denotes an auction or public sale.

VENDUM, in Ancient Geography, the name of one of theour towns pofted by the Japodes, in the country that
extended itself from the Pannonians to the Adriatic see.

VENECAC, a town of Asia, in the interior of Media.
Ptolemy.

VENEDI, a people originally of Sarmatia, who occu-
pied the whole coalt of the Venedic gulf, and who paffed
from thence into Germania with the Slavi, where they in-
habited the territory abandoned by the Germans. Ptolemy.

Jonnades says that these people, before this migration, had
been vanquished and subjugated by Hermericus, king of the
Goths.

VENEDICI MONTES, mountains of European Sarm-
matia. Ptolemy.

VENEDICUS SINUS, a port of the Baltic see, in which
were found the mouths of the Turunta, Chefinus, Rube,
and Chronus. Ptolemy.

VENEDITOVA, in Geography, a town of Ruffia, in
Vol. XXXVI.
the government of Irkutsk, on the Amur; 8 miles E.N.E. of Nertchinsk.

Veneering, Veneering, or Fineering, a kind of marquetry, or inlaying, by which several thin slices, or leaves of fine wood, of different kinds, are applied and fastened on a ground of some common wood.

There are two kinds of inlaying; the one, which is the more ordinary, goes no farther than the making of compartments of different woods; the other requires much more art, and represents flowers, birds, and the like figures.

The first kind is what we properly call veneering; the latter we have already described under Marquetry.

The wood intended for veneering is first fawed out into slices, or leaves, about a line thick: in order to faw them, the blocks or planks are placed upright, in a kind of saw-prefs; the description of which may be seen under the article Press.

These slices are afterwards cut into slips, and fashioned divers ways, according to the design proposed; then the joints being carefully adjusted, and the pieces brought down to their proper thickness, with several planes for the purpose, they are glued down on a ground, or block of dry wood, with good strong English glue.

The pieces thus joined and glued, the work, if small, is put in a press; if large, it is laid on the bench, covered with a board, and pressed down with poles, or pieces of wood; one end of which reaches to the ceiling of the room, and the other bears on the boards.

When the glue is quite dry, they take it out of the press and finish it, first with little planes, then with divers scrapers, some of which resemble rasps, which take off dents, &c. left by the planes.

When sufficiently scraped, the work is polished with the skin of a sea-dog, wax, and a brush and polisher of thave-grafs: which is the last operation.

Venelius, or Venelli, in Ancient Geography, a people who inhabited the maritime part of Lyonnese Gaul, and whose capital was the town of Crociatunum. Ptolemy.

Venellis. See Vicius & venellus mundandis.

Venenum Coeci, a term used by many of the ancients for the purple tinge, which the kermes berry, as it is usually called (see Kermes), gave to linen, or other things.

The word venenum being generally understood to express poison, it has been supposed by many, that the kermes was esteemed poisonous, or that there were two sorts of this drug; the one a harmless medicine, the other poisonous. But there is no warrant for this in any of the old writers, and the whole seems indeed but a mistake about the sense of the word venenum, which we find by many passages of the best authors, signified a fainth, as well as a poison.

The ancients called the infemts dyed scarlet with the kermes indifferently, by the names of flammea or venenate. Servius tells us, that in certain sacred ceremonies, it was necessary that the priest should be clothed in a scarlet robe; and he uses the word venenate to express it in some places, and flammeo in others.

Vener, one of the many names by which the chemists call mercury.

Veneré, Cape or Capo di Venere, in Geography, a cape on the coast of Genoa. N. lat. 44° 4'. E. long. 9° 40'.

Venera Conchla, in Natural History, the name of a very large and elegant genus of shells, more usually called porcellane. See Porcelain Shell.

Veneral, something belonging to Venus.

A venereal person is one addicted to venery, or venereal pleasures. Venereal medicines are called aphrodisiacs, provocatives, &c.

Veneral Virus, in Surgery. Of all the maladies which afflict human nature, none has excited greater controversy than that to which we now refer. Fortunately, however, it is likely in the end to prove a means of inducing an accuracy in description, a clemency of reasoning, and legitimacy of induction, for which we have in vain looked in the healing art. A diseased taint, as it was called, was supposed to be everywhere present, to remain for ever with a person once infected, and to descend to his posterity. Even Aflruc, who detected some of the laws of this poison, affinities it to a Pandora's box, and describes the supposed changes it has undergone at different periods of the world, as similar to the revolutions of empires; thus eluding the most important question in his whole dissertaiton by a poetical image, and by an illustration of the immutable laws of nature, taken from the vicissitudes of human institutions. Yet even Aflruc was rational compared with some of his successors. He at least described the primary symptoms with accuracy; in the others, he seems puzzled by an attempt to reconcile contradictory opinions, and, we ought to add, by a want of confidence in his own observation: this however can only be said of primary symptoms.

On secondary symptoms, he was as much at a loss as every honest man before and since his time; and his only error was in attempting to account for these difficulties, instead of acknowledging his incapacity to do so. Boerhaave did not suppose himself to be a Tyro in this disease, after all Europe had pronounced him qualified to be a teacher in the whole science of medicine. Sydenham, with every other writer of any celebrity, will be found either admitting his ignorance, evading the question, or solving it in an unsatisfactory manner.

After all we have already said, (see Morbid Poison, and Lues Venereal,) it might seem unnecessary to return to the subject, were it not, that even in so short a time since the publication of those articles, new facts have occurred; and we shall in this, as in most inquiries into nature, every new discovery proves not only a confirmation, but in some measure an illustration of what Mr. Hunter taught us. We might add, as a further apology, that his manner of conducting this single inquiry by the facts he produced, now universally admitted, by the caution with which he drew his inferences, and the legitimate inductions which necessarily followed, affords, if not the first, the most perfect model of this mode of reasoning to be met with in the whole science of pathology.

The first consideration was to establish the true character of the venereal ulcer, or chancre. For want of this, every ulcer found in fulphurous parts was considered the effect of that morbid poison; and from this unhappy error, the firmest constitutions were often destroyed by repeated applications to cure diseases, which, if not the effect of, were exasperated by mercury. During his life-time, Mr. Hunter had the happy chance to see a little remission of this cruel practice. But unfortunately, when he could be no longer consulted in person, another error arose, namely, that all such ulcers as yielded to this remedy were venereal. Hence arose a practice the most truly empirical, that of preferring for a disease by its suppos'd name, and judging of its reality by the effect of our remedy. In vain was it argued from his writings, that the cure by the same remedy was no proof of the identity of diseases, and that even this proof, if sufficient, was rarely present; for that these ulcers which had not the true venereal character, yielded to mercury with a readiness very different from that constitutional effect which was necessary for the cure of the true venereal chancre.

Dr. Adams has since showed, (see his Morbid Poisons,) that...
all these ulcers, excepting the venereal, were well known to
Celsus, who describes with much accuracy in his chapter
de observarum partium vititi all those ulcers on the genitals
which are mentioned by writers since the appearance of
syphilis as varieties of or anomalies in the venereal charac-
ter. Yet it is hardly credible, that almost to this day
there are writers who will conceive that local diseases,
different in character in all their stages, in their mode of spreading
and healing, and requiring different modes of treatment,
must still be the same; who, while they admit that the ve-
neral diseafe is of comparatively recent origin, will still confound
it with appearances most accurately described more than
twelve centuries past.

Mr. Hunter, with that accuracy which distinguishes all
his remarks, began by fixing the character of the disease,
even shewing, that from the laws of the economy, as
afcertained in all other local diseases, such must be the char-
acter of an ulcer arising from some external cause, and for
the cure of which animal economy had made no provifion.

Firstly: In every local irritation, he shewed that a secretion
of some fluid would take place, by which the irritatting sub-
ject might be removed. The venereal matter, therefore,
irritating a solid part, induces ulceration, that the part may
rid itself of this irritating cause. But from the nature of
a morbid poison, the effeét of that irritation is to pro-
duce a local action, by which a substance is secreted similar
to that which induced the irritation. In some cases, as in
small-pox, as soon as this effeét is produced it ceaftes, and
the parts heal as readily as after any other loss of substance;
but such is not the ease with an ulcer from venereal poison.
When this is once set up, this action continues until some
substance induces a more powerful irritation, and thus super-
fede the venereal.

Secondly: When the curative process of a sore from any
cause is interrupted, it must spread, or a new action must be
set up. This new action, in common ulcers, is the formation
of thick, or, as they are usually called, callous edges, after
which the ulcer remains stationary. This was well re-
marked by Celsus, who gives this process the name of
venifus, describing the thickened lips, and remarking, that
whilst they continue, no applications to the ulcer are of
any ufe.

Thirdly: The peculiarity which distinguishes the venereal
ulcer from all others is, that the incapacity in the part to
alter the diseased action, produces the fame effeét as in
parts where there is any other impediment to healing;
namely, the thickened edge and bafe. But though the
attempt at healing is given up, still the irritation continues
from the constant prefeence of the virus, and consequently the
ulceration also, in order to rob the part of the caufe of such
irritation. Hence we have what is not to be met with in
any other ulcer, namely, a continued ulceration, attended
with or accompanied by a hard edge and bafe. This is
the only true primary venereal ulcer, and the only ulcer or
vitium not defcribed by Celsus in the chapter before
alluded to.

The next question was, in what manner a disease incur-
able of itself was always relieved by mercury. For this a
thousand whimsical caufes were afligned, the most common
of which was, that mercury was its antidote. This no one
could doubt, but did such an effeétion do more than aflign
a word where we were looking for an action? At length
Mr. Hunter shewed, that this also was perfectly confident
with what had been before obferved; namely, if the venereal
ulcer is the effeét of an action arising from the irritation
of a specific substance, the cure must be effected by the
ufe of another substance, the effeét of whose irritation
would be greater than the irritation excited by venereal
matter; and the manner in which the disease always yields
to the remedy, confirms the doctrine. For no quantity
of this antidote, as it is called, will produce any effeét on
a venereal ulcer, unless an excitation is induced greater
than the venereal; that is, if the chancr is recent, a very
light mercurial irritation will be fufficient to alter its action;
if more irritative, the mercurial irritation must be excited
proportionally higher, and be longer continued.

It may at first feem that we have gained little, inasmuch
as we have now a more fevere diseafe than before. But it
will readily occur, that the parts themselves are capable of
forming venereal matter, which is the caufe of the first irri-
tation, and which will continue till the action excited by that
irritation is fuperfeded. But the parts are not capable of
forming mercury, by which the fecond irritation is induced;
we might therefore expect, as actually happens, that when
the ufe of mercury is fuperfeded, the action excited by it
would gradually ceafe also, and the parts be reftored to
their original or healthy action.

But other difficulties remained. After the ulceration of the
facets was perfectly healed, it sometimes happened, at un-
certain periods, that the throat, the skin, or the bones, or
all of them, would fhew diseased actions, which, though very
different from those on the genitals, were equally incurable
without the remedy; and which, from their uniformity in fo
many subjects, whether during the primary symptoms, or
after they were healed, evidently arose from the fame cause.
The ignorance of former practitioners induced them to
fufpect that thefe symptoms of confirmed pox, as they were
called, arose from an inflicted ufe of the remedy when the
chancr was healed. Yet it was impossible they should
be ignorant, that in many instances in which but comparative-
lily little mercury had been ufed, none of thefe symp-
toms on dilatent parts of the body had occurred; and in
other parts in which the mercury had been ufed to a very
great excess, the patient had been a fecord or a third time
affected, though always in different parts, and with local
complaints, different from primary ulcers, yet arising from
a similar cause. Besides, if the disease occurred from the
want of a fufficient ufe of mercury, how did it happen that
the parts first affected should remain found, and parts not
previously fhewing any diseased action, should now become
in a state of open ulceration?

To account for this, Mr. Hunter shewed, that though it
is now well afserted, that mercury will with certainty
cure every form of the venereal disease which we can
detect; it does not follow that it will cure it before fuch
an action has commenced, as vinceis itself by fome alteration
in the texture of the part; in other words, that it will fuper-
fede the venereal action by its higher irritation; but in order
to do this, the venereal action must have commenced.
But it is urged, that doubtles the venereal action has com-
enced before we can trace it by our fenfes, and that there-
fore mercury ought in this flate to fuperfede it, and to
prevent its arriving at open ulceration. In anfwer to that,
Mr. Hunter produces his facts, and shews that when the
action has appeared, it invariably yields to mercury, and
never appears again from the fame fource of infection in the
fame order of parts. He taught us alfo what is now
universally admitted, that in the skin and throat it is always
curable by a much flichter course of mercury, than was
necessary for curing the primary chancr. Confequently, if
mercury could prevent the venereal action in thefe secondary
parts, the firft course would prove fufficient for that purpofe.
But the concurrent testimony of all the best writers goes to
prove, that none of them knew when to expect nor how to
prevent the appearance of the disease in more distant parts of the body, after it had been cured in the parts first affected; yet all knew how to cure it when it appeared in those distant parts. Boerhaave fancied he had discovered the cause of these difficulties, by comparing the solid texture of the bones with the more yielding condition of the softer parts. Both he and Dr. Swan were sensible how easy it was to cure the disease when it occurred in the skin and throat; but, as honest men, they were forced to confess their incapacity to prevent it, or even after they had cured it in those parts, to prevent its re-appearance in the bones, though in them also they could cure it with equal certainty after the diseased action had commenced.

An accurate attention to all these events induced Mr. Hunter to construct a series of experiments, by which he might ascertain the laws which govern the actions excited by this poison, and thus meet all the difficulties of former writers. His first object was to fix the precise character of the chancre, or primary venereal ulcer. Having done this, he watched, by every possible means, those cases in which secondary symptoms occurred, and was convinced that it did not depend on any causes which could with certainty be controlled. This he urged was not different from many other morbid poisons. In inoculating for small-pox, no one can ascertain whether the patient will have pustules beyond the spot inoculated. Had he lived to witness the effect of cow-pox, he would have found a still more striking analogy. It is well known that secondary vehicles from cow-pox, that is, a cutaneous eruption usually fourteen days after inoculation, and some few days after the inoculated part has scabbed, will sometimes appear at distant parts of the body; but we have no means of ascertaining under what circumstances these secondary eruptions occur, nor of preventing them, nor of producing them.

The conclusions drawn by Mr. Hunter were, first, that from every local action arising from a morbid poison, absorption takes place; secondly, that the absorbed virus circulating with the blood, and is ejected at some of the emunctories, probably the skin; thirdly, that for the most part it passes without contaminating any part in its pittance; but that sometimes the throat, or the skin, or the bone, or all three are contaminated. In these cases the parts thus contaminated take on the diseased action at certain periods, according to the nature of their structure, and the property of the morbid poison; for it is well known that, if any, morbid poisons produce their effect, till a certain period after their application. The small-pox effluvia are received usually from ten to fourteen days, before the diseased shews itself; and the effect then commences on the face several days before the lower extremities exhibit any pustules. Under inoculation, the pustules on distant parts of the body appear at periods later than on the inoculated parts. But though every morbid poison requires a certain period between its application and the effect produced, and though this period is different in different morbid poisons, yet there is a medium in each; and Mr. Hunter ascertained, that the medium for the appearance of the secondary symptoms of syphilis is usually on the skin or throat, six weeks after the cession of the irritation excited by the mercurial douche which cured the primary disease or chancre; that the appearance on the bones is usually three months after the same event; and that if the patient remains well longer than those periods after the healing of the chancre, he may for the most part consider himself free from any further danger from that source of infection. It must be admitted, that these periods are not always precise; but the same may be said of the small-pox, cow-pox, and other morbid poisons; and when we consider that the medium in one instance is from ten to fourteen days, and in the other from six weeks to three months, it must follow that the variations in each are not greater than their comparative medium would lead us to expect.

From these facts Mr. Hunter improved the practice in this disease so much, that we are often led to believe the disease itself to be milder than heretofore. But the truth is, that we now have some method in directing our treatment, which till his time could hardly be said to be the case. It was known, indeed, that mercury would prove a cure; but neither was the character of the disease accurately ascertained, nor the laws by which it yielded to the remedy, nor to which the secondary symptoms were imputable. Hence mercury was indiscriminately applied to all ulcers on those parts, and many were greatly exasperated by it; and as in the true disease secondary symptoms sometimes occurred, the patient was overwhelmed with a disgusting and deleterious remedy, to prevent what could not be prevented, though it rarely occurred; and when it did occur, was readily cured. But the mode of treatment was far from being the only advantage of Mr. Hunter's discovery. By ascertaining the laws of the disease, he relieved the practitioner from every embarrassment, when secondary symptoms occurred; and the patient from the perpetual dread of an evil, from which it was supposed neither he nor his offspring were ever secure.

It is not to be wondered if the obscurity of Mr. Hunter's mode of writing on a subject familiar to himself, but new to every reader, for a long time precluded the world from the benefit they have since derived from his discoveries. For this benefit we are indebted to Dr. Adams, and perhaps to those writers who attempted to controvert the doctrine itself. The latter were very numerous, and, as often happens, few were acquainted with the subject they opposed. Dr. Adams explained the difficulties principally by shewing the errors of his master's antagonists, and at this time we believe the doctrine is universally admitted by all those who take the trouble to study it. That is, that the antitodal property of mercury conflicts in the high irritation it excites; that no ulcer on the genitals is syphilitic, unless it continues to spread with a hard edge and base; that it is useless to give mercury in order to prevent the secondary symptoms of the disease, either in the skin or bones, though that remedy will always cure them, if they should appear; and that if these secondary symptoms do not appear before a certain period after the primary ones, there is no reason to apprehend their appearing at all, unless the patient exposes himself again to the same cause. Such is the general doctrine of Mr. Hunter, divested of certain expressions, by which action is with more technical precision distinguished from disposition. As this language is not necessary we have not introduced it, but refer such of our readers as wish to be acquainted with the precise terms of the discoverer, to the article Lues Venerea.

Dr. Adams has carried one of Mr. Hunter's opinions somewhat further than the inventor. Mr. Hunter had observed, that after the venereal action of the primary ulcer was superseded by the mercurial irritation, new flesh would sometimes arise, but that it rarely happened that such new flesh would regularly cicatrize or heal. His commentator shewed that this was not peculiar to this disease, but extends to all morbid poisons; that in the small-pox and cow-pox it produces the pitting from the first; and that in all other morbid poisons where there is a loss of substance, that loss is never restored by the common means.
VENERY is used for the act of copulation, or coition, of the two sexes.

It takes its name from Venus, the supposed deity of the passion of love.

VENERY also denotes the art or exercise of hunting wild beasts; which are also called beasts of venery, and beasts of the forest.

Such are the hare, hart, hind, boar, and wolf. See BEAST, GAME, and HUNTING.

VENESCATION, in Surgery, the operation of opening a vein, for the purpose of taking away blood for the relief of diseases. See BLEEDING.

VENESS, in Geography, a cape on the S.E. coast of the island of Eady. N. lat. 59° V. W. long. 2° 38′.

VENETA BOLUS, a fine red earth used in painting, and called in the colour-shops Venetian red. See Red.

It is improperly denominated a bole, being a genuine species of red ochre. It is of a fine bright, and not very deep red, approaching, in some degree, to the colour of minium, or red-lead, and is moderately heavy, and of an even and smooth texture, yet very friable, and of a dusty surface: it adheres firmly to the tongue, is very smooth, and soft to the touch, easily crumbles to pieces between the fingers, and very much stains the skin in handling. It has a flight astringent taste, efficaciously considerably with aquafortis, and in water immediately breaks into a fine powder.

It is dug in Carinthia, and sent from Venice into all parts of the world, being an excellent colour, and very cheap; our colourmen, however, find too many ways of adulterating it. Hill and Da-Cola.

VENETI, in Ancient Geography, a people of Italy, in Venetia, of Celtic origin. According to some historians they were the descendants of a colony of Trojans, who came to establish themselves here on the ruins of their own country; but Herodotus says that they were an Illyric nation.—Alfo, a people of Gallia Celtica, in Armorica, who inhabited the peninsula above the Namnet, according to Caesar (De Bel. Gall. lib. iii. c. 8) who ascribes to them the glory of being the most powerful of all the people who inhabited this coast, and who avoided themselves of their shipping, and of the science and practice of navigation. Ptolomy calls their capital Dariorium. Caesar denominates their territory Venetia, although the Veneti, who inhabited that province of Gaul which is now called Britain, excelled, as Caesar says, all the nations on the continent in their knowledge of maritime affairs, and in the number and strength of their ships; yet, when they were preparing to fight a decisive battle against the Romans by sea, they asked and obtained auxiliaries from Britain; which they certainly would not have done, if the Britons could have afforded them only with a few wicker-boats, covered with skins. It is therefore probable, that the people of Britain had ships much of the same form and construction with those of their friends and allies the Veneti, with which they joined their fleet on that occasion. The ships of the Veneti are described by Caesar as very large, lofty, and strong, built entirely of thick planks of oak, and fo solid, that the beaks of the Roman ships could make no impression upon them. The combined fleets of the Veneti and Britons, in the famous sea-fight off the coast of Armorica, now Brittany, against the Romans, consisted of two hundred and twenty of these large and strong ships, which were almost all destroyed in that unfortunate engagement; by which the naval power both of Gaul and Britain was entirely ruined. This great disaster is believed, by some of the best of our antiquaries and historians, to have been the reason...
reason that the Britons never attempted to make any opposition to Caesar by sea, when the very year after it he invaded their country.

VENETIA, a country of Italy, which commenced E. of Gaul, near the lake Benacus, and the river Mineius, which flowed from it. Its boundaries to the N.E. were not very distinctly ascertained. Its principal rivers, beside the Po, were the Atheis, the Medoacus Major, and the Plavis. It was very fertile in pasture, and furnished excellent horses. The people were denominated Veneti or Heneti. Their principal towns were Hadria, Attele, Patavium, Verona, Vicentia, Altimin, Tarvisium, &c. See VENICE.

VENETICE, INSULA, or VENETORUM INSULA, comprehended, under this denomination, a great number of islands situated on the western coast of Gallia Celtica or Lyonensis. This general appellation included Belfile, Houat, Hedie, Gron or Groniais, now Quiberon. These islands occupied that part of the sea which was opposite to the continent inhabited by the Veneti; which fee.

VENETICO, in Geography, a small island in the Mediterranean, near the coast of the Morca. N. lat. 26° 41'. E. long. 25° 53'.—Alfo, a small island in the Grecian Archipelago, near the S. coast of the island of Scio.

VENETORI, a town of Walsachia; 24 miles W. of Buchareft.

VENETUS LACUS, in Ancient Geography, the name of one of those two lakes, which the Rhine formed near its source in the Alps. The lake now called Boden-fee, or more commonly the lake of Conflance, is called "Brigantium" by Pliney, and "Brigantia" by Ammianus Marcellinus. Strabo affigns to it 300 statia of length, and 200 of breadth. Its name Boden-fee is derived from a place called Bodman, situated at the extremity of the lake opposite to which is Bregenz, whence the appellations Brigantia and Brigantium.

VENEV, in Geography, a town of Russia, in the government of Tula, on the Ofer; 40 miles N.N.E. of Tula. N. lat. 54° 20'. E. long. 38° 14'.

VENEW. See VENICE.

VENEZIANO, ANTONIO, in Biography. Of this early painter the birth-place is not exactly known, as he is by one author supposed to have been a Venetian, and by another a Florentine. His principal works are at Pisa and Florence, and in the Ducal palace at Venice. He certainly improved upon the fyle of those painters who preceded him, if we except Giotto; his manner was less formal, and he is said to have painted well in fresco, and to have carried the management of it to a considerable degree of perfection. He died in 1384, at the age of 74.

VENEZIANO, DOMENICO, was born at Venice in 1429, and was a disciple of Antonio da Meffina, after he had, as Valari relates, learned the secret of oil painting from J. V. Eyck: and to him Meffina communicated his secret. He painted several pictures at Loretto and Perugia, and afterwards settled at Florence; where the novelty of his manner, and the ability with which he executed it, acquired for him considerable renown. Unfortunately for him, he formed an intimacy with Andrea Callagno, an eminent Tucan painter, and taught him the management of oil colours; when his treacherous friend conceived the horrid design of assassinating him, that he might remain sole possessor of the secret, and effected his detestable purpose in 1476, when Domenico had attained his 56th year.

VENEZIANI, ANTONI, a Sicilian poet, was born in 1543, at Monreale, and acquired great celebrity in science and polite literature, so that it was fashionable to cultivate acquaintance with him; and amongst those who fought this honour was Tasso. In 1578 he was taken, on a voyage to Rome, by an Algerine corsair, but redeemed; on his return to his native country, he was imprisoned under a suspicion of being the author of some writing against the viceroy of Sicily, and being confined at Palermo, he was destroyed in the castle by the explosion of a powder-magazine in August 1593. His writings consist chiefly of sonnets and lyric poems in the Sicilian dialect; and some of his compositions in pure Italian were printed at Palermo in 1572. A large collection of his Sicilian poems exists in MS. Gen. Biog.

VENEZUELA, in Geography, a province of the easter part of Terra Firma, or of Spanish America, included within the jurisdiction of the captain-generalship of Caraccas, which is not only the capital of this province, but the metropolis of the captain-generalship, the seat of the royal audience and of the intendancy, whose authority extends over the provinces of Venezuela, Maracaibo, Varinas, Camana, Guiana, and the island of Margarreta; extending from N. lat. 12° to the equator, and from 62° to 75° long. W. from the meridian of Paris. The name of Venezuela, which is in Spanish a diminutive of Venice, was given to this province on account of some Indian villages, which the first conquerors found on the lakes of Maracaibo. Others have erroneously ascribed the origin of this name to the following circumstance; viz. that Alphono Ojeda, having landed here in 1499, caused some huts to be constructed upon poles, in order to elevate them above the flagrant water which covered the plain; but though it is true that Ojeda, in 1499, visited the easter shore of Terra Firma, he never thought of erecting any huts over its flagrant waters. The chief place of the province of Venezuela has never been nearly on a level with the water. Caraccas is at least sixty toises above the level of the sea, and has no other water besides that of three brooks which pass rapidly through it, and of a small river which bounds it on the south. The first settlement of the Spaniards on the borders of the lake of Maracaibo took place in 1527. The population of Venezuela, including Varinas, conflated, in 1801, of 500,000 persons; that of the government of Maracaibo, of 100,000; of Camana, 80,000; of Spanish Guiana, 54,000; and of the isle of Margarreta, 14,000; making a total, according to the statement of Depons, of 728,008. The population of Caraccas, in 1802, is stated at from 41,000 to 42,000, consisting of whites, slaves, freed persons, and very few Indians; the first class forming nearly a fourth of the whole, the slaves a third, the Indians a twentieth, and the freed persons the rest. All the whites are either planters, merchants, military men, priests, monks, or persons employed in the administration of justice or finance. In this population, the whites are computed at two-tenths, the slaves at three, the defendants of freed-men at four, and the Indians compose the remainder. A late writer, professing himself a "South American," in his "Outline of the Revolution in Spanish America," (1817), says, that in the town of Caraccas alone there were 45,000 inhabitants; and the whole population of Venezuela, including the several provinces above enumerated, amounted in 1811 to more than 800,000. The foil of Venezuela is fertile, and yields, with prodigious liberality (says Depons), all the productions which are to be met with in the West India islands, besides many others which they do not possess. If a man labour, he must grow rich; and if he vegetate merely in idleness and sloth, he has only to flit, in order to gather from the soil more than sufficient to satisfy the wants of nature. The cacao of this province is abundant and excellent. It likewife furnishes
nilies Indian corn, indigo, tobacco, cotton, sugar, and coffee. Its vanilla, produced from a creeping plant, which, like the wild vine and ivy, entwines round the trees, is obtained in great plenty. Wild chilli is also the product of this country, and with due cultivation, it might be made to furnish a variety of woods, banks, and plants for the dye; and also gums, resins of balsam and medicinal oils; its farfaparilla is said to be as good as the whole of Europe; theaffras and liquorice abound; squills are plentiful; so are likewise florax, calia, aloes, &c. The horned cattle, affording the article of exportation (hides), the horses, mules, sheep, and deer, are here very numerous. It abounds in all kinds of game, and its rivers and lakes supply plenty of fish.

In order to give a brief account of the revolution that has lately taken place in this province, and in other parts of Spanish America, we shall trace the origin and progress of the Spanish establishments in this part of the world. Terra Firma was discovered by Christopher Columbus in 1498, in his third voyage from Spain to America. After having discovered the gulf of Paria, he coasted along Terra Firma as far west as the Teltigo islands, from which point he failed with a fair wind to St. Domingo. Ojeda obtained permission from the Spanish government to pursue the discovery; and having arrived at the territory of Maracapana, in the year 1499, he followed the coast as far as Cape de la Vela, entering several ports in order to collect more minute information. From Cape de la Vela he failed for St. Domingo, according to Oviedo and Robertson; but according to Charlevoix, he returned before that to Maracapana, a village upon the coast of Guatimala, and there had a brig built. Not long after, the account which Columbus had given to the Spanish government attracted to Terra Firma another vessel from Spain, whose real object was commerce, but which concealed its design under a permission from the king to prosecute the discovery of the country. This vessel, commanded by Christopher Guerra, touched on the coast of Paria, at Margareta, Cagua and Cumanagotl., now called Barcelona. In these places, in exchange for trinkets, he obtained a great quantity of pearls, gold, Brazil wood, &c. of which he formed a very rich cargo. Guerra pursued his course along the coast of the westward, and landed only at Coro, where he found, to his great astonishment, some Indians, as much disposed to take away from him whatever he had got, as those on the eastern coast had been given to them. He had too much to lose to run the risk of a war, by which neither glory nor enrichment was to be acquired. He, therefore, wisely took the resolution of returning to Spain, in order to place his riches out of the reach of danger.

The report of his arrival and fortune spread over the whole kingdom, and immediately from every part expeditions were fitted out for Terra Firma. At the same time, Charles V. gave permission to make slaves of the Indians who would submit or embark the conquest; a grant so much the more deplorable to humanity, as it strongly excited the avarice of those in whose hands men shipped the place of every other consideration. It is easy to imagine, that upon those coasts, where pilage had nothing to fear either from the vigilance of the magistrate, or the sword of justice, there must have been established a nefarious commerce which had no other object than inhuman avarice, no other reft but rapacity, tyranny, and ferocity. The crimes committed by that swarm of robbers, who contended with one another for superiority in feats of plunder, were so great and so numerous, that the cries of the victims reached the audience of St. Domingo, who are entitled to our applause for having immediately taken measures to make it appear to the inhabitants of the new world, whom they wished to lead rather than to drive into obedience, that the enormities of that scene of the Spanish nation were not properly chargeable on the nation itself. The audience sent thither, in quality of commissary and governor, a man of very great merit, named John Ampues, who arrived on the Coriana coast in 1527, with sixty men. His mildness, affability, and knowledge soon gained the confidence of the cacique of the Coriana nation; and a solemn treaty confirmed the union and alliance which they formed, and the cacique took the oath of allegiance and vassalage to the Spanish monarch. On the 26th of July, 1527, Ampues laid the foundation of Coro. Thus the province of Venezuela had the pleasing prospect of arriving, without commotion, to a degree of prosperity which would crown the happiness of its inhabitants. However, the commercial house of the Weflers, established at Augsburg, being considerably in advance to Charles V., the emperor submitted to the demand which they made of granting to them, under the title of an hereditaryief of the crown, the province of Venezuela, from Cape de la Vela as far as Maracapana, with the right of extending indefinitely towards the south. But the province having suffered much from the monopoly and tyranny of the agents of the Weflers, the treaty with them was rescinded, and the emperor appointed as governor the licentiate John Peres de Tolotla, who, according to Oviedo, had likewise the title of captain-general. This new reform produced a favourable change in the fylum and mode of conquest; and it was an established point, that instead of committing devastation, the conquerors should farm settlements; and instead of plundering, respect property. Laws, which had been enacted in 1526, 1542, 1550, and 1552, were put into execution. These laws declare the Indians to be free, not even excepting those who should be taken prisoners in the act of bearing arms. As soon as an Indian nation was subjected to the Spaniards, a convenient fite was chosen on which to build a town, for the better security of the conquest. One hundred Spaniards formed the population of the new city, to which a cabildo was attached. They afterwards divided the city in portions among the new inhabitants, according to their rank and merit; and after having made an enumeration of the Indians, they shared them among the Spaniards, who thus acquired over them a right, not of property, but of superintendence. This is what is called "Provinciamiento de Indios," the dividing of the Indians. This measure was followed by more fixed regulations, under the name of "encomiendas;" the effect of which was to place under the immediate superintendence and authority of a Spaniard, exemplary for his morals, the Indians who lived within a limited extent of ground, corresponding to that of the communes in France. In return for these attentions, the Indians were to pay the commisioned superintendants of the encomiendas, who were called encomenderos, a yearly tribute in laurour, fruits, or money. When this tribute was once paid, the Indians were exempted from every other personal service. It appears that, according to the solemn and special contract entered into between the kings of Spain and the conquerors, encomenderos, and settlers in Spanish America, politically divided by the Spanish government, and comprehending the vicerealties of New Spain or Mexico, Santa Fe de Bogota or New Grenada, Peru, Buenos Ayres, or the provinces of Rio de la Plata, and the captain-generalships of Guatemala, Venezuela, and Chili; these last were to remain lords of the country, on the basis of feudal vassalage, under the names of "encomenderos." Such, however, was the inhuman conduct of the first of these towards the natives, that Charles V. and his successors were under the necessity of
of gradually abolishing many of their privileges, and the "encomiendas" fell at length, in most of the provinces, to the crown; and certain inferior privileges were then granted to the settlers, in lieu of those originally poissified, with the titles of marquis, count, &c. Spanish America was from that time considered as a kingdom, independent in itself, yet united to Spain, as being both under the government of one king. The incorporation of this country to the crown of Castile was decreed by Charles V. in Barcelona, September 14, 1519, and confirmed by Donna Juana, Philip II., and Charles I. Accordingly, in the opening of the royal decree published in the year 1524, for the nomination of a supreme council for the Indies, the term kingdom is expressly used, and its use admits, that the habitants had a natural right to hold the appointments of profit and honour in the country. The energetic remonstrances of Montefino, Cordova, Las Cañas, and others, to the court of Spain, against the arbitrary measures of the conquerors and settlers, gave rise to the establishment of the Council of the Indies. (See Council of the Indies.) Whilft the legislative power of the kingdom of the Indies rested in this council and the king, the executive power belonged to the viceroy and captain-general. The viceroyos were also invested with royal power, that is, they were authorized by a special commission to act with plentitude of power in extraordinary and delicate emergencies.

From the most exact calculations, it is concluded that the continental part of Spanish America contains thirteen millions of inhabitants; part of which population is employed in agriculture, particularly in Venezuela, Guatamala, Guayaquil, Chili, Caraguatenga, &c.; and many in the care of cattle, especially in the provinces of Rio de la Plata and part of Venezuela; while the habitants of several provinces of Mexico, Peru, and New Grenada, are almost wholly employed in working the mines. The Indians and Negroes have retained, in a great measure, their primitive customs; the Creoles have received theirs from the Spaniards. The Catholic religion being that of Spanish America, the church-government and ecclesiastical dignities are the same in the mother-country. The inquisition was also established in the new continent: all access to the Spaniach settlements was not merely closed against foreigners, but even the habitants of the different provinces were prohibited from intercourse with one another. Commerce was exclusively carried on with Spain, and was almost entirely in the hands of Spaniards; about the end of the last century, however, some special licences were obtained from the viceroyos and captains-general to trade with the Antilles, when communication with the mother-country was very difficult; and in 1797 the court of Madrid was obliged to allow some of the ports of Terra Firma to be opened for the advantage of commerce. Urged by similar motives, Ciferos, the viceroy of the provinces of Rio de la Plata in 1809, opened the ports of Buenos Ayres, that a free trade might be carried on with the nations in alliance with Spain.

The court of Madrid long maintained its power in the new continent, by a small number of Spanish troops, as the Creoles were cordially attached to the mother-country, and the Indians unable to free themselves; but about the middle of the last century, a plan of conspiracy was formed in Caracas, with a view of destroying the company of Guipuscoa, to which the privilege had been granted of exclusively trading with Venezuela. The design was discovered, and the head of the conspiracy condemned to death. (See Caracas and Guipuscoa.) The oppressions of the repartimientos, and other grievances, gave rise also to the insurrection which took place in Peru in 1780. By the system of the repartimientos, the Indians were obliged to receive their necessary supplies of goods, hardware, and mules from the corregidores (officers named by the king), at the prices they fixed, and on the credit they thought proper to give. In 1781, some reforms and additional taxes were introduced in New Grenada, in the province of Socorro, one of the most populous of the vicereignty; but the province openly declared against these changes, and having assembled near 17,000 men, marched against Santa Fé de Bogota, exclaiming, "Long live the king, but death to our bad governors."

Some few Creoles and Spaniards, well acquainted with the principles laid down by the French politicians in the early period of the French revolution, and with those of the writers who preceded that period, formed a plan for revolution in Caracas in 1797. They treated the Spanish government with contempt, and trufed to the protection of the English, in consequence of Mr. Pitt's well-known plan of giving independence to Terra Firma. The conspiracy was discovered, and the infamous leaders made their escape; but one of them was afterwards apprehended and hanged. Sir Thomas Picton, governor of Trinidad, staled at this time a proclamation, in which he says, towards encouraging the habitants (of the continent near to Trinidad) to refit the oppressive authority of their government; "I have little more to say, than that they may be certain, that whenever they are in that disposition, they may receive all the favours to be expected from His Britannic Majesty, be it with forces, or with arms and ammunition to any extent; with the assurance, that the views of His Britannic Majesty go no further than to secure to them their independence, without pretending to any sovereignty over their country, nor even to interfere in the privileges of the people, nor in their political, civil, or religious rights." To affit the revolutionarv party in Spanish America, the English cabinet is said to have paid the expedition of Miranda to Venezuela in 1806, and to have lent that of Whitelocke to Buenos Ayres in 1807, both of which failed. It is certain that the inhabitants of Spanish America have been long discontented, and that they have complained of various grievances to the court of Madrid. This court, however, knew how to answer petitions without redressing grievances. But Napoleon Bonaparte, when he became in fact master of the Peninsula, and possessor of the wealth of America by the influence he had in this court, having invaded the kingdom and seized the royal family of Spain, loosened those bonds which united the new to the old world, and gave rise to a revolution which, from the wide extent of the country in which it is fested, its character, and its confquences, is unparalleled in the annals of history. When Bonaparte had not only invaded the kingdom, but seized king Ferdinand, and assemblies under the denomination of "juntas" were established in various provinces of Spain, each assuming in its respective district the supreme authority, the Spanish Americans were perplexed and dubious as to the conduct which they ought to pursue. The moment for freedom seemed at length to present itself, after they had been weary and exhausted by a series of sufferings for three centuries. However, Spanish America was still attached to the mother-country: and when it was announced at Caracas, in July 1808, that Joseph Bonaparte had taken possession of the Spanish throne, the city was immediately in arms: 10,000 of its inhabitants surrounded the residence of the captain-general, and demanded the proclamation of Ferdinand VII. as their king: which he promised to do next day. But such was their ardour, that they proclaimed him that evening by heralds in form, throughout the city, and placed his portrait, illuminated, in the gallery
of the town-house. Some months after this wonderful display of attachment to the mother-country and its sovereign, many respectable families of Caracas concurred in presenting a petition to the captain-general, Cajas, for permission to elect a junta similar to those in Spain. The petitioners indeed were arrested; but after a confinement of very few days they were released. About the end of July, 1808, Liniers, viceroy of Buenos Ayres, received intelligence of the events that had occurred in the Peninsula; and in a proclamation addressed to the people, he exhorted them, in the name of Bonaparte, to remain quiet. Xavier Elio, the governor of Monte-Video, accosted him of disobliged and thus separated the country under his command from its allegiance to him, by forming a junta resembling those of Spain.

The news of the general insurrection in Spain reached Mexico on the 20th of July, 1808; and a junta was immediately established. La Paz, which was the capital of one of the districts under the dominion of the audience of Charcas, considering Spain too feeble to free herself from the power of the French, wished to provide for its own security; and, in the beginning of the year 1809, formed a government for itself, composed of many respectable persons, which was styled "junta intituticia." The viceroy of Buenos Ayres sent an army to oppose this motion; and Goyeneche marched, by order of the viceroy of Peru, against La Paz, who succeeding, ordered numbers of the patriots to be ignominiously and cruelly executed. Quito, nevertheless, capital of the audience bearing its name, established a separate government, August 10th, 1809. But the viceroy of Santa Fe de Bogota halted to destroy the junta of Quito by force of arms; and Abascal, the viceroy of Peru, did the same. The defenders of the junta were obliged to yield to superior force, receiving a promise from the Spanish president of Quito, that all events should be forgotten. But regardless of this promise, many patriots, amounting to more than 300, were murdered in cold blood. In 1810, the junta of Caracas commemorated the fate of these victims with funeral honours equally magnificent and solemn. Upon the dispersion of the central junta in Spain, and an illegal election of a regency, the inhabitants of Caracas resolved to try to obtain by force what reasonable representation had failed to gain for them. The municipal body, in conjunction with many persons named by the voice of the people, assumed the reins of government, and the appellation of "junta suprema." The acts of the junta were published in the name of king Ferdinand VII.

The establishment of the junta of Buenos Ayres was effected with more tranquillity than that of Caracas. A junta was formed at Chile in September; and disaffection, occasioned in Mexico by violent measures, produced an insurrection, September 16th, 1810, in the town of Dolores, near Guanajuato; which insurrection soon extended through the whole country.

When the council of regency received intelligence of the proceedings at Caracas, by the which the inhabitants declared themselves independent of the mother-country, and determined upon forming a governing junta to execute this toppled independent authority, it resolved to adopt vigorous measures for preventing the progress of this evil; and, for this purpose, consulted the council of Spain and the Indies. Accordingly the regency declared the province of Caracas in a state of rigorous blockade. The measures thus adopted evinced the prevalent spirit that actuated the Spanish Americans, though the different provinces were not acting in concert with each other. War seemed to be the wish of the merchants of Caracas, and of the Cortes that had been assembled by the regency; and various methods were used to excite and encourage it. Its long continuance, and the savage manner in which it is prosecuted, evince the irreconcilable animosity of the contending parties. "The Spaniards fight for reconquering their once poffessed territories, and the Spanish Americans to obtain independence: the first are cruel in the hour of triumph, and with aversity their enmity increases; the latter are courageous in attack, and, when defeated, ready to place confidence in their leaders, and to rally under their banners. The first posseffes great military skill; the latter, superiority of number. Both have uniformly shewn a firmness and decision in action suited to the high objects they have in view, and to the great obstacles they have to overcome. In these contests, the blood of thousands has already inundated an extent of country of more than 1500 leagues, which comprise the Spanish settlements in the new continent; and as the mortality in the field of battle were not sufficient, numbers are daily murdered in cold blood."—"The Spanish chiefs and rulers, it is said, gave the first example of violating capitulations, of shooting prisoners, and of refusing all means of accommodation, in the cruel war carried on in the new continent, by the authority of the Cortes of Spain, and by Ferdinand VII. The old Spaniards of either world will be altogether unable to find an excuse, or even a palliation, for their want of humanity, and breaches of faith, since the beginning of the revolution. The cruelty of the Spanish chiefs, and tokens of approbation on the part of the regency and cortes, have exasperated the newly-formed governments in Spanish America, and given strength to their decisions. At first the revolutionary spirit was confined to very few persons, but it soon spread through the whole continent.

This sufficiently appears in the spirit and language of the act of independence published by the congress of Venezuela on July the 5th, 1811. Similar declarations to those of the congresses of Venezuela were made in Mexico, and in Carthagena, Socorro, Tunja, Pamplona, Antioquia, and the other provinces, which composed the federation of New Grenada, and more lately by the congress of Buenos Ayres."

When king Ferdinand, in his decree of the 4th of June, 1814, announced to the South Americans his return to his country, he ordered that they should lay down their arms; and this order was enforced by an army of 10,000 men, equipped at Cadiz, and placed under the command of Morillo. This army appeared on the coast of Venezuela in April, 1815. All hopes of reconciliation were now abandoned, and a revolt in Spanish America against Ferdinand VII. may be dated from this period. From Campano general Morillo proceeded to Margarita, and from thence to Caracas; and in the following August he besieged Carthagena. Although diffentions had occurred between Bolivar and Castello, both commanders of the South American forces, and leffened the means of defence which Carthagena possessed, the inhabitants, nevertheless, supported by nearly 2000 regular troops, prepared for a vigorous retaliation. But provisions failed, and more than 3000 persons died of famine. On the 5th of December, 1815, the governor and garrison of Carthagena evacuated the place, and on the following morning the king's troops entered. General Morillo, thus poffessed of Carthagena, was enabled to conquer New Grenada. He entered Santa Fe de Bogota in June, 1816, and remained there till November. More than 600 persons of those who composed the congresses and provincial governments, as well as the chiefs of the independent army, were shot, hanged, or exiled; and the prorns were full of others waiting their fate.

The first decree of the junta suprema of Caracas, formed April
VENEZUELA.

April 19th, 1810, contained orders to arrest the captain-general, and the members of the audiencia, who were sent to the United States of America: it was decreed that the alacabala, or duty on selling any commodity, should be abolished, the tribute paid by the Indians, and the slave-trade; that freedom of commerce, agriculture, &c. should be established; and that these political changes should be made public, and communicated to the English government. Juntas were formed for similar purposes in different provinces. The regency of Spain was incensed, and it declared all the ports attached to the new government to be in a state of blockade; and orders were given for reducing Venezuela to its former subjection. When these orders proved ineffectual, spies and emissaries of every description were sent to all parts of Venezuela, for the purpose of effecting a counter-revolution. General Miranda reached the shores of Caracas in the end of 1810, notwithstanding the instructions given by the junta suprema for opposing the return of the general to his native country, with a view of evincing the moderate plan of conduct which the junta had adopted towards Spain. A general congress met, and the plan of a confederation, as the best form of government for Venezuela, was formed and adopted. Miranda, however, opposed it, and his conduct gave offence. In April, 1811, the congress nominated three persons, who were to constitute the executive power, which was very limited. Although several persons were secretly desirous of reunion with the mother-country, they durst not avow it, so carnal were the inhabitants of Caracas for independence. The anniversary of the revolution, on the 19th of April, was kept with great rejoicings. A most alarming conspiracy was just ready to break out in June, 1811, but it was discovered and defeated. In the midst of the prosperity of Venezuela, it was visited, March 26th, 1812, by a most tremendous earthquake, which destroyed nearly 20,000 persons. The towns of Caracas, La Guayra, Marquesia, Merida, and San Felipe, were totally demolished; and Barquisimeto, Valencia, La Victoria, and others, suffered very considerably. At this crisis, general Miranda had the command of the army, and general Monteverde commanded the royalists. Caracas at length fell under the power of the royalists; the republican army was disbanded; and Miranda, with many others, proceeded to La Guayra, intending there to embark for Carthagena. But Miranda was betrayed, and he, with nearly 1000 patriots, were thrown into dungeons at La Guayra and Puerto Cabello. In consequence of this disaster, Cumana and Barcelona acknowledged the authority of Monteverde; and other similar events occurring, the Spaniards refused the authority in Venezuela. Vengeance filled the mind of Monteverde. The Spaniards thought, by destroying the inhabitants of Venezuela, the first province which had shaken off their yoke, to punish in them the infraction of the whole southern continent. Every royalist became a public accuser; every priest was filled with patriotism; and almost the whole population were under confinement. This conduct of the royalists, instead of conciliating, excited the hatred of the inhabitants; and the courage of those who were attached to the cause of independence revived. The province of Cumana first opposed the oppression of Monteverde; and here he was twice defeated. Don Simon Bolivar, one of the most distinguished natives of Caracas, obtained from the congress of New Grenada near 600 men; and with these he felt confident that he should be able to conquer the enemies of his country. Bolivar, after a variety of prosperous adventures, was rapidly advancing towards Caracas, where the inhabitants waited for him, as their deliverer. A junta was assembled, and it was propounded to make proposals of capitulation to Bolivar. The general accepted the offered treaty, and granted leave to any person, who was desirous of it, to emigrate from Venezuela, and to withdraw his property. The articles of the treaty, though they were extremely liberal, were disapproved by the captain-general Monteverde, because it was derogatory to the dignity of the Spanish nation to treat with insurgents. Bolivar made his triumphant entry into the city of Caracas, amidst the congratulations of the inhabitants, on the 4th of August, 1813. The dungeons of La Guayra were thrown open, and those who had suffered a year's confinement were restored to their country and friends; while the people, shouting with joy, blessed their deliverer, at the sight of every individual who rushed from the prisons. In the midst of this popular ferment, none of the Spaniards were insulted. The provinces which formed the republic of Venezuela were again in the power of the patriots; but Monteverde obstinately persisted in refusing to treat with Bolivar. In the mean while, Monteverde received from Spain a re-inforcement of about 1200 Spanish troops; and thinking himself warranted to act offensively, he attacked the republicans, but was completely defeated. Almost all the Spaniards were killed or taken prisoners, and Monteverde himself was severely wounded. After this defeat, Bolivar laid siege to Puerto Cabello both by sea and land. But the royalists retiring into the fortresses, determined not to surrender. Bolivar, in invading Venezuela under the protection of the congress of New Grenada, had received orders to reinstate the republican congress; but this he did not think it advisable to do. Bolivar, however, having given an account of his intentions and operations, in the invasion of Venezuela, to an assembly that had been convened of persons of all ranks, regarded the supreme authority which he held. But the governor of Caracas propounded, and his proposal was agreed to, that Bolivar, denominated the "Libertador de Venezuela," should be invested with dictatorial authority, till the reunion of the provinces of Venezuela to those of New Grenada, under the same representative form of government. The Spaniards, not being able to subdue Venezuela, determined to destroy it. Accordingly the slaves were to be raised in rebellion against their masters. The number of slaves in Venezuela amounted to 70,000; and one of the most formidable emissaries for this purpose was Boves, over whom Bolivar obtained a signal victory at La Vittoria. After gaining several other considerable advantages over the royalists, Bolivar considered himself as secure in the possession of Venezuela; and turned his attention to Coro and Los Llanos, whither the enemy had fled. But as the three divisions of the republican army were separated many leagues from each other, Bolivar was attacked by Boves on a plain called La Puerta, nearly 50 leagues from Caracas, and after many hours fighting, compelled to abandon the field to Boves. Other disasters also occurred, and from this time confusion reigned among the patriots, and there was no longer any army for the protection of Caracas. Success no longer attended Bolivar; his former good fortune had forsaken him, and even the commander of his flotilla, which protected the coast, refused to obey his orders. Despairing of the independence of his country, he and a few of his chosen officers, who were willing to partake his ill fortune, embarked for Carthagena. From Carthagena he proceeded to the town of Tunja, where the congress of New Grenada was sitting; and he was commissioned by the congress to compel by force the city of Santa Fe de Bogota to acknowledge its authority. In this he succeeded; after which he was lent with 3000 men
men to reduce to allegiance the province of Santa Marta. Carthagena was to contribute troops and guns; but it was prevailed upon to refuse the demanded supply, under pretence of Bolivar's ambitious views, and his fanguard career in Venezuela. Bolivar marched against Carthagena; but intelligence having been received of the expedition from Spain having reached this city, Bolivar gave up his plan, quitted the army, and his troops united to those of Carthagena to defend that city. The royalists entered Carthagena about four months after the siege had begun; but in the mean while, Bolivar, who had gone to Jamaica, proposed to assist Carthagena by landing an expedition on her shores. The capture of Carthagena prevented the execution of his plan, and he again turned his attention to Venezuela. Stimulated by the hopes of once flattering prospects, Bolivar planned an expedition for afflicting the efforts of the patriots of Margarita; and joining Borion, an affluent native of Caracoa, assembled the emigrants from Venezuela, and part of the garrison which had evacuated Carthagena. Borion was appointed commander of the maritime forces, which were to be employed on this occasion. Sailing from Aux Cayes at the end of March, 1816, they landed in the beginning of May at La Margarita. From Margarita Bolivar failed for Carapano, about five leagues west of the town of Cumana, of which he dispossessed the royalists; and having armed many of the corps of guerrillas, who had advanced to join him, they failed for Ocmara. When he landed at Ocmara, he issued a proclamation, giving liberty to the slaves. This proclamation, dated July 6th, 1816, does honour to his judgment and feelings. "Your tyrants," says he, "shall be destroyed or expelled, and you shall be restored to your rights, your country, and peace."—"No Spaniard shall be put to death, unless in battle." No American shall suffer the least injury for having joined the king's party, or for having committed acts of hostility against his fellow-citizens."—"That unhappy portion of our brethren, which has groaned under the miseries of slavery, is now set free. Nature, justice, and policy, demand the emancipation of the slaves: henceforward there shall be only one class of people in Venezuela—all shall be citizens."

Bolivar, who after the defeat at Ocmara had returned to Aux Cayes, brought new reinforcements to Margarita, where he landed in December, 1816. There he published a proclamation, convoking the representatives of Venezuela to a general congress; and went afterwards to Barcelona, where he organized a provisional government. In this place he repulsed the royalists under Real and Morales, in February or March, with great loss. Although the patriots lost the town of Barcelona on the 7th of April this year (1817), and the royalist forces in Venezuela received an addition of 1600 men from Spain in May last, it is now (Aug.) reported, that Bolivar has succeeded in completely establishing the republic of Venezuela.—Travels in South America, by Depons, ii 2 vols. 1807. Outline of the Revolution in Spanish America, by a South American, 1817.

VENETIA. See CORO.

VENEGAMBOOR, a town of Hindoostan, in Myfore; 17 miles S.E. of Erroad.

VENEGAPALEAM, a town of Hindoostan, in Myfore; 11 miles N.N.W. of Daraporm.

VENEGOLINA, in Ornithology, an African bird, which seems not to have been described by any of the ornithologists. According to the Hon. Daines Barrington's account, it is of the fuch tribe, and about the same size with our aberdavine, or filkin; the colours are grey and white, and the cock hath a bright yellow spot upon the rump; it is a very familiar bird, and sings better than any of those which are not European, except the American mocking-bird. Phil. Trans. vol. lxxiii. part ii. p. 254.

VENHUYSEN, in Geography, a town of Holland; 4 miles S.W. of Enckhuysen.

VENIA, among our Ancient Writers, denotes a kneeling, or low prostration, to the ground; used by penitents. See GENIAL EXULATION.

Walfingham, p. 196. "Rege interim prostrato in longa venia. Per venias, centum verrunt barbis pavementum."—VENIAL, a term in the Romish Theology, applied to flight fins, and such as easily obtain pardon. In confounding to the priest, people are not obliged to accufe themselves of all their venial fins. The thing that gives the greatest embarras to the Romish caiufala is, to distinguih between venial and mortal fins. See POPEN. The reformed reject this distinction of venial and mortal fins; and maintain, that all fins, how grievous soever, are venial; and all fins, how flight soever, may be mortal: and the reason they urge is, that all fins, though of their own nature mortal, yet become venial, or pardonable, by virtue of our Saviour's passion, to all such as fulfil the conditions on which it is offered in the Gospel. To which the Romanists anfer, that the chief of these conditions is confession.

VENICE, in Geography, a city of Italy, and for a long time the capital of a republic. This city makes a very grand appearance at a distance, as seeming, from its being built on a multitude of islands, to float on the sea; or rather, with its stately buildings and cloisters, as it were, rising out of it. The number of these islands is uncertain: some reckoning 60, others 72, and others again making them amount to 138. The Laguna, or marshy lake, which lies between the city and the continent, and is five Italian miles in breadth, is too shallow for large ships; but, by the attention of the republic, was prevented from becoming part of the continent, and from being ever frozen so as to bear an army. Towards the sea, the access to the city is also difficult; but the safe and navigable parts are indicated by piles; which, at the approach of an enemy’s fleet, can be cut away. Besideas, as a considerable number of galleys and men of war could be fitted out very expeditiously for sea from the docks, which contained vaft quantities of naval stores, the city was strong without fortifications. The fift, caught even at the very doors of the houses, might be reputed a good prefervative againft famine. The return of the fift is sometimes later here than every fith hour, and it generally rises between four and five feet, keeping the water between the islands of the city in continual motion. Some of the canals being very narrow, the mud is not fo effectually carried off as to prevent ill smells in hot weather. The great canal, which winds through the city, and divides it into two parts, is 1500 paces long. The belt way of going up and down the city is in gondolas, which, indeed, like the eye with a mournful appearance, being all lined either with black cloth or ferge, or painted black. Over the severaL canals are laid forty four hundred and fifty (some fay upwards of five hundred) bridges, great and small, and the better part of them flone: the highest and longeft is the Rialto. (See BRIDGE.) The city may, indeed, every where be traversed on foot; but the streets are very narrow, and the free-stone pavement very slippery in wet weather. The many small bridges, with their steps, are also not a little troublesome. The whole city is laid to be fix Italian miles in circumference; and to make the tour of it in a gondola, takes up somewhat more than two hours. Venice contains seveny parifi-churches, besides others, fifty-four convents of
of monks, twenty-six nunnerys, seventeen rich hospitals, eighteen oratories, forty religious fraternities with their chapels, and fifty-three squares. The buildings, indeed, are all of stone; but the greater part mean, without beauty or elegance. St. Mark's square, it is true, is very fine, and so are the several stately marble palaces that border upon the grand canal, though most of them are of Gothic architecture. In the churches and convents, the most admirable parts are the paintings; and indeed Venice, highly renowned for fine paintings, is said, in this very respect, to have surpassed even Rome itself. Venice, from the fertility of its neighbourhood, and the facility of carriage, enjoys a constant plenty. The spring-water being very indiffercnt, almost every house has a ciffern, into which the rain-water is conveyed from the roof, and clarified by being filtrated through sand. Water is also brought from the river Brenta, and preferved in cifferns. Among the diversions of Venice, the carnival is accounted the chief: it usually begins the second day of Christmas, and continues till Shrove-Tuesday; consisting chiefly of masquerades and ridottos: St. Mark's place is the general rendezvous. Other diversions are plays and operas. The trade in cloth, especially scarlet, silk goods, and looking-glasses, is still very considerable. Here also gold and silver flufis are manufacured; which, although not so beautiful as those of France, have a very good face in the Levant. The brocatellas, a kind of stuff like brocade, made of coarse silk, are much used for carbets. Venice is divided into fix parts, called Seiiferie di Seifiera. S. Marco contains the piazzetta di S. Marco, with the adjacent buildings. This square, the pride of the city, forms a right angle, the shorteft side of which, two hundred and forty paces long, and seventy-five broad, reaches along the ducal palace. The ducale palace, towards the water-side and St. Mark's place, is entirely Gothic; but on the side of the small canal, and in the court, of modern architecture, and mostly of marble. It not only served for the residence of the doge, but also for the meeting of the council. The finest ornaments of the council-chamber and other apartments, are the paintings of famous ancient masters. In one side of the palace, towards the canal, Rio di palazzo, were dark prisons, strongly secured with iron grates. The lower gallery, or arched walk, on the side of St. Mark's square, together with the opposite hall, is called Broglio. Here, at a certain hour of the day, the nobles took their walks, and at this time no Venetian of an inferior rank must be seen on it; though a foreigner, as supposed unacquainted with the custom, is not desired to quit the place. Between these two buildings and the piazza were two pillars of Oriental granite, on one of which stood St. Mark's lion in brass, and on the other a marble statue of St. Theodore. Between these is the place for the public execution of malefactors, through which no nobleman is ever seen to pass. A galley, completely rigged and armed, lay close to the Broglio, for the defence of the ducal palace on any sudden emergency. Contiguous to the north part of the doge's palace is St. Mark's church, also filled the doge's chapel. Its materials justly entitle it to be called magnificent, being, both on the out and inside, covered with fine marble; but the architecture is entirely Gothic. The best part of it consists of the Mosaic paintings, and the four braffs horfes, formerly gilt, standing over the great door, and said to have been brought here from Constantinople. In the church treasury is kept a very famous manuscript of the gospel of St. Mark, pretended to be autographical; but the dampness of the place where it lies has spoiled it to such a degree, that no part of it is any longer legible, and it is not fo much as certain whether it be written in Latin or Greek. In the Seiiferia di Castello is the arsenal or dock, two Italian miles and a half in circuit, walled and moated in, with twelve towers along its walls; and within the enclosure a great variety of buildings, in which everything requisite for a land or sea armament is kept in readiness, with shops, storeshouses, and bafions and slips for ship-building, &c. Within it lie the men of war, frigates, galleys, and other vessels, with the Bucentauro, which is also laid up here. In the Seiiferia di Canal Regio is the theatre, and in this quarter the Jews live, to the amount of fifteen hundred, who must wear a scarap of red cloth in their hats, by way of distinction from Christians. Seiiferia ci S. Pavolo contains the exchange, the bank, &c. On the invasion of Italy, in the fifth century, by the Huns, under their king Attilla, and the general defolation that every where appeared, great numbers of the people who lived near the Adriatic took shelter in those islands where now stands the famous city of Venice; and which islands, about the year 421, particularly Rialto, had, in some measure, been built upon by the Palladins, for the advantage of commerce. (See Venetia.) Here having settled their small places or fates, they were at first governed by consuls; afterwards by tribunes; and formed a kind of republic, the council of which was represented by the presidents of these magnificent courts. These islands became still better inhabited by the succeeding incursions of the Goths and Longobardi into Italy; multitudes from Rome and other large cities repairing thither, so that this state became soon able to make some head against these bold invaders. At length the chief of these islands and the Longobardi came to an agreement, by which the former were to remain unmodelled. This was the commencement of the city and state of Venice. About the beginning of the eighth, or end of the seventh century, the former government of these islands was abolished, and an unlimited power conferred on Paulus Anafeto, with the title of duke. Under this sovereignty the state greatly increased, till the people, justly becoming weary of the ills of domestic despotism, chose, in the year 1171, another duke, but curtailed his power, by assigning him a council of 240 persons, composed of commons as well as nobles. Duke Ziani sided with pope Alexander III. against the emperor Frederick, and obtained over him such a signal victory at Sles, that the pope presented him with a ring, which he was to drop into the Adriatic, as a sign of his marriage with, and perpetual sovereignty over it. The Venetians, who had already extended their dominion into Ifiria, Dalmatia, Syria, Lombardy, and other places, made a very considerable acquisition in the beginning of the thirteenth century, by poifening themselves of the principal islands in the Archipelago and Mediterranean, particularly that of Candia. From this time they alone carried on, at an immense profit, the trade for East India goods, which they imported from Alexan- dria, in Egypt, to which place they were brought across the Red seas, and by the way of Suez. Under duke Ma- rio Morosino was introduced the form of electing the doge; and it was at this juncture that jealousy and envy cemented the war with Genoa, which, after continuing 130 years, was at last put an end to by a treaty, in 1591. During this war, duke Peter Grandonigo, in the year 1296, ordained that the nobility alone should be capable of sitting in the grand council. Thus the government became aristocratical. In the 15th century, the Venetians extended their possessions in Lombardy; and, in 1473, the laft king of Cyprus appointed the state of Venice his heir. Towards the end of the 15th century, the Venetian commerce, and consequently power, began to decline, when the Portuguese discovered a route by sea to the East Indies, which opened the trade to all nations. In the 16th century, the pope, the emperor, France, and Spain, joining in a league against them, they
were dispossessed of all their towns and places in the kingdom of Naples, the ecclesiastical state, and the Milanesi. They received another severe blow from the Turks, who drove them out of the island of Cyprus. In the 17th century a sharp contest arose between the state, the clergy, and the pope, in which, however, they had the advantage. They were also long engaged in troublesome wars with the Turks, losing Candia, and gaining part of Dalmatia, and all Morea; but the greater part of these have been lost in succeeding wars. Thus the republic of Venice continued upwards of 1300 years, amidst many foreign wars and intestine commotions. Its grandeur was chiefly owing to trade and liberty; and since the decline of the former, its strength and confluence must have suffered a considerable diminution. The power was lodged in the hands of the nobility, faithful to the state, and to the decree that the council should perpetually consist of the families which then composed it, and some others which it ennobled. This produced a second class of nobility, who, accordingly, were then registered in the golden book. It consisted of upwards of eighty families, and some of great wealth and reputation. With these there were also included families raised to nobility after the Genoese war, on account of their large contributions towards carrying it on with vigour. The third and last class was composed of the Cittadini, or citizens, whose nobility was purchased for 100,000 Venetian ducats, a resource of the republic for raising money in necessitous times. Crowned heads, German and other princes, have not thought it any degradation to be made nobles of Venice. The habit of the nobility, whilst at Venice, was a black furred gown, reaching to their heels, with a belt about three inches broad, and plated with silver. Instead of hats they had long caps. The head of the republic was the doge, or duke, who, on the demise of the former, was chosen in a peculiar manner, by forty-one nobles, selected for this purpose by a process which is needless to describe. The forty-one electors were confirmed by the grand council; and, being shut up in a chamber of the ducal palace, there remained till they had chosen a new doge. To the due and legal election of a doge, it was required, that out of the forty-one he should have twenty-nine votes. His election was followed by a kind of coronation; the ducal cap being placed with great ceremony on his head. This was performed at his public entrance into St. Mark's church. His yearly income was 12,000 Venetian ducats. He was subject to a variety of restrictions; and he was under the inspection and control of the council of ten, who kept a watchful eye over his whole administration, and, at any time, could come and search his most private apartments. In general, his authority, essentially considered, was no greater than that of a private person, unless he could influence the whole council. On his death a formal inquiry was made, whether he had abused his power; whether, from a care of his own concerns, he neglected those of the public; whether he lived agreeably to his dignity, &c. If found guilty of any thing alleged to his charge, his heirs were fined in proportion to the nature of the crime. On Ascension-day, the doge, or, in case of illness, the vice-doge, performed the annual frivolous ceremony of marrying the Adriatic sea. (See Doge.) In the grand council, all nobles of the age of twenty-five years might take their place, though some younger found means to obtain admittance. The senate, or pregadi, were a committee of the grand council, by whom they were also chosen. This senate had the management of the most secret and important state affairs, as the making alliances and peace, declaring war, sending ambassadors, coining money, filling up offices, imposing taxes, &c. Next was the collegium, in which all public instruments directed to the state and doge were read, audiences given to foreign ministers, and other matters of importance transacted. The procurators of St. Mark had not only the inspection of the church of St. Mark, its library, and the records of the republic, but likewise managed all affairs relating to the poor, together with wills, guardianships, redemption of Christián slaves, and bringing over-rogid creditors to a reasonable composition. Their number never exceeded nine: their office was of great authority, and during life; and out of them the doge was generally chosen. Titular or extraordinary procurators of St. Mark were more numerous; the republic gladly filling these titles in a public sacrifice of money. In the consiglio dei dieci was a high penal court, which consisted of ten counsellors, the doge, who was president, and his six consiglieri. The established religion was the Roman Catholic; but Greeks, Armenians, and Jews, were all the public exercise of their worship, and Protestants, observing privacy, remained unmolested. The patriarch of Venice, the chief ecclesiastic of the republic, was chosen by the senate; and though confirmed by the pope, now in all other respects, he is independent of the papal chair. The territories of the republic were under governors chosen out of the nobility, changed at the expiration of a certain term of years. The annual revenue of the republic was computed at 8,200,000 ducats, and was under the direction of three governors dell' Entrate. In war-time, both the nobles and the other subjects, even the doge, contributed, proportionally to their incomes, towards defraying the public expences. The states of Italy subject to the Venetians were the Dogado, the Paduan, the Poleline di Ravigo, the Veronese, the Vicentini, the Breffan, the Bergamasco, the Cremona, the Trevigiano, the Feltrin, the Bellunese, the Cadorna, great part of Friul and Istria; to these may be added a part of Dalmatia, the islands of Corfu, Zante, Cephalonia, and some others. The number of inhabitants in the city of Venice was estimated at 160,000, and of the whole state, at 2,500,000. In the year 1797, in consequence of some partialities which the Venetians showed to Austria, the French attacked and made themselves masters of the city. By the peace of Lunéville, Venice with its dominions was given to Austria; but by the peace of Pressburg transferred to the new kingdom of Italy. In December 1807, prince Eugene Napoleon was created prince of Venice by the emperor Napoleon.

Venice has always been renowned for its cultivation of the fine arts, and for giving birth to great profilers, particularly in painting, architecture, and music. At the head of the first, Titian, Paul Veronese, and Tintoret; of the second, Palladio and Scamozzi; and of the third, Zarlino, Lotti, Marcello, and Galuppi; names that can never be heard without pleasure by the votaries of those arts. Printing, too, has been carried on at Venice with great spirit ever since the year 1459, when it was established there by Nichola
Nicholas Janfen; and in the beginning of the next century, purveyed by the Aldi with more accuracy than in any other part of Europe.

But Venice has long manifested its attachment to music by the establishment of its conservatories, or musical schools, of which it has four; the Ospidale della Pietà, the Mendicanti, the Incurabile, and the Ospidalletto a S. Giovanni e Paolo; at each of which there is a performance every Saturday and Sunday evening, as well as on great festivals. The performers at them all, both vocal and instrumental, are females: the organs, violins, flutes, violoncellos, and even French horns and double-basses, are supplied by these females. See Conservatorio.

Though the composers of the Venetian school are, in general, good contrapuntists, yet their chief characteristics are delicacy of taste and fertility of invention; but many circumstances concur to render the music of Venice better, and more general, than elsewhere. The Venetians have few amusements but what the theatres afford; walking, riding, and all field-sports, are denied them. This in some degree accounts for music being so much, and in so costly a manner, cultivated; the number of theatres, in all which the gondoliers have admission gratis, may account for the superior manner in which they sing, compared with people of the same class elsewhere. And in the private families, into which the girls of the conservatories marry, it is natural to suppose that good taste and a love for music are introduced.

Venice, in 1639, was the first city in Italy that opened public theatres for the performance of operas; and in less than a century from that period, 658 musical dramas were brought on the several stages of that city, the chief part of which were produced by natives of the Venetian state. In the last century, not only the poetry and music of the lyric theatre were greatly superior to those of preceding times, but the performers; for at Venice all the great vocal talents to which the opera had given birth, were more constantly summoned, patronized, and cherished, than in any other city of Europe.

Accounts are kept at Venice in lire of 20 soldi or marchetti; and each soldo is divided into 12 denari or lira. They are also kept in ducats of 24 grossi; and the grosso is divided into 12 grossetti, or denari of ducato. A ducato of account is worth 64 lire, or 124 marchetti. The gold coins of the old republic are zecchini, or sequins, with halves and quarters. The sequin is commonly reckoned at 22 lire, but its agio fluctuates, and in the year 1805 it was 37 per cent. The silver coins are the scudo Veneto, or della croce, of 12 lire 8 soldi, and halves and quarters in proportion; the ducatone, or quintina, of 11 lire; the ducato effettivo of 8 lire, with halves and quarters; and the grossi of 30 soldi, called liraazz, and of 20, 15, 10, and 5 lire. There are also pieces of 10 lire, which were coined in 1796. The copper coins are soldi and half-soldi, or bagattini.

When Venice became subject to Austria, in 1797, a bache for mone was introduced, called moneta provinciale, which, in 1802, was declared to be out of currency; and a new coinage took place, confisting of pieces of 12, 6, 3, 2, and 1 soldi, or, in Austrian money, of 18, 12, and 6 kreutzers, which contained only a fourth of fine silver, but they were heavier than the former coinage. This money was called "mo- neta di nuovo flamo." The Austrian government also intro- duced copper pieces of 6 and 3 kreutzers, or 10 and 5 soldi, and pieces of 2 and 1 soldi. All the above-mentioned monies and coins are now valued in "moneta piccola," which is the effective currency of Venice.

The bank of Venice was instituted in 1587; its original capital being five millions of ducats. The owners received no interes for their money, but could draw it out on demand or transfer it in payment, like the banks of Amsterdam, Hamburg, and other banks of deposit. Bills of exchange were mostly paid in banco, and also wholesale bargains of merchandise above 300 ducats. The bank received no money but sequins and silver ducats. The bank of Venice was in high credit and prosperity from its first institution to the year 1797, when the French seized upon the city, and closed it to Austria; from this period it declined. In 1805 Venice was incorporated with the kingdom of Italy; and in 1808, the bank was totally discontinued.

According to the rate of coinage, 68½ sequins are to contain a Venetian mark of fine gold, with a very small, but uncertain, quantity of alloy. No remedy was allowed at the mint of Venice, either in the weight or fine- ness of its coins. The Venetian sequin, weighing nearly 5½ English grains, is therefore worth 92.6d. sterling. The silver ducat weighs 35½ English grains, and is 9 oz. 185 dwts. fine, which gives its value at 40½d. sterling; hence the ducat of account of 64 lire piccola is worth 31½d. nearly, and the lira about 5d. sterling; or, more exactly, l. sterling = 47 lire 8 soldi piccoli. But taking the value of the lira from the coinage introduced by the Austrian government, it will be found worth about 42½; and l. sterling = 56 lire 9½ soldi piccoli.

Venice has two different weights for merchandise, viz. pezzo grosso, or large weight; and pezzo fottile, or small weight: the pound of the former is divided into 12 oz. and 192 carats, in all 2304 carats; and the pound of the latter into 12 oz. and 144 carats, in all 1728 carats. The pound pezzo grosso weighs 19 oz. pezzo fottile; hence 12 lbs. pezzo grosso = 19 lbs. pezzo fottile; and 18 lbs. pezzo grosso, or 28½ lbs. pezzo fottile = 19 lbs. avoirdupois. A carico is 400 lbs. pezzo fottile. The ounce for weighing silk and thread is divided into six faggi or fazi, and these into halves, quarters, &c. Oil is sold either by weight or measure: a migliaio weight contains 400 mili, each 25 lbs., and all 1000 lbs. pezzo grosso. A migliaio measure should contain 1210 lbs., or 40 mili, each 304 lbs. pezzo grosso; such a miro answers to about 4½ English gallons. The amphora, a wine measure, contains 4 bigoncia; a bigoncia, 4 quartari, 16 fascie, or 256 lbs. pezzo grosso; but a bigoncia of brandy is only 14 fascie.

Two forts of long measure are used at Venice, both of which are called the braccio; that for woolens is 26® English inches, and that for silk is 24® English inches. The Venetian foot is 154 French lines, or 133 English inches; hence 36 Venetian feet = 41 English feet.

Venice exchanges with London 50 lire piccola, more or less, for 1½ sterling, at three months' date. The figure for bills drawn from London is three months after date. Bills are allowed six days grace, after which they must be either paid or protested. Protests are made by the fanti or clerks of the commercial college, who enter all the bills they have protested in a book, to which every merchant has free access. Thus many bills, which would otherwise be returned, are accepted and paid for the honour of the drawer or indorser. This practice is likewise useful in giving early notice of approaching insolvency. (Kelly's Uni. Camb.) Venice is situated 216 miles N. of Rome. N. lat. 45° 28'. E. long. 12° 18'.
VENICONTES, a people of Britain, S. of the Cal-
domii to the W., whose town was Orca. Ptol.
VENIERO, DOMENICO, in Biography, an Italian poet,
born was of a noble family at Venice in 1517; and after
receiving a good education, and being introduced to the
friendship of Bembo, and having been thus led into the
way of advancement to honourable and lucrative flats,
the he left the use of his limbs at the age of thirty-two, and was con-
fined to his chamber for life. In this condition he fought
falsely from poetry and the conversation of his learned
friends, who in great numbers return to his house. These
meetings laid the foundation of the celebrated Venetian
academy, of which Veniero was the principal ornament.
Notwithstanding the pain which he experienced, his poems
are distinguished by liveliness of imagery and force of
expression. He died in 1582, at the age of sixty-five. His
poems were first printed in the collections of Dolce and
Ruccelli; and they were edited at Bergamo in 1551 and
1753, with those of his nephews, Maffeo and Luigi Ve-
nero, the former of whom was archbishop of Corfu. Their
father Lorenzo was also a poet. Gen. Biog.
VENIRE FACIAS, or Low, is a judicial writ, lying
where two parties plead, and come to issue; directed to the
sheriff, to cause twelve men, of the same neighbourhood,
to meet, to try the fame, and recognize the truth upon the
issue taken.
Afterwards, a compulsive process is awarded against the
jurers, called holcas corpora juratum, or distringas, that
they may appear upon the day appointed. See Jury.
VENIRE Facias is also the name of a writ, which is the
proper process in an indictment for any petty misdemeanor,
or on a penal statute, and which is in the nature of a summons,
to cause the party to appear. And if by the return to such
venire it appears, that the party hath lands in the county
by which he may be disdained, then a diverse shall be
issued from time to time till he appears. But if the sheriff
returns that he hath no lands in his bailiwick, then, upon his
non-appearance, a writ of capias shall issue; and if he cannot
be taken upon the first capias, a second and a third shall
issue, called an alias, and a partes capias.
VENIRE Facias tPost Matronas. See VENTRE Insuiciendo.
VENISON, VENISON; the flesh of beasts of game, or
of animals to be caught in the way of game, i.e. by hunting,
&c. as dear, hare, &c.
The word is French, venaison; formed of the Latin ven-
natio, hunting.
The old huntsmen have determined, that every beast of the
foret, that is food for man, is venison. In many parts of
the world the bears are as regularly hunted as the hare
and buck, &c. are with us, and there are called venison.
but with us, at present, the word venison seems limited to
the flesh of the hart, the hind, the buck, the doe, and the
other creatures of that kind.
Some have extended the signification of the word to the
beasts of the forest which were chaced as game, and afforded
the diversion of hunting, whether their flesh were eaten or
not: thus, in some places, the wolf and the fox are reckoned
among the venison beasts.
VENIUS, or VAN-VEEN, OTHO, in Biography, was of
a distinguished family in Holland, and was born at Leyden
in 1556. He received an excellent education from his
parents, and though his progress in literature was unufual,
yet he was permitted to pursue his desire of becoming a
painter. He received lessons in design from Isaac Nicolas,
but is more indebted to John Van Vingen. The war in the
Low Countries drove him to Liege at the age of fifteen,
and there he continued to prosecute his studies in literature
and the arts. He acquired the favour of cardinal Grobeck,
at that time prince bishop of Liege, who, desirous of his
advancement, advised him to visit Rome, and furnished him
with letters of recommendation to cardinal Marducio, then
in that city. On his arrival there he was kindly received
and entertained by his eminence, and he became a disciple
of Fred. Zuccaro, by whose instructions, and his own in-
dustry in studying the beautiful works of antiquity with
which he was surrounded, he acquired a very great degree of
correctness in design, and a more elevated taste than his
countrymen usually exhibited in their works.
Having devoted seven years to his studies in Italy, he
visited Germany, where he raised some time, and received a
flattering invitation to remain in the court of the emperor;
but his desire to revisit his native country prevailed, and he
decided this honourable proposal. As he passed through
Munich and Cologne, he was employed by the duke of Ba-
varia and the elector; and on his arrival at Brussells, the
governor, Alexander Farene, appointed him his principal
engineer and painter, and sat to him for his portrait.
After the death of his patron he established himself at
Antwerp, where he was much engaged in painting histori-
cal works for the churches, &c. and gained a great reputa-
tion; which has not been diminished by his having had for
his disciple so renowned an artist as Rubens.
When the archduke Albert was appointed governor of
the Netherlands, Otho Venius made the designs for the
triphal arch erected on his entrance, with which the arch-
duke was so much gratified, that he invited him to Brussells,
and appointed him his principal painter, and master of the
mint, which situations he occupied until his death in 1634,
at the age of 78.
Otho Venius did not confine himself to painting, he wrote
and published several works adorned with prints, chiefly en-
graved by his brother, Gilbert Venius, from his designs.
Among them are, a translation of part of Tacitus; Horace's
Emblems, with notes and observations; the Life of Thomas
Aquinus; and the Emblems of Love, divine and profane.
VENIY, in Geography, a town of France, in the de-
partment of the Yonne; 3 miles N. of St. Florentin.
VENLO, a town of France, in the department of the
Lower Meuse, late the duchy of Guelders, situated on the
E. side of the Meuse, takes its name from the two
Flemish words Veenen and Loo, which signify a low meadow.
Before the year 1343, it was only a small town, when Ru-
naud II., duke of Guelders, fortified it, and gave it the title
and privileges of a city. It has only one parish-church,
which is dedicated to St. John. After several changes of
poles, it was ceded, in 1715, to the States-General by the
barrier treaty. In this town was made the first trial of
bombs, about 1588; and they were first used by Alexander
Farene, duke of Parma, at the siege of Watchendonck,
not long after. In 1794, it was taken by the French; 12
miles N.N.E. of Ruremon. N. lat. 51° 29'. E. long.
6° 2'.
VENO, a town of the republic of Lucca; 5 miles
S.S.W. of Lucca.
VENOE, a small Danish island, in the gulf of Lym-
ford. N. lat. 56° 34'. E. long. 8° 38'.
VENOM, VENENUM. See Poison.
The terms venom and poison only differ from each other
in this, that the latter is more frequently used where
the noxious matter is taken inwardly, as in foods, drinks, &c.;
and the former, where it is applied outwardly, as in stings
and bites of serpents, scorpions, vipers, spiders, &c.
The pike is said to have a venomous tooth. All venomous
beasts, in the general, have that quality in a greater degree,
when
when bred in mountains and dry places, than when in wet and marshy places; and the southern more than the northern; thofe hungry and enraged, more than others; and all of them in summer more than winter. See Viper.

VENONIS, in Ancient Geography, a town of Britain, in the 9th Iter of Antonine, situated between Ratis or Leicelte, at the distance of 12 miles from it, and Bannaventum near Daventry; supposed to be the ancient Cleyelte.

VENOSA, CARLO GESUALDO, Prince of, in Biography, a Neapolitan nobleman, whose fame has been extended by his musical productions more than by his high rank, though this rank will be found reciprocally to have added luster to the compositions, was nephew to cardinal Alfonso Gesualdo, archbishop of Naples, and had his title from the place which gave birth to Horace, the Venustum of the ancients. Pomponius Nenna, a voluminous and celebrated composer of madrigals, had the honour to intrust him in music. His productions consist of fix sets of madrigals for five voices, and one for fix. The principal editor of his works was Simone Molinaro, maeftra di capella at Genoa, who, in 1585, published the first five books in separate parts; and, in 1613, the fame madrigals, with the addition of a sixth book, in folio.

The numerous editions of thefe madrigals in different parts of Europe, and the eulogies bestowed on the author by perfoners who rank high in literature, as well as music, made us extremely curious to see and examine them. Gerard Vossius, Bianconi, Bapt. Doni, Taffoni, and many others, speak of him as the greateft composer of modern times; as one who, quitting the beaten track of other musicians, had discovered new melodies, new measures, new harmonies, and new modulations; fo that fingers, and players on instruments, defpifing all other music, were only pleased with that of this prince.

Taffoni tells us, that James I. king of Scotland, had not only composed sacred music, but invented a new species of plaintive melody, different from all others; "in which he has been imitated by the prince of Venosa, who, in our times, has embellifhed music with many admirable inventions."

This paffage in Taffoni, which has fo often been cited by Scots writers, seems to imply, not only that James, king of Scotland, had invented a new species of melody, but that his melody had been imitated by the prince of Venosa; at least, this is the fenfe in which the paffage has been understood by the natives of Scotland, and indeed by ourselves, till, on finding no kind of similarity between the national tunes of North Britain and the melodies of the prince of Venosa, we examined the paffage anew, with more attention; when it appeared to us as if Taffoni's words did not imply that the prince of Venosa had adopted or imitated the melodies of king James; but that these princely deliitants were equally cultivators and inventors of music. See David Rizzio, Scots Tunes, and Ossian.

The Neapolitan prince seems to merit as little præfence on account of the expreffion of words, for which he has been celebrated by Doni, as for his counterpart; for the syllables are constantly made long or short, juft as it befuit his melody; and in the repetition of words, we frequently fee the fame syllable long in one bar, and fhort in another, or the contrary; by which it is manifest that their fufficient accentuation was never thought of.

The remarks of Taffoni certainly must have been hazarded either from conjecture or report; as is but too frequently practifed by men of letters, when they become musical critics, without either induftry or science fufficient to verify their affections.

The prince of Venosa was perpetually flattering at new expreffion and modulation, but feldom succeeded to the satisfaction of pofterity, however dazzled his contemporaries may have been by his rank, and the character he bore among the learned, who fo frequently get their musical information from tradition, that whether they praife or cenfure, it is ufally sans connoiflance de cause.

Dilettanti ufually decide in the fame summary way, with an additional prejudice in favour of their own little knowledge, and a difpofition to cenfure whatever they are unable to acquire, be it science or execution.

Cicero has long fince faid, that "it is not with philofofy and science, as with other arts; for what can a man fay of geometry or music, who has never f tudied them? He muft either hold his tongue, or talk nonfence."

With refpect to the excellencies which have been fo liberally bfeffed on this author, who died in 1614, they are all difputable, and fuch as, by a careful examination of his works, he feemed by no means entitled to. They have lately been faid to confift in "fine contrivance, original harmony, and the faultefs modulation conceivéable." As to contrivance, it muft be owned that much has been attempted by this prince; but he is fo far from being happy in this particular, that his points of imitation are generally unmanageable, and brought in fo indiscriminately on concords and fifords, and on accented and unaccented parts of a bar, that, when performed, there is more confusion in the general effect than in the music of any other composer of madrigals with whose works we are acquainted.

His original harmony, after foaring a great part of his madrigals, particularly thofe that have been the moft celebrated, is difficult to discover; for had there been any warrantable combinations of founds that Palestrina, Luca Marenzio, and many of his predeceffors, had not used before him, in figuring the fakes, they would have appeared. As to his modulation, it is fo far from being the faultefs conceivable, that, to us, it fefms forced, affected, and difgutting.

We have bfeffed more remarks on this prince of musicians, and more time in the examination of his works, than perhaps they now deferve, in order to furnish our readers with what fets, to our comprehension, a truer idea of that which partiality and ignorance have hitherto given. A fcore of one of his madrigals in the 3d vol. of Burney's Gen. Hift. of Mus. p. 223, will justify our cenfures of the musical productions of this tuneful prince.

VENOSA, in Geography, a town of Naples, in Baflieate, the fce of a bishop, suffragan of Matera. It contains seven churches, and as many convents. In the 9th century, Venosa was taken by the Saracens, and in 1528 by the French; 9 miles N.N.W. of Acerra. N. lat. 40° 58'. E. long. 15° 48'.

VENOSA Arteria. See Arteria Venosa.

VENOSTA, in Geography, a valley of the Tyrolefe, on the banks of the Adige; 20 miles S. of Glurentz.

VENOSUM Foliwm, in Botany and Vegetable Phyfilogy, a veiny leaf. See Leaf and VEN.

VENOUS, Venous. See VEN.

VENT, in Geography, a river of England, in the country of Cumberland, which runs into the South Tyne.

VENT, formed from ventus, wind, vent-hole, or spiracle, a little aperture left in the tubes or pipes of fountains, to facilitate the air's escape; or, on occasion, to give them air; as in frothy weather, &c. for want of which they are apt to burst.

A vent, taken in this fenfe, is properly the end of a pipe, placed
placed erect, and reaching above the ground; usually folded to the turns, or elbows, of pipes. The vents of large pipes are to be as high as the supericies of the reservoir, unless there be a valve in them.

*Vent* is also used for a little hole, pierced in vessels of wine, beer, &c. that are on tap; and which admits air enough to make the liquor run, but not so much as to corrupt and spoil it.

*Vent*, again, is applied to the covers in wind-furnaces, by which the air enters, which serves them for bellows; and which are stopped with register, or flaps, according to the degree of heat required; as in the furnaces of glass-houses, aﬄayers, &c.

*Vent* is also used for a pipe of lead, or other matter; one end of which opens into the cell of a necessary-house, and the other reaches to the roof of the house, to give room for the corrupt fettid air to exhale.

There are also vents, or apertures, made in the walls which sustain terraces, to furnish air, and give a passage for the waters.

This kind of vent the Italians, and we from them, call a *barbaccia*.

*Vents*, in Gunners. See Touch-hole.

The common method of placing the vent is within about a quarter of an inch from the bottom of the chamber or bore. Some, however, have thought, that if the vent was to come out at the middle of the charge, the powder would be inflamed in less time than in any other case; but Mr. Muller, by firing mortars with two vents, one at the bottom and the other in the middle, and so contrived that one was shut whilst the other served to fire, found always the range of the shell greater when the lower vent was used, than when the powder was fired by the middle one. Artillery, p. $5$.

Mr. Thompson (Count Rumford) has lately made a number of experiments, in order to determine the best position of the vent; from the result of which it appears, that the effect of placing the vent in different positions with respect to the bottom of the chamber, is different in different charges; but the difference in the force exerted by the powder, which arose from the particular position of the vent, was in all cases so inconsiderable, as to afford occasion for concluding, that any given charge of powder exerts nearly the same force, whatever is the position of the vent. He infers, upon the whole, that in the formation of fire-arms no regard need be had to any supposed advantages that gunsmiths and others have propounded to derive from particular situations for the vent; such as diminishing the recoil, increasing the force of the charge, &c. but the vent may be indifferently in any part of the chamber where it will beft anfwcr to other accounts; and he thinks there is little doubt but the fame thing will hold good in great guns, and all kinds of heavy artillery. Workmen in general agree, that the vent in fire-arms should be as low or far back as possible, in order, as they conceive, to leffen the recoil: accordingly some make the bottom of the chamber flat, and bring the vent out even with the end of the breech-pin; others make the vent flanging through the breech-pin, in such a manner as to enter the bore jut in its axis; others again make the bottom of the chamber conical; and there are thofe who make a little cylindrical cavity in the breech-pin, of about two-tenths of an inch in diameter, and near half an inch in length, coinciding with the axis of the bore, and bring out the vent even with the bottom of this little cavity.

The objection to the firft method is, that the vent is apt to be fopped up by the foul matter that adheres to the Vol. XXXVI.

piece after firing, and which is apt to accumulate, especially in damp weather. The fame inconvenience in a greater degree attends the other methods, with the addition of another, arising from the increased length of the vent; for the vent being longer, is not only more liable to be obstructed, but it takes a longer time for the flame to pass through it into the chamber; in consequence of which the piece is flower in going off, or, as sportsmen term it, is apt to hang fire. Mr. Thompson propofes, that the bottom of the bore should be in form of a hemifphere; and that the vent should be brought out directly through the side of the barrel, in a line perpendicular to its axis, and pointing to the centre of the hemifpheric concavity of the chamber. In this case the vent would be the shortest possible; it would be the leaft liable to be obstructed, and the piece would be more easily cleaned. Similar advantages, he apprehends, would be gained by making the bottom of the bore and vent of the great guns in the fame manner. Phil. Tranf. vol. lxxi. part ii. p. 372, &c.

From a variety of experiments made by order of the king of Pruflia in 1765 and 1766, it appears, that the concave chamber produced the greatest ranges, and that the bottom of the chamber is the best place for the vent.

*Vent*-Aftragal, is that part of a gun or howitz which determines the vent-field.

*Vent*-Field, is the part of a gun or howitz between the breech-mouldings and the aftragal.

*Vent*, Port. See Port-vent.

*Venta*, in Ancient Geography, a name given to several Britifh towns, of which our antiquaries have given different etymologies. Mr. Baxter’s conjecture may be allowed to be most probable, who fuppofes that it is derived from *ventum*, or *vent*, which signifies head or chief. For it is observable, that all the towns which were named Venta, were the capitals or chief towns of the nations or people to whom they belonged.

*Venta Belgarum*, a town of Britain, placed in the seventh Iter or route of Antonine, from Regnum or Chichefter to London, between Caflentum or Old Southampton, and Calleva Atrebatum or Silhchifter; and situated at the preent Winchester, as our antiquaries agree. It was the capital of the Belges.

*Venta Iceniara*, a town of Britain, placed at the head of the ninth Iter or route of Antonine, 128 miles from London. This town was probably the capital of the Iceni, or ancient inhabitants of Norfolk, Suffolk, Cambridgshire, and Huntingtonshire; and it is generally fuppofed by our antiquaries to have been situated at Caifer, upon the river Yare, about three miles from Norwich, which is thought to have arifen out of the ruins of this ancient city. Here have been found some faint veftiges of this ancient capital of the Iceni.

*Venta Silurum*, a Britifh town, placed in the fourteenth Iter or route of Antonine, from Ifca or Caerleon, to Calleva or Silhchifter. This was a confiderable town of the Silures, between Ifca and Abona. It is our Caergwent. See Silures.

*Venta Cibay*, Lut, in Geography, a town of Spain, in Guipjufcoa; 6 miles from Tregvino.

*Vento de Cruz*, a sea-port town of America, on the Jthmus of Darien, on the river Chagre, where the merchandise from Panama is put on board barks to be conveyed to Porto Bello; 20 miles N. of Panama. N. lat. $9^\circ 26’$.

*Vento Quemada*, a town of Spain, in the province of Jaen; 42 miles N. of Jaen.

*Vento de en Medio*, a town of Peru; 20 miles N. of Oruro.
VENTALDA, a town of Sweden, in the province of Smaland; 34 miles S.E. of Jonköping.

VENTAROLI, a name given in Sicily, &c. to grottoes formed under their houses, from which issues a constant extreme cold wind, and at times with impenetrability, and a noise like water dashing upon rocks. These are shut up with doors like cellars, and made use of as such, as also to keep provisions fresh, and to cool liquors. At Cefi, in the Roman flat, there are many such ventaroli; and the inhabitants of that town, by means of leaden pipes, conduct the fresh air from these into the rooms of their houses, so that by turning a cock they can cool them to any degree. Some who have refined still more upon this luxury, by smaller pipes, bring cold air under the dining table, so as to cool the bottle of liquor upon it. On mount Etna and Vesuvius, and in the island of Ichia, there are many caverns of this kind. Phil. Trans. vol. lxx. part i. p. 73.

VENETANATIA, in Botany, was so named by M. Paliflet-Beauvois, in honour of the late M. E. P. Venetan, member of the National Institute, a distinguished French botanist, who was formerly an ecclesiastic, and, if we mistake not, of some religious order; but he took advantage of the revolution to free himself from such unnatural and immoral shackles, in order to fulfil the duties of a man and a Christian. He has distinguished himself by the publication of a Tableau du Régne Végétal, selon la Méthode de Jussieu, in 4 vols. 8vo.; as well as the magnificent Jardin de la Malmaison, with coloured plates, in large folio; and the uncoloured Jardin de Cels, and Choix de Plantes; the latter having been soon cut short by his death. The writer of this article had dedicated to the name of M. Venetan, a New Holland genus, (see Stillingia,) which now yields to the prior right of the genus before us.—Palif. Beauv. Fl. d'Oware et de Benin, fusc. 2. De Their 479. Poiret in Lamarck Dict. v. s. 450.—Clafs and order, Polyandria Monogynia. Nat. Ord. Tiliaee Juff. ?

Gen. Ch. Cal. Perianth inferior, in three deep, equal, oblong, obtuse, concave, coriaceous, deciduous segments. Cor. Petals numerous (eleven or twelve), filamentate, spreading, strongly veined; rounded at the extremity; contracted into a claw at the base. Stam. Filaments numerous, thread-shaped, erect, unequal, much shorter than the petals, inserted, like them, into the receptacle; anthers... Pfl. Germen superior, oval; style thread-shaped, undivided, longer than the stamens; stigma thick, obscurely five-lobed. Peric. Berry oval-oblong, of five cells, furrowed longitudinally, terminating in a kind of mammillar point. Seeds numerous in each cell.

Efl. Ch. Petals numerous. Calyx in three deep deciduous segments. Berry superior, of five cells, with many seeds.

Obf. M. Paliflet Beauvois remarks, that this genus is obviously referrible to Jussieu's 15th clafs, (Poiret by mistake says the 3d,) but its order in that clafs is not so easily determined. Deflections of the ripe seed are wanting to ascertain this point. The fruit nearly accords with Jussieu's Aurantas, but the structure of the flower, and the want of pellucid dots in the leaves, exclude it from that order. The want of Azipulas prevents its perfect agreement with the Thiaees, and M. Beauvois considers this genus as probably marking one of a new order, confounded by Jussieu with his Thiaees.

1. V. glauca. Glaucous Venetanatia. Palif. Beauv. Fl. d'Oware et de Benin, 29. t. 17. Poiret n. 1. — Native of elevated, airy, open situations, near Agathon, on the coast of Africa. A shrub, with alternate, round, smooth branches. Leaves alternate, stalked, very large, elliptic-oblong, entire, tipped with a long acute point; rounded at the base; smooth on both sides; covered on the under surface with a kind of glaucous viscidity, which when dry becomes almoast powdery. Stipulas none. Flowers lateral, towards the extremity of each branch, solitary, stalked, alternate, sometimes opposite to the leaves; their flasks half the length of the leaves, cylindrical. Calyx short, smooth. Corolla large, of a fine crimson, beautifully veined. Poiret.

VENTER, in Anatomy, the abdomen; called also minus venter. See ABDOMEN.

Venter is also used for the womb, or uterus, of women. And hence the writ de ventre inspiciendo.

Hence, also, in the civil law, we say, partus sequitur venterem, the child follows the belly; meaning, that its condition is either free or servile, according to that of its mother.

They also say, to appoint a curator for the belly, with regard to posthumous children, yet in the mother's womb. With regard to princes, the venter, or belly, has been sometimes crowned in form.

Venter is also used, in speaking of a partition of the effects of a father and mother, among children born, or accruing, from different marriages.

This partition is so ordered, as that a single child of one marriage, or venter, takes as much as several of another marriage, or venter; in order to which, the estate is divided into so many parts as there have been venters, or marriages.

Venter, or Belly, of a muscle. See Belly of a Muscle.

Venter Draconis, Dragon's Belly, in Astronomy. See Dragon's Belly. See also DRAGON-in Astronomy.

Venter Equi, Horse's Belly, among Chemists, denotes horse-dung, or a dunghill, on which are included certain vehicle for particular operations, to be performed by means of the gentle heat of it.

VENTES les Grandes, in Geography, a town of France, in the department of the Lower Seine; 9 miles N.W. of Neuilly.

VENTHIE, LA, a town of France, in the department of the Straits of Calais; 9 miles N.E. of Bethune.

VENTIA, in Ancient Geography, or Venetianum Civitas, a town situated in the Maritime Alps. Dion Callius, speaking of an expedition, dated in the year of Rome 693, against the Allobroges, who had revolted, mentions a town under this name, at a small distance from the Ifere. According to some circumstances pertaining to this expedition, there is reason to believe that it is Vini, between Moirène, or Tullin and St. Marcellin, at some distance from the right bank of the Ifere.

VENTIDUCTS, in Building, are spiracles, or subterraneous places, where fresh cool winds, being kept, are made to communicate by means of tubes, funnels, or vaults, with the chambers, or other apartments of a house, to cool them in sultry weather.

These are much in use in Italy, where they are called ventidotti. Among the French they are denominated prifons des vents, and palais d'Eole. See VENTAROLI.

VENTILAGO, in Botany, so called by Gertner, because the appendage to the feed-vehicle was thought to bear some resemblance to a winnow or flapper, ventilabrum. It does not answer to the common idea of a fan, being neither plaited, nor much dilated upwards.—Gertn. v. 1. 223. t. 49. Willd. Sp. Pl. v. 1. 1106. Roxb. Coromand. v. 1. 55. Mart. Mill. Dict. v. 4. Poiret in Lamarck Dict. v. 8. 452.—Clafs

Gen. Ch. Cal. Pienanth inferior, of one leaf, cup-shaped, with five equal, triangular, deciduous, marginal segments. Cor. Petals five, spatulate, inserted into the rim of the calyx, alternate with its segments, and rather longer. Stam. Filaments five, awl-shaped, opposite to the petals, the length of the calyx; anthers of two round lobes. Pjfi. Gernen superior, invested below with the tube of the calyx, nearly globose; style short, cloven half way down; stigma two, divaricated, acute. Peric. Capsule globose, of one cell, and two valves; splitting at the base; crowned at the summit with an elliptic-oblong, flat, coriaceous, ribbed wing, many times longer than the capsule. Seed solitary, globose.

Eff. Ch. Calyx cup-shaped, with five deciduous segments. Petals five, opposite to the flamen. Capsule of one cell, crowned by an elongated wing. Seed solitary.

Obf. Gærtner did not see the capful in a sufficiently advanced state to discover that it has really two valves, which separate at the base, connecting with the apex by their long coriaceous wing, in which the most remarkable character of the genus consists. The flowers are occasionally dioecious, from the imperfection of one or other organ of impregnation.

1. V. maderaspatana. Yerra Chirtaly of the Te-lingas. Wildl. n. i. Roxb. Coromand. v. i. 55. t. 76. (Funnis viminalis; Rumph. Amboín. v. 5. 3. t. 2.)—Native of forests and uncultivated places, among the mountains of Hindooiland and Ceylon, and of rocky thicketts on the shores of Amboyana, flowering in the cold season. The stem is woody, climbing to a great extent, with long, round, pliant, tough, leafy, often downy, branches. Leaves alternate, on short filks, ovate, bluclift, two or three inches long, coriaceous, more or less obscurely crenate, feldom quite entire, smooth or minutely downy, furnished with one midrib, and many transverse ones, connected by extremely fine parallel veins. Flowers very numerous, small, greenish-white, in large, terminal, compound panicles, their scent highly offensive, resembling Sterculia faida. Wing of the capule entire, greenish-yellow, slightly downy, above an inch in length. — Wildenow, according to Poiret, has distinguished two species of this genus, in the new Transactions of the Berlin Society; one having entire and smooth, the other crenate and downy, leaves. But we are persuaded, from an examination of wild specimens from Roxburgh and Koenig, that these characters are variable.

VENTILATION OF MINES, comprises the various modes by which impure air is removed, and a current of atmospheric air supplied through the subterranean openings and passages of mines. The health, the safety, and lives of a very large and indistinguishable class of the community depend on the regular ventilation of mines; yet the application of the principles on which this should be undertaken has been but imperfectly understood, and it is but very recently that the subject has engaged the attention of men of science. Since the constitution of the atmosphere was ascertained, (see Atmosphere,) it is well known that the one-fifth part of it, or the oxygen gas, is essentially necessary to support the processes of respiration or combustion, by which it undergoes a chemical change, and is converted into carbonic acid gas, a gas destructive of animal life, and in which flame is instantly extinguished. It is also as well known, that the remaining four parts of the atmosphere, or the azote, are equally destructive of life, and incapable of supporting flame; hence the necessity of ventilation, or a regular supply of fresh air, in all confined situations, where men are to labour or exist, is very easily explained. Besides the destruction of oxygen gas by respiration or combustion, which takes place in confined apartments above ground, there are other causes that render the air impure in almost all subterranean passages or mines, through which there is not a regular current of wind constantly passing. The causes by which the air in mines is rendered impure, or destructive of animal life, are of three kinds. First, the respiration of men and horses in the mine, and the combustion of the lamps, &c.; secondly, the production and evolution of carbonic acid gas in the beds or strata in which the mine is situated; and thirdly, the production of carburetted hydrogen or inflammable gas. For the properties of these gases, see Gas. The two former sources of impurity are much less destructive of life than the latter, the inflammable gas or fire-damp of the miners; when this becomes mixed to a certain degree with the air of the mine, it explodes with great violence on the approach of a lamp or candle, and occasions the most fatal accidents, destroying all the vital air in the mine, and burning or suffocating the workmen. By explosions of this nature, it was estimated that not less than six hundred persons perished during the years 1813 and 1814, in the coal-mines on the rivers Tyne and Wear, in Northumberland and Durham; and the destruction of human life in other coal districts has been perhaps equally great, in proportion to their extent. In the ventilation of mines, where the air is impure from respiration, combustion, or the evolution of carbonic acid gas, called by the miners chok-damp, the object of the miner is simply to introduce a current of fresh air through the works; but besides the difficulties to be overcome in effecting this, where the works are extensive, the miner who has to combat with the fire-damp must guard against the greater evil of an explosion, to which he is almost constantly exposed.

In the working of metallic mines, the veins being generally nearly vertical, the currents of water, or the natural passages, aided by the varied temperature of the mine, are frequently sufficient to infuse the circulation of air; and these mines are very rarely affected by the production of the fire or chock damp. It is principally where a shaft or well is sunk, or a horizontal passage or gallery is made, that any means of artificial ventilation are necessary. The mode of opening a communication with some other part of the mine, or with the surface; and when this is done, the ventilation is found to be perfect by the rushing of the currents, which often takes place with considerable force, from the different degrees of temperature in the lower and upper air, and these currents change their direction as the temperatures above and below alternate. The great objection to this mode is the expense with which it is commonly attended wherever the gallery is at a great depth, and the intervening rock of a very hard kind, and where a shaft is merely wanted to supply air, and not for the passage of the water. To avoid this, the shaft or level is sometimes divided into two distinct parts, communicating near the part intended to be ventilated, so that a current may be produced in opposite directions on each side of the partition; and this is often effectual to a certain extent. It has, however, its limits at no very great distance, and the current is but a feeble one, from the nearly equal temperature of the air on each side of the partition.

The other mode employed is to force air down tubes with a large pair of bellows worked by the hand, or by boxes or cylinders of various forms placed on the surface, with a large opening against the wind, and a smaller one communicating with the air-pipes by a cylinder and pinion working...
VENTILATION.

Mr. John Taylor, in the Transactions of the Society of Arts for 1810, has described a method of effecting this process more easily, by attaching an air-pump of a very simple construction to a small fall of water. The engine discharges more than two hundred gallons of air in a minute, and a stream of water supplied by an inch and a half bore falling twelve feet is sufficient to keep it regularly working. This method may be introduced with great advantage into narrow passages or wells, but would be obviously inadequate to ventilate the immense excavations in coal-mines, except it were directed only to some confined part of the works. In metalliferous mines, the generation of the fire-damp is much less frequent than in coal-mines, and the extent and position of the excavations make the ventilation of the latter a labour of much greater difficulty. The most valuable beds of coal in England, with the exception of Staffordshire, are from two to nine feet in thickness, and they rarely incline more than about fifteen or twenty degrees from the horizontal level, and are frequently nearly flat. Each pit has two shafts or wells, called the downcast pit and the upcast pit. The excavations or passages in the coal, which communicate from one pit to the other, are frequently not less than forty miles or more in length, through which circuitous route the air has to take its course, though the distance from the downcast to the upcast shaft, in a right line, may not be more than a few hundred yards or feet, or even much nearer. And here we cannot but observe, that as the means to force the air through a route of such extent must be very complicated, and as a failure or accident to a part might destroy the whole ventilation, we conceive that much too large a surface is frequently worked from two shafts, in order to avoid the expense of additional shafts for several detached workings of a smaller extent. By this, the risk of the workmen is greatly increased, to evade expence to the owners of the coal. In the year 1813, some gentlemen in the north of England, impressed by the dreadful catastrophes which had recently taken place, very laudably established a society, with a view to inquire into the causes of these calamities, and the possible means of prevention. They entituled themselves "A Society for preventing Accidents in Coal-Mines:" Mr. John Buddle, an eminent coal-viewer in Northumberland, addressed a letter to the president, which was published by the society in 1815. In this letter he details the various methods which had been employed for the prevention of accidents by fire, which, he says, "conflict in a mechanical application of the atmospheric air to the removal or sweeping away of the inflammable gas, as it is generated in the workings of collieries, or as it issues from the fissures which the workings intercept in their progress." He details the various methods by which this is effected: these are explained by a number of figures and sections, without which they could not be rendered intelligible to the reader. We shall endeavour to give an idea of the principle on which the various modes of ventilating mines depend, by stating one of the simplest forms in which they can act. If two wells or shafts were sunk at a given distance, say fifty yards from each other, and a horizontal passage were cut from the bottom of one well to the other, so soon as the communication were made, there would be a tendency in the air to defend one shaft and ascend the other, whenever the temperature of the external air varied from that of the air below. The currents of air in natural caverns, that are open at each extremity, proceed from the same cause. In certain states of the atmosphere, should the current not be sufficient, or should a quantity of impure air be generated in the passage, the circulation may be increased by kindling a fire at the top or at the bottom of one of the wells, so rarely the air and cause it to ascend more rapidly. Or the air may be forced down the other well, by causing a stream of water to fall into it. Alto by means of vanes, or by an air-pump attached to a steam-engine, the circulation may be easily increased according to the will of the engineer, and the facilities which may be prelented for carrying away the water, &c. Thus little difficulty could arise in a case of simple ventilation of this kind; but if from the horizontal passage which runs from one shaft to the other, we make a number of passages on each side at right angles with it, as is done in coal-mines, the current of air which passes through it will not enter these lateral passages, or occasion any circulation in them. In order, therefore, to make the air pass through the whole series, another passage must be opened, connecting the further extremities of the lateral passages with each other: the first passage must then be closed, and the air which descends conducted along the lateral passages, up one and down the other, taking a circuitous route through the whole, until it arrives at the upcast shaft, which it ascends. To conduct the air in this manner, a number of trap-doors and flaps are necessary, in order to prevent the mixture of the air from the different passages, which would entirely destroy the ventilation. See Plate IV. Geology, fig. 8, which represents part of the workings of a coal-mine; the shaded part is the bed of coal, in which the workings are carried along the different passages, from the pit or shaft a, to the pit or shaft b. The current of air is represented by darts and dotted lines. The flaps and trap-doors, which close to prevent the passage of the air, and confine the currents to a particular course, are represented by double lines and crofs lines, as at t. This figure represents the improved system of ventilation, by which the current of air sweeps every part of the workings. By tracing the darts and dotted lines, it will be seen that the current of air from the downcast pit a, first passes along the main passage to a, and the adjoining passage MB, to which it has access through lateral passages, called walls, 1, 2, 3, 4: its further progress in every direction is closed, except at 5, where it enters the passage C, from which it has access to the passage D, through the openings 6, 7, 8, 9; at E, the currents unite in one stream, and enter an advanced part of the workings, called the head-ways, ventilating the passages F and G, being forced into them by partitions called brattices, placed at X, by which the air must pass in its progress to H. Where the current of air divides and sweeps along two passages at the same time, and unites again as above-described, it is called double courting; but where it runs down one passage and up another, as may be seen in its further progress from H on the south side, to H on the north side of the mine, it is called single courting.

The remaining part of the ventilation back to the passage K, is in double courtes, along which it is forced by the flappings at s, t, and the other flappings r, r, r, so that it ascends the upcast shaft at b. Under this system, says Mr. Buddle, if the flappings, &c. be all in order, and the passages kept sufficiently open for the current of air to circulate freely, there can be no partial stagnations in the workings,—no accumulation of inflammable gas. For in the event of a large discharge of gas, from what is called a blower, commencing at any place, as at M, N, P, Q, its stream is immediately carried off by the circulating current of atmospheric air, and so diluted that it cannot explode, unless indeed the discharge of inflammable air should be so copious as to mix with the current up to the firing point, or to that degree
degree in which it would inflame by access to a lighted candle or to fire.

This improved system of ventilation by double courses was introduced into the collieries on the Tyne and Wear about the year 1760, and has ever since continued in general use; but it is found inadequate to the intended purpose in the following cases.

1. When sudden discharges of inflammable gas mix with and raise the whole circulating mass of air to the firing point.

2. When the wind is south-easterly, and the weather wet or hazy, and the barometer sinks below twenty-nine inches.

In this case the atmospheric current, which under the most favourable state of the air is merely sufficient to sweep the noxious effluvia from some mines, gets so contaminated by the discharge of inflammable gas, and the fumes of its own progress, as to be exceedingly unsafe, and generally inaccessible with candles.

3. When inflammable air fills a part of the mine between the workmen and the upcast shaft.

4. When the gas is ignited by lightning, as it ascends the upcast shaft.

The presence of inflammable gas from the lighted mixture, through all its gradations to the first firing point, is readily discoverable by an experienced collier, and he judges very correctly of the degree of inflammability and danger which threaten the safety of the mine, by observing attentively the appearance of the spire upon the top of his candle. The common pit-candles vary in size, but those generally used are forty-five to the pound; the wick is of cotton, and the candle made of ox or sheep tallow; but clean ox-tallow is best.

The mode of trying the candle, as it is called, to ascertain the mixture of inflammable gas, is as follows.

In the first place, the liquid fat is wiped off, the wick snuffed close, and carefully cleaned of red embers, so that the flames may burn as purely as possible. The candle, being thus prepared, is held between the fingers and thumb of the one hand, and the palm of the other is placed between the eye of the observer and the flame, so that nothing but the fire and the flame can be seen, as it gradually towers over the upper margin of the hand. The observation is generally commenced near the floor of the mine, and the light and hand are gently raised upwards, till the true state of the circulating current be ascertained. The first indication of the presence of inflammable air, is a flight tinged by blue or a blue-grey colour shooting up from the top of the spire to the candle, and terminating in a fine extended point. The spire increases in size, and receives a deeper tinge of blue as it rises through an increased proportion of inflammable gas, till it reaches the firing point; but the experienced collier knows accurately enough all the gradations of show (as it is called) upon the candle, and is very rarely fired upon, excepting in sudden discharges of inflammable gas. The show upon the top of the candle varies very much, according to the length of run or distance which the current of air has passed through before it is mixed with the inflammable gas. The shorter the run of the current of air before it is mixed with the inflammable gas, the less will be the show upon the candle when at the first firing point, and vice versa.

The flame size of spire which would indicate danger in a current which had passed only one mile, might be perfectly harmless in a current that had run five or six miles; consequently the length of run of the current of air is to be taken into consideration, as well as the appearance of the top of the candle. The air-course, too, for a short distance beyond a small discharge of fire-damp may be highly inflammable; but by palling a few yards further, it becomes so diluted as to be perfectly secure. The distance, therefore, within which a blower can be safely approached with candles, is regulated entirely by the magnitude of the discharge and power of the current of air. Long experience and attentive observation are consequently necessary to obtain a thorough practical knowledge of this art.

The workings of a colliery are very often inaccessible with candles near the downcast pit, called the first of the air, while they may be safely entered with any description of light near the upcast pit, called the last of the air. This arises from the inflammable gas, as it is carried from the place of its discharge, being gradually diluted by the atmospheric current. Hence the advantage of sufficient extent of pit-room, to obtain length of run to dilute the inflammable air. It is from the want of pit-room, that the explosions in newly-opened collieries are generally the most violent. The distance which the current of air passes through, between the downcast and the upcast pits, varies much according to circumstances. Mr. Buddle has known it to exceed thirty miles.

After the current of atmospheric air is so highly mixed with inflammable air as not to be accessible with lighted candles, steel-mills may be employed with safety. We shall further notice Mr. Buddle's observations on steel-mills, but we believe the discovery of the safety-lamp will entirely supersede their use. "Although the inflammable air has frequently fired at the sparks of the steel-mills, it only happens, from all the facts which I have been able to collect, when the mills are played near the place where the hydrogen gas is discharged, and this by due attention may be safely avoided.

"I never indeed witnessed an explosion from the sparks of flint; but from my own observations on their appearance in dangerous states of the air, as well as from the observations of several intelligent men, I believe that in most cases the change of the appearance of the sparks, if attentively observed, gives sufficient notice of the threatening danger. When elicited in atmospheric air, they are of a bright appearance, rather inclining to a reddish hue, and as they fly from the wheel seem sharp and pointed. In a current of air mixed with inflammable gas above the firing point with candles, they increase considerably in size and become more luminous. On approaching the firing point with steel-mills, they grow still more luminous, and assume a sort of liquid appearance, nearly resembling the sparks arising under the hammer from iron at the welding heat. They also adhere more than usual to the periphery of the wheel, encompassing it as it were with a stream of fire, and the light emanating from them is of a bluish tint. When the inflammable gas predominates in the circulating current, the sparks from the steel-mill are of a blood-red colour; and as the mixture increases, the mill totally ceases to emit sparks. They have the same bloody colour in carbuncle acid." The steel-mill here mentioned is what has been used till very recently in coal-mines, confining of a wheel and spring, which is wound up and let in motion, whereby a constant collition of flint and steel is effected, eliciting a copious stream of sparks.

With the concluding remarks of Mr. Buddle's letter we can by no means agree, when he adds, "On the strength of my own experience in collieries thus circumstanced, I freely hazard my opinion, that any further application of mechanical agency towards preventing explosion in coal-mines would be ineffectual." Among the means enumerated by this gentleman, the very obvious one of depending on the greater specific levity of the carburetted hydrogen gas is entirely omitted;
omitted; nor is it even flatted, that the general inclination of the flrata present facilities for the ascent of the inflammable air, were requisite precautions taken to conduct it by channels to the mouth of the upcast pit, which in many situations might be done at a trifling expense.

The public have been given to understand, that an improved and complete system of ventilation, depending on this principle, had been introduced into some of the Staffordshire collieries; but on recent inquiry at the place, we were informed, that the method of ventilation proposed by Mr. Ryan had never been carried into practice to the full extent flatted, but considerable advantage had been derived from a partial application of the principle, by making channels near the roof of the mine for the escape of the inflammable gas.

Where the flrata rise regularly for a considerable extent, unbroken by faults, it appears easy to discharge the inflammable gas as fast as it is generated. The specific gravity of carbureted hydrogen is little more than one-half the weight of atmospheric air, being as 555 to 1000.

If, therefore, it were conducted along the roof by an unobstructed passage to the upcast shaft, it would rise and discharge itself.

Explosions not unfrequently take place at the upcast shaft, from the inflammable air passing near the fire placed at the bottom to rarefy the air and increase the circulation. The only expedient at present suggested is the use of charcoal, as the gas will not ignite at a red heat without flame; but charcoal does not promote so rapid a circulation of air as coal or wood, which produce smoke and flame. The carbonic acid gas generated by the combustion of charcoal, being also heavier than atmospheric air, would in some degree retard the ascent of air from the upcast shaft; and if a small particle of coal fell upon the charcoal fire, it would produce flame, which might cause an explosion.

A series of most interesting experiments was undertaken by Sir H. Davy in 1815, on the degree of inflammability of different admixtures of carbureted hydrogen when passed through small tubes or apertures, which led to the very important and unexpected result, that carbureted hydrogen, mixed with atmospheric air in the proportion which is most explosive, and then ignited, will not set fire to another portion of the same air, separated from it by a sheaf of small wire, the meshes of which amount to two hundred and fifty in the square inch. On this principle he constructed a lamp surrounded by a small wire-fie in the place of born or glass, having no aperture for the admission or transmission of air but through the meshes of the fie. This lamp, when lighted, was found to burn in explosive mixtures with perfect safety, the flame being confined within the lamp by the intervening wire-fie. This lamp has since undergone considerable improvements, and some of the objections to which it was first exposed have been removed. Important additions to it are still making by its illustrious inventor. For a full account of its construction and recent improvements, we must refer to the article Wire-Gauze Safety-Lamp.

VENTILATOR, a machine by which the noxious air of any clofe place, as an hospital, gaol, ship, chamber, &c., may be discharged and changed for fresb.

The noxious qualities of bad air have been long known; and no one has taken greater pains to let the mischiefs arling from foul air in a just light than Dr. Hales; who has also proposed an easy and effectual remedy by the use of his ventilators; his account of which was read to the Royal Society in May, 1741. In the November following, Mr. Triewald, military architect to the king of Sweden, informed Dr. Mortimer, secretary to the Royal Society, that he had in the preceding spring invented a machine for the use of his majesty's men of war, in order to draw out the bad air from under their decks, the length of which was 96, 172 cubic ffe of air in an hour, or at the rate of 21,173 tons in twenty-four hours. In 1742 he lent one of them, formed for a sixty-gun fhip, to France; which was approved of by the Royal Academy of Sciences at Paris; and the king of France ordered all the men of war to be furnished with the like ventilators.

The ventilators invented by Dr. Hales consist of a square box A B C D (Plate XVII. Pneumatics, fig. 1.) of any fize; in the middle of one side of this box a broad partition, or midriff, is fixed by hinges X, and it moves up and down, from A to C, by means of an iron rod Z R, fixed at a proper distance from the other end of the midriff, and passing through a small hole in the cover of the box up to R. Two boxes of this kind may be employed at once, and the two iron rods may be fixed to a lever F G (fig. 2.) moving on a fixed centre O; so that by the alternate raising and lowering of the lever F G, the midriffs are also alternately raised and depressed, by which these double bellows are at the same time both drawing in air, and pouring it out through apertures with valves made on the fane side with, and placed both above and below the hinges of the midriffs. In order to render the midriffs light, they are made of four bars lengthwise, and as many across them breadthwise, the vacant spaces being filled up with thin panes of fir-board; and that they may move to and fro with the greater ease, and without touching the sides of the boxes, there is an iron regulator fixed upright to the middle of the end of the box A C (fig. 1.) from N to L, with a notch cut into the middle of the end of the midriff at Z, so that the midriffs, in rising and falling, suffer no other friction than what is made between the regulator and the notch. Moreover, as the midriff Z X moves with its edges only one-twentieth of an inch from the sides of the box A B C D E, very little air will escape by the edges, and, therefore, there will be no need of leathern fides, as in the common bellows. The end of the box at A C is made a little circular, that it may be better adapted between A and C to the rising and falling midriff; and at the other end, X, of the midriff, a fip of leather may be nailed over the joints, if needful. The eight large valves, through which the air is to pass, are placed at the hinges-end of the boxes B K (fig. 2.) as at 1, 2, 3, &c. The valve 1 opens inward to admit the air to enter, when the midriff is depressed at the other end, by means of the lever F G. And at the same time the valve 3 in the lower ventilator is shut by the compressed air which passes out at the valve 4. But when that midriff is raised, the valve 1 shuts, and the air passes out at the valve 2. And it is the same with the valves 5, 6, &c. of the other box; so that the midriffs are alternately rising and falling, and two of the ventilators drawing in air, and two blowing it out; the air entering at the valves 1, 3, 5, 6, and passing out at the valves 2, 4, 5, 7.

Before these last valves there is fixed to the ventilator a box Q Q N M (fig. 3.), as a common receptacle for all the air which comes out of these valves: which air passes off by the trunk P, through the wall of a building.

For a farther account of this machine we refer to the author himself, who gives a full detail of it, and of its manner of working. See Description of Ventilators, by Stephen Hales, D.D. Lond. 1743, 8vo.

The doctor has shewn the use of his ventilators very fully. As to ships, in particular, he observes, that the wind-fall (see Wind-Sail) made use of at sea to introduce fresh air between
between decks, is far from being sufficient for that purpose; nor can it be used with equal safety to the sick, and those who are sleeping, by means of the strength of the wind, which conveys the air with too much violence. But when the foul air is carried off by means of ventilators, notwithstanding the great velocity with which they throw out the air, which they may do at the rate of sixty turns in a minute, yet the motion of it downwards into the hold, to supply what was carried off, is so very gentle that it cannot be perceived; because the sum of all the open passages for it through the deck exceeds the opening of the trunk of the ventilator, in so great a proportion as 120 to 1, or more. Besides, in a calm, the wind-fail can do little or no good; nor when the ship is under sail, at which time the wind-fail is not used. And it is to be observed, that it is not the ventilating of a ship now and then with a wind-fail, when wind and weather serve, that will suffice; it ought to be done daily, if due regard be had to the health of the ship's crew. The great quantity of rancid noxious vapours, which are incessantly exhaling from a number of living human bodies, the fetid air that incessantly arises from the bilge-water, and from the hot, flagrant, putrid air in the hold, makes it very advisable to refresh so bad an air continually, either with the wind-fail, when that can be properly used, or else with ventilators, which are intended to supply the defects of the wind-fail.

Ventilators must also be of particular service in new ships, which are observed to be more unhealthy, on account of a greater quantity of fappy wreck which arises from new timber, and makes the confined air the more unwholesome.

They will also be an effectual preservative of horses in transports, where they are sometimes suffocated, when in a flom there is a necessity to fly the hatches down.

These ventilators will also drive out of the hold of a ship that dangerous vapour which arises from corn, which is so noxious, that sometimes they dare not venture into the hold, till after the hatches have been opened for some time.

Ventilation will not only be of service to preserve several kinds of goods, but also the timbers and planks of the hold itself, when laid up in ordinary, as well as when in use, and will make the air in the hold less noxious, though it will still be offensive to the smell, by reason of the bilge-water. But this may be made less offensive, by often letting in sweet water from the sea, and then pumping it out; which good practice ought to be continued, notwithstanding the use of the ventilators.

What is here said of the foul air of ships may be applied to that of mines, gaols, workhouses, barracks, and hospitals. In mines, ventilators may guard against the suffocations, and other terrible accidents arising from damp; which see. (See also Ventilation.) The air of gaols has been often known to be infectious; and we had a fatal proof of this, by the accident that happened some years ago at the felicions at the Old Bailey. To guard against the like for the future, as well as to preserve the health of the prisoners, a worthy magistrate, in 1753, had ventilators placed in Newgate, which were wrought by a windmill; and in the beginning of the year 1753, Dr. Hales gave an account of the good success attending the use of these machines, by a remarkable decrease in the usual mortality and sickness of that place.

Although the old prison at Newgate is now taken down, and a much more commodious one erected near the same spot, it may not be improper to give a brief account of the manner in which the ventilators of Dr. Hales were constructed, and how they were moved by the windmill annexed to them. The midriifs, b, b, (fig. 4.) of these two ventilators, two pair of which were laid upon one another, were each nine feet long, and four and a half wide, and moved up and down by the flat iron rods e, f, passing through the lower and upper ventilators, and through an iron plate at s, about three inches square; over which is another broader iron plate, with a wide hole in its middle, to give room for the iron rod at g to move sideway to and fro, with the under plate, the hole of which exactly fits the iron rod, so that no air can escape at g; and there are the like plates at i, the top of the ventilator; and at f, s, are joints, where the iron rods are fixed to the midriifs, by which means both are moved up and down at the same time; and the iron rods of both sides of the ventilators being fixed to one common lever at c, all the four midriifs are thereby alternately worked up and down and at the same time. The valve-holes w, v, a, x, &c. are twenty-three inches long, and fix and a half wide, covered with buckram glued on them, and move on rails of tamed sheep-skin, and fall on rails of wooden cloth naled round the valve-holes. A very large nofe (fig. 5.) is fixed with iron hooks b, b, to the ventilators i, i; and this nofe is divided into three spaces, the middle and largest of which, m m, receives all the foul air blown into it from the eight middle valves x, y, z, x, s. (fig. 4.), whence it passed through a trunk i, i, sixteen inches wide, through the leads of the prison, into the open air; the top of this trunk being covered with weatherboards to keep the rain out, and the middle valves hanging fo as to open outwards. The two other outer spaces of the nofe p p, receive the foul air, drawn into them, from the several wards, through the trunks p, p, and passing off into the ventilators, through the eight outer valve-holes v, y, v, &c., whose valves open inwards. In these outer partitions of the nofe there are two holes s, s, (fig. 5.) covered with boxes, in the bottom of each of which there is a large moveable valve, opening upwards, and towards the ventilators: these are made of such a weight, as to open only when all the trunks to the several wards are shut; by which the ventilators will always be supplied with air, so as not to endanger the breaking of the midriifs for want of it. These ventilators, about eighteen inches deep in the clear, were fixed in an upper room of Newgate, in order to be near the windmill on the leads, which worked them. From each of the outer midriifs there went a trunk, twelve inches in the clear within; and from these trunks, which descended through all the floors as far as a little below the ceiling of the ground rooms, leffer trunks, six inches square within, branched off, near the ceiling of every room; and extended more or less into the several wards, fo that when the foul air was drawn out of any ward, the fresh air might enter on the opposite side, and drive out all the foul air before it. By other contrivances with sliding shutters and handles, the several wards might be ventilated at such a time, or in such a degree, as was found necessary. In the case of a prison that is built with an open area in the middle, Dr. Hales observes, that the side of the prison which is opposite to the side where the ventilators are, may be commodiously ventilated in its turn, by having a round brick air-gutter under ground; through which the foul air of those wards might easily be drawn.

The windmill for working the ventilators was contrived to move with a small degree of wind, and to obtain a sufficient power in a small compass. In fig. 6, e is one of the crofs-trees which support the mill-pole d, and the braces c, c;
the crofs-trees rift on the blocks \(a, a\), and are fixed to the floor by strong iron bolts. The mill-pole \(d\), being hollow, admits the iron rod \(b\) to pass through from the crank of the iron axle-tree \(i\); the turning-frame \(g\) moves on the girdle \(f\), on which lies a broad circular iron plate, where is the bearing of the brads friction-wheels, whose iron axle-trees move in brads collars: the turning-frame \(g\) carries the axle-tree \(i\), and the falls \(i, k\), which are turned, so as always to face the wind, by the vane \(h\); the frame is kept from wrinkling by iron braces \(a, r\), represented by the double pricked lines. The crank \(x\) is six inches and a half long, and therefore gives a stroke of thirteen inches; but the lower end of the rod \(x\) is fixed to the lever of the ventilator (fig. 4.) at such a distance from the centre of its motion, as to raise and fall the midribs fifteen inches. The iron axle-tree extends forward, about two feet and a half beyond the face of the falls; from the extremity of which, \(i\), eight iron braces, \(l, l\), go to each arm, to which they are fastened by iron screw-bolts, which bind them and the iron circle of pricked lines \(m m\) (fig. 7.) fast together: the diameter of this circle is six feet, and the sweeps or arms of the mill \(k k\) are seven feet three inches long, and they are mortised into the drum \(y y\). A void space of about six inches breadth is left between the falls, as represented in the figure, that the direct current of the wind, as it passed through, might give a turn to the course of the wind; which otherwise, being driven obliquely from the face of the preceding fall, would be forced to act on the back of the following fall, and thereby abate the force, and retard the motion of the mill. The brake-pole (fig. 6.) is \(n\); and the single pricked line \(t\) at the end of it is the fword which is to clasp round the nave to stop the mill, by pulling the rope \(o; o\) is the bottom of the tree of the turning-frame; and \(p\) expresses the manner of screwing the brads into the axle-tree nearer and nearer, as they wear away. For a farther account of this machine, see Hales's Treatise of Ventilators, part ii. 1758, p. 32, &c.

Dr. Hales farther suggests, that ventilators might be of use in making salt, in order to which there should be a stream of water to work them, or they might be worked by a windmill, and the brine should be in long narrow canals, covered with boards or canvas, about a foot above the surface of the brine, in order to confine the stream of air, so as to make it act upon the surface of the brine, and carry off the water in vapours. Thus it might be reduced to a dry salt, with a faving of fuel, in winter and summer, or in a rainy or dry state of the air. Ventilators, he apprehends, might also serve for drying linen hung in low, long, narrow galleries, especially in damp, rainy weather, and also in drying woollen cloths, after they are full or dyed, and in this case they might be worked by the fulling water-mill. Ventilators might also be an useful appendage to malt and hop-kilns; in which case it would be beat to have the air-trunk enter the kiln about eighteen or twenty-four inches from the ground, and just opposite to the fire; but in order to prevent the air blowing too strongly on the fire, a screen of brick-work might be formed about a yard distant from the hole of the air-trunk, and a yard square; for thus the air from the ventilators would be better diffused through the whole kiln.

Dr. Hales is also of opinion, that a ventilation of warm dry air from the adjoining stove, with a cautious hand, might be of service to trees and plants in greenhouses; where it is well known that an air full of the rancid vapours, which perpiss from the plants, is very unkindly to them, as well as the vapours from human bodies are to men. For fresh air is as necessary to the healthy state of vegetables as of animals.

The larger kinds of ventilators used by the doctor, are ten feet long, five feet broad, and two feet high in the clear within. Those he used by way of experiment on board the Captain, a seventy-gun ship, were ten feet long, four feet three inches wide in the clear within, and thirteen inches deep; one inch of which being occupied by the midriif, there remained a foot depth for it to rife and fall in. A ventilator of these dimensions will, through a trunk of a foot square, drive the air at the rate of twenty-five miles in an hour, which is double of what Marjorib aligns for the velocity of a pretty strong wind.

But besides these large ventilators, the doctor made a smaller fort, four feet in length, sixteen inches in breadth, and thirteen inches deep, all in the clear within. This smaller ventilator may be very useful in preferring the bread in the bread-room of a ship, sweet and dry. Peas also, and oatmeal, which are apt to heat and spoil in casks, may be preserved, by putting them into a large bin, with a false bottom of hair-cloth laid on bars, by which fresh air may be blown upwards through them with these small ventilators.

Ventilators are also of excellent use for the drying of corn, hops, and malt. See Granary.

Gunpowder may be thoroughly dried, by blowing air up through it by means of ventilators.

What advantage dry gunpowder has over that which is damp, may be seen by the experiment mentioned in the article Gunpowder.

These small ventilators will also serve to purify moist easily and effectually the bad air of a ship's well, when there is occasion for persons to go down into it, by blowing air through a trunk, reaching within a yard of the bottom of the well, both for some time before, and during their stay there. They may be also made ufe of at sea to sweeten the air, and prevent sickness, &c. See Sea-Water.

Dr. Hales made also several trials for curing ill-tafted milk by ventilation.

For these and other uses to which they might be applied, as well as for a particular account of the construction and disposition of ventilators in ships, hospitals, prisons, &c. and the benefits attending them, see Hales's Treatise on Ventilators, part ii. p. 332, &c.

The ventilators in large ships, since the order for ventilating the fleet, illfused by the lords of the Admiralty in 1758, are fixed in the gunner's foore-room, and generally a-head of the foal-room. The foul air is carried up through the decks and foore-castle, near the fore-mast, sometimes afo and sometimes abaft it, but more frequently on its flatboard side; the lever, by which the ventilators are worked, is under the foore-castle in two-deck ships, and between the upper and middle decks in three-deckers, sometimes the lever is hung athwart-ships; in some ships afoe and aft; and in others oblique. The iron rod, which communicates the motion from the lever, passes through the partners of the fore-mast, and is connected with another lever, suspended at or near the middle; in some ships over the ventilators; in others under them, when it is found necessary to fix them up to the deck. The belt method to fave room is to place the ventilators over one another, with their circular ends together; the air-trunk should be so high above deck, that the men on deck may not be incommoded by the foul air which blows out of it; and therefore the trunk comes through the upper deck, near and behind the
The construction of twenty-gun ships being various, the
sizes of ventilators for these must be left to the direction of
the officers of the yard.

When the hold is to be ventilated from one end to the
other, the three doors of the gang-way into the gunner's
fore-room must be opened, and all the gratings on the gun-
deck be covered with tarpaulins, leaving all doors open,
whose rooms want ventilation, on the orlop and the wardroom
hatch. But when it is thought proper to ventilate between
decks, then the doors of the gang-way into the gunner's
fore-room must be shut, and the scuttle in the headmolt trunk or pipe upon the gun-deck must be opened; and all
the gratings of the middle deck, if the ship be a three-decker, or of the upper deck, if it be a two-deck ship, be
left with tarpaulins; and, if possible, one of the stern-
poles opened, or the aftermole hatch-way, or a scuttle on
purpose, through the deck, as near the stern as possible.

Hales's Treat. 2d. p. 97. &c.

The method of drawing off air from ships by means of
fire-pipes, which some have preferred to ventilators, was
published by Sir Robert Moray in the Phil. Trans. for
1665. These are metalline pipes, about two inches and
a half in diameter, one of which reaches from the fire-place
to the well of the ship; the other three branches go to other
parts of the ship; the stove-hole and anh-hole being closed
up, the fire is supplied with air through these pipes. The
defects of these, compared with ventilators, are particularly
examined by Dr. Hales, ubi supra, p. 113. See Air-Pipe
and Ship.

Mr. Erasmus King proposed to have ventilators worked
by the fire-engines in mines; and Mr. Fitzgerald has sug-
ggested an improved method of doing this, which he has also
illustrated by figures. See Phil. Trans. vol. I. p. 727, &c.

There are various ways of ventilating the air of rooms:
Mr. Tidd contrived to admit fresh air into a room, by
taking out the middle upper sash-pane of glafs, and fixing
in its place a frame-box, with a round hole in its middle,
about six or seven inches diameter; in which hole are fixed,
behind each other, two or three small timpaned windmills,
with falls of very thin broad copper-plates, which spread
over and cover the circular hole, so as to make the air which
enters the room to spread round in thin sheets sideways;
and thus not to inconvenience persons, by blowing directly
upon them, as it would do if it were not hindered by the
falls, which turn on the same axle-tree, each less than the
other. See LEBULUS.

This method of refreshing rooms is much approved of,
and used by many, not only in England, but also in other
countries. For other methods of ventilating ships, build-
ings, rooms, &c. see Air-Chamber, Bellows, Air-Pipe,
Centrifugal Wheel, and Wind-Sail.

VOL. XXXVI.

VENTILLA, in Geography, a town of Peru, in the
diocefe of La Paz; 9 miles S. of La Paz.

VENTININA, a term used by Paracelsus and his fol-
lowers, to express the art of divining, or knowing by the
winds and the courses the good or ill effects of fea-
lots.

VENTIS PONTIS, in Ancient Geography, a town of Hif-
pania, in Betica, in the vicinity of Caraccia.

VENTO, Matteo, in Biography, a Neapolitan, and dif-
icute of Rome. That, however, is not discoverable in his
compositions, which are easy and graceful, but have none of
the solidty or originality of his matter. Arriving in
England in 1764, at the inauspicious termination of the
reign of the Mingotti and Giardini at the Opera, he had
the good fortune to be engaged by Gordon and Vincent, the
new impresarios, to compose an opera, in which Manzoli was
to perform the principal part. The opera which he had to
fet was the Demofonte of Metaftafo, of which the airs are
natural, graceful, and pleasing; always free from vul-

garity, but never very new or learned. They were, how-
ever, in great public and private favour a considerable time.

In 1765, on the second arrival of Elfi, he fet Sofoniba,
in that easy and graceful stile which pleased more generally
than what professors would call better music. This drama
was repeated more frequently than any other during the
seafon, and the fongs, printed by the elder Wilkie, were
long after in favour at concerts and public places, as well as
among lifting miffes and dilettanti.

In 1767, on the arrival of Guarducci, Vento fet the
opera of "La Conquista del Mefico," of which the airs, like
theo of his former operas, were elegant and pleasing.
After this he seems to have fulfilled up his whole time in
teaching, till the arrival of Gabrielli, in 1776, when he fet
"La Veilale," in his usual easy stile; and when we told him
that his airs were somewhat too familiar for great fingers, he
saw, "God forbid I should ever compose difficult music!"

This composer's harpsichord pieces are flimsy, and so
much alike, that the invention, with respect to melody and
modulation of the eight fets, may be comprifed into two or
three movements. In these sonatas, as well as in his fongs,
he avoids vulgar paffages, and has a graceful, easy, and
flowing melody; but his bases are too like Alberti's, and
his treble too like one another, either to improve the hand
or delight the ear. He had a great number of scholars,
which ensured the efuture of printing his pieces, though
not their general and public favour. One or two fets of
such easy compositions would, indeed, have been very useful
to scholars in the firft fages of their execution; but eight
books, in which there is fo little variety, can never be
wanted, or indeed borne, but by thofe who think it right
implicitly to receive all their mafter's prefcriptions. His
duos for voices are alike trivial and unintereting, and the
opera of "Artaferse," which he composed for the Harmonic
Meeting, that was fet up in 1771 by the friends of
Guadagni and Giardini against the great Opera, under the
management of Mr. Hobart, which people of the firft rank
were fo impatient to hear in a clandestine way, as to run the
risk of pains and penalties for it, when published, appeared to
have lefs merit and novelty than any one of his former works.

Vento died in 1777, very rich, as there was every rea
on of industry, parfimony, and avarice, to imagine; but by
some strange disposition of his property and affairs, none of
his effects could be found at his death; and his widow and
her mother were left wholly delitute of support, but from
charity and the lowest menial labour.

VENTOSA, Spina. See SPINA Ventosa.

VENTOSITY, in Medicine. See Flatus and
Tympanites.
VENDO, in *Geography*, a cape on the N.E. coast of the island of Cabrera, in the Mediterranean. N. lat. 39° 10'. E. long. 2° 55'.

VENDOTIENNA, in *Geography*, an island in the Mediterranean, near the coast of Naples, anciently called Pandataria; according to sir William Hamilton, composed of volcanic matter thrown up by fire. It is now, as it seems to have been for ages, used as a place of banishment for criminals of a superior rank. Hitherto Julia, the daughter of Angitus, was sent, accompanied by her mother Seribonius. Some years the virtuous Agrippina was also confined here; and Octavia, wife of Nero, and daughter of Claudius, was at the instigation of Poppaxa banished and murdered in this island; 17 miles W. of Itchia. N. lat. 40° 53'. E. long. 13° 19'.

VENTRE, in Ancient Geography, a town of Italy; to which the Romans sent a colony about the year 351 from the foundation of Rome, according to Diodorus Siculus.

VENTRE, in *Geography*, a town of Hindoostan, in the circle of Eullore; 7 miles W. of Eullore.

VENTREJCI, in *Laee*, a writ for the search of a widow that fays she is with child, and thereby holds land from him that is, otherwise, next heir at law. See Jur of Matrons.

VENTREVRE, in *Geography*, a small island in the Atlantic, near the coast of France. N. lat. 47° 28'. W. long. 2° 59'.

VENTRICULUS, in *Anatomy*, the stomach. See STOMACH.

VENTRICAL Cordis, the two cavities of the heart, which propel the blood into the arteries; they are the right and left, or pulmonary and aortic. See HEART.

VENTRICLE or Ventricles of the Brain, cavities in different parts of its substance. They are the two lateral, right and left, called alve roumes; the 3d, 4th, and 7th, or ventricle of the septum lucidum. See BRAIN.

VENTRICULAR Arder. See ARDOR.

VENTRICALUS Sucettenturatius, in *Medicine*, a name given by some to the duodenum, when very large. Med. Eff. Edinb. abr. vol. ii. p. 34.

VENTRIOIQUEUS, Ventriloquus, compounded of venter, belly, and loquor, I speak, gontriloquis, or engastrimythus; a term applied to persons who speak inwardly; having a peculiar art of forming speech, by drawing the air into the lungs; so that the voice, proceeding out of the thorax, to a bystander seems to come from some distance, or in any direction. See ENGAstrIMYThUS.

Such a person we had formerly in London, a smith by profession, who had the faculty in such perfection, that he could make his voice appear, now, as if it came out of the cellar; and the next minute, as if in an upper room; and nobody present could perceive that he spoke at all. Accordingly, he has frequently called a person first up, then down stairs; then out of doors, then this way, then that, and all this without stirring from his seat, or appearing to speak at all.

We cannot forbear making a few extracts from this curious subject from a work, published in 1772, entitled "Le Ventriloque," &c. or the Ventriloquy, by M. de la Chapelle, canon royal at Paris, member of the Academies at Lyons and Rouen, and F.R.S. Some faint traces of the art or faculty of ventriloquism are to be found in the writings of the ancients; but many more are to be discovered there, if we adopt this author's opinion, that the recensions of many of the ancient oracles were actually delivered by persons poifting this quality, so very capable of being applied to the purport of priestcraft and delusion. The abbé de la Chapelle, having heard many surprising circumstances related concerning one M. St. Gille, a grocer at St. Germain-en-Laye, near Paris, whose powers as a ventriloquist had given occasion to many singular and diverting scenes, formed the resolution of seeing him. Being seated with him on the opposite side of a fire in a parlour on the ground-floor, and very attentively observing him, the abbé, after half an hour's conversation with M. St. Gille, heard himself called, on a sudden, by his name and title, in a voice that seemed to come from the roof of a house at a distance; and whilst he was pointing to the house from which the voice had appeared to him to proceed, he was yet more surprised by hearing the words "it was not from that quarter," apparently in the same kind of voice as before, but which now seemed to issue from under the earth, at one of the corners of the room. In short, this factitious voice played, as it were, every where about him, and seemed to proceed from any quarter, or distance, from which the operator chose to transmit it to him. To the abbé, though conscious that the voice proceeded from the mouth of M. St. Gille, he appeared absolutely mute, while he was exercising this talent; nor could any change in his countenance be discovered. He observed, however, that M. St. Gille pretend only the profile of his face to him, while he was speaking as a ventriloquist. On another occasion, M. St. Gille fought for shelter from a storm in a neighbouring convent; and finding the community in mourning, and enquiring the cause, he was told, that one of their body much esteemed by them had lately died. Some of the religious attended him to the church, and saw him the tomb of their deceased brother, spoke very feelingly of the scanty honours that had been bestowed on his memory; when suddenly a voice was heard, apparently proceeding from the roof of the choir, lamenting the situation of the defunct in purgatory, and reproaching the brotherhood with their want of zeal on his account. The whole community being afterwards convened into the church, the voice from the roof renewed its lamentations and reproaches, and the whole convent fell on their faces, and vowed a solemn reparation. Accordingly they first chanted a de profundis in full choir, during the intervals of which the ghost occasionally expressed the comfort he received from their pious exercises and ejaculations in his behalf. The prior, when this religious service was concluded, entered into a serious conversation with M. St. Gille, and inveighed against the absurd incredulity of our modern sceptics, and pretended philosophers, on the article of ghosts and apparitions; and M. St. Gille found it difficult to convince the fathers that the whole was a ludicrous deception.

Another instance of his extraordinary powers occurred in presence of a large party, consisting of commissaries from the Royal Academy of Sciences at Paris, and other persons of the highest quality, together with a certain lady, who was not in the secret, and who was only told, that an aerial spirit had lately established itself in the forest of St. Germain-en-Laye, and that they were assembled to enquire into the reality of the fact. When the party sat down to dinner, the aerial spirit began to address the lady with a voice that seemed to be in the air over her heads; sometimes he spoke to her from the trees around them, or from the surface of the ground at a great distance, and at other times from a considerable depth under her feet. The lady, being thus addressed for more than two hours, was firmly persuaded that this was the voice of an aerial spirit; and it was some time before she was deceived.

Several other instances of M. St. Gille's talents are related; and the abbé, in the course of his inquiries, was informed,
formed, that the baron de Mengen, a German nobleman, professed this art in a very high degree. He also relates, from Brodean, a learned critic in the sixteenth century, one of the singular feats performed by a capital ventriloquift in his time, who was called Louis Brabant, and was valet de chambre to Francis I. Our countryman Dickenfon speaks of him particularly, in his tract entitled "Delphi Phoenizizantes," printed in duodecimo at Oxford, in 1655. Louis had fallen in love with a beautiful and rich heiress, but was rejected by the parents as an unfit match, on account of his low circumstances. However, the father dying, he visited the widow; and on his first appearance in the house, she heard herself accoited in a voice resembling that of her dead husband, and which seemed to proceed from above.

"Give my daughter in marriage to Louis Brabant, who is a man of great fortune, and excellent character; I now endure the inexplicable torments of purgatory, for having refused her to him; obey this admonition, and I shall be soon delivered; you will provide a worthy husband for your daughter, and procure everlasting repose to the soul of your poor husband." The dread summons, which had no appearance of proceeding from Louis, whose countenance exhibited no change, and whose lips were close and motionless, was instantly complied with; but the deceiver, in order to mend his finances for the accomplishment of the marriage contract, applies to one Cornu, an old and rich banker at Lyons, who had accumulated immense wealth by usury and extortion, and was haunted by remorse of conscience. After some conversation on demons and spectres, the pains of purgatory, &c. during an interval of silence, a voice is heard like that of the banker’s deceased father, complaining of his dreadful situation in purgatory, and calling upon him to rescue him from hence, by putting into the hands of Louis Brabant, then with him, a large sum for the redemption of Christians in slavery with the Turks; threatening him at the same time with eternal damnation, if he did not instantly exorcise his own sins. Upon a second interview, in which his ears were saluted with the complaints and groans of his father, and of all his deceased relations, imploring him for the love of God, and in the name of every saint in the Calendar, to have mercy on his own soul and others, Cornu obeyed the heavenly voice, and gave Louis ten thousand crowns, with which he returned to Paris, and married his milftres. The mifer, being afterwards undeceived, was so mortified, that he took to his bed and died.

The abbé de la Chapelle takes occasion to account for all the circumstances attending Saul’s conference with the Witch of Endor, (which see,) and endeavours to shew that the speech, supposed to be addressed to Saul by the ghost of Samuel, actually proceeded from the mouth of the reputed forceress, whom he supposes to have been a capital ventriloquift. On these grounds he explains that transfiguration, and reconciles all its circumstances to the relation given of it in Scripture; where it is to be observed, that Saul is not said to have seen Samuel, but only to have heard a voice, which a ventriloquift can produce and transmit from any quarter, and with any degree of strength whatever. He afterwards brings many instances to prove, that the ancient oracles principally supported their credit, and derived their influence, from the exercife of this particular art. Many other learned men have given the same account of the witch of Endor. Though she is said to have a familiar spirit, yet the Hebrew word אֱלֹהֵי (Elæ) is rendered generally by the LXX ἐνσατισμένος, ventriloquif. Thus it is rendered in Isaiah, xix. 3. It appears from Plutarch (De Defect. Orac. tom. ii. p. 414.) Suidas (tom. i. ad voc. ἐνσατισμένος, p. 667.), and Josephus (Antiq. lib. xiv. p. 354.), that those who were anciently called ventriloquists had afterwards the name of Pythonizers, which implies a pretence to divination. Accordingly Python is the word used by the Vulgate version, i Sam. xxvii. 7, 8.; though not, as Voltaire seems to intimate, in the Hebrew; and, therefore, there is no ground for the conclusion which he draws, viz. that the history was not written till the Jews traded with the Greeks, after the time of Alexander, i. e. for determining the date of a Hebrew book from the use of a word in a Latin translation, made many hundred years after it, and not to be found in the original.

From baron de Mengen’s account of himself, and the observations made by M. de la Chapelle in his frequent examinations of M. St. Gille, it seems that the factitious voice produced by a ventriloquift does not (as the etymology of the word imports) proceed from the belly, but is formed in the inner parts of the mouth and throat. The art, according to this author, does not depend on a particular structure or organization of these parts, peculiar to a few individuals, and very rarely occurring, but may be acquired by almost any ardently desirous of attaining it, and determined to persevere in repeated trials. The judgments we form concerning the situation and diflance of bodies, by means of the senses mutually assisting and correcifg each other, seem to be entirely founded on experience (see Reid’s Inquiry into the Human Mind, p. 70. edit. 2.); and we pass from the sign to the thing signified by it immediately, or at leasf without any intermediate steps perceptible to ourselves. Hence it follows, that if a man, though in the same room with another, can by any peculiar modification of the organs of speech produce a sound, which in faintness, tone, body, and every other sensible quality, perfectly resembles a sound delivered from the roof of an opposite house, the ear will naturally, without examination, refer it to that situation and distance; the sound which the person hears being only a sign, which from infancy he has been accustomed, by experience, to associate with the idea of a person speaking from a house-top. A deception of this kind is practifed with success on the organ, and other musical instruments; and there are many similar optical deceptions.

Rolandus, in his Aglofpoligomographia, mentions, that if the mediaflnium, which is naturally a fingle membrane, be divided into two parts, the speech will seem to come out of the breast; so that the by-flanders will fancy the person poffefied.

For some facts and observations tending to explain the curious phenomena of ventriloquism by Mr. John Cough, we refer to the Manchester Memoirs, vol. v. part 2. p. 622. London, 1802, in which the ingenious author investigates the method whereby men judge by the ear of the position of honorous bodies relative to their own persons. This author observes in general, that a sudden change of direction in sound, our knowledge of which, as he conceives, does not depend on the impulse in the ear, but on other facts, will be perceived, when the original communication is interrupted, provided there be a sensible echo. This circumstance will be acknowledged by any person who has had occasion to walk along a valley, intercepting with buildings, at the time that a peel of bells was ringing in it. For the sound of the bells, instead of arriving coninually at the ears of a person so situated, in its true direction, is frequently reflected in a short time from two or three different places. These deceptions are in many cases so much diversified by the succesive interpositions of fresh objects, that the fieple appears, in the hearer’s judgment, to perform the part of an expert ventriloquift on a theatre, the extent of which is adapted to its own powers, and not to those of the human voice.
voice. The similarity of effect which connects this phenomenon with ventriloquism convinced the author, whenever he heard it, that what we know to be the cause in one instance is also the cause in the other, viz. that the echo reaches the ear, while the original sound is intercepted by accident in the case of the bells, but by air in the case of the ventriloquist. In order that the cause which gives rise to the amusing tricks of this uncommon talent may be pointed out with the greater clearness, it will be proper to describe certain circumstances that take place in the act of speaking, because the skill of the ventriloquist seems to confound in a peculiar manner of them. Articulation is the art of modifying the sound of the larynx, by the affiduity of the cavity of the mouth, the tongue, teeth, and lips. The different vibrations, which are excited by the joint operation of several organs in action, pass along the bones and cartilages, from the parts in motion to the external teguments of the head, face, neck, and chest; from which, a succession of similar vibrations is imparted to the contiguous air, thereby converting the superior moiety of the speaker's body into an extensive feat of sound, contrary to general opinion, which supposes the passage of the voice to be confined to the opening of the lips.

When an orator addresses an audience in a lofty and spacious room, his voice is reflected from every point of the apartment, of which all present are made sensible by the confused noise that fills up every pause in his discourse; nevertheless, every one knows the true place of the speaker, because his voice is the prevailing sound at the time. But were it possible to prevent his words from reaching any one of the audience directly, what would then follow? Undoubtedly a complete case of ventriloquism would be the consequence, and the person so circumstanced would transport the orator, in his own mind, to the place of the principal echo, which would perform the part of the prevailing sound at the infant. This he would be obliged to do, because the human judgment is bound, by the dictates of experience, to regard the person as inseparable from the voice; and the deception in question would be unavoidable, being produced by the same concurrence of causes which makes a peal of bells, situated in a valley, seem to change place in the opinion of a traveller. It is the business of a ventriloquist to amuse his admirers with tricks resembling the foregoing delusion; and it will be readily granted, that he has a subtle sense, highly corrected by experience, to manage, on which account the judgment must be cheated as well as the ear. This can only be accomplished by making the pulsed, constituting his words, strike the heads of his hearers, not in the right lines that join their persons and his. He must, therefore, know how to disfigure the true direction of his voice, because the artifice will give him an opportunity to substitute almost any echo he chooses in the place of it. But the superior part of the human body has been already proved to form an extensive feat of sound, from every point of which the pulses are repelled, as if they diverged from a common centre. This is the reason why people, who speak in the usual way, cannot conceal the direction of their voices, which in reality fly off towards all points at the same instant. The ventriloquist, therefore, by some means or other, acquires the difficult habit of contracting the field of sound within the compass of his lips, which enables him to confine the real path of his voice to narrow limits. For he, who is master of the art, has nothing to do but to place his mouth obliquely to the company; and to dart his words, if the expression may be used, against an opposing object, whence they will be reflected immediately, so as to strike the ears of the audience from an unexpected quarter, in consequence of which the reflector will appear to be the speaker. Nature seems to fix no bounds to this kind of deception, only care must be taken not to let the path of the direct pulses pass too near the head of the person who is to be played upon; for, if a line, joining the exhibitor's mouth and the reflecting body, approach one of his ears too nearly, the divergency of the pulses will make him perceive the voice itself, instead of the reverberated sound.

The author has given the following narrative of a ventriloquist, whom he attended in the exercise of his art. His audience was arranged in two opposite lines, corresponding to the two sides of a long narrow room. The benches on which they were seated reached from one end of the place to the middle of it, the other part remaining unoccupied. The seats exhibited by him were the three following. First: he made his voice come from behind his audience, but it never seemed to proceed from any part of the wall, near the heads of the people present; on the contrary, it was always heard resembling the voice of a child, who seemed to be under the benches. He filled during the time of speaking in a floating posture, having his mouth turned towards the place from which the found issued; so that the line, joining his lips and the reflecting object, did not approach the ears of the company. Second: advancing into the vacant part of the room, and turning his back to the audience, he made a variety of noises, that seemed to proceed from an open cupboard which filled directly before him, at the distance of two or three yards. Third: he placed an inverted glass on the hands of his hearers, and then imitated the cries of a child confined in it. His method of doing it was this; the upper part of the hearer's arm laid close along his side; then the part below the elbow was kept in a horizontal position, with the hand turned downwards, which was done by the operator himself. After taking these preparatory steps, the man bent his body forwards in a situation which prevented the profile of his face nearly to the front of his hearer, whilst his mouth pointed to the cup; in which posture he copied the voice of a confined child so completely, that three positions of the glass were easily distinguished by as many different tones, viz. when he pressed the mouth of the cup close against the palm, when one edge of it was elevated, and when the vessel was held near the hand, but did not touch it. The second and third instances of ventriloquism afford strong proofs, that this delusive talent is nothing more than the art of substituting an echo for the primary sound; for, besides the change perceivable in the direction of the voice, it was found to be blended with a variety of secondary sounds; such as we know by experience are produced, as often as a noise of any kind issues from a cavity.

The method of preventing the vibration of the vocal organs from reaching the external teguments is still wanting, as our author acknowledges, to complete his theory of ventriloquism; and this, he presumes, can only be supplied by an adept in the art.

VENTURINE, or VENTURY, in geography, a small town of the county of Kerry, Ireland, situated on a harbour to which it gives name, on the Atlantic ocean. It is 43 miles W. of Dingle. VENTURINE, or ADVENTURINE, is sometimes used for the finest and flenderest gold wire, used by embroiderers, &c.

When reduced into powder, as fine as it can be clipped, or filed, this powder may be wrought on the first layer of pure varnish, made use of in japanning, after the varnish is dry, in order to lay any colour over it.

VENUE, or VENEW, in Law, a neighbouring or near place. Locus quem vicini habent.

Thus
VEN

Thus we say, twelve of the affines ought to be of the same venue where the demand is made.

In transitory actions, the courts will very often change the venue, or county, in which the cause is to be tried. The statute 6 Ric. II. cap. 2. having ordered all writs to be laid in their proper counties, this, as the judges conceived, empowered them to change the venue, if required, and not to infilt rigidly on abating the writ, which practice began in the reign of James I.; and this power is diiferentially exercised, so as not to cause, but prevent a defect of justice. Therefore the court will not change the venue to any of the four northern counties, previous to the spring circuit; because there the affines are held only once a year, at the time of the summer circuit. And it will sometimes remove the venue from the proper jurisdiction, (especially of the narrow and limited kind,) upon a suggestion, duly supported, that a fair and impartial trial cannot be had therein. Blacklt. Comm. book iii.

VENUS, in Astronomy, one of the inferior planets; denoted by the character ♈.

Venus is easily distinguished by her brightness and whiteness, which exceeds that of all the other planets; and which is so considerable, that, in a dusky place, the projects a sensible shadow. Her place is between the earth and Mercury.

She constantly attends the sun, and never departs from him above 47° 48' or 44° 57'. If S be the sun (Plate XXI. Astronomy, fig. 8.), E the earth, V Venus or Mercury, and E V a tangent to the orbit of the planet, then will the angle S E V be the greatest elongation of the planet from the sun; which angle, if the orbits were circles having the sun in their centre, would be found by saying, E S : S V :: rad.: sin. S E V. But the orbits are not circular, in consequence of which the angle E V S will not be a right angle, unless the greatest elongation happens when the planet is at one of its apsides. The angle S E V is also subject to an alteration from the variation of S E and S V. The greatest angle S E V happens, when the planet is in its aphelion, and the earth in its perigee, and the leaf angle S E V, when the planet is in its perihelion, and the earth in its apogee. M. de la Lande has calculated these greatest elongations, and finds them 47° 48' and 44° 57' for Venus, and 28° 20' and 17° 36' for Mercury. If we take the mean of the greatest elongations of Venus, which is 46° 22.5', it gives the angle V S E = 43° 37.5'; and as the difference of the mean daily motions of Venus and the earth about the sun is 37', we have 37': 43° 37.5': 1 day: 70.7 days, the time that would elapse between the greatest elongations and the inferior conjunction, if the motions had been uniform, which will not vary much from the true time. See Elongation.

To find the position of a planet when stationary. Let S be the sun (fig. 9.), E the earth, P the contemporary position of the planet, X y the sphere of the fixed stars, to which we refer the motions of the planets; let E F, F Q, be two indefinitely small arcs described in the same time, and let E P, F Q, produced, meet at L: then it is manifest, that whilst the earth moves from E to F, the planet appears stationary at L; and on account of the immense distance of the fixed stars, E P L, F Q L may be considered as parallel. Draw S E, S F E, S F, S P, and S Q; then, as E P and F Q are parallel, the angle Q F S = P E S = P E S = E S F, and S P F = S Q F = S F Q = P S Q; that is, the contemporary variations of the angles E and P are as E S F : P S Q, the contemporary variations of the angular velocities of the earth and planet, or, (because the angular velocities are inversely as the per- 

odic times, or inversely in the sesquiplicate ratio of the distances) as $S \frac{P^3}{P^3}$ : $S \frac{E^3}{E^3}$, or (if $S \frac{P}{S} : S \frac{E}{E}$ :: $a : i$) as $a^2 : 1^2$. But sin. S E P : sin. S P E being as $S \frac{P}{S} : S \frac{E}{E}$, or $a : i$, the contemporary variations of these angles will be as their tangents. Hence, if $x$ and $y$ be the sines of the angles S E P and S P E, we have $x : y :: a : i$, and 

$$
\frac{x}{\sqrt{1-x^2}} = \frac{y}{\sqrt{1-y^2}} :: a^2 : 1, \text{ whence } x^2 = \frac{a^2 - a^2}{a^2 - 1} = \frac{a^2 + a}{a + 1}, \text{ and } x = \sqrt{\frac{a^2 + a + 1}{1}}.
$$

The planet's elongation from the sun, when stationary.

Ex. If P be the earth, and E Venus; and we take the distances of the earth and Venus to be 100000 and 7233, we find $x = 0.48264$ the sine of 28° 51' 50", the elongation of Venus when stationary, upon the supposition of circular orbits.

For eccentric orbits, the points will depend upon the position of the apsides and places of the bodies at the time. We may, however, get a very near approximation thus. Find the time when the planet would be stationary, if the orbits were circular, and compute for several days, about that time, the geocentric place of the planet, so that you get two days, on one of which the planet was direct, and on the other retrograde, in which interval it must have been stationary, and the point of time when this happened may be determined by interpolation.

To find the time when a planet is stationary, we must know the time of its opposition, or inferior conjunction. Let m and n be the daily angular velocities of the earth and planet about the sun, and $v$ the angle P S E, when the planet is stationary; then $m - n$, or $n - m$, is the daily variation of the angle at the sun between the earth and planet, according as it is a superior or inferior planet; hence, $m - n$, or $n - m$, : $v :: 1$ day : $v$, or

$$
\frac{v}{m - n}, \text{ the time from opposition or conjunction to the stationary points both before and after. Hence, the planet must be stationary twice every synodic revolution.}
$$

Ex. Let P be the earth, E Venus; then the angle S P E = 20° 51' 50"; therefore, P S E = 1°; also, $n - m = 37'$; hence, $37'$ : $13'$ :: 1 day : 21 days, the time between the inferior conjunction and stationary positions.

If the elongation be observed when stationary, we may find the distance of the planet from the sun, compared with the earth's distance, supposed to be unity. For $x^2 = a^2$; hence, $a^2 + x^2 - 1 \times a = \frac{x^2}{x^2 - 1} = \frac{x^2}{x^2 - 1}$

$$a = i^2; \text{ consequently, } a = \frac{1}{4} i^2 + \frac{1}{4} i^2 \text{ upon the supposition of circular orbits.}
$$

A superior planet is retrograde in opposition, and an inferior planet is retrograde in its inferior conjunction; for let E be the earth (fig. io.), P a superior planet in opposition; then, as the velocities are as the inverse square roots of the radii of the orbits, the superior planet movesslowest; hence, if E F, P Q, be two indefinitely small contemporary arcs, P Q is less than E F, and on account of the immense distance of the sphere y Z of the fixed stars, P Q muft cut E P in some point x between P and m, consequently the planet appears retrograde from m to n. If P be the earth, and E an inferior planet in inferior conjunction, it will appear
pear retrograde from \( v \) to \( w \). These retrograde motions must necessarily continue till the planets become stationary. Hence, a superior planet appears retrograde from its stationary point before opposition to its stationary point after; and an inferior planet, from its stationary point before inferior conjunction to its stationary point after.

When Venus appears west of the sun, that is, from her inferior conjunction to her superior, she rises before him, and is called Phosphorus, or Lucifer, or the Morning Star; and when she appears east of the sun, that is, from her superior conjunction to her inferior, the fets after him, or shines in the evening after he sets, and is called Hesperus, or Vesper, or the Evening Star: being each in its turn for two hundred and ninety days.

To delineate the appearance of a planet at any time. Let \( S \) be the Sun (fig. 11), \( E \) the earth, \( V \) Venus, for example; \( aVb \) the plane of illumination perpendicular to \( SV \), \( cVd \) the plane of vision perpendicular to \( EV \), and draw \( a\nu \) perpendicular to \( c\nu \); then \( a\nu \) is the breadth of the visible illuminated part, which is projected by the eye into \( e\nu \), the vered fine of \( C = a \alpha \), or \( SVZ \), for \( SV \) is the complement of each. Now the circle terminating the illuminated part of the planet, being seen obliquely, appears to be an ellipse; therefore, if \( e\mu d \) represent the projected hemisphere of Venus next to the earth, \( m\mu \), \( c\mu \), two diameters perpendicular to each other, and we take \( e\nu \) the vered fine of \( SVZ \), and describe the ellipse \( m\nu \), \( v\mu \), \( e\nu \) is the axis minor, and \( m\nu v\mu \) will represent the visible enlightened part, as it appears at the earth; and from the property of the ellipse, this area varies as \( e\nu \). Hence, the visible enlightened part: the whole disc = the vered fine of \( SVZ \) : diameter.

Hence, Mercury and Venus will have the same phases from their inferior to their superior conjunction, as the moon has from the new to the full; and the same from the superior to the inferior conjunction, as the moon has from the full to the new. Mars will appear gibbous in quadratures, as the angle \( SVZ \) will then differ considerably from the two right angles, and consequently the vered fine will sensibly differ from the diameter. For Jupiter, Saturn, and the Georgion, the angle \( SVZ \) never differs enough from two right angles to make those planets appear gibbous, so that they always appear full-obliterated.

Dr. Halley proposed the following problem: To find the position of Venus when brightest, supposing its orbit, and that of the earth, to be circles, having the fun in their centre. Draw \( S\rho \) perpendicular to \( EVZ \), and put \( a = SE \), \( b = SV \), \( x = EV \), \( y = VR \); then \( b - y \) is the vered fine of the angle \( SVZ \), which vered fine varies as the illuminated part; and as the intensity of light varies inversely as the square of its distance, the quantity of light received at the earth varies as \( b - y \); but \( a^2 = b^2 + x^2 + 2xy \); hence, \( y = \frac{a^2 - b^2 - x^2}{2x} \); substitute this for \( y \), and we get the quantity of light to be as \( b - a^2 - b^2 - x^2 = 2bx - a^2 + b^2 + x^2 = \text{a maximum} \), put the fluxion = \( a \), and we get \( x = \sqrt{3}a^2 + b^2 - 2b \). Now, if \( a = 1 \), \( b = 0.72333 \), as in Dr. Halley's tables, then \( x = 0.43026 \); hence, the angle \( ESV = 22^\circ 21' \); but the angle \( ESV \), at the time of the planet's greatest elongation, is \( 43^\circ 42' \); hence, Venus is brightest between its inferior conjunction and its greatest elongation; also, the angle \( ESV = 39^\circ 44' \), the elongation of Venus from the sun at the same time, and \( \angle SVZ = VSE + VES = 62^\circ 52' \), the vered fine of which is \( 0.53 \), radius being unity; hence, the visible enlightened part: whole disc = \( 0.53 : 2 \); Venus, therefore, appears a little more than one-fourth illuminated, and answers to the appearance of the moon when five days old. Her diameter here is about \( 39^\circ \), and therefore the enlightened part is about \( 10^\circ.25 \). At this time, Venus is bright enough to cast a shadow at night. This situation happens about 36 days before and after its inferior conjunction; for, supposing Venus to be in conjunction with the sun, and when seen from the sun to depart from the earth at the rate of \( 37^\circ \) in 1 day, we have \( 37^\circ = 22^\circ 21' = 1 \text{ day} : 36 \text{ days} \); nearly, the time from conjunction till Venus is brightest.

If we apply this to Mercury, \( b = 0.3171 \), and \( x = 1.00058 \); hence, the angle \( ESV = 78^\circ 55' \); but the same angle, at the time of the earth's greatest elongation, is \( 67^\circ 13' \). Hence, Mercury is brightest between its greatest elongation and superior conjunction. Also, the angle \( ESV = 22^\circ 18' \), the elongation of Mercury at that time.

When Venus is brightest, and at the same time is at its greatest north latitude, it can then be seen with the naked eye at any time of the day, when it is above the horizon; for when its north latitude is the greatest, it rises highest above the horizon, and therefore is more easily seen, the rays of light having to come through a less part of the atmosphere, the higher the body is. This happens once in about eight years, Venus and the earth returning to the fame parts of their orbits after that interval of time. Vince's Elements of Astronomy.

The diameter of Venus is to that of the earth as \( 11.72 \) to 10 nearly, her apparent diameter equal to \( 59^\circ \), and real diameter equal to \( 9330 \) miles; her apparent diameter, when reduced to the mean distance of the earth, is, according to Dr. Herchel, \( 18^\circ.79 \), and her real diameter a little larger than that of the earth (see PLANET); her horizontal parallel about \( 30^\circ \); her distance from the sun is to that of the earth from the sun as \( 72333 \) to \( 100000 \), and her real distance is \( 68,891,456 \) miles; her excentricity is \( 0.05^\circ \) of her mean distance from the sun (see EXCENTRICITY); the inclination of her orbit to the plane of the ecliptic is \( 3^\circ 23' 35' \); her periodic course round the sun is performed in two hundred and forty-two days seventeen hours nearly; and her motion round her own axis in twenty-three hours, or, according to the observations of Bianchini, in twenty-four days eight hours: according to Dr. Herchel uncertain, but not so slow as twenty-four days. See Diamter, Distance, Excentricity, Node, Parallax, and Period. See also Planets, Planetarium, and Solar System.

Venus, when viewed through a telescope, is rarely seen to shine with a full face, but has phases just like those of the moon; being now gibbous, now horned, &c. and her illuminated part is constantly turned towards the sun, i.e. it looks towards the east, when Phosphorus; and towards the west, when Hesperus.

These different phases of Venus were first observed by Galileo, who thus fulfilled the prediction of Copernicus: for when this excellent astronomer revived the ancient Pythagorean system, affirming, that the earth and planets moved round the sun, it was objected that in such a case the phases of Venus should resemble those of the moon; to which Copernicus replied, that some time or other that resemblance would be found out. Galileo sent an account of the first discovery of these phases in a letter, written from Florence in 1611, to William de Medici, the duke of Tuscany's ambassador at Prague; desiring him to communicate it.
VENUS.

it to Kepler. The letter is extant in the preface to Kepler's Dioptrics, and a translation of it may be seen in Smith's Optics, p. 416.

Having related the observations which he had made, he adds, "we have hence the most certain, feasible decision and demonstration of two grand questions, which to this day have been doubtful and disputed among the greatest matters of reason in the world. One is, that the planets in their own nature are opaque bodies, attributing to Mercury what we have seen in Venus; and the other is, that Venus necessarily moves round the sun, as also Mercury, and the other planets; a thing well believed indeed by Pythagoras, Copernicus, Kepler, and myself, but never yet proved, as now, by ocular inspection upon Venus." He closes with explaining the eyphr that had been sent, in the following words: "Hae immatura à me frustra legitur, a y; i.e. Cynthiae figuris amalutor mater amorum, or, Venus imitates the phases of the moon."

M. Maraldi made several observations on Venus in 1729, but could perceive no spot; and, therefore, those observed by Bianchini must either have disappeared, or the air at Paris was not so clear as at Rome.

Martin Folkes, e.q. formerly president of the Royal Society, spoke of Bianchini with respect, as too accurate to make any mistakes in astronomical observations, and too honest to publish any thing that was not exactly agreeable to truth. See Nature of the Planets.

Sometimes Venus is seen in the disc of the sun, in form of a dark round spot. This happens when the earth is about her nodes at the time of her inferior conjunction. These appearances, called transits, happen but seldom. We have had two in the last century, viz. one in June 1761, and another in June 1769. The next will not occur before the year 1874. See Parallax.

The effect of the parallax being determined, for computing which Dr. Mackelyne proposed a new method in relation to the transit of Venus in 1769, the transit affords a very ready method of finding the difference of the longitudes of two places where the same observations are made. For compute the effect of the parallax in time, and reduce the observations at each place to the time, if seen from the centre of the earth, and the difference of the times is the difference of the longitudes. From the mean of sixty-three results from the transits of Mercury, Mr. Short found the difference of the meridians of Greenwich and Paris to be 9° 15'; and from the transit of Venus in 1761, to be 9° 10' in time.

Except such transits as these, Venus exhibits the same appearances to us regularly every eight years; her conjunctions, elongations, and times of rising and setting, being very nearly the same, on the same days, as before.

In 1762 and 1786, Cašini, with a telescope of 34 feet, thought he saw a satellitie moving round this planet, and distant from it about three-fifths of Venus's diameter. It had the same phases as Venus, but without any well-defined form; and its diameter scarcely exceeded one-fourth of that of Venus. Dr. Gregory (Ait. lib. vi. prop. 3.) thinks it more than probable that this was a satellitie; and supposes the reason why it is not usually seen, to be the unfitness of its surface to reflect the rays of the sun's light; as is the case of the spots in the moon: of which, if the whole disk of the moon were composed, he thinks, that planet could not be seen as far as to Venus.

Mr. Short, in 1749, with a reflecting telescope of 16½ inches focus, perceived a small star near Venus; with another telescope of the same focus, magnifying fifty or sixty times, and fitted with a micrometer, he found its distance from Venus about 10°; with a magnifying power of 240, he observed the star assume the fame phases with Venus; its diameter seemed to be about one-third, or somewhat less, of the diameter of Venus; its light not so bright and vivid, but exceeding sharp and well defined. He viewed it for the space of an hour, but never had the good fortune to see it after the first morning. Phil. Tranf. N° 459. p. 646, or Martyn's Abr. vol. viii. p. 268.

M. Montaigne, of Limoges in France, we are told in the Encyclopédie, art. Venus, preparing for observing the transit of 1761, discovered in the preceding May a small star about the distance of 20° from Venus, and its diameter was about one-fourth of the planet. He made other observations for several days, which were communicated to M. Bandounin, who read two memoirs on the subject to the Royal Academy of Sciences, in which he endeavoured to state the elements of the orbit of this satellitie; but it is to be considered, that Montaigne's telescope had no micrometer, and that his distances must be very vague and uncertain. If Venus has a satellitie, it must, according to Dr. Herchel, be less in appearance than a star of the eighth or ninth magnitude. Phil. Tranf. for 1795.

After all, it must be acknowledged, that Venus may have a satellitie, though it is difficult for us to see it. Its enlightened side can never be fully turned towards us, but when Venus is beyond the sun; in which case, Venus appears little bigger than an ordinary star, and, therefore, its satellitie may be too small to be perceived at such a distance. When the side is between us and the sun, her full moon has her dark side turned towards us; and when Venus is at her greatest elongation, we have but one half of the enlightened side of her full moon towards us, and even then it may be too far distant to be seen by us. But it was presumed, that the two transits of 1761 and 1769, would afford opportunity for determining this point; and yet we find that, although many observers directed their attention to this object, no satellitie was seen in the sun's disc; and, therefore, it is reasonable to conclude, that Venus has no satellitie.

The phenomena of Venus evidently shew the fality of the Ptolemaic system; for that system supposes, that Venus's orb, or heaven, inclines the earth, paffing between the sun and Mercury. And yet all our observations agree, that Venus is sometimes on this side of the sun, and sometimes on the other; nor did ever any body see the earth between Venus and the sun; which yet must frequently happen, if Venus revolved round the earth in an heaven below the sun.

Dr. Defaguliers contrived a planetarium to represent the phenomena of Venus, according to the discoveries of Bianchini; as did also Mr. Fergufon an orrery for the same purpose. The principal properties of these machines are the following: that the angle of the axis of the globe representing Venus makes, with the ecliptic, an angle of 15°; that the tropics are 75° from the equator; that the tropics are 15° from the equator; that the plane of a polar horizon for the longest day cuts the plane of the equator at an angle of 15°; that the sun's greatest declination is 75°; that there are but 94 days in every revolution round the sun; and that to bring the days to an even reckoning, every fourth year must be a leap year, which, taking in the four quarters of a revolution, will make the leap year in Venus confit of ten of her days, equal to 7½ months of our time; and that the long day for the north pole will contain 4½ apparent diurnal revolutions of the sun. For a detail and illustration of the phenomena resulting from these properties, see Defaguliers's Exp. Phil. vol. ii. p. 554, &c. Phil. Tranf. vol. xiv. p. 127, &c. &c. Fergufon's Astron. p. 8, &c. For the history and account of various instruments of this kind, see Orrery and Planetarium.

<td>9 8</td>
</tr>
<tr>
<td>11</td>
<td>10 8</td>
</tr>
</tbody>
</table>

The greatest Equation diminishes 25" in 100 Years. The others are proportional at the Rate of 0" for a Minute.
<table>
<thead>
<tr>
<th>Argument (Sig. I.)</th>
<th>Logarithm (Sig. III.)</th>
<th>Diff. Logarithm (Sig. IV.)</th>
<th>Logarithm of Sine (Sig. V.)</th>
<th>Diff. Logarithm (Sig. VI.)</th>
<th>Corr. Logarithm (Sig. VII.)</th>
</tr>
</thead>
</table>

Note: This table shows the logarithms of the sine of angles from 0 to 90 degrees, with corrections for the difference in the logarithms of the sine of angles from 90 to 180 degrees. The corrections are for the equation of the mean anomaly, and the equations of the equation of the mean anomaly from 90 to 180 degrees.
**Table VII. — Heliocentric Latitude of Venus, with the Reduction to the Ecliptic.**

**Argument.** The Longitude of Venus — that of the Node.

Explanation of the Tables.—Table I. contains the epochs of the mean longitude, of the aphelion and node. Table II. contains the mean motions of the same, for years. Table III. contains their mean motions for days. Table IV. contains their mean motions for hours, minutes, and seconds. Table V. contains the equation of the orbit for the year 1780; but this equation diminishes 25" in 100 years. Table VI. contains the logarithm of the distance of Venus from the sun, for the year 1780, with the corrections for 100 years, owing to a change of the eccentricity. Table VII. contains the heliocentric latitude of Venus, the reduction in longitude to the ecliptic, and the reduction of the logarithm of the distance, in order to get the curtaile distance from the sun.

The greatest equation (Table V.) of the orbit is 47² 20"; and this diminishes at the rate of 25" in 100 years; that is, the diminution for every minute of the equation is 25.0.5; we shall, therefore, take the secular diminution at the rate of 0.5 for every minute of the equation; thus, if the equation be 16', the diminution is 4" for 100 years; and for any other number of years, the diminution is in proportion. For any time before 1780, this correction must be added to the equation.

In Table VI. there is a small table for the correction of the logarithms of the distance of Venus from the sun, for 100 years; entering it with the mean anomaly of Venus, and applying the correction according to the sign, for any time after 1780; but with a contrary sign, before 1780.

To find the heliocentric Latitude and Longitude of Venus, and the Logarithm of her Distance from the Sun.—From Table I. take out the epochs of the mean longitude, the aphelion and node, for the given year; and place them in a horizontal line. But if the given year be not found in that Table, take the nearest year preceding the given year, as an epoch, and take out as before; under which (Table II.) place the mean motion in longitude, of the aphelion and node, answering to the number of years elapsed since the epoch, to the given year.

Under these, write down (Table III.) the mean motions of the fame, for the given day of the month.

Under these, write down (Table IV.) the mean motions of the fame, for the given hours, minutes, and seconds.

Add together the numbers in the several columns, reducing 128, or any multiple thereof, if they occur, and you get the mean longitude, places of the aphelion and node, for the given time.

Subtract the longitude of the aphelion from the mean longitude, and the remainder is the mean anomaly.

With the mean anomaly enter Table V., and take out the equation of the orbit with its proper sign, making proportion for the minutes and seconds, if there be any. But this requires a correction, at the rate of 0.5 for every minute of the equation for 100 years; and for any other time, the correction will be in proportion; to be subtracted after 1780, and added before that time.

Apply the equation with its proper sign to the mean longitude, and you get the longitude on the orbit, from the mean equinox.

From the longitude of Venus in her orbit, subtract the longitude of the node; and you have the argument, called the Argument of Latitude.

To the longitude on the orbit, apply the reduction (Table VII.) with its proper sign, and you have the longitude upon the ecliptic, from the mean equinox.

To the longitude thus found, apply the nutation with its proper sign, and you get the true longitude of Venus on the ecliptic, from the true equinox.

With the argument of latitude enter Table VII., and take out the latitude, making proportion for the minutes and seconds, if necessary; and this is the true heliocentric latitude of Venus.

With the mean anomaly of Venus enter Table VI., and take out the logarithm of her distance from the sun, making proportion for the minutes and seconds, if necessary. But this must be corrected by the small Table, to be entered with the mean anomaly, and you get the correction for 100 years; and for any other time, the correction will be in proportion, to be applied with a contrary sign, before 1780.

With the argument of latitude enter Table VII., and take out the reduction in the column under Sub. Log., making proportion for the minutes and seconds, if necessary; and subtract it from the logarithm of the distance last found, and you have the logarithm of the curtaile distance.

Ex.—On June 23, 1690, new style, at 1h 18' 11" mean time at Greenwich; to find the heliocentric latitude and longitude of Venus, and the logarithm of her distance from the sun.
VENUS.

Venus, in Chemistry, is used for the metal Copper; which see. Its character is $\varphi$; which, fay the adepts, expreffes it to be gold, only joined with fome corroeive and arfentical menstruum; which, removed, copper would be gold.

Venus is univerfally allowed, by the chemifs, &c. to be one of the moft powerful medicines in nature: of this, is faid to have been composèd the famous Butler's ftone, which cured mealf diseases by only licking it. Of this is composèd that noble remedy of Van Helmont, viz. the sulphur of vitriol, or ena vitrioli, fixed by calcination and cohabitation. Of the ena vitrioli of Venus is likewife composèd Mr. Boyle's arcanum, the colcotlar vitrioli.

It is certain copper is a powerful emetic, and an antidote againft poifons; for it is no fooner taken, than it exerts its force: whereas other vomitaries lie a good while in the stomack: but one single grain of ruft of Venus immediately vomits. Hence fyrups, that have flood over night in copper vessels, create a vomiting.

However, pure copper, in its metallic state, or calcined by fire, appears to be indiffolubile, and of no confiderable effect, in the bodies of animals: but diffolved in the nitrous or marine acids, and cryftallized or exficcated by heat, it proves a strong caufive. Preparations of this kind, though formerly used, are now laid aside. Copper, combined with the vitriolic acid, or with vegetable acids, or corroded by the air, acts outwardly, as an efficacious dextergent and a gentle efcharotic, and internally as a virulent emetic and cathartic. Some have ventured on small dozes, as quick emetics for expelling poifons; but the end may be obtained by fels dangerous means.

It has been ali reckoned an excellent medicine in chronic cafes: hence a famous phyfician is recorded to have cured Charles V. of a dropfy by the ufe of copper.

A faturated folution of the metal in volatile ftirps is recommended by Boerhaave in disorders proceeding from an acid, weak, cold, phlegmatic caufe. He fays, that if three drops be taken in the morning in a glass of mead, and the dofe doubled every day, to twenty-four drops, it proves attenuating, warming, and diuretik: that by this medicine he once cured a confirmed afctic; though in other fimilar cafes it failed; that it is the only preparation of copper which does not prove emetic; and that it may be tried with safety. Dr. Lewis, however, is of opinion, that in confiderable dozes it would exert the fame virulent operation with the other foluble preparations or folutions of copper. A folid preparation of this kind, made by rubbing together in a glafs mortar two parts of blue vitriol, and three of the volatile falt, procure from falt ammoniac, till all effevercesence has ceafed, and then gently drying the concrete, is ordered in the late Edinburgh Pharmacopeia, under the name of cuprum ammoniacum. It has frequently been given with fuccefs in epileptic and convulsive disorders. Lewis. See Sulphate of Copper. See also Saffphrina Aqua, and Aqua Cupri Ammoniaci.

Venus is difsoluble by all the falts known, both acid, alkaline, and nitrous; nay, even by water and air, confidered as they contain falt.

It is from this common reception of all menstruums, that copper is called Venus, q. d. meretricus publica, a common prostitute: though others take the denomination to have been occafioned by its turning of a fea-green colour, when diffolved by acid. It muft be given internally, with great caution.

Venus, Crystals of. See Crystal, Verdegrease, and Copper.

Venus, Spirit of. See Acetic Acid.

Vol. XXXVI.
Venus.

Celestis, that is to say, the planet of that name; and Astarte, the wife of Adonis, whose worship was intermixed with that of the planet, or, which comes to the same, that Syrian Venus, the fourth in Cicero, fo celebrated in antiquity. The Phoenicians, in conducting their colonies into the islands of the Mediterranean sea, and into Greece, introduced thither the worship of this goddess. They floated first in the island of Cyprus, which lies next the coasts of Syria; and there the worship of this goddess was generally received. From hence they went to Cythera, an ile near the continent of Greece; there the Greeks began to traffic with them, and to get some knowledge of their religion; and this is the reason of their giving out, that it was near this island the goddess was seen for the first time, because it was there they came to hear of her first. A very convincing proof that the worship of Venus was established in that island, before it passed into the continent, is, that the temple of Cythera was accounted the most ancient of any that Venus had in Greece, as Pausanius remarks.

From Cythera the worship of this goddess passed into Greece; and as those who had brought it thither were by sea, the Greeks, who endeavoured to give every thing a marvellous dres, say she had sprung from the sea, and gave her the name of Aphrodite, a word which imports foam. This, no doubt, is the true explication of this fiction, and it is needless to search into it for any other mystery. The Greek poets embellished this fable according to their own fancy. Having heard of Astarte's passionate love of Adonis, they took care to apply this circumstance to their Venus; and, moreover, they considered Love as the son of this goddess, and gave her the three Graces for her daughters. In fine, they formed that love-lykeem, of which the ideas have served, in after-ages, to embellish the works of their brother-poets. A young virgin rises out of the foam of the sea, and appears upon a shell-fish; she sits down on a mount Cythera, where the flowers spring up under her feet; the Hours, charged with the care of her education, conduct her to heaven, where all the gods, charmed with her beauty, make love to her; she matches with Vulcan, the most deformed of all; she disgraces herself by her gallantries with Mars and Mercury; by the one she has Cupid, and by the other Anti-Cupid; Bacchus is her 'fiquire; in fine, she presides over marriages and gallantry; and, therefore, has a mysterious girdle given her, called the ceiuis of Venus, which not only makes herself amiable, but has virtue to kindle the flame of an extinguished passion, &c.

This was not all, they foisted into the history of the goddess Venus, most of the celebrate pieces of gallantry. Some beauty being surprized in an intrigue, gave rise to the adultery of Mars with Venus, and to the stratagem of Vulcan.

Venus, whatever might be the dishonourable ideas entertained concerning her, was nevertheless regarded as one of the principal deities; and as she patronized scandalous passions, she was worshipped in a manner worthy of her. Her temples, open to profligation, taught the corrupt world, that in order to pay due honour to the goddess of love, they were to have no regard to the rules of modesty. The virgins prostituted themselves publicly in her temples, and there the married women shewed as little reserve. Amathus, Cythera, Gnidus, Paphos, Idalia, and the other places especially consecrated to this goddess, were distinguished by the most infamous abuses.

Farther, as there were several Venusfs, her worship was not everywhere the same. In some places they only burned incense upon her altars; elsewhere they made her an offering of sweet odours, one ingredient of which was the flesh of a sparrow; in other places they sacrificed to her a white goat. The women had also a custom of confecting their hair to this goddess; and the tresses of Berenice, which she had vowed to Venus, were placed among the stars.

Among the flowers, the rose was particularly consecrated to this goddess, because this flower had been tinged with the blood of Adonis, whom one of its thorns had wounded, which changed it into red from white, which it was before this adventure. The myrtle, too, was dedicated to her, because it commonly grows upon the borders of the water where this goddess was born. The swans and sparrows were peculiarly consecrated to her, but above all the pigeons, from the fable which fets forth, that while this goddess was one day playing with Cupid, the little god would needs wager to gather more flowers than she, and a nymph named Periferta, having affilted the goddess, she won the wager, with which Cupid was so provoked, that he transformed the nymph into a pigeon. As there were several persons who bore the name of Venus, her worship was not every where the same.

Venus was known under several appellations and characters; derived either from the places where she was worshipped, or from some particular circumstances that had given rise to her worship. Accordingly we read of the Venus Amaltheia, Amica, Anaitis, Apturares or Deidamo, Aphrodite, Archia, Argynnis, Armata, Aurea, Barbarata, Bajfilia, Calypgia, Calvius, Clacixia, Colias, Cypria, Cytherea, Elephanta, Elysia, Erycina, Etaia, Genurtis, Hortensia, Improme, Libina, Marina, Nephis, Papia, Praxis, Ridenus, Verticordia, Vittoria, Zerynthia, &c. &c.

Praxiteles executed two statues of Venus, one clothed, bought by the inhabitants of Cos, and another naked, which he sold to the Cnidians. See ANACOMENES, and VENUS DE MEDICIS.

The Venus of M. MaffeI seems to have been formed in conformity to the well-known paffage of Terence,

"Sine Cerere & Baccho friget Venus."

The goddess in this statue is accompanied with two Cupids, and crowned with ears of corn, holding a thyrsus, wrapped about with leaves and clusters of grapes; and as she carries in her hand three arrows, she seems to teach us that her arrows fly more unerringly when Ceres and Bacchus concur. Pausanius informs us that he had seen in Elis a fine statue of Venus Urania or Celestia, whose feet rested upon the back of a tortoise; and another of terrestrial Venus, placing her feet upon a he-goat.

We have on medals the Venus Urania, or Celestis, with a star or sun, or celestial globe in her hand; and the Venus Paphia, almoft naked, leaning on a column, with a helmet and the arms of Mars in her hands, bearing an inscription Veneri Vitorici, or Veneri Generifici. She is sometimes seen armed, sometimes resting upon a dolphin, holding a pigeon in her lap, or with Adonis, accompanied by his dogs, or with Cupid and the three Graces; but more frequently rising from the sea, seated upon a shell borne by two Tritons, or upon a chariot drawn by two sea-horses, or by a female sea-goat, or rather he-goat; for, according to Pausanius, her statue, made by the famous statuary Scopas, was upon that animal, and in that cale she is accompanied by Nereids and Cupids, mounted upon dolphins, one of the Nereids holding a lute in her hand, and mounted upon a sea-centaur; but more frequently her chariot is drawn by swans or pigeons, birds consecrated to her. Sometimes the
she appears herself supported by a Triton, having a  
buckler in her hand, on which is represented a head;  
sometimes mounted upon sea-horses, the seems to  
skim over the waves of the sea, her head being covered  
with a veil which swells in the wind, with Cupid  
swimming at her side. An oar at the foot of the gods  
seems to represent the Venus Pelagia or Marine:  
and the figure which she holds in her hand, a cornucopia,  
expresses the blessings produced by maritime commerce.  
There is also a picture of the Venus Deified in the Barberini  
palace at Rome, which is one of the finest-coloured pictures  
that is left us by the ancients; the hair of whose head may be compared with Guido's,  
and the colouring of the flesh reminds us of Titian. Part of  
this picture is lost, and part restored by Carlo Marat.  
Venus is described by Statius (lib. i. fylv. v. 56.) much  
in the same manner as she is represented in the Barberini  
picture.  

We shall only add, that Venus is sometimes described by  
the poets of the third age under the character of the goddesses  
of jealousy, rather than as the goddesses of love; in which  
Valerius Flaccus (Argon. ii. v. 106.) and Statius (Theb.  
v. v. 69.) have drawn two very terrible pictures of her.  
Spence's Polymetis, p. 74.  

Venus de Medici, in the history of Ancient Sculpture,  
a famous statue of white marble, about five feet high,  
brought from the Medici palace at Rome to Florence, by order of  
duke Colmo III., and now standing in the great duke's  
palace. The hips, legs, and arms, were broken off by  
the removal of this statue; but they have been rejoined  
with an art, that renders their former separation imperceptible.  
The inscription on the base intimates that this  
was the work of Cleomenes, an Athenian, the son of  
Apollodoros; the pedestal is modern; the statue seems  
to bear a little forwards; the right knee advances a little;  
the left-hand is placed before that part which disfigure  
s the fexes, and the right across her breasts; yet  
without touching the body. The head inclines a little  
to the left shoulder; so that her face seems to be turned  
away a little from the observer: and from this circum-  
fstance some have taken occasion to remark, that the hair  
of the head of this Venus expresses three different passions;  
as you first approach her, you perceive avenion or denial  
in her look; as you advance a step or two nearer, she  
seems compliance; and one step more to the right, it is  
fair, turns into a little indius and insulating smile: but  
Mr. Spence does not allow that this account is justified by  
the statue itself.  

The attitude of the Venus de Medici is peculiarly graceful:  
that attitude may be described in two vers of  

"Ipsa Venus pubeum, quoties velamina ponit,  
Protegitur laeva semi-reducta manu."  

The bloom of youth, the pleasing softness of her look, and  
her beauty and modesty, seem to rival each other in the  
charms of her countenance. Her person is somewhat plump,  
and the flesh is so admirably executed, that it seems so soft  
as if it would yield to the touch. Time has given to the  
white marble a yellowish hue, though still in the fun-shine  
it is almost transparent: her hair is brown, which may be  
no more than the faded gilding not unusual among the  
ancients. The head, which is said to be too small in propor-  
tion to the other parts, is inspected by fome not to have  
been executed by the fame artist who made the body: this  
will ever be the standard of female beauty and softness:  
the breasts are also the finest that can be conceived, small,  
delicate, and delicate, suggesting an idea of softness, which  
no copies can imitate, and also of firmness: from the  
breasts, her shape begins to diminish gradually down to her  
waist; but with an exquisite fineness of shape, the Venus  
of Medici has what the Romans call corpus solidum, and the  
French the enbonpoint; and her waist in particular is not  
represented as flinled by art, but as exactly proportioned  
by nature to all the other parts of her body. There is  
also a tenderness and elegance in every other part of her  
form: her legs are neat and slender: the small of them is  
finely rounded, and her feet are little, white and pretty: so  
that the poiflesst all those fofter beauties which the poets  
have marked out in the female make; the teretes fura (Hor.  
lib. ii. od. iv. ver. 21.), and the pes caudius (Id. lib. iv.  
od. i. v. 27.), and exigus (Ovid. Am. lib. ii. el. iii. ver. 7.)  
and one may well fay of this statue, what one of the  
performers in Plautus's Epidicus (act v. sc. 1.) says of a  
complete beauty:  

"Ab unguiculi ad capillum sumnum, eft festiviffima."  

Though the Venus of Medici has not escaped cenfure,  
with regard to the smallness of her head and hips, the large-  
ness of the nofe, the depth of the partition along the  
verbrae of the back, the length of the fingers, which, except-  
ing the little finger on the left-hand, are without joints;  
and though, in comparing the parts separate, as the head,  
nofe, &c. of this statue, with those of others, the similar  
parts might be found even of superior workmanship; yet  
for such a combination of beauties, the delicacy of shape  
and attitude, and symmetry of the whole, it is univerfally  
allowed that the world do not afford its equal. This  
incomparable statue flands between two others, which in any  
other place would be esteemed admirable pieces: that on the  
right of the Venus de Medici is twice as big, with the  
golden apple in her hand, and is called Venus Vietrix; the  
other, by Hercules Ferrata, is diftinguifhed by the name of  
Venus Urania. Spence's Polymetis, p. 6, &c.  

Venus, in Heraldry, is used for the colour vert.  
Venus, in the Latinne sytem of Natural History, a  
genus of the Tellaces order of worms. See Concoology  
Venus, Mount of, Moni Veneris, among Anathomis, is a  
little hairy protuberance in the middle of the pubis of  
women; occasioned by the collection of fat under the skin in  
that place.  

Among chiromancers, the mount of Venus is a little emi-  
nence in the palm of the hand, at the root of one of the  
fingers.  

Venus's Comb, in Botany. See Scandian.  
Venus's Fly-Traps. See Dionea.  
Venus's Looking-Glafts. See Campanula and Specu-  
lum Veneris.  

Venus's Navel-Wort. See Cotyledon, n. 19, and Cy-  
nglossum, n. 18.  

Venus, Cape, in Geography, a cape on the coast of  
Otaheite. N. lat. 1° 29'. W. long. 149° 36'.  

VENUSIA, VENOSA, in Ancient Geography, a town of  
Italy, in Apulia, near mount Vultur, watered by a small  
river called Auidus. It is said to have been denominated  
Aphroditia. It became a Roman colony in 460 U.C. It  
was formerly a magnificent city, but its baths, theatres,  
and temples have been destroyed. It was the birth-place  
of Horace.  

VENUSTI, MARCELLO, in Biography. This painter  
was born at Mantua in 1515, and was a pupil of Pierino  
del Vaga. He is however far better known as the painter  
of several designs of Michael Angelo, (to which he gave a  
colour unknown to that great composer,) than by any ori-
original works of his own. The cardinal Farnefe engaged
him to copy the great work of the Last Judgment in the
Capella Scitina, upon a small scale, which he accomplished
very much to the satisfaction of M. Angelo, who in confe-
quency engaged him to paint an altar-piece for the Capella
de Cesi in the church of La Pace, from a design of his
own, of the Annunciation. There are several pictures in
England, which are called Michael Angelo's, that have
every appearance of being painted by Venuti. Some works
of his own are spoken of with respect, particularly the
Martydor of St. Catherine, in the church of S. Agolino;
and St. John in the Wilderneys, in St. Catherine alli Funari.
He died in 1576, aged sixty-one.

VENZONE, in Geography, a town of Italy, in the
country of Friuli, on the Tajoamento; 18 miles W.N.W. of
Friuli.

VEPELLUM, or Vepellum, in Ancient Geography, a
town of Africa, S. of Carthage, situated two leagues S.E.
of Almanza, which has still some vestiges of the Romans.

VEPRECUITAE, in Botany, the thirty-first natural order
among the Fragmenta of Linneaus, named from verpeps, a
brier or bramble, because the plants which compose this
order are plant shrubs, of humble growth. The genera
mentioned at the end of the Genera Plantarum are Datis,
Qualis, Dirca, Daphne, Gnidia, Lachnea, Pafferia, Siel-
tera and Thesium; to which Linneaus has added in manu-
script, Struthiola, Santalum (with a doubt whether it should
not rather be referred to the Bicorne), and Scleranthus.
No remark occurs, in Gifeke's publication of the Predica-
tiones of Linneaus, on this order. As far as concerns the
eight first named of the above genera, with Struthiola, it is
precisely analogous to Jussieu's Thymeae, see that article.
Thesium and Santalum belong to Mr. Brown's Scleranthae,
an order extracted from the Onagre and Elegani of Jussieu,
which the reader will find in its proper place. Scleranthus
seems naturally one of the Caryophylleae, notwithstanding
the insertion of its flatus into the calyx, which obliged Jussieu
to range it with his Portulaceae. Perhaps this decision may
partly be supported by the habit, and the aspect of the flower.

VEPRIS, Juff. 371, a name given by Commeron to
what is now called Scopolia; see that article.

VER-PUCERON, in Natural History, a name given to a
kind of insects which are fond of eating the puceron, and
destroy it in vast numbers.

They are thus called, as the ant-eater is, formica-leo, from
their destroying great numbers of them.

These ver-pucerons are a sort of worms produced from
the eggs of flies, and are of two principal kinds; the one
having legs, the other none.

When we observe the vast number of young produced
by every puceron, and the quick progres they make in
their multiplication, we are apt to wonder, that every plant
and tree in the world are not covered with them; but on the
contrary, when we observe the devastation these devourers
make among them, we are apt to wonder how any of them
escape at all, to perpetuate the species. These worms
indeed seem created for no other purpose but to destroy
them; and this they do in so violent a manner as is scarcely
to be conceived. As the flies of many kinds lay their eggs
on meat and other substances, which they know will afford
food for the young ones, when hatched from them: so the
parents of these worms lay their eggs on the branches and
leaves of trees loaded with pucerons, on which they know
they will feed. The worms produced from these are de-
vourers from the very instant they are hatched, and find
themselves placed in the midst of prey, being every way sur-
rounded by a nation of creatures which are their proper
food, and which are furnished with no weapons, either offen-
sive or defensive, and which never so much as attempt to
fly from them, but seem wholly ignorant of their danger,
till seized upon by the devourers. Reaumur's Hist. of In-

The flies, which are produced from these worms, are all
of the two-winged kind; but there are several different
species of them; the generality of them resemble wasps,
and have a very flat body. Goedart, who has described
some of these flies, was surprized to see them very small
when first produced from the chrysalis, yet growing very
large in a quarter of an hour's time, and that without
taking any nourishment; but this was only owing to their
several parts having been squeezed while in the chrysalis,
and expanding themselves when they were at liberty from
the compression. These are the changes of this kind of
leo-puceron; but the other devourer of these creatures,
which has six legs, is of a different kind, and indeed is in
itself reducible to several species, some of these fix-legged
worms becoming four-winged flies, and others a kind of
beetles. These, from their near resemblance to the fornicia-
leo, are by Reaumur distinctly called puceron-lions.

Ver-Polype, a name given by Reaumur, and some other
authors, to a species of water-worm, by no means to be
confounded with the creature called simply the polype, and
which is so famous for its reproduction of parts cut off,
and for many other singular properties.

This ver-polype is a species of water-worm, produced
from the egg of a tipula, and had this name given it from
some remarkable productions, placed at the anterior and
posterior parts of the body, which are supposed to have
some analogy with the parts of the sea-fish called the polypus.
These worms are found in muddy ditches, usually either
crawling upon, or buried in the mud. Reaumur's Hist.
Insects, vol. ix. p. 49.

Ver du Gard, in Geography, a town of France, in the
department of the Gard; 6 miles S.E. of Uzes.

VERA, in Ancient Geography, a town of Africa, in Media,
on an eminence, and strong by its situation.—Alfo, the name
of a river of Gaul.

VERA, in Geography, a town of Spain, in Navarre; 25
miles N. of Pamplona.—Alfo, a town of Spain, in the
province of Grenada; 34 miles N.E. of Almeria. N. lat.
37° 8'.—W. long. 2° 41'.—Alfo, a river of European Tur-
key, which runs into the gulf of Salonichi, near the mouth
of the Vardar.

VERA Billa. See Billa.

VERABADURGAM, in Geography, a town of Hindoo-
stan, in Myfors; 8 miles W.S.W. of Caveripatam.

VERACICI, ANTONIO, in Biography, uncle and mater
to Francesco Maria Veracini, the celebrated performer on
the violin, publifhed at Florence, in 1692, ten fonatas, the
usual number, till Corelli's time; and afterwards, "Sonate
da Chiefa," two fets; but this author not being possessed
of the knowledge, hand, or caprice of his nephew, his
works are now not sufficiently interfeting to merit further
notice, particularly as there was nothing marked or original
in his style; the harmony indeed was correct; but "much
may be right, yet much be wanting."

VERACINI, FRANCESCO MARIA, a native of Florence,
and contemporary with Tartini, who were regarded as the
greatest masters of the violin that had ever appeared; nor-
were their abilities confined merely to the excellence of
their performance, they extended to composition, in which they
both manifested great genius and science. But whatever re-
semblance there may have been in the professional skill of these
two masters, it was impossible for any two men to be more
dissimilar.
difimilar in disposition: Tartini was so humble and timid, that he was never happy but in obscurity; while Veracini was so foolishly vain-glorious as frequently to boast that there was but one God, and one Veracini.

Being at Lucca at the time of the 'Felicia della Croce', which is celebrated every year on the 14th of September, when it is customary for the principal professors of Italy, vocal and instrumental, to meet, Veracini entered his name for a solo concerto; but when he went into the choir, in order to take possession of the principal place, he found it already occupied by Padre Girolamo Laurenti, of Bologna; who not knowing him, as he had been some years in Poland, asked him where he was going? Veracini answered to the place of first violin. Laurenti then told him, that he had been always engaged to fill that post himself; but that if he wished to play a concerto, either at vespers, or during high masses, he should have a place assigned him. Veracini, with great contempt and indignation, turned his back on him, and went to the lowest place in the orchestra. In the act or part of the service in which Laurenti performed his concerto, Veracini did not play a note, but listened with great attention. And being called upon, would not play a concerto, but deigned the hoary old father would let him play a solo at the bottom of the choir, defiling Lanzetti, the violincellist of Turin, to accompany him; when he played in such a manner as to extort an e vivat! in the public church. And whenever he was about to make a cloze, he turned to Laurenti, and called out: "Cosi fiuona per fare il primo violino!!!" "this is the way to play the first fiddle." Many silly stories of this kind are handed about Italy concerning the caprice and arrogance of this performer, who was usually qualified with the title of Capo pazzo.

Veracini would give lessons to no one except a nephew, who died young. The only master he had himself in his youth, was his uncle, Antonio Veracini, of Florence; but by travelling all over Europe he formed a style of playing peculiar to himself. Besides being in the service of the king of Poland, he was a considerable time at different courts of Germany, and twice in England, where, during the time of Farinelli, he composed several operas; among which was "Adriano," in London, in the winter of 1735 and 1736, which had a run of twelve nights; and in 1744, "Il Eratore di Salomone," in which Monticelli performed.

Veracini's first arrival in England was in the year 1714, when in the advertisements of the time for the opera of Dorinda, it is said that "Signor Veracini, lately arrived, will perform symphonies;" and the same year, with the operas of Crefo, Arminio, and Ernanclla, solos on the violin were frequently performed by Veracini.

We saw and heard him perform in the year 1745, at Hickford's room, where, though in years, he led the band at a benefit concert for Jozze, the second fiddle, at the opera, in such a bold and masterly manner as we had never heard before. Soon after this, in returning to the continent, Veracini was shipwrecked, and lost his two famous Steiner violins, thought to have been the best in the world, and all his effects. He used to call one of his violins St. Peter, and the other St. Paul.

As a composer he had certainly a great share of whim and caprice, but he built his freaks on a good foundation, being an excellent contrapuntist. The peculiarities in his performance were his bow-hand, his shake, his learned arpeggios, and a tone so loud and clear, that it could be distinctly heard through the most numerous band of a church or theatre.

Veracini and Vivaldi had the honour of being thought mad for attempting in their works and performance what many a sober gentleman has since done unfencured; but both these musicians, happening to be gifted with more fancy and more hand than their neighbours, were thought infane; as friar Bacon, for superior science, was thought a magician, and Galileo a heretic.

VERA-CRUZ, in Geography, a sea-port of Mexico, in the province of Tlaxcala, with a secure harbour, defended by a fort, upon a rock of a neighbouring island, called St. John d'Alva, in the gulf of Mexico. This is fortified with 300 pieces of cannon; and signals are made from a high tower. This is a place of very great extent, and perhaps one of the most considerable in Spanish America for trade, it being the natural centre of the American treasure, and the magazine of all the merchandise from New Spain, or of that transported hither from Europe. It receives a prodigious quantity of East India goods over land from Acapulco, brought from the Philippine isles. Upon the annual arrival of the flota here from Old Spain, a fair is opened, which lasts many weeks, when this place may be said to be immensely rich. Its situation is unhealthy, from the hogs round it, and the barrancas of the soil. It parts the sea in a semicircle, and is inclosed with a fingle wall or parapet, fifty feet high and three broad, surmounted by a wooden palfafade much decayed. The wall is flanked with fixed felable battions, on square towers twelve feet high. On the shore to the S.E. and N.W. are two redoubts, with some cannon to defend the port. The houses are well built with stone and lime, and have wooden balconies. The streets are wide, well paved with pebbles, and kept in excellent order. The churches are much decorated with silver; and in the dwelling-houses, the chief luxury consists of porcelain and other Chinese articles. The principal inhabitants are merchants; but European commerce is mostly carried on at Xalapa. The population is about 7000 or 8000: the inhabitants are generally proud, insolent, and devout; but commerce is well understood, and here are seven or eight houses, each worth a million of dollars. The women are rarely handsome, and live in retirement; the only amusements being a coffee-houfe and processions, or religious masquerades, the penitents whipping themselves with much bloodshed. A charity of 30000 dollars to marry four poor girls has, as is usual in such cafes, reverted to the rich. The harbour of Vera-Cruz might offer anchorage to 40 or even 60 ships of war in four to ten fathoms; but the northern winds are terrible, and often drive vessels on shore. In the rainy season the marshes on the south are haunted by caymans, or alligators, from seven to eight feet in length, but innocent. The sea-fowl are innumerable, and the mosquitoes very troublesome. The north winds are said to be so violent, that the ladies are excused from going to mass; and these galessometimes load the walls with sand. In the rainy season the water regularly falls in the night. Earthquakes are frequent. Vera-Cruz having been taken and plundered several times by the Buccaneers, the Spaniards have built forts, and placed centinels along the coast; their ordinary garrison consisting only of 60 horse and two companies of foot; 180 miles E.S.E. of Mexico. N. lat. 19° 5'. W. long. 97° 26'.

VERA-CRUZ, a port in the bay of St. Philip and St. Jago, in Terra Australis del Espiritu Santo, discovered by Quiros in 1606, and, according to him, capable of containing 1000 ships, with clear foundings of black sand, and water from three feet to 40 fathoms.

VERA-CRUZ, OId, a sea-port of Mexico, in the province of Tlaxcala. This is the port where Cortez landed in 1519; 15 miles N. of Vera-Cruz. This is situated fabulously; and the river is full of caymans, so strong as to draw an ox under water. They are fond of the flesh of dogs. N. lat. 19° 20'. W. long. 97° 40'.
VERACUNDALORE, a town of Hindoostan, in the Carnatic; 20 miles S.W. of Bomrauzepolam.

VERAGILÀ, a small island in the gulf of Venice. N. lat. 44° 17'. E. long. 15° 32'.

VERAGRI, in Ancient Geography, a people of the Alps, in the Pennine valley. Caesar places them between the Nantuates and the Seduni.

IVERAGUÀ, in Geography, a province of Mexico, bounded on the N. by the gulf of Mexico, on the E. by the province of Darien, on the S. by the Pacific ocean, and on the W. by Costa Rica. This coast was first discovered by Columbus, in the year 1503, to whom it was granted, with the title of duke. To the river now called Veraaguà, he gave the name of "Verdes-aguàs," on account of the green colour of its water; or, according to others, because the Indians called it by that name in their language. But however that may be, it is from this river that the province derives its name. In 1538, the captains Gasper d'Espinoza and Diego de Alverza, renewed the discovery by land; but, being repulsed by prince Urraca, were obliged to content themselves with a settlement in the neighbourhood; and even here the Spaniards were not able to maintain their ground against the frequent incursions of the Indians; so that finding the absolute necessity of a stronger settlement, they built the city Santa Fé, on the spot where it now stands. This province, though geographically belonging to North America, is included within the kingdom or territory of Terra Firma. The country is rugged and mountainous, but abounding with beautiful and excellent woods, and having vales that afford rich parishes. The monkeys found here are small but beautiful, being of a buff-colour, with a white crown; but too delicate to be removed from their native home. It is said to rain here every day in the year; and the rain is attended with tremendous thunder and lightning, and produces torrents that defend with rapidity and violence from the mountains. Its gold-mines are rich, but little wrought, because every article must be carried on the shoulders of the Indians over steep mountains. The Doraces, and other savage tribes, live naked in the mountains, on roots and fruits; but several have been converted since the year 1760 by the Franciscans, who have founded some Indian villages. The capital of this province is called by the same name, and also St. Jayo de Veraguà (which feé); it is situated in a warm and moist climate, abounding in maize, yucca, a root of which bread is made, plantains, and cattle, but principally in swine. The natives dye their cotton of a rich and permanent purple, with the juice of a sea-fennel found on the coast of the Pacific, akin to the murex of the ancients; with which, and some gold from the mines, they carry on trade with Panama, and the provinces of the kingdom of Guatemala. Here is an elegant hospital; and fourteen villages are subject to the jurisdiction of this town, which is ruled by a governor.

VERAL, a river of Spain, which runs into the Aragon.

VERALA, in Ancient Geography, a town of Hilopia Citerior, between Calagurus and Triorum.

VERAMALLY, in Geography, a town of Hindostan, in the Carnatic; 18 miles S. of Tretchipemony.

VERANO AVE, or Ave de Verano, in Ornithology, the name by which the Portuguese in the Brazil call a large bird of the thrush kind, approaching to the size of a small pigeon, remarkable for its loud noise; and more commonly known by its American name guiranga.

VERANOCA, in Ancient Geography, a town of Asia, in Phœnicia.

VERAPATCHY, in Geography, a town of Hindostan, in the Myfore; 20 miles W.N.W. of Dindigul.

VERÀ-PAZ, a province of Mexico, in the domain of Guatemala, bounded on the N. by the province of Chiapà, on the E. by the bay and province of Honduras, on the S. by Guatemala, and on the W. by Soconusco; about 120 miles in length, and 74 in breadth. In one part of the country the air is healthy, in the other not. The country is subject to earthquakes, thunder, and nine months' rain. The soil is mountainous, yielding little corn, but abounding in forests of cedar, &c. in which are many wild beasts. The principal commodities are drugs, cocoa, cotton, wool, honey, &c.

VERÀ-PAZ, or CORAN, a town of Mexico, and capital of the province of Verà-paz, situated on a river which runs to the bay of Honduras; 600 miles S.E. of Mexico. N. lat. 15° 50'. W. long. 91° 14'.

VERATO, a town of Naples, in the province of Otranto; 4 miles S. of Alefiano.

VERATRUM, in Botany, which derive from verès atrum, truly black, because the root is, externally at least, of that colour; may more safely be left among those ancient names whose origin is unknown. It occurs in Lucrètius and Pliny, indicating some very active or poisonous plant; and is generally supposed synonymous with the ἄοντος Dioecedros λακτός of Dioscorides, itself rather doubtful, and whose particular designation is a contradiction to the above etymology. Whatever difficulties may attend the determination of the ancient verès atrum, this name is now universally applied to the genus we are about to describe, one of whose primitive species having nearly white, and the other as nearly black, flowers, the English appellations, of White and Black Helbor, suit them so well, as to efface all memory of old uncertainties.—Linn. Gen. 540. Schreb. 715. Willd. Sp. Pl. v. 4. 895. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 425. Pursh 242. Juss. 47. Tourn. t. 145. Lam. Ex. Illustr. t. 843. Grern. t. 18.—Clas, and order, Polygamy Monoea, or more properly Hexandria Trigynia. Nat. Ord. Coronarie, Linn. Junz, Juff. Melanthacae, Brown.

Gen. Ch. Cal. none, unless the corolla be taken for such. Cor. Petals five, elliptic-oblong, fessile, thinner at the margin towards the base, and finely ferrated or fringed in that part, permanent. Stam. Filaments five, inserted into the base of the petals, awl-shaped, converging round the germs, spreading at the fummit; anthers quadrangular, veri, attached by the back. Píl. Germs three, superior, oblong, compressed, crept, combined, terminating in three very short styles, with fimple spreading stigmas. Peric. Capsules three, oblong, crept, compressed, of one cell and one valve, bursting at their inner margins by which they are originally connected. Seeds several, obliquely imbricated, inserted into each margin of the capsule, oblong, compressed, winged at each end; the wing at the lower part rounded. Several flowers, on the same plant, have only rudiments of a píl.

Obf. This genus has been thought too near Melanthium, fee that article. The capsùles of the latter are fingle, of three cells, and in some species the cells burst externally, but this is not the case with M. frührichum, whose cells burst at the inner angle only. The subject wants revision. The habit of Melanthium, for the most part an African genus, is very unlike Verà-trum, the leaves being slender, and inflorècence more simple. The corolla is more coloured, with elongated claws; and though permanent, has less of the coriaceous nature of a calyx. Helonias, (fee that article,)
Veratrum.

1. *V. album*. White Veratrum, or Common White Hellebore. Linn. Sp. Pl. 1479. Wild. n. 1. Ait. n. 1. Jacq. Ann. t. 335. Fl. Dan. t. 120. Mill. C. t. 271. Mill. Ill. fl. t. 169. Woods. Med. Bot. t. 100. Helleborus praecox; Ger. Em. 440. Elleborum album; Matth. Valgr. v. 2. 555. —Panicle thrice compound. Petals ascending, elliptical. Native of alpine meadows in most parts of Europe, from Norway to Greece; but not of Britain. It is, of course, a hardy perennial in our gardens, where it has been cultivated time out of mind, flowering from June to August. The root is tuberous, black on the outside, with long, simple, white, cylindrical fibres. Stem from two to four or five feet high, robust, erect, simple, leafy, terminating in a large, branching, downy panicle, of innumerable greenish-white flowers, with little or no sepal, an inch broad, whose petals when in full perfection spread horizontally, but in fading return to their original ascending posture, becoming green, leafy, and coriaceous. The leaves are large, elliptical, entire, with many ribs, plaited, smooth, of a fine green; the uppermost becoming oblong or lanceolate bractea. Each partial flower-flute is also accompanied by an elliptic-lanceolate downy bractea, various in length. This flatly plant, accompanied by *Genista lutea*, makes a magnificent appearance in rich pastures on the alps of Switzerland and Savoy, where they both grow more luxuriantly than in gardens.—Mr. Sieber of Prague has sent us from the alps of Austria, under the name of "*V. viride Bernh.", what seems a greener-flowered variety of the album, and different from the following; but it is extremely difficult to decide on this point, without seeing the plants alive.

2. *V. viride*. Green Veratrum. Ait. n. 2. Wild. n. 2. Pursh n. 1. Bigelow Bot. 246. (V. album; Michaux Boreal.-Amer. v. 2. 249. Heloniæ viridis; Curt. Mag. t. 1096.) —Spikes panicked, dense, cylindrical. Petals ascending, elliptical. In swamps and on mountain bogs, from Canada to Carolinas, flowering in July. A flatly plant, from three to six feet high. Pursh. Dr. Bigelow, in his Flora Boissonianis, says this plant, not unfrequent in meadows and swamps about Bolton, is called Poke root, or Swamp Hellebore. It was cultivated in England by Peter Collinson, in 1742. The foliage and habit are like the preceding, but the panicle is larger and greener; its branches longer and more cylindrical, spiked, not racemose, each flower being nearly or quite sericeous. The petals are broader; their margins thickened and mealy about the base.

3. *V. nigrum*. Dark Veratrum. Linn. Sp. Pl. 1479. Wild. n. 3. Ait. n. 4. Jacq. Ann. t. 336. Curt. Mag. t. 963. (Helleborus albus praecox; Ger. Em. 440. f. 2.) —Clusters panicked, dense, cylindrical. Petals obovate, widely spreading; at length reflexed.—Native of dry mountainous situations, in Siberia, Hungary, Austria and Greece, flowering in July. Perfectly hardy in our gardens, where it blooms freely, and increases without any care, providing the soil be dry. It agrees with the first species in habit and leaves, but is rather taller, and is very remarkable for the dark purpleish-brown, almost black, hue of its flowers, which exhale a faint cadaverous scent. They compose long, cylindrical, steaking clusters, assembled into a long panicle, accompanied by narrow strap-shaped bractea in the lower part. Each flower is but half as broad as those of *V. album*, and the petals turn backward as they fade, becoming finally of a dull green.

4. *V. virginicum*. Virginian Veratrum. Ait. n. 3. (Melanthium virginicum; Linn. Sp. Pl. 483. Wild. Sp. Pl. v. 2. 266. Pursh 240. Helonis virginsca; Curt. Mag. t. 985. Aphydole alpins floridana, ramofo caulis, floribus ornithogali obololetis; Pluk. Amath. 49. t. 434. f. 8.) —Clusters panicked, loose. Petals elliptical, spreading, with two spots at the base; hairy at the back. —In low grounds, amongst luxuriant herbage, from New York to Carolina, flowering in June and July, perennial. Rather scarce in gardens, though tolerably hardy. The stem is from three to five feet high, downy. Leaves linear-lanceolate, folded, ribbed, pointed. Panicle pyramidal, of numerous, loofly racemose, many-flowered branches, whose partial flanks are about half as long again as the petals. Flowers green, with two brown spots on each petal. After being expanded for some time, they turn to a red-brown.

5. *V. parviflorum*. Small-flowered Veratrum. Michaux Boreal.-Amer. v. 2. 250. Wild. n. 4. Pursh n. 2. —Clusters panicked, with slender branches. Petals ovate-lanceolate, acute at each end. Leaves elliptical, flat, smooth.—On high mountains in Carolina, flowering in July. Flowers small, green. Root perennial. Pursh. The leaves are like those of *Veratrum*, but not so much furrowed, or pilate. Petals without glands. Inflorescence that of a Melanthium. Michaux. We have seen no specimen nor figure, neither of this nor the following.

7. *V. Sabadilla*. Caufic Veratrum, or Indian Caufic-Barlet. Ray. Bot. flac. 3. 1. 107. Wild. n. 5. (Cevadilla; Dale Pharmac. 286. Hordeum cauificum; Bauh. Flora, 2. 457, with a probable fictitious figure. Yztrinmpathi, feu Canis interfeclor, vel Hordeolum; Hern. Mex. 376, with an apparently authentic figure.) —Leaves linear-lanceolate, ribbed. Clusters simple, dense, foliary, terminal.—Native of the colder regions of Mexico. The leaves appear to be all nearly radical. Stem solitary, simple, erect, almost naked, three spans high. Clusters erect, cylindrical, a span long, nearly or quite simple. Flowers turned to one side, of a very dark purple. Petals ovate.—Retzius, who first introduced this plant into a scientific botanical work, found a specimen of the flowers, imported along with the seeds, in a druggist's shop. They answered to the character of a genuine *Veratrum*, as might be expected from the seeds and capsules, which we have occasionally met with, and whose qualities are analogous to those of *V. album*. But the learned proféfior never thought of tracing out the synonyms, or searching for any figures, of this little-known plant; which defect we have endeavoured to supply. For the medical properties of the seeds in question, see Cevadilla.

For *V. luteum*, Linn. Sp. Pl. 1479. Wild. n. 6, see *Helonia, n. 3*.

Veratrum, in Gardening, contains plants of the hardy, herbaceous, perennial kind, among which the species cultivated are, the white-flowered veratrum, or white hellebore (*V. album*); the dark-flowered veratrum (*V. nigrum*); and the yellow-flowered veratrum (*V. luteum*). The first sort has the stems three or four feet high, and branching out on every side almost their whole length; the branches and principal stem being terminated by spikes of flowers set very close together, which are of a greenish-white or herbaceous colour, and appear in July.

The second sort has the flanks rising higher, but the flowers are of a dark-red colour, which appear almost a month sooner.

The third sort has a large tuberos root with a single stem, about a foot high, having the flowers produced at the top, in a single thick close spike, which are small, and of a yellowish-white colour, appearing in June.
Method of Culture. — All these plants may be increased by feed and parting the roots.

The feed should be sown in the autumn or early spring, upon a bed or border of light earth, or in a box filled with the same sort of mould. When the plants are come up in the spring, keep them clear from weeds, and refreshed with water occasionally when the season is hot and dry; and in the following autumn, when the leaves decay, take them up carefully without injuring the roots, and plant them out about half a foot square in a fresh bed of light mould; and when they have remained in it till fit for flowering, they should be removed into the borders, clumps, or other parts.

This is, however, a tedious method, as they seldom flower in less than four years; therefore the root method is mostly what had recourse to.

The roots may be divided in autumn, when the leaves decay, and be planted out in a light, fresh, rich mould where they are to grow; they should not be removed oftener than once in about four years. The roots should not be parted too small.

These plants have a fine effect in the middle of large borders, clumps, and other similar situations, in pleasure grounds and other places by the singularity of their large furrowed leaves, and their different modes of flowering.

The first sort is much cultivated as a medicinal plant for the use of its root, as well as the black sort occasionally; in which situation the plants should be set out in beds or borders in any common parts of the ground.

Veratrum, in the Materia Medica. See Hellebore.

Mr. James Moore has suggested that a vinous infusion of the root of the veratrum album, or white hellebore, constitutes the active ingredient in the eau médicinale d'Huffen. Mr. Moore gives the following preparation: take of white hellebore-root, eight ounces; white wine, two pints and a half. The root is to be cut in thin slices, and infused for ten days, occasionally shaking the bottle. Let the infusion be then filtered through paper.

The dose of the mixture, in cafes of gout, may be from one fluid-drachm to three fluid-drachms.

VERB, in Grammar, a word serving to express what we affirm of any subject, or attribute to it; or, it is that part of speech, by which one thing is attributed to another, as to its subject; as the words is, underlands, hearts, believes, &c. This is, in other words, the definition of a verb adopted by Dr. Priestley in his Grammar. But this definition seems to include not only verbs, but likewise all adjectives, and abstract nouns signifying qualities; for when we say "God is good," or "Goodness belongs to God," do not the words "good" and "goodness" express what is affirmed of or attributed to the Deity? But if in this definition it is merely affirmed, that the essence of the verb confides in affirmation, it might have been expressed with greater precision, thus: "a verb is a word affirming something of, or attributing something to, a thing." It is, says Dr. Blair, the affirmation that seems to be that which Chiefly distinguishes the verb from the other parts of speech, and gives it its most conspicuous power. Hence there can be no sentence, or complete proposition, without a verb either expressed or implied; for whenever we speak, we always mean to affirm, that something is or is not; and the word which carries this affirmation, or affirmation, is a verb. This ingenious writer, however, seems to have improperly included time as one of the three things implied in all verbs, adding this to the attribute of some Substantive, and an affirmation concerning that attribute. The definition of Dr. Beattie seems to be more objectionable. He defines a verb to be "a word necessary in every sentence, signifying the affirmation of some attribute, together with the designation of time, number, and person." According to this definition, neither infinitive moods, nor gerunds, nor supines, nor participles are verbs; for they neither contain an affirmation, nor signify time, nor are limited either to number or person. If affirmation, which we conceive to be the case, be essential to verbs, it is possible to form a tolerably copious language with only one verb in it; for infinitives, participles, adjectives, &c. may be fo united to nouns by the copula, or verb is, alone, as to express almost any idea which we can have occasion to communicate. But if the circumstances of time, person, and number, be essential to verbs, it is more than probable that languages may subsist in the world, which have not a single verb in them. And in this case Dr. Beattie cannot consistently maintain, as he affirms, that a verb is "a word necessary in every sentence." In the Malay language, e.g. which is held in high estimation, and which has wide extent in the East Indies, the verb admits of no modification whatever, on account either of person, tense, or voice; in all these respects, the personal pronouns only, with particles prefixed, determine the sense.

The verb is thus called of the Latin verbum, word, by way of eminence; as being the principal word of a sentence. Accordingly verbs, as Dr. Adam Smith observes, must have been coeval with the first attempts towards the formation of language. No affirmation can be expressed without the assistance of some verb. This writer argues, that the radical verb, or the first form of it, in most languages, would be what we now call the Imperfetive verb: as "it rains," and the like: as this is the simplest form of the verb, and merely affirms the existence of an event, or of a state of things. By degrees, after pronouns were invented, such verbs became personal, and were branched out into all the varieties of tenses and moods. On this subject, see Verb, Substantive, infra.

The common definition given by grammarians is, that the verb is a word which betokens being, doing, or suffering. This is the definition of the learned bishop Lowth, and it includes nothing more than what is essential; so that it is equally applicable to the verb in all languages, in all its various forms, comprehending not only infinitives and participles, but likewise gerunds and supines. If it is in any respect defective, it is because it does not in all cases sufficiently distinguish verbs from verbal nouns. Infinitives and participles, gerunds and supines (see each in its place), not only signify actions, but govern the cases of nouns and pronouns in the same manner with the verbs, and therefore should be comprehended under the name of verbs. But those verbal nouns which do not govern accussative cases have not the same pretensions; for they have not the regimen of verbs, but of Substantives, and consequently more properly belong to that class.

To conceive the origin and office of verbs, it may be observed, that the judgment we make of any thing, as when we say the earth is round, necessarily includes three terms. The first, called the subject, is the thing we affirm of, e.g. earth. The second, called the attribute, is the thing affirmed, e.g. round. The third, is, connects those two terms together, and expresses the action of the mind, affirming the attribute of the subject.

This last is what we properly call the verb; and which some of our later grammarians, particularly the Port Royalists, choose to call by a more significant word, affirmation. The reason is, that its principal use is to signify affirmation; that is, to shew the discourse in which that word is used, is the discourse of a man who does not only conceive things, but judges and affirms somewhat of them.
By this circumstance, a verb is distinguished from nouns, which also signify an affirmation, as *affirmans affirmatis*; those only signify affirmation, as that, by a reflection of the mind, is rendered an object of thought: so that they do not shew, that the person who utters *affirm*., but only that he conveys an affirmation.

Though the principal use of verbs be to signify affirmation or assertion, they also serve to express the other motions of the soul; as to desire, pray, command, &c.; but this they only do, by changing the mood, or inflexion.

Here, we only consider the verb in its primary significatio, which is that it has in the indicative mood. On this footing, the verb should have no other use, but to mark the connection which we make in the mind, between the two terms of a proposition; but the verb *affirms, to be*, is the only one that has retained this simplicity: nor, in strictness, has this retained it, but in the third person, as *am*, is.

In effect, men being naturally inclined to shorten their expressions, to the affirmation they have almost always added other significations in the same word: thus, *is* they add that of some attribute, so as that two words make a proposition; as in *Petrus vivit*. Peter lives: where *vivit* includes both the attribute and affirmation: it being the same thing to say *Petrus vivit*, as that *Peter is living*. And hence the great variety of verbs in every language.

For if people had been contented to give the verb its general significatio, without any additional attribute, each language would only have needed one verb, viz. the verb *volatile*, *is*. But on some occasions, they also superadd the subject of the proposition, as *sum homo*, I am a man; or *vivo*, I live: and hence the diversity of persons in verbs.

Again, we also add to the verb, a relation to the time, with regard to which we affirm; so that one single word, as *canditatus*, signifies that I attribute to the person I speak the action of being, not for the present time, but for the past: and hence the great diversity of tenses in most verbs.

The diversity of these significations, or additions in the same word, has perplexed and deceived many of our best authors, in the nature of a verb; and has led them to consider it, not according to what is essential to it, which is to affirm; but according to some of these its accidental relations.

Thus, Aristotle, taking up with the third of those additional significations, defines verb to be *vox significans cum tempore;* a word signifying something with time.

Others, as Buxtorf, adding the second relation, define it, *vox flexivis cum tempore et persona;* a word admitting of divers inflexions, in respect of time and person.

Others, taking up with the first of the additional significations, which is that of the attribute, and considering that the attributes men ordinarily add to the affirmation, were actions and passions, have supposed the essence of a verb to consist in signifying actions or passions.

Lately, Scaliger imagined he had made a great discovery in his book of the Principles of the Latin Tongue, in saying, that the distinction of things into *permanentes, and fluentes*, into what remain, and what passes away, is the proper source of the distinction between *nouns* and *verbs*; the first being to signify what remains, and the second what passes.

But from what we have said, it is easy to perceive, that these definitions are all false: and that the only true definition is *vox significans affirmationem;* this definition includes all that is essential to the verb: but if one would likewise include its principal accidents, one might define it, *vox significans affirmationem, cum designatione persona, et temporis;* a word which signifies an affirmation, with a designation of person, number, and tense; which is what properly agrees to the verb *volatile*.

For as to other verbs, considered as becoming different by the union of certain attributes, one may define them thus: *vox significans affirmationem aliqualvis attributum, cum designationo persona, numeri, et temporis;* a word which expresses the affirmation of some attribute, with a designication of person, number, and time.

Verbs, according to Mr. Harris, are those *attributives*, which have a complex power of denoting both an attribute and an affirmation: those which take the attribute alone without the affirmation are *participles*; and all other attributes are included under the general name of *adjectives*. And as some attributes have their influence in motion, e.g. to walk, to live, &c. others in the privation of motion, e.g. to die, &c. and others again in subjuncts, which have nothing to do with either motion or its privation, as *great* and *little*, *white* and *black*, &c. these last are *adjectives*, and those which denote motion or its privation are either verbs or participles. But motions and their privation, comprehended under the general term energy, imply time as their concomitant, and hence, he says, verbs which denote them, come to denote time also. See *Tense*. See also *Mood.*

Every energy has a reference, says this ingenious writer, to some energizing substratum, and is conversant about some subject; and hence he derives the distinction between verbs *active* and *passive*: and as every energy respects an energizer, or a passive subject; hence appears the reason why every verb, whether active or passive, has in language a reference to some noun for its nominative case. When among the infinite subjuncts, to which the energy refers, that happens to occur, which is the energizer also, as Brutus loved *himself*, *flowed himself*, &c. in such case the energy hath to the same being a double relation, both active and passive; and this gave rise among the Greeks to that species of verbs, called *verbs middle*; but in other languages, the verb still retains its active form, and the passive subjunct (*je* or *himself*) is expressed like other accussatives. Again, in some verbs, it happens that the energy always keeps within the energizer, and never passes out to any foreign subject, because the energizer and the passive subject are united in the same person; and then we obtain that species of verbs, called by grammarians *verbs neuter*, as if they were void both of action and passion, though they may rather be said to imply both. Of the above species of verbs, the middle cannot be called necessary, because most languages have been without it: those remaining are, therefore, the *active*, the *passive*, and the *neuter*, which seem essential to all languages whatever. Mr. Harris observes, that though the greater part of verbs denotes attributes of energy and motion; there are some which appear to denote nothing more than a mere simple adjective, joined to an affirmation, as *isr.a* in Greek, *equatein* in English, *alco* and *tumo* in Latin; and there are also verbs, which are formed out of nouns, or in which the subjunctive is converted into an attributive. There are other supposed affections of verbs, besides moods and tenses, such as number and person. But these are, in fact, the properties not of attributes, but of substantives. Hermes, chap. vi. viii. and ix.

Verbs are variously divided: with respect to the subject or signification, they are divided into *active*, *passive*, *neuter*, &c.; with respect to their conjunction, into *transitive* and *intransitive*; with respect to their formation or inflexions, into regular and irregular, personal and imperatival, auxiliary, *infinitive*, &c. See *Language*, *Grammar*, and the subsequent articles.
VERB Active, is a verb which expresses an action that falls on another subject, or object. It is called also transitive, because the action paffeth over to the object, or hath an effect upon some other thing. See Active.

VERB Passive, is that which expresses a passion; or which receives the action of some agent, and necessarily implies an object acted upon, and an agent by which it is acted upon: it is conjugated, in the modern tongues, with the auxiliary verb I am, je suis, je fono, &c.

Some do not allow of any verbs passive in the modern language; the reason is, what we call passive is nothing but the participle of the verb, joined with the auxiliary verb, to be; whereas the verbs passive of the Latin, &c. have their particular terminations. See Passive.

VERB Neuter, is that which signifies an action that has no particular object on which to fall; but which, of itself, takes up the whole idea of the action: or a verb neuter expresses being, or a state or condition of being; when the agent and the object acted upon coincide: as, I sleep, thou vàwlaft, he knows, we walk, you run, they stand.

The Latin's call them neuters, because they are neither active nor passive; though they have the force and signification of both: as, I languish, signifies as much as, I am languishing: I obey, as much as I exercise obedience, &c. only that they have no regimen to particularize this signification. The verb neuter is called intransitive; because the effect is confined within the agent, and doth not pass over to any object.

The distinction between verbs absolutely neuter, as, to sleep, and verbs active intransitive, as, to walk, though founded in nature and truth, is of little use in grammar, the construction of both is the same. Lowth's Gram. p. 62.

Of these verbs, there are some which form their tenses by the auxiliary verb to have; as, I have slept, you have run. These, grammarians call neuter active.

Others there are, which form their component parts by the auxiliary to be; as, I have come, to arrive, &c.; for we say, I am come, not I have come, &c. These are called neuter passive.

The neuter verb is varied like the active; but, having somewhat of the nature of the passive, admits in many instances of the passive form, retaining still the neuter signification; chiefly in such verbs as signify some sort of motion, or change of place or condition; as, I am come, I was gone, &c.

In English, many verbs are used both in an active and neuter signification, the construction only determining of which kind they are.

VERB Substantives, is that which expresses the being, or substanee, which the mind forms to itself, or appoises in the object; whether it be there, or not: as, I am, thou art.

Existence, says Mr. Harris, may be considered as an universal genus, to which all things of all kinds are at all times to be referred. The verbs, therefore, which denote it, claim precedence of all others, as being essential to the very being of every proposition in which they may still be found, either explicit, or by implication: express, as when we say, the sun is bright; by implication, as when we say, the sun shines, which means, when resolved, the sun is rising. The verbs is, grows, becometh, es, fit, veb, xovn, 

Verbs of experience, a name more apt, as being of greater latitude, and comprehending equally as well attribute as substanee. The principal of these verbs is the verb is, es, x. All existence is either absolute, as when we say, B is; or qualified, as when we say, B is a animal, B is black, &c. And with respect to this difference, the verb, is, can by itself express absolute existence, but never the qualified, without subjoining the particular form; consequently, when is only serves to subjoin some form, it has little more force than that of a mere affirmation. Under the same character, it becomes a latent part in every other verb, by expressing that allertion, which is one of its essentials: e.g. rifles means is rising, &c.

Moreover, as to existence in general, it is either mutable, as in the objects of fation; or immutable, as in the objects of intellection and science. All mutable objects exist in time, and admit the several distinctions of present, past, and future; but immutable objects have no such distinction, but rather stand opposed to all things temporary. And hence result two different significations of the subjunctive verb is, as it denotes mutable or immutable being: e.g. if we say, this orange is ripe, is means that it existeth now at this present, in opposition to past time, when it was green, and to future time, when it will be rotten; but if we say, the diameter of the square is incomparably large with its side, we do not intend by is that it is incomparable now, having been formerly commensurable, or being to become so hereafter: on the contrary, we intend that perfection of existence, to which time and its distinctions are utterly unknown. Under the same meaning, we employ this verb, when we say, truth is, or God is: the opposition is not of time present to other times, but of necessary existence to all temporal existence whatever. Hermes, p. 88, &c.

In every language, says Dr. Adam Smith, in his "Formation of Languages," annexed to his "Theory of Moral Sentiments," there is a verb, known by the name of the subjunctive verb, in Latin, sum, in English, I am. This verb, he says, denotes not the existence of any particular event, but existence in general. On this account it is the most abstract and metaphorical of all verbs, and consequently could by no means be a word of early invention. Nevertheless he allows, that it is in every language; and therefore in languages which are in their earliest infancy. Others are of opinion, not without reason, that the verb subjunctive, or copula, is, is not only the most necessary, but the most simple of all verbs, for it contains nothing more than an allertion, or affirmation, that a thing exists. The idea conveyed by this simple proposition is coeval with thought itself: for what can we think about, unless we think that something is, or is not? This copula, or verb of existence, is, must appear to be coeval with language itself. But we cannot reasonably infer from hence, that this was the case with respect to any other finite verb. It is probable, that people, in their first attempts to express their ideas by words, would be some time before they invented any other word containing in itself an allertion or affirmation: for they would not, at a very early period, think of contriving words so complex in their nature as to include in them both the name of an action and an allertion.

An ingenious writer on the subject of verbs (see Pick- bourn's Differtation on the English Verb) conjectures that the first mode of expressing actions or passions would be by participles or verbal nouns; i.e. words signifying the names of the actions or passions they wanted to describe, and these words, connected with their subjunct by the copula is (a word coeval with speech itself), might, in these rude beginnings of language, tolerably well supply the place of verbs; e.g. from observing the operations of nature, such words as rain or raining, thunder or thundering, would soon be invented; and, by adding the copula is, they would say, raining, thundering, or thunder, is, or is not; rainings, or rain, is; which, by the rapidity of pronunciation, might in time
time form the verbs rains, thunders, &c. The observation of their own actions, or the actions of the animals around them, would soon increase their flock of ideas, and put them upon contriving suitable expressions for them. Hence might arise such words as these: sleep, or sleeping; stand, or standing; run, or running; bite, or biting; hurt, or hurting; and by joining these to substantives, by means of the copula, they might form such fentences as these, Lion is sleeping, or perhaps Lion sleeps, stand, &c.; which would soon be contracted into Lion sleeps, stands, runs, bites, hurts, &c.

Thus our little inflected family might become possessed of verbs including an attribute and an affirmation in one word. The next step would probably be a distinction between actions in their progress and in their finished state; i.e. actions going on in their presence, and perceived by their senses; and such as were ended, and consequently only known to them by memory, by report, or by their effects: and they might perhaps apply such words as raining, thundering, sleeping, &c. to the former kind of actions; and such as rained, thundered, slept, &c. to the latter. And by joining the copula is to these words signifying perfect actions, in the same manner in which they had joined it before to the words signifying imperfect ones, and afterwards contracting them into single words, they might soon acquire a verb expressing a finished action and an affirmation in one word. This improvement would probably suggest to them the idea of making such further alterations in, or additions to, their verbs, as would make them significant of all the grand divisions of time.

But still their verbs would have neither person nor number, and would probably remain in that state till the invention of pronouns. But this, requiring some degree of abstraction, would probably not happen very early; for, in their first efforts to express themselves, they would be more likely to say, "Thomas loves William and Henry," than "I love thee and him." However, in process of time, pronouns would no doubt be introduced: and they might perhaps make such alterations in their verbs, as to accommodate them to their numbers and persons, though such an accommodation does not seem absolutely necessary. Languages may therefore exist which do not vary their verbs to express either number or person. And, further, it is possible that there may be languages so constructed as not to admit any variation in their verbs, even to express time; for if the verb only contains, in itself, an assertion or an attribute, the time of it may be fixed by adverbs and other adjuncts. This author concludes that a definition applicable to the verb in all languages, and in all its forms, cannot comprehend in it any thing more than what bishop Lowth has expressed by saying, "A verb is a word signifying to be, to do, or to suffer."

The copula, or substantive verb, is, according to this author, is, as we have already stated, the simplest of all verbs; and must necessarily have been contemporary with the first efforts of mankind to express their ideas by words. Without this we cannot unite an adjective to a substantive, or affirm that any thing is good or bad, or possesses any quality whatever, or even exists. But this is the only verb, containing an affirmation, which is so perfectly simple in its nature as not to comprehend, at least, two ideas, which may be easily separated, nay which must necessarily be separated, in the operations of the mind, whenever it endeavours to express them. Plus, it rains, or it is raining, comprehends the idea which the mind forms of that operation of nature which we call rain or raining, and likewise an affirmation of the judgment which the mind forms concerning its present existence; and therefore cannot be expressed more briefly and naturally than by is raining, or rain is, which is easily contracted into, rains.

**VERB.**

**VERBS, Auxiliary, or Helping, are those which serve in conjugating active and passive verbs; such are, I am, I have &c.**

The auxiliary verbs are like prepositions, words of a very general and abstract nature. They imply the different modifications of simple existence, considered alone, and without reference to any particular thing. In the early state of speech, the import of them would be incorporated with every particular verb in its tenses and moods, long before words were invented for denoting such abstract conceptions of existence, alone and by themselves. But after these auxiliary verbs, in the progress of language, came to be invented and known, and to have tenses and moods annexed to them, like other verbs; it was found, that as they carried in their nature the force of that affirmation which distinguishes the verb, they might, by being joined with the participle which gives the meaning of the verb, supply the place of most of the moods and tenses.

The abbot de Dangeau distinguishes all verbs into two general kinds; auxiliary verbs, and verbs which make use of auxiliaries.

This distinction may tax as not very just: in regard auxiliary verbs sometimes make use of auxiliaries themselves: but this does not destroy the division; it only shews, that the auxiliary verb has two formalities, or two different qualities, under which it is to be considered; in virtue whereof, it constitutes, as it were, two sorts of verbs.

The verbs which make use of auxiliaries, he divides into active, neuter, and pronominal. Verbs neuter, he farther distinguishes into neuters active and neuters passive. Pronominals he distinguishes into identical, reciprocal, neuterized, and passified. But several of these are peculiar to the French language. See Auxiliary Verbs.

When an auxiliary is joined to the verb, the auxiliary goes through all the variations of person and number; and the verb itself continues invariably the same. When there are two or more auxiliaries joined to the verb, the first of them only is varied according to person and number. The auxiliary may admits of no variation.

**VERBS, Regular, are those which are conjugated after some one manner, rule, or analogy.**

**VERBS, Irregular, or Anomalous, are those which have something singular in the terminations or formations of their tenses.** See anomalous verbs.

The formation of verbs in English, both regular and irregular, is derived from the Saxon. The irregular verbs in English are all monosyllables, unless compounded; and they are for the most part the same words which are irregular verbs in the Saxon. The first class of irregulars comprehends those that are become so from some kind of contraction; thus, some verbs ending in d or t have the present, the past time, and the participle perfect and passive, all alike without any variation; as, beat, burst, cast, &c. which are contractions from beat, bursted,asted, &c. because of the disagreeable sound of the syllable ed after d or t. Others in the past time and particeip perfect and passive, vary a little from the present, by shortening the diphthong, or changing the d into t; as, lead, led; meet, met; bend, bent, &c. Others not ending in d or t are formed by contraction; as, have, had, for havved; fix, fled, for fleved, &c.

The following, beside the contraction, change also the vowel: felt, fold; tell, told; clothes, clad. The second class of irregulars are those that end in ght, both in the past time and participle, and change the vowel or diphthong into an or au: they are taken from the Saxon, in which the termination is bte: as, bring, bought; buy, bought; seek,
feet, fought, &c. The third class of irregulars form the past time by changing the vowel or diphthong of the present; and the participle perfect and passive, by adding the termination en to these also derive their formation from the Saxon: such are, fall, fell, fallen; flake, flaked; draw, drew, drawn; flag, flew, flung, &c. &c. When on follows a vowel or liquid, the e is dropped. Some verbs, which change i short into a or u, and long into o, have dropped the termination en in the participle; as, begin, began, begun; sing, sang, sung; &c. To this third class belong the defective verbs, be, been; go, gone; i.e. gone.

The whole number of verbs in the English language, regular and irregular, simple and compounded, taken together, is about four thousand three hundred. See in Dr. Ward's Essays on the English Language the catalogue of English verbs. The whole number of irregular verbs, including the defective, is about one hundred and seventy-seven. Lowth's Gram. p. 85. See conjugation.

Verbs, Defective, are those which are not only for the most part irregular, but are also wanting in some of their parts. Such are the auxiliary verbs, most of which are of this number. They are in use only in some of their tenses and moods; and some of them are a composition of tenses of several defective verbs having the same signification.

Verbs Inchoative. See inchoative.

Verbs Imperfective. See imperfective.

There are also reduplicative verbs; as, resound, recall, &c.; and frequentative verbs, &c.

Verbs Transitive; and Verb Active, supra.

For the observations of an ingenious and learned coadjutor on the origin, nature, distribution, and properties of verbs, we must content ourselves with referring to the article Grammar. It will be found that his sentiments differ in a variety of respects from those of much approved and popular writers, above stated; and we therefore prefer submitting them in the language of the author to the judgment of the philological reader, without any abridgment, and without any recapitulation, which would encroach too much on the limits to which we are confined. On this subject, see language.

Verbal, something that belongs to verbs, or even to words spoken with the mouth. Verbal nouns, are those formed from verbs. See in- finitive.

A verbal contradist, is that made merely by word of mouth, in opposition to that made in writing.

Verbal Accident. See accident.

Verbano, in Geography, a department of Italy, constituted of part of the duchy of Milan, situated on the side of lake Major, anciently called Verbanus Lacus, and the bailiwicks ceded by the Swits. It contains 166,842 inhabitants, who elect twelve deputies. Varefo is the capital.

Verbanus, in Ancient Geography, a lake of Gallia Transpadana: its northern part was in Rhedita, and its southern part in Gaul.

Verbas, in Geography, a river of Bosnia, which runs into the Save; 25 miles N.N.E. of Banjaluka.

Verbasculum, in Botany, the diminutive of Verbas, perhaps from some similarity of colour and aspect, which may be traced in the Primrose and Cowslip. Bauh. Pin. 241. This is precisely synonymous with Primula; see that article.

Gen. Ch. Cal. Perianth inferior, of one leaf, small, permanent, in five deep, erect, acute, nearly equal, segments. Cor. of one petal, wheel-shaped, unequal; tube very short; limb spreading, in five deep rounded segments. Stam. Filaments five, awl-shaped, unequal, dilatant, declining, woolly, shorter than the corolla, inserted into its base; anthers compressed, erect, more or less kidney-shaped, burrting lengthwise, imperfectly two-celled. Pist. Germen superior, roundish; style thread-shaped, slightly swelling upwards, declining, rather longer than the stamens; stigma obtuse. Peric. Capsule roundish-ovate, or ovate-oblong, slightly compressed, of two cells and two valves, burring in the upper part, the valves sometimes splitting half way down; partition double, from the inflamed parallel margins of the valves, but often incomplete. Recept. ovate or globular, central, connected at each side, in an early state at leaf, with the valves. Seeds numerous, minute, angular, dotted, inserted into the receptacle.

Ob. There is so great a space between the inner edges of the inflamed valves and the central receptacle, in V. pulmonatum and some other species, that the ripe capsule is literally of but one common cell, though originally of two. Hence arose an error in Engli. Bot. p. 58, 59, which is corrected at p. 457 of the same work. Celia (see that article) differs from this genus in having four stamens only, two long and two short. Professer Schrader, in the first part of an excellent monograph on Verbascum, published at Göttingen in 1813, p. 14, affirms that this difference is very confant and invariable, and therefore he is not disposed to concur with those botanists who combine these two genera. We heartily assent to this determination. With regard to the new genus of Ramonda, founded, if we mistake not, on V. Myconi, and distinguished by having a capsule of one cell, with two lateral linear receptacles; we must suspend our judgment till we can examine into that character, but the habit of the plant, and its oblong heart-shaped two-celled anthers, indicate a very distinct genus.

The species of Verbascum are among the most uncertain of any well-known genus. They are more than commonly variable in the colour and size of their flowers, and appear to be very subject to croes impregnation. Hence we are led to mistrust some reputed species, descried even by the ablest writers. The production of several mule ones has been traced and recorded, and we have observed others. Professer Schrader indeed has long cultivated and studied what he has described, and his accuracy is indisputable. We shall give his new species, on his own authority, and we shall profit by his remarks in the general characters here prefixed to the particular descriptions.

The root is generally biennial, rarely perennial, its form tapering. Stem generally solitary, from a foot and a half to four or eight feet in height, erect, sometimes peculiarly stiff and straight, rarely a little zigzag, leafy, in several

flances

VERBASCUM.

flaxes alternately branched, many-flowered, panicked, with racemose flaks; in V. Myconi only altogether wanting. Leaves all radical the first year, subequally all cauline: flaked, felfile, or decurrent; always alternate, limpe, ob- long; undivided, lobed or pinnaflid; limply or doubly cre- nate or toothed, rarely entire; generally covered with denfe, white, flaggfry or flary, or mealy and deciduous, woyllines; fometimes nearly smooth. Flowers racemose, generally aggregate, crowded, and very numerous; mottly yellow, rarely yellow-whifh-white, or purple, or brownish. Bractes moffly ovate, or lanceolate, pointed, of two orders, external and internal. The whole genus is nearly, if not entirely, European, the species found in America, except perhaps V. Clayfoni of Purfli and Michaux, having been apparently introduced from this quarter of the world. The Levant produces many fine ones, not well known to Linneus.

Sect. 1. Leaves decurent.

1. V. Thafpus. Great Mullein; or High Taper. Linn. Sp. Pl. 252. Wild. n. 1. Schrad. n. 1. Purfli n. 1. Pf. Brit. n. 1. Engl. Bot. t. 549. Pf. Dan. t. 631. (Tapus barbatus; Ger. Ein. 773. Chalcois danum affum; Diofl. book 4. chap. 104.)—Leaves decurrent, crenate, woolly on both sides. Stem fimple. Cluster denfe. Flowers almofl felfile.—Frequent throughout Europe, on banks and wale ground, flowering in July and August; very common in Greece. Mr. Purfli observes that, though common in America, this plant was probably introduced from Europe; nevertheless it springs up abundantly in the moft remote parts of the country, in fields newly cleared and burnt. The root is biennial. Stem from three to five feet high, crefet like a flaff, woolly, winged with decurrent acute leaves, which are cloathed with white entangled hairy woo, like cloth or futm. Flowers very numerous, large, of a bright golden-yellow, with orange-coloured hairy fllamens, and roundifh red anthers. Mr. Robfon of Darlington communicated to Dr. Withering a mule plant, produced under his own eyes, from this fpecies impregnated by V. nigrum. Mr. D. Turner found a correpofponding fpecimen, now before us, at Barton, near Swaff ha, Norfolk. The leaves are but flightly decurrent. Spike elongated and fider.—The leaves of V. Thafpus, about a handful boiled in a pint of milk, fweetened with fugar, frained, and the milk taken at bed-time, are useful in coughs, and more efpecially fervice- able in allaying the irritation of the piles. V. pulvulatum has the fame qualities. V. thapsiformes, Schrad. n. 2. fcems fcarcey more than a variety with a largcer corolla, and two of the anthers oblong, instead of their being all round.

2. V. crofififolium. Thick-leaved Mullein. Schrad. n. 3. "Hoffmannfeg and Link Luft. v. 1. 213. t. 26."—Leaves decurrent, obscurly crenate, denfly woolly; the upper ones rather acute. Chiffer denfe. Flowers almofl felfile. Filaments smooth. Two of the anthers oblong.—Found in sandy ground in Portugal. The smooth filaments afford the chief diftinction between this plant and the last, at leaft its variety called thapsiformes. Experience must fhow, by cultivation, whether this be permanent.

3. V. cuspidatum. Pointed-leaved Mullein. Schrad. n. 4. t. 1. f. 1. (V. Thafpus; Ehrl. Pl. Off. n. 111.)—Leaves decurrent, crenate, woolly on both fides; the upper ones pointed. Cluster somewhat interrupted. Two of the an- others oblong.—Found in mountainous woods near Vienna. Schott. Near Uplal. Ehrlhart. This Dr. Schradr mentions as the V. Thafpus of the Vienna botanifts, agreeing in habit with the two foregoing, but the ifem is of more humble nature, and more flender. Leaves smaller, lefs denfly woolly; the upper ones taper-pointed. Inflofence and flowers more like V. phlonofoles, the cluffers being interrupted, the flowers more flaked, and aggregate in little tufts. Corolla large. Two longer fllamens having oblong anthers; and in our ifpecimen from Ehrhart smooth filaments, though the rest are hairy.

4. V. niveum. Snow-white Mullein. Tenore Hort. Neap. 109. Schrad. n. 5.—Leaves half-decurrent, crenate; woolly and very white beneath; more fjtightly fo above. Chiffer denfe. Flowers nearly felfile. Anthers uniform. —Found near Naples. Stem two or three feet high, round; at length smooth and brownish. Leaves thickfif, foft; their upper surface becoming green and flightly downy, though the under is snow-white. Flowers yellow, in tufts, almofl felfile, about the fize of V. Thafpus. Filaments clothed with white wool. Schradr. This appears to be really a very diftinct species.

5. V. denfiflorum. Denfe-flowered Mullein. "Bertol. Pl. Rav. Ital. v. 3. 52." Schrad. n. 4.—Leaves downy; the radical ones lanceolate, elongated, crenate, deeply fer- rated at the fabe; upper item-leaves pointed, toothed, half- decurrent. Cluster denfe. Flowers aggregate, nearly felfile.—Found on the fummit of mount Bruciana, between Carrara and Maffa. Stem four or five feet high, an- gular, clothed with tawny woyllines, especially the upper part. Radical leaves more than eighteen inches long, two or three broad in the middle; green above; fott hairy be- neath; thofe of the item gradually shorter upward, ovale, pointed, felfile, with a small decurrent wing on each fide, more downy all over, especially the uppermoft. Chiffer very denfe, above a foot long. Flowers large, yellow, in tufts on extremely short flarks. Pubefcence of the whole plant yellow or tawny, compered of branched entangled hairs, and much the moft denfe in the upper part. Bertoloni.

6. V. thapsoides. Long-speared Mullein. Schrad. n. 7. t. 5. f. 2. "Hoffmannfeg et Link Luft. v. 1. 214, excluding the fynonymes."—Leaves filden crenate, downy; radical ones oblong-lanceolate; the refl oblong, acute, half-decurrent. Flowers on short flarks, aggregate, rather crowded. Anthers nearly equal.— Native of Portugal. Perennial. Stem three or four feet high, or more, generally branching at the top into several long, rather fnder, tolerably denfe cluffers of yellow flowers, smaller than V. Thafpus. Schradr. We conceive this to be no other than the Linnean V. Thafpus; see V. Lychnitis.

7. V. maccranthus. Great-flowered Mullein. Schrad. n. 8. "Hoffmannfeg et Link Luft. v. 1. 215. t. 27."—Leaves filden crenate, downy; radical ones elliptic-oblong, tapering at the base; the refl oblong, acute, half-decurrent. Cluster interrupted, with diffant tufts of flowers. Two of the anthers oblong.—Found by fide fides, in the northern part of Portugal. Root fupposed to be biennial. Stem two or three feet high, crefet, fimple, at length smooth and of a purplifh-brown. Leaves thick, reticulated with veins beneath; their upper fide becoming green and almofl naked by age; radical ones flaked, three or four inches long, and half as broad. Flowers large, handifome, yel- low. Hair of the fllamens orange-coloured. Caffule feall. Schradr.

Leaves ovate, filden crenate, downy on both fides; lower ones flaked; upper pointed, cloathing the item, flightly decurrent. Cluster interrupted.—Native of barren waste ground
VERBASCUM.

9. V. condensatum. Denf-flowered Round-leaved Mullein. Schrad. n. 11. t. 5. 3.—"Leaves downy; radical ones elliptic, oblong, tapering at the bafe, doubly and unequally crenate; tho' of the stem oblong, acute, finely crenate; uppermoft roundish-ovate, pointed, slighdy decurrent. Clusters denfe. Two of the anthers oblong."—Observed by Mr. Schott in Austria, on a barren soil. Biennial. We cannot but fupect this to be a variety of the lef, with a more denfe inflorefcence; larger, more ftrongly crenate, radical leaves, and broader upper ones. The two species are, at leaft, very nearly akin.

10. V. nemorosum. Grove Mullein. Schrad. n. 12. t. 1. f. 2.—"Leaves acute, crenate, downy; radical ones oblong, tapering at each end; lower stem-leaves lanceolate, contracted at the bafe; middle ones oblong-lanceolate; upper oblong, slighdy decurrent. All the tufts of flowers a little remote. Two anthers oblong."—Found by Mr. Schott in groves in Austria. Biennial. Akin to V. phlomoides, but diftinguished by its ftraight, wand-like stem, four feet high, with a foltary lax cluster, and the narrow elliptic-lanceolate shape of all its leaves, which are of a yellow-green, the radical ones becoming finallly rather naked on the upper surface.

11. V. montanum. Mountain Mullein. Schrad. n. 13. "Hort. Gotting. fasc. 2. 18. t. 12."—"Leaves downy; radical ones oblong-elliptical, crenate, falked; tho' of the stem oblong, rather acute, slighdy crenate; uppermoft acute, rather decurrent. Flowers nearly fefile, in rather crowded tufts. Anthers almoft equal."—Native of the Pyrenees, as well as of the alps of Switzerland and Germany. Biennial. Stem eighteen inches or two feet high, cref, fimple, clothed, like the reft of the herbage, with yellowfifty puberfence. Leaves somewhat wrinkled, reticulated beneath; the radical ones three to four and a half inches long, two to two and a half broad, obtufe, loing part of their thick downines by age; lower stem-leaves tapering into a footstalk; the reft acute, fefile, or, about the top of the stem, slighdy decurent. Clusters from about three to fix inches long. Flowers nearly fefile, in tufts more or less crowded; some foltary. Bracteas ovato-lanceolate, pointed, scarcely exceeding the flowers, except the lowermoft. Calyx as in V. phlomoides. Corolla molt like V. Thapius. Two of the filaments more slighdy hairier than the reft, sometimes naked; their anthers perfect, but rather larger and more oval than the three others. If cultivated in shady situations, the stem sometimes reaches the height of fix feet, and becomes branched in the flowering part; the leaves also grow much larger, of a dirty green, a little polifhed on the upper side; the clusters above a foot long, thicker, and more compact. Schrader.

12. V. callithum. Hill Mullein. Schrad. n. 14. t. 5. f. 1.—"Leaves crenate, downy; lower ones elliptic-oblong, falked; tho' about the middle of the stem oblong-lanceolate, rather acute, tapering at the bafe; uppermoft oblong, acute, slighdy decurrent. Tufts of flowers foltary. Anthers equal."—Native of hillocks, and dry graffy ground, in fome parts of the north of Germany. Perennial. Stem two or three feet high, cref, fimple, flightly angular in the upper part; rediff below. Leaves fott, wrinkled, downy on both fides; pale green above; hoary and reticulated beneath; radical ones four or four and a half inches long, and half as broad; the reft gradually smaller upwards, the top ones being about an inch and a half in length. Clusters twelve or eighteen inches long, rarely having a branch at the bafe. Flowers yellow, fweet-fcented, refembling V. nigrum, with purple-beraided filaments, and compofing numerous little tufts, often near an inch from each other. Schrader. We should fuppofe this might be a mule progeny of V. nigrum, impregnated by fome of the foregoing fpecies; having found near Norwich what has every appearance of being a familar offfpring of nigrum, from the pollen of V. palmarum.

13. V. veriflorm. Various-flowered Mullein. Schrad. n. 15.—"Leaves crenate, downy; lowermoft elliptic-oblong, falked; tho' of the stem oblong, acute, flightly decurrent; uppermoft pointed. Clusters paniied. Tufts foltary, of few flowers. Anthers equal."—Found in fandy ground near Prag, but barely. The herbage is clothed with denfe down, of a dirty yellow-fifty green hue. Stem two or three feet, or more, in height, branched in the flowering part, rarely fimple. Leaves rather thick and ruffled; radical ones from three and a half to fix inches long, one and a half to two and a half broad, moft evidently and acutely crenate at the bafe; tho' about the middle of the stem only fefile. Clusters paniied, a foot long, or more. Flowers generally the size of V. phlomoides, flightly fragrant, in rather diftant tufts. Partial stalks half as long again as the calyx. Bracteas ovato-lanceolate, with long points; the inner ones linear, much smaller. Corolla of a rufty red, but variable, the bafe of its smaller segments bearded with the fame kind of yellow wool that clothes the three fmalier filaments. Two larger ffilaments covered entirely with purple wool, fome of which alfo is feen about the middle of the three others. Anthers kidney-shaped; tho' of the two longer filaments rather larger, and finally more oval. Pollen whitif. Sometimes the corolla is found twice its usual fize, and the partial flower-stalks are occasionally more long and flender than above defcribed. Professor Schrader received this from Mr. Tauch, a Bohemian botaniff, as V. rubiginosum of Waldftein and Kitaiifei; a fpecies unknown to us, but which he fays is widely different.

14. V. ramigerum. Branched Decurrent Mullein. Schrad. n. 16. t. 4.—"Leaves finallly downy; radical ones oblong-lanceolate; tho' of the stem oblong, acute, doubly crenate,
nate, half-recurrent; uppermost pointed. Clusters panied. Tufts Dalton, many-flowered. Anthers equal."—Native of the duchy of Mecklenburg-Swinem. Link. The habit of this species refembles f. Lychnitis. Root biennial. Stem from four to six feet high, erect, thick; rather angular, brown, and much branched in the upper part; the branches spreading, angular, and, like the rest of the stem, slightly downy. Upper side of the leaves covered with very thin pubescence; under more hoary, and more thickly clothed; the radical, and lower stem-leaves, often a foot or more in length, four or five inches wide, tapering down into the footstalk. Flowers yellow, from fifteen to twenty in each tuft of the principal cluster, on stalks twice the length of the calyx; fewer in the lateral clusters; the lower tufts many of them very distant from each other. Bracteas ovato-lanceolate. Calyx and corolla larger than in f. Lychnitis. Stamens like those of that species. Schrader.

15. V. mucronatum. Pointed-leaved Mullein. Lamarck Dict. v. 4. 218. Schrad. n. 17; excluding perhaps Tournouf's synonym. — "Leaves esurate, clothed with dense hoary down; radical ones oblong-lanceolate; those of the stem, green, acute, half-recurrent; uppermost ovate, long-pointed. Spikes panied. Flowers in nearly sessile heads." Found in Crete by M. Labillardiere. Root biennial. Whole herbage covered with hoary down. Stem, in the cultivated plant at least, from six to eight feet high, straight, thick, branched upwards. Lower leaves one and a half, or two feet long, on short stalks, acute; the rest more pointed, and unequally decurrent. Spikes panied, various in length, their points somewhat incurved. Flowers yellow, rather large, in danty, many-flowered, feffile heads, hoary with deciduous woolinefs. Bracteas lanceolate. Filaments all clothed with whitish wool. Schrader.

16. V. finatum. Scallop-leaved Mullein. Linn. Sp. Pl. 254. Wildn. n. 12. Ait. n. 14. Schrad. n. 18. Sm. Fl. Grac. Sibth. t. 227, unpubl. (V. criphum et finatum; Bauh. Hift. v. 3. 860. V. alud; Camer. Epit. 882. Matth. Valgr. v. 2. 492. V. laciniatum Matthii; Dalech. Hift. 1302. qroes meta; Diof. book 4. chap. 104.)—Leaves serrated, powdery; radical ones pinnatifid and wavy; the rest unaned, decurrent. Stem panied, many-flowered. Native of dry barren exposed situations, in the south of Europe, and north of Africa; a hardy biennial, long known in our botanical gardens, but seldom long preserved. Dr. Sibthorpe observed this to be the most common Mullein throughout Greece and all the circumjacent islands. The root is brown, and rather woody. Herb of a dark green, beksprinkled with loose tufts of powdery, hoary, flarrv pubefcence, but far less woolly, or uniformly hoary, than any of the preceding species. The leaves also differ widely from all the foregoing, in being pinnatifid half way to the midrib, with jagged and plaited lobes; the radical ones a span long, on shortifh stalks; the rest smaller, feffile, decurrent; the upper ones very small, ovato-lanceolate, undivided, more decurrent, reflexed; all of them reticulated with veins, rugofe; most hoary beneath. The stem is erect, one or a half or two feet high, zigzag, alternately branched from top to bottom, panied, often tinged with dark purple. Panice spreading, with copious, hoary, somewhat winged branches. Flowers generally tufted, flaked, yellow, with purple hairy filaments. Capsule small, roundift. The figure of Matthiols, copied by Dalechamp and Tabernamontanus, is more like the cultivated variety of the following species, but differs in its branching panied stem.

Seft. 2. Leaves not decurrent.

17. V. platicum. Plaited-leaved Mullein. Prodr. Fl. Grac. n. 524. Fl. Grac. t. 226, unpubl. (V. finatum f.; Linn. Sp. Pl. 255. V. pinnatifidum; Ait. n. 15, but not of Vahl nor Willdenow. V. gracum fruticosum, folio finato candidissimo; Tourn. Cor. 8. Voyage, v. 1. 128, with a figure. Placenta fens feada; Diof. book 4. chap. 104.)—Leaves pinnatifid, crisped, somewhat crenate, downy on both sides. Spikes simple, imparted, leafy.—Native of the isle of Hydra, and very plentiful about Athens. Root tapering, possibly perennial. Stem ascending, simple, leafy, clothed, like the foliage and calyx, with dense, flary, rigid, yellowih woolinefs. Leaves obovato-oblong, thick; plaited or crisped at the margin; their upper surface even, and almost without sign of veins; under reticulated; radical ones flaked, near a span long; the reft feffile, clasping the stem, and gradually smaller upward; floral ones very small and pointed. Spike solitary, erect, a foot long, leafy or fractuated. Flowers three or four feffile together in the bobom of each bractes, yellow, almost an inch broad. Filaments yellow, bearded from the middle to the summit. Anters all nearly alike. Capsule ovate, acute, hard, smooth when ripe. The leaves vary in acuteness; and in the garden plant, raised from Dr. Sibthorpe's seeds, become more dilated, flattened, and leaf crisped, refembing the figure of Matthiols, cited under our preceding species, but the pubefcence still remains totally different.

18. V. auriculatum. Auricled Mullein. Prodr. Fl. Grac. n. 523. Fl. Grac. t. 225, unpubl. (V. orientale maximum candidifimum, ratis candelabrum amnulatibus; Tourn. Cor. 8.)—Leaves elliptic-oblong, downy on both sides, auried at the base. Clusters panied, zigzag.—Native of the island of Samos. Biennial. The whole herb is clothed with dense snow-white down. Stem two feet high, fount, leafy; branched and becoming smooth in the upper part. Leaves crowded, feffile, two or three inches long, bluntly pointed, accompanied by axillary tufts of smaller ones; their upper surface covered with a dense and even coat of wool, hardly marked by rib or veins; the under reticulated, scarcely less densely clothed with a fluffy cobweb-like pubefcence; their base contracted, but augmented with a rounded lobe at each side, embracing the stem. Flowers yellow, flaked, tufted and bracteated, as in V. plomoids, but only half as large. Calyx with smooth points. Beard of the filaments yellowish-white. Anters orange-coloured, nearly uniform. We think Tournouf's synonym is here rightly applied, though cited by Lamarck and Schrader for mucronatum, n. 15, which must be a different plant from the present, unless it be inaccurately described.

19. V. pinnatifidum. Pinnatifid Mullein. Vahl Synb. v. 2. 39. Wildn. n. 13, excluding the synonym of Tournef, which belongs to our n. 17.—Leaves flat, pinnatifid, cut, powdery; nearly naked on the upper side; radical ones flaked. Stem panied, many-flowered.—Gathered by Dr. Sibthorp, on the sandy sea-shore near Yalla, in Bithynia. Root perennial, blackish, divided at the summit. Stem one to two feet high, erect, very much branched in all directions, leafy, round, dark-purple, sprinkled with downy meafines. Radical leaves three inches long, on long stalks, flat, deeply pinnatifid, cut, wrinkled and veiny; dark green and almost naked above; paler, and powdery with flary hairs, beneath; the younger ones very densely woolly; those of the stem not half so large, feffile, not decurrent, leaves divided; floral ones aggregate, spreading, extending for the most part beyond the flowers, which are feffile, crowded, yellow, hoary externally, with orange-coloured flaments. Capsule nearly globose.

20. V. Boerhanufl. Boerhaavian Mullein. Linn. Mant. 45, excluding the reference to Miller; see n. 8. Wildn. n. 3. (V. blat-
VERBASCUM.

(V. blattarize folis nigrum, ampliorius floribus luteis, apicibus purpurascensibus; Boerr. Lugg.-Bat. v. 1. 228.)—Leaves obovate, somewhat lyrate, doubly crenate, veiny, slightly downy. Spike interrupted. Flowers in nearly sessile tufts. Bracteas all linear.—Said to be a native of the south of Europe. The Linnean specimen grew in the Uppsal garden. This species is very little known, perhaps from Linneus having cited a plate of Miller's, which is as little like his specimen as almost any Verbasum can be, and belongs to V. pluoides. Hence V. Borchartii is admitted, without sufficient grounds, into the catalogue of our garden plants. We have, at least, never seen any thing answering to it. The leaves are a foot long, and almost four inches broad, membranous, copiously reticulated with veins; pinna-tifid, in a lyrate manner, at the base; nearly smooth on the upper surface; the under partly clothed with light, deciduous, flary wool, resembling mouldinefs. Spikes (whether solitary or numerous, does not appear from the specimen) a foot long, slightly and loosely woolly, of numerous scattered tufts of large yellow flowers with purple flaments.

21. V. harmsroidale. Madeira Mullein. Ait. n. 5. Willd. n. 4.—"Leaves ovate-oblong, downy, slightly and minutely crenate; tapering at the base. Clusters elongated. Flowers in sessile tufts, without bracts."—Native of Madeira, from whence it was brought to Kew by Mr. Maffon, in 1777. This is marked as a biennial greenhouse plant, flowering from June to August.

2. V. Thaph.; Linn. Sp. Pl. 1669. (V. Thaphoides; Willd. n. 2. Ait. n. 3. Hoffmann. et Link Fl. Litt. v. 1. 214.) V. angulifolium ra-mofum, flore aureo, folio craffio; Bauh. Hist. v. 3. 860.)

Leaves wedge-shaped-oblong; flippred of down on their upper side. Stem angular, panicked. Native of palures, road-fides, and waste ground, in various parts of Europe, flowering in July and August. In England it rarely occurs, except on chalky ground in Kent, where it abounds. The root is biennial, scarcely perennial. Stem a yard high, strait and upright, finely downy; copiously panicked at the top. Leaves elliptic-oblong, tapering at the base, crenate, reticulated with veins; white and woolly beneath; dark green and slightly downy, or quite naked, above; thofe at the root, and lower part of the stem, blafked; the rill fett, not decurrent, all narrow at the base. Branches of the panele racemose, with many woolly tufts of blafked, rather small, flowers, whose corolla is cream-coloured, tinged with yellow. Filaments yellowish, hairy. Anthers orange, coloured, uniform.

The variety 3, a very celebrated and much disputed plant, is not preferred in the Linnean herbarium. It is described as the mule offspring of V. Lychnitis, from the pollen of V. Thaphi. We have specimens, artificially produced in this manner, by Dr. Griffith, of Garn, Denbighshire. These agree with the Portuguese plant, bent by professor Link, as his V. Thaphioides. So that we conceive the real V. Thaphi, or Thaphioides, is before us. Yet there are parts of the Linnean description, Sp. Pl. 1670, that puzzle us; such as the purple beard attributed to the filaments of V. Lychnitis and of this variety. Our specimens are intermediate, in every respect, between Lychnitis and Thaphi. Their corolla is yellow. Beard of the filaments white. Upper leaves somewhat decurrent. As the real

2. V. nigro-pulverulentum; Fl. Brit. ibid.

Leaves ovate-oblong, obscurely serrated, covered on both sides with powdery deciduous wool. Stem round, panicked, much branched.—Native of banks, and the borders of fields, on a gravelly or chalky soil, in England, Austria, and Switzerland, flowering in July. This beautiful and flately plant is frequent about Norwich, and most parts of Norfolk; also near Bury, Suffolk; and, according to Ray, at Wollerton, near Nottingham. No species can be more diftinct from the last, with which it has been confused, even by Linneus. The root is biennial. Stem three or four feet high, branched from top to bottom in a conical form, covered with innumerable golden flowers, larger than the half, whose filaments are clothed with white hairs, and their anthers are vermilion. The whole herbage is invested with white mealy down, easily rubbed off. Leaves all fett, thick and woolly; the radical ones numerous, a foot long; upper ones ovate, pointed, clasping the stem, not decurrent. Mr. Sieber has lent an Austrian specimen of this species, named V. flocofoam; but we know not of its having been published under that denomination.

Our variety 3 is found near Hellesdon, and in other parts of Norfolk. The leaves are like pulverulentum, flowers, and purple woody flaments, like nigrom; so that, according to the opinion of Linneus, the latter was the mother of this apparently mule production. We believe it moreover to be perennial.

V. pulverulentum displays a remarkable degree of irrigability, if the stem be frantly dry, twice or thrice, with a small fllick. In the space of a few minutes, the flowers close, and begin to drop off, all in their turn falling to the ground in the space of a quarter of an hour, if the weather be warm and still; if otherwife, this quality is less perceptible. We were first informed of it by the very ingenious Mr. Correa de Serra.

24. V. gallicum. Dauphiny Mullein. Willd. n. 11. (V. Chaxi; Villars Dauph. v. 2. 491. t. 13; synonym all very doubtful.)—Leaves ovate-oblong, crenate, downy beneath; radical ones flaked; heart-shaped and pinnatifid at the base. Stem angular, panicked at the top.—Native of several parts of Dauphiny, in rocky situations. The habit of this plant, its panicule, and the soft durable pubescence of the backs of its leaves, as well as the shape of such as grow on the stem, mottelable V. Lychnitis; the yellow flowers, purple hairy flaments, as well as the size, form, and long footstalks of the radical leaves, which are doubly crenate, rather accord with V. nigrom. But these radical leaves are remarkable for a few deep parallel segments at their base. We have a specimen from the author himself, or his bad figure would little avail us.

The late Mr. Donn favoured us with a specimen, above twenty years ago, from the Cambridge garden, of a tall Mullein, agreeing with this in most respects: but the lower leaves are taper at the base, and finely pinnatifid. This came from Poland, and is doubtless V. polandicum of his Hort. Cantab. ed. 5. 451; but unfortunately a name does not make a species, any more than flocofoam of the same useful work, see our n. 73. This Polifh plant seems a mule between
between nigrum and Lychnitis; or it may be a variety of gallicicum.

25. V. nigrum. Dark, or Black, Mullein. Linn. Sp. Pl. 253. Willd. n. 8. Fl. Brit. n. 4. Engl. Bot. t. 59. Ger. Em. 775. Fl. Dan. t. 1088. (V. tertiurn; Matth. Valgr. v. 2. 489.)—Leaves oblong-heartshaped, stalked, waved and crenate, slightly downy. Clutter solitary, spikelike, many-flowered.—Native of banks, and road-sides, in most parts of Europe. With us it occurs chiefly on a chalky or gravelly soil, in shady lanes, or on glairy hillocks, flowering in July and August. The root is perennial. Stem erect, simple, angular, leafy, brown or purplish, two or three feet high, rarely branched. Leaves of a fine deep green, not hoary, though somewhat downy; all stalked, except the very small upper ones. Clutter very long, slender, compact, though here and there interrupted, composed of innumerable tufted golden flowers, with bearded violet filaments, and orange anthers. This is altogether a very elegant species.

We received, many years since, from the late Mr. Davall, specimens and seeds of a variety of this species, having white flowers. These dried specimens differ little from our wild plant, except a slight degree of luxuriance, owing to culture, nor can it be doubted that they are the white-flowered variety, mentioned by Caspar Bauhin, and others. But the far more luxuriant progeny from their seeds, in lady Amelia Hume’s garden, bore large copper-coloured flowers, almost like V. cupreum, Curt. Mag. t. 1226, which, for its solitary flower-flasks, we should believe to be our plant. Such is the Proteus-like nature of this whimsical genus!

26. V. ferrugineum. Ruly Mullein. Ait. n. 9, excluding the reference to Andrews. Willd. n. 7.—Leaves somewhat villous, wrinkled; thoe on the stem nearly febil, equally crenate; radical ones oblong-heartshaped, doubly crenate.—Native of the south of Europe; said to have been cultivated, at Edinburgh, by Mr. Sutherland, in 1683, and marked by Mr. Aiton as a hardy perennial, flowering from May to August. We have no specimen, but we remember to have examined an authentic one in Sir Joseph Banks’s herbarium, which proved totally unlike the Greek plant of Dr. Sibthorp, figured as ferrugineum by Mr. Andrews, which is our V. trilfolium, hereafter described. Such errors are execrable in such a tribe. We have a notion that the specimen betrayed some affinity to V. Boerhaaeii, n. 20, but we dare not affirm it.

27. V. trilfolium. Brown-flowered Mullein. Prodr. Fl. Grec. n. 529. (V. ferrugineum; Andr. Repof. t. 162.)—Leaves elliptical, wavy and partly toothed, nearly fmeath; radical ones stalked. Clutter solitary, simple. Stem leafy.—Gathered by Dr. Sibthorp on Mount Athos. By his means the plant has been introduced into the gardens of England, where it proves a hardy perennial, flowering most of the summer, and propagating itself copiously by seed, without requiring any care. This species differs from all the foregoing, in its very long simple clutter terminating the stem at first drooping, but gradually becoming erect, and, as it flowers, extending itself to the height of five feet, being composed of innumerable, scattered, solitary, spreading, almost capillary partial flasks, each three or four times as long as its accompanying lanceolate bractese, and bearing a solitary nodorous flower, an inch broad, of a peculiar dull greenish or yellowish brown, whose filaments are densely bearded with purple. Sometimes, from luxuriance, two of these flasks grow together, but each has always its own bractea. The whole clutter, bractea, and obtuse calyx, are clothed with glandular vifcid hairs. The radical leaves

are numerous, on longish stalks, wrinkled, slightly downy, a little veifcid, green, reticulated with veins; their margin variously waved, or bluntly toothed: those on the stem are nearly fsehile, ovate or heart-shaped, more or less acute. We cannot perceive any alteration in this plant after cultivating it for fifteen years, and yet there is scarcely a permanent specific character, to distinguish it from the following. Can Tournefort’s Blattaria orientalis, bugula folio, &c. Voy. v. 2. 83, with a plate, acknowledged to be a variable plant, possibly belong to our trilfolium?

28. V. phaeum. Purple-flowered, Mullein. Linn. Sp. Pl. 254. Willd. n. 9. Ait. n. 11. Jacq. Austr. t. 125. Curt. Mag. t. 885. (Blattaria flore purpeo; Ger. Em. 776.)—Leaves ovate, crenate, smooth, chiefly radical and fsehile. Clutter solitary, simple. Stem nearly leafless.—Native of Austria, and the south of Europe. A hardy perennial, cultivated in England ever since Gerard’s time. It is of more humble growth than the last. Leaves chiefly radical, and nearly fsehile, scarcely at all downy; their margin finely or doubly crenate. Inflorifcence like the preceding, but the flowers are of a dark violet hue, and the filament less hairy. Sometimes the stem becomes leafy, as in Jacquin’s figure, and perhaps, as he represents it, branched; but we have never seen an instance of the latter.

29. V. ovifolium. Oval-leaved Mullein. Donn. Cant. ed. 5. 45. Siims in Curt. Mag. t. 1037. Ait. n. 2.—“Leaves oval, fsehile, acutely crenate; smoothish on the upper side. Stem erect, simple. Flowers spikelike.”—Native of mount Caucasus. Introduced into England by Mr. Lodidges, in 1804. A hardy biennial, flowering from July to September. This has the aspect of several species in our first figure, the flowers being as large as any of thofe, yellow, with orange-coloured, partly hairy, filaments; and nearly fsehile, in a long dense spide. But the leaves are not deciduous, nor, though downy, at all hoary or woolly. We have seen no specimen.

Dr. Sims has exhibited in Curt. Mag. t. 1226, by the name of V. cupreum, a Mullein, whose stalked leaves, and racemose flowers, variegated with tawny-buff and purple, each on a partial clatter of considerable length, all appear to differ from V. ovalifolium, the bractea, and calyx like—wide, being altogether unlike the figure of this species, that, but for our confidence in its excellent cultivator Mr. Lodidges, we could scarcely believe it came up from seeds of the ovalifolium. Perhaps, as Dr. Sims suggests, the parent may have been impregnated by V. phaeum, or we would rather lay our trilfolium. When the plant blooms within-doors, the corolla is pale yellow, with a purple eye. The inspection of this plant is enough to damn the most ardent student of species of Verbasculum, and to cause a general mistrust of them all.

30. V. virgatum. Large-flowered Primrose-leaved Mullein. With. Bot. Arr. 250. Fl. Brit. n. 5, Engl Bot. t. 530. Ait. n. 12. (Blattaria flore ampio; Ger. Em. 778. B. magni flore; Bauh. Hilf. v. 3. 859. L. 1c. 564.)—Leaves ovato-lanceolate, toothed, fsehile; heartshaped at the base; radical ones downy, and somewhat lyrate. Stem branched. Flowers axillary, on short flacks, partly aggregate.—Native of Worcecthire. Biennial, flowering in July and August. Stem five or fix feet high. Whole plant green, not hoary, though more or less covered with short, prominent, often forked, glandular hairs. The radical leaves, which resemble those of a primrose, are always so clothed. Those on the stem are very numerous, acute, toothed or sharply crenate, broad and rounded at the base, gradually diminishing upwards. Flowers from the bofoms of many of the upper leaves, large, yellow, some

Vol. XXXVI.
Vermont nearly coming the town Verbascum. English the the nor and a common Geography, the stranger and in spinifolium. Blat-A Botany, L. Ger.

Two former, illustrated with spinifolium rigid primul. Flowers become Bauk. gardens, partially bright flowers, or fpecies

Two of the lowermost five, or six together, the right solitary, as are all those of the weaker branches. Flower-stalks hairy and viscid, seldom so long as the calyx, whose segments are lanceolate, acute, and glandular. Filaments bearded with purple. Anthers uniform.

31. V. Blattaria. Moth Mullein. Linn. Sp. Pl. 254. Wild. n. 10. Fl. Brit. n. 6. Engl. Bot. t. 393. (Blattaria flore luteo; Ger. Em. 778.)—Leaves oblong-lanceolate, acute, smooth, serrated; lower ones bluntish, tapering at the base, or flaked. Stem branched, racemose. Flower-stalks much longer than the bracteas. —Native chiefly of the southern parts of Europe, rare in England, flowering in July. Root tapering, annual. Stem three or four feet high, leafy. Leaves much narrower, and more deeply serrated or notched than in the last, the upper ones becoming gradually more pointed, and smaller, to the bottom of the long simple clumps, where they are replaced by a small, solitary, lanceolate bract, under each flower-stalk, as in V. triloba and phanicecum. The corolla is smaller than the last, bright yellow, more or less streaked with purple. Filaments clothed with purple hairs; sometimes the corolla seems to become purplish all over.

A supposed variety, with large white flowers, marked partially with purplish-brown at the back, is common in gardens; coming up from seed, and remaining unaltered, through many successive years. This is Blattaria alba, Bauh. Pin. 241, but we can discover no specific difference between it and the wild or cultivated yellow-flowered kind.

32. V. phlomoides. Thorny Mulllein. Linn. Sp. Pl. 254. Amoen. Acad. v. 4. 397. Wild. n. 16. Vahl Symb. v. 2. 39. Sm. Fl. Grce. Sibth. t. 229. (Leucocoeo phlomoides erectum; Cluf. Hift. 299. Ger. Em. 459. L. phlomoides strictum; Alpin. Exot. 37. t. 36. Gaalattidiva primi Candidi; Pop. Bald. 114.)—Stem leafy, shrubby, much branched, spiny. Leaves all flaked, hoary.—Native of the higher mountains of Crete; a stranger in our gardens, even by name. This differs widely from all the rest, in its hardy, shrubby, bushy stem, a foot high, whose very compound branches harden at their points into smooth rigid thorns. Leaves crowded, an inch or inch and half long, oblong, obtuse, deeply toothed, downy and white on both sides; contracted at the base into the flower-stalks. Flowers scattered, flaked, lateral and terminal, yellow, hardly above half an inch broad. Stamen orange-coloured. Calyx obtuse. Capsule small, villous.

Two other species, mentioned by Linnaeus, remain to be noticed; V. Ojhecki, and V. Mycena, Linn. Sp. Pl. 255. The former we have shewn to be the Triguria of Cavanilles (fee that article) nor does it answer to the characters of a Verbascum. The latter, figured in Curt. Mag. t. 236, an elegant, herbaceous, stemless plant, long known in our gardens, appears to be the Ramonda of Schradter and others, as we have mentioned in our remarks subjunctive to the generic character of the present genus, from which this species must, doubtless, be excluded.—Wildenow has a V. Bannatii, adopted from Vahl’s Symb. v. 2. 39, and compared with V. Ojhecki. With this we are quite unacquainted.

From the present view of Verbascum, more complete than any that has hitherto been given, and yet so far from perfect, the reader may chiefly learn that no certain limits have as yet been found for many of the species of this genus, while others, apparently much alike, remain permanent and distinct. To fix them all, a long course of experiment, by crofs impregnation, would be necessary.

Verbascum, in Gardening, furnishes plants of the hardy, annual, biennal, and perennial kinds, among which the species cultivated are, the annual mullein (V. boerhaavi); the moth mullein (V. blattaria); the great mullein (V. thapsus); the woolly mullein (V. phlomoides); the white mullein (V. lychitits); the scollop-leaved mullein (V. finatum); the rufy mullein (V. ferrugineum); the purple mullein (V. phanicecum); and the borage-leaved mullein (V. myconi).

In the first fort the flowers have an agreeable scent at a little distance; but if smeal too long, or too near, it becomes less pleasant.

The second fort has white flowers, which are streaked more or less with purple, and is very ornamental, flowering from July to November, or even later in mild weather.

It varies with white flowers.

The third fort has a biennial root, and the flowers are of a bright yellow colour, and sometimes, but rarely, white.

The fifth fort is remarkable for its straight wand-like angular stem, and cream-coloured flowers, which are produced in great numbers in a compound clustered terminating raceme. Sometimes the colour of the flowers is yellow.

The ninth fort has the flowers large in proportion to the size of the plant, of a blueish-purple colour, and highly ornamental, somewhat like the auricula, appearing in May, and continue successively in blossom for several months. It is a desirable plant to cultivate, especially for decorating rock-work.

Method of Culture.—These plants may all be increased by seeds, and offsets taken from the roots.

The well-ripened seeds should be sown in the autumn, or early spring, in a bed of light mould, or in the borders or other parts where they are to remain, covering them lightly in. When the plants are up a few inches in height, in the bed method, they should be removed into nursery rows till the autumn, when they must be removed to where they are to remain.

The annual fort is, however, best sown at once where the plants are to grow, which is best done in patches.

The offsets of all the perennial forts should be taken off in the autumn, or very early in the spring, and be planted out where they are to grow. This is better than afterwards transplanting them.

They are all hardy plants, that succeed in almost any common soil and exposure, in borders, &c.

They afford a good effect in their different foliage, modes of flowering, and sweet scent of their flowers, in the large borders, clumps, and other parts of pleasure-gounds; the larger forts being placed backwards in them.

VERBELIET, in Geography, a town of Hungary; 6 miles S.W. of Erlau.

VERBENA, in Botany, among the Romans, was the name of some evergreen aromatic shrub, esteemed sacred, and employed in various solemn ceremonies. Hence it was called Hierobotane, and Herba sacra. Some derive Verbena from verro, to sweep, or cleanse; because the plant might be used for cleaning the altars or temples; others from Her- benna, corrupted from herba bona, or good herb. But these rather prove that no good Latin etymology was to be found. De Theis gives a much better, and indeed a direct, derivation of the word, from Blullet’s Dictionaire Celtique, where the Celtic name of the plant is said to be Ferfas, whence comes, still left changed, its English appellation, Vervain. The Roman shrub, above alluded to, is sometimes thought to have been our Rosemary, which could hardly be the Celtic plant; and we must rely on tradition, which has handed down our Common Vervain, the Linnaean Verbena, with much superstitious celebrity, even to the present day, as the Ferfas of our barbarous ancestors. It still, from time to time, makes the fortune of quacks and village
V. mexicana. Mexican Vervain. Linn. Sp. Pl. 28. Willd. n. 6. Ait. n. 1. (V. mexicana, tracheliol folio, fruets aparines; Dill. Elth. 407. t. 302.)—Leaves ovate, acute, harfl. Spike lax. Calyx of the fruit reflexed, hilpild, of two round lobes. Seeds two.—Native of Mexico. Cultivated in Sherard's garden in 1726. A flowe plant, flowering in summer. *Stems* herbaceous, two or three feet high, square, leafy, rough and furrowed, branched in the upper part. *Leaves* opposite, on short stalks, strongly ferrated into those of a common nettle, rough with minute rigid bristles. *Spike* terminal, flalked, ecret, long and slender; lax and interrupted in the lower part. *Flowers* very numerous, small, pale purple. The *calky* when in fruit becomes flalked, recurved, timid, and is at all times hoary with brily hairs. We are not certain that this species has always four perfect *flaemen*. Two of the *anthers* are most visible in the mouth of the tube. 

2. V. flachofolia. Oval-spiked Vervain. Linn. Sp. Pl. 27. Willd. n. 7. Ait. n. 2. (V. n. 4; Browne Jam. 115. t. 3. f. 1.)—Lavandula frutescent, folis latioibrois crenatis; Plum. 1c. 154. t. 162. f. 1.)—Spikes denfe, imbricatis, ovulo-cylindricis. *Leaves* lanceolate, woody, toothed, clothed with depreffed hairs; hoary beneath. Stem hardy. —Native of the West Indies. *Stems* spreading five or six feet, woody, but not lafting above two or three years. The *leaves* are flalked, two or two and a half inches long, acute, reticulated with veins, flat, not plaited, as the erroneous engraving, after Plummer's drawing, is made to express, but wavy at the margin, with small acute teeth; the upper surface is covered with rigid depreffed bristles; the under with softer hairs. *Spikes* hairy, an inch long, about thrice the length of their *flaemen*. Of the *flamens*, *leaves* or colour of the *flowers* we are ignorant.

3. V. globiflora. Round-headed Vervain. L'Herit. Stirp. 23. t. 12. Willd. n. 8. (Nheta maxima, flore albo, ficica habitutis; Sloane Jam. v. 173. t. 108. f. 1.)—Spikes denfe, imbricatis, roundifh-ovatis. *Leaves* ovate, crenatus, rugosæ, downv. Stem hardy, erect. —Native of South America; perhaps, as L'Heritier thought, of Buenos Ayres. We have from thence a specimen somewhat like it, but smaller in every part, possibly because it is a wild one. L'Heritier's plant was cultivated at Paris, being a *fubur* of humble growth, of a strong disagreeable odour. The *leaves* are shorter and more ovate than in the last, differing also from that species in being finely and closely crenate, not wavy or toothed. The *spikes* also are much shorter, nearly globose. *Flowers* white. *Stamens* four, all perfect. *Seeds* two.

4. V. javanica. Java Vervain. Burm. Ind. t. 2. f. 2. Willd. n. 9. (Zappania javanica; Poir. in Lam. Dict. v. 8. 840.)—Spikes denfe, imbricatis, cylindricis. *Leaves* elliptic-lanceolati, crenati, finely downv. —Native of Java. *Stems* ascending, roundifh, clothed, like the rest of the plant, with fine, ftshort, close hairs. *Leaves* an inch and a half long, acute at each end. *Flowers* in short cylindric *spikes*, on axillaries, often opposite, *flaemen* of the length of the *leaves*. *Linneas* fulfilled this not to be different from *V. flachofolia*, but they are very unlike in the margin of their *leaves*, as well as in general appearance.

6. V. bonariensis. Clutter-flowered Vervain. Linn. Sp. Pl. 28. Willd. n. 11. Ait. n. 5. Poir. in Lam. n. 13. (V. bonariensis altiflora, lavandule canariensis *spicâ* multiplici; Dill. Elth. 406. t. 300.)—Spikes aggregate, tufted, level-toppted. *Leaves* lanceolate, leaff, clapping the *flerum*. —Native of Buenos Ayres, from whence it came into Sherard's garden; and is still seen in some curious collections, being a hardy biennial plant, flowering throughout autumn. The *flerum* is often six feet high, square, rough, clothed with long, harfl, coarrefly ferrated *leaves*, and terminating in copious tufts of blue *flowers*, made up of short *spikes*, on very long, opposite, paneled *flaemen*. *Seeds* four, linear, striated, curiously rough on the inner side.

7. V. rugosa. Rugose Vervain. Willd. Enum. 633. Purth. n. 8. (V. angustifolia; Michaux Boreal.-Amer. v. 2. 14. Ait. n. 7. Poir. in Lam. n. 11.)—Spikes thread-shaped, solitary, terminal or axillary. *Leaves* lanceolate, sparingly ferrated, furrowed with veins; tapering at the base. —In dry soil, by road-sides, particularly on lime-stone, from Pennsylvania to Tennessee, flowering from June
VERBENA.

tid.—By road-sides in wet situations, and on the banks of rivers, from Canada to Carolina, perennial, flowering in July and August. From two to five feet high. Flowers purple, sometimes white. Purflb. The leaves are three inches, or more, in length, rough to the touch, like a fine file. Spikes two inches long, becoming longer, and lax, after flowering.

11. V. triphylla. Lemon-scented Vervain. L'Hérit. Stirp. 21. t. 11. Willd. n. 13. Ait. n. 4. Curt. Mag. t. 357. (Zappania citrodora; Poiret in Lam. Dict. v. 8. 845.)—Spikes panicled. Leaves lanceolate, minutely and dually toothed, three in a whorl. STEM hrubby.—Native of Chili, where it was found by the unfortunate Doméry, (see that article,) and introduced into the gardens of Europe. In Italy, Spain, and the south of France, this valuable shrub is quite naturalized, and its delightfully scented leaves, having the flavour of lemon, are useful in fevers, and other inflammatory disorders, being taken as tea, like balm, hyflop, &c. With us it is a hardy greenhouse plant, flowering in summer. The Laves are of a light bright green, roughish, two inches long, apparently entire to a flight oblique, foan dressing, and fragrant for a long time afterwards if rubbed. Flowers small, pale lillac, in aggregate, panicled, loose, terminal spikes. The specific name of this plant is not well known, to many Peruvian and Chili shrubs having three leaves in a whorl. Ortega, who thought it a new genus, called it Alyxia citrodora, and the French retain the latter appellation, as if circa would not far more elegantly express their meaning. But who shall weed the rank wilderness of recent botanic names? in which the venerable fabric raised by Linnaeus is almost hidden, like the temples at Paftum, before they were cleared.

date heads. Uppermost anthers club-shaped at the back. Leaves whorled, wedge-shaped, undivided or lobed.—Native of Peru, in fandy situations, flowering in August and Sep
tember. The flens are numerous, erect, much branched, hoary; naked below. Leaves five or six in each whorl; some entire, linear-lanceolate, revolute; others divided or three-cleft, hardly an inch long, moderately downy, a little fringed. Flowers terminal, felled, collected into a head in the form of an umbel, each with one or two linear, oblong, downy, fringed bracteas. Corolla purplish-red. Stamens four. Anthers heart-shaped, furmounted by a small club-shaped appendage. Seeds four. Poiret.

tered. Leaves ovate, acute, sharply serrated.—Native of waite ground and stony places, in the West Indies. The flens are herbaceous, two or three feet high, branched, leafy, square, smooth, hollow. Leaves falked, two inches long, slightly brifly. Clusters from the forks of the stem, long, weak, and slender, of numerous, diftant, little, pale-blue flowers, on very short flals. Calyx downy; as the fruit ripens becoming globule, including the four hard seeds, which are closely combined, befit externally with four thick spines. Dr. Swartz, in his Flora Ind. Occ. 1909, points out the affinity of this species to his own genus Ghinia, (see that article,) founded on Verbena ceroovifaca of Lin
teus. The fruit of Ghinia, however, is a drupa, with a nut of four cells.

15. V. caroliniana. Carolina Vervain. Linn. Sp. Pl. 29. Willd. n. 16. Ait. n. 8. Pursh n. 9. (V. carolinensis, meliflæ folio, aspero; Dill. Eth. 407. t. 301.)—Spikes aggregate, lax and slender. Leaves elliptic-lanceolate, acute at each end, forked, nearly fide; rough above; somewhat downy beneath.—In dry sandy fields, from Caro
olina to Georgia, perennial, flowering in June and July. Purflb. Herb erect, branched, somewhat hairy. Leaves harth, with minute brifly tubercles, on the upper side, an inch and a half or two inches long, unequally, not deeply, ferral. Flowers pale red, very small. Calyx brifly, twice the length of the minute, ovate, pointed bracteas. Seeds four, oblong.

16. V. urticifolia. Nettle-leaved Vervain. Linn. Sp. Pl. 29. Willd. n. 17. Ait. n. 9. Pursh n. 6. (V. folio urtice angustiore; Rivin. Monop. Irr. t. 57. V. reço canadensis; Morf. fit. 11. t. 25. f. 3. V. peregrina, foliis urticæ; Dodart Mem. 627. t. 53.)—Spikes aggregate, lax and slender. Leaves ovate, acute, forked, falked, hairy on both fides.—About road-sides and culti
cated grounds, from New England to Carolina, perennial, flowering from June to September. Flowers very small, white.
white. *Purp.* Akin to the last, but taller, and clearly distinguished by its flaked, coarsely serrated, nettle-like leaves. *Braetes* ovate, slightly pointed, shorter than the calyx.

17. *V. stridula.* Stout Upright Vervain. Venten. Hort. Cell. t. 55. Ait. n. 10. Willd. Enum. 633. Pursh n. 10. Donn. Capt. ed. 5. n. 10. (V. rigens; Michaux Boreal-Am. v. 2. 14. *V. paniculata*; Donn. Capt. ed. 5. n. 8.) — Spikes aggregate, corymbose, straight, dense, obtuse. *Braetes* taper-pointed, as long as the calyx. Leaves ovate, on short stalks, unequally serrated, downy and hoary on both sides. Native of Carolina, and the Illinois country, perennial, flowering in July and August. *Purp.* A tall, stout, hoary plant, whose fluff round *flem* is clothed with numerous, coriaceous, veiny leaves, an inch and a half to two inches long, acute, coarsely serrated; mottled downy beneath. *Spikes* from two to four inches long, in strong plants numerous, crowded at the top of the stem, in a corymbose manner, hoary, imbricated. *Braetes* ovate, with taper points, generally exceeding the calyx, whose teeth are also long and slender. *Corolla* large, of a violet blue.

18. *V. diffusa.* Spreading Vervain. Poiret in Lam. n. 14. Pursh n. 7. — Spikes very long, lax, panicked, widely spreading. *Braetes* acute, about as long as the calyx. Stem erect, much branched. Leaves ovate-lanceolate, serrated, somewhat downy. — Native of North America; cultivated at Paris, according to Poiret, on whose authority Mr. Pursh gave this species a place in his Flora. He speaks of it as having a near resemblance to *V. urticaefolia*, with very small, somewhat purple, flowers. We have seen no specimen.

19. *V. paniculata.* Compound-panicked Vervain. — Lamarck Illust. v. 1. 57. Diet. n. 8. Pursh n. 5. — Spikes compound, in a corymbose panicle. Leaves lanceolate, deeply serrated and jagged; tapering at the base; harsh on both sides, slightly downy. — In the natural meadows of the high mountains of Virginia and Carolina, perennial, flowering in July and August. — From four to six feet high. *Flowers* very numerous, purple. We have from the Paris garden a specimen marked *V. paniculata* of Jullien, which answers well to the description by Poiret in Lamarck’s Dictionary, and is doublets of what they all intended. Our specimen indeed is but eighteen inches high, and the leaves are about two inches, not four or five, in length. They taper down into short flanks, and are not much pointed. Both surfaces are rough like a file, as is likewise the square *flem*, which terminates in a corymbose *panicle* of compound or branched *fiskes*. The *Braetes* are ovate, with a fine point, shorter than the calyx. *Corolla* rather small. — What we received from the late Mr. Donn of Cambridge, as his *V. paniculata*, is not this, but our *fridula*, n. 17.

ground in Peru, flowering from March to May. The whole plant is bristly, two feet high, branched. Leaves sessile, half clasping the stem; contracted at the base; divided almost half way down into three large, oblong, ferrated lobes, rough and hispid on both sides, two or three inches long, and about as broad. Spikes short, ternate. Flowers blue. Poiret.

Native of Illinois and Kentucky, perennial, flowering in July. Flowers light purple. Pursh. A small very hairy plant, said to have some resemblance to V. supina, n. 23, but the long wide-spreading bracteas are peculiar. The stems are from six to nine inches in length. Spikes from the ends, as well as the forks, of the branches, two or three inches long. Seeds only two.

27. V. Aubletia. Rose-coloured Vervain. Jacq. Hort. Vind. v. 2. 82. t. 176. Lindl. Suppl. 86. Willd. n. 18. Ait. n. 11. Pursh n. 1. Curt. Mag. t. 308. (Buchnera canadenis; Lindl. Mant. 88. Obletia; Journ. de Rozier, v. 1. 367. t. 2. Erinus lacinianus; Lind. Sp. Pl. 879. Lychindea verbeana tenuifolia; Feuille. Peruv. v. 3. 35. t. 25.)—Spikes capitate, solitary; cylindrical after flowering. Bracteas awl-shaped, as long as the taper-pointed calyx. Leaves three-lobed, cut. Stem erect.—Native of Carolina and Georgia, flowering in June and July. The seeds appear to have been brought to Europe by M. Richard, senior, and were sent by him to Kew garden, in 1774. The plant is biennial in our climate, requiring the shelter of a frame in winter. The herbage is green, roughish to the touch. Stem a foot high, or more, square, leafy, branched from the bottom. Leaves flaked, broadish, variably cut. Flowers larger than most of the genus, of a fine pink or crimson, numerous, in flaked heads, which afterwards become thick, close, cylindrical spikes. The bracteas are very narrow, permanent, downy as well as the calyx, whole teeth are also very long and slender. Seeds four, oblong; furrowed in the lower, reticulated in the upper part. This is undoubtedly a genuine and most obvious Verbenas, nor can we account for the error of Linnaeus, who, with the ripe naked seeds on his original specimen, and the long-pointed calyx, referred it to Buchnera. It was called Obletia, either by its discoverer, or by La Tourrette, who sent a specimen and figure to Linnaeus, by which the latter corrected his mistake. Their intention was to honour Aublet, whose name was sometimes written Oblet. With respect to the other Linnaean synonym, hitherto neglected by most of those who have noticed this Verbenas, it depends entirely on Feuille's plate and description, which led Linnaeus to refer this, as well as the following species, to Erinus, without seeing a specimen of either. Lamarck, Poiret, and Willdenow, apply these latter synonyms to their V. erinoides, Willd. Enum. 634, which is V. multifida, Fl. Peruv. v. 1. 21. t. 33. f. C.

28. V. veronicaefolia. Speedwell-leaved Vervain. (Erinus peruvianus; Lindl. Sp. Pl. 879. Lychindea veronicea folio, flore coccineo; Feuille. Peruv. v. 3. 36. t. 25.)—Spikes capitata, solitary, cylindrical after flowering. Bracteas awl-shaped, as long as the taper-pointed calyx. Flowers ovate, ferrated, acute at each end. Stem erect.—Found by Feuille in fields on the north side of the river de la Plata, in Paraguay. This seems to agree with the habit in the flowers and inflorescence, differing only in the simple undivided form of the leaves; but whether that difference be constant and specific, can be determined by future comparison of the two plants. The other synonym of Feuille having been misidentified, and, as we presume, distinguished without reason from V. Aubletia, we have here recorded this for the consideration of those who may hereafter meet with materials for solving our doubts.

VERBENA, in Gardening, contains plants of the hardy, herbaceous, and tender exotic kinds, among which the species cultivated are, the Indian vervain (V. indica); the trailing vervain (V. supina); the betony-leaved vervain (V. orubica); the Jamaica vervain (V. jamaicensis); the Mexican vervain (V. mexicana); the globe-flowered vervain (V. globiflora); the cluster-flowered vervain (V. bonariensis); the halbert-leaved vervain (V. haftata); and the three-leaved vervain (V. triphylla).

And there are many other species that may be cultivated for variety.

The first fort is an annual plant with a purplish flower. In the second fort the flowers are of a light blue colour, and large. The third arises with a shrubby flalk, and the flowers grow in thick terminating spikes about a foot in length; are large, and of a fine blue colour. The fourth fort is three or four feet high in the stem, and much branched, the flowers blowing in succession, beginning at the bottom, but very few together, violet-coloured, with the throat and long slender incurved tube of a white colour. The seventh fort has four-cornered flalks, which rise to the height of five or six feet, the flowers of which are blue, appearing late in summer. The eighth has many four-cornered furrowed flalks, which are terminated by spikes of blue flowers, in clusters, which appear in August. The ninth is a very sweet-smelling under shrub, and very pleasant, like that of the lemon.

Method of Culture.—These plants are not raised without difficulty or attention. They may be increased by seeds, which should be sown in pots, or on a hot-bed, in the early spring, plunging the pots in the bed. When they are in a state of growth to remove, they should be planted in separate pots, and re-plunged in a fresh hot-bed, shade being given till they have taken new root, when they must have the management of tender plants of the exotic kind. The annual forts should be kept in the flower, or a glass case, where there is a bark-bed to plunge them in, when too large to be continued under the frames; and the perennial forts may be placed simply in such cases, air being admitted in a cautious manner.

Of these kinds, such as do not afford good seeds in this climate, may be increased by planting cuttings in the summer months in pots of good mould, placing them in the bark-bed of the flower, where they may be preferred many years. The eighth fort may be raised from seeds by sowing them in the autumn, and by parting the roots and planting them out at the same time. They succeed best on a soft loamy soil, and are so hardy as to thrive in the open air. The ninth fort may be readily increased, by planting cuttings in the spring or autumn in pots of good mould. It should have the protection of the greenhouse or a glass case. They afford variety among other potted plants in the greenhouse and flower, and some of the hardy forts occasionally in the open ground.

VERBENACA, in Botany, with the earlier botanists among the moderns, and even with Pliny himself, seems to be synonymous with Verbenas, see that article. Linnaeus indeed uses this word as the specific name of a common English species of Salvia, not supposed by any body, that we can find, to have been the so much honoured Verbena of the Romans, see Pliny, book 25. chap. 9. He was led to
to this adoption of the name by Triumfetti, who compares the division of the leaves of this plant to those of Verbena, or Ver Vain. The application, therefore, is faulty, and causes a confusion of ideas. See Salvia.

VERBENICO, in Geography, a town of the island of Veglia, with a small harbour, containing about 1200 inhabitants.

VERBERATION, formed from verber- \( \text{of the verb} \) \( \text{to strike} \), a term used to express the cause of found, which arises from a verberation of the air, when struck, in divers manners, by the several parts of the fowens body first put into a vibratory motion.

VERBERIE, in Geography, a town of France, in the department of the Oise: near it is a medicinal spring; 9 miles S. of Compiègne.

VERBESINA, in Botany, according to Ambrosius, who is followed by Linnaeus, Phil. Bot. 175, originated in Forskoh; which latter arose from the leaves being divided like a pair of forceps. Professor Martin, however, derives Forskoh from σφυς, 

Gen. Ch. Common Calyx concave, of several oblong, channelled-concave, erect, mostly equal leaves, in a double row. Cor. compound; radiated, of the numerous perfect florets in the disk funnel-shaped, five-toothed, erect; of the few (about five) female florets of the radius ligulate, either broad and three-cleft, or very narrow and undivided. Stam. in the perfect florets, Filaments five, capillary, very short; anthers united into a cylindrical tube. Pistil. in the same florets, Gennis rather oblong; style thread-shaped, the length of the flammers; filaments two, reflexed; in the female ones, the same. Pericarp. none, except the unchanged calyx. Seeds in all the florets alike, solitary, thickish, angular, crowned with a clefty crown of two, or more, acute teeth. Recept. covered with deciduous clefty scales.

Obf. We have shewn, under the article Phaethusa, that the genus established by Gaertner, with that name, is a real Verbena, though a Syngenia of Linnaeus. The bristly-pointed crown of the seed in the genus before us being wanting in V. Lavenia, alba and prostrata of Linnaeus, the two latter are removed to Eclipta, and the first to Lavenia; see those articles. The number of radiant florets is uncertain in many species.

Seet. 1. Leaves alternate.

1. V. alata. Wing-flaked Verbesina. Linn. Sp. Pl. 1727. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 1716. (Cannabis indica, folii integra, alato caule; Magn. Hort. 40. t. 8. Chrysanthes Americanum, alato flore apollo globo aurantio, foliis baccharidis; Commel. Hort. v. 1. fol. 3. C. corallavicu, alato cale, flore globulis aurantis; Her. Parad. 125, with a plate.)—Leaves alternate, decurrent, undulated, bluish. Brittle of the seed two, very unequal.—Native of South America and the Weft Indies. Cultivated ever since the beginning of the last century in our florist, where it flowers most part of the summer, and being not uncommon, has been figured in more publications than we have thought necessary to quote, but which are cited by those mentioned above. The plant is perennial, hoary when young, erect, branched, three or four feet high, readily known by its winged stem. Leaves three or four inches long, veiny, wavy, and toothed. Flowers of a very rich orange-colour, almost globular, three quarters of an inch broad, on long, naked, alternate, or opposite, peduncle, at the ends of the branches. Florets of the radius, in our gardens at least, numerous. Seeds bordered with a membrane; their terminal awn-filament, rigid, one much longer than the other, incurved and hooked. Linnaeus has hinted that this species differs so much in habit and structure from the roll, as almost to constitute a distinct genus. Gaertner makes it the type of Verbesina, and yet asserts that this genus is only Spianthus with a radius. Indeed these two genera do run very much into each other, and the radius occasionally appears or vanishes in several species of each, nor are the bristles of the seed perhaps strictly constant even in the same species. We scarcely think the difficulty would be much lessened by removing V. alata to Spianthus, fee that article; though such a measure might be sanctioned by the habit of the plant. The remaining species, very various in habit, have not been sufficiently examined or compared to allow of a clear decision respecting them, and we must take them in general as we find them.

5. V. mutica. Parley-leaved Verbesina. Linn. Sp. Pl. 1727. Willd. n. 5. Ait. n. 2. Swartz Obs. 1746. 1. 175. (Bidens apiifolia; Linn. Am. Acad. v. 5. 452. Chrysanthemum palustre minimum repens, apiifolia; Sloane. Journ. v. 2. 185. f. 155. f. 1. Humile, ranuncula folio; Plum. 1. 85. f. 1.)—Leaves alternate, deeply three-cleft, toothed; radical ones obvate, serrated. Stems procumbent. Seeds without awns.—Found in rather moist pastures, and by way-fides, in the West Indies. Swartz. Miller cultivated it in 1768, from seeds sent by Houton, from whom Gronovius received specimens in 1732. This species,
Species, having no brily crown to the seed, belongs rather, as Dr. Swartz observes, to Anthemia; but the habit is somewhat adverese. The *flims*, a span long, spread every way on the ground, and are leafy, more or less branched. Leaves much divided and toothed; glabrous beneath. Flowers small, yellow, with numerous radiant florets. Seed bordered.

6. *V. Bofwellia*. Fennel-leaved Verbeina. Linn. Suppl. 379. Willd. n. 6.—Leaves alternate, three-cleft, with many capillary segments. Stems prostrate. Seeds hairy, with two bristles. Female floret solitary.—Native of the East Indies. Used by the natives in fomentations. An annual, herbaceous, decumbent plant, having the taste and smell of fennel; the divisions of the leaves also resembling that herb, only shorter and fewer. Flowers softly foliary, axillary or terminal, stalked. Calyx-seals few, broad, elliptical, with a membranous edge. Florets five or six only; of which one is ligulate and female; the rest four-cleft. Seeds compressed, black, clothed with faggy golden hairs, and crowned with two black bristles. Limnosus, or rather Koenig, who sent this plant, appears to have had an intention of making it a new genus, by the name of *Bofwellia*, which might have been done without violence to nature. We are not informed of the origin of the name.

7. *V. gigantea*. Great Pale Verbeina. Jacq. Coll. v. 18. 159. Ic. Tarr. t. 175. Willd. n. 7. Ait. n. 3. Swartz Ind. Occ. 1368. (Bidens frutecens, fihonphlyli folio et facie; Plumb. Ic. t. 1. 51.)—Leaves alternate, pinnatifid, finely toothed. Stem frutaceous.—Native of mountainous thickets, in Jamaica and other parts of the West Indies, flowering in December and January. Though often seen in our most curious flave collections, it is very rarely flowers. The stem is ten to twelve feet high. Leaves deeply pinnatifid; downy beneath; the lower ones twelve to eighteen inches long. Flowers small, white, or flesh-coloured, numerous, in large, corombose, terminal panicles. Seeds, according to Jacquin, crowned with a solitary bristle.

8. *V. Coreopfitis*. Alternate-leaved Winged Verbeina. Michaux Boreal.-Amer. v. 2. 134. Purf. n. 3. (Coreopfitis alternifolia; Linne Sp. Pl. 1283. Willd. Sp. Pl. v. 3. 2257. Jacq. Hort. Vind. v. 2. 50. 110. Chrysanthemum virginianum, caule alato, ramamius, flore minore; Plumb. Phyt. t. 150. f. 3. C. caule alato, virginianum, &c.; Moris. lect. 6. t. 7. f. 75. 96.)—Leaves alternate, lanceolate, serrated, toothed. Stem winged. Panicle corombose, leafy.—On the mountains of Virginia and Carolina; perennial, flowering from July to September. From three to seven feet high, the stem furnished with several narrow, green, entire, leafy leaves. Leaves four or five inches long, roughest on the upper side; the lower ones opposite, or three or four in a whorl; but the greater part are alternate. Flowers several, in a downy-stalked branched panicle. Calyx widely spreading, almost flat, so that the disk becomes nearly globose, subtended by four or five orange-coloured, spreading, ligulate florets, near an inch long. Seed crowned with two short bristles. This species is naturally very nearly allied to *V. Siegfbeckia*, hereafter described, fee n. 11, nor can they be genetically separated.

Michaux and Purf. mention a white-flowered variety, always defective of rays, found by the latter on the coast of Carolina, which is Athcanoja paniculata, Walt. Carol. 201. This Mr. Purf. strongly suspects to be a very different species.

9. *V. helianthoides*. Sun-flower Verbeina. Michaux Boreal.-Amer. v. 2. 135. Purf. n. 4.—Leaves alternate, broadly lanceolate, acute, slightly toothed; rough above; downy and hoary beneath. Stalks single-flowered, aggre-

10. *V. pinnatifida*. Pinnatifid Yellow Verbeina. Cavan. Ic. v. 1. 67. t. 100. Willd. n. 8. Jacq. Hort. Schoenbr. v. 3. 30. t. 305.—Leaves opposite, pinnatifid, serrated. Stem winged. Native of Mexico, flowering in the European flaves in December and January, but not yet known in the English collections. The stems are several, rather frutaceous, with four, slightly woody, membranous wings. Leaves about a foot long, tapering at the base. Inflorescence like *V. gigantea*, but the flowers are more numerous, yellow, with several conspicuous rays. Seeds crowned with two bristles.

11. *V. Siegfbeckia*. Half-rayed Verbeina. Michaux Boreal.-Amer. v. 2. 134. Purf. n. 6. Ait. n. 4. Purf. n. 2. (Siegfbeckia occidentalis; Linn. Sp. Pl. 1269. Phaethusa americana; Gartn. v. 2. 425. t. 169. Purf. 561. Chrysanthemum americanum, caule alato, amploribus folis hinnatis, floribus e palleste luteofentibus parvis; Pluck. Mant. 46. t. 342.)—Leaves opposite, ovato-lanceolate, serrated, toothed; tapering at the end. Stem winged. In shady woods, from Virginia to Carolina; perennial, flowering from July to September. A tall herbaceous plant, with four, or more, narrow, uninterrupted wings, running along the stem and branches. Leaves six inches long, undeviately, bright green; roughish above; downy beneath; the upper ones sometimes three in a whorl. Panicle terminal, forked, downy, leafy. Radiant florets from one to three, near an inch long, ligulate, bright yellow. We have already (see Phaethusa) given reasons for the above synonyms. Purf. rightly suspected these two plants to be the same, but retained Phaethusa out of deference to Michaux, who nevertheless has omitted it in his Flora.

12. *V. ferrata*. Serrated Downy Verbeina. Cavan. Ic. v. 3. 7. t. 214. Willd. n. 10. Ait. n. 5.—Leaves opposite, oblanceolate, with tooth-like frratures; downy beneath. Flowers corombose.—Native of Mexico. We have a garden specimen from the original author. Mr. Lambet received seeds from him in 1803. The root is perennial. Stems three feet high, erect, round, clothed with white cottony down, especially when young. Foot-flanks short, combined by a divided downy base. Leaves three inches long, strongly and unequally serrated; green, but rather silky, above; more hoary, and densely downy, beneath, conspicuously reticulated with veins. Flowers yellow, numerous, in a downy corombose panicle. Outer calyx-lower ovate, recurved. Rays four or five, broad, toothed. Seeds bordered, crowned with two short bristles.

13. *V. caenothifolia*. Five-ribbed Verbeina. Willd. n. 11.—Leaves opposite, ovate, serrated, with five combined ribs; their under side downy. Flower-flanks racemose, Paniced, axillary.—Native of the neighbourhood of Acapulco, in Mexico. The stem is round, erect. Leaves on short flanks, oblong-ovate, bluntly serrated, veiny, clothed on both sides with short flattened hairs; rough beneath. Flower-flanks long, from the borders of all the upper leaves. Akin to the following. Willdenow.

14. *V. bi flora*. Twin-flowered Verbeina. Linn. Sp. Pl. 1272. Willd. n. 12. ("Valliamanga-nari; Rheede Hort. Malab. v. 10. 79. t. 40") willd.—Leaves opposite, flat, ovate, serrated, with three combined ribs; their under side pales, scarcely downy. Flowers solitary or in pairs, on axillary and terminal flanks.—Native of the East Indies. The stem appears to be herbaceous, or slightly shrubby,
Shrubby, with forked and subdivided, fringed, nearly smooth, leafy branches. Leaves two inches or more in length, pointed, their three ribs united a little above the base; their upper side rough with minute depressed bristles; under smooth, or besprinkled with softer hairs. Flower-stalks long, either from the forks of the branches, or about their extremities, bearing one or two yellow flowers, an inch broad, almost always accompanied by a lanceolate leaf opposite to each partial stalk. Outer calyx-scales ovate, bristly. Radiant flowers several, elliptical, toothed at the end. Seeds abrupt, triangular, deli- tituate of a crown, or terminal bristles. The scales of the receptacle are obovate, concave, furrowed, abrupt, rough, at the extremity, resembling the inner leaves of the calyx. Linnaeus points out the affinity of this species to his V. Lavenia; but this regards their habit only, for Lavenia, now a separate genus, (see that article,) has a naked receptacle, and three bristles to the seed.

15. V. sativa. Oil-seed Verbesina. Sims in Curt. Mag. t. 1017. Ait. n. 6.—Leaves opposite, oblong; clasping the stem, distinctly serrated. Calyx simple, of five leaves.—Native of the East Indies; cultivated in the Mye country, and several other parts of India, for the sake of the expressed oil from its seeds, which serves as a substitute for that of Sesamum. Dr. Roxburgh found some of these seeds in 1805, to Mr. William Sallibury, the affiduous pofter of the botanic garden at Brompton. The plant is annual, either to keep in the flower, or raised on a hot-bed, and then planted out, flowering in autumn. Leaves four inches or more in length, green, not hoary. Flowers yellow, two inches broad, with about eight large broad radiant flor- ests, jagged or toothed at the end. The flowers stand on long simple stalks, from the forks of the stem, and botoms of the upper leaves. The simple calyx, of five broad leaves, agrees with that of the next species; so that, as Dr. Sims observes, if one could reckon a Verbesina the other must. We are not inclined to disturb them, because the whole genus, though in many respects very natural, fill labours under some strange exceptions and anomalies, which ought all to be well considered by those who attempt a reform.

16. V. calendulacea. Marigold Verbesina. Linn. Sp. Pl. 1272. Willd. n. 13. Ait. n. 7. (Caltha flore foliari- tario, ex alis foliorum longissimo pedunculo prodeunte; Burm. Zeyl. 52. t. 22. f. 1. "Pee Cajont; Rheede Hort. Malab. v. 10. 83. t. 42.")—Leaves opposite, oblong-lan- cecolate, very remotely serrated, fertile; taping at the base. Calyx simple, of five leaves.—Native of Ceylon, and other parts of the East Indies; cultivated by Miller. An annual flower-plant, flowering from July to September. The stem is branched, clothed, as well as the leaves, with rigid de- pressed bristles. The upper surface of the latter is, besides, usually rough with callous tubercles: their length and thae are variable, and their marginal ferratures are few and re- mote. Flowers yellow, not half the size of the leaf, on long, simple, mostly axillary, stalks. Radiant flowers from five to eight or ten, elliptical, toothed. Seeds very nu- merous, composing a globular head, wedge-shaped, abrupt, each crowned with two short bristles.

at Chelsea, and in Sherard's garden, being a tender annual, raised and kept in the flower, for the sake of curiosity, but having nothing to recommend it to popular notice. The stem is erect, a foot high, branched from the base. Leaves two or three inches long, broadly ovate, tapering suddenly into a winged footstalk. Flowers solitary, or in pairs, small, yellow, with several emarginate rays. Calyx certainly of two very different rows of scales, though the outermost consists of but two leafy ones. Seed crowned with two rigid awns.

18. V. dichotoma. Forked Verbesina. Willd. n. 15. Ait. n. 9.—Murray in Comm. Goot. for 1779. 15. t. 4.—"Leaves opposite, ovate, pointed, serrated, hairy, with three combined ribs. Stalks axillary, single-flowered. Stem forked."—Native of the East Indies. Annual. Whole herb befet with copious, short, white hairs. We have seen no specimen.

19. V. fruticosa. Shrubby West Indian Verbesina. Linn. Sp. Pl. 1271. Willd. n. 16. Ait. n. 10. (Bidens frutescens, ilicis folio, flore luto; Plum. Tc. 42. t. 52.)—Leaves opposite, stalked, ovate, serrated, rough, with three combined ribs. Stalks single-flowered, axillary. Stem shrubby.—Native of the West Indies. We have a specimen from Dr. Swartz, though this species is not mentioned either in his Prodromus or Flora. The stem is woody, re- peatedly branched and forked. The leaves appear to vary in hairs, as well as fize, but are always rough with minute tubercles. Flowers yellow, with numerous broad rays. Seed compressed, crowned with two bristles.

VERBESINA, in Gardening, affords plants of the herbace- ous and woody flowering exotic kinds, among which the species cultivated are, the wing-flaked verbesina (V. alata); the Chinesee verbesina (V. chinensis); the sily-flowered verbesina (V. nodiflora); the shrubby verbesina (V. frut- icosa); and the tree verbesina (V. gigantea). The first is an herbaceous perennial plant, with the flowers in fingle heads, of a deep orange-colour, appearing most part of the summer.

The second is a shrubby plant with yellow flowers.

The fourth rises with a shrubby stalk seven or eight feet high, and has yellow flowers.

Method of Culture.—These plants may be increased by fowing the seeds upon a moderate hot-bed, or in pots plunged into it, in the early spring months; and when the plants are of sufficient growth, they should be removed into separate pots, or into a new hot-bed, giving shade till they become new-rooted; afterwards managing them as tender annual plants, being careful not to draw them up weak: about the middle of summer they may be taken up with balls to their roots, and be planted in a warm sheltered border, being protected and watered till re-rooted, little care being after- wards necessary: these produce seeds often in the autumn; but in the flower they may frequently be preferred over the winter.

They produce variety in flower and greenhouse collec- tions, and sometimes in the borders during the summer sea- son, especially the first sort by its orange flowers.

VERBIAGE, in Grammar and Rhetoric. See Ver- sobity.

VERBICÆ, in Ancient Geography, a people of Africa, in Mauritania Tingitana.

VERBIEST, FERDINAND, in Biography, a celebrated missionary, was born in Flanders, and attained distinction as a mathematician in China about the beginning of the 17th century. He was appointed by the emperor Cam-Hi pre-ident in the tribunal of mathematics, and entrusted with the care of the Calendar. He also obtained permission to preach.
preach the Christian religion in China, and made many efforts for inducing the emperor to embrace the Christian faith; but though Verbiest succeeded in prevailing with him to acknowledge his belief in one God, he failed in his attempts to convert him to Christianity. Such, however, was the respect which the emperor entertained for this missionary, that on occasion of his death, in 1688, he composed an elegy upon him, and ordered him to be interred with Christian honours. The principal work of Verbiest is entitled, "Astronomia Europaea, sub Imperatore Tartaro-Sinico Cam-Hi, ex umbra in lucem revocata a P. Ferdinando Verbiest, Flandro-Belga, e S. J. Academice Astronomico in Regia Pequeniana Praefecto," Diligente, 1687, 140. He also caused to be constructed, at the request of the emperor, a variety of astronomical instruments, and wrote sixteen volumes, in the Chinese language, on their construction and use. Verbiest contrived likewise to convey over a long bridge, by means of pulleys, several immense blocks of stone for building a mausoleum for the emperor, which, it is said, 500 horses could not have drawn, and extended an aqueduct several furlongs over a wide plain. He moreover caused upwards of 130 pieces of brass cannon for the use of the Chinese government, and calculated astronomical tables with eclipses of the sun and moon for 2000 years. Montuelia Hilt. des Mathem. Gen. Biog.

VERBINUM, in Ancient Geography, a town of Belgic Gaul, belonging to the Veromandui, upon the route from Bagaicum Nerviorum to Druritortum, between Buronum and Catuacum. Anton. Itin.

VERBO, in Geography, a town of Hungary; 16 miles N.W. of Leopoldiisad.

VERBOASIA, a town of European Turkey, in Bosnia; 15 miles W.N.W. of Bonaera.

VERBOSITY, in Rhetoric, an offence against energetic and vivid brevity or conciseness in writing. This differs from pleonasm; as in the latter, words are used which make no addition to the sense, whereas in the verbose manner, not only single words, but whole clauses, may have a meaning; but it would be better to omit them, because their meaning is unimportant; and therefore, instead of enlivening the expression, they make it languid. Another difference is, that in a proper pleonasm, a complete correction is always made by expunging; but this will not always answer the purpose in the verbose style, as it is often necessary to alter as well as to raze. Moreover, verbosity does not mean the same thing which the French express by the term "verbiage," which is commonly understood to denote a parade of fine words, plastically strung together, so as either to conceal a total want of meaning, or to disguise something weak and inconclusive in the reasoning. The former, or verbality, is merely an offence against vivacity; but the latter is more properly a transgression of the laws of perspicuity. One instance of a faulty exuberance of words is the immoderate use of circumlocation. In some circumstances, circumlocation is a beauty, in others it is a blemish. It is often used for the sake of variety; sometimes for the sake of decency; at other times, propriety requires the use of circumlocution, as when Milton says of Satan, who had been thrown down headlong into hell,

"Nine times the space that measures day and night To mortal man, he with his horrid crew Lay vanquish'd rolling in the fiery gulf."

In this case, "nine days and nights" would not have been proper, when speaking of a period before the creation of the sun, and consequentely before time was portioned out to any being in that manner. Sometimes even the vivacity of the expression may be augmented by a paraphrase, as when it is made to supply the place of a separata sentence. An instance to this purpose occurs in the words of Abraham, (Gen. xvii. 5.) "Shall not the judge of all the earth do right?" This circumlocation for God serves as an argument in support of the sentiment, and conveys more to conciseness. Such also is the paraphrase employed by Cicero, who, instead of saying simply, Milo's domestics killed Clodius, says, "they did that which every master would have his servants to do in such an exigence."

Another source of languor in the style is the insertion of such clauses, as to a superficial view appear to suggest something which heightens, but on reflection are found to presuppose something which abates the vigour of the sentiment. Such is the following sentence from Swift: "Neither is any condition of life more honourable in the sight of God than another, otherwise he would be a respecter of persons, which he affures us he is not." The last clause enervates the thought, as it too plainly implies, that without this assurance from God himself, we should naturally conclude him to be of a character very different from that here given him by the preacher. Akin to this is the juvenile method of loading every proposition with affectations. Such a practice in conversation tends to suggest a fupposition of the speaker's veracity, rather than to engage the belief of the hearer; and it has a somewhat similar effect in writing. Thus in our translation of Gen. ii. 17. God is represented as saying to Adam, concerning the fruit of the tree of knowledge, "In the day thou eatest thereof, thou shalt surelie die." The adverb surely, instead of enforcing, enfeebles the denunciation. Another example, somewhat similar, is the manner in which our interpreters have attempted, in the New Testament, to strengthen the negative, wherever the double negative (ς μη) occurs in the Greek, even in the most authoritative threatenings, by rendering it sometimes in no cafe, sometimes in no wise; neither of which phrases express more than the single adverb not; and as they partake of the nature of circumlocation, they in effect dilute the expression. Another cause of a languid verbo is the loading of the style with epithets. Epithets used sparingly, and with judgment, serve to enliven the expression; but a profusion of them has an opposite tendency. Besides, they lengthen the sentence, without adding proportional strength. We may also add, that the crowding of epithets into a discourse betrays a violent effort to say something extraordinary; and nothing is a clearer evidence of weakness than such an effort, without a correspondent effect.

There is, however, one kind of composition, the paraphrase, of the style of which verbosity is the proper character; because it is the professed design of the paraphrase to say in many words what his text expresses in few. Another species of verbosity is a prolixity in narration, arising from the mention of unnecessary circumstances. Campbell's Philosophy of Rhetoric, vol. ii.

VERBOVETZ, in Geography, a town of Croatia, at the confluence of the Cernets and Glocavia; 7 miles N.E. of Ivanitz.

VERBO AAS, a river of Denmark, in North Jutland, which runs into the sea, 6 miles W.N.W. of Holring.

VERBROECK, a town of Flanders; 8 miles E.S.E. of Hullt.

VERCEL, a town of Flanders, in the department of the Doubs; 11 miles N.E. of Ornans.

VERCELLAE, in Ancient Geography, a town of Italy, in Gallia Transpadana, and the capital of the people called Sebells. It had within its territory a temple and a wood consecrated
consecrated to Apollo. Here the Cimbri were defeated by the Romans, under Marius and Catullus. After the decline of the Roman empire, it became a republic, and from that state it fell under the dukes of Milan; and, lastly, it was given as a marriage portion to Amadeus III., duke of Savoy. See VERCELLI.

VERCELLI, or Vercellin, in Geography, a town of Piedmont, and, under the French dynasty, the capital of the department of Sofia; which fee. It is situated at the junction of the Cerva with the Sofia, and was anciently called Vercellae. It is the fee of a bishop, suffragan of the archbishop of Milan. There are two churches which are called cathedral, and twelve others, two abbeys, nineteen convents of both sexes, three provostships, two priories, three poor-houses, and five hospitals; the inhabitants are about 25,000. In 1800, the French took Vercelli from the Austrians, with considerable stores; 30 miles S.W. of Milan. N. lat. 45° 22'. E. long. 8° 26'.

VERCHATURSKY GORY, mountains which divide European and Asiatic Russia, extending almost north and south to a great length, and about 40 miles in breadth. They are covered with wood, firs, larch, birch, &c.

VERCHEN, a town of Anterior Pomerania; 6 miles S.W. of Demmin.

VERCHES, LES, a town of France, in the department of the Mayne and Loire; 10 miles S.W. of Saumur.

VERCHIERE, a town of Canada, on the right bank of the St. Lawrence. N. lat. 45° 47'. W. long. 73° 9'.

VERCHODVESK, a town of Russia, in the government of Viatka; 40 miles N. of Viatka.

VERCHOIANSKII, an offshoot of Russia, in the government of Irkutsk, on the Yana. N. lat. 65° 40'. E. long. 130° 14'.

VERCHOKIZLOSK, a fort of Russia, in the government of Upha, at the union of the Kizil and Ural; 40 miles S. of Verchnouralsk.

VERCHOLENSK, a town of Russia, in the government of Irkutsk, on the Lena; 120 miles N. of Irkutsk. N. lat. 54°. E. long. 105° 34'.

VERCHOTOMSKII, a town of Russia, in the government of Kollan; 32 miles N.N.W. of Mungatzkoi.

VERCHOTURA, a town of Russia, in the province of Ekaterinburg, near the river Tura. This was the first town which the Russians built in Siberia. It has four churches and two convents, besides chapels; and is the seat of a bishop. Verchotura is situated on a rising ground, and fortified with palisadoes and a ditch, and defended by a garrison under a commandant. The adjacent country is inhabited by a people called Vogulitz, who live on fruits in the woods, and on fish and deer. The soil is fertile, and agriculture is carried on. In the beginning of the 18th century, they were many of them converted to Christianity, and now mix probably with the rest of the people; 120 miles N. of Ekaterinburg. N. lat. 58° 45'. E. long. 60° 14'.

VERCHOVAGSKII, a town of Russia, in the government of Vologda, on the Vaga; 48 miles S. of Vielik.

VERCHOURALSK, a town of Russia, in the government of Upha, on the Ural; 120 miles S.E. of Upha. N. lat. 53° 36'. E. long. 59° 14'.

VERD, or VERDE, Cape, a cape on the west coast of Africa. N. lat. 14° 48'. W. long. 17° 31'.

VERD, or Verde Islands, Cape, islands of Africa, in the Atlantic, deriving their name from the cape opposite to which they are situated, and discovered by the Portuguese in 1446. They are so called, as some fay, from a green plant, called Sargofio, resembling water-cress, and bearing fruit like a gooseberry, which is found floating near them, and in such abundance as to impede the progress of vessels in their course. They are usually reckoned ten in number, and including rocks, they amount to fourteen. The two largest are St. Jago or Yago in the south-east and St. Anthony in the north-west. Four of these islands are situated towards the east, viz. Santiago, Mayo, Bonavista, and Salt isle; four towards the north-west, viz. St. Nicholas, St. Lucia, St. Vincent, and St. Anthony; and two are somewhat detached towards the south, viz. Brava and Fuego. (See each island respectively.) These islands are generally mountainous; some of them are barren and uninhabited; others are productive of rice, bananas, oranges, cotton, and sugar; and it is said the goats produce thrice a year, and the vines twice; they abound with poultry and rabbits, and turtles are plentiful on the shores. The air is hot and infaludious, rain being very rare; but a north-east breeze commonly rises before four in the afternoon. The manufacture of leather and felt confitute the chief riches. Many of them have been furnished by their proprietors with cows, goats, hogs, assles, mules, &c. These islands are situate about 390 miles W. of Cape Verd, and between 15° and 18° of N. lat.

VERDACHELON, a town of Hindoostan, in the Carnatic; 20 miles S.W. of Trivady.

VERDAPETTY, a town of Hindoostan, in the province of Mysore; 22 miles S. of Madura.

VERDE, Cape, a mountainous cape on the coast of Peru. S. lat. 6° 25'.—Alfo, a cape on the coast of Gaoa. N. lat. 43° 50'. E. long. 7° 50'.

VERDE, or Green Island, an island on the north coast of South America, at the mouth of the river S. Martha.

VERDE Island, or Verde Key, one of the small Bahamas. N. lat. 22° 54'. W. long. 75° 26'.

VERDEGREASE, VERDIGREASE, VERDIGRIS, or VERDIGRIS, a kind of rust of copper, formed from the corrosion of copper by a fermented vegetable, and into a bluish-green substance, of great use among painters for a green colour. The word is formed from the Latin, viride avis, it is also called arago. Others call it the flowe, and others the vitrific salt of copper; though, in reality, it is rather the proper substance of the metal.

The greatest quantities of verdigris have been manufactured at Montpellier, the wines of Languedoc being very proper for this preparation; and it has been exported thence in cakes, each weighing about twenty-five pounds. The following process for making it is described by M. Monet, of the Royal Society of Montpellier, and is published in the Memoirs of the Academy for the years 1750, and 1753. Vine-alks, well dried in the sun, are steeped during eight days in strong wine, and afterwards drained. They are then put into earthen pots, and wine is poured upon them; the pots are carefully covered; the wine undergoes the acetous fermentation, which in summer is finished in seven or eight days, but requires longer time in winter, although the operation is always performed in cellars. When the fermentation is sufficiently advanced, which may be known by observing the surface of the liquid of the pots, which during the process of the fermentation is continually wetted by the moisture of the rising vapours, the flasks are then to be taken out of the pots: these flasks are by this method impregnated with the acid of the wine, and the remaining liquor is but a very weak vinegar. The flasks are to be drained during some time in tanks, and layers of them are to be put into earthen pots with plates of Swedish copper, so disposed, that each plate shall rest upon and be covered with layers of flaks. The pots are to be covered with lids, and
and the copper is thus exposed to the action of the vinegar, during three or four days, or more; in which time the plates become covered with verdigris. The plates are then to be taken out of the pots, and left in the cellar three or four days; at the end of which time they are to be moistened with water, or with the weak vinegar above-mentioned, and left to dry. When this moistening and drying of the plates have been three repeated, the verdigris will be found to have considerably increased in quantity, and it may be then scraped off for sale.

A solution or eration of copper, and consequently a verdigris, may be prepared by employing ordinary vinegar instead of wine, as directed in the above process. But it will not have the unctuity of ordinary verdigris, which is necessary in painting. Good verdigris must be prepared by means of a vinous acid or solvent, half acid and half spirituous. Accordingly, the success of the operation depends chiefly on the degree of fermentation to which the wine employed has been carried; for this fermentation must not have been so far advanced, that no sensibly vinous or spirituous part remained in the liquor. Macquer’s Dict. Chem. See the processes as described by Chaptal, under the article Copper.

The Society of Arts, &c. offered a premium in 1756 for the making of verdigris in England; and in 1760 intimated, that it might be made by moistening with the cheapest and worst sort of cyder, the marc or remains of apples, pears, gooseberries, currants, floces, crabs, blackberries, or any fruits deprived of their juice by expression, proceeding afterwards by the processes above described. The premiums offered by the Society were several times claimed and allowed; and it was resolved, in 1763, that verdigris actually made of British materials, and submitted to various trials, was even superior to the foreign. Accordingly, a considerable manufactory was established, and successfully carried on for the purpose of making verdigris.

The good effects of verdigris is judged of from the deepness and brightnes of its colour, its dryness, and its forming, when rubbed on the hand with a little water or salve, smooth pale, free from grittines. This concrete is partially diffusible in water and rectified spirit, and almost totally in vinegar; from the acetic solution, well saturated, and left to exhale slowly in a warm air, the greatest part of the verdigris may be recovered in a crystalline form, called distilled verdigris. See Crystals of Venus, and Copper.

The crystals, distilled with a suitable fire, in a retort or other like vessel, give over the acetic acid in a highly concentrated state, but somewhat altered by the process. See Acetic Acid.

The matter which distilled vinegar leaves undissoled, on being mixed with some borax and linseed oil, and fixed in a crucible, yields a brittle metallic substance, of a whitish colour, not unlike bell-metal. Neum. Chem. by Lewis, p. 64, n. 4.

Verdigris is employed externally for deterring foul ulcers, and as an elapharotic; but it is seldom used, though milder than the sulphate or blue vitriol. It is employed as a collyrium in chronic ophthalmia. Hoffman recommends it particularly for destroying the calculi of old sitzun; tents of powdered verdigris, made up with salva, or other liquids, not fat or oily, conlume, he says, the harden callus in three or four days, so as to render it completely separable.

A detergent ointment, called mel egyptiacum, is prepared by boiling five parts of verdigris in fine powder with sixteen of honey, and seven of vinegar, till reduced to a clear consistence. The thinner matter which floats on the top of this mixture, after standing some time, is generally used, unless it be required more acid; in which case, the thick part which has subfided is thrown up among it.

In the Edinburgh dispensatory, an ointment, called unguentum ex ering, has been directed, composed of white wax and resin, each two ounces, olive oil one pint, and verdigris half an ounce. When these kinds of applications are employed for venereal or other ulcers in the mouth or tonsils, great caution is necessary, lest they should pass into the system; in which case, dangerous and even fatal consequences may ensue.

Verdigris is rarely or never given internally. It has been reckoned tonic, and administered with this view in a dose under gr. 3. Some recommend it, in the dose of a grain or two, as an emetic, which produces almost instantaneous effect, where poisonous substanies have been taken, for the immediate rejection of them. But warm water, milk, and oils, are much less dangerous, and more proper. In too large doses, it quickly proves fatal; and, on digestion, the coats of the stomach appear much thickened, and of a green colour. Lewis’s Mat. Med.

M. Navier has lately evinced the salutar effects of liver of sulphur, and particularly of liver of sulphur of Mars, as an antidote against the poison of verdigris.

Verdigris makes a blue-green colour in paint; but is generally used in yellow, which, by a proper mixture, renders it a true green. It is bright when good; but soon flies, when used in oil. When dissolved in vinegar, it is used in water painting, and is more durable; it may be also dissolved in the juice of rue, and thus produces a fine full green colour, equally fit for washing with that dissolved in vinegar.

Verdigris, with a decoction of logwood, strikes a deep black, which, when diluted, becomes a fine blue. See Dyeing.

VERDELLO, in Natural History, the name of a green marble used in Italy as a touchstone, for the trying of gold, &c.

VERDEN, in Geography, a town of Germany, and capital of a principality of the same name, on the Aller, which divides itself here into two branches, the smaller of which lies near the town, and is at present only frequented by the ships going up and down the Aller. In the town are four churches and a Latin school; 56 miles S.S.W. of Hamburg. N. lat. 52° 58'. E. long. 9° 15'.

Verden, a principality of Germany, bounded on the north and west by the duchy of Bremen, and on the east and south by the duchy of Lunenburg; about twenty-four miles in length, and nearly as much in breadth. This principality confits for the most part of heath and dry land, as also of forests; but on the rivers Wefer and Aller is good marsh-land. The Aller waters almost all the southerly; but the Wefer a part only of the westerly boundaries of the country. Verden was formerly a bishopric, founded by Charlemagne. At the peace of Wolfsbidad, in the year 1648, the crown of Sweden obtained the bishopric as a duchy. In 1712, the Danes invading the duchy of Bremen, the inhabitants of Brunswick-Lunenburg possessed themselves of it. In 1715, by virtue of the alliance concluded at Wismar, it was ceded, together with Bremen, by the king of Denmark, to the electoral house of Brunswick-Lunenburg; such cession being also made again, in the year 1719, by the crown of Sweden. This duchy has the same regency with the duchy of Bremen. The inhabitants are Lutherans.

VERDERER, or VERDERO, formed from viridarius, which Ulpian used in the like signification, a judicial officer.
VERDICT, Attainder by. See ATTAINDER.

VERDICT, False. See ATTAIN.

VERDIER, ANTONY DU, in Biography, lord of Vau-privas, was born at Montbrison in Forez in the year 1544, and distinguished himself not only by his writings, but by encouraging literature, for which purpose he granted to men of letters the use of his well-furnished library. He was advanced to the office of historiographer of France, and having occupied the rank of gentleman in ordinary to the king, died in the year 1600. Of his numerous writings, the only work that has been noticed by posterity is his "Bibliothèque des Autors François." It was first printed at Lyons in 1585, fol. and again published, under the title of "Bibliothèque de la Croix du Maine," by De Juvigni at Paris, in 5 vols. 4to. 1772-3, with notes and corrections.

VERDIER, CLAUDE DU, the son of Antony, though a man of learning, gained little reputation by his Latin and French publications. Having mismanaged a good estate transmitted to him from his father, he lost the latter part of his life in obscurity, and died in 1649, aged above 80. Moreri.

VERDISTAN, CAPE, in Geography. (See Cape Bar-
distan.) This cape is a land-mark which ships generally look out for in their passage up the Peruvian gulf. There is a dangerous shoal, which extends a considerable way to sea, and those are fortunate who pass by this place without meeting with a gale of wind. Here they manufacture an excellent kind of cloth, which is much worn by the Arabs. On this coast lies Congon or Kungoon, a large and populous town, which carries on a considerable trade with the gulf, and also with the inland country. The Portuguese had once a considerable settlement here. Between this and Tahire or Tahirea there is another town of some note, called Toombuch, and also the villages of Shilee (Sheeloo), Burg, and Yrist.

VERDITER, VERDITER, a kind of mineral substance sometimes used by the painters, &c. for a blue, but more usually mixed with a yellow for a green colour. See TERRE-VERTE.

Verdier, according to Savary, ought to be made of the lapis Armeonis; or, at least, of an earthy substance much like it, brought from the mountains of Hungary, &c. only prepared by powdering it, and cleaning it by lotusa.

But this stone and earth are very rare; and the verdier used is not a native, but a factitious substance, or blue pigment, obtained by adding chalk or whiting to the solution of copper in aquafortis. (See COPPER.) It is prepared by rosiners of silver, who employ for this purpose the solution of copper, which they obtain in the processes of paring; by precipitating silver from aquafortis with plates of copper. It is said, that a fine-coloured verdier cannot be obtained from a solution of copper prepared by dissolving directly that metal in aquafortis; and that the silver is necessary. According to Dr. Merer's account of the method of preparing it, a quantity of whiting is put into a tub, the copper solution poured on it, and the mixture stirred every day for some hours together, till the liquor loses its colour. The liquor is then poured off, and more of the solution of
of copper added; and this is to be repeated till the matter appears of the proper colour; after which it is spread on large pieces of chalk, and laid in the sun to dry. Boyle observes, that the procés often miscarried, and that heating the liquor, before it is poured on the whiting, has been found to contribute to its success. It is still, however, Dr. Lewis says, very apt to fail in the hands of the most skillful workmen; the preparation, instead of a fine blue, turning out of a dirty green.

From the liquor poured off in making verditer, Mr. Boyle says (Works Abr. vol. i. p. 169.), that the refiners obtain, by boiling, a kind of falfepetre, fit with the addition of vitriol to yield them a new aquafortis. Some have said that a deeper and brighter kind of verditer may be made by using a filtered solution of pearl-ashes instead of the chalk, in the above process.

Verditer, when good, is a cool full blue, but without the leafy transparency either in oil or water. In oil it is subject to turn greenish, and sometimes black; and in water it is not always found to hold. It is chiefly used for paper-hangings and coarce work, and in varnish.

**VERDON, or FORDON, in Geography, a town of Pfuf- fian Pomerelia; 60 miles S. of Dantzig.**

**VERDONE, a river of France, which runs into the Durance, at Pertuis, in the department of the Mouths of the Rhône.**

**VERDONE, in Ichthyology, the name of a fish of the turdus or wraffe kind, called by some authors turdus viridis minor. See Turdus and Laenus.**

It is of a fine green colour in all parts of its body; the back, sides, and belly, have all plainly the same colour; but in different degrees: the back being of the deepest dye; the belly has something of yellowness with the green, and the sides are variegated with lines of a fine blue. It has only one long fin on the back, which has thirty rays or ribs, the eighteen foremost of which are rigid and prickly, the others soft and flexible. It is caught in the Mediterranean, and sold in the markets in Italy. Salvian de Aquat. p. 88.

**VERDOY, in Heraldry, is applied to a bordure of a coat of arms, charged with any kind or parts of flowers, fruits, feeds, plants, &c. Of these there are eight in number.**

**VERDUN, in Geography, a town of France, and principal place of a district, in the department of the Meuse. Before the revolution the capital of a province, called Verdunia, and the see of a bishop, suffragan of Toul. It is large, populous, and consists of three parts, the Upper, Lower, and New Town. Exclusive of its fortifications, this place is farther defended by a fine citadel. The bishop, before the city and district were annexed to the crown of France, was a prince of the empire, and afterwards styled himself such, as also earl of Verdun. Exclusive of the cathedral in this city, are one collegiate and nine parish churches, six abbey, and one college. Verdun was formerly an imperial city; 33 miles N.W. of Toul. N. lat. 49° 9'. E. long. 5° 27'.—Alfo, a town of Spain, in Aragon; 15 miles W. of Jaca.—Alfo, a town of France, in the department of the Aude; 6 miles N.E. of Calet- naudary.**

**VERDUN-sur-Garonne, a town of France, in the department of the Upper Garonne; 12 miles S.S.E. of Castel- Saran.**

**VERDUN-sur-Saône, a town of France, in the department of the Saône and Loire, situated at the confluence of the Saône and the Doubs; 9 miles N.E. of Châlons-sur-Saône. N. lat. 46° 54'. E. long. 5° 7'.**

**VERDURE, the quality of greenness. The word is French, formed of verd, green.**

**VERE, Sir Francis, in Biography, an English officer in the reign of queen Elizabeth, was a defencdant from a branch of the De Veres, earls of Oxford, and born in 1554. Being lent with a body of troops, under the command of the earl of Leicester, to the affiance of the United Provinces in 1587, he distingufihed himself firel in the defence of Sluys, and in 1588 at Bergen-op-Zoom by refifting the arms of the duke of Parma. For his services on this occasion he obtained the honour of knighthood, and was employed on many subsequent occasions, in which he gained fiigid reputation, in which he was at length entrusted with the command of the English forces serving with the States. When these forces were withdrawn in the year 1592, Sir F. Vere was chosen representative for the borough of Leominister. In 1596 he successfully executed a commission with which he was entrusted to the States, and on his return obtained the command of a ship, with the rank of vice-admiral. In the expedition against Cadiz, he acquitted himself with skill and courage, and was principally instrumental in the capture of the town. On his return from an expedition with the earl of Eflifex to the Azores, he was appointed governor of Brill, one of the towns allotted to queen Elizabeth as security for money advanced to the States. At the battle of Nieuport, in 1600, his conduct, and the valor of the English whom he commanded, contributed very essentially to the success of the day, though the loss of lives was considerable, and Vere himself received a wound, which he concealed till victory was secured. The States, duly apprized of his merit, appointed him, in 1601, governor of Ofsend, which was besieged by a powerful army under the command of archduke Albert. By means of artifices which some have thought incompatible with the character of a generous soldier, he prolonged the siege, and deferred a surrender by negotiation, till he obtained a re-inforcement of troops, and then informed Albert that the treaty was at an end. The prince was indignant, nor were the States pleased with the fraud. This circumstance probably occasioned his resignation of the command at Ofsend; but being solicited by the States to procure fresh supplies of men from his own country, he succeeded in obtaining them. His government of the Brill, which expired with the death of Elizabeth, was renewed by James I.; but his peace with Spain in 1604 terminated the occupation of military men. Sir Francis was also governor of Portsmouth, and remained at home till his death, in 1608, the 54th year of his age. A splendid monument was erected to his memory in Westminster Abbey by his widow. His exploits have been recorded by himself, in a work entitled "The Commentaries of Sir Francis Vere, being dierfe Pieces of Service wherein he had Command, written by Himself in way of Commentary," published from his MSS. by William Dil- lingham, D.D. fol. Cambridge, 1657.**

**VERE, Horace, baron of Tilbury, younger brother of the preceding, whom he accompanied in many of his actions in the Low Countries, and distinguished himself on several occasions. He succeeded his brother in the government of Brill, and held it till the year 1616, when it was restored to the States. Although he was entrusted, in 1620, by king James with a tardy and scanty aid to his fon-in-law the king of Bohemia, he contributed for some time to preserve the Palatinate from being overrun by the Imperialists; and at last surrendered on honourable terms to Tilly at Münich. On the accession of Charles I. he was the first peer created by the king, under the title of lord Vere of Tilbury. Retaining the post of general of the forces in the
the service of the States-general, he was appointed master of the ordinance in 1629; but retired from public employment some short time before his death, which was occasioned in 1635, in the 70th year of his age, by an apoplectic fit. Lord Vere, no less skilful and brave than his brother as a commander, was of a milder and more modest temper. Biog. Brit.

VERE, in Geography, a river of England, in the county of Herts, which runs into the Coln, 2 miles S.E. of St. Albans.—Also, a county or parish on the south side of the island of Jamaica.

VERE, Cape, a cape on the W. coast of Calabria. N. lat. 39° 20'. E. long. 16° 10'.

VEREA, in Botany, for so it ought to be written, not Verica, was thus named by Mr. Andrews, in compliment to James Vere, esq. F.L.S. of K Pensford Gore, whose garden has long been celebrated among the richest, and best cultivated, in the neighbourhood of London.—Andr. Repof. t. 21. Wildl. v. 2. 471.—We regret that this memorial of our amiable and liberal friend cannot be preferred. This suppos'd genus is merely the Cotyledon, with four-cleft octandrous flowers, of which several are known, (see Cotyledon,) nor can they, on any found principle, be separated therefrom.

The Verica crenata is Cotyledon crenata, Venten. Malm. t. 49. Ait. Hort. Kew, v. 3. 110. Leaves crenating each other in pairs, ovate, obtuse, crenate, fleshy. Flowers four-cleft, erect, in cymose panicules.—Native of Sierra Leone; kept in the dry flove or tub-bed, where it flowers in summer and autumn. The stem is shrubby. Leaves green, large and handfome, very juicy. Flowers an inch long, yellow, with a green tube and orange mouth.

VERELIUS, Olof, in Biography, a Swedish antiquary and librarian in the academy of Upsal, was the son of a clergyman of East Gothland, where he was born in the year 1618. Having commenced his education in the gymnasium at Linkoeping, he pursued it for five years at the academy of Dorpt, and in 1638 removed to Upsal. Soon after he became tutor to some young Swedish gentlemen, whom he accompanied in their travels through various parts of Europe, and on his return in 1650, he was, by favour of the queen, appointed professor of eloquence at Dorpt in 1651, and in 1653 became treasurer of the academy of Upsal. In 1662 he was appointed professor of the antiquities of his native country, and in 1666 antiquary of the kingdom. He was in the same year nominated alderman in the college of antiquities, and died at Upsal in 1682. He was a good Latin scholar, and well skilled in Swedish antiquities, so that some of his countrymen honoured him with the appellation of "Parens Eloquentiae, et Filium Aradiaeum Antiquitatum Patriae." He was a zealous advocate for the ancient origin of the Swedes, inasmuch as to contend that the Goths who took Rome flied from Sweden, and to affect, "that those who deny their antiquity ought to have their brains knocked out with Runic stones." His dispute with professor Scheffer, concerning the former situation and name of the town and temple of Upsal, produced a number of publications. Among his other principal works are, "Gothisci et Rolfs, Vedfo-Gothico Regnum, Historia lingua antiqua Gothicia coniectura, quam & Manucripto vetuliflimo edidit, Verfione et Notis illantur," Upsal 1664, 4vo. and several publications relating to Gothic literature and Swedish history. Gen. Biog.

VERELLA, Cape, in Geography, a cape on the E. coast of Cochinchina. N. lat. 12° 35'. E. long. 109° 18'.

VERELLA, Cape, Palce, a cape on the S.E. coast of Cochinchina. N. lat. 11° 45'. E. long. 109° 4'.

VERELST, Simon, in Biography, was born at Antwerp
ment, in Addison county, on Otter creek, about six miles from its mouth in lake Champlain. It contains a congregational church and a gaol, and 835 inhabitants. In its vicinity are several mills; 115 miles N. of Bennington, and 519 from Washington.

VERGENTUM, in Ancient Geography, a town of Spain, in Bética.

VERGER DE HAURANE, JOHN DU, abbot of St. Cyran, in Biography, was the descendant of a noble family, and born at Bayonne in 1581. After having enjoyed some inferior preferments he removed to Paris, and in 1620 became abbot of St. Cyran. He was distinguished as a zealous defender and propagator of Jansenism; and under this character gained a great number of partisans. But being suspected of holding several erroneous doctrines, and of contumely of the church, he was denounced as a dangerous person to cardinal Richelieu, who caused him to be imprisoned at Vincennes in 1638, in which state of confinement he remained till the death of the cardinal; and soon after his liberation, he died at Paris in 1643, aged sixty-two.

As a champion in the cause of the Jansenists against the Jesuits, the abbot wrote several works, which were evidences of his zeal and diligence rather than of his judgment and ability. Although these works were held at the time of their publication in high estimation, they are now forgotten, as well as the controversy that occasioned most of them; and it is therefore needless to enumerate them. Moreri.

VERGERIO, Pier-Paolo, the elder, a reviver of literature, was born about the year 1549 at Jaffinopolis, now Capo d'Itria. Having studied at Padua and Florence, he passed some years in different towns of Italy, particularly at Padua, where he officiated as professor of dialectics; and he studied Greek at Venice, under the celebrated Emanuel Chrysoloras. At Padua he took the degree of doctor of laws in 1504, till which mature period of his life his condition bordered on that of indigence. From Padua, where he was attached to the interests of the princes of Carrara, he removed to Venice, and afterwards accompanied his friend Zabarella, when he became cardinal, to the council of Conclave. Having left this patron in 1417, he is said to have sunk into a state of mental derangement, and to have died in Hungary, about the time of the council of Basil, which commenced in 1431. His works caused him to be ranked among the most successful cultivators of literature at that period. His "History of the Princes of the House of Carrara, from its Origin to the Year 1535," composed in Latin that was deemed elegant in that age, has been published in Muratori's Collection of Italian Historians. His treatise "De ingenuis Moribus et liberalibus Adolectcentiis fluidis," addressed to one of the princes of Carrara, was very popular at the time of its publication. He also wrote "A Life of Petrarch," published in the "Petrarcha Redivivus" of Tommassini, and an eulogy of St. Jerome; and he left several manuscripts. Moreri.

Vergerio, Pier-Paolo, the younger, one of the few prelates converted from popery, belonging to the same family with the subject of the preceding article, was born about the beginning of the 16th century at Capo d'Itria; and having studied law at Padua, and graduated, he became, in 1522, professor of the notary's art in that university. At Padua and at Venice he maintained the character of an able orator, as well as that of a man of good morals. The charges brought against him by an enemy, and particularly that of poisoning his wife, have been sufficiently refuted. From Venice, where he resided in 1530, he went to Rome, and being introduced to pope Clement VII., was sent by him as nuncio to Ferdinand, king of the Romans, pro-

probably about the close of the year 1532. On this occasion he used all his efforts in support of the papal fee, and for the purpose of restraining the progress of Lutheranism. Paul III. recalled him from this embassy, but afterwards deputed him on the fame mission, which gave him an opportunity of holding several conferences with Protestant princes, and of an interview with Luther himself at Wittenberg. In 1536 he was sent by the same pope to Charles V. in Naples, and for his services to the church he was made a bishop of his native city. From thence he returned to Germany, and was one of the commissioners who drew up the indictment of the council. At the close of the year 1540 he attended the conference at Worms, as a deputy from the king of France. However, before this time he was suspected by the court of Rome of a secret attachment to Lutheranism, but he still contrived to keep up appearances. Upon his subsequent retirement to his diocese, whilst, as it is said, he was preparing a confusion of the German Separatists, he became convinced that they were right; and having communicated his sentiments to his brother, bishop of Pola, he adopted the same opinions; and they both resolved to propagate them in their respective dioceses. The monks were alarmed, and reported them to the inquisition. Vergerio, after having in vain fought an asylum, determined in 1546 to justify himself before the council of Trent. The council referred his cause to the nuncio and patriarch of Venice. But the consideration of it being procrastinated to the year 1548, he was ordered not to return to his church; and he soon after withdrew to the country of the Grifons, where, as well as in the Valteline, he for some years exercised his ministry. His brother died before he left Italy. The younger Vergerio, having received an invitation to Tubingen from the duke of Wirtemberg, died there in 1565. His works, written in the Italian language, were numerous; and their principal object was to expose the impostures and absurdities of popery. Its advocates were of course much incensed, and circulated against the author many malignant, and probably unfounded, reports. Some Protestant writers have represented him as unfeudal, and little acquainted with theological subjects. Bayle.

VERGERS, Virogateores, Servientes, are officers who carry white wands before the justices of either bench; called also, porters of the verge.

Vergers of cathedral or collegiate Churches, are inferior officers, who go before the bishop, dean, &c. with a verge, or rod tipped with silver.

VERGES, in Geography, a town of Spain, in Catalonia; 10 miles E. of Gerona.

Vergier, James, in Biography, a French poet, was born at Lyons in 1657, and educated at Paris with a view to the ecclesiastical profession; but he soon laid aside the clerical habit and became a man of the world. He recommended himself to those whose society he frequented by his gaiety and polished manner, and in 1690 he obtained the post of secretary of marine, and afterwards that of president of the council of commerce at Dunkirk. But his love of pleasure, combined with idleness, prevented his acquiring the character of a man of business. His career of pleasure was terminated at Paris in 1720, by the piltol of a robber, at the age of 63. Rouille characterizes him as a philo-

sopher, formed for society, without any mixture of gall or malignity, and extols the noble and elegant simplicity of his convivial songs, which entitles him to the appellation of the French Anacreon. In his other productions, such as odes, madrigals, sonnets, epigrams, tales, fables, epistles, &c. it is acknowledged that his style is negligent, and occasionally profane. "Vergier," says Voltaire, "is with regard
VERGIL, in Geography, a mountain of Naples, in Laur; 7 miles E. of Nola.

VERGIVIUS OCEANUS, in Ancient Geography, a name given by Ptolemy to that part of the sea which bathed the southern coast of Hibernia, and the western provinces of the isle of Albion. It is now called St. George's channel and the Irish sea.

VERGNIE, LOUIS-ELISABETH DE LA, Comte de Trefson, in Biography, a French miscellaneous writer, was born of a noble family at Mans in 1705. Introduced at Paris, when young, to an acquaintance with Fontenelle, Voltaire, and others, he imbibed a taste for polite literature. But devoted also to military service in common with other persons of his rank, he attended Louis XIV. in the campaigns of Flanders, on occasion of the war in 1743, and became his aide-de-camp at the battle of Fontenoy. Having risen to the rank of lieutenant-general, he withdrew upon the peace to the court of Stanislao at Luneville, which he contributed to adorn and enliven by his agreeable and sprightly talents. The king's Jesuit-confessor, dreading his influence, accused him of the crime of philosophy. When Stanislao preferred this charge against him, he replied, "I request your majesty to recollect, that there were 3000 monks at the procession of the League, and not one philosopher." After the death of Stanislao, the count lived in solitude, and employed himself as an author. In his youth he had penned some epigrams, which are thought to have prevented his obtaining admission into the French academy till his 75th year, an honour of which he was ambitious, and which gratified him much, though he did not long live to enjoy it; for he died of the gout, to which he had been much addicted, in the year 1752, at the age of 77. His love and talent for poetry were retained to the close of life. Several of his works, which were numerous, are romances, or compositions of that clafs, either original or altered from tho' of other authors. A posthumous work of different character is entitled "An Essay on the Electric Fluid, considered as an Universal Agent," in 2 vols. 8vo. A collection of his works was published in 1731, in 12 vols. 8vo. Nouv. Dict. Hist.

VERGOBRETS, a name given to magistrate in certain provinces of Gaul, who were like the archons of Athens, but only with an annual power.

VERGORAZ, in Geography, a town of Dalmatia, situated at the foot of some mountains which separate the dominions of Venice (now Italy) from those of the grand signior. It was formerly rich and flourishing, but is now a poor place; 20 miles E. of Narenta.

VERGUENNI, in Ancient Geography, a people of the Maritime Alps, S. of the Veamini.

VERGUTTUM, in Geography, a town of Hindoostan; in the circle of Cicacco; 20 miles N.N.W. of Cicacco.

VERGY, a town of France, in the department of the Côte d'Or; 10 miles S.S.W. of Dijon.

VERHEYEN, PHILIP, in Biography, an eminent anatomist and physician, was born in 1648 at Vethrouck, in the country of Waes, and having been noticed by the rector of the parish, was instructed by him in the rudiments of Latin, and in his 24th year, sent to commence a course of classical education at Louvain. His diligence amply compensated for loss of time; and having assumed the clerical habit, he devoted himself to the study of theology. But his views were changed by an amputation of his leg, occasioned by an inflammation; and he substituted medical pursuits for those of divinity. These he followed at Louvain and Leyden, and taking his degrees at the former place, he there fixed his residence. In 1689 he was nominated professor of anatomy.

VERGILIO, in Biography, an Italian, was born at Urbino in the 16th century, and became first known to the learned by a Latin collection of proverbs, preceding that of Erasmus and the occasion of some bickering between them. It was first printed in 1498, and frequently republished. In the following year appeared his work "De Rerum Inventoribus," a very learned performance, but defitute of found criticism, and exhibiting many evidences of the credulity of the author. About the commencement of the following century, pope Alexander VI. deputed him to a commission to England, for the purpose of collecting the papal tribute called Peter-pence. As he was admired in this country for his learning and Latin stile, he was promoted to the archdeaconry of Wells, and engaged by Henry VII. to write a history of England. This work was begun in 1505, and printed at Basil in 1548, with a dedication to Henry VIII. Enjoying in this country the preemptions of prebend and archdeacon, he wished to continue in it, notwithstanding the changes of religion that had occurred, and the cessation of his office as collector of a tax that no longer subsisted; more especially as he evinced himself, by his approbation of the marriage of the clergy and his condonation of the worship of images, to be no strict Catholic. He had likewise introduced into his treatise "De Inventoribus," some passages in which the Inquisition expunged, and reflected on the pride of the clergy, by suggesting that St. Peter would not suffer Cornelius the centurion to kiss his feet. He ventured, however, in 1550, being in advanced life, to return to his own country for the benefit of a warmer climate. His English benefices were continued till his death, which happened at Urbino about the year 1555. Of his history of England, contained in twenty-six books, and extending to the reign of Henry VIII., it is sufficient to observe, that its style is clear and elegant, but that the matter of it has been censured by various writers. Sir Henry Savile says, that as Polydore was an Italian, little acquainted with public business, polliheing no great degree of genius or judgment, and for the most part taking falsehood instead of truth, he has left us a history full of errors, as well as poorly and jejuneley written. Our antiquaries also have severely treated him, on account of the contempt which he has expressed for the fables of Geoffrey of Monmouth, and other legendary narrations. He has been represented on the one hand as a columnist of our country and an enemy to its glory; whilst, on the other hand, the French and Scotch have accused him of partiality to England in those incantations with regard to which their translahtions have been blended with its history. Besides, it is said that he destroyed many MSS. with which he was intrusted, in order to prevent a detection of his errors; but Tiraboschi considers this as a tale which no man of sense can credit. By others it has been reported, that he sent off a whole ship-load of MSS. to Rome. Both these stories are defitive of proof. Polydore also published, in 1526, a book "De Prodigis," in which he strongly contends against the divinations of the ancients. Vossius. Tiraboschi. Nicollon's Hist. Lib. Gen. Biog. Vol. XXXVI.
VER

It has its name from a large sort of grape, called verjus, or bourdelas; which is said never to grow perfectly ripe; or rather, which in its utmost maturity is too auster and four to be used in wine; whence it is commonly turned into verjuice; though in France all unripe grapes are denominated verjus.

There is also tolerable verjuice made of crabs, gathered, and laid in an heap to sweat; the stalks, &c. separated; they are then stamped, or ground, and the crab mahl put in a hair bag; the juice squeezed in a press, then barrelled up close, and set in a warm place to work for ten or twelve days.

Verjuice made for sale shall pay the same duty as cyder or perry.

VERIXA, in Geography, a town of Asiatic Turkey, in the government of Moful; 15 miles N.W. of Naufs.

VERKENS VISCH, in Ichthyology, the Dutch name of a fish caught in the East Indies. It is about seven inches long, of a blackish-green colour, with fins and tail wholly black, and with yellow irises to the eyes. It is caught in fresh waters in the East Indies, and is a very delicate fish. It is very nearly related to the capricious, or goat-fish, if not the same species.

VERLUCIO, in Ancient Geography, a place of Britain, in the fourteenth route of Antonine, between Aquæ Solis or Bath, and Cunelio or Marlorough. It is placed by Dr. Gale at Welbury, and by Dr. Stukeley at Hedington; but Mr. Horfley, following the route of the military way from Bath to Marlborough, and the distances from both these places, thinks it more probable that it was situated near Leckham, or at Silverfield near Lacock, where great quantities of Roman money have been found.

VERMAND, in Geography, a town of France, in the department of the Aïnè. Before the revolution, the capital of a district in Picardy, called Vermelidois; 6 miles W. of St. Quentin.

VERMANTES, a town of France, in the department of the Indre and Loire; 6 miles N.W. of Bourgenil.

VERMANTON, a town of France, in the department of the Yonne; 12 miles N.W. of Avalon.

VERMANTREE, one of the smaller Shetland islands. N. lat. 60° 27'. W. long. 1° 55'.

VERMEJO, or RIO GRAND, a river of South America, which rises near Cabañido, in the province of Tucuman, and runs into the Parana, near its union with the Paraguay; opposite Corrientes.

VERMEJO. See BERNALDO.

VERMELHO, in Ichthyology, the name of an American fish, more usually known by the name of the pudiano.
